In conclusion, I wish to add that I observed no type of mental reaction that may be regarded as peculiar to the blind. The fact that these men were interested

and entertained, and made to realize the many possible personal accomplishments open to them, tided them over that critical period of adaptation and nervous strain which otherwise would probably have thrown many of them into a life of inadequacy and hypochondriacal invalidism. Those patients who developed psychiatric conditions, such as paranoid ideas, represented cases of constitutional psychopathy, or had sustained organic damage to the brain by reason of concussion, penetrating wounds or other cause.

## FETAL DEATH

### A STUDY OF ONE HUNDRED AND NINETEEN DEATHS IN A SERIES OF CASES\*

J. G. McQUARRIE, M.D.

SAN FRANCISCO

Williams<sup>1</sup> reported, in 1915, his series of 705 fetal deaths occurring in 10,000 consecutive cases at the Johns Hopkins Hospital. His total of 7 per cent. mortality included babies from the seventh month of gestation to fourteen days after delivery. Holt and Babbitt<sup>2</sup> reported in the same year a series of 10,000 cases from the Sloan Maternity Hospital. Their total mortality was 7.2 per cent., of which 4.2 per cent. represented stillbirths, while 3 per cent. occurred in infants who died within fourteen days following delivery; of these, half died during the first day. The mechanism of the various causes of death during labor has been discussed in a paper by Reed.<sup>3</sup>

My purpose, in this paper, is to record another series of carefully observed cases, which should be of added interest since, as far as I can determine, there is only one similar report from any of the Pacific or Middle Western states, that being a report of a series of 500 cases, with twenty-seven deaths, issued from our own clinic by Slemmons,<sup>4</sup> in 1915, in a paper discussing placental bacteremia as a cause of fetal death.

The present report covers a series of 2,717 deliveries in the University of California Hospital, the series terminating, Dec. 31, 1918. Patients in 2,215 cases were delivered in the hospital, and in 502, at their homes. Reckoning from the period of possible viability (the thirtieth week) to twelve hours after delivery, there were ninety-seven fetal deaths. So many factors play their part in causing the death of a child after the first twelve hours of life that it has been most difficult to assign correctly the part played by injury at birth. We have, in consequence, restricted our limits as above indicated. Within these limitations, the fetal mortality was 3.6 per cent.

In addition, there were found in this series twenty-two cases of fetal death occurring before the age of viability, namely, during the fifth and the sixth months, bringing the total deaths up to 119, or 4.4 per cent. We have entered these for comparison in several of our tables. As there were two instances of the delivery of

twins, there were only 117 mothers who lost their babies.

In Table I, we have attempted to classify our cases according to the cause of death. For the sake of clearness, we have assigned each case to one definite category, although it is obvious that it could not have been always strictly correct to do so, since several factors may present themselves for consideration, each of which contributes to the final result. For instance, if a case of toxemia of pregnancy calls for interference before the onset of labor, a bag may be introduced, and if the membranes are ruptured in the process and the head fails to engage, prolapse of the cord may occur, with indications for hurried extraction. The child is dead, and the question is, What killed it: toxemia, introduction of the bag, or extraction? It is often difficult to decide. But when a definite cause for premature labor or premature induction of labor is apparent, we have attributed death to this cause rather than to prematurity as such.

### CAUSE OF DEATH

*Syphilis.*—In this group are fifteen cases. All of the mothers had syphilitic treatment during pregnancy. The cases were diagnosed by (1) a strongly positive Wassermann reaction in the mother, or (2) by syphilitic changes in the placenta, or definite syphilitic lesions in the fetus. Microscopic examination was made

TABLE I.—CAUSE AND PERIOD OF ONE HUNDRED AND NINETEEN FETAL DEATHS

Cause	Under 30 Weeks	Over 30 Weeks	Percentage	Williams in 10,000 Cases
Syphilis.....	0	15	15.5	26.4
Unknown.....	6	17	17.5	18.0
Birth trauma.....	0	36	37.1	17.6
Toxemia.....	4	9	9.2	6.5
Fetal abnormality.....	1	8	8.2	3.4
Prematurity.....	2	6	5.3	7.1
Placenta praevia.....	2	2	2.0	3.1
Varicella.....	8	5	5.2	11.2
Total.....	22	97	100.0	

of each placenta in this entire series. The Wassermann test has been made in all doubtful cases since 1911, and in every case since 1914. It is quite possible that some syphilitic cases have escaped detection, even with these methods of diagnosis. The greater percentage of fetal death from syphilis in Williams' cases is due undoubtedly to the great prevalence of syphilis in the negroes of his clinic; 21.6 per cent of the negroes in his clinic gave manifestations of syphilis, which was present in only 4.8 per cent. of his whites. Our series includes few negroes.

*Unknown Cause.*—There are seventeen cases in this group, and of this number the infants in ten were macerated. Sufficient evidence could not be found to make a definite diagnosis at necropsy, although it is considered that about 80 per cent. of these cases were really syphilitic. Even should we class all of the macerated cases as syphilitic, there remain seven cases in which we have not been able to determine the actual cause of death.

*Birth Trauma.*—Included in this group are thirty-six cases, comprising 37.1 per cent. of the total. The different traumas and the number of deaths for which each was responsible appear in Table 2.

Undoubtedly, some of the deaths in this group represent the premium paid for experience, yet the majority were unavoidable. The cases of prolapsed cord

are of considerable interest. In one instance, the prolapsed cord was not discovered until two pains before delivery; one pulsating cord might have been replaced; interference was not attempted in another case because of a previous complete rectovaginal laceration through which liquid feces constantly poured into the vagina. In other cases, the cords were pulseless when first examined in the hospital.

We have reviewed the breech cases carefully without finding hope for better results than were obtained under the treatment given—except in one case in which the baby was spontaneously delivered at home before the physician arrived. The body had been born nearly twenty minutes, the head remaining undelivered.

Combining the forceps and prolonged labor cases, we find contracted pelvis of moderate grade in seven of the sixteen cases. The patient, in this type of case, is either brought into the hospital far advanced in labor or else is given the test of labor, and the case gets beyond the point at which ideal treatment from the standpoint of the child can be given, because of increased risk to the mother. In his group, it is possible that different treatment would have saved four babies. One patient had been given, before admission, 1 c.c. of pituitary extract during the first stage of labor, and 1 c.c. during the second stage; finally, high forceps were applied. No record of pelvic measurements had been taken before admission. One patient

toxemia. Our clinic has used every effort to reduce mortality in this group by a well organized prenatal service in which the registered patient is seen at the clinic or visited at her home at two-week intervals. Yet there are always patients entering hospitals who have not had prenatal care. Moreover, eclampsia often comes without warning, as has been emphasized by Lynch.<sup>5</sup> At least one patient in the series developed eclampsia, whose blood pressure and urine had been normal a few days before admission. Williams cites similar cases of rapidly developing toxemia.

TABLE 3.—DEATHS OCCURRING IN DIFFERENT TYPES OF FETAL ABNORMALITY

Abnormality	No. of Deaths
Meningocele—double cleft palate	1
Congenital cystic kidney	1
Anecephalic in uterus	3
1 mother, aged 40, quartidipara	
1 mother, aged 25, primipara	
1 mother, aged 16, primipara	
Lymphocele	1
Edema of lungs with right hydrothorax	1
Congenital heart disease	1
Perforated inter-lobular septum	—
Chronic endocarditis with pulmonary stenosis	—
Total	8

In one case, the mother used alcohol habitually to great excess. She was drunk when she entered and had, moreover, a systolic blood pressure of 185 and a diastolic pressure of 130, with a heavy trace of albumin in the urine. The child was born macerated.

*Fetal Abnormalities.*—This group comprises eight cases, or 8.2 per cent. of the total. The nature of the abnormalities and the number of times of occurrence of each appear in Table 3.

The infants in all of these cases were stillborn, except the hydrocephalic child, which displayed abortive respiratory efforts during the attempt to extract it. The aftercoming head was delayed twelve minutes after the appearance of the umbilicus. It might better have been perforated.

*Prematurity.*—There are only five cases left in this group after our various subtractions from it, noted above, of those instances in which the children were born alive but succumbed within a few hours. In these five cases we could find no other cause for premature death than immaturity. Necropsy disclosed only at-

TABLE 2.—DEATHS CAUSED BY DIFFERENT TYPES OF TRAUMA

Nature of Trauma	No. of Deaths
Prolapsed cord	0
Low and midforceps	5
High forceps	5
Prolonged labor	2
Breech	3
Version and extraction	3
Asphyxia—due to delayed delivery after signs of danger were apparent	3

was allowed to continue in labor six days before there was any interference in this distressing state of false labor pains and prolonged first stage. The cervix was finally dilated manually, and the child was delivered by a most difficult forceps operation. Early interference by cesarean section might have saved one other case in this group, in which a generally contracted pelvis of moderate degree greatly delayed delivery. In one case, pituitary extract was given three times before low forceps were applied. In another case, "twilight sleep" was attempted in a woman with a simple flat pelvis. Labor was greatly prolonged and was finally terminated by pubiotomy, the application of high forceps, wide episiotomy and craniotomy. To these there must be added three other cases in which incision and delay after the appearance of danger signs undoubtedly contributed to cause death. In the light of the records of the remaining cases, the treatment given seems to have been without criticism.

*Toxemia.*—Under this heading we have grouped nine cases, representing 9.2 per cent. of the total mortality in which some toxemia, as eclampsia or a marked disturbance of kidney function, either caused premature labor or gave definite indications for the termination of pregnancy. Since the mother's welfare is the first consideration, we may naturally expect a high percentage of fetal death when the maternal condition demands interference before term in the presence of

TABLE 4.—FETAL DEATHS FROM MISCELLANEOUS CAUSES BEFORE THE AGE OF VIABILITY

Cause of Death	No. of Deaths
Premature separation of normally implanted placenta	3
Premature separation of membranes	1
Laceration, laceration and removal of fetus from an anteverted or retroverted uterus	1
Swelling of mother's chest delivered by post-mortem cesarean section—level 15 centesimae	1
Psyllid with severe toxæmic symptoms	1
Decompensated heart disease of mother	1

letaxis in each case. Otherwise, the infants were normal for their respective periods of development.

*Placenta Prævia.*—In this group, there were only two cases in which hemorrhage from placenta prævia occurred before manifestations of labor. In one case, the membranes and placenta had been ruptured prior to the insertion of a bag. When the bag was removed from the vagina, the pulseless cord was found to have been prolapsed. The placenta was born before the head. The child was full term and stillborn. In the

Other case the patient was delivered by podalic version, after dilatation of the cervix by Voorhees' bag. The child was at term and stillborn.

**Various causes.**—We have grouped in this class cases from which only one or two deaths occurred. As a result of premature separation of a normally implanted placenta, there was one fetal death; of premature rupture of the membranes, two deaths; of abdominal pregnancy, one death, and of cord hemorrhage, one death.

In the first three of these cases, the fetus was dead before the onset of true labor. The membranes rupture prematurely rather frequently, though they rarely cause fetal death. It would appear that they ruptured one month before delivery in one case, the child dying from an ascending infection through the cord.

The case of abdominal pregnancy was definitely diagnosed some weeks before the operation, while the child was still alive. The difficulty of controlling hemorrhage after the removal of the large placenta from the noncontractile pelvic tissues seemed so great, in the presence of an enormous child (10 pounds), that the case was allowed to go over term, with the expectancy of fetal death with consequent involution and cessation of the placental circulation. Two weeks after cessation of motion, the mother presented sharp rises of temperature and pulse, which were interpreted as definite indications for operation. Abdominal section was performed, and the dead fetus and the partially involuted placenta were removed without marked bleeding. Drainage was made over the placental site, through the abdominal wall. This method was chosen deliberately after all possible methods had been explained to the patient who, because of many small dependents, could not afford to take the added risk of a section for a living child. The mother made a good recovery.

The child that died of hemorrhage from the cord was delivered from a woman with placenta praevia,

The relation of the age of the mothers to fetal death (Table 6) shows a remarkable lack of variation. The ages are arranged in groups of five years. The smaller percentage of fetal death when the mothers were under 19 years and over 35 years probably does not indicate the lower incidence of death at these ages, but is a result of the smaller number of cases in these groupings of the series.

Normal pelves were found in ninety-eight cases, generally contracted pelvis in eight, simple flat pelvis in four, and rachitic flat pelvis in three; and there was one case each of rachitic transverse contracted,

TABLE 7. PRESENTATION OF FETUS

Presentation	No. of Cases	Percentage
Left occipito-anterior	20	33.3
Breech	29	21.8
Right occipito-anterior	17	14.5
Right occipitoposterior	11	9.4
Occiput anterior	3	2.8
Left occipitoposterior	2	1.8
Right occipitotransverse	2	1.8
Face	2	1.8
Transverse position	2	1.8
Cesarean section (position not given)	7	5.9
No data	5	4.3

rachitic generally contracted, assimilation, and funnel pelvis.

The presentation and position of the fetus is given in Table 7.

The high percentage of breech presentations will be noticed, 24.8 per cent., as compared to Pinard's finding of 3,301 breech presentations in 100,000 cases more than seven months pregnant. In the greater percentage of our breech cases, birth was premature, and the position as such complicated labor or caused difficulty in the extraction, and was thus responsible for death in only five cases. The majority of the macerated fetuses in our present series presented the breech. The infrequency of left occipito-anterior and right occipito-anterior positions confirms the general idea that they predispose to easier labor and happier results. Nearly all the unusual positions are represented in the series. 2859 Jackson Street.

## ETIOLOGIC STUDIES IN TUBERCULOSIS

LAWRASON BROWN, M.D.

S. A. PETROFF

AND

GILBERTO PASQUERA, M.D.

TRUDEAU, N. Y.

The etiology of pulmonary tuberculosis is far from being a closed subject, and this communication is an attempt to supply what seems to some workers missing links in the etiologic chain. The dicta of many authorities have been apparently blindly accepted by their followers. On close scrutiny it is seen that many statements rest on inference rather than on fact. We have attempted in these few experiments on guinea-pigs to accept no statements, and to trace the tubercle bacillus, if possible, directly from the source of infection to the apparently exposed animal. The final test was of course the necropsy of the guinea-pig. In succession we studied the dust of rooms, the telephone receivers, the eating utensils, the infected hands of patients, the saliva, the transmission by kissing, the infection of tooth brushes, and the danger of flies and of coughing in tuberculous infection for guinea-pigs.

TABLE 6.—THE RELATION OF THE NUMBER OF PREGNANCIES TO FETAL DEATH

Pregnancies	No. of Cases	Percentage
Primipara	51	43.6
Secundipara	17	14.5
Tripipara	15	12.8
Quadrupara to quinquipara	17	14.6

TABLE 8.—AGE OF MOTHER IN RELATION TO FETAL DEATH

Age of Mother	No. of Cases	Percentage
15-19	18	15.4
20-24	30	25.5
25-29	28	23.4
30-34	21	17.4
35-39	12	10.0
40-44	7	5.8

in perian section. Presumably, the cord was loosely tied, since the baby was found dead two hours after birth, with considerable blood in the cord dressing. The child was premature, at the seventh month. A larger child might have survived the accident.

**Miscellaneous Causes.**—Deaths from miscellaneous causes, in fetuses under the age of viability, are given in Table 4. I have tabulated several other items of interest brought to light during the review of this series of cases. Reed is of the opinion that there are three times as many deaths in primiparas as in multiparas. In this series, they are nearly equally divided.

## I. THE DUST OF ROOMS

Since Hance found tubercle bacilli in the dust of a room on the floor of which a patient had spat, and failed to find them in other rooms, several attempts have been made to discover tubercle bacilli in the dust at the Trudeau Sanatorium. The dust collected by a vacuum cleaner from a large rug in the living room was negative on injection into a guinea-pig. The same result was obtained with the dust from a room in the infirmary occupied by a patient with numerous tubercle bacilli in the sputum and a cough so explosive that the mouth was rarely covered. Notwithstanding these results, we again investigated the subject and chose only rooms occupied by patients with severe cough and many tubercle bacilli in the sputum. Dust was collected before the daily cleaning by swabbing with sterile swabs the bed, tables, chairs, bed frames, corners of the rooms and walls near the patient. The swabs were washed in sterile broth, the washings treated with normal sodium hydroxide, incubated for one-half hour, then neutralized with normal hydrochloric acid, centrifugalized, and the sediment divided into three portions. Of these portions, one was inoculated into gentian violet mediums, another was stained in a slide for microscopic examination, and the third was inoculated subcutaneously in the inguinal region into guinea-pigs, two for each swab. In all, twenty-four animals were used.

*Results.*—As the gentian violet mediums were all contaminated, chiefly by molds, this method of study was abandoned.

As the slides stained for tubercle bacilli were all negative and not satisfactory, it was decided to pursue the study only by the inoculation of guinea-pigs.

The twenty-four guinea-pigs inoculated, Feb. 9, 1916, were killed forty-one days later and all organs, except a few enlarged bronchial glands and spleens, appeared normal macroscopically. The suspected organs were macerated and inoculated into a second series of guinea-pigs, March 22, 1916, which were killed, April 27, 1916, and were all negative for tuberculosis.

We then investigated the dust of two rooms in Saranac Lake Village, formerly occupied by two patients both long since dead, one a young colored girl, the other an advanced case. Both had numerous tubercle bacilli and violent coughs. The results were also negative. Since that time the sister of the colored girl who nursed her has developed pulmonary tuberculosis.

The mouthpiece of the telephone used in common by the patients at Trudeau was carefully swabbed out. The results of inoculation were also negative.

Thinking that infection by inhalation might prove more efficacious, we constructed a special glass box in which a guinea-pig was placed and kept in a definite position. This box was then attached to a vacuum cleaning apparatus, and dust drawn through it for one half hour. The three guinea-pigs used were not infected (subjected to dust, Aug. 7, 1916; intracutaneous test, Sept. 20, 0.5 c.c. of 1 per cent. old tuberculin, negative; necropsy, Sept. 24, and suspected organs were macerated and inoculated into a second series of guinea-pigs, which at necropsy, Nov. 20, 1916, showed no tuberculosis).

## II. EATING UTENSILS

The plates, cups, glasses (water and milk), forks, spoons and knives of patients who had numerous tubercle bacilli in their sputum (Gaffky VII and IV)

were studied immediately after breakfast. Particular attention was paid to those parts of the cups and glasses that come in contact with the lips. For purposes of study, plates and knives, cups and glasses, and spoons and forks were grouped together. Swabs were used and treated as in the first study. With the exception of two glasses (as noted above) and two spoons, one each of the utensils mentioned was studied for each patient.

*Results.*—The spoons, forks, glasses and cups were contaminated with tubercle bacilli, while the knives and plates remained free. In each necropsy a small portion of the spleen and the pus from the glands were used for smears, and acid-fast organisms were demonstrated.

As Price<sup>1</sup> had previously proved, ordinary washing and rinsing in very hot water is sufficient to sterilize these utensils.

## III. CONTAMINATED HANDS

Two patients with abundant sputum loaded with tubercle bacilli were instructed to cough hard and frequently on their hands, which were then washed in a small quantity of sterile water. The entire wash water was then (Sept. 1, 1916) injected into guinea-pigs, two for each patient. At necropsy (Oct. 20, 1916) generalized tuberculosis was found in all four guinea-pigs. This confirmed the work of Baldwin.<sup>2</sup>

An attempt was then made to infect the hands of a second person by hand shaking and a doorknob by rubbing it with the infected hand. After coughing on the hand, the patient immediately shook hands with a person whose hands had been previously cleansed. The hands of the second person were washed as previously described, and the entire wash water injected subcutaneously in the inguinal region into four guinea-pigs (Sept. 1, 1916), all of which remained free from tuberculosis (necropsy, Oct. 20, 1916).

Jan. 26, 1919, this experiment was repeated and two guinea-pigs were injected, in which at necropsy (Feb. 24 and March 6, 1919) no tuberculosis was found. The patient employed to cough had been so impressed with the danger of coughing that his attempts were considered too feeble, and again, March 14, the experiment was repeated and the two guinea-pigs killed, June 3, and found to contain no tuberculosis. In all these experiments cultures of the wash water on gentian violet mediums and slides stained with carbolfuchsin were negative.

A patient with positive sputum was made to cough several times into his hands and rub his hand over a doorknob previously sterilized. The doorknob was washed with sterile physiologic sodium chlorid solution, and this was injected subcutaneously in the inguinal region into two guinea-pigs, Jan. 26, 1916. At necropsy, June 3, the guinea-pigs showed no tuberculosis, and the slides stained by carbolfuchsin and the gentian violet mediums inoculated were all negative.

## IV. THE SALIVA

Before studying the danger of transmission of tubercle bacilli through kissing, it was deemed advisable to study the saliva. The saliva of two patients with numerous tubercle bacilli in the sputum was collected in a sterile container just before coughing and inoculated subcutaneously in the inguinal region into two

1 Price, J. W. The Disinfection of Objects from Table Contaminated with Tubercle Bacilli. *J. A. M. A.* 52: 208 (Feb. 13), 1914.  
2 Baldwin, E. R. *Tr. Am. Otolaryngol. A.* 1: 1: 102, 1913, cited in *Am. M. J.* 2: 1198, 1908.

guinea-pigs (Sept. 1, 1916). At necropsy, Oct. 20, 1916, both showed extensive tuberculosis.

#### V. KISSING

The lips are constantly moist with saliva and frequently contaminated with sputum. To prove transmission of tubercle bacilli to the object kissed, a patient with many tubercle bacilli in the sputum (Gaffky VIII) was instructed to kiss a sterile Petri dish which was washed with sterile physiologic sodium chlorid solution and inoculated, as previously described, into guinea-pigs. The guinea-pigs inoculated with the washings from plates kissed, some immediately after and some ten minutes after coughing, developed generalized tuberculosis, while those inoculated twenty minutes after coughing remained free from tuberculosis.

As infectiousness of the dishes seemed to vary somewhat with the time of coughing, it was deemed advisable to investigate the question of time more closely. A patient with numerous tubercle bacilli in the sputum was requested to kiss sterile Petri dishes at 7, 9 and 11 a. m., 2, 4, 6 and 9:30 p. m. and to return the dish to the laboratory immediately after kissing it. The dishes kissed at 11 a. m., 4, 6 and 9:30 p. m. were negative, the remainder positive. The experiment was repeated with a patient with fewer tubercle bacilli (Gaffky IV to VII) and only at 7 a. m. was the dish found to be positive.

#### VI. THE TOOTH BRUSH

The tooth brush of a patient with tubercle bacilli in the sputum was washed, immediately after it had been used by the patient, in 2 c.c. of sterile physiologic sodium chlorid solution, which was injected, Jan. 26, 1919, subcutaneously in the inguinal region into two guinea-pigs. One guinea-pig died in three days, and the other, examined at necropsy, June 3, 1919, showed marked tuberculosis. While slides stained with carbolfuchsin were only questionably positive, gentian violet mediums showed growth on the twenty-first day.

March 28, 1919, the experiment was repeated and was positive by stain, by culture and by inoculation. On this date, the washings made twelve hours after the brush had been used were studied. One guinea-pig died the day after inoculation, and the second showed marked tuberculosis at necropsy, June 3, 1919. Slides stained and gentian violet mediums inoculated were both negative.

#### VII. FLIES

Many have definitely proved that flies fed on tuberculous sputum are contaminated with tubercle bacilli and deposit specks that contain tubercle bacilli. To verify this we placed three flies in a large sterile baker and fed them on sputum containing many tubercle bacilli. The flies apparently developed diarrhea and deposited soft white specks, forming large circles, which contained on examination tubercle bacilli. A study of the bodies and wings of the flies by inoculation into guinea-pigs showed that they were generally contaminated with tubercle bacilli, for all the guinea-pigs developed generalized tuberculosis.

Next a study was made of the real practical danger to young guinea-pigs (two-thirds grown) by such flies when they crawled over and contaminated their food.

Five guinea-pigs were placed in a wire-covered cage or box, and twenty to thirty or more flies confined with them. As the flies died off they were replaced by others. A receptacle containing sputum with

numerous tubercle bacilli in it was placed high in the cage. The flies fed on the sputum and on the carrots, which they specked. The specks were shown to contain tubercle bacilli by inoculation of guinea-pigs, and the guinea-pigs in the cage ate the specks on the carrots. All the guinea-pigs in the cage failed to react to old tuberculin given subcutaneously, and at necropsy showed no trace of tuberculosis.

This experiment was repeated, November 18, and two sets of guinea-pigs (four each) used. The first set was exposed to food contaminated by flies with tubercle bacilli from sputum (Gaffky IV to IX) and the second set to bovine tubercle bacilli which had been mixed with negative sputum. The flies were changed weekly. The results were all negative.

#### VIII. COUGH

Only one experiment was done with cough. Two patients with numerous tubercle bacilli in the sputum, when performing their pulmonary toilet in the morning, were instructed to cough into the faces of guinea-pigs. This was done, Nov. 12, 1916, but the two guinea-pigs showed at necropsy no tuberculosis.

#### COMMENT AND SUMMARY

No originality is claimed for many of these experiments. The whole study was an attempt to discover whether infection in guinea-pigs at least followed exposure to what many have by inference referred to as sufficient exposure for infection of man. We do not wish to imply that these few experiments should be looked on as proof positive in a matter so important as this, but we contend that they emphasize the caution that must be used when infection is inferred to follow proof of contamination. The danger of the dust of rooms in a health resort, from telephone receivers, the danger from properly cleansed eating utensils, the danger from infected hands through handshaking or from knobs of doors, the danger of transmission by infected flies (at least in guinea-pigs) have not yet been conclusively proved, and these experiments tend to belittle it. On the other hand, the danger of transmission of tubercle bacilli by kissing, or the transference of the tubercle bacilli to eating utensils, and thence if not cleansed to a second person, has been borne out. Our hope in publishing these experiments is that others may realize that the etiology of tuberculosis is not a closed book, but one that contains many disconcerting and confused pages that need to be rewritten.

**Beginning an Attack on Tuberculosis.**—The question of health as related to industrial efficiency is a question of life. It is a paramount question. On this hinges happiness and this is determined by effectiveness. Effectiveness in life is related to health more closely and more absolutely than to any other thing. It should be the positive duty of every one to bring health to its highest state of perfection. The line between dependence and independence is drawn on the ability of the individual to go to work tomorrow. He who cannot work becomes a dependent. Charity organization statistics show that 85 per cent. of dependence is due to ill health and sickness; the other 15 per cent. is divided among desertion, drunkenness and other causes. A large mass of the people are afflicted with tuberculosis. We know how to cure it. But this means separation of the sick from the well. Until this is done the progress of the disease will not be stamped out. This means proper homes in which the people can be kept and in which danger to the community will be lessened. Tuberculosis is curable in the early stages. There are two ways to deal with it: (1) As it casually arises; cases are then often too far advanced; (2) go find it.—H. B. Favill.

PROTEOSOTHERAPY BY THE INTRA-  
VENOUS METHOD\*

P. NOLF

Lieutenant-Colonel, Belgian Army; Professor of Physiology,  
University of Liège  
BRUSSELS, BELGIUM

The most active measures used before the war against infectious diseases can be divided into three groups: (1) vaccines; (2) serums, and (3) specific chemical substances. According, then, to the measures employed, we practiced vaccinotherapy, serotherapy or chemotherapy. In the last few years a new form of therapy has been developed which has been called proteosotherapy or proteinotherapy, according as one gives a proteose as a protein foreign to the internal medium (blood and lymph) such as the casein of milk. The characteristic feature of this method is the administration of the protein or proteose by a channel which avoids the action of the digestive juices; that is to say, by a parenteral route, subcutaneous, intramuscular or intravenous. Permit me to present to you briefly my experience with proteosotherapy, which I believe I was the first to use.

## FIRST USE IN NONINFECTIOUS DISEASES

I used it first successfully in the treatment of non-infectious diseases. I began its use in 1908 in cases of hemorrhagic diathesis in order to increase the coagulability of the blood, later in paroxysmal hemoglobinuria, in which it inhibits the occurrence of the paroxysms, at least temporarily. During the war I introduced proteosotherapy into the treatment of infectious diseases, making use of intravenous injections of peptone.

## ACUTE INTOXICATION PRODUCED BY THE PROTEOSES

It has long been known to physiologists that, when given intravenously, the proteoses produce a state of acute intoxication, characterized chiefly by the non-coagulability of the blood, a great and rapid fall of blood pressure, and a state of great excitability of certain nerves or ganglions of the autonomic nervous system. This excitability manifests itself in the lungs in a state of spasm of the bronchi leading to acute emphysema and in the digestive tract by vomiting and diarrhea. This state has been called "peptone shock." It is not specific for peptone. One can produce it equally well by the intravenous injecting of a great number of substances, such as microbial toxins, animal or vegetable toxins, organ extracts, etc., whose common characteristics lie in their protein nature and in the fact that they are substances foreign to the normal humoral medium. These are the substances which have been termed antigens.

## EXPERIMENTAL SHOCK

One can easily obtain this shock in dogs by reinjecting into the veins a little defibrinated blood which has been taken from the animal itself. The same experiment performed in man gave the same results. If instead of defibrinated blood the serum freed from corpuscles is used, the result is the same; namely, that the simple coagulation of the plasma transforms it into a violent poison for the same species, if it is rapidly introduced into the vein; in other words, transforms

it into an antigen. In place of serum one can use red or white corpuscles provided they are first destroyed by placing them in distilled water to which an esoteric dose of sodium chlorid is added after hemolysis. Such an emulsion of hemolyzed corpuscles acts like peptone if introduced into a vein. If an antigen is given several times, at sufficiently long intervals, to an animal, the animal becomes more and more sensitive and reacts more and more violently. It has been placed in a state of anaphylaxis. The anaphylactic shock is not different from peptone shock; it is only an exaggeration of it.

## THE MECHANISM OF THE SHOCK

It is not possible for me to analyze here the mechanism of this shock. The question is obscure. The opinions of different authors are very divergent. But if the differences of opinion are great as regards the mechanism, the accord is almost perfect as regards the significance of the phenomenon. Almost all regard it as the expression of an effort which the organism makes to fix and to assimilate the antigen introduced into the veins. From the fact that the shock is identical in character no matter what sort of antigen has been injected, whether blood corpuscles, microbes, toxin or peptone, I think that one can draw the conclusion that the organs or tissues which have for their function this assimilation are always the same, contrary to the opinion of Ehrlich.

If this assimilation took place by the normal route of the digestive tract it would go on without any marked effect. Even by a parenteral route the assimilation could be complete and unnoticeable if the dose were not too large and if the passage into the blood stream took place only very slowly, as for example, after a subcutaneous injection. The shock is produced only if the introduction is rapid, which is the case after an intravenous injection when this contains a large enough dose of antigen.

## AVOIDANCE OF SHOCK

When one employs proteosotherapy to cure a patient of an infectious disease one should avoid shock—at least the violent shock which I have just described. But it seems to be an advantage to produce a mild reaction which I have called the "peptone effect" in contrast to "peptone shock." For this reason it is preferable to inject the peptone in a small dose into a vein rather than under the skin or into a muscle. This intravenous injection of an even very small dose of peptone is an intervention, which can only be performed by a physician who is acquainted with its dangers. It is necessary to proceed extremely slowly. The injection must take many minutes and during the entire period of the injection it is necessary to watch the pulse carefully in order to permit the operator to interrupt or slow down the injection in case the pulse becomes too rapid, for this indicates a rapid fall of blood pressure. If one is prudent the procedure usually takes place without accident. One may find a little transitory tachycardia, some very deep breathing or dyspnea, and a transitory headache. All this passes off within a few minutes, but after the lapse of a half hour to two hours after the injection the patient often suffers from a more or less prolonged rigor, which is followed by a state of devesescence with profuse sweating. The fall of temperature may last until the next day. This is accompanied by a subjective sensation of amelioration and by a diminution in the objective signs of the infection. I repeat the

\* Read in the General Medical Meeting at the Seventeenth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

injections only every other day. In a great number of cases the improvement is shown after one or two injections, but it is necessary to continue these until a complete cure has been established, in order to avoid recrudescence.

This treatment was applied by me with good results, at first in typhoid fever, then in numerous cases of septicemia due to streptococcus and staphylococcus. In a large number of cases one finds a rapid disappearance of the germs from the circulating blood. I have also obtained good results in severe erysipelas, in acute polyarticular rheumatism, and in nonrheumatismal arthritis when taken at the start. It appears, then, to be well established that the judicious intravenous administration of peptone can exercise a favorable action in certain infectious conditions and especially in the septicemias.

#### ASSUMED MODE OF ACTION

One can assume that the mode of action is the following: Peptone is an easily assimilable antigen. The pathogenic microbes, on the other hand, antigens, are difficult of assimilation. A single mechanism brings about the assimilation of both when they are given by a parenteral route. It is probable that the administration of peptone has the power of stimulating this mechanism and of thus augmenting the destruction of the microbes. As the proteosotherapy is essentially a nonspecific method, it can with advantage be given in association with more or less specific chemical substances when the latter alone are insufficient for bringing about the cure. For this reason I have used proteosotherapy in conjunction with hexamethylenamin in the treatment of typhoid fever, and with sodium salicylate in daily doses of 6 gm. in the treatment of septicemia caused by streptococci and staphylococci and in acute arthritides.

#### COMPARISON OF VACCINOTHERAPY AND PROTEOSOTHERAPY

The vaccinotherapy differs from the proteosotherapy in that it is specific. It attempts to provoke the formation of a specific antibody by the administration of a vaccinal antigen. It thus differs from proteosotherapy in its much greater accuracy. However, it would be an error to regard these two methods as being diametric opposites. One must not forget that the vaccine is an antigen like the peptone, and that in the reaction which it provides in the organism there exists a nonspecific element which is common to all organisms. The proof of this lies in the fact that different diseases, notably typhoid fever, can be cured by the administration of cultures of microbes different from the specific germ, such as *Bacillus coli*, *Streptococcus proteus*, etc. One advantage of proteosotherapy is that it permits of the experimental study of the nonspecific element of vaccinotherapy, and, as the result of this, of a better understanding of the latter; and of better measures for its application. By way of illustration I will cite the following fact: Having determined that the proteosotherapy is much more effective when given by the vein instead of subcutaneously I concluded that this would also be true with vaccinotherapy. Starting from this fact, I have constantly administered vaccines by the vein, beginning with very small doses. My experience embraces numerous cases of septicemia due to the streptococcus, the staphylococcus, the pneumococcus and the meningococcus; certain

urinary infection due to *Bacillus coli*, and the staphylococcus, and finally the bacillary dysentery. In all these cases vaccinotherapy by the intravenous route gave results more certain and more rapid than those obtained by the subcutaneous route and permitted one to attain the desired results with doses of vaccine about a thousand times smaller than those which are necessary when given under the skin.

### DERANGED SEBACEOUS SECRETION AS AN ETIOLOGIC FACTOR IN DISEASES OF THE SKIN \*

II. R. VARNEY, M.D.

DETROIT

#### CLINICAL OBSERVATIONS

It is the duty of every one to keep physically well and to convey the appearance of physical well-being through a healthy skin. Others must observe us, and in all walks of life, among all classes of society, the healthy-looking person is the one most graciously received. The complex condition resulting in a healthy appearance of the skin is most difficult of adequate definition, yet every one has a rather clear objective knowledge of a perfect skin.

It is my intention to discuss in a most elementary manner a deviation of a well understood function of the skin which is an important etiologic factor in the case of many recognized skin conditions.

#### SEBACEOUS GLAND SECRETION

The daily physiologic sebaceous gland secretion amounts to about 1 or 2 gm.; it is quite constant in amount, somewhat less in children and much less in the cold season. The normal sebaceous secretion consists of a liquid and a solid part: the horny-changed membranes of the gland cells after the fat has left them.<sup>1</sup> Analyses have shown the presence of fats (olein, palmitin and stearin), and fatty acids (oleic, palmitic and stearic), inorganic salts, cholesterol, epithelial debris, and water. The cholesterol is thought to be a product of cellular degeneration, and its chemistry is that of the secondary alcohols.<sup>2</sup> It is most plentiful in the skins of ichthyosis and psoriasis, and in comedones.<sup>3</sup> The large polyhedral cells deeper in the glands have been found to contain many fat droplets, and through this cell degeneration, the sebaceous secretion is greatly assisted in its function, which explains why 2 gm. of sebaceous secretion can cover so extensive an area and afford protection.

Endeavoring to discover the true function of the sebaceous secretion, Dr. Max Joseph excised the coccygeal glands of several geese. They survived the operation and were apparently normal, but after entering the water and wetting their feathers, it was noted that the feathers held more water and took longer to dry than those of normal geese.

As is well known, diet greatly influences the sebaceous secretion. Montgomery says:

Modern man frequently suffers a penury of oxygen; because of this, he tends to select the easily split, easily fermentable

carbohydrates and the easily absorbable fats, and these are the very foods that favor seborrhea.<sup>4</sup>

Kuznitzky says:

The sebaceous matter in increasing amounts, as we find it in seborrhea oleosa, is not, as was formerly assumed, the cause of the accompanying acne, but, on the contrary, in all likelihood, we have an ever easily recognized weakening of the defense against the organism.<sup>5</sup>

In every recognized skin disease there is always some derangement of the sebaceous function.

EFFECTS OF INSUFFICIENT OIL

The lack of oil is a far more common deviation than the excess. At the adolescent age, when all glandular activities are greatly increased, the activity of the sebaceous function predisposes to a few dermatoses, such as the seborrheas and some forms of acne. This stage of hypersecretion of oil is of short duration, is most amenable to treatment, and is not nearly so troublesome nor so common an etiologic factor as the insufficient amount of oil. It is this phase of the abnormality that I wish to discuss.

The skin that lacks oil is the skin that is sallow and nontransparent. It makes its possessor appear older than is really the case and does not present an appearance of a state of physiologic well-being. Oil intensifies colors and conveys the healthy look to the skin, and, as well, absorbs soil and prevents its entrance into the skin.

How much better would be the careful training of the daughter in her teens in order that she might convey a healthy, normal color to her cheek, than to see her apply artificial color in a vain attempt to produce a healthy appearing skin!

In the normal outer covering of the body, protected from all external irritants by proper cleanliness and sufficient sebaceous material, are embodied the essentials for a comfortable state of the skin. It is thus able to ward off many skin diseases.

No organ of the human body is more generally and constantly mistreated than are the skin and its appendages, and it is this daily improper care that is responsible for a large percentage of skin diseases.

Many of the adult white inhabitants of the north temperate zone, during the cold months of the year,

fail to produce sufficient oil properly to protect the skin and to keep it in a healthy condition. There is another large class of persons who have a sufficient allowance of oil, but who are daily removing this protection by too frequent bathing with soap and water, and having no thought for its replacement. American travelers demand hotel rooms with bath, and the excessive bathing in the cold months of the year is not at all necessary to the proper care of the skin. Yet less frequent bathing with soap stimulates oil production, through the dissolving action of the soap on the oil plug long after the soap has been washed away. This is demonstrated clinically following a shampoo, when the scalp and hair shaft become oilier forty-eight

hours afterward than they were before. In the Middle West, where lake water constitutes the water supply of the large cities, the water is made more irritating to the skin by the chemical agents used for disinfecting purposes, such as chlorin and lime.

Of the number of individuals who come to the dermatologist with skin affections, the majority definitely show a lack of oil, due, in most cases, to improper toilet, or to a temporary derangement from recent local or constitutional diseases.

How readily one forgets the function of oil in the human skin! When sufficient oil is present, the skin is flexible, whereas a penury of oil gives us a harsh, dry skin, the epithelium of which cracks, exposing sensory nerve endings, with resultant itching and burning. Through these fissures infection may enter, and a weeping, deplorable dermatitis may result. The pyogenic infections and their resulting dermatoses are the most frequent. The bath pruritis of the legs, which develops during the

first cold, windy days of fall in the frequent bathers, is the most common illustration.

A general lack of oil produces a constant wasting of bodily heat, resulting in the patient's feeling every sudden change of temperature, which the normal oil prevents. He requires more clothing, as well as bedding, sleeps in a curled or flexed position to keep warm, and thus does not receive the refreshment that should come from a relaxed, straight repose. We are familiar with the fact that without oil it would not be possible for the Eskimo to live in his country, where clothing, even the warmest of furs, would not keep him from freezing if he did not preserve or retain his

Fig. 1.—Condition resulting from a deranged sebaceous gland secretion, showing the roughened epithelial layers of the skin.

4. Montgomery, P. W.; J. Cutan, Dis 34: 829 (Dec. 16) 1916.  
5. Kuznitzky; Arch. f. Dermat. u. Syph. Orig. 111: 691 708, 1913.

body heat by applying nature's first covering for warmth, that of oil. To demonstrate further the retention of surface body heat, apply a bland oil and retire with the same coverings as usual. Within a very short time one will note an uncomfortable rapid heating of the body. This also illustrates that if an oil medication is to be applied to a large surface of the skin, it should be applied some time before the patient retires, for the retention of body heat from the oil base, and the discomfort following will often not only derange the comfort of the patient, but interfere with the effect of an appropriate medication. The accompanying temperature charts of a patient with dermatitis exfoliativa illustrate most interestingly the continuous subnormal temperature from loss of body heat, which in turn was caused by loss of oil. The temperature could be brought up to normal for about two hours following a hot bath and saturation with oil.

More food is required to keep up bodily heat because of surface waste, since the power of heat retention afforded by oil is lacking. This patient cannot wear wool or coarse fabrics, because of the uncomfortable condition resulting from the roughened, warped epithelial layers of the skin, for the filaments of the wool are constantly pulling on this outer layer of roughened cells.

The man who lacks oil is unable to shave comfortably, and he is led to believe that he has a tender skin and a very wiry beard. True, his skin is hard and rough, and he often cuts himself because of its lack of elasticity and smoothness, and his hair is wiry and hard to cut through lack of oil.

also hardened by water and alcoholic lotions. How promptly, if we practice replacing the oil after shaving, will we note the greater ease with which the hairs can be cut, the resultant longevity of the razor's edge and the greater comfort! And we may perhaps escape becoming a slave to the barber.

The dry skin that is constantly cracking admits any and all forms of infection that the human skin is capable of harboring, from the pyogenic organism to *Spirochaeta pallida*.

The normal amount of oil of the skin has many functions, some of which are well interpreted, others that are very indefinitely understood, or knowledge of them poorly applied, and still others, I believe, that are unrecognized.

Fig. 2.—Cracked skin and rough, fully developed finger-nails consequent on a deranged sebaceous gland secretion.

ABSTRACT OF DISCUSSION

DR. RICHARD L. SUTTON, Kansas City, Mo.: I think Dr. Varney has covered rather a broad subject in a very good manner. Many of us do not appreciate and realize the discomfort which a dry, harsh skin may cause. During the past two or three years I have frequently prescribed for the relief of this condition a combination first suggested by a

dermatologist of Chicago. It consists of powdered tragacanth, 4 gm.; phenol, glycerin and oil of bergamot, of each, 5 minims; olive oil, 120 c.c. and distilled water, sufficient to make 480 c.c. Persons whose skins are dry and hard can use this mixture with excellent results. For a long time we prescribed it under the designation of "Pusey's mixture"; but the resultant amount of advertising was too great for a competitor so close a hand, and in my office we now invariably refer to it as "the dew of Sahara."

DR. HAROLD N. COLE, Cleveland: I want to bear witness to the value of this remedy. I have used it most successfully in many cases of pruritus.

Fig. 3.—Persistent subnormal temperature from a loss of body heat, due to lack of oil, in a case of dermatitis exfoliativa.

The average man cares more for the leather in his shoes than the skin on his face. For when the leather of his shoe becomes dry and hard, he knows the life of the leather will be shortened by cracking, and he at once seeks what the leather most needs, oil; yet seldom or never replaces the oil in his own skin, even though it is most evident that it is needed. He is fond of alcoholic applications after shaving, which remove the little oil that remains, rather than of putting back into his skin the oil that he has taken out with soap and water. When he puts this oil back, his hair shaft will cut much more easily, and his skin will not so readily be cut in shaving, for the wiry beard is the hair that is not only devoid of most of its normal oil, but

DR. JOHN E. LANE, New Haven, Conn.: I am rather surprised at Dr. Varney's experience that washing the scalp increases the amount of oil secreted and that this is noticeable as early as forty-eight hours after the shampoo. My experience has been exactly the opposite and while I use other agents for combating seborrhea of the scalp, I have found frequent shampoos about the best single treatment for this condition. The dry skin of the face caused by too vigorous use of soap is a common condition in men, but I see it much less frequently in women. This is probably due to the fact that the latter use more cold cream and frequently use it as a substitute for soap and water.

DR. G. A. HARE, Fresno, Calif.: The temperature is increased or diminished by the use of oil, if I understood correctly. To put the question another way, does not oil

increase the retention of heat? I wish Dr. Varney would tell us of any observation he may have made on that. Also whether a dry skin, which is so annoying, is due to a retention of heat or to interference with the nerve mechanism. I wonder whether he has any evidence to guide us in the use of the shampoo in these cases, as to whether the soap and water have anything to do with the production of oil or whether the active massage is the factor of most importance.

DR. C. A. SIMPSON, Washington, D. C.: I should like to ask Dr. Varney if senile atrophy of the skin does not play a large part in hypo-activity of the sebaceous glands. Most of my patients, excluding those with xerodermatous lesions, who suffer from dry skin are over 35 years of age. They have a thin, atrophic skin, prominently visible blood vessels, and other signs of cutaneous atrophy, such atrophy being more conspicuous on the extensor than on the flexor surfaces. I agree with all that Dr. Varney says, but I believe that senile atrophy of the skin (not necessarily in a senile person) is very often the primary lesion. The lessened activity of the sebaceous glands and their final atrophy simply share in the general and primary cutaneous atrophic process seen in some patients at a relatively early age.

DR. HENRY R. VARNEY, Detroit: In classifying oil deviations, I have arranged them in two general classes—the excess and the insufficient. The excess is manifested at the age of hyperactivity of all glandular functions. The excessively oily skin is caused by the constant attempt of the patient to remove the oil by frequent use of soap, thereby stimulating and liquefying the oil plug.

The less frequent use of soap will clearly demonstrate this fact through prompt reduction of the amount of oil. We must entertain the varying effect which water has on the skin owing to the great difference in its softness in different sections. The water supply of the lake sections of the United States is treated chemically for disinfecting purposes, and these chemicals have a decidedly drying and roughening effect on the skin because of their direct action on the normal oil of the skin. The people who are taught to bathe daily and use soap freely can carry on such a toilet without discomfort during the summer months, but during the winter months many adults have insufficient oil and through frequent bathing render the skin rough and dry and more susceptible to itching dermatoses. I do not think that I can answer Dr. Hare's questions, but it is a fact that oil does assist in retaining and equalizing body heat. The senile atrophies are a different condition from the congenital ichthyoses. We have to rely on oil, not only for protection and cleansing purposes, but for comfort, and patients with beginning senile atrophies, with the pigmented patches and the roughening, which appears later, of the epithelial layer with ulcers, etc., could be given much comfort and protection from all outward irritation and perhaps carcinoma later by a proper amount of protective oil.

## AN OPERATION FOR "CLAW FOOT"\*

RUSSELL A. HIBBS, M.D.

Professor of Orthopedic Surgery, Columbia University, College of Physicians and Surgeons; Surgeon in Chief, Orthopedic Hospital

NEW YORK

The term "claw foot" is generally accepted to mean a foot with exaggerated arch, prominent metatarsals and hammer toe, with corns on the toes, and callosities on the sole of the foot over the distal end of the metatarsals.

The cause of this deformity may be either a limit to dorsal flexion, or an impairment of the intrinsic muscles of the foot from paralysis, or both.

In cases in which there is only a limit of dorsal flexion—"muscle bound feet"—especially in children, a marked change in the position of the tarsals, metatarsals and toes may be prevented from developing by a restoration of freedom in dorsal flexion. In cases in which a gross change has taken place in the position of the tarsals and metatarsals, with shortening of the plantar structures, exaggerated arch and hammer toe, a much more complicated problem is encountered. The shortening of the plantar structures accentuates the effect of the common extensors in deforming the toes, and the hyperextension of the toes accentuates the shortening of the plantar structures.

A study of many roentgenograms of such feet shows that this deformity takes place chiefly at the articulation between the astragalus and the scaphoid. The relation between the cuneiform and cuboid and the metatarsals is very slightly changed, if at all.

In these cases there may appear to be, on account of the exaggerated arch, a displacement downward of the os calcis, but such is not the case. The upper half of Figure 1 is a roentgenogram of an approximately normal foot; the lower half of Figure 1, one of a markedly developed claw foot—it shows at what point the deformity takes place.

In these cases, therefore, there are two problems to be solved: first, the correction of the exaggerated arch, and second, the removal of the deforming power, on the toes, of the common extensors, at the same time making more direct and effective their function as

Fig. 1.—Comparison of normal foot (above) with claw foot (below), showing exaggerated arch of the claw foot and elevated toes: *A, B*, axis of astragalus; *C, D*, axis of os calcis; *E, F*, axis of navicular, internal cuneiform and first metatarsal. Compare angle made by *D, C* and *E, F* in upper figure with the angle made by *A, B* and *C, D* in the lower. The comparison shows that the deformity is caused by the dropping down of the front foot at the mediotarsal joint.

\* From the service of the New York Orthopedic Hospital.  
\* Read before the Section on Orthopedic Surgery at the Seventieth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

dorsal flexors of the foot, which has been lost because of the deformity of the toes. Elongating the plantar structures, by separating them from their attachments to the os calcis, makes possible the correction of the exaggerated arch by elevating the foot anterior to the astragalus.

The second problem cannot be successfully met without destroying completely the power of the common

Fig. 2 Lines of incision.

extensors to extend the toes and transferring their attachment to a point in the foot which will insure the most powerful and direct exercise of their force in elevating the front foot at the mediotarsal articulation and in dorsal flexion at the ankle joint. This may be done by the division of the common extensors and the insertion of their proximal ends into the external cuneiform bone. This point of attachment is selected because it will insure the exertion of their force in elevating the front foot, and in serving as direct and positive dorsal flexors of the foot at the ankle joint. In most of these cases, there is some degree of inversion of the foot, and the attachment of the common extensors at this point such as that described insures correction of the inversion. In those cases in which there is also any serious degree of limitation of dorsal flexion at the ankle joint, subsequent lengthening of the Achilles tendon may be necessary.

After the usual preparation of the foot, an incision  $1\frac{1}{2}$  inches long is made internally through the skin and subcutaneous tissue over the os calcis, and with a periosteal elevator the plantar structures are separated from their attachment to the bone. The suggestion for this feature of the technic is from an article by Stender.<sup>1</sup> With the exercise of force the front foot is elevated, the exaggerated arch corrected, and the position of the metatarsals improved. Second, through a curved incision, 3 or 4 inches long, on the dor-sum of the foot to the outer side of the median line, the common extensor tendons and the internal cuneiform bone are exposed (Fig. 2). The tendons are divided low down, and their proximal ends pulled through a tunnel in the external cuneiform bone, and held there by a suture of forty-day chromic catgut. Subcutaneous tissue is closed by plain catgut, and the skin with ten-day chromic gut.

The foot is then put in plaster, with the metatarsals in corrected position and the toes straight, with a thick felt pad under the sole. The plaster is worn for five weeks, when it is removed daily for exercises and massage. After seven weeks, the patient is permitted to walk without plaster, though massage and exercises are continued for six weeks longer.

The importance of not lengthening the Achilles tendon at this time is obvious; its resistance is a great aid in correcting the cavus. As has been indicated above, the Achilles tendon may be lengthened, if it seems necessary, after six months.

Our first operation for clawfoot was performed, April 24, 1917, and since then nineteen others have been performed: in fifteen cases, on one foot, and in five cases, on both feet. Operations, therefore, were performed on twenty-five feet, all at the New York Orthopaedic Hospital.

A sufficient length of time has elapsed in all of the cases referred to here, and especially in the earlier ones, to permit a fair estimate of the result. In every instance there has been shown a definite amount of improvement, and the effect of the common extensors' acting from their new point of attachment has been conspicuously shown to enhance their power in elevating the front foot, and their power as dorsal flexors at the ankle joint.

Figures 3 and 4 are photographs taken before and after operation in the case of a boy, aged 12, with a single claw foot, and are fairly representative.

It seems unnecessary to publish in detail a report of each case, as there have been no complications, and no failure of the tendons to hold in any case; nor has there been any reappearance of the deformity of the toes, nor any impairment of their control, as their control is sufficiently maintained by the short extensors.

#### ABSTRACT OF DISCUSSION

DR. BENJAMIN P. FARRELL, New York: I agree with Dr. Hibbs. The results from this operation are very satisfactory, and it was a surprise to me to find where the deformity took place. It was my opinion that the deformity was between

Fig. 3.—Claw foot of a boy, aged 12, before operation.

Fig. 4.—Same foot as in Figure 3, after operation.

the tarsal and metatarsal joints. The procedure gives very satisfactory results.

DR. FRED S. WILLIAMS, Bridgeport, Conn.: I wish to report two cases in which I followed the technic of Dr. Hibbs. One patient was a man, 23 years of age; and the other was a girl, 16 years of age. The results in both cases were as satisfactory as those described by Dr. Hibbs. If the Achilles tendon is lengthened, this condition should be corrected. In many cases, the tendon is not short, but merely has that appearance. This should not be overlooked.

DR. JOHN PRENTISS LORD, Omaha: I have been undertaking to cure these feet by separating the tendons from the toes, and preserving just as much of the length as possible,

<sup>1</sup> Stender, Arthur, *Operative Treatment of Pes Cavus*, Surg., Gynec. & Obs., 24: 611 (May) 1917.

boring holes through the heads of the metatarsals and putting the tendons through the holes, making a half hitch of the tendon, and usually suturing it. The results of the operation have been very gratifying; although it must be considered that in some persons, particularly in adults, the deformity is so extreme that a perfect foot cannot be hoped for. I have been undertaking, however, in some cases, to improve this badly shaped foot by doing a cuneiform osteotomy through the navicular region and removing as much bone as may be necessary in order to reshape the foot. That procedure has proved most effective in relieving the deformity and meeting, as far as may be, the other mechanical and functional conditions. It may be said in criticism of doing so radical a procedure as cuneiform osteotomy in adults, that the subjects are subsequently disabled for a considerable length of time, from three to four months or more.

DR. JOHN RIDLON, Chicago: I have done the operation advised by Dr. Lord, which, I understand, is the procedure devised by Dr. Sherman of San Francisco, in many cases, and have never found it of much use. I have been accustomed for many years to lengthen the dorsal tendons of the toes by tenotomy at the first operation, holding that lengthening by putting the foot in plaster of Paris for long periods, and then doing a second operation, the cuneiform operation advised by Dr. Hibbs. I think that is the only operation that will give a permanent result in these bad feet. In feet that are not very bad, many things can be done that will be satisfactory; but in bad cases in adults, the only thing is to destroy the deformity in the way mentioned by Dr. Hibbs.

DR. EDWIN W. RYERSON, Chicago: This work is, of course, a modification of the work originally done by Sherman of San Francisco, and published a number of years ago, in which the extensor tendons were fastened to the distal ends of the metatarsal bones. It is efficacious, if done well. The only way to do it successfully is to loosen the plantar structures at first. It is also well to destroy the astragalonavicular joint. Make an arthrodesis there. These cases are very numerous. It has been a constant surprise to me to find how many women and men have a hollow clawfoot. There is also apt to be an inward deviation, as Dr. Hibbs states. The one mistake is to think that there is a shortening of the Achilles tendon. As the pictures show, the posterior part of the os calcis is more apt to be dropped than raised. It was a pleasure to me to see the demonstration of the deformity that I had always considered to be a dropping of the metatarsal bones, but Dr. Hibbs has shown that it is at the astragalonavicular junction that the deformity occurs. The detail of whether we use silk or something else is unimportant. We must force the toes down into complete plantar flexion. If we do not, we shall be chagrined to see how dorsiflexed they will become after a while, and how rigidly they will persist in that position.

DR. JAMES W. SEVER, Boston: I think that it would be interesting if Dr. Hibbs, in closing the discussion, would give us some idea of the etiology of the cases. I believe that they represent what we have known as the nondeforming Shaffer clubfoot. At the Children's Hospital, in Boston, we have been operating on a number of these patients, but by no means doing as well as Dr. Hibbs has done. We have been using the extensor longus hallucis, transplanting it into the head of the first metatarsal. In view of what Dr. Ryerson has said, if you do an arthrodesis at the astragalonavicular junction, provided you get a loosening of the plantar fascia, I do not see the use in transplanting the tendons.

DR. SAMUEL W. BOORSTEIN, New York: We must remember that many cases of clawfoot are really due to spastic paralysis. It seems to me, therefore, that Dr. Ryerson's suggestion of destroying the joint at the astragalonavicular articulation is practical. If this is not done, the spasm of some muscles may cause a recurrence of the deformity. It is well to relieve the spasm of the muscles by the transplanting advocated by Dr. Hibbs and also destroy the joint, combining the two procedures.

DR. RUSSELL A. HIBBS, New York: In reply to Dr. Sever's question, as to the cause of this condition, there are two classes of cases; one, in which there is simply a limitation

of dorsal flexion in early life. The other class consists of cases with paralysis, perhaps poliomyelitis, probably undetected, as many cases have been; or perhaps the spastic form of paralysis. The whole point of my paper, if it had one, was that in the first class of cases the removal of the limit to dorsal flexion may prevent the development of the deformity and that in the second the performance of this operation earlier will prevent the necessity of an arthrodesis. I have operated on ten or twelve adult feet, and in all there has been a distinct improvement. I am not prepared to say whether I should have done an arthrodesis also or not; but if we can avoid doing that, at that articulation, it is most important to do so; for this articulation is important in maintaining the flexibility of the foot.

DR. JOHN L. PORTER, Chicago: I have been waiting to hear Dr. Hibbs tell us the advantage that his operation has over Sherman's operation which we have been doing, and he has failed to do that in his response.

DR. HIBBS: In my paper I said that that bone was selected for two reasons. One was that by attaching these tendons to the external cuneiform bone, you get a direct pull from these tendons at a concentrated point, as elevator of the front-foot. In the second place the inversion is corrected.

DR. ELLIS W. JONES, Los Angeles: We have studied a number of these cases and find that about 30 per cent. have an occult spina bifida. The remaining 70 per cent. of the cases of claw foot are due to infantile paralysis or spastic paralysis; but I think this etiology of spina bifida has a very definite place in claw foot.

## A CONSIDERATION OF SOME OF THE PROBLEMS PRESENTED BY AMPUTATIONS \*

CLARENCE L. STARR, M.D. (TORONTO)

Lieutenant-Colonel, C. A. M. C.

OTTAWA, ONT.

Apart altogether from the psychologic factors pertaining to amputation cases, the desire of some to stay indefinitely in comfortable quarters, the effort of some to get all that is "coming to them," the anxiety of others to secure a "square deal," the personality of the individual, and other similar difficulties that will not be considered in this paper, the chief problems relate themselves to (1) the stump and (2) the artificial appliance to be used as a substitute for the member lost.

Up to the present time we have had slightly more than 3,000 amputations to deal with in the Canadian army medical corps.

The policy of the government has been to treat all amputation cases in a central depot, and to supply them with artificial limbs from a government controlled and operated factory in the same center, with subsidiary plants, to take care of alterations and repairs, in strategic points in various military districts of the dominion. The central treatment depot is at the Dominion Orthopedic Hospital, Toronto, and the limb factory is adjacent.

I am related to these two institutions as consultant and adviser, and therefore have had an opportunity seldom given to one person to study these cases, and to become acquainted with the problems presenting themselves.

### AN IDEAL STUMP

An ideal stump might be defined as one the length of which will best permit the instrument maker to fit

\* Read before the Section on Orthopedic Surgery at the Seventeenth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

the most suitable appliances for the portion of the limb amputated. It should have a linear scar free from puckering or infolding of the skin, with sufficient flap to cover readily the end of the bone, but without redundancy. It should have a pad of fat and subcutaneous tissue over the bone end, and should not be adherent. The joints above the amputation should have a full range of motion.

While this ideal may be kept before one at all times, it is seldom realized, and the ingenuity of the surgeon, and the mechanical skill of the artificial limb maker are therefore constantly taxed to make the most of the possibilities as they are presented.

In the early stages of the war the tremendous problem of infection, and the difficulty of dealing with it adequately, gave us a great many so-called guillotine amputations. These practically always made impossible stumps to which to fit artificial limbs, even if healing became complete; and a secondary amputation became necessary.

In the later stages, with a better knowledge of dealing with infection, and the methods of primary or delayed primary suture, much better stumps resulted.

At the present stage, the amputation cases seen are for the most part healed, but there are still some surgical conditions remaining, such as septic conditions, ulcerations and sinuses, as well as certain deformities and edemas, which must be cleared up before the artificial appliances may be usefully applied. Our problems at present, therefore, fall into several groups.

#### SURGICAL PROBLEMS

1. It is thoroughly established that all tissues harbor latent infection, which may be lighted up very easily. In some instances, massage and manipulation of the stump may be sufficient to start afresh a cellulitis which may become very troublesome. A traumatism, such as a fall or a bruise, may be the occasion of similar infection. This condition is usually cleared up by antiseptic baths or compresses and rest, and in some cases incision is required to drain local collections of pus.

2. Ulcers still remain in some cases after old, so-called guillotine operations, or may result from breaking down of scars. These ulcers and the scar tissue should be excised and a linear scar substituted. This is often possible without sacrificing any length of bone, if adhesive strips are attached to the skin above the ulcerated area, and extension made by means of weight and pulley, or by means of the modified Thomas knee splint. It is never good practice to attempt skin grafting in these ulcerated areas, as they almost invariably break down under the stress of the use of an artificial limb. If the scar or ulcer cannot be excised, and a good covering of the bone end accomplished without shortening of the bone, a reamputation becomes necessary.

3. A sinus or series of sinuses may combine, and are sometimes very difficult to get permanently healed. In my experience these sinuses persist as a result of either a foreign body at the bottom, or owing to the fact that they have developed a rigid, noncollapsible

wall of fibrous tissue, and on removal of the cause they will invariably heal promptly. The foreign body is most frequently a silk ligature, a bit of clothing, a shrapnel fragment, or a sequestrum. The careful removal of these, and cleaning out of the unhealthy granulation tissue of the sinus is followed by closure. I should like to urge the necessity of this being done thoroughly in order to be effective. It is often unfortunately the case that the medical officer simply goes after this with a curet, in a bleeding field, and he may or may not succeed in finding the cause of the persisting sinus. A tourniquet should be used, the sinus excised by an elliptic incision to its bottom, the edges of the wound retracted, so that the cavity may be inspected, and the foreign body removed by forceps. There is no need of using a scoop, and no new areas are opened up to infection. This same course should be followed in all cases of osteomyelitis with sequestrums, and if the bone sinus is properly beveled, so that the cavity left is funnel shaped with its base outward, healing will readily follow. If there is no foreign body, the excision of the rigid sinus wall will allow the sinus to collapse, and healing will take place.

4. Spurs of bone or exostoses are of frequent occurrence, and various explanations are given for their presence. The most common explanation given and accepted is that they are due to a tearing up and partial detachment of shreds of periosteum, from which new bone is developed in all sorts of irregular shapes. To those of us who do not believe that the periosteum of adult bone, as it is stripped in process of amputation, is capable of reproducing bone, the theory does not appeal. A much more reasonable theory is therefore offered that they are due to small bone fragments broken off by the saw, or

by snapping the last small bit before the saw cut is complete, or maybe by the sawdust itself carried into the soft tissues surrounding the bone end, developing bone which in time becomes attached to the bone end. So firmly am I impressed with the

last mentioned possibility that I have invariably followed the rule, in all amputations, of thoroughly washing off the cut surface of bone and soft tissues with an antiseptic solution previous to closure of the wounds. Roentgenograms of stumps so treated show in practically all instances no spur formation. The presence of spurs, on the other hand, is not sufficient justification for their removal, for we are convinced that in the great majority of cases they give no inconvenience, particularly if the patient has not seen the roentgenogram, and is therefore not aware of their existence.

5. Nerve buds or fibromas are not infrequently found, and being tender to touch, and often a source of discomfort to the patient, call for treatment. These neuromas are formed by the nerve fibers and sheath

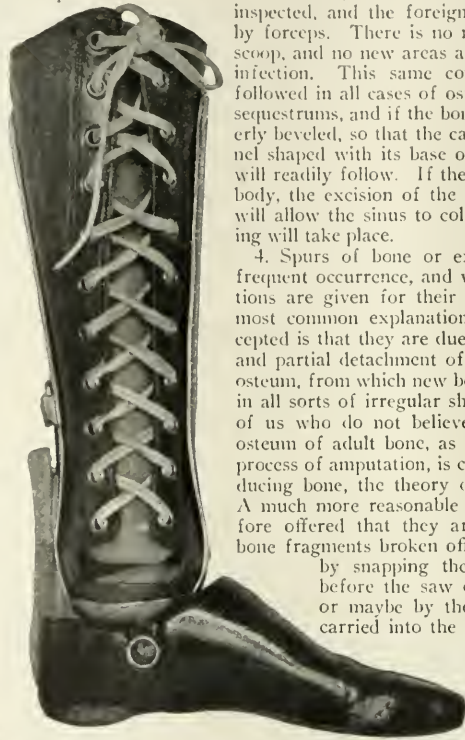

Fig. 1.—New Syme apparatus.

cells growing out from the cut end of a nerve and, finding resistance, curling back on themselves, forming a bundle or bulb which is always tender to touch, and refers pain to the terminal portion of the extremity supplied by such nerves. Numerous suggestions have been made for the prevention of the formation of these buds with only partial success. The oblique cutting of the nerve, the fish-tail section, the stripping back of the sheath, cutting the nerve at a higher level, and then tying the sheath over the cut ends—all these methods are advanced, with the greatest amount of success probably following the last named method. The nerve should always be cut back far enough to prevent its inclusion in the healing scar, and if deeply buried in muscle tissue will usually give no trouble. Attention is especially directed to the fact that the mere presence of nerve buds, tender to pressure, is not in itself sufficient reason for operative interference. Operation should be reserved for those cases in which the nerve is obviously caught in scar tissue, or is so placed that it will likely be pressed up by an artificial limb. Pain may be caused also by cutaneous nerves being caught in the scar, and the subsequent contraction produces irritation. This is overcome by the excision of a portion of the scar and the removal of the adherent nerve.

NONOPERATIVE PROBLEMS

1. Edema persists in most stumps for some weeks after all wounds are healed. No permanent appliance should be applied until this has subsided, and the atrophy of unused muscle tissue has taken place. The disappearance is hastened by suitable pressure by bandage, together with massage of stump. It is more efficiently treated, however, by the additional use of a temporary peg, with plaster or leather bucket. Deformity is nearly always present in a greater or lesser degree in the joint above the amputation. This is due to contraction of the muscles controlling the joint, to long continued flexion position, to adhesion of opposing muscles to one another and to the bone, to infection or infiltration with blood, or it may be due to adhesion from infection or blood in the joint itself. The milder degree of this deformity may be corrected by massage or by manipulation with the leverage obtained from the use of a temporary peg or skeleton arm in the gymnasium or therapeutic workshops. The severe degrees of deformity, especially of the knees, may require forcible manipulation by means of a hinged plaster cut across on the flexed side and wedged after daily manipulation. The various types of elastic pressure, and hinged steel braces with reverse screws have not proved as satisfactory as the well padded plaster splint with wedging.

2. Loss of muscle power as a result of disease exists in all amputation stumps, and a considerable training is necessary before the stump is in a good condition to swing an artificial appliance, and make good use of it. For the purpose of improving muscle tone, regular classes are formed in the gymnasium and work-

shops. At this stage all men with amputations carry on certain work in gymnasium or therapeutic workshops, to encourage confidence and balance, and to strengthen muscles. Special exercises with wall weight and pulley machines, walking in pegs, between parallel bars, leg bowling with specially constructed peg, racquets, and badminton with skeleton arms are all part of the scheme to develop better stumps. In the workshops, wood work, steel metal work, leather work, boot making and repairing, painting, drafting and printing are all found of value along similar lines. The foregoing exercises and games are not only physically developmental, but they tend to improve the morale, and successfully bridge the gap between hospital life and civilian occupation. In order to insure systematic and uniform treatment of this class of patients, when there were so many that one officer could not personally supervise and control the treatment of each patient, a circular of instruction was issued to each medical officer who had anything to do with amputation cases. I give herewith the copy of instruction.

Fig. 2.—A useful leg for long stumps below the knee.

FITTING OF AMPUTATION CASES WITH SATISFACTORY ARTIFICIAL LIMBS

It is desired that soldiers being fitted with artificial limbs should not be discharged until they have been fitted with a limb to the satisfaction of the surgeon concerned, and that the soldier at the time of discharge should have sufficient training in the use of the artificial limb to establish its suitability and a reasonable amount of dexterity in its use prior to his entering employment in civil life. For this purpose it has been decided that such cases will be graded as shown below and that the soldier will progress from one class to another as rapidly as his physical condition and adaptability to the new appliance will warrant.

1. Cases requiring surgical treatment, such as reamputation, removal of sequestrum, etc.
2. Cases in which the stump is healed, but which have some joint stiffness or edema of the stump. This class will be given passive treatment, such as massage and manipulation of the joint, to improve the action.
3. Graduates of Class 2, both upper and lower extremities equipped with skeleton arm and peg leg who may be given active treatment, such as gymnasium work, playing rackets, bowling, etc.
4. Cases of Class 3 who have improved to such an extent that they may be allowed to use the skeleton arms and peg legs in the workshop.
5. Cases supplied with permanent artificial limbs continuing work as in Class 4 for one month prior to their discharge.

A CONSIDERATION OF THE VARIOUS TYPES OF AMPUTATIONS

The necessarily brief character of this paper makes it impossible to consider the problems associated with each individual type of amputation; but some of the amputations may be dealt with to serve as examples.

In the lower extremity, an amputation of the toes, provided the plantar flap is brought up on top, is almost no disability. One toe should never be left, as it soon becomes distorted, and adds no element of usefulness. The tarsometatarsal amputation can be made very satisfactory if the peronei are left intact on the outside, and the tibials on the inside. The midtarsal amputation results in an unbalanced foot with elevation

of the heel, and downward pointing of the foot. This form of amputation cannot be properly fitted with either artificial foot or boot, and should under all circumstances be reamputated and made into a Syme amputation.

The Syme amputation is theoretically and practically the best in the lower extremity, and yet it is surprising how many of these are faulty. The chief defect is too long a flap, or too much bone removed from the end of the tibia and fibula, resulting in a bearing end which is not stable, and which rolls forward or to one side. This can be remedied by taking a cuneiform section of soft tissue from the anterior portion of the flap, thus diminishing the size of the walking pad. If the surfaces of the malleoli are trimmed down at the same time, a better artificial appliance may be fitted.

In the leg an amputation should not be done within a hand-breadth of the ankle, in order to give ample room for an ankle joint properly placed in an artificial leg. Above this point the longer the stump can be made, the better leverage is given, and consequently the easier the man will walk, and the less limp is developed.

The term "seat of election" as applied to leg amputations should be dropped, as it is a constant source of confusion. Below the knee there is a point at which the stump is so short as to be useless. The test of this point is the complete flexion of the stump; and if the continuation of the line of hamstrings is in the same plane with the face of the amputation stump, a suitable artificial appliance cannot be applied to utilize the natural movements of the knee.

A knee-bearing apparatus for this type of amputation, or a disarticulation at the knee, is a clumsy type, and not easily or firmly fitted, and as a consequence a supra-condylar amputation is preferable. In the thigh, as in the leg, the longer the lever the better the artificial limb may be used. The Gritti-Stokes is the best of the thigh amputations, and is to be selected in preference to the knee-bearing. This gives a very good end-bearing stump when the operation has been well done, and yet there are a good many of these stumps which are not good. The chief fault is a lack of close approximation of the patella to the cut end of the femur, and in consequence a nonunion with slipping or unstable surface, or a malunion, the patella becoming united in an oblique plane. These defects should be remedied before attempting to fit an artificial limb.

All other amputations of the thigh give no serious problems, other than those already considered in general problems, until the upper part of the thigh is reached. A stump under 5 inches in length from the perineum can scarcely ever be fitted with an artificial leg without a pelvic band, and all such should be so

fitted. Amputations at the level of the trochanter minor or above, including disarticulation at the hip, have insufficient leverage to use a thigh bucket, and a pelvic cradle, the so-called "tilting table" of the English manufacturers, must be adopted, with automatic lock joints both at hip and knee.

The end-bearing stump is of great assistance in permitting the easy locomotion of the wearer of an artificial limb, but aside from the two types, a Syme in the leg and a Gritti-Stokes in the thigh, a complete end-bearing stump is never possible. It is possible both in the leg and in the thigh to get a partial end-bearing stump in a good many cases, properly supplied with a good pad over the end of the bone. This partial end-bearing stump is best accomplished by means of the hammock suspended in the bucket, by means of which the wearer may graduate his weight bearing.

In the upper extremity, problems present themselves, chiefly from the fact that up to the present time mechanical appliances have not yet been devised which satisfactorily act as substitutes for the lost member. Any of the digits which can be saved in a useful position may be found of great assistance as an opposing factor to a mechanical appliance. On the other hand, fingers whose tendons, both flexors and extensors, are hopelessly tied up, and the joints of which are destroyed by the overgrowth of the fibrous capsule, may be advantageously sacrificed to make way for a hook or some similar device. At the wrist, the whole carpus is rather a detriment than a benefit, and should not be saved, especially when the carpal joints are fixed. The

artificial appliance supplied to such a hand will be long and cumbersome and not easily manipulated.

When possible, the radio-ulnar articulation at the wrist should be maintained, as it permits of the most useful movement of pronation and supination. In the forearm, the length of stump is the chief factor in determining the usefulness of the arm, as each inch of stump adds materially to the leverage, and therefore to the power of such arm. A stump of  $1\frac{1}{2}$  inches or less below the fold of the elbow is useless, as it pulls out of the bucket in attempts at flexion. When movement alone is of value, even if no power can be developed, a leather cap over the short stump with a compound lever may be utilized successfully.

As in the knee, a disarticulation at the elbow is not so readily fitted with an appliance, as an amputation just above the condyles of the humerus. With a stump shorter than 3 inches in the upper arm, a controlled artificial appliance is not yet supplied, although attempts are being made to reach a solution of the difficulty.

For disarticulation at the shoulder, only a sleeve filler may be supplied, and it is found that very few of the men with such amputation care to wear the appliance, as it is difficult of adjustment, and adds materially to the time it takes a man to dress.

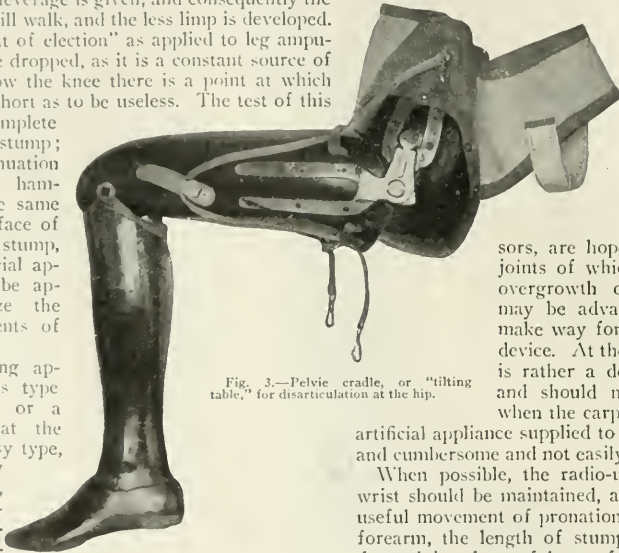

Fig. 3.—Pelvic cradle, or "tilting table," for disarticulation at the hip.

## ARTIFICIAL LIMBS

As previously indicated, the supply of all artificial limbs and orthopedic appliances is under the department of Soldiers' Civil Reestablishment, and the policy of the department, in cooperation with the consultant in orthopedic surgery, has been to establish a standard limb for all types of amputations. This has been possible of accomplishment most successfully in regard to the lower extremity, but unfortunately the difficulties of finding any appliances suitable for amputations of the upper extremity has been so great that constant changes have been necessary, and it is only just now that the department is arriving at a point that permits that the arms may be more or less standardized.

A rather important development of the work has been the establishment of a mechanical research department, which has nothing to do with the factory output, and the mechanics devote their whole time to the study of problems, and working out of mechanical ideas, brought to them from any source through a central research committee. This laboratory has already resulted in much good, and as fast as any improvements are made, which have passed the test of the committee, these are incorporated as part of the standard type. The policy has been to furnish a permanent peg and an artificial limb to each man who has an amputation of the lower extremity, and a working arm and a so-called dress arm to those who have an amputation in the upper extremity. The attempt to combine the two arms in one appliance has not been satisfactory.

## THE PEG LEG

The peg leg is a temporary appliance based on the Thomas knee splint. It has a shaped ring at the top, taking the top of the bucket of the artificial leg as a pattern. This takes the bulk of weight on the tuberosity of the ischium, and eliminates the troublesome pressure on the perineum. The ring is well padded and leather covered. A little behind the center of the ring, two steel bars drop to a point well below the stump, where they unite in a ferrule, into which is fitted a wooden peg ending in a wide rubber walking pad. A leather bucket is attached to the posterior half of the ring only, and by a loop around each side bar. The lacing is made smaller than the circumference of the thigh, so as to permit snug fitting, for the purpose of shrinking the stump. A hammock is slung in the lower part of the bucket to permit of padding to encourage weight bearing, or short of that to keep up even pressure on the stump to prevent local edema. This whole splint is suspended from the opposite or both shoulders by the usual webbing braces. The peg without joint at the knee for above-knee amputations has been selected because, from the evidence of the men themselves, it has been established that they get about more securely, and walk better and with more confidence than they do with either a peg with flexible knee joint, or with a temporary leg of the usual pattern. In the more or less shaky condition that these men

are, when they first start out to walk with artificial appliances, it is easily observed that they walk with much more confidence in the peg than with the knee joint. A lock joint at the knee may easily be added, if thought desirable, so that the man may sit without the peg sticking out too far in front. The statement often made that men who learn to walk with a peg get a bad gait, and tend to throw the peg to the outside, and carry the foot around the circumference of a half circle, is not borne out by facts. If a man walks in such fashion with a peg it is an evidence of the fact that the peg is too long, and he must either swing it round, or elevate his pelvis on that side to permit of its coming through straight. All pegs should be at least three-fourths inch shorter than the corresponding leg.

The plaster pegs were used at first in our work, and proved very satisfactory for purposes of shrinking, but the lifetime of the average plaster peg was only three months, and had nothing artistic about it to recommend it to the average soldier. There was an evident necessity also for a permanent peg, as on occasions the permanent leg requires repairs, and the peg acts as a substitute. Some men with amputations also find it the greatest comfort to exchange the artificial leg for a light peg at some part of the day to rest the stump, and many men doing heavy work prefer to work with the peg, and change to the artificial leg in the evenings or on Sundays. A flat sandal affair or wooden foot is sometimes attached to the peg to facilitate walking in soft earth.

Wood was selected for the bucket of the standard limb because it appeared that it is worn the most comfortably of any of the materials used for the purpose. It does not sweat and macerate the skin; it is lighter than leather, and once having been fitted accurately, does not change its shape. This is especially true of the below-the-knee type.

The standard limb is made of seasoned willow, in a general way, after the Hanger type; the toes are of felt, the foot of maple, the ankle bushing is of bronze working in leather, and is bolted through the bottom of the foot. The knee is of the usual type with control from inside the bucket, of the modified Rowley pattern. Below the knee a wooden bucket is always used for 4 inch stumps or longer, and a slip-socket double leather bucket for shorter stumps.

## ARTIFICIAL ARMS

After thorough trial it has been found that the very complex mechanical arms are not satisfactory, and they have been eliminated. They are found heavy, with the greatest weight at the point farthest from the body, namely, in the hand. They are for the most part of metal, and in our western country are claimed to be very cold. Their complexity makes repairs frequent, so that the limb spends a great part of its life in the workshop. Simplicity has been aimed at, and the nearer we can come to this ideal, the better the product. A light dress arm of wool controlled at the elbow from the opposite shoulder with a catch lock that will fix the joint in three positions, or released, will allow the joint to play free, with a detachable hand and

Fig. 4.—Permanent peg for above-knee amputation

controlled spring thumb, is the type supplied for all above-elbow amputations. For the forearm, the same pattern without elbow control, and a leather corset about the upper arm is substituted. The working arm is a simple leather bucket, reinforced with band steel to which is attached a short steel tube into which may be inserted a special clasp hook, devised in our workshops, or a lighter hook of the Dorrance type.

A recent development has been what we call the "Canada" arm, which, in addition to the arm described above, may carry an elbow joint controlled from the opposite shoulder, and a short forearm steel tube into which may be fitted the utensils noted above. As the appliances, such as forks, knives, hooks, safety razors or similar appliances, all are of standard type, they will fit any arm either above or below the elbow. This short forearm device may carry a hand on a long stem with gauntlet, so as to obviate the necessity of changing to the dress arm on completion of work. For long forearm stumps, a bucket with soft leather sleeve to lace above the elbow, after the Williams type, into which our standard appliances may be fitted, is found the most serviceable.

After all one's ingenuity is exhausted, and every device has been tried, it is still found that it is difficult to fit some men with apparatus with which they can "carry on" in civilian life, unless one can instil into them that element which seems to be lacking, namely, personality or character. On the other hand, it is impossible to prevent others who have this character in large measure from doing anything that "any white man can do," as one of them expressed it, even if their appliances are crude or home-made.

For this reason every effort is made by encouragement, by example, by contact with others similarly afflicted who are able to accomplish useful tasks, and by training and enthusiastic support of the medical officers to improve the morale of this type of afflicted patient.

**Poisoning with Potassium Chromate.**—A pharmacist at Brethlau made up a salve for treatment of scabies at the public clinic for skin diseases, and by mistake used potassium chromate instead of the sulphur ordered. A number of persons were severely poisoned by it and twelve are said to have died, according to the *Nederlandsch Tijdschrift*. Burning pain was complained of at once and some vomited. Two soldiers developed serious symptoms, fever, dark brown and bloody urine and albuminuria the twenty-seventh hour after the application. A number of those affected developed anisocoria and retinal hemorrhages, but the most threatening symptom was the inhibition of kidney function. The employment of venesection, diuretics, intravenous injections of sugar and decapsulation of the kidneys failed to display any favorable influence.

## AMPUTATION STUMPS IN RELATION TO THE FITTING OF ARTIFICIAL LIMBS\*

E. J. ROSE, M.D.  
Captain, M. C., U. S. Army  
GALLIPOLIS, OHIO

One of the most useful by-products (if we may use the term) of the unhappy war just closing would be the proper recording and preservation of all experiences—especially in surgery—that may be of future value to humanity. The object of this paper is to open for discussion some of the observations made during the present war.

There is very little published information on the subject of amputation. Volumes have been written on surgery with only a casual reference to this most important branch of orthopedic surgery.

It is recognized that in the field many amputations must be primarily life saving operations; but the dominating idea in the performance of every amputation, next to that of saving life, must be the suitability of the resulting stump for the fitting of an artificial limb. The site and often the method of a primary amputation are mainly determined by the injury, the amount of shock, the severity of the septic infection, and the environment. Rapidity of operation must occasionally be the dominating consideration. Amputations undertaken under war conditions cannot, therefore, always yield the stumps best suited for the fitting of artificial limbs and subsequent operations often become necessary.

While the exigencies of military practice are responsible for many unsatisfactory stumps, some, it is to be feared, are due to an insufficient appreciation by the surgeon of the qualities necessary in a stump if the greatest possible benefit is to be obtained from an artificial limb. It is necessary that the

surgeon should not only be concerned with the amputation itself, but also should have a knowledge of what the fitter of an artificial limb requires of a stump, so that the combined efforts of surgeon and fitter may obtain better results than they have been able to do in the past working separately. As a rule, the surgeon gives little attention to the fitting of artificial limbs and rarely sees his patient after the healing of the wound, but turns him over, usually without supervision, to the artificial limb maker. Thus the surgeon loses one of the most valuable means of control in the perfection of his technic, and

Fig. 5.—Permanent peg for below-knee amputation.

\* Read before the Section on Orthopedic Surgery at the Seventieth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

frequently errs in comparatively small details which a knowledge of the fundamental points of the artificial limb maker's art would enable him to avoid. In brief, if the surgeon had clearly in mind, from the prosthetic point of view, the essentials of a good stump he would be better equipped to carry out that system of treatment which will restore a man who has suffered an amputation to the greatest functional efficiency.

An ideal amputation should be of such a length as to enable the artificial limb maker to fit the most useful type of limb built to perform as nearly as possible the function of the absent member. The stump should be covered by skin and subcutaneous tissue just slack over the end, and freely movable. There should be no redundant skin or pointed corners. There should be a firm nonadherent scar or cicatrix, the scar should be linear and placed where it will not be subjected to pressure or irritation by the artificial limb. The edges of the skin about the scar should not be turned in. The stump must be entirely free from pain or tenderness. The principal nerves should be cut as short as possible at the primary amputation. There should be no superficial or deep edema. There should be shrinkage and consolidation of all parts of the stump. The joint next above the amputation should possess full range of voluntary movement. The integument must become so hardened as to be able to bear subsequent pressure and especially is this true of stumps of the lower extremity whose duty is primarily that of a support, and secondarily acting as a lever for moving the apparatus. This leads us to a very brief discussion of the sites of amputations best suited for the fitting of an artificial limb.

#### AMPUTATIONS OF THE UPPER EXTREMITY

The importance of preserving as much as possible of the thumb or even of one finger can scarcely be insisted on too emphatically. A thumb or part of a thumb, or finger with fair range of motion and nerve supply intact though there be no portion of the hand to which it can be opposed, is very much more useful than any artificial contrivance. Amputation at the wrist should never be done if it is at all possible to retain any portion of the hand or carpus. Amputation through the pronator quadratus is preferable to a disarticulation of the wrist.

From the prosthetic point of view probably the best site for amputation in the forearm is at the junction of the middle and lower thirds. However, if an appliance is not to be worn, as long a stump as possible should be preserved. The minimum forearm stump measured from the tip of the olecranon process is 3 inches. A forearm stump less than this ceases to exist as a stump anteriorly when flexed. When it is possible to retain only such short portion of the bone, the flexor muscles of the wrist and fingers, the supinator longus and the extensores carpi radialis longior and brevior should be removed at their humeral attachments so as to leave the anterior surface of the forearm stump as flat as possible. Amputation through the elbow joint offers no advantage over amputation immediately above it, since in the former case the satisfactory fitting of an artificial arm is more difficult.

The point best suited for amputation in the upper arm is about 1 inch above the condyles of the humerus. Above this point it is particularly desirable to secure as long a stump as possible. Some power of movement over an artificial arm can be obtained with a

stump containing 1 inch of humerus below the anterior axillary fold, but a stump with less than 3 inches of bone forms a poor lever for moving an artificial arm. A short arm stump may be lengthened by dividing a portion of the pectoralis major and teres minor tendons and thus raise the anterior axillary fold. It seems advisable to retain any portion of the upper end of the humerus even if only the head, rather than remove it since the appliance is fitted much more easily when the glenoid cavity is filled.

#### AMPUTATIONS OF THE LOWER EXTREMITY

Amputation of the toes requires a "Planter flap" to get a good result and this is rarely available. A single toe should never be left as it will become deformed and painful. Amputation just back of the head of the metatarsal bones, in front of the attachment of the tibialis and peronei muscles, gives a very useful foot. The tarsometatarsal disarticulation (Lisfranc's operation) sometimes gives a very useful foot provided the ends of the tarsal bones are well covered with a Planter flap. A midtarsal disarticulation (Chopart amputation) is usually unsatisfactory and sooner or later a condition of equinus is likely to result, due to contraction of the unopposed calf muscles, and walking becomes difficult or impossible. Both Pirogoff's and subastragaloid amputations give stumps which make very difficult the fitting of effective artificial limbs. The Syme amputation is preferable to a Pirogoff as it gives more room for an ankle joint mechanism and avoids the difficulty frequently encountered in keeping the end of the os calcis in position. A Syme which is not entirely end-bearing is inferior for functional purposes to an amputation through the leg. The most favorable site for amputation in the leg is the middle third with a from 8 to 9 inch stump. Below this point the stump is not so satisfactory for end-bearing and the fitting of an artificial appliance is more difficult and the flaps are usually wanting in vitality. Above this point the leverage power is diminished. With proper surgical precautions an end-bearing stump should be secured at this level, and with a good modern artificial leg the gait should be practically normal. Many artificial limb makers prefer amputation at this site of the leg to any amputation back of the toes. Fair results have been obtained in fitting in a case with as little as 2 inches of tibia; but a stump as short as this is usually inadvisable, as it ordinarily will have to be fitted with the older type of knee-bearing leg, with the tibial stump bent to a right angle. However, a below knee appliance supplemented with perineal bearing, has given very satisfactory results in this type of case.

Amputation through the knee gives a very satisfactory stump with good end-bearing, provided the condyles are amply covered, preferably with an anterior flap. Under septic war conditions implantation of the patella on the cut surface of the divided condyles (Stokes-Gratti) is apt to be followed by displacement of the patella, by nonunion, or necrosis. When the union between patella and femur is complete, the results have been very gratifying. In the thigh the best amputation is one just above the condyles. Above this point all the length possible should be saved.

Unless 2 or 3 inches of bone below the lesser trochanter is left, a very unsatisfactory thigh stump results and it is practically impossible to fit the stump with a thigh bucket. If 2 inches of bone below the lesser trochanter cannot be saved, reamputation should be

done through the neck of the femur or through the hip joint. It is now possible to fit an exarticulation of the hip with a very satisfactory appliance called the "tilting table." In many cases the gait is even better than the shorter thigh stumps fitted with the thigh bucket.

In fitting an appliance one should make the amputation stump and the artificial limb one. This can best be done by the cone principle. Every stump through a smaller or greater part of its extent resembles a cone with a base upward. When this condition is utilized every change in the form of the stump, through pressure, only tends to make the fit more secure and perfect.

The American artificial legs are efficient since the beginning of the war little effort has been expended on this feature of the problem. However, considerable has been done in attempting to improve provisional appliances. In the treatment of civilians with amputations the artificial limb makers recommend the use of numerous stump shrinkers. This is merely an admission by them of the advisability and necessity for the early fitting of a provisional limb. During this period the amputation stump is constantly changing in size and shape. To fit a man at this time with a permanent type of prosthetic appliance would be a costly and unprofitable procedure. The artificial limb makers have recognized this difficulty but have not been able to solve it satisfactorily. It has been the practice of those with an amputation of the lower extremity to use crutches for ambulatory purposes. In so doing the stump is left hanging as a useless appendage, not participating in the movement of walking and if sufficient time elapses disuse and atrophy result. The use of crutches always results in a bad postural attitude which is very difficult to correct, to say nothing of crutch palsy and other complications which may develop. A provisional limb, under the plan now followed, is fitted at a very early date after the amputation, often before the complete cicatrization of the wound. In so doing the stump comes quickly to participate in the action of walking, thereby developing its muscles and nerves under the control of the spinal and cerebral centers. The parts of the stump are energized thereby and their new functions developed. The balance of the body is adjusted to the new condition and the equilibrium is established. The shrinkage of the amputation stump to its new dimensions is rapidly secured. The mental effect is likewise of service, so that from all points of view the early application of the provisional limb is desirable. The cost of the provisional limb should be as low as is consistent with effective service, because the rapid changes in the dimensions of the stump necessitate frequent changes in the provisional appliance.

Probably the most satisfactory all around provisional appliance so far devised has been made of plaster-of-Paris. With moderate skill practically every amputation stump can be fitted with this form of provisional appliance. The materials needed are simple and are available to practically every surgeon.

The bucket or socket is made of plaster of Paris, applied in the form of bandages carefully molded to the stump, so it supports the usual bony prominences and in addition exerts even pressure on the entire contour of the stump. It has the advantage that the pressure can be modified to comply with the characteristics of any particular amputation stump. Artificial

legs or set-ups without sockets (either for above-knee or below-knee cases), to which the plaster socket can be attached, can be purchased from the artificial limb makers and should be kept in stock.

The chief difficulty in devising an appliance capable of performing the work done by the lost hand is due to the high degree of differentiation in the hand functions. When a leg is lost the chief requirement to be met is support and hence no complicated mechanism is required. An artificial arm of similar construction would serve little more than a cosmetic purpose. The usefulness of a natural hand depends on these factors: First, rapidity and precision of movements; second, strength, and third, a sense of touch.

Strength is the only one of these requirements for which it is possible to make adequate provision in the artificial arm. Since only two pulls are usually practical in an artificial hand it is evident that its usefulness will be necessarily restricted to grasping movements of a very simple nature. Thus, it is obvious that the one-armed man will use an artificial arm only for a few and relatively simple acts. Most important acts will be done with the remaining hand. In an armless person the problem is entirely different. Instead of provision for the few and relatively simple acts required by the one-armed, the demand now is provision for every act possible, yet the means at our disposal are the same. Practically every armless person wears very simple artificial appliances with various forms of attachments designed to do the simple things which will make him independent after he has obtained sufficient skill in their use.

#### CONCLUSIONS

1. The amputation stump should have a satisfactory length, a good mobile covering, a firm nonadherent cicatrix so placed as not to be subjected to pressure or irritation by the artificial limb, a freedom from pain and tenderness, and absence from edema, a shrinkage and consolidation of all parts of the stump, and a free normal mobility of the joints above.

2. The surgeon should have clearly in mind the sites of amputation best suited for the fitting of an artificial appliance.

3. The surgeon should have a knowledge of the artificial limb makers' requirements of a stump and also a knowledge of the fundamental points of the artificial limb maker's art.

4. Experience has proved the value and wisdom of using provisional appliances in the early treatment of men with amputations, and it is hoped that there will be a universal acceptance, by surgeons, of this as the approved method of treatment.

5. However perfect a prosthetic appliance may be, it must be remembered that it will never reproduce the anatomic and physiologic characteristics of the amputated limb, and will never actually replace the lost member, but observation of many cases shows that faithful and intelligent practice, under guidance, will add immeasurably to the effectiveness of the artificial limb.

#### ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. STARR AND ROSE

DR. PHILIP D. WILSON, Columbus, Ohio: I wish to commend particularly the remarks Dr. Rose made about the necessity of surgeons learning the sites of amputation that will give the best results with artificial limbs. I should like

to comment on the forearm amputation. It has been found that a stump less than 3 inches below the elbow is not useful. The biceps tendon has a tendency to work off the bucket in contractions of the forearm. Against this must be urged the fact that artificial arms are not successful. The experience in foreign countries is that less than 20 per cent. of those who have artificial arms wear them, if they have one good hand. We must consider that against the advisability of converting a short forearm stump into an upper arm amputation. A forearm stump without apparatus is useful as a support for paper, and in many other ways. We have seen demonstrations of how men with double forearm amputations can, without wearing appliances, do a number of things by using their forearm stump as a kind of large finger.

The plan of lengthening an upper arm stump by cutting the pectoralis major and the anterior and posterior axillary folds has been suggested; but it seems to me doubtful whether such a stump can be lengthened sufficiently in this way to make the operation worth a great deal. In the foot, I would speak of Symes' amputation, which is being developed principally by the English. The results with it have been exceedingly good, but they are dependent on making this stump fully 100 per cent. end bearing. It usually is made with two redundant flaps, which have a tendency to evert, turn over and, in the end, produce a painful stump. By a little careful tailoring and attention to detail, this can be remedied; and attention to the nerve endings is extremely important. The site of election for an amputation of the leg is said in the textbooks to be 4 inches below the knee. That is based on the idea that such mutilees should walk with the knee bent. The modern conception is that they should never walk with the knee bent. A man is better off with an amputation above the knee than he is walking around on one of those old bent knee affairs. When the stump is less than 9 inches below the knee, we should try to save every inch we can. The Stokes-Gritti amputation is not necessary. The matter of end bearing of a stump is more a question of the after-treatment of the patient than of the type of operation. By the inauguration of gradually increasing end pressure exercise, as described by Lyle, three or four years ago, the stump can gradually be toughened so that full pressure can be borne on the stump end. Even when this is done, however, the value of such a procedure is very doubtful. The artificial limb makers, in actual practice, do not utilize it. That is partly their fault, but there is a reason for it. It is almost impossible to fit an artificial limb in such a way as to divide the pressure equally between the end of the stump and the tuberosity of the ischium. Unless pressure is put on the latter, the leg lacks stability and there is a tendency to turn. The introduction of plaster-of-Paris legs should be generalized. Getting the patients up as early as possible on these provisional legs, the functional results will be improved 50 per cent. and will be reached in one-third the time.

DR. REGINALD H. SAYRE, New York: One of the bothers with amputations is the old ulcerated stump. In a case of edematous stump with a large ulcerated area, which had existed for four years, I operated just as I would on any varicose area, slitting it all around and applying pressure to prevent the edema. I found difficulty in keeping pressure on the end of the stump, and I employed a procedure that was then new to me. After scarifying the ulcer, I made compression and put adhesive plaster on the sides, front and back of the thighs, with eyelet holes at the lower extremity. I then made a cross of adhesive with eyelets at the four ends and put a dab of balsam of Peru on the ulcer. I fastened the cross of adhesive to the other adhesive strips by means of elastic strings passing through the eyelets and pulled as tight as possible on the side. In the course of six months, the thigh had healed up and the patient had a perfectly good stump. Just as in ulcers of the shin, the fundamental necessity of relieving the edematous condition of the leg by equitable pressure does not seem to be appreciated. I have brought this forward as a practical method of getting rid of it in these ulcerated stumps. Another man had been

operated on three times before he came under my observation, for thrombo-angiitis obliterans. This man had an unhealthy and crooked stump. At the last operation, his stump had contracted at an angle of 45 degrees, and it was impracticable for him to wear the curiously contrived artificial leg with the wobbling bucket, as he had to let this rudder stick out at the back while walking. I straightened the knee. A plaster-of-Paris bandage was applied around the thigh and stump, the plaster being held in position by adhesive running up the thigh and then incorporated in the plaster of Paris to keep it from turning over. When it was hard, the plaster shell was sawed in two, and a wedge of wood was put in behind the knee with a band of plaster of Paris around it to hold it in position. It was removed in four days, and a larger wedge of wood was inserted. This was repeated at intervals, until we got the leg into a straight position. I have found this a practical way of getting these legs straight. Later, as the scar tended to open every time he stretched it by using the artificial leg, a piece of adhesive plaster was put across the scar after it had been pulled together to relieve the tension on the cicatrix until it healed up.

DR. JABEZ N. JACKSON, Kansas City, Mo.: It is striking how little attention is paid to anatomy in the ordinary textbook description of amputation, and, I think, that a great deal of dissatisfaction with the stumps is dependent on this. We are told to cut down to the fascia. I think it is better to cut through the fascia and lift up the fascia with the skin. Do not close the wound by a through and through stitch. Suture accurately the aponeurosis of the muscles and close the skin separately. If this fascia is brought over and sutured separately, you can close the skin with any kind of stitch.

DR. REGINALD H. SAYRE, New York: I should like to hear whether any one has had experience with Vanghetti's kinoplastic operation for getting muscles and tendons that will be able to manipulate the fingers in upper arm amputation.

DR. EDWIN W. RYERSON, Chicago: Huber, of the University of Michigan, has shown that if the last three fourths of an inch or 1 inch of nerve be injected with alcohol at amputation, no neuroma will be formed. As Dr. Starr says, the neuroma is formed by the growing down of the neurofibrillae and the formation of a painful bulb. If this simple technic of injecting with alcohol is observed, there will be no growing down and no neuroma. No neuroma is formed above the site of the injection, because the neurofibrillae do not proliferate except at the cut end. I think that this method is worthy of a trial, because painful nerve bulbs are frequent.

DR. C. W. HOPKINS, Chicago: One point that I was glad to hear brought out in the discussion was in regard to the site of amputation in the leg in cases where the doctor can use his discretion, when the injury is low down. The general tendency for many years has been to save all of a leg possible, giving the patient a very long stump, by performing the amputation just above the ankle. In my railroad work I have had many men come to me who were operated on years before, requesting that a reamputation be done higher up, stating that the long stump caused a very unsightly bulge in the lower end of the artificial limb, just above the ankle, and that the long stump seemed to suffer considerably from cold and to be in the way generally, and many times developed ulceration on account of poor circulation. We must remember that in wearing an artificial leg, the weight bearing is entirely on the condyles, the length of the stump making very little difference if it extends 8 or 9 inches below the knee. For that reason I have been doing all amputations of the leg at about that point even where the injuries consisted of a destroyed foot or lower end of the leg, and since that time I have found that the patients have had very little trouble and seldom ever return for any further work. There is one point in leg amputations which has not been brought out, and that is the removal of the head of the fibula where the stump is very short. If the leg stump is not over 4 or 5 inches long, or does not leave more

than 4 inches of the fibula, the fibular head should always be removed at the time of the amputation otherwise the patient will invariably experience discomfort by the fibula being pushed toward the tibia which keeps up a constant irritation. I was very glad to hear the remarks made by Dr. Jackson and will say that my own experience has proven him to be correct. I also heartily approve of the early weight bearing or use of a leg soon after amputation by some good method which prevents a long drawn out employment of a crutch, raising the morale of the patient 100 per cent.

DR. CLARENCE L. STARR, Toronto, Ont.: All the amputation cases I spoke of were in war conditions. As almost all the men had had anywhere from twelve to fifteen operations, I could not suggest the idea of a reamputation for the formation of an ideal stump. We had to take the material presented and make the best of it. Take the question of peg legs. We all agree that in the treatment of these conditions, the sooner you get the men into temporary apparatus of some sort for walking, the better; and yet the psychology of the situation is so marked that it is difficult to get these men into pegs. For instance, a man appearing with his leg tied up and his trousers leg pinned up, and walking on crutches, does not go far before he is picked up by some kind hearted woman in an automobile and given a ride. If he has a leg on, however, this will not happen. That is a difficult thing in itself to overcome. It is not a question of ideal types, but a question of some of the difficulties that we meet in attempting to deal with these amputation cases. The subject is so large that it is almost impossible to touch the fringe of it. In the question of a double arm amputation, one arm being an amputation 1½ inches below the elbow. One of the speakers said that this would not produce a movable arm. We had that difficulty until we put a small cap over the end of the bucket and ran a compound lever up the arm and then back to the forearm piece. That gives him a double lever, by which he can use a safety razor, a comb and brush, a knife and fork, etc., and he is capable of taking care of himself. He can travel, if necessary, without a valet. A double amputation with that sort of apparatus is in a fairly good condition. It is such problems that we try to meet with the material that we have on hand.

DR. PHILIP D. WILSON, Columbus, Ohio: With reference to Dr. Sayre's question about the Vanghetti amputation—my observations in Italy were not such as to convince me that this is a useful procedure. It offers hope from the experimental standpoint, but is not far enough along for us to take it over and make it practical. It cannot be done unless a man has a prosthetic workshop that he is controlling. Tendon and muscle loops are made, the movement of which is to be used to actuate artificial hands; so it is necessary to have in mind the apparatus that is to be made to fit on it. It is not enough to do the operation and say that we have a fine result because the tendon moves an inch. It is necessary to harness it up and make it practicable. Three or four such amputations have been made in the American army, and the three that I know of had to be removed as not practicable.

DR. E. J. ROSE, Gallipolis, Ohio: In civilian practice we do not see the ulcerated stumps that we see in war amputations. In the front area work in France practically all amputations following gunshot injuries were of the guillotine type and the stumps were left wide open. As a result of this method, even if the best secondary method is carried out, large central scars with varying sized ulcers will persist and often times refuse to heal. It has been our procedure in General Hospital No. 3 to treat these ulcers and granulating areas until a sterile culture is obtained. If there is no bone involvement, an excision of scar tissue and a plastic closure is done; however, many cases require excision of a small portion of bone before closure is done. The length of the stump determines to a great degree the mode of operative procedure because the object for which we are working is to obtain the best possible stump for the fitting of an artificial limb.

## UROLOGIC FINDINGS IN DISEASES OF THE CENTRAL NERVOUS SYSTEM

A STUDY OF FIVE HUNDRED CASES\*

JOHN R. CAULK, A.M., M.D.

HARRY G. GREDITZER, M.D.

AND

FRANCIS M. BARNES, M.D.

Chief of the Genito-Urinary Clinic, Surgeon to Outpatients, Genito-Urinary Clinic, and Associate in Psychiatry, Respectively, Washington University Medical School

ST. LOUIS

Urologic recognition of disease of the central nervous system is a phase of medicine of such magnitude that physicians should be keenly alert to it. For this reason we have made a comprehensive urologic study of 500 cases of nervous and mental diseases, in the hope of determining definite facts which might serve, in conjunction with our previous knowledge, to insure our intimate acquaintance with this phase of urology and enable us to be an important aid to a thorough neurologic investigation. To be of value an investigation must result in definite findings concerning factors constantly present in organic disease of the central nervous system. These we seem to have made. We have known it for some time, yet, when one reviews the recent urologic textbooks, it is notable that there is a shocking absence of the slightest reference to the fact, though the findings constitute, certainly, one of the most important chapters in urology.

Of the significant urologic observations, the most important of which are loss of sexual power, relaxation of the rectal sphincter and the bladder picture

Fig. 1.—This and the accompanying illustrations are drawings from a cystoscopic examination: A, internal sphincter muscle; B, floor of urethra; P, bladder wall, showing trabeculation.

as revealed by the cystoscope, the last named is the most reliable. Cystoscopic findings in disease of the central nervous system, particularly those affecting the lower segments of the spinal cord, of which tabes dorsalis is the most notable example, are definite, constant and characteristic to a degree that stamps them as being of very considerable diagnostic importance.

\* Read before the Section on Urology at the Seventieth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

Since such a large percentage of diseases of the central nervous system manifest themselves initially by disturbances of bladder function, and since so many surgical diseases presenting bladder disturbances are either complicated by or associated with tabes, it is apparent that the recognition of this type of bladder is extremely important.

Owing to the confusion in the interpretation of the term "tabetic bladder," which would seem, as its name implies, to indicate only the bladder associated with

On further withdrawal, the verumontanum may be brought plainly into view, the orifices of the utricle and ejaculatory ducts inspected; and, very frequently, seminal ejaculation from the orifices may be observed (Fig. 2). Various degrees of relaxation of the sphincter and prostatic urethra are seen: In some instances, only the first part of the urethra is visible; in others, the whole urethra permits inspection, but indistinctly, and still others show considerable relaxation but do not allow vision.

The first type of pronounced relaxation, with the guttering of the urethra and visibility of the verumontanum, is the characteristic and significant finding in cases of definite nerve lesions. The other types are less positive and seem to occur quite frequently in the presence of a negative neurologic examination, frequently in certain psychoses, but rarely in pronounced organic disease. This group, which may be termed minor relaxations, offers a very interesting series of cases and one about which considerable confusion exists at present. While cystoscopic findings are not positive, they are highly suggestive, and in many instances individuals showing these changes have later presented definite neurologic developments.

These findings are commonly associated with functional disorders, neurasthenias, reflected pains in the perineum, groins and testicles, and general atonic conditions, and it may be that they are representative of a general let-down in physical tone. As previously stated, however, we should always be careful in construing this picture and offering a prognosis to the patient. We have frequently observed these slight relaxations in early syphilitics, in fact, such changes have prompted us, in many instances, to have Wassermann tests taken.

Associated with this orifice picture, the trigon (Fig. 3) is usually elevated, but seldom husky and

Fig. 2.—B, floor of urethra; C, verumontanum, showing orifice of utricle; L, lateral urethral walls.

locomotor ataxia, we have designated recently the condition in which there is bladder disturbance complicated by or associated with tabes, as the neurogenous bladder, because we feel confident that the findings in the bladder are strikingly suggestive, if not absolutely positive, of neurologic disease, even though in many of our cases there has not been a neurologic substantiation.

Among urologists, there has been considerable discussion as to the characteristic findings in the bladder in disease of the central nervous system, and most of the previous reports on this subject have dealt with the great importance of trabeculation as being pathognomonic, without regard to the internal sphincter. It is our belief that the internal orifice is equally decisive. The combination of the two, however, really forms the definite cystoscopic picture.

#### CYSTOSCOPIC EXAMINATION

With the cystoscope in the normal position, there is a feeling of relaxation which one does not get in normal cases. Furthermore, the posterior urethra is usually more tolerant, and in definite tabetics, as is well known, often anesthetic. In a great many instances, the external sphincter is spastic, and if one has passed a catheter before the cystoscope, urine is frequently withdrawn on entering the posterior urethra. The sphincter margin has been found to be without striking appearance, above and laterally; but as one approaches the floor, the striae of the urethra can easily be seen, external to the sphincter. On depressing the eyepiece of the cystoscope and withdrawing the instrument, one may inspect the posterior urethral floor or the supramontane urethra, its folds, the guttered appearance of the urethra, and the lateral urethral walls being shown (Fig. 1).

Fig. 3. I, tip of trigon, showing elevation and fanlike appearance of trabeculation; T, trabeculation.

hypertrophic, as when behind mechanical obstructions; the interureteric bar is usually lifted and thin. Laterally, the trigon at its tips frequently fans out into trabeculae, which spread out over the lateral walls of the bladder. The ureteral orifices show nothing in particular, except that in some cases they are sluggish in their ejaculation of urine. With this picture of relaxation at the internal orifice of the bladder, there is usually bladder trabeculation (Fig. 4), which does not always show particular characteristics, except that pos-

sibly it may be a little more delicate than trabeculation seen back of mechanical obstructions. Koll believes that it has a predilection for the lateral fornices and has a specific appearance; but our cases have not been so definite in this respect, as they have all been more or less generalized, and various grades of trabeculation were assumed.

In the female, the diagnosis is somewhat more difficult, since we miss the anatomic landmarks which serve to illustrate this relaxation. Nevertheless, there is always considerable relaxation of the sphincter, and this, coupled with the trabeculation of the bladder, suggests the diagnosis.

The roentgen-ray findings of the bladder have been interesting. We have made cystograms with thorium, collargol and argyrol. These cystograms have usually shown a clean-cut line below, in the internal sphincter region, while in several of the very relaxed cases there has been a funneling due to the material in the deep urethra, as has been observed at the Johns Hopkins Clinic also. It is quite surprising that this funneling is not more uniform, since one would expect from the cystoscopic appearance of the urethra that it would be so. It is evident that the sphincter tone is sufficient to resist intervesical pressure until some mechanical instrument holds it open. There has been one observation in particular that has been of interest to us. If the bladder is filled with a solution, and comparative plates are taken with the patient lying and then standing, there is noticed in tabetics a dropping down, with forward toppling, of the bladder. This is probably due to the marked relaxation of the various bladder and prostate supports, namely, the ligaments and muscular supports in this region.

#### RESULTS IN FIRST SERIES

In the series of 500 cases observed by us, 188 were studied

with Dr. Francis Barnes, psychiatrist at the St. Louis City Sanitarium, and were cases representing various types of psychoses. In this series, we had no tabulated record of the symptoms, but confined ourselves to an investigation of the urologic findings in the individual patients and checked them with the diagnoses in the sanatorium. In carrying out this part of the work, we were very careful that the cystoscopic and other examinations should be made without prejudice.

All knowledge of the character of these cases was therefore concealed from Drs. Greditzer and Caulk, who made the urologic examinations. This series, including, exclusively, cases of mental disorders, embraced 158 males and thirty females. There were eighty cases of paresis, two cases of tabes dorsalis with psychosis, nine cases of cerebro-spinal syphilis, thirteen cases of organic brain disease, not syphilitic, eleven cases of alcoholic psychosis, eleven cases of epilepsy with psychosis, forty-four cases of dementia praecox, six cases of defective states with psychosis, and twelve cases of manic depressive insanity.

In the cases of paresis, 50 per cent. showed typical positive cystoscopic pictures, 38 per cent. of the cases having present or exaggerated knee jerks were cystoscopically positive; while in 74 per cent. of the cases with diminished or absent knee jerks, the picture was positive. Concerning the 38 per cent. of cases in which the cystoscopic examination was positive and the neurologic examination negative, it should be stated that it is claimed that 99 per cent. of all paretics have pathologically demonstrable lesions of the posterior columns of the spinal cord, such as are found in tabetics. It is possible that these posterior column changes may not be of sufficient intensity to produce general clinical signs, but of such character as to involve the segment which would give rise to the bladder changes above described. Cases of tabes with paresis were 100 per cent. urologically positive. Of cerebrospinal syphilis, 55 per cent. gave urologically positive pictures. We wish to call attention to the invariable positive cystoscopic picture in hemiplegias. Of the organic nonsyphilitic brain diseases, including arteriosclerotic dementia, senile dementia, multiple sclerosis and Huntington's chorea, 30 per cent. were cystoscopically positive,

these being the cases of arteriosclerotic dementia and those of multiple sclerosis. Of the eleven cases of alcoholic psychoses, including Korsakoff's syndrome, alcoholic dementia and chronic alcoholism, only that of Korsakoff's syndrome was positive; and it is interesting that the knee jerks were absent, although there were no other signs of neuritis. Epilepsy with psychosis showed 27 per cent. positive bladder findings.

Of the cases of dementia praecox, the findings were positive in 22 per cent. One of these cases, associated with alcoholism, is interesting because of the positive finding, in view of the fact that at the time of the patient's admission the diagnosis had been paresis but later observation did not confirm it. The percentage of positive cases in this group, more than one fifth, seems high, but we must remember in this connection that there are those who argue for the organic basis of dementia praecox. There were six cases of defective state. In one of these, an imbecile who had had a severe syphilitic meningitis in infancy, there was a positive picture.

Manic depressive insanity contributed twelve cases with negative bladder findings.

In summary of this study of 188 cases of psychoses, it may be said that the neurologic findings were such as to lead us to suspect a positive bladder picture in 25 per cent., whereas this positive picture was found in 50 per cent. If we separate these cases into organic and functional groups, we find that the neurologic and urologic observations practically tally. In other words, the cystoscope reveals bladder findings in a large proportion of so-called functional cases. Dr. Barnes has recently reviewed the cases studied in this series, two years after the previous examination: There has been no change in their neurologic status.

Fig. 4.—B, air bubble; T, trabeculation at dome of bladder.

## DIAGNOSIS IN THE SECOND SERIES

The remaining 312 cases were studied in the Washington University Medical School Clinic, at Barnes Hospital and in private practice, and comprise the routine types of organic and functional nerve disorders. Of the previous diseases, syphilis and gonorrhea stand at the head. Forty per cent. of the patients gave a previous history of syphilis, and the same percentage showed positive Wassermann reactions. Seventy-five per cent. of these patients, with cord lesions, gave positive spinal fluid tests.

Definite neurologic diseases, such as tabes, cerebrospinal syphilis, postapoplectic conditions, spinal cord tumor, and paresis, occurred in 46 per cent. of the series. Of this number, the diagnosis was made first in the urologic clinic in 46 per cent. of the cases, a fact demonstrating the frequency with which such diseases manifest themselves by bladder symptoms, and lead the patient to consult the urologist first for bladder disturbances. In 54 per cent. of the cases, patients consulted the neurologic clinic first. Of the cases positively diagnosed by the cystoscopic examination, in only 50 per cent. was the diagnosis confirmed by the neurologist. In about 5 per cent. of the 50 per cent. of unconfirmed cases, lesions have since developed. In this group there were two cord tumors, eventually diagnosed neurologically, in one case a year after we had found a definite picture. The remaining 45 per cent. of unconfirmed cases we have tried to trace, but have experienced great difficulty in getting any replies. Only a few replies have come to our inquiries; the majority of cards read "wrong address." Patients who have returned have remained neurologically negative, but still definitely cystoscopically positive—the smaller group—and cystoscopically suggestive, of the larger.

## DIAGNOSTIC SYMPTOMS AND FINDINGS

A. *Urinary Symptoms.*—Ninety-three per cent. of the patients had urinary symptoms. Seven per cent. presented no urinary symptoms. Of the 93 per cent. half were definitely neurologic and half unconfirmed. Of the 7 per cent., it was again half and half.

1. Frequency: Frequency of urination occurred in about 60 per cent., equally divided between the confirmed and unconfirmed.

2. Incontinence: Incontinence of urine occurred in 38 per cent. of the series, of which the patients in 63 per cent. proved to be those with definite central nervous system disease. One of the patients with incontinence, who showed a positive picture, but in whom the diagnosis was not confirmed by the neurologist, later proved to have had a spinal cord tumor. Our findings were confirmed at necropsy.

3. Urinary Obstruction: This occurred in 36 per cent. of the cases. Of these, one half were neurologic. In one of the negative cases, however, paresis later developed. Other causes of obstruction associated with this group were stricture, prostatic hypertrophy, bladder tumors, cancer of the rectum, cystocele, etc.

4. Pain, Burning and Urgency of Urination: This condition occurred in 41 per cent., and, of these, the diagnosis in 41 per cent. was confirmed.

B. *Sexual Powers.*—One of the very important and most uniform findings was disturbed sexual capacity. In about 80 per cent. of the cases of organic lesions of the central nervous system there was either complete loss or considerable disturbance of the sexual

powers. Of the nonconfirmed cases, 50 per cent. showed this disturbance.

C. *Pain.*—Pain was present in about 70 per cent. of all the cases, being the lightning pains of tabes, and pains in the back, legs, perineum, pubis, scrotum and rectum. A very suggestive pain has been a puckering, pulling pain in the perineum and in the rectum. These are often ascribed to prostatitis and vesiculitis, but frequently indicate nerve lesions and not reflexes.

D. *Uremia.*—One of the chief factors in the production of toxicities in patients suffering from central nervous system disease is uremia. It not only manifests itself with the ordinary obstructive type symptoms, but also serves to augment many of the toxic pains from which these patients suffer. A great deal of the pallor, weakness and dizziness also emanates from this cause. We have noted repeatedly that the relief of the uremic condition of a patient has improved his appearance and symptoms to a surprising degree. Therefore, we feel that the correction of uremia is one of the most important phases in the treatment of the pronounced tabetics.

E. *Hematuria.*—This occurred in 15 per cent. of the series, one third being in tabetics and two thirds in nontabetics. The hemorrhages occurring in tabes are very interesting, and, indeed, very alarming. Hemorrhage often occurs with vesical crisis, and is so profuse that several of the patients have looked almost exsanguinated. These hemorrhages seem to come from both the urethra and the bladder wall, and have been controlled with epinephrin. One patient in this series bled to death from a small incision in the back for the drainage of a perinephritic abscess. With relaxation of pressure, there was profuse hemorrhage, which could not be controlled and which was probably due to a vasomotor phenomenon.

## EXAMINATION

*External Genitals.*—These are frequently flabby. Varicocele is common. Various degrees of penile atrophy have been noticed, and in several instances there have been marked spasms of the whole anterior urethra, so that it was difficult to insert a catheter, and more difficult to remove it.

*Urine.*—Thirty-two per cent. of the patients in all the cases had infected urines; 66 per cent. of these were tabetics; the remainder, the unconfirmed. Furthermore, 40 per cent. of all tabetics had infected urines; 60 per cent. had not. The infections were almost entirely of the colon bacillus group.

*Prostate and Vesicles.*—Sixty-eight per cent. of the patients had prostatitis and vesiculitis. This percentage was divided equally between the confirmed and the unconfirmed. About 5 per cent. of the patients with definite cord lesions had an associated prostatic hypertrophy. This is very important, and serves to emphasize the necessity of thorough recognition of this bladder picture and the advisability of always making a cystoscopic examination prior to prostatic surgery, since the symptoms which seem to be due to the prostate may have their origin in a nerve lesion. It seems certain that many of the unfavorable results following prostatectomy, particularly incontinence, are due to the fact that the prostate has been removed from patients suffering with nervous diseases. Otherwise, incontinence would not result, for it is hard to produce.

*Rectal Sphincter.*—This offers itself as an extremely important symptom, and often creates the first intelligible

of suspicion. In our series, we have found it to be relaxed in 88 per cent. of the cases. Indeed, in regard to several patients who were in the medical ward with obscure symptoms, we were able to predict, by the rectal examination, a possibility of nerve lesion, and in several of these cases the predictions have been fulfilled. About an equal proportion of the patients were in the confirmed group. There was normal tone in 8 per cent. In only two instances did this normal sphincter occur in tabetics. Associated with the relaxed sphincter there is frequently a ballooning of the rectum. At times it is very spacious, and, invariably, this combination of relaxation and ballooning is a very important monitor of cord lesions.

*Internal Sphincter and Verumontanum.*—In this series we found the internal sphincter relaxed to various degrees in 98 per cent. of the cases. About 79 per cent. of these relaxations were of such a degree as to allow cystoscopic inspection of the verumontanum. The diagnosis, in 40 per cent. of these cases, was neurologically confirmed; in the remainder it was not. But 80 per cent. of the tabetics had sufficiently relaxed sphincters to allow inspection of the verumontanum, and 20 per cent. had not. This high percentage of relaxation of the internal sphincter in diseases of the nervous system places it as one of the most important criteria. Twenty per cent. of the cases showed internal sphincter relaxation, but not of a sufficient degree to allow inspection of the verumontanum. The condition, in these cases, was associated also with a relaxed rectal sphincter. This group of cases must be repeatedly examined, as such a combination is highly suggestive of nerve lesions.

*Trigon.*—The trigon was elevated and spread out like a fan in 56 per cent. of the cases. Of this number, 56 per cent. occurred in diseases of the central nervous system. It was also observed that 75 per cent. of tabetics had elevated and veiled trigons, whereas, in 25 per cent. the trigon was normal.

*Trabeculation.*—Trabeculation was present in more than 90 per cent. of the cases. Of these, 46 per cent. were confirmed. On the other hand, trabeculation was reported in 96 per cent. of the patients with diseases of the central nervous system. This high percentage of trabeculation occurring in organic nerve lesions presents itself as a very important diagnostic finding.

#### TREATMENT

There is no type of urinary disease which has received in the past such meager attention as the bladder disorders associated with diseases of the central nervous system. This is particularly true of tabes. The treatment of the tabetic has been one of pity rather than one of therapeutics. And actually, proper treatment is rewarded with quite a degree of satisfaction in a large percentage of such patients. As such a proportion of these cases are secondary to syphilis, general treatment directed toward syphilis is one of our first considerations. From our observations, we are led to believe that patients with active blood Wassermann reactions, from ++ to ++++, are much more controllable than those with a negative or slightly positive reaction. It has been our principle to treat these patients quite actively with arsphenamin and mercury alternately, in order to stop further progress of neurologic involvement (of course one cannot hope to correct old nerve scars; but we believe that one can hope to allay certain nerve symptoms—for instance, light-

ning pains are often immediately stopped after the administration of arsphenamin)—and also to prevent the virus from involving further nerve structures.

These patients should be kept under very strict hygiene, and their diet and bowels carefully regulated. Urinary antiseptics, particularly acid sodium phosphate in 20 grain doses and hexamethylenamin in 10 grain doses, three times a day, are helpful in the infected cases, and serve as preventives in the uninfected.

*Local Treatment.*—It must be understood that the treatment of a bladder lesion secondary to an old nerve lesion is entirely different from that of one due to traumatic injury. It has been definitely shown that the latter group should be left alone, as the automatic bladder will usually develop, and the condition will frequently take care of itself. The lesion which is secondary to an old nerve lesion, on the contrary, demands a different therapeutic regimen. As has previously been said, this type of bladder has frequently passed unnoticed, the treatment has been neglected, and even patients with overflow have been allowed to go on dribbling. In our experience in handling this series of cases, we feel firmly convinced that these patients can be enormously benefited, many of them made comparatively comfortable, and some, particularly those with early involvements, entirely relieved of every bladder symptom.

The method of treating such bladders varies according to whether or not there is residual urine. This difference in treatment, of course, is in the employment of systematic catheterization in those patients with residual urine. Otherwise, the treatment is similar, consisting, in the first place, in relieving irritability, in keeping the patients clean and in training them to exercise their enfeebled musculature by regular, systematic attention to urination, and by practicing stopping and starting the urine at frequent intervals. This is designed to give more muscle tone and power to the fibers not involved, and, by means of such compensation, enable them to replace the loss of fibers which are destroyed, thereby preventing their injury from overstretching as a result of a chronically distended bladder.

These patients should all receive systematic treatment for the prostate and the bladder neck, such as massage, dilatation, instillations and applications to the urethra; and even though instrumentation has been tabooed for this class of patients, we feel that it has been on unjust grounds, since the benefit derived is entirely out of proportion to the occasional slight trouble that it may cause. When careful technic has been observed and gentle manipulation employed, we have seen very few instances of trouble following such treatment, and these slight upsets have been only temporary.

Patients with residual urine, whether infected or not, are treated by regular catheterization and irrigations or instillations. This, of course, for the purpose of relieving the internal pressure and allowing the overstretched muscles which are not neurologically involved to regain control, and it is surprising how promptly a bladder which has held a high residuum for a long period will empty itself. Indeed, in several instances after one or two catheterizations, the residuum has entirely disappeared, and several patients have for more than a year, carried only a few ounces of residuum after only a few catheterizations. The average patient, however, has to be catheterized regularly, that is, daily for a while, after which the interval between

catheterizations is gradually increased in length, the time depending on the results obtained. As a rule, after a course of treatment, the condition of such patients can be kept under control by weekly or fortnightly inspection. It is very comforting to see many such patients improve in general health. Their previous pallor, weakness and general toxic symptoms largely dissipate. We know of no more appreciative patients in the world than this class.

Since 80 per cent. of pronounced tabetics are suffering with uremia, systematic drainage has the same beneficial effects as in cases of mechanical obstruction. Besides, it allays, in many instances, the toxic nerve pains which are so frequently magnified by toxemia.

We hope the profession, therefore, confronted with these gratifying results of local, general and specific treatment, will divert from the previous conception of the treatment for these patients, and animadvert to this form of therapy, which yields such relief.

SUMMARY

There are definite findings which enable urologists to diagnose early and late nerve lesions involving the bladder; and since the bladder is so frequently primarily symptomatically involved, it behooves us to appreciate these clinical features in order that many patients may have the advantage of an early reference for complete neurologic investigation, so that they may be protected against further progress of the disease, and also that we, as surgeons, may be protected against operating on an unsuspected central nervous system disease.

SHELL FRACTURES OF THE SPINE

WITH OBSERVATIONS ON KIDNEY AND  
BLADDER FUNCTION \*

H. W. PLAGGEMEYER, M.D.  
DETROIT

In the preparation of this brief report of a series of seventeen cases of shell fracture of the spine as observed at the Walter Reed General Hospital, the subject was approached with a full realization of the period of time that necessarily elapsed between the inflicting of the wound and our first clinical view, connoting the transition from the primary stage of spinal shock with depression and retention to the succeeding stages usually characterized as the stages of: (1) paradoxical, or passive incontinence; (2) periodic reflex micturition, or active incontinence, and (3) paralytic or complete incontinence, in which latter phase evacuation of the urinary bladder is continuous, automatic and complete.

It was in these later stages, with their bewildering array of signs and symptoms, that the cases first came to our attention, and it is on these phases only that we feel entitled to make comment, our primary approach having been made from an entirely agnostic point of view, with no prejudices and with no deliberately acquired knowledge of what one might expect to find.

The cases had been, in every instance, referred to the department of urology from the neurosurgical section, with a diagnosis of fracture of the spine and

urinary incontinence. The patients were all in the third decade, and in no case was there history of previous incontinence. The time between the inflicting of the injury and of the first observation varied from two and a half to eight months, with a mean average time of four and a half months. Every patient had been catheterized abroad, all of them were infected, and many of them demanded catheterization as their right. Needless to say, it was on this assumption only that we took the liberty of doing simple cystoscopy on the bladders examined.

All cases gave a history of complete retention following injury. The onset of incontinence varied from twenty-four hours in five cases to six months in one case, but this patient had an inlying catheter when admitted, and four others, in which the history was given as three, four, five and six weeks, respectively, had apparently been catheterized as a routine. Barring these, the mean average of onset of incontinence was forty-eight hours.

The site of the lesion varied from the sixth cervical to the cauda equina, the lumbar cord being the favored site in nine cases, the dorsal in five, the cervical in two, and the sacral in one. Several of these overlapped; thus two of the lower lumbar lesions involved the first sacral vertebra, one of the upper dorsal involved the seventh cervical, one lower dorsal included the first, second and third lumbar, and the sacral case evidently involved the emanation of the cauda equina and the conus.

Rectal involvement was general and ran a course symptomatically parallel to that of the bladder, as we should expect from the innervation and developmental analogy of their respective sphincters. Sexual desire and ability were absent in all. None of the cases showed edema while observed.

CLINICAL FINDINGS

In eleven of the cases of this series cystoscopy was performed after consultation, every care being taken to preclude further infection, and with no untoward results. The picture was practically unvarying, and the findings might be summed up in a composite group:

1. Normal or hypertonic contraction of the external sphincter.
2. Complete relaxation of the posterior urethra, the floor definitely falling away from the roof. The verumontanum is plainly seen, in most cases appearing to lie in the floor of the bladder. The internal sphincter is almost wholly obliterated as such, though its site is marked by a slight convexity in its antero-posterior aspect.
3. The trigon in six cases was definitely atrophic in appearance, one case presenting a right lateral congestion, sharply demarcated in the midline. Four cases gave a picture of raised trigon, the elevation being especially marked at the interureteric ridge, and being rather apparent than real, owing to the *bas fond* lying posterior to it.
4. Generally the ureteral orifices were within range of normal, as to position, excursion and mobility.
5. Trabeculations were found in every case, gigantic in size, as a rule transverse and coarse on the floor, rather evenly distributed on the lateral walls, and having their greatest complexity on all the faces surrounding the vertex. It is probable that here the greatest local attempt at facilitation was made, as this is the site of distribution of the nervous plexus from the sacral autonomic supply—the anterior branch of

\* Read before the Section on Urology at the Seventieth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

Because of lack of space, this article is abbreviated in THE JOURNAL. The complete article appears in the Transactions of the Section and in the author's reprints.

the pelvic nerve. These trabeculations are strikingly coarse throughout in comparison with the lacelike, insular picture presented (according to Koll) by tubes in its incipient state, and even at times after ataxia has first supervened, as we noted in three cases of tubes with beginning ataxia examined in the course of the series.

6. There was no case of diverticulitis, and no case of trophic ulceration of the bladder.

7. Nearly all the bladders had a general vasomotor disturbance particularly marked on the floor, and chiefly characterized by irregular, ill defined areas of venous congestion. This we should expect *a priori* from the work of Gaskell, Langley and Anderson, who showed that the motor nerves of the blood vessels of the entire body, the motor nerves of the sweat glands, and the internal vesical sphincter and posterior urethral muscles, all belong to the same system. In none of these cases, however, was there evidence of hematuria, during the period of observation.

8. The level of the lesion apparently had nothing to do with either the functional activity of the bladder, or the excreting power of the kidney. The most marked evidence of neurotrophic bladder disturbance was found in Case 10, with the lesion involving the seventh cervical and the first three dorsals only. This is a typical automatic bladder of the Head type. Here the involvement was cervical; in other words, the zone of distribution of analgesia was entirely above the ninth dorsal. In this case the passage of urine and feces is not only automatic but is a completely unconscious act.

9. In none of the cases could we discover hyperhidrosis on forcible distention of the bladder; nor could we, in a single case, establish a history of hyperhidrosis, though in every case except one there was a previous history of zonal hyperhidrosis confined within the segmental limits of the thoracolumbar outflow, and always below the segment involved.

10. Each presented residual urine in varying amounts, though there were intervals when some of them would give every evidence of true incontinence; that is, a spontaneous emptying of the bladder as soon as it had filled to a certain point. The same patients, however, would at other times, after an apparent evacuation, present as much as 250 c.c. residual. It was very evident from observing them that the summation of stimuli necessary to establish a peripheral reflex is a variable quantity in any given patient, certainly one of the three types of incontinence, after the incontinence has once been established. The residual retained varied from 0 to 810 c.c., with a mean average of 180 c.c.

#### OBSERVATIONS IN FOUR SERIES

With the universal picture of residual urine present, even in those cases offering, at times, a picture of true incontinence, during which the bladder automatically emptied itself, the possibility of back pressure was considered. Retention was studied through estimation of urea nitrogen, nonprotein nitrogen, creatinin and uric acid in the blood, and excretion was determined by means of phenolsulphonethylphthalein, with examination of carefully collected twenty-four hour specimens of urine for urea nitrogen, sodium chloride, uric acid and creatinin with regard to milligrams per pound of body weight. The first series showed as follows:

Controls on a 1,500 calory diet at 135 pounds averaged 12.5 mg., urea nitrogen per hundred c.c. plasma, with a nonprotein nitrogen of 38 mg. The spinal cases exhibited a range of urea nitrogen from 13.8 in the lowest, the patients at that time appearing in excellent condition and giving a two hour phenolsulphonethylphthalein test of 60 per cent. plus 12 per cent., to 113 mg. in the highest (nine times normal), with a bare trace of phenolsulphonethylphthalein, the mean average urea nitrogen being 64.6 mg., or about five times normal for the diet. Phenolsulphonethylphthalein tests in this series ranged from 35 per cent. to 65 per cent. for two hours, with a mean of 45 per cent., the majority of cases in this group showing a lower output in the first hour than in the second, evidencing a lack of facility on the part of the kidney to resume function.

Creatinin in the blood stood at normal throughout, averaging 1.52 mg. per hundred c.c. We desire at this point to emphasize the fact that even in the very serious cases the blood creatinin stood at normal, the highest being 2.2 mg.; this in spite of the previous wide excursions of urea nitrogen. The practical point to be borne in mind here is that by the time creatinin has registered a serious rise in its curve, the patient is critically ill, whereas the urea nitrogen curve and the excretory function have long since given the prognostic sign.

The patients were kept on practically the same food values for a month, given free access to water, and given massage of the whole body daily, especially over the region of the hypogastric and inferior mesenteric plexus, with the triple idea of adding to the general tone of the organism, stimulating peripheral mass reflexes, and expediting the vicarious compensatory activity of the skin for urea and uric acid. At the reading of the next series, one month later, the following results obtained: The blood urea was: lowest, 11.98 mg.; highest, 67.2; mean, 26.82, or only twice normal. Creatinin averaged 1.1 mg.

In this series was a case of previous left nephrectomy with suprapubic drainage. This patient was improving rapidly, had a urea nitrogen concentration of 13.8 (normal), creatinin normal, phenolsulphonethylphthalein test of 72 per cent., when suddenly his blood urea nitrogen shot up to 67.2, his excretory function became practically nil, and death resulted with all signs of acute pyonephrosis and uremia. Aside from this adventitious circumstance the mean average urea nitrogen would be 23.71 mg. The average phenolsulphonethylphthalein test for this series was 60 per cent. for two hours, the first hour averaging 37 per cent., the second 22 per cent., with a distinct tendency in all cases for the first hour to take up the bulk of function.

The third series, done one month later, showed a blood urea concentration averaging 15.10 mg. per hundred c.c. plasma, the lowest being 8.2 mg. in a patient clinically improving with a phenolsulphonethylphthalein test of 61 plus 28 per cent. and the highest being 32.6 mg. with a phenolsulphonethylphthalein test of 6 plus 9 per cent. equaling 15 per cent. The average phenolsulphonethylphthalein test was 48 per cent., which included two very septic patients (aside from these the average would be 57 per cent.), the average of the first hour being now appreciably increased over that of the second, except in the two patients who were still very sick.

The fourth series, done one month later, showed an average blood urea of 14.27 mg., the highest being 31.6 mg., the lowest 5.6 mg. All of the phenolsulphonephthalein tests were distinctly good as regards the relationship of the first and second hours, except in Case 10, in which the blood urea was still 31.6 per cent, and the condition was not good.

It had been suggested in noting the very high urea nitrogen retention that possibly the marked cases of trophic ulceration seen in six of the soldiers could be

\* In each monthly block the upper figure represents milligrams of urea nitrogen per hundred c.c. of blood plasma, the lower figures showing the output of phenolsulphonephthalein in two periods of seventy and sixty minutes, respectively.

† Fifth reading, June 2, 1919, 25 mg. urea nitrogen per 100 c.c. blood plasma, output of phenolsulphonephthalein for seventy and sixty minutes = 12; improved. No. 10 was slowly improving when the fifth reading was done. The rise in phenolsulphonephthalein as urea nitrogen decreases should be noted. This was an automatic bladder, with profound disturbance. The persistent retention of nitrogen in Case 10, even after careful daily removal of the residual, should be noted. This is probably due to renal infection, and would be a better indication of the power of operation on the lower tract than the creatinin which remained persistently at 2 mg. per 100 c.c. plasma.

accounted for by urea poisoning, the necrosing effect of quinii urea hydrochlorid in wounds operated on by anacriassation being used as an analogy. This is scarcely tenable, as all the cases showed the trophic disturbance below the zone of distribution of the spinal involvement, which would not be so if the trophism were the result of a toxic agent in the blood stream. Moreover, they were all normal as to blood sugar, and to carbon dioxide tension in the blood, and the urines were persistently negative to a reducing agent, on ferred carbohydrate diet.

COMMENT

We have, then, for our consideration a general picture of unusually high urea nitrogen, with high non-protein nitrogen, and persistent normal creatinin in the blood, balanced by a comparatively low renal concentrating power for urea, with a low output of creatinin in twenty-four hours, and low uric acid output; and collaterally, a colorimetric curve rising, as a whole, where the retention curve falls.

That there is not an essentially reciprocal curve existing between urea retention and phenolsulphonephthalein excretion would seem, however, to be borne out frequently in studying individual histories, though the number in this series is certainly too small to form a basis for dogmatic statement. At one time, the phenolsulphonephthalein curve rises more rapidly than the urea curve drops, and vice versa, but the curves always crossed sooner or later, and, taken altogether, gave an astonishingly good prognostic picture of the clinical change that later supervened, even though the curve changes have not always been synchronously reciprocal. Also in the stage of high urea retention, the renal function, though it appears fairly high in the total, is much lower the first hour than the second, which is an important point in interpretation.

It was at first assumed that the retention phenomena observed were caused by back pressure leading to hydronephrosis. That this need not necessarily be true is shown in one case on which we obtained necropsy. This soldier had 103 mg. of urea nitrogen before death, and 68 mg. of nonprotein nitrogen. His phenolsulphonephthalein test was fairly high, 20 and 45 per cent., but the first hour was less than half the second, and the appearance time was twenty-one minutes (gluteal). His average residual was 135 c.c., with a relaxed bladder, and a bullet in the spine at the emanation level of the ninth, tenth and eleventh thoracic vertebrae which would certainly be expected to involve the ureters. Nevertheless, at necropsy there was found no evidence of hydro-ureters or hydronephrosis, as the specimens will show. There was evidently a distinct protective tendency seen in the local compensatory activity of the bladder, even with a spinal cord on which complete transection was diagnosed clinically in England, in which case necropsy disclosed the posterior half of the cord completely shot away.

Another case in a collateral series of nontraumatic spines showed at operation a giant-cell sarcoma involving the lower dorsal and the upper lumbar vertebrae. This case showed the same bladder picture described above, but there was no evidence of back pressure on the kidneys, the blood urea being 11.2 mg. per hundred c.c. of plasma, the nonprotein nitrogen 36.6 mg., and the creatinin 1.2 mg.

This early protective tendency may possibly be explained by the work of Elliott, who found in his decentralized bladders an overgrowth of mesenture associated with an increase in the number of unstriated muscle fibers, as well as an increase in the cross section of each fiber, with an increased suppleness and irritability of the muscle itself. This increased thickness of the bladder wall was observed many times at the operating table by Thompson Walker. In the one case in our series that came to necropsy this was also demonstrated, and clinically we have noted a repeated tendency for the residual or contained urine to be greater than the capacity, showing a decided tendency

on the part of the bladder to resist suddenly injected fluid.

There must be some other ground than hydronephrosis for the retention phenomena exhibited, for otherwise the high nitrogen concentration would have been relieved by the previous catheterization.

The architectural incompetence of the kidneys to withstand long continued back pressure is recognized in the domain of prostatic obstruction; but here we are dealing with a sudden shock, with a tendency for the musculature of the lower tract to compensate quickly, and, at least for many months, to protect the higher tract. If hydronephrosis supervenes it certainly must be at a much later stage than in the cases we have observed. In addition to possible hydronephrosis I would be inclined to ascribe retention to several other factors. In the cases, as first seen, the blood urea nitrogen was inordinately high; first, because of the tremendous tissue waste resulting from neurotropicism,

The urea nitrogen and the nonprotein nitrogen decreased month by month, and the kidney excretory and concentrating capacity increased absolutely if not relatively for any given point of the curve.

It is aside from the province of this report to discuss at length the early care of these cases. I would simply suggest, if possible, entire abstention from catheterization, for catheterization means ure infection, and the replacement fibrosis following renal infection is more lasting and more dangerous to the patient than a hydronephrosis, even granting a permanent hydronephrosis to exist in these cases.

The first retention is a shock phenomenon and undoubtedly involves both sphincters, the internal sphincter playing the dominant rôle. Later on, the internal sphincter relaxes and the external sphincter takes up its compensatory hypertonic action. The problem is to evoke an automatic activity at the earliest possible moment, and resolves itself down to an inhibi-

TABLE 2.—STATISTICAL RESULTS IN SELECTED CASES

Case	Reg. No.	Age	Rank	Date	Catalase, Total		Character of Urine	Total Amount Excreted (Hrs., g.)	Body Weight, Pounds	Phenyl-sulphonic-methidein		Urea N.		Creatin		Uric Acid		Food Calories				
					First Hour	Second Hour				First Hour	Second Hour	Non-protein	Urea N.	Sulphim.	Hours	Mg. per 100	Mg. per 100	Mg. per 100	First Day	Second Day

\* At the time the report of these cases was prepared, the first three patients were in distinctly bad condition; the last three were distinctly "proving." The results, as tabulated, were rather surprising, but one may say that they are all steadily progressing upward. Patient 10, with persistent high urea did not improve, as we were able to progress from these cases.

† In cases 9, 10, 11, and 12, the upper figures show values obtained when first seen; the lower figures show values at end of third month of convalescence. The phenyl-sulphonic-methidein tests in this series were all intramuscular, either deltoid or gluteal.

‡ Was the blood urea low and the urinary urea also low, the patients are showing marked clinical improvement, and the greater the blood urea the more marked is the picture of tissue re-absorption. This is specially true of Patients 2 and 3. Patients 7 and 8 have had a surprising so long they are no longer reabsorbing into the tissues.

tion of this internal sphincteric hypertonicity. This shock phenomenon is probably due to the inhibiting action of the brain. Even a decentralized bladder will functionate on reception of noxious stimuli, after cerebral inhibition is relaxed. This, as Head has shown, is due to a peripheral mass reflex, and as these patients are all hyperesthetic, it may be effected in various ways, from stimulation of the plantar flexor spasm, to irritation of the prostatic plexus, the most direct approach, however, being anatomically by way of the hypogastric plexus. The first problem is to relax this tension by working backward from the periphery, and observations abroad by Young, Keyes, McCague, Besley, Horrax and others have proved that this method has merit.

If intervention has to be, there is surely no contra-indication to the use of the aspirating needle until incontinence is established. Thompson Walker even advocates the use of suprapubic cystostomy as preferable to the continued use of the catheter. This would hardly be necessary if immediate resort were had to the use of general sedatives, with careful atten-

is evidenced in the body weight and general appearance of emaciation; secondly, these patients while abroad, and in transit, lacked free access to water, in the attempt to avoid too frequent catheterization, until they were almost completely dehydrated. Consequently, with a low fluid content in the blood stream, the solid content would rise proportionately. Add to this the neurotropic hyperhidrosis that takes place in all these cases, which would further increase the concentration, and augment this with the steady addition of tissue nitrogen, the whole being offset by a resistance on the part of the kidneys to concentrate adequately for excretion, owing to infection or inhibition of neuropathic origin (as seen in the bladder), and the explanation would seem complete. Certain it is that with free access to water (which they drank copiously at first), daily massage, and attention generally to peripheral stimulation, and to the reestablishment of normal skin function, with particular attention to stimulation of peripheral areas segmentally involving the inferior mesenteric and hypogastric plexus, the picture changed markedly.

tion to stimulation of mass reflexes, by irritating the periphery, especially over the hypogastric plexus, with the idea of relaxing immediately the floor of the bladder and the internal sphincter. The external sphincter will relax very shortly thereafter, as the pudic nerve has been proved by repeated experiments to fatigue very rapidly after continuous stimulation.

Strange to say, these bladders do not rupture; and as they are insensate, no discomfort is experienced. The extent of their dilatation can be readily determined, and if by judicious use of extravasical stimuli the onset of incontinence can be established early without the use of the catheter, the patient is further protected from the otherwise inevitable infection, which abroad has resulted in a mortality of 50 per cent.

## REPORT OF CASES

CASE 1.—B. B., Pvt., G., 120th Inf., Reg. No. 25920, Serial No. 198164, aged 28. No previous history of incontinence. Injured, Oct. 10, 1918. Catheterized four times. Subsequent pressure over bladder to facilitate extrusion, during four weeks, followed by use of inlying catheter till Nov. 26, 1918. Onset of incontinence: Vague, Nov. 26, 1918 (?). Lesion: Third and fourth lumbar (?). Roentgenogram, C. S. C. 41.

Operation, Oct. 10, 1918. Entrance through fifth lumbar; rifle bullet removed from "center of canal," Base Hospital No. 29.

Blood urea (Walter Reed General Hospital), Feb. 7, 1919: 23.3 mg. per hundred c.c. plasma, urea nitrogen: Feb. 10, 1919: 16.8 mg.; March 25, 1919: 20.0 mg.; April 18, 1919: 10.2 mg. Creatinin in blood, March 25, 1919: 2.22 mg. per hundred c.c.; April 18, 1919: 1.2 mg. Phenolsulphonephthalein output, Feb. 18, 1919: 30 per cent. first seventy minutes plus 15 per cent. next sixty minutes, total 45 per cent.; March 26, 1919: 45 per cent. first seventy minutes plus 30 per cent. next sixty minutes, total 75 per cent.; April 18, 1919: 38 per cent. first seventy minutes plus 29 per cent. next sixty minutes, total 67 per cent. Hemoglobin, March 1, 1919: 70 per cent. Blood count, March 25, 1919: leukocytes, 11,260; March 21, 1919: leukocytes, 12,350; erythrocytes, 3,261,000.

Cystoscopy, Feb. 8, 1919: Residual urine, 200 c.c.; capacity, 420 c.c. Sensation on pressure present; expulsive force with cystoscope in situ, good. Internal sphincter relaxed completely, posterior urethra practically part of floor of bladder, with verumontanum plainly seen with Brown-Bueger simple examining cystoscope; trigon atrophied; interureteric ridge not seen as such. Left ureteral orifice rather wide and gaping, right not seen. Fine trabeculations on the lateral walls; none on the floor.

Residual urine, Feb. 8, 1919: 200 c.c., cloudy, full of pus and colon organisms; March 1, 1919: 150 c.c.; March 3, 1919: 375 c.c.; April 8, 1919: 530 c.c., heavy sediment of pus; April 19, 1919: 370 c.c., slightly cloudy with pus.

Trophic ulcers: Right heel, small size, present, Feb. 8, 1919. Urine: Albumin trace; pus ++; casts negative; B. P. 135-110. Rectal involvement: Yes. Sexual powers: Absent; sexual desire absent. Hyperhidrosis: Extensive areas involved at times, notably for three days, about March 13, 1919. No relation to fulness of bladder.

Clinical course: Generally good; improving slowly.

Neurologic findings: Motor: This is a root lesion, not a cord lesion—extending from cauda up to and including first lumbar. Left penis, left scrotum dead to tactile sense. Right perineal touch partially gone on right, all gone on left, showing conus involvement. Plantars, Achilles and patellars all lacking. Diagnosis: Root lesion including conus up to first lumbar inclusive on left side.

Comment: This soldier was first seen four months after injury, at which time he had a definite paradoxical incontinence, with poor rectal control. There is no control of bladder, and practically no sensation, even on forced distention. Would come under the general head of automatic bladder. The difference in residual urine at various times should be noted, evidently due to irregular action of mass

reflexes of which the patient is not aware at the time. The blood urea dropped from 23.3 mg. to 10.2 mg. in two months on the same diet, during which time phenolsulphonephthalein rose from 45 to 75 per cent, creatinin remaining normal.

CASE 2.—R. S., Cpl., E., 48th Inf., Reg. No. 24931. Serial No. 2260123, aged 22. Injured, Oct. 31, 1918. Machine gun bullet, .32 caliber, still in spine. Previous history: incontinence negative. Paralysis of both legs at once. Tingling and burning in feet and legs ever since. Catheterized: For five weeks after injury, since which time has "emptied" freely and without control. Incontinence (?).

Lesion: Bullet at level eleventh dorsal; roentgenogram, Walter Reed General Hospital, Jan. 14, 1919.

Blood urea nitrogen, Feb. 4, 1919: 94.0 mg. per hundred c.c. plasma; March 25, 1919: 19.5 mg.; April 19, 1919: 10.2 mg. Blood creatinin, March 25, 1919: 1.66 mg. per hundred c.c. plasma; April 19, 1919: 0.90 mg. Glucose, May 15, 1919: 0.14 per cent.; carbon dioxide tension, 65 per cent. Renal function, Feb. 18, 1919: 25 per cent. plus 10 per cent. total, 35 per cent., two hours and ten minutes; March 26, 1919: 20 per cent. plus 25 per cent., total, 45 per cent., two hours and ten minutes; April 19, 1919: 34 per cent. plus 10 per cent., total, 44 per cent., two hours and ten minutes.

Blood pressure, April 19, 1919: 110—65, Tyco's auscultatory test. Hemoglobin, March 3, 1919: 60 per cent. Blood count, Jan. 24, 1919: Whites, 4,800; March 3, 1919: Whites, 14,200.

Cystoscopy: Contraindicated.

Residual urine, Feb. 18, 1919: 160 c.c., cloudy; March 1, 1919: 90 c.c., cloudy; April 19, 1919: 100 c.c., cloudy.

Trophic ulcers: Right hip, right crest; left hip, left crest; right and left heels, sacrum; right and left knees, mesially; all severe; the areas over both anterior superior spines being 20 by 10 cm.

Urine: Yellow, turbid, alkaline, 1,018, albumin +++, much mucus, no blood or casts. Triple phosphate crystals, and large amount of amorphous phosphates. Rectal involvement: Yes; no sensation; diarrhea. Sexual powers: Absent. Bladder: Urine collects in bladder for an hour or more, then passes without sensation of fullness and without awareness by the patient. No sensation on forced distention, nor any change in sensation on emptying. Hyperhidrosis: Continuous sweating, body and upper extremities; onset about Feb. 1, 1919. Five to six changes of pajamas nightly until recently. Examination, April 22, 1919, 9 p. m.: Moist over whole back, chest and abdomen; legs and feet dry. No relation to fulness of bladder according to statement.

Clinical course: Very sick patient.

Comment: This is paradoxical incontinence, but it is also a case of automatic bladder. Rising blood count is probably due to infection from trophic ulcers, which grew steadily worse in spite of all care. Phenolsulphonephthalein output slowly rising as urea decreases. The third series of functions (44 per cent.) is decidedly better than the second (45 per cent.) because of the relative values in the first and second hours. Creatinin remains normal throughout up to April 9, 1919. Patient slightly improving.

CASE 3.—J. H., Cpl., D., 362d Inf., Reg. No. 24408, Serial No. 2260123, aged 31. Previous history of incontinence negative. Injured, Sept. 26, 1918, Argonne. Catheterized three or four times after injury. Incontinence began in two days. Unconscious after injury.

Lesion: Single plates, Jan. 7, 1919, reveal no bony changes. Bullet wound on back to right of eighth dorsal. Roentgenogram, Feb. 1, 1919: hypertrophic osseous changes of fifth lumbar (old injury). Gunshot wound, third dorsal.

Blood urea nitrogen, Feb. 4, 1919: 80.0 mg. per hundred c.c. plasma; March 25, 1919: 15.8 mg.; April 23, 1919: 8.4 mg. Glucose: May 15, 1919: 0.17 per cent.; carbon dioxide tension, 51 per cent. Blood creatinin, March 25, 1919: 1.63 mg. per hundred c.c. plasma. Renal function, Feb. 18, 1919: 15 per cent. plus 20 per cent.; totals, 35 per cent., two hours and ten minutes; March 25, 1919: 55 per cent. plus 25 per cent.; totals, 80 per cent., two hours and ten minutes; April 23, 1919: Not done on account of refusal of patient; hyperirritability. Hemoglobin, March 3, 1919: 60 per cent. Blood pressure, March 26, 1919: 112—65, Tyco's auscultatory test. Blood count: Whites, 7,800.

Cystoscopy. Contraindicated. Residual urine, Feb. 18, 1919: 210 c.c.; March 1, 1919, 60 c.c. Trophic ulcers: Back, left hip, both heels.

Urine, Feb. 24, 1919: Acid, 1.028; albumin ++; triple phosphate crystals. Rectal involvement: Slight control of rectum, for two or three minutes if stool is hard, but sphincter quickly fatigues. Bladder: Was catheterized four times to his knowledge. Unconscious for unknown period of time after injury, does not know how many times he was catheterized in hiatus. Slight control; calls for urinal. Sexual power: Desire absent; no erections. Hyperhidrosis: Denies sweating up to April 22, 1919. No sweating on fullness of bladder.

Clinical progress: Very poor, May 1, 1919. Urine: Albumin trace, pus ++; no casts. Blood pressure: 140-110, Tycos auscultatory test.

Comment: This is a case of hyperirritability, with general hyperesthesia. In this type of case, when the peripheral involvement has an equal or greater signature than the central involvement, there is no sweating. Also this type has local registration of bladder and bowel distention reflex, and does not present cases of true incontinence. The rise in phenylsulfonphthalicin both as to total and also as to hourly relationship compared with fall in urea nitrogen should be noted.

CASE 6.—R. O., Pvt., E., 9th Inf., Serial No. 293922, aged 29. Previous history of incontinence negative. Injured, Sept. 14, 1918: Struck with shrapnel right hip, and almost immediately thereafter with rifle ball which entered about tenth dorsal. Catheterization: None, according to statement (?). Onset of incontinence: Two days from time of injury—constant dribbling. Lesion: Seventh, eighth and ninth spinal vertebrae.

Operation, Evacuation Hospital No. 1, Sept. 14, 1918: Diagnosis, gunshot wound, battle, penetrating lumbar region, posteriorly severing spinal cord. Wound debrided and closed.

Blood urea nitrogen, Feb. 4, 1919: 103 mg. per hundred c.c. plasma. Renal function, Feb. 18, 1919: 20 per cent. plus 45 per cent.; total, 65 per cent.

Cystoscopy: Not done; patient died, Feb. 28, 1919. Residual urine, Feb. 18, 1919: 135 c.c., cloudy; Jan. 5, 1919: Alkaline, specific gravity 1.012, albumin trace, sugar and acetone negative, occasional red cell, no casts, many pus cells. Blood count, Jan. 3, 1919: White blood count, 10,000.

Trophic ulcers, report from Base Hospital No. 26, Sept. 21, 1918: Both feet, legs, left hip and buttocks. Base Hospital No. 8, Oct. 23, 1918: Large suppurating wound on back, sacral and gluteal regions; gangrenous. Deep suppurating ulcers, right hip. Rectal involvement: Yes; involuntary and without knowledge of patient. Bladder: Report from Base Hospital No. 26, Sept. 20, 1918, says there was retention of urine; catheterized twice daily; this was evidently not residual, and not complete retention. Sexual power: Desire and ability absent since injury. Hyperhidrosis: No history.

Clinical course: Terminated fatally, Feb. 28, 1919; diagnosis, asbestosis.

Comment: In this case there was an involvement of the ureters, with encroachment of bladder as demonstrated at autopsy, in the very level where one would expect involvement of the ureters with dilatation and secondary hydro-nephrosis from negative ureteritis. Also from the history obtained from Base Hospital No. 26 it would seem that at some time there must have been considerable back pressure. He had a blood urea of 103 mg. per hundred c.c., but his post-mortem report states within ten days of death was 65 per cent. for two hours and ten minutes, with an appearance time of twenty-one minutes, pointing to a paralytic rather than type of involvement. The bladder is mildly typical of the kind we are dealing with dilatation of the posterior urethra, universal trabeculation, etc., and yet there was no evidence of hydro-ureter, and no sign of hydronephrosis, or of pyonephrosis present, even with a practical transection myelitis at the region of the ninth dorsal. This proves that high blood urea, at least, does not necessarily prove hydronephrosis, and that retention, with involvement of the lower

thoracic spine is not necessarily accompanied by hydro-ureter and hydronephrosis. Possibly if this case had gone on a hydronephrosis might later have resulted, but even at this stage the patient had all the clinical findings assumed to lead to this condition, with negative necropsy.

CASE 10.—McL., L.; 1st Lieut., K., 309th Inf., Reg. No. 25002, Serial No. 1173172, aged 27. Previous history of incontinence negative. Injured, July 18, 1918. Catheterization: None. Onset of incontinence: At once. Lesion: Seventh cervical and first to fourth dorsal.

Operation, Oct. 19, 1918.

Blood urea nitrogen, Feb. 4, 1919: 113 mg. per hundred c.c. plasma; March 25, 1919: 28.4 mg.; April 24, 1919: 32.6 mg. Blood glucose, May 15, 1919: 0.14 per cent.; carbon dioxide tension, 57.9 per cent. Creatinin, March 25, 1919: 2.0 mg. per hundred c.c. plasma; April 24, 1919: 2.0 mg.

Renal function, March 25: 3 per cent.; two hours and ten minutes; April 24: 6 per cent. plus 9 per cent.; total, 15 per cent. Blood pressure, April 24: 165-110, Tycos auscultatory test. Residual, Jan. 27, 1919: 375 c.c.; April 24: 175 c.c.

Cystoscopy, Jan. 27, 1919: Residual, 375 c.c. After this is withdrawn, bladder resists forcibly at 225 c.c. distention. Much washing necessary, to clear bladder of detritus and pus. Mild catarrhal cystitis throughout. Pain sense lacking in bladder on distention, but can tell the difference between hot and cold water injected. Beginning diverticulum on floor midline 1 cm. behind interureteric ridge. Catheter vaulting throughout. Trigon slightly congested in center. Roof particularly trabeculated. Prostatic outline in range of normal. No relaxation of posterior urethra.

Bladder: Emptied by pressure over lower abdomen for first three weeks after injury; then up to Feb. 1, 1919, dribbled a few drops at a time without knowledge of patient. Since being cystoscoped and washed at Walter Reed Hospital, he has sensation and desire to urinate at times, evidently verumontan irritation is increased; has, May 1, 1919, ability to hold water three or four minutes after desire to empty is manifest. Rectum: Did not know when bowels were moving until Oct. 1, 1918. Since that time gradually returning sensation in rectum and awareness of desire to defecate. Sexual powers, May 1, 1919, desire and ability returning slowly.

Trophic ulcers: One size of half dollar on sacrum. Hemoglobins, Feb. 3, 1919: 60 per cent.; white blood count, 16,900; March 3, 1919: 55 per cent.; white blood count, 14,600; March 21, 1919: 70 per cent.; white blood count, 12,350; reds, 3,216,000; March 25, 1919: White blood count, 11,500 (Polymorphonuclears, 75 per cent.).

Hyperhidrosis: Onset, Feb. 1, 1919; genuine chills with sweating. During the month of February he ran a septic chart and high leukocyte count. This may have been from absorption from the ulcer. As this healed, the general picture of sepsis subsided. Urine: Albumin, plus +++; no casts. Blood pressure: 165-110.

Clinical progress: Poor.

Comment: His renal function did rise, it is true, concomitantly with the fall in urea nitrogen in the blood, but the general picture in this case is bad. His hyperhidrosis is not typical and is due undoubtedly to sepsis, but this, on the other hand, is not a typical retention case of the worst type. The lesion is so high that the area of hyperhidrosis is vast, and it is possible that fluid emanation by the skin may have been imperceptible, and still compensated for the mild retention left over from the almost constant dribbling. The patient has, however, an automatic bladder of the head type.

## ABSTRACT OF DISCUSSION

ON PAPERS OF DRs. CAULK, GREITZER AND BARNES,  
AND PLAGGEMEYER

DR. BEND C. CORBUS, Chicago: Dr. Caulk presented a very interesting condition of the bladder as a result of syphilis. But this condition is only an incident in the general infection; I think, as far as general management goes, especially in relation to a cure, these findings come rather late for the benefit of the patient. The time to diagnose and treat syphilis of the bladder is long before it reaches the stage that the

picture described represents. Ogilvie said that if cerebrospinal syphilis is recognized long before the interstitial tissue or its coverings are involved, its treatment and cure is a possibility. Recently there has been formed in the state of New York a society whose sole aim is the early recognition of involvement of the central nervous system. There seems to be some confusion in regard to the blood Wassermann. A blood Wassermann has nothing to do with the spinal fluid, as 65 per cent. of all tabetics have negative blood Wassermanns, and positive spinal fluid Wassermanns. What are we going to do when we get a case of tabes? Is it our problem to make a diagnosis by cystoscopy? I do not think so. A recent speaker emphasized emphatically the dangers of infecting the urinary bladder in conditions where there is a paralysis due to fracture of the vertebrae. In syphilitic bladders we have practically the same condition. We have an injury to the cord and its coverings, and it seems to me just as unpractical to attempt to catheterize in these cases as it would be in the case where the paralysis was due to a direct traumatism. It is easy to do a spinal puncture and it is nearly absolutely diagnostic, being positive in about 98 per cent.; the bladder in cerebrospinal syphilis is paralyzed, and you are not going to improve that condition by daily prostatic massage, irrigations, or what not. The thing to do is to treat the condition *per se*, long before it gets to the paralytic stage.

DR. ABRAHAM L. WOLBARST, New York: One point in Dr. Caulk's paper that appealed to me very strongly is the possibility of differentiating between a nerve lesion and prostatic hypertrophy. In the former I have observed that a man may have a great deal of residual urine one day and none whatever the next day. I have never been able to explain it, but I have seen it a number of times. I have under observation now a case of tumor of the lower spinal cord, which illustrates this point; some days I can withdraw from 500 to 800 c.c. of foul smelling urine, and a few days later there will be no more than a few drams of residuum. Nevertheless, the patient has incontinence all the time. In prostatic hypertrophy the residuum is constant. It is well to remember this difference. As regards trabeculations in early tabes, I do not think Dr. Caulk intended to convey the impression that he would look into the bladder in order to make a diagnosis of syphilis. Many of these cases come to us solely with urinary symptoms, and when we find these trabeculations, we are at once brought face to face with an unsuspected case of syphilis. This is a very important fact to remember, for it will help us out of many difficult situations if we bear it in mind. Within the past few weeks I saw a man who had been treated for cystitis for nine months without relief. When I cystoscoped him, I found the typical tabetic bladder. This led to further examination, and the man was found to have a well-advanced case of tabes.

DR. FRANCIS R. HAGNER, Washington, D. C.: Nine months ago a man was sent to me with supposed prostatic obstruction. This man had complete obstruction for almost a year and had been catheterizing himself. A slight spasm of one leg was present and there was some loss of reflexes on that side. On rectal examination a definite diagnosis of cancer of the prostate could be made. It was a typical, hard, infiltrated prostate, with extension along the urethra and upper edge of the prostate. On cystoscopic examination there was absolutely no evidence of obstruction at all. This man had fine trabeculations of the bladder, and had the typical picture seen in tabes. The roentgen ray showed a mass in the third or fourth dorsal vertebra, involving two vertebrae. The carcinomatous infiltration could be seen distinctly. The patient died two or three months after I saw him, the paralysis of both legs being complete. This is the first case of the kind I have seen and I think it was rather unusual.

DR. V. D. LESPINASSE, Chicago: Last year I made a diagnosis of the nerve lesion through examination of the bladder. This patient complained one day that he had trouble urinating and that he could not see very well. He entered a hospital. They examined him as regards his vision, and found it normal. He was then referred to me. I examined his

bladder, and found the typical picture of a nervous bladder and referred him to the neurologist. There were no other complaints at that time that would have given an indication for a neurologic examination. The next day he began to complain of headache, and he went on and finally died of a complicated involvement of the meninges of the brain and cord. The neurologists got into quite a discussion as to just what the lesion was, but the patient died. From this experience one can see that this picture of nervous bladder is of value as a diagnostic picture, and when it is interpreted properly I think it will lead occasionally to early diagnoses of nerve lesions that otherwise would not be made till later.

DR. HUGH H. YOUNG, Baltimore: Dr. Plagemeier has made the first very comprehensive study from all standpoints of those very remarkable bladder conditions following wounds of war. It was a subject in which we were greatly interested in France, because, as we made our preliminary studies with the French and with the British, we saw them reporting high mortalities as the result of renal infections from all spinal lesions. Thompson Walker, for instance, was reporting anywhere from 60 to 80 per cent. of deaths as the result of infection of the spinal cord from the urinary tract. It was recognized that infection carried off these patients. In the French army it had been made a rule that all these patients had to have a suprapubic cystotomy done on them promptly. This was also done in the British army without waiting to catheterize. That was often done in the advance surgical stations. Besley for years had been treating these cases by a nonoperative treatment, allowing the bladder to distend until finally it would overflow, the residual urine would gradually decrease until the condition was not at all dangerous. Many of those patients would go on for years without any infection of the bladder or kidneys, and although they might have incontinence, the incontinence was no worse than a suprapubic drain, which was often more difficult to manage. The Canadians had adopted that method and were using it in several of their advance hospitals. A few British and French surgeons were also using the same method. The result was that in the manual of military urology we laid down the rule that if possible in all surgical formations, men with wounds or injuries of the spine, associated with complete retention of urine, were not to be operated on and not to be catheterized, but simply allowed to distend, watched carefully, with the hope that most of them would have involuntary incontinence and would get along without any great difficulty. When the time comes that we can get all these cases together we will find that our results, so far as the element of fatalities is concerned, will be very much better than was the case in the earlier times. There are certain cases in which the beginning of that incontinence was very difficult. In those cases massage of the abdomen, of the prostate, rectal irrigations, irrigations by urethra, and stimulation of various sorts were induced, and in some cases it did hasten the beginning of the incontinence. As Dr. Plagemeier pointed out in those cases of dilated internal sphincter, the trabeculations which developed were really due to extreme efforts of the bladder to empty itself. But the main thing brought out was the fact that the bladders could distend very greatly, without rupturing, and with eventual diminution in size, and in some cases restoration of normal urination. The important point brought out by Dr. Plagemeier was the remarkable ability of the body to take care of the great retention of urine.

DR. WILLIAM E. LOWEY, Cleveland: In many of these patients that have been operated on for all sorts of things, the real seat of the trouble was entirely missed. This work is epoch making. It will put cystotomy on its proper basis as a means of diagnosis in these cases. Cystotomy will probably come to be the very best method for early recognition of the beginning of spinal cord lesions.

DR. JOHN R. CAULK, St. Louis: I thought I had made it clear in the paper, that we were not endeavoring to diagnose syphilis by means of the cystoscope. But the fact that we have so frequently observed this orifice with the cystoscope in individuals who had been treated for all sorts of diseases without improvement and who had never been neurologically

mgs, and from this observation had a Wassermann made which proved to be positive, made me suggest that in such instances recognition of this picture is extremely important. Furthermore, since such a large number of these individuals consult the urologist first it behooves him to be acquainted with this picture. I endeavored to impress you with the fact that we have not sufficiently directed our attention to this phase of urology, as a complete absence of any mention of it in the textbooks will testify. As far as the treatment goes, there is quite a decided difference in the handling of an acute bladder from trauma and the bladder of the old progressive tabetic, or some other chronic central nervous system disease. I said in the paper that the automatic bladder would develop, and this type of case did not need systematic catheterization. But for the old tabetic, whose symptoms are in such great measure magnified by absorption and anemia, catheter drainage offers as much benefit as in any other type of urinary obstruction; he improves as well as the prostatic, not in every instance, but in the great majority. So then, we have a picture we must all recognize in order to protect both our patients and ourselves.

DR. HARRY W. PLAGGEMEYER, Detroit: I wish to reiterate almost word for word what Dr. Caulk said. Our two studies, done individually and, of course, without any knowledge of what the other was doing, represent almost identical points on the subject. In addition he has been studying a chronic, or at least, a subacute condition, and I have been studying acute shock. These bladders had a very different type of trabeculation from the type we have been discussing previously, which simply corroborates what he says, that close observation will aid us in differentiating the underlying causes.

In the bladders that we have studied there is a very apparent attempt to compensate. Cross section of the muscle of the bladders we have been studying shows the diameter increased about five times over the normal. I dare say that in the type Dr. Caulk has been studying we would find that the individual muscle fiber is atrophied. But here we are studying what is termed a torpid bladder in England. I think that word is a misnomer. Here we have an increased suppleness or reaction to the electric current, and there is a distinct local attempt, irrespective of the integrity of the spinal cord, to facilitate the reflex through what are termed peripheral masses. Sheridan showed, on his dysanurized bladders in dogs, that the ones that were not catheterized were not infected. But Golds had shown in 1906 that every one of his cases that were catheterized were infected. These bladders attempt to compensate for this sudden shock. As far as I can determine hydronephrosis is not an early sequel, consequently we have to do catheterization, with inevitable infection, inevitable insult to the kidney and replacement tissue in the kidney. Why do that to an already nephrotrophic organism which is struggling for life?

**Epidemics of Poliomyelitis.**—The first great epidemic of infantile paralysis of modern times occurred in Norway and Sweden in 1945, 2,000 cases being reported in Norway and Sweden together. In 1907 the first great American epidemic occurred, 2,800 cases being reported in and about New York City (the largest epidemic on record); about 2,900 cases were reported that year. Infantile paralysis first appeared in the United States to any considerable extent in 1894, when Scribn of Rutland reported 132 cases in the Otter Creek Valley, Vermont. In 1908 the disease was apparently quiescent, only 392 cases being reported in the United States. In 1909 there were outbreaks in various parts of the country and in 1910 for the first time, with a total for the year of 2,243 cases in all. In 1910 the disease assumed much more serious proportions. It was present in forty-three states. Several states had epidemics, 500 or more cases occurring in the District of Columbia, Iowa, Massachusetts, Minnesota, Indiana and Pennsylvania, and from 200 to 500 in Kansas, Maryland, New Hampshire, New York, Rhode Island, Virginia, Washington and Wisconsin.—Infantile Paralysis in Massachusetts During 1915. Report by Massachusetts State Board of Health.

## THE ACTIVITY OF AMERICAN DIGITALIS\*

J. H. PRATT, M.D., AND HYMAN MORRISON, M.D.  
BOSTON

Before the world war the greater part of the digitalis used in this country came from Germany and Austria. Some digitalis was imported from England; but, in the vicinity of Boston at least, the preference for the high grade German leaf in the three or four years before the war was so pronounced that the use of selected English leaf, previously held in high favor, greatly diminished. Biologic tests made in this laboratory in 1909<sup>1</sup> showed that the best German digitalis on sale in Boston was of greater activity than the best English digitalis obtainable here.

Our attention was directed to the possibility of using American digitalis as early as 1910, when a tincture of digitalis made from leaf grown in the Rocky Mountains was found by Wesselhoeft, working in this laboratory, to be nearly twice as strong as the tincture in use at that time in the Massachusetts General Hospital. This tincture from American digitalis was prepared by E. R. Squibb & Sons in January, 1909; and as it was not tested until December, 1910, it was nearly two years old and had probably lost some of its original potency.

Duffield,<sup>2</sup> as early as 1868, had made tests of American grown digitalis, prepared by the Shakers of Mount Lebanon, and had found, by crude chemical methods, that the percentage of active principles was higher than in samples of English leaf, and these in turn higher than in German leaves that he examined at the same time. "I am compelled," he says, "to claim for our own home-grown digitalis, if rightly dried and gathered, superiority instead of inferiority." His work seems to have led no one to study and report the therapeutic value of American digitalis leaf.

For many years American leaf was unused. In spite of the shortage in the supply of digitalis caused by the war, several unsuccessful attempts were made to obtain American digitalis from wholesale drug houses as late as 1916. It should be mentioned, however, that for a number of years the H. K. Mulford Company has grown in their drug garden at Glenolden, Pa., the digitalis used by them.

Hale,<sup>3</sup> in 1911, published assays which showed that first year leaves from American digitalis grown at Arlington, Va., Madison, Wis., and Seattle, Wash., were stronger than the select English leaves that he tested at the same time for comparison. Second year leaves grown in Seattle were somewhat weaker than the English digitalis.

We retested leaf put up by Caesar & Loretz which, when examined in Germany, had a value of  $V = 5$ . This value is approximately equal to fifty frog units per gram, but it was found in our assay to contain only twenty-four units measured by Gottlieb's scale. As the leaf had been carefully dried and preserved in a tightly corked bottle, deterioration of the leaf probably does not explain this difference. As no digitalis leaf in our series tested at that time contained more than twenty-four units, and as Gottlieb found that

\* From the Laboratory of Medicine, Medical School of Harvard University.

1. Pratt: Boston M. & S. J. 143: 279, 1910.

2. Duffield, Am. J. Pharm., 41: 55, 1869.

3. Hale: Bull. 74 Hyg. Lab., U. S. P. H. S., 1911, p. 27.

good leaf contained fifty or more units, the most plausible explanation of our lower values is that *Rana temporaria*, used by European investigators is killed by smaller doses than the common American grass frog, *Rana pipiens*, which was used in our tests. We have found that *Rana viridens* is more susceptible to digitalis than *Rana pipiens*. Apparent variation in toxicity due to different species of frog used in England and America is worthy of more attention than it

was kept at about 20 C. After the injection had been made, each frog was put in a jar containing a little water, and this jar was placed in a large pan partly filled with water, the temperature of which was maintained at 20 C. The temperature of the air of the room was noted and recorded. It usually ranged from 18 to 21 C. Healthy frogs of medium size were selected. They were weighed immediately before the injections were made. Few weighed less than 20 or more than 35 gm. The injections were made into the ventral lymph sac. A 1 c.c. syringe graduated into hundredths of a cubic centimeter was used. The needle was inserted through the skin of the thigh just below the groin and passed upward into the lymph sac. Incomplete absorption was found to be the most frequent source of error in the assays. Careful scrutiny should be made for unabsorbed fluid after the lymph sac has been opened up at the end of the hour. The degree of absorption was noted in the protocols. If more than one or two drops were found, the test, if negative, was repeated with the same dose.

TABLE 1.—RESULTS OF A TEST OF SAMPLES OF AMERICAN GROWN DIGITALIS

Description of Sample	Lethal Dose of Syntal Tinctures in C.c. per Gram Frog Weight
1. Oregon, wild, 1916.....	0.004
2. Oregon.....	0.004
3. Oregon.....	0.004
4. Oregon.....	0.002
5. Washington, wild, 1916.....	0.001
6. Washington, cultivated, 1916.....	0.007
7. Wisconsin, cultivated, 1914.....	0.003
8. Ohio, cultivated, 1914.....	0.006

has received. If we are correct in our belief that *Rana temporaria* is killed by a smaller amount of digitalis than *Rana pipiens*, then leaf tested in England and found to be equal to the standard of 0.006 c.c. of tincture per gram frog weight of the American Pharmacopœia would actually be considerably below this standard when tested on the American frog, *Rana pipiens*.

Rowntree and Macht,<sup>4</sup> using the cat method of Hatcher and Brody,<sup>5</sup> found that digitalis from the drug garden of the University of Wisconsin was more active than any of four lots of Allen's English leaves tested, and far stronger than an old stock of German leaf. One of us (J. H. P.) obtained some of this same lot of Wisconsin digitalis from Dr. Rowntree at the Johns Hopkins Hospital. A 10 per cent. infusion was prepared. The minimum lethal dose of this was 0.012 c.c. per gram frog weight. This was stronger than the majority of English and German leaves examined in this laboratory.

Roth<sup>6</sup> tested samples of American-grown digitalis with the results shown in Table 1.

Out of these eight samples, six fulfilled the requirements of the Pharmacopœia. Two of these were twice the standard strength, and all the specimens of wild Oregon leaf were above the standard. The first six samples were air-dried. The method of drying the last two samples was not known. Roth concluded "that the wild digitalis which is found in the Northwestern States may be utilized as a source of supply for making the various preparations of digitalis and that by using ordinary methods in handling and preparing the leaves we may secure a highly active product, which compares favorably with the activity of cultivated leaves grown under more favorable conditions."

METHOD OF TESTING

The one-hour frog method recommended by the Pharmacopœia was used in our work. The comparative tests were all made at a temperature of 20 C. The frogs were brought into the laboratory from the storage tank at least several hours before they were used, and placed in a small tank, the water in which

As a control, the dose of strophanthin necessary to produce systolic standstill was determined for each lot of frogs at 20 C. This varied from 0.000004 gm. to 0.0000015 gm. per gram frog weight. Usually from eight to ten frogs were used in testing a single sample of digitalis. In one series twenty-two frogs were required to determine with sufficient accuracy the minimal dose required to produce systolic standstill. The temperature of the water in which the frogs are kept before and during the experiment was carefully regulated, and the temperature of the air in the room was noted and recorded.

TABLE 2.—ASSAYS OF TINCTURES. MINIMAL DOSE OF TINCTURES REQUIRED TO PRODUCE SYSTOLIC STANDSTILL OF VENTRICLE

Sample No.	Source and Description of Sample	Minimal Dose in C.c. per Gram Frog Weight
1	Washington (Hobart), 1st year leaf, 1916 crop, wild.....	0.004

We have tested in all twenty-eight samples of American grown digitalis. Tinctures of twenty-five of these were prepared and assayed. Freely made 10 per cent. infusion were used in testing the other three specimens. In obtaining digitalis from various sources we were aided by Dr. C. L. Alsborg, chief of the Bureau of Chemistry, Department of Agriculture, Washington, D. C. A summary of the assays of tinctures is given in Table 2.

All the tinctures were tested soon after they were made, except the "Rocky Mountain" tincture, which was nearly two years old when first assayed. Only

eight of the twenty-five, or 32 per cent. of the samples of digitalis, yielded tinctures that equaled the standard set by the United States Pharmacopeia IX.<sup>7</sup> With one or two exceptions they had been carefully collected and dried. Most of the cultivated samples had been grown in drug gardens. The series is large enough and representative enough to justify the conclusion that most of the digitalis grown in the United States is below the pharmacopeial standard. As we have shown earlier in the paper, this is true of most of the digitalis imported from England and Germany. The standard set by the Pharmacopeia is a high one. Clinical investigations in the future may show that it is unnecessarily high.

Six samples of American digitalis were stronger than the standard, and two of these were twice the strength required. One of these was from wild first year plants from the state of Washington and the other from cultivated plants grown on a commercial drug farm in Virginia. The former was assayed in February and the latter in April. These two lots were stronger than any imported digitalis tested in this laboratory. They were more active than the samples of American digitalis assayed by Hale.<sup>8</sup> Roth<sup>9</sup> reported assays on one sample of wild Oregon digitalis and one of cultivated Wisconsin leaf that equaled them in strength.

From Prof. Edward Kremers of the University of Wisconsin we obtained digitalis grown on the university drug farm at Madison that was of very high activity, and from Prof. Edwin L. Newcomb we secured cultivated digitalis from the drug farm of the University of Minnesota that was of nearly equal strength. The slight difference of 1 mg. in the minimal dose required to stop the heart in systole might be due to errors inherent in the method of assay, especially as the tests were not made on the same lot of frogs. Samples of digitalis from the drug farm of the University of Nebraska, and from Marion, Va., crop of 1918, were also found to be more active than the Pharmacopeia requires. The lot of digitalis from Virginia was secured from a Boston pharmacist who obtained it from a wholesale dealer in drugs. It is seen from this study that digitalis of great toxicity has been produced in widely different parts of the country.

Hale found that digitalis from the government drug garden at Arlington, Va., harvest of 1907, was of high potency. Our sample from this source also had a high assay value. It was obtained from the Bureau of Plant Industry in the fall of 1916.

Digitalis grown by Mr. F. A. Miller at Greenfield, Ind., from Oregon seed, was equal to the pharmacopeial standard. Another sample of digitalis grown on the same farm from Oregon seed was tested by Miller and Baker,<sup>9</sup> and found to have a value of 0.000 c.c.

Roth, as we have already stated, examined four samples of wild Oregon leaf and all yielded tinctures that were found on biologic assay to be stronger than the Pharmacopeia demands. That large quantities of wild Oregon leaf is strong enough to be of therapeutic value in the usual dosage is a view apparently widely held, not only in Oregon but also in other parts of the country. It seems to be based largely on Roth's studies.

Three samples of wild Oregon leaf examined by us were all weak. One of these was a well mixed sample from a lot of 840 pounds gathered in the summer of 1918. A tincture made from this was only a little more than half the strength demanded by the Pharmacopeia. Two samples of wild leaf from Linton, Ore., were obtained for us by Dr. A. E. P. Rockwell of Worcester, Mass. One lot was gathered in May, 1917; the other in June, 1917. The two tinctures prepared from these were of the same strength. The amount necessary to produce systolic standstill was 0.01 c.c. per gram frog weight, or 60 per cent. of standard strength. A sample of cultivated digitalis was gathered in April, 1917, in the same locality. The leaves were the first shoots of spring. Most of them were less than 4 inches in length. A 10 per cent. infusion prepared from this had a value of 0.01 c.c. As only five out of nineteen lots of American digitalis yielded stronger infusions, it is probable that a tincture of this leaf would have equaled the pharmacopeial standard. Leaves from second year cultivated plants growing in the same neighborhood were gathered in July just before flowering. The buds were fully developed and would have unfolded within a few days. Some of the leaves were 27 inches long. A tincture from these plants had a value of 0.014 c.c., or 43 per cent. of the standard. All of these four lots were grown on similar soil with the exception of a small application of fertilizer in the garden samples and were developed under the same general conditions. The leaves were artificially dried.

Six lots of leaf grown in the state of Washington were examined. The strongest and the weakest digitalis in our series of twenty-five samples came from this state. Only one of the six tinctures prepared from the Washington grown digitalis equaled the pharmacopeial standard. The strongest leaf from Washington (crop of 1916) had a value of 0.003 c.c. In 1917 the collector who furnished this gathered and preserved for us a quantity of Washington leaf that had a value of only 0.011 c.c.

Three lots of digitalis grown in Nebraska were assayed. One of these yielded a tincture that was stronger than the standard, the value being 0.005 c.c. The other two were not quite up to the required strength. Tinctures from these had values of 0.007 and 0.008 c.c.

Three of the four lots grown in Virginia were above the standard. Leaf from Balleston, Va., of the harvest of 1916, had a value of 0.003 c.c. No one, to our knowledge, making biologic assays on *Rana pipiens*, has reported any observations on digitalis of greater toxicity. A sample of digitalis from the same locality, the following year, had a strength of only 0.007 c.c.

A specimen of "digitol" furnished by the H. K. Mulford Company and made from leaf grown at Glen Olden, Pa., was slightly below the pharmacopeial standard.

Three lots of digitalis grown in Massachusetts have been tested. All were of poor strength. The one tested in Table 2 was obtained from mature second year plants. Wesselhoeft tested a homeopathic tincture (10 per cent.) made from fresh, undried digitalis grown in Hyde Park, a suburb of Boston. This had a value of 0.040 c.c., or 15 per cent. of the standard. A 10 per cent. infusion of digitalis put up by the "Shakers of Ayer" yielded a negative result when a dose of 0.050 c.c. was given.

7. The Pharmacopeia requires that digitalis leaf should be of such strength that 0.036 c.c. of a tincture prepared from it per gram frog weight will produce systolic standstill of the heart in one hour.

8. Miller and Baker, J. Am. Pharm. A. 131: 304, 1914.

A lot of digitalis grown in Portland, Maine, was found to be fairly strong, but not quite up to standard strength.

DIFFERENCE IN STRENGTH DUE TO SOIL  
AND CLIMATE

*Digitalis purpurea* is a European wild plant that is found in Portugal, Spain, France, Germany, England and the Madeira Islands. In some of these countries it grows much more profusely than in others. Brought to America for cultivation in flower gardens, it has in some sections become a weed and is now found growing wild in great abundance in California, Oregon, Washington, and to some extent in West Virginia. Prof. J. U. Lloyd<sup>9</sup> says that in the valley of the Honeoye River, N. Y., digitalis planted in 1820 in a flower garden was growing in 1912 as a great wild weed, self sown from year to year. It will grow in Oregon, according to information obtained by Roth, on practically any soil that will absorb moisture. The samples he tested grew on clayey soil. Digitalis does not do well on limestone lands, as Lloyd learned from personal observation, when he attempted to cultivate the drug in Kentucky. It is found generally on soil containing iron and manganese. The latter is assumed to be essential for the growth of the plant. It is said that digitalis does not grow in Switzerland, and this is attributed to lack of iron and manganese in the soil.

The toxicity of the leaf may vary with the locality in which it grows. It has been long known that the digitalis from the neighborhood of Strassburg is so strong that when given in the usual doses poisonous effects are quickly manifested. By biologic tests on frogs, Alsatian digitalis has been found to be twice as strong as the standard value established by Focke,  $V=5$ . Gottlieb used a frog unit similar to a diphtheria antitoxin unit. The amount of digitalis that will produce systolic standstill in a frog of 30 gm. weight within thirty minutes was taken as the unit. Good leaf, according to Gottlieb, should contain fifty units. Digitalis grown in the Vosges Mountains obtained from the pharmacy of the Strassburg Medical Clinic contained from 100 to 120 frog units.<sup>10</sup>

Cushny, according to Symes,<sup>11</sup> has found only small variations in different samples obtained from the same source.

Symes<sup>12</sup> examined a large number of samples of English digitalis grown in three successive years. The average activity of tinctures made in 1911 was about twice the standard adopted; namely, that of Dixon and Haynes,<sup>13</sup> a minimal lethal dose of 0.75 c.c. per hundred gm. (Houghton's<sup>14</sup> twelve-hour method, using *Rana temporaria*). Samples from the same sources in 1912 were notably weaker than those collected in 1911, but still 40 per cent. above standard. Samples of the harvest of 1913 were less active, but averaged 10 per cent. above the standard. The weather in the spring and summer of 1910 in Great Britain was dry, dull and variably warm; in 1911 bright and hot; in 1912 wet, dull and cold, and in 1913 dry, dull and warm. Only leaves of second year plants were gathered, so that two years of weather should be considered

in comparing strength of leaves to weather conditions. It would seem as if the good year 1911 influenced the activity of the leaf of that harvest and also, by its effect on first year plants, the harvest of the following year.

Our studies show that digitalis of the highest activity has been grown in Washington, Virginia, Nebraska, Oregon and Wisconsin. Digitalis that yielded tinctures of standard strength have been obtained from Indiana and Minnesota. Leaf of very poor quality, grown apparently under similar conditions, has been found in the same states (Oregon and Washington) that have yielded the best digitalis. The three samples of Massachusetts digitalis assayed were weak. Apparently the soil here is not favorable for the growth of active digitalis, although more samples should be studied.

That soil and climatic conditions are more important than the selection of seed, is suggested by the experiments of Miller and Baker. Seed of *Digitalis purpurea* from Japan, England and Oregon were planted in the drug farm at Greenfield, Ind. All three yielded leaves of the same strength. Tinctures made from each produced systolic arrest of the heart with a minimal dose of 0.009 c.c.

DIFFERENCE IN STRENGTH DUE TO METHOD  
OF DRYING

The relation of the method of drying to activity of leaf is not clearly brought out by our studies. Focke<sup>15</sup> maintains that the leaf should be dried within three days of gathering at a temperature between 60 and 80 C., until the moisture content is reduced to 1.5 per cent. He directs that it should be then packed in air-tight containers. Newcomb,<sup>16</sup> of the University of Minnesota, dries the leaf at a temperature of 100 C. for eight-hour periods on three successive days. It will be seen in Table 3 that the University of Minnesota leaf we examined contained considerable moisture, although less than the other samples. It was sent to us in a closed container.

TABLE 3—PERCENTAGE OF MOISTURE IN DIGITALIS LEAF

University of Minnesota, 1915 crop	6.8
Washington state, received from Department of Agriculture	6.8
Graciel College, Graciel, Iowa	6.4
Washington (Hobart), second year leaf	7.3
Washington (Hobart), first year leaf	7.6
Pennsylvania (Glen Olden), received from the H. K. Mulford Co.	8.7

One of the two strongest samples in our series, the first year digitalis leaves from Hobart, Wash., had 7.6 per cent. of moisture. It should be remembered that the leaves take up considerable water after they are dried, unless kept in air-tight receptacles.

It has never, to our knowledge, been demonstrated by biologic assay that leaves dried at room temperature are less potent than the leaves from the same plants dried rapidly at a high temperature. It is possible that they deteriorate more quickly, as Focke maintains. Most of the lots of digitalis studied by us were artificially dried. The air-dried samples of Oregon leaves assayed by Roth were stronger than the Pharmacopoeia requires. Our sample of air-dried Oregon digitalis, harvest of 1918, contained considerable moisture and was of low strength, the value of the tincture being 0.011 c.c.

ACTIVITY OF WATER-SOLUBLE GLUCOSIDS IN  
AMERICAN DIGITALIS

The active principles in digitalis leaves have not been obtained in a pure state. The view is held by Cushny<sup>17</sup> that there are two active glucosids present. These are digitoxin and digitalein. The former is insoluble in water. Kiliani's studies<sup>18</sup> have inclined him to the view that a pure digitalein existed in the leaves that was easily soluble in water and very active. All attempts to isolate it were unsuccessful. Schmiedeberg and Kiliani believe that the digitalein that has been obtained from both the seed and the leaves is a mixture of substances. They have used the term for the water-soluble glucosids that are certainly present in digitalis.

Kraft<sup>19</sup> obtained a water-soluble substance which he maintained was the pure digitalein that chemists had been seeking. He calls it "gitalin." It is easily decomposed by heat and reagents. The hydrate of gitalin was obtained in a crystalline state. It was almost insoluble in water. The so-called digitoxin obtained by Keller's method of quantitative analysis consists chiefly of gitalin with a little pure digitoxin. After a watery extract of the leaves had been made, a small amount of pure digitoxin and a considerable amount of gitalin was obtained from the residue by treatment with alcohol. Kiliani, after carefully examining a number of specimens of gitalin, concluded that it was not a chemically pure body, but a mixture. The crystalline gitalin "hydrate" closely resembled a substance Kiliani has studied and named  $\beta$ -digitoxin.

This brief summary of recent chemical studies shows how meager is the present knowledge of the subject. It indicates the importance of studying, by biologic methods, the aqueous as well as the alcoholic extracts of the leaves.

The activity of the water-soluble substances has been studied in nineteen samples of American digitalis by injecting frogs with freshly prepared 10 per cent. infusions. The samples are arranged in order of their strength in Table 4.

For comparison, the dose of tincture required to produce systolic standstill is also given. Some of the 10 per cent. infusions were stronger than the majority of tinctures examined. The greatest strength in water-soluble principles was exhibited by the samples of first year leaf from Hobart, Wash., which furnished also one of the two strongest tinctures. The 10 per cent. infusion of this leaf was exceeded in toxicity by only five of the tinctures in our series. No imported digitalis examined in this laboratory has yielded an infusion as strong as this. All the leaves that equaled or exceeded the requirements of the Pharmacopœia were found to be strong in water-soluble principles.

There was, however, no fixed relation between the activity of the tincture and the infusion, even when the tests were made on the same lot of frog. If the tincture is taken as a measure of this total toxicity, then the aqueous extract of the Minnesota leaf tested, March 20, 1917, which gave a value of 0.007 c.c., was 71 per cent. of the strength of the leaf, as the tinctures tested, March 22, 1917, had a value of 0.005 c.c. On the other hand, the strength of the aqueous extract made from Washington leaf obtained from the Department of Agriculture was found to be 0.028, March 1, 1917, which was only 38 per cent. of the activity of

the tincture of the same leaf tested, March 15, 1917. The results of these comparative tests show that the proportion of water-soluble principles differ widely in different lots of digitalis. Most of the lots of imported

17	Virginia (Balleston), 1917	5 23/17 0.023	9 27/17 0.007
18	Massachusetts (Andover)	5 31/17 0.025	9 27/17 0.011
19	Washington; obtained from the Department of Agriculture	3/ 1/17 0.028	3 15/17 0.001

leaf examined have contained less of the water-soluble principles than the majority of the samples of American digitalis we have assayed.

TOXICITY OF VARIOUS SPECIES AND VARIETIES  
OF DIGITALIS

There are twenty-three or more species of digitalis and numerous varieties. As early as 1888, Paschke<sup>20</sup> stated that *Digitalis ambigua* contained the same constituents as *Digitalis purpurea*, and that the medicinal properties of the two are identical. Boudgest<sup>21</sup> found that *Digitalis ambigua* was fully as active therapeutically as *Digitalis purpurea*.

Miller and Baker<sup>2</sup> tested on frogs a number of different species of digitalis that they had grown at Greenfield, Ind. Eighty-three per cent. of the samples tested had a greater toxicity than *Digitalis purpurea*. *Digitalis lanata*, a species quite distinct from *Digitalis purpurea*, had the highest value. The amount required to produce systolic standstill of the heart was 0.0003 gm. of leaf in the form of tincture, per gram frog weight. Only two of the lots of leaves of *Digitalis purpurea* tested in our laboratory have equaled this in strength (Table 2). The weakest leaf assayed by Miller and Baker was *Gloxinae flora alba*, which had a value of 0.0019. Haskell and Miller<sup>22</sup> found that the *Digitalis ambigua*, dried at 100 C., had a value of 0.00055 and *Digitalis grandiflora* a value of 0.0009.

R. E. Morris of the University of Minnesota tested *Digitalis lutea* on cats. He used tinctures and infusions from the leaves of Minnesota first year plants. He was impressed with the absence of irritating action on the nervous system and the quiet lethal

20. Paschke: Apoth. Ztg. 1888, p. 869, cited by Miller and Baker (Footnote 8).

21. Boudgest: Pharm. Ztg. 18: No. 42, 1913, cited by Miller and Baker (Footnote 8).

22. Haskell and Miller: J. Am. Pharm. A. 3, 1914.

period. With the hope that it would cause less gastrointestinal disturbance than *Digitalis purpurea*, he studied with S. M. White<sup>23</sup> its therapeutic action on patients, and found that it produced effects apparently the same as *Digitalis purpurea*, except that nausea and vomiting appeared to be less frequent.

We have tested on frogs the activity of a sample of *Digitalis lutea*, grown in 1913 on the drug farm of the University of Minnesota and furnished to us by Dr. Morris. The tincture made from this had a value of 0.004 c.c. per gram frog weight. This assay was made, May 18, 1917. Only two of our twenty-five samples of *Digitalis purpurea* were stronger.

Specimens of two hybrids were sent to us by F. A. Miller of Greenfield, Ind. Our results are given in Table 5.

TABLE 5.—DIGITALIS HYBRIDS TESTED BY ONE-HOUR FROG METHOD AT A TEMPERATURE OF 20 C.

	10 per Cent. Tincture	10 per Cent. Infusion
Hybrid digitalis ambigua × purpurea.....	0.008	0.010
Hybrid digitalis ambigua × lanata.....	0.007	0.008

Both were fairly strong in alcohol-soluble constituents, but not equal to the standard. The striking feature was the high percentage of water-soluble principles, amounting in the hybrid *Digitalis ambigua* × *lanata* to 88 per cent. Only three of the samples of *Digitalis purpurea* we studied yielded an aqueous extract of greater toxicity than *Digitalis ambigua* × *lanata*.

#### CONCLUSIONS

The best American digitalis, both wild and cultivated, is equal in activity to the best European digitalis. Specimens of high potency have been obtained from Virginia, Nebraska, Wisconsin, Minnesota, Oregon and Washington. The majority of samples of American digitalis examined were of low potency. No less than seventeen out of twenty-five samples of American digitalis were below the standard of strength established by the Pharmacopœia. The average strength of the American digitalis, however, was greater than that of the imported digitalis we have examined.

All digitalis should be tested biologically before it is gathered in large quantities for therapeutic use.

**The Ravages of Smallpox.**—In the eighteenth century, smallpox was more common than is measles today. In 1802 a speaker in the British Parliament declared that "it is proved that in this United Kingdom alone 45,000 persons died annually of the smallpox, but throughout the world what is it? Not a second is struck by the hand of time but a victim is sacrificed on the altar of that most horrible of disorders, the smallpox." A few years later Lord Macaulay said of the disease: "Smallpox was always present, filling churchyards with corpses, tormenting with constant fear all whom it had not yet stricken, leaving in those whose lives it spoiled the hidden traces of its power, turning the babe into a changeling, at which the mother shuddered, and making the eyes and cheeks of the betrothed maiden badges of horror to the lover." The history of smallpox in our own country tells the same story. In 1702, 14.4 per cent. of the population died from the disease. Nineteen years later, 5,989 out of the 11,000 inhabitants of Boston contracted the disease, 840 fatal. In 1730, it again ran riot in Boston, claiming nearly 500 victims out of a sick roll of 4,000. It stalked among the colonies like the instrument of a remorseless avenger.

## Clinical Notes, Suggestions, and New Instruments

### GANGRENE FOLLOWING AN INJECTION OF ARSPHENAMIN

L. A. SUTTER, M.D., WICHITA, KAN.  
Surgeon to Wesley Hospital

**History.**—O. P. M., aged 35, married, an American laborer, family history negative, had his first attack of gonorrhœa in 1903 and got over this in a short time. One year later he had a second attack, developing a double epididymitis, and was in the hospital five days. The next year he had a chancreoid on the dorsum of the foreskin, which healed promptly. In June, 1917, when I saw him, he had a chancre on the right side of the shaft of the penis about 1 cm. from the pubis. I gave him an injection of 0.4 gm. of arspenamin and a second one a week later. About one month after this his wife was in the hospital for a double pyosalpinx. She also had an ulcer the size of a dime on the anterior part of the cervix uteri. I gave her one injection of arspenamin, after which she left the hospital, and I did not see either her or her husband again until Aug. 31, 1919.

In June, 1919, a soft chancre appeared on the penis. At this time the patient had a double adenitis. These did not need to be opened, however, and in two weeks he was able to resume work. In June, 1919, he had an attack of tonsillitis. His throat grew worse, and in August he had his tonsils removed. They were badly diseased. The next day at 9 a. m. he was given an injection of arspenamin in the vein of the left elbow. The physician who gave this injection describes his technic in a letter to me as follows:

The amount of solution used was about 250 c.c. and was given by the three-way cock method with a 10 c.c. syringe. First the syringe was filled with physiologic sodium chlorid solution and the needle filled and inserted into the vein. The blood flowed freely into the syringe, the salt solution basin was set aside, and the arspenamin substituted in its place. The syringe was filled by means of the three-way cock with the arspenamin solution and the solution injected into the vein. This process was repeated until the 250 c.c. solution of arspenamin had been given. The vein was entered by the needle at the first attempt. The patient complained of a severe pain in his hand at the time. In a few minutes after the injection his hand was white and death-like cold. He complained of anesthesia and inability to move the hand, and there was a decided wrist drop. Three hours later there was tonic contraction of all the fingers and the wrist. The peripheral circulation was poor. The hand was cold all the time. The next day the tonic contracture was somewhat less, and from that time until two weeks later, at which time he left the hospital, there was very little feeling in the hand. It was apparent that his fingers were becoming gangrenous. About twenty minutes were consumed in giving the injection.

The patient states that when the solution was started it felt as though a match had been touched to his fingers, or he had taken hold of an electric wire. The pain grew worse during the injection and was not relieved until the next afternoon. Within two hours after the injection his arm began to swell around the needle hole, the swelling extending down over the forearm and up over the biceps muscle. Hot applications were applied to the arm. These were used continuously for two days, after which warm alcoholic dressings were kept on the arm for forty-eight hours. At some time during the use of the hot applications the dorsal surface of the forearm, hand and fingers was quite badly burned. Owing to the anesthetic condition that prevailed he knew nothing about the burn until he saw the large blisters. After ninety-six hours a dry powdered dressing was used on his arm.

**Examination.**—He said he had lost 29 pounds. He was 6 feet tall, weighed 146 pounds. The eyes were sunken and he had an anxious expression. The left arm was carried at an angle of 45 degrees. It could be flexed until the hand was within 6 inches of the shoulder. This caused him considerable pain, however. The forearm could be extended to

within 15 degrees of a straight line. The teeth were in poor condition. The eyes showed normal reaction at the pupils to light and distance. The reflexes were lively throughout. The heart showed a soft mitral systolic murmur. The lungs and abdomen were negative.

The back of the left hand and forearm were covered with large blisters. There were also blisters over the dorsal surface of the fingers and thumb. The cutaneous covering had been removed from the blisters of the back of the hand, leaving a large oozing surface. All the nails were black. The thumb was black for 5 mm. on the palmar surface. The gangrenous area extended through to the nail. There was also a black ring extending around the thumb over the last joint. The skin over all the gangrenous area was extremely shriveled, dry and hard.

The index finger was dead and shrunken from the middle phalangeal joint. The middle finger was also dead, black and shrunken within 5 mm. of the middle phalangeal joint. The ring finger had a well marked line of gangrene midway between the second and third phalangeal joint. About one half of the last phalangeal joint of both little finger and thumb were gangrenous.

There were a number of blisters over the tops of the fingers and thumbs, each containing quite a little pus.

The muscles of the forearm were very hard, and the entire cutaneous covering of the forearm and hand, excepting where raw areas were, was shrunken, hard and thick. There was very slight sensation for hot and cold over the hand and fingers and very little pain sensation on being stuck with a pin.

The wrist could be moved slightly.

*Operation and Result.*—September 11, under ether anesthesia I amputated the thumb slightly distal to the end of the last phalanx. The index finger was amputated 1 cm. proximal to the middle phalangeal joint. The middle finger was disarticulated at the middle phalangeal joint. Owing to the desire to save as much of the fingers as possible, the ring finger was amputated 1 cm. distal to the middle phalangeal joint.

Five mm. of tissue were removed from the end of the little finger.

The wound healed in a surprisingly kind manner.

At this time there is increased motion of the elbow joint, the wrist and some of the finger stumps. Sensation has greatly improved. The oozing areas of the hand are entirely healed.

369 Schweiter Building.

#### AN EASY METHOD OF MARKING THE SKIN

WILLIAM ALLEN PUSEY, M.D., CHICAGO

It is often desirable to outline a figure on the skin, but it is not always easy to do so. A skin pencil is not always available and one, even of the best quality, marks the skin with some difficulty. According to a method suggested by Pusey the spot to be marked is wiped off with a bit of cotton wet with gasoline. This moistened surface can then very readily be marked with a "paper pencil." This method uses the carbon that gasoline must be at hand, and also care of an inflamed or broken surface this preliminary application of gasoline is irritating or painful. A much simpler method without the objection of irritation, is to moisten the surface with water from a cotton sponge and then use an ordinary copying pencil. The lead of a copying pencil marks with ease on the moistened skin. With this method it is possible to outline with a distinct violet line any area on the skin. Such markings can be made even on a sterile surface by first washing the end of the pencil in a concentrated solution of mercuric chlorid, and by moistening the surface with a sterile solution. The mark can readily be wiped off with soap and water. The purple lines may be photographed, but not very well.

### USE AND ABUSE OF CATHARTICS\*

(Continued from page 1529)

#### LIQUID PETROLATUM AS A LAXATIVE

The rapidity with which "mineral oil," one of the more recent additions to our materia medica, has conquered the globe has been phenomenal. It is now a most extensively used medicinal substance; and, if its sale were a real indication of its medicinal value, we should have to consider it one of the most valuable of medicaments. While not ready to grant this preeminence, we may at least view its popularity without alarm; for, of all substances with which mankind has belabored its system, petrolatum is surely the most inert and perhaps the most harmless.

Petrolatum is a bland, odorless, tasteless and colorless liquid, indigestible, as well as incapable of decomposition by bacteria; hence it cannot become rancid. It is not absorbed; therefore it cannot produce poisoning in any dose. A pint of liquid petrolatum has been given in a few hours without untoward results.

Owing to its innocuousness, this substance should be the laxative of first consideration. While it is merely of temporary value in habitual chronic constipation and possibly may still further increase the intestinal sluggishness by lessening the amount of work—of exercise—of the intestinal and abdominal muscles, it seems to have an actual curative effect in certain conditions, as, for instance, in spastic constipation, in which, by lessening the irritation, it may ultimately succeed in lessening the irritability.

Liquid petrolatum is indicated whenever it is desired to soften the feces. The oil, being indigestible, remains in the feces in the form of globules. To speak of this action as "lubrication," as is often done, is hardly correct. Lubrication depends on the formation of an oil film, and such a one it is impossible to apply to a water-soaked membrane like the intestinal mucosa, or to the ordinary moist fecal mass. When an excess of oil has been ingested it does not apply itself as a film to the surface, but remains separate from it, giving rise to the much complained of "leak" of oil through the anus, which may occur even with small doses.

As liquid petrolatum does not give rise to irritant products such as the fatty acids liberated by the digestion of fatty oils, especially of castor oil, it may be given with safety for irritation of the gastro-intestinal tract. By its softening effect on the stools it may even have a healing action on superficial lesions of the mucosa.

In intestinal stasis due to crippling of the intestine, be this from kinks or other forms of obstruction, or even malignant tumor, its softening effect on the feces is likely to prove valuable.

The dose varies from 15 to 90 c.c. When larger dosage is employed, there is likelihood of leakage of the oil. Sometimes free oil is passed in a bowel movement, or even without one. It was supposed that the

\* Bécérel, H.: J. de radiol. d'électrol. 3: 272 (June) 1919; abstr. J. A. M. A. 73: 724 (Aug. 30) 1919.

\* This is the sixth of a series of articles on the pharmacology, physiology and practical application of the common laxatives and cathartics. The first article appeared October 18.

"heavy" liquid petrolatum, by reason of its greater viscosity, would be less likely to give rise to leakage. That this is not the case was shown by a collective investigation carried on by Bastedo,<sup>2</sup> under the auspices of the Committee on Therapeutic Research of the Council on Pharmacy and Chemistry. To ascertain whether any difference existed in the efficacy of the different varieties of liquid petrolatum, clinicians were furnished with specimens of light Russian liquid petrolatum, heavy Russian liquid petrolatum, and an American brand of light liquid petrolatum. To avoid bias, the specimens were designated by numbers or letters. The conclusion of this study was that the differences were too slight to be of importance. There was no difference in the dose required, in effect on stomach or stools, or in their tendency to give rise to leakage.

As a general proposition, when leakage occurs, it is an indication that the dose should be reduced. If such reduced dose is insufficient to act on the bowels, it may be reinforced by a specific stimulant to peristalsis, such as cascara sagrada. The oil seems to be devoid of any effect on the intestinal musculature except that it diminishes the work of the muscle by softening the feces. In cases in which synergistic use of cascara is contraindicated, as for example in spastic constipation, it might be well to try a petrolatum of higher melting point, like petrolatum, U. S. P., which it is reasonable to assume might be less likely to produce this undesirable effect.

Emulsification is another expedient that it seems ought to be capable of overcoming the tendency to leakage. The National Formulary contains the following formula:

EMULSUM PETROLATI, N. F.

	Gm. or Cc.
Petrolatum .....	25.5
Expressed oil of almond.....	22.5
Acacia .....	12.5
Syrup .....	10.0
Tincture of lemon peel .....	1.5
Water, to make .....	100.0

Average dose: one tablespoonful.

This preparation would be worth trying in such cases; and reports on its success or failure in meeting the requirements of activity, pleasantness, and absence of tendency to "leak" would be of interest.

Our choice among the different brands of petrolatum should be chiefly determined by palatability. This depends on the degree to which the refinement of the oil is carried out.<sup>3</sup>

Fancy named products should be avoided. Not only are such products more expensive, but when any one

of these half hundred brands is prescribed, the druggist, who may have half a dozen other brands that are just as good on his shelves, will have to buy a full bottle of the product specified and charge the patient the price of the whole bottle, even though the prescription calls for but part of it—the rest, probably, remaining on his shelf indefinitely. Such specifying is an injustice to the druggist and to the patient. Why not trust pharmacopeal quality? If the druggist does not dispense U. S. P. quality, he can be legally prosecuted. Of course, if U. S. P. quality is not good enough, specifying may be necessary until the quality of the official product has been improved. The official quality of heavy liquid petrolatum (petrolatum liquidum grave) is satisfactory. If, however, one desired an extra fine product, and higher price is no object, one might specify the name of a distributor who promotes a possibly somewhat superior product in an ethical manner, for instance, Squibb, to mention one such.

As the oil is tasteless and odorless, it is probably best taken in its pure state. It may be floated in some pleasantly flavored fluid, such as orange juice or grape juice. Flavoring by means of a pleasant volatile oil may be resorted to, should the patient prefer a distinctive flavor to the insipidness of the liquid petrolatum. Hilton has experimented on this matter, and found that per 500 c.c. of oil, these quantities of one or the other flavoring oils are suitable: anethol, 10 drops; oil of almond, 15; oil of cloves, 10; oil of cinnamon, 5; oil of peppermint, 15; oil of spearmint, 15, and methyl salicylate (wintergreen), 25 drops. To him, peppermint seemed the most pleasant flavor, with cardamom a close second. We must recognize the fact, however, that there are people who abhor one flavor, such as peppermint, enjoyed by another; and that any one is liable to tire of a decided flavor used frequently. Combinations of flavors—bouquets—are often more acceptable than single flavors, and enjoyed for a longer time. Thus the oil combination used in the flavoring of aromatic elixir might be used to make liquid petrolatum aromatic: oil of orange, 2.00; oil of lemon, 0.50; oil of coriander, 0.20; oil of anise, 0.05; liquid petrolatum, 1.000.

As the oil, when taken after meals, is likely to lie heavily on the stomach and produce other gastric distress—in Bastedo's investigation 20 per cent. complained of nausea or tendency to repeat—it is best to take it in such a way that it will interfere least with gastric digestion. This is secured by giving a dose, from 15 to 60 c.c. of it, at bed time, or else administering 15 c.c. one hour before each meal.

Patients given this laxative for the first time should understand that it does not produce an immediate effect, but that it may have to be taken for several days before results will be noted. When the desired effect is not obtained with the initial dose, the quantity should be increased until the stools have been sufficiently softened. The efficient dose is then to be maintained for a while—several weeks, perhaps—and then gradually reduced until regularity of bowel action has been secured or the minimal dose has been ascertained that is required for satisfactory function. It must be remembered that if kept up for some time a habit may be formed. While it may not be a serious one so far as concerns harm to the system, it is an expense to the individual and especially a nuisance.

(To be continued)

2. Bastedo, W. A. Clinical Experience with Liquid Paraffin (Liquid Petrolatum). J. A. M. A. 44: 808 (March 9) 1915.

3. In 1914, THE JOURNAL (May 30, p. 1740) published the following list of names under which liquid petrolatum was then known: adepsine oil, amulec, atoleine, atolin, blandine, erysualin, deeline, glyco, glycoline, glymol, heavy petroleum oil, liquid alboline, liquid cosmoline, liquid fossoline, liquid geloline, liquid paraffin, liquid petrolatum, liquid secoline, liquid vaseline, mineral glycerin, mineral oil, neutralol, oleo paraffin oil, paroline, petrolol, petro, petrolax, petrolax, petrolol, petroloso, rock oil, Russian liquid petrolatum, Russian mineral oil, Russian paraffin oil, Russol, saxol, terraline, terralibolia, usoline, water-white mineral oil, and white paraffin oil. To this list many more names, such as "nupol" and "puripetrol," would have to be added to bring it up to date. Here is a good illustration of the inexpediency of employing coded and copyrighted names in prescribing standard official products. S. I. Hilton (Petrolatum Liquidum, U. S. P. VII), J. Am. Pharmac. S. 1: 577, 1914) quoting the wholesale prices of various brands of liquid petrolatum, found that those with fancy named names commanded a very much higher price than other oils on the open market, and, nearly all, coming from the same source. Of course, manufacturers and dealers would not own names if they did not expect to obtain something substantial out of them.

## THERAPY AND RESEARCH

Few persons who have occasion to use arsenamin (*salsarsan*) and its derivatives, or who contemplate the therapeutic usefulness which the introduction of these drugs into medical practice has embodied, realize the long and laborious scientific investigations that preceded the success inaugurated by Ehrlich. Modern chemotherapy of this sort has been the product of careful research in which ingenious and novel chemical syntheses were undertaken to evolve new compounds that were subsequently tested by animal experimentation before any attempt at clinical application was made. It is important to keep in mind the fundamental fact that the great discoveries of curative drugs were not made over night or by chance, as one may stumble on precious stones; they are rather the outcome of untiring effort directed by experimental genius. Each success is but the fortunate companion of almost innumerable preliminary or preparatory trials and many failures. Research is both the laborious and the continued search after truth, not the mere chance finding.

Some of the results of diligent and persistent researches in chemotherapy have recently been published from the Rockefeller Institute for Medical Research.<sup>1</sup> They involve the synthesis of certain new types of organic arsenic compounds intended to be applicable to the treatment of experimental trypanosome and spirochete infections. One of the promising products synthesized by Jacobs and Heidelberger<sup>2</sup> for trial is *N*-phenylglycinamid-*p*-arsonic acid,

in which the arsenic is present in the pentavalent form as presented by the arsenic acids. The aim has been

to attempt to eliminate certain of the well known practical disadvantages of the now familiar arseno compounds. Trypanosomiasis affects different species in unlike ways. Brown and Pearce point out that in some, as rats and mice, it is chiefly characterized by the constant and progressively increasing number of trypanosomes in the peripheral blood, by the lack of any clinical manifestations, and by the relatively early death of the infected animal. Consequently, an effective therapeutic compound for the treatment of trypanosomiasis in such species must be biologically available within a short time after its administration, and must have sufficient speed and duration of action to halt and overcome the rapidly increasing blood infection, which is comparable with a fatal bacteremia. The trypanosomiasis of many of the larger animals, like the rabbit, on the other hand, is preeminently a tissue infection. To combat this, an effective drug must possess tissue penetration as well as trypanocidal power. These illustrations are sufficient to indicate the varied practical conditions that must be met to solve the therapeutic problem. They are likely to tax the ingenuity and persistence of the most assiduous and intelligent investigator.

The first of the new compounds described by the workers at the Rockefeller Institute is extremely easily soluble in water, forming neutral solutions that are stable. The animal tests indicate that the toxic effects are confined to doses relatively close to the minimum lethal dose, and the recovery from sublethal doses is rapid and complete. The new arsenic acid has already given indications of being "an agent of marked therapeutic action in the treatment of experimental trypanosomiasis in mice, rats and guinea-pigs." The "curative ratio" or fraction of the minimum lethal dose is small. Therapeutic doses are not followed by signs of organic or functional disturbance, but, on the contrary, the general physical condition of the treated animals shows an immediate improvement. In the more penetrating invasion of trypanosomes in rabbits, therapeutic efficiency has also been recorded by Pearce and Brown. Finally, they have noted promising effects in experimental infections with spirochetes of the *recurrens* group and by *Spirochaeta pallida*. The infection is ameliorated even though the spirochetes are not immediately destroyed. The Rockefeller Institute pathologists summarize this by comparing the result with that produced by more powerful spirocheticidal agents. The infecting micro-organisms are either affected in such a way that they eventually die off, or are destroyed by the host in such a way that no lasting immunity is developed in consequence of their destruction. For the present, the investigators go no further than to state that the new arsenic acid acts somewhat differently from the usual spirocheticidal agents. While it does not possess a considerable degree of spirocheticidal action, its chief effect is seen in the peculiar way it modifies or controls the course of these infections.

1. Jacobs, W. A., and Heidelberger, M. Chemotherapy of Trypanosomiasis and Spirochetosis, Chemical Series, I, *N*-phenylglycinamid-*p*-arsonic acid, *J. Exp. Med.* 240:241 (Nov.) 1919; Brown, W. H., and Pearce, L. G. Chemotherapy of Trypanosomiasis and Spirochetosis, Biological Series, I, The Toxic Action of *N*-phenylglycinamid-*p*-arsonic Acid, *ibid.*, p. 317; II, The Therapeutic Action of *N*-phenylglycinamid-*p*-arsonic Acid in Experimental Trypanosomiasis of Mice, Rats and Guinea Pigs, *ibid.*, p. 337; III, The Therapeutic Action of *N*-phenylglycinamid-*p*-arsonic Acid in Experimental Trypanosomiasis of Rabbits, *ibid.*, p. 475; IV, The Action of *N*-phenylglycinamid-*p*-arsonic Acid on Spirochete Infections, *ibid.*, p. 483.  
2. Jacobs, W. A., and Heidelberger, M.: *J. Am. Chem. Soc.* 41: 1587, 1919.

It is not certain that these purely tentative experimental observations can be applied ultimately to the control of human infections. However, the persistence of the investigators, who have labored literally for years without signs of immediately successful results, needs appreciation and deserves high commendation. Such work is less conspicuous than brilliant feats of surgery or successful campaigns in public sanitation; it is none the less worthy of due recognition because it surely paves the way to permanent advances.

#### SYPHILITIC AORTITIS

Though a disease may spring suddenly into prominence, it is not always certain that there is an actual increase in its prevalence. In recent years the importance of syphilis of the aorta in the production of a variety of clinical pictures has been emphasized with increasing frequency. Probably this is due to the great advances that have been made in the methods of detecting syphilis, particularly the discovery of the causal organism and the perfecting and wide use of the complement fixation test.

Physicians generally have not realized the frequency and importance of syphilitic aortitis. Recognition of the disease at the earliest possible moment is essential because of the necessity for prompt and energetic treatment. Recent figures cited by Schrupf<sup>1</sup> indicate the frequency with which syphilitic aortitis occurs. Of more than 4,000 syphilitic males included in the report, about 10 per cent. presented definite evidence of syphilis of the internal organs, and half of this group of patients showed evidence of syphilis of the circulatory system. Over 5 per cent. of syphilitic males may therefore be expected to show definite changes in the circulatory organs. Three fourths of these will be cases of syphilis of the aorta, either with or without aneurysm.

Three common pictures are likely to be produced by syphilitic aortitis. These are aneurysm (particularly of the thoracic aorta), aortic regurgitation, and angina pectoris. Schrupf analyzes 140 cases of aortic regurgitation and shows that practically three fourths of them are of syphilitic origin, the other one fourth being due to rheumatic endocarditis or to ordinary arteriosclerosis.

It is questionable whether we have yet developed satisfactory criteria for the early recognition of these cases. Schrupf<sup>1</sup> states that the average period elapsing between infection with syphilis and the development of aortic lesions is ten years. It is hardly likely that during these ten years the process in the aorta is entirely latent. The natural history of the disease would lead us to expect that there are periods of latency alternating with periods of activity. The chief early symptom is retrosternal pain, which is often most marked under the upper sternum, is not usually

dependent on exertion, and does not usually radiate to the neck or arms like the pain of true angina pectoris. This pain is accompanied by very few physical signs. There are no cardiac murmurs, but the first aortic sound may be dull and distant, and there may be so-called pulsatory plethora, namely, a marked pulsation of the peripheral vessels. During the active stages the Wassermann test is always strongly positive. The use of the roentgen ray may be valuable, particularly if local dilatations of parts of the aorta can thus be shown.

One may perhaps question whether such an outspoken symptom as substernal pain is associated with the early stages of a chronic process like syphilitic aortitis. It seems likely that by the time definite pain is produced the lesions are quite extensive, and it is questionable whether a really early diagnosis can be reached if symptoms are waited for. It seems highly probable that in the aorta, just as in the central nervous system, definite lesions may be present without any symptoms whatever, and it would seem that some method of diagnosing syphilitic aortitis during the presymptomatic period must be devised. Whether the use of the roentgen ray will furnish the solution is problematic, but at present no more promising method is in sight. Perhaps the most essential procedure is the return of syphilitic patients at stated intervals for thoracic roentgenography. Even in the absence of positive roentgenographic findings a syphilitic patient with a positive Wassermann reaction and no obvious evidence of the disease externally may be assumed to have a lesion in the aorta, especially if lumbar puncture shows that the nervous system is free from evidence of disease.

#### THE PITUITARY IN DIABETES INSIPIDUS

Extracts of the posterior lobe, or pars nervosa, of the pituitary structure provoke an unmistakable change in the secretion of urine when they are introduced directly into the circulation. This renal effect has been compared to the secretion-promoting effect exerted by extracts of the duodenum on the pancreatic cells. Because of such experimental observation the pituitary has been assumed to exercise a regulatory influence on the functions of the kidney. Such reasoning, often applied in connection with the ductless glands, has grave limitations and is rarely conclusive. As a recent writer has remarked, it is by no means logical to assume or infer that the functional importance of an organ is demonstrated by the properties of an extract of it. If one applies such an argument to the galactogogue substance in the pituitary of a fish, the absurdity is obvious.

Other evidence for the functional interrelation of kidney and pituitary has been sought in the domain of pathology. In the chronic polyuria most frequently referred to as diabetes insipidus, involvement of the

<sup>1</sup> S. Schrupf: *Arch. f. Dermat. u. Syph.* **126**, Part 3, 1919

pituitary, particularly of its junction with the brain, has been demonstrated repeatedly at necropsy; in fact, there are no records in which the pituitary was examined and found to be perfectly normal. Experimental pathology, by damaging the structures in the neighborhood of the posterior lobe of the pituitary, has frequently produced abnormalities in the flow of urine. Polyurias lasting from one to six months have followed the artificial lesions; yet such results have been exceptional and attained only by chance, apparently.

Kennaway and Mottram<sup>1</sup> of the Middlesex Hospital in London have added clinical evidence to the problem of pituitary function in connection with the kidney. The antidiuretic effect of pituitary extract given by subcutaneous injection was demonstrated both in a normal subject and in a case of diabetes insipidus. Administration of such preparations by mouth is ineffectual. It has been suggested that the antidiuretic effect is due to diminished absorption from the bowel so that less water is available for secretion through the kidneys. If we may trust the evidence of Konecny and Schuster,<sup>2</sup> however, the effect is rather attributable to direct action on the kidneys. Kennaway and Mottram maintain that the immediate restoration of a normal state of the urine when pituitary extract is administered in diabetes insipidus provides the strongest evidence for the normal activity of the gland in regulating the secretion of urine. We must confess, however, that in view of the contradictions in the literature of the subject, and the indirect nature of both clinical and experimental evidence, it would be far-fetched to maintain without reserve that disorder of the pituitary is in all cases the cause of chronic polyuria. Injection of pituitary extracts now appears to be the most effectual mode of treatment. However, every day obvious examples of the limitations of such a procedure are encountered.

#### THE SURPRISING CALORIC VALUE OF DAINTIES EATEN BETWEEN MEALS

Now that the war is over, many of the restrictions imposed by governmental mandate, the exigencies of commerce, or a patriotic conscience need no longer apply to the behavior of our population. "Sugar and candy and everything nice" may once again be included in the diet of American homes. We may at length return to the consumption of those dietary luxuries that have attained great popularity in the United States. Candy is no longer tabooed, nor is purchase restricted by a food administration. Strangely enough, the enforcement of prohibition has apparently increased the use of candy, as it has augmented the consumption of

the sugar-containing temperance beverages. The caloric potency of alcohol is likely to be replaced by the fuel value of "sweets" eaten here and there between meals.

It is commonly believed that these "extra foods" consumed apart from our regular meals on the most varied occasions, frequently several times a day, play a relatively insignificant rôle in the total value of our food fuel. Not long ago, however, Benedict<sup>1</sup> called attention to the true value which ice cream, soda water and various comparable popular American extra foods really represent in terms of calories, the standard units of food energy. Some of the commonly served portions eaten in haphazard fashion on the spur of the moment may be equivalent to as much as 500 calories, while 100-calory portions are anything but unusual. In a more recent contribution,<sup>2</sup> the same investigators have brought further actual evidence of the unexpected food value of many of the items innocently consumed without thought of possible nourishment therein by thousands every day. Prior to the recent inflation of prices, from 50 to 60 calories were frequently obtainable in so-called penny candies; in some of the cheap nut candies the yield even exceeded 100 calories for the small coin that delights the child.

The eating of "extra food" is by no means confined to children. The adult man and woman who depend on the meal-time food fuel of from 2,000 to 3,000 calories a day indulge in candy as a pastime or eat an after-theater lunch for the sake of sociability—not because they feel the need of more food nor because they appreciate the magnitude of the diet intake. It will come as a surprise to most persons to learn on reliable authority that a single caramel, a nougatine or a penny's worth of candy may furnish sufficient energy to supply the extra heat needed for walking a mile or more. Equally startling will be the news that the ingestion of three seemingly insignificant, medium-sized olives can yield the amount of heat liberated in a half-mile walk. We are informed<sup>2</sup> that for a man of average weight to walk from the bottom to the top of Washington Monument would require an extra heat production of 80 calories. The energy expended in this not inconsiderable effort may be completely replaced by the consumption of less than half a doughnut, six walnuts, five large olives or four pretzels. Perhaps we shall learn from such facts how futile a "constitutional" walk is in any attempt to combat the accumulating energy from undue eating between meals. Or possibly, on the other hand, the doughnut will gain a reputation as a standby in times of muscular stress and thus retain in peace the unique favor that it won through the efforts of the Salvation Army in the days of military stress.

## Current Comment

### THE COMPLEXITY AND COST OF MODERN DIAGNOSIS

It has frequently been stated that scientific medical diagnosis and treatment are a privilege accorded only to the very poor and the very rich. The recent establishment of diagnostic clinics and diagnostic institutes indicates that the principle of group practice is being recognized to a greater extent than has heretofore been the case. The general hospitals have for many years been diagnostic institutes for group practice, a fact which is sometimes not remembered by those who proclaim that group practice represents a new principle. The diagnostic institute of the present day is, however, not a hospital but an ambulatory clinic, the idea being that many patients who do not care to go to hospitals and who do not need to do so can have their ailments studied at such an institution. A perusal of the charges for service made by some of these institutions indicates that while they have doubtless solved the problem of medical cooperation they have not completely solved the financial problems of the patient. The fee for a general examination is a modest one well within the reach of the average citizen who falls into neither the pauper class nor the group of the wealthy. More complicated examinations, such as are necessary in patients with obscure diseases, cost a sum which in many instances would be quite beyond the means of the average wage-earner. The question of obtaining efficient medical diagnosis and treatment for cases of obscure disease among those who can pay only a modest fee is one of the live questions of the day. It is doubtful whether it can be met by diagnostic clinics unless they are heavily subsidized organizations along the lines of the existing dispensaries, but differing from them in the fact that a small fee is charged. Attempts have been made to meet the situation in this way, but as yet there has been no widespread effort to care for the man of moderate means. As individuals of this group furnish the great bulk of patients, some machinery must be devised which will enable them to receive inexpensive but adequate care when they develop obscure diseases.

### THE POPULATION OF THE WORLD AND THE RATE OF ITS INCREASE

Every so often, sociologists and statisticians begin to "view with alarm" the rapid increase in the world's population and to predict world catastrophe as an inevitable result. Recently the statistician for the Commonwealth of Australia, G. H. Knibbs, in a monograph on population,<sup>1</sup> stated some significant facts and estimates in regard to the present and the future population of the earth. Knibbs puts the population of the earth for the year 1914 at 1,649,000,000, or about thirty-nine million in excess of the estimate of Jaraschek, the French statistician, for 1910. The annual rate of increase in the world's population for the five-year period 1906 to 1911 Knibbs estimates at 0.01159, or

1.159 per cent. of the population. Should such a rate of increase be continued, it must result in a severe strain on the resources of Nature. Knibbs asks whether medical men in future will take a stand in favor of so colossal a population that the masses will scarcely be provided with the bare necessities of life, or will they favor birth control and a limitation of births in such a manner that the population of the earth shall never be greater than can be adequately provided for on a high plane of physical, mental and moral existence?

### VACANCIES IN ARMY AND NAVY MEDICAL CORPS

As stated elsewhere, there are 710 vacancies in the regular medical corps of the army and 429 vacancies in the regular medical corps of the navy for young physicians who wish to undertake this work. Under the present law, reserve officers on active duty may be continued on such duty with their consent until July 1, 1920. The departments are also permitted to assign officers for temporary service until that time. For this reason the large vacancy list does not indicate any distress on the part of the service or immediate need of men to fill these positions. However, with the passing of the emergency covered by the law, both services will require young men to fill these positions. The reason for these resignations is of course understood. It is not dissatisfaction with the service but the fact that the increasing cost of living makes the present pay absolutely inadequate. Fortunately, there are now in Congress bills for increased pay to officers of the military service which will permit the corps to offer more attractive opportunities to interested young men, and it is likely that as soon as these bills pass—which they undoubtedly will—numerous young men will wish to avail themselves of the opportunities offered by these permanent positions. Those interested should communicate at once with the Surgeon-General of the Army or Navy, with a view to having on hand complete information so as to carry through the application, examination and appointment with the least possible delay.

### CHANGING POTABILITY OF GROUND WATER SUPPLIES

A recent review by two experienced army officers, who have been specially engaged with problems of the quality of water supplies in the army camps, cantonments and posts in the United States, contains some interesting suggestions for future practice and procedure. The authors, Hyde and Haskins,<sup>1</sup> lay emphasis on the importance of making frequent examinations of ground water supplies. Considerable variability in bacterial quality has been observed in various places, and it is plain that unless a ground water supply can show consistently good quality throughout a considerable period of time, it should be regarded with suspicion and treated accordingly. They also conclude that except under extraordinary circumstances involy

1. Knibbs, G. H.: *Census of the Commonwealth of Australia, Appendix A, The Mathematical Theory of Population, of Its Character and Fluctuations, and of the Factors Which Influence Them*, Melbourne, Commonwealth Bureau of Census and Statistics, 1917.

1. Hyde, C. G., and Haskins, C. A.: *Notes on the Water Supplies of Army Camps, Cantonments, and Posts in the United States*, *J. Am. Water Works Assn.* 4:4: 60, 1919.

ing successful design and construction as well as vigilant and intelligent operation, the effluents of rapid sand filter plants, treating significantly polluted waters, cannot be considered to be uniformly safe and should receive further systematic treatment, as by adequate chlorination. It is noteworthy that the authors consider that all water supplies, from whatever source, should be regarded as potentially unsafe, and that they apparently believe chemical disinfection (chlorination) should be resorted to in many instances. A significant warning for civilian conditions is contained in the paragraph: "An extraordinary inefficiency and lack of intelligence is too frequently to be noted with respect to the operation of rapid sand filter plants, especially those of municipalities, and of these, naturally, the smaller communities in which the authorities do not recognize the value of expert services and the relative economy of the highest skill."

#### THE INFLUENZA PHOBIA

The influenza phobia has evidently not been limited entirely to this country; the following is from a recent issue of the *Medical Press and Circular*, London:

Mostly during the past two months the public have been deluged by would-be prophets predicting that the coming winter will herald another visitation of influenza. It is needless to say that these prognostications have been limited to the lay journals. The prophetic attempt would suggest that the idea is to angle for an honor of a "I told you so" type. Or it may be that the subject fills a gap when "copy" is short. The repeated reiteration of nursery rhyme precautions against chills, exposure to cold and changes in the weather must now be boring the public, should they happen not to be alarmed thereby. The inexpediency of all these warnings and suggestions of woes is that no one knows whether another influenza epidemic will or will not become an accomplished fact. Why, then, should prophets anticipate an evil which, as far as our knowledge goes, may not materialize? Why should the public be kept on tenter-hooks by continually reminding them of something which may never happen? We learnt last week from the *Times* that there had been under treatment some cases of influenza-pneumonia, and naively the remark was added that "So far, happily, there were not many in number." And so the ball is kept rolling to the injury of the public—of those, that is, who fail to recognize that the surest way to precipitate an evil is to become obsessed in the anticipation of it.

There is elemental truth in the last sentence. From the physician's point of view, the influenza phobia hangs to the danger that he may call any respiratory complaint seen in the course of his work "influenza." Many health authorities, reviewing the history of previous epidemics, would say that the three to four years following such epidemics were marked by recurrences of a milder character, yet there do not seem to be any reliable statistics to show that there had actually been such recurrences in epidemic form; there appears to have been more pneumonia in the years immediately following the epidemic. And that is all. To be forewarned is to be forearmed, and to be prepared is to be safe; but to be hysterical and to look for trouble is to invite catastrophe.

**Industrial Nursing.**—The trained nurse probably first entered industry in 1895, when the Vermont Marble Company engaged a nurse to visit the homes and care for the sick workers and their families.—Florence S. Wright.

## Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

### CALIFORNIA

**Personal.**—Dr. William R. Molony, Los Angeles, has been appointed a member of the State Board of Medical Examiners.

**New Home for Nurses.**—A new home for nurses at the Agnew Sanatorium, consisting of two large residences near the hospital annex with a bridge connection, was ready for occupancy, November 1.

**Restoration of License Refused.**—Dr. George H. Richardson of Los Angeles is reported to have been unsuccessful in securing the restoration of his license which was revoked several months ago for unprofessional conduct.

**Hospital for Women Abandoned.**—The Mission Valley Hospital for Women, San Diego, was abandoned following a recommendation to the city council of the state health officer. Under the new plans the city health board will have all cases of venereal disease treated at the general clinic.

**Rehearing Denied.**—It is reported that the California State Board of Medical Examiners denied Dr. Gideon M. Freeman of Los Angeles the privilege of a rehearing. Freeman's license was revoked following his conviction in Los Angeles on a charge of using the mails to defraud, when he was fined \$1,500.

**Stanford Clinic to Study Mental Diseases.**—A clinic for the study of retardation and degeneration among children will be opened for advanced students of psychology at Stanford University in cooperation with the Good Cheer Club at San Jose, under the direction of Dr. G. C. Bassett. Subjects for study will be found in the Juvenile Court of San Jose.

**Physicians' Licenses Revoked.**—According to newspaper reports, the California State Board of Medical Examiners recently revoked the license of John Lafayette Berry, known as "Bloodless" Berry of Los Angeles and Modesto, for using a name other than his own.—The license of Dr. R. May Mmacker, San Francisco, it is reported, was also revoked on the charge of performing a criminal operation which resulted in the death of the patient.

### FLORIDA

**Personal.**—Dr. Samuel D. W. Light, acting quarantine inspector for Key West, was severely injured, October 25, by falling through a hatchway on the U. S. S. *Sialia*. Dr. Joseph Y. Porter, Sr., Key West, has taken over the duties of quarantine inspector until Dr. Light recovers.

**Examination of Schoolchildren.**—The state board of health, November 1, completed the examination of 9,600 schoolchildren in Escambia County. It was developed by the examination that trachoma and hookworm are considerably more prevalent among white than among negro children.

**Ambulatory Venereal Disease Clinic.**—The Florida State Board of Health has established an ambulatory clinic for the treatment of venereal disease, which went into operation the first week in November, under the charge of Dr. Daniel C. Campbell, Marianna, who will accompany it to all of the rural districts and labor centers in the state. In addition to giving treatment, Dr. Campbell will conduct an educational campaign against venereal disease.

### ILLINOIS

**Schools Closed by Diphtheria.**—The Granite City public schools were ordered closed indefinitely, October 27, as the result of the discovery of twenty-one cases of diphtheria and scarlet fever among the pupils.

**Personal.**—Dr. Carl E. Black, Jacksonville, has returned from Greece, and has resumed his work with the Professional Committee for medicine, connected with the Department of Registration and Education, succeeding Dr. Jonathan L. Wiggins, East St. Louis.

**Illegal Practitioners Fined.**—It has been reported that the Illinois Department of Registration and Education arrested P. J. Krackowski of 2339 West Twenty-First Street, Chi-

ago, and W. A. McLeod, a mechanotherapist of Joliet, for practicing medicine without a license. They were both fined \$25 and costs, and Krackowski was placed on parole for one year.—Dr. Berry S. Henderson, Quincy, whose license was revoked a few months ago by the Illinois Department of Registration and Education for unprofessional conduct, was found to be practicing medicine in Decatur. On being arrested for practicing medicine without a license he plead guilty and was fined \$75. State's Attorney Deck of Macon County was very active in the prosecution. Henderson agreed that if Mr. Deck did not recommend the maximum fine, he would never again practice medicine in Illinois unless he secured another bona fide license.—Andrew Henry, a chiropractor at Peoria, was also arrested by the Illinois Department of Registration and Education for practicing without a license and was fined \$25 and costs. Henry told the court he was going to leave Illinois.—A. Scott of Peoria, who styles himself "Dr." A. Scott, paid a fine of \$100 and costs for practicing medicine without a license. Scott asserted that since he is an Indian, he did not need a license to practice in Illinois. This is the second time Scott has paid a fine within the last year. He has now taken down his sign and says he will quit business.—Albert G. Dellenbaugh of 855 Oakwood Boulevard, Chicago, plead guilty to an information filed against him in the Municipal Court in Chicago by the Department of Registration and Education of Illinois and was fined \$25 and costs for violating the medical practice act. The records of the department at Springfield show that, in 1918, Dellenbaugh was arrested for writing a number of prescriptions as a physician which were filed at a drug store. The records also show that Dellenbaugh was arrested in San Antonio, Texas, in 1913, for violating the Texas Medical Practice Act and that he was fined \$50 and costs and was confined one day in jail. Furthermore, they show that Dellenbaugh was arrested for forgery in Boston, in 1909, for signing the name of a Dr. Gill to a death certificate.

**Chicago**

**Midwife Held for Abortion.**—Mrs. M. P. Urbanas, a midwife, is said to have been arrested recently and put in jail charged with performing an illegal operation.

**Professor McCollum to Address Institute of Medicine.**—At the meeting of the Institute of Medicine of Chicago, Nov. 25, 1919, at 8 o'clock, in the City Club, Prof. E. V. McCollum, Baltimore, will speak on "The Fundamental Principles Underlying Modern Nutrition Investigations." All interested are invited.

**Personal.**—Dr. Clarence W. Leigh was reappointed city physician by the mayor, November 10.—Dr. William Ardlur Clark, formerly a member of the staff of St. Luke's Hospital, has been discharged from the army and has left Chicago to work in the department of orthopedic surgery at the Mayo Clinic, Rochester, Minn.

**Physicians Named in Drug Trial.**—Drs. A. F. Zwih, Joseph E. King, Frank A. Butler, Harlon H. Gordan, Charles W. Wren and Wesley E. Burnett are said to have been arrested, charged with prescribing habit-forming drugs to drug addicts. One of these defendants is said to have issued 3,000 prescriptions for morphin and its derivatives.

**Wesley Hospital Adopts Insignia for Staff.**—The Wesley Memorial Hospital has adopted a key to be worn by members of the resident staff who have completed a satisfactory term of service. Former Wesley interns who completed one year of service with honorable record may secure keys on application to the superintendent or to Dr. D. W. Propst.

**Traveling Clinic.**—The Chicago Tuberculosis Institution has already one traveling clinic and hopes, through the sale of Red Cross Christmas Seals, to secure sufficient funds to purchase a second automobile. The car is a completely equipped clinic which travels a regular route through the county towns. It is to be accompanied by a physician and a nurse.

**INDIANA**

**Osteopath Sues Hospital.**—Kent S. Seaman, an osteopath of Fort Wayne, has filed suit for \$50,000 against the staff of St. Joseph's Hospital, Fort Wayne, alleging that his business has been greatly damaged because osteopaths and chiropractors have been barred from St. Joseph's and other local hospitals.

**Hospital Items.**—A maternity hospital, with a department for the feeding and care of infants, will be established at the Florence Crittenton Home, Indianapolis. There is no home of this sort nearer than Chicago or Detroit and the need is urgent. The hospital will have 150 beds and the

work of caring for babies will be in the hands of the trained nurses and nurses' aides. Most of the \$100,000 necessary has been pledged and a drive will soon be started for the remainder.

**Personal.**—Dr. Venice D. Keiser, Indianapolis, has been appointed pathologist to the Peoples Hospital, Akron, Ohio.—Dr. Howard W. Burkley, Loganport, assistant medical examiner for the Pennsylvania System at Loganport, has been appointed medical examiner for the system at Alliance, Ohio, and has been succeeded by Dr. Harry M. Shultz.—Dr. Fleetwood H. Sale, Dillsboro, after practicing medicine in the community for more than thirty years, has retired.—Dr. Samuel E. Smith, superintendent of East Haven Hospital, Richmond, has been elected vice president of the board of trustees of the Indiana University.

**The Teaching of Health and Hygiene in Public Schools.**—The state board of education has recommended "That health and hygiene be taught in Indiana public schools, whenever and wherever, in the judgment of the school officers, the advancement of the pupils require it and when conditions generally justify." These subjects are to be taught by a regularly licensed teacher, and no person shall be eligible to take the examination or to be licensed in the state, who is not a high school graduate and a registered nurse in the state of Indiana. The license when issued will entitle the holder to supervise and teach hygiene and health in both elementary and high schools in the state.

**KENTUCKY**

**Personal.**—Dr. Frederic G. Larue, superintendent of the Western State Hospital, Hopkinsville, is reported to be seriously ill with kidney disease in the Riverside Hospital, Paducah.

**New State Officers.**—The annual meeting of the Kentucky State Medical Association, convened in Ashland, September 22, under the presidency of Dr. James S. Lock, Barbourville, and Dr. John G. South, Frankfort, was installed as president. The following officers were elected: president-elect, Dr. William W. Anderson, Newport; vice presidents, Drs. Porter C. Layne, Ashland, Irvin Lindenberger, Louisville, and Daniel J. Travis, Eddyville.

**Old Member Honored.**—At the meeting of the Franklin County Medical Society, held in Frankfort, November 4, Dr. Urbane V. Williams, Frankfort, who recently celebrated his eighty-sixth birthday anniversary, was the guest of honor. Dr. Williams entertained the society with reminiscences and paid a tribute to his boyhood friend, the late Dr. William Bailey, Louisville.

**MARYLAND**

**Conference of Mental Hygiene Society of Maryland.**—The annual conference of the Mental Hygiene Society of Maryland was held, November 19 and 20, in Osler Hall, Baltimore. The general subject under discussion was "Modern Psychology Applied in the Classroom." Dr. Agnes Rogers, head of the department of education, Goucher College, spoke on the evening of the 19th on "The Message of Educational Psychology to Parents and Teachers"; the address was followed by a general discussion opened by Dr. Adolf Meyer, Baltimore, head of the department of psychiatry, Johns Hopkins Hospital. On the second day, Dr. William Kilpatrick, professor of education, Teachers' College, Columbia University, delivered an address on "Learning Through Purposeful Activity."

**New Hospital for Montgomery County.**—The new Montgomery County General Hospital, located near Olney, is nearing completion and will be formally opened on Thanksgiving Day. It will be ready to receive patients by December 15. The building, equipment and grounds, comprising about 12 acres, will cost about \$50,000, and nothing has been spared to make the institution one of the most complete and up-to-date hospitals to be found in the country. There will be accommodations for thirty-five patients. A nurses' home with accommodations for seven persons adjoins the hospital. The enterprise is the outgrowth and development of a small establishment known as the Wrenwood Hospital, between Ashton and Brighton, which was started Jan. 1, 1916, in a private dwelling.

**MASSACHUSETTS**

**Conservation of Vision.**—At the recent session of the state legislature, \$10,000 a year was appropriated for the use at the Massachusetts Commission for the Blind for the purpose of procuring adequate equipment for classes on conservation of vision, already in existence, and establishing new

classes for children on the waiting list. The commission plans to open classes in Revere, Somerville, Waltham, Water-town, Chelsea and Newton. Miss Marjorie Campbell has been named to take up industrial art work in Massachusetts in the near future.

**Boylston Medical Prize.**—The Boylston Medical Committee appointed by the president and fellows of Harvard College and consisting of Dr. William F. Whitney, chairman, Dr. Harold C. Ernst, Harvard Medical School, Boston, secretary, and Drs. William F. Porter, Edward H. Nichols, Reid Hunt, Henry A. Christian, and John Warren, announces that at the annual meeting, held in Boston, in 1919, a prize of \$500 was awarded for an essay entitled "Studies of the Streptococcus of Smith," by Dr. Wilson G. Shullie, Cambridge, Mass. For 1919 there is offered a prize of \$300 together with the Boylston Prize Medal for the best dissertation on the results of original research in medicine, the subject to be chosen by the writer. The medal will be added to the money prize only in case the winning essay shows special originality in the investigations detailed. Essays entered for this prize must be in the hands of the secretary on or before December 31. Each paper must be printed or typewritten, bound in book form, and must bear, in place of the author's name, some sentence or device, and must be accompanied by a sealed packet, bearing the same sentence or device and containing within the author's name and residence. Preference will be given to theses which exhibit original work, but if no dissertation is considered worthy of the prize, the award may be withheld.

### NEW YORK

**Otisville Hospital Closes.**—United States General Hospital No. 8, Otisville, ceased functioning as a hospital, November 15.

**Personal.**—Dr. John A. Herring, a member of the staff of the Metropolitan Life Insurance Sanatorium, Mt. McGregor, for two years, has accepted a position on the medical staff of the students' health board of Cornell University, Ithaca.

—Dr. Gedney Jenks, Hastings-Upon-Hudson, has just opened a hospital.

### New York City

**New York University Admits Women to Medical School.** For the first time in its history the New York University Medical College has enrolled twenty women on its roster of students. These women will have equal privileges with the men, attending the same classes, and working in the same laboratories and clinics.

**Personal.**—Dr. Otto V. Huffman, Brooklyn, has been appointed a member of the consulting staff of the North Westchester Hospital, Mt. Kisco. —Mr. James Arnold Taylor has been appointed chief pathologist for Long Island Hospital. —Dr. Frederick Tinley, Brooklyn, has been appointed consulting neurologist to the Mountsinai Hospital, Manhattan.

**Health Consolidation as Educational Aid.** The New York Association for Medical Education has evolved plans for consolidating the interests of hospitals, including those controlled by the city with a view to making their facilities available in accordance with the purpose of the organization to extend the opportunities for medical education in New York City. The first plan includes a proposal to raise \$12,000,000 to \$15,000,000.

**Large Fund for Mount Sinai Hospital.**—The Guggenheim Center, Dr. L. Morris, F. C. Simon and Solomon, have received \$25,000 more to Mount Sinai Hospital. This makes a total of \$500,000 which they have contributed to a new fund which is to be a memorial to the parents of the donor. The plan for the new building, which will cover the entire block on Fifth Avenue between Ninety-Ninth and One Hundred Streets, has been drawn, and work will begin early next spring. Work on the old new structure will represent an outlay of \$1,000,000. It will provide accommodations for 100 patients in private rooms.

**Health Department to Demonstrate Schick Test.**—The Health Bureau of the New York Department of Health announces that the Bureau of preventable diseases will conduct a demonstration of the technic of the Schick test, and its interpretation, for the benefit of all private physicians who may desire to become acquainted with the application of this test. Medical officers attached to each of the clinics of the Bureau have been specially instructed in the method of performing the test and interpreting the reaction, and are

prepared to give the benefit of their knowledge to any physician who will visit the clinics between 2 and 4 p. m.

### PENNSYLVANIA

**Personal.**—Dr. Raleigh R. Huggins, Pittsburgh, has been appointed professor of gynecology in the School of Medicine of the University of Pittsburgh, succeeding Dr. Xavier O. Werder, resigned.—Dr. Walter W. Seibert, Easton, has been appointed a trustee of the Rittersville State Hospital.

**Tri-Borough Dispensary for Tuberculosis.**—A tuberculosis dispensary under the supervision of the state health department will be established in the Citizen's General Hospital, North Kensington, as soon as that institution is ready to receive patients. It is expected that forty or fifty patients will be sent to the dispensary immediately after the opening, and that cases will be transferred from the Allegheny Valley General Hospital, Tarentum, where a dispensary is already in operation. Applications for admission to the state sanatoriums will be made through the dispensary.

### Philadelphia

**Red Cross Base Hospital.**—A base hospital costing approximately \$50,000 will be established in this city by the South-eastern Pennsylvania Chapter of the American Red Cross. The hospital will be paid for by memberships obtained in the annual Red Cross Roll Call, which ended on Armistice Day, November 11. The new building will be complete in every detail, and will be so conducted as to be available for use in the event of a great catastrophe or any other emergency. According to Howard Wayne Smith, executive secretary of the Southeastern Chapter, the proposed institution already has been accepted by the city.

**Personal.**—Dr. Samuel T. Orton has been appointed superintendent of the new psychologic hospital connected with the State University of Iowa, Iowa City, which has recently been erected at a cost of \$175,000.—Dr. Alonzo E. Taylor, Rush Professor of physiological chemistry in the University of Pennsylvania, will deliver the annual Gross lecture of the Pathological Society of Philadelphia, November 20, instead of November 13, in Thompson Hall, College of Physicians Building.—Dr. Allen Jackson, chief resident physician at the Philadelphia Hospital for the Insane, was elected superintendent of the Danville State Hospital for the Insane. He will enter on his duties, January 15, and will succeed Dr. Hugh B. Meredith who has been superintendent of the hospital for twenty-eight years.

### RHODE ISLAND

**Endorse Hospital Project.**—Following a general discussion of the subject "Should the Pawtucket Valley Have a Hospital," Kent County Medical Society at a regular meeting, formally endorsed and adopted a resolution approving the project.

**Welcome to Service Men.**—The medical profession of this state united in tendering a complimentary dinner on Armistice Day to the members of the profession who were in the medical service of the army and navy during the great war. About 250 persons were present and it was said to be the largest meeting of medical men ever held in this state. Of the 108 men in the service, 109 were present. There were also three of the four surviving physicians who served in the civil war. The dinner was enlivened by the singing of songs and at its close the men were given an enthusiastic welcome by a few medical and lay speakers. After this there was a varied entertainment including songs, a moving picture show and a boxing match. —Dr. John M. Peters, Providence, president of the Rhode Island Medical Society, presided.—Kent County Medical Society held a banquet and reception at the Hotel Uppike, October 22, in honor of Fenwick G. Taggart, Major, M. C., U. S. Army, East Greenwich, who recently returned from overseas.

### TEXAS

**New Society Organized.**—The Ranger Medical Society was organized at Ranger, November 4. Dr. Cabel O. Terrell, Ranger, was elected president; Dr. Austin K. Weir, Staff, vice president; Dr. Carl S. Wilson, Ranger, secretary, and Dr. Brutus C. Kutherford, Ranger, treasurer.

**Prevention of Blindness.**—Under the auspices of the state board of health, the field secretary of the National Committee for the Prevention of Blindness gave a series of illustrated lectures in the schools and colleges and before general audiences in thirty of the leading cities of the state, during October.

WISCONSIN

**Another Case of Leprosy Discovered.**—The second case of leprosy to be reported in Wisconsin was reported by Dr. Cornelius A. Harper, Madison, state health commissioner, October 16, who inquired about hospital care in Milwaukee for the second victim, Andrew Anderson, a farmer living with his wife near Cambridge. This case is said to be of the contagious type.

**Personal.**—Dr. Corwin A. Freeman, South Milwaukee, was operated on for the removal of gallstones, at Trinity Hospital, Milwaukee, and is reported to be doing well.—Dr. Alfred W. Wilmarth, Chippewa Falls, superintendent of the State Home for Feeble-minded for twenty-two years, has resigned.—Dr. John E. English, Baraboo, is reported to be critically ill.—Dr. Harry Cohn, Wauwatosa, who resigned as associate medical director of the Mairdale Sanitarium to become director of the new Milwaukee County Dispensary, was given a farewell party and presented with a loving cup by Mairdale patients and employees, October 1.

CANADA

**Degrees Conferred.**—At a recent convocation celebrating the founding of Dalhousie University, Halifax, N. S., two medical men of that city were presented for the degree of Doctor of Laws: Drs. John Stewart and Murdoch Chisholm.

**Smallpox Outbreak.**—Toronto is experiencing a considerable outbreak of smallpox. There are at present more than 300 cases reported and about 1,000 contacts quarantined. The disease is of a mild form. There are several other centers in the province of Ontario, notably Woodstock and Stratford. Unvaccinated and those with unsatisfactory vaccination scars are being rapidly vaccinated.—The province of Quebec is also experiencing some alarm over smallpox, there being about 300 cases in that province.

**Code of Ethics for Ontario.**—Following on the suggestions of Dr. Edmund E. King, Toronto, president of the Academy, a code of ethics is being framed for the profession in Toronto. Copies of the pamphlets of Ethics of the American Medical Association were handed around, and certain suggestions for alteration to meet local conditions were suggested and are likely to be adopted.—The Workmen's Compensation Act, the New Ontario Medical Act, and the Ontario Temperance Act will likely be discussed at future meetings.

**Hospital News.**—St. Luke's Hospital, Ottawa, will share in an exceedingly generous bequest from a late citizen of Ottawa. The amount will reach about \$500,000; and the Lady Grey Hospital, Ottawa, receives a legacy, from the same estate, of \$2,000.—The orthopedic and surgical appliances branch of the department of Soldiers' Civil Re-Establishment have depots scattered throughout Canada where disabled men can receive immediate treatment and attention Canada sent representatives to the recent conference in New York City to discuss the best means and methods of overcoming the handicap of war as represented in maimed and wounded soldiers.

**Health Conference.**—There was held recently in Hull, Que., the Public Health Service Convention. It was largely attended by medical men from the province of Quebec and some from adjoining vicinities in Ontario. Dr. John V. Amyot, Toronto, deputy minister of public health for Canada, was present, and spoke of the functions of the new federal department of health. Dr. J. G. Urgel Archambault, Hull, Que., was elected president, and Dr. Joseph G. de Varennes, Quebec, secretary. There are 1,200 municipalities in the province of Quebec that should have a board of health, and the medical officer of health of each board should be required to attend every annual convention of the health services.

GENERAL

**Tri-State Physicians Meet.**—At the annual meeting of the Northern Tri-State Medical Association, held in Kalamazoo, Mich., November 5, Dr. Charles C. Terry, South Bend, Ind., was elected president; Dr. Louis A. Miller, Toledo, Ohio, vice president; Dr. George W. Spohn, Elkhart, Ind., secretary, and Dr. Joseph A. Weitz, Montpelier, Ohio, treasurer.

**Request for Trephined Stammerer.**—An investigator on stammering desires, if possible, to secure a stammerer whose skull has been trephined in order that direct observation may be made as to whether cerebral congestion accompanies stammering. If such a subject comes to the attention of a physician, THE JOURNAL will be glad to communicate the name and address of the inquirer.

**Ohio Valley Physicians Meet.**—At the twentieth annual meeting of the Ohio Valley Medical Association, held in Evansville, November 11 and 12, Evansville was selected as the place of meeting for next year, and the following officers were elected: president, Dr. Virgil H. Moon, Indianapolis; vice presidents, Drs. Charles T. Soutler, Cincinnati, Louis Wine Bremerman, Chicago, and Sidney J. Eichel, Evansville, Ind., and secretary-treasurer, Dr. Benjamin L. W. Floyd, Evansville, who has held that position since the organization of the society.

**Legislation to Promote Physical Training of Women.**—The physical development of women is the chief aim of a bill introduced by Senator George W. Chamberlain of Oregon. The measure authorizes the War Department to grant the use of land and camp equipment to the United States Training Corps for Women and details officers at certain camps for their instruction in military training. The camp sites and equipment would be loaned by the government free of charge, under such terms as would protect the best interests of the government. It is understood that the measure has the approval of the United States Public Health Service.

**Prevention of Blindness.**—The annual meeting of the National Committee for the Prevention of Blindness, Inc., will be held November 25 at 4:30 p. m., in the south hall of the Russell Sage Building, 130 East Twenty-Second Street, New York City. Hon. William Fellows Morgan will preside and the annual address will be given by Dr. Thomas D. Wood, New York City, chairman of the Joint Committee on Health Problems in Education of the National Council of the National Education Association and of the American Medical Association. Mrs. Winifred Hathaway, secretary of the National Committee for the Prevention of Blindness, will present the subject of "Conservation of Vision Classes in Public and Private Schools," giving lantern slide demonstrations.

**Legislation for Rural Health Work.**—A bill providing for the cooperation of the federal government with the state governments in the promotion of "rural health work" has been introduced in the House of Representatives by Congressman Mann of South Carolina. The measure would provide "methods and means for the prevention, control, and mitigation of the diseases of the people of rural districts of the United States, including towns in such districts having a population of not more than 5,000, as shown by the latest available census." The work would be carried on by the division of public hygiene, which would be established in the United States Public Health Service, and which would cooperate with the department of agriculture. Appropriations on a sliding scale for the work are provided for until June 30, 1921, after which the sum of \$1,000,000 a year would be made available, annually. Other similar measures are pending, the chief differences being that the other measures place the work under the department of labor. The measure is H. R. 19510 and has been referred to the house committee on agriculture.

**Vocational Rehabilitation.**—In the Smith-Parkhead bill which has just passed both houses of Congress, vocational rehabilitation, similar to that now in operation for disabled soldiers and sailors, is provided for "persons disabled in industry or otherwise." The bill provides \$1,000,000 yearly to enlarge the original Smith-Lodge act which created the federal board for vocational education and its recent extension to cover war cripples, so as to assist the maimed victims of industrial accidents also to the opportunity for vocational retraining into skilled occupations suitable to their physical powers, and restoration to useful employment. It is stated that there are at present more than 10,000 permanently incapacitated workers in the United States and the army of casualties is being increased at a rate of 11,500 every year. Under the bill the individual states must provide at least \$1 on behalf of their own crippled workers for every dollar expended by the federal government. Several states have already taken favorable action in anticipation of the congressional cooperation now assured in the bill.

**Bequests and Donations.**—The following bequests and donations have recently been announced:

- St. Luke's and Sacred Heart Hospital, St. Louis, Wash., each \$10,000, by the will of W. Parker Sargent.
- St. Mark's Hospital, New York City, \$5,000, by the will of Henry D. G. Lutz, of Madison, Ind., and Home for Aged and Infirm Hebrews, \$5,000, by the will of Isaac J. Wolf.
- New York State and Connecticut, \$20,000, General Memorial Hospital, New York City, \$5,000, by the will of Mrs. Margaret F. Zimmerman.

Chicago and Brazilian Missions of the Presbyterian Church, each \$2,000; Hospital for Orphanettes of Maryland, \$5,000, by the will of Robert L. Wilson, Baltimore.

Medical Society of the District of Columbia, the remainder of the estate after a bequest of \$800 has been paid, to be used for the construction of the new building of the society, "it being understood, that a proper memorial to be is placed in same," by the will of Henry Morris Hubbard, Washington, D. C.

St. Luke's Hospital, Philadelphia, a donation of \$40,000 from Charles M. Schwab, to be used to pay the newly built Liberty ward. A gift of \$5,000 to the memorial fund in memory of James Z. Haydon, one of the charter members of the board of trustees.

Dr. William G. Doran, New York City, a bequest of \$25,000, by the will of Mrs. Margaret A. Howard.

#### Sale of Surplus Dental Outfits by the War Department.

The House of Representatives, Wednesday, November 5, adopted Joint Resolution 222, directing the Secretary of War to dispose of surplus dental outfits in the hands of the Medical Department of the Army, providing that not more than one outfit shall be sold at private sale to any one person and that they shall be sold preferentially to honorably discharged dental officers. The discussion showed that at the beginning of the war with Germany, there were eighty-six commissioned dental officers in the Dental Corps. At the time of the signing of the armistice, one year ago, there were 5,000 commissioned dental officers, 3,000 on duty in the United States and 2,000 abroad. Four thousand dental officers have been discharged from the service in the last year. The government now owns about 6,000 dental outfits, only 1,400 of which are required or in active use at present, the remaining 5,000 outfits being in storage. An army of 550,000 men, such as is proposed by pending bills, would require 700 dental officers and would not need more than 1,000 dental outfits. There is a scarcity of dental instruments and supplies and many of the discharged dental officers are unable to secure satisfactory outfits for civil practice. During the discussion, Dr. C. R. Layton, congressman at large from Delaware, said, ". . . I shall introduce another resolution relating to the disposition of vast quantities of medical and surgical supplies, including all sorts of surgical instruments and appliances now held by the government far beyond its needs. There are millions upon millions of cotton gauze bandages, for instance, held in storage by the government which now retail for from 15 to 30 cents, the prewar price of which was 5 cents. They should be disposed of for the benefit of the whole people. I find that the chairman of the committee on military affairs has a bill dealing with supplies, and when that bill comes before the House I wish to oppose it. In addition to dental outfits, there is a vast amount of supplies of all kinds that are required in hospital and civilian practice that are needed in this country for the benefit of our people. I am opposed to a bill which, I understand, will be presented whereby all this vast material will be handed over to the Red Cross solely for use in foreign countries. . . . The medical profession in the United States today needs these supplies here in America. . . . To take those supplies out of the country instead of giving them to hospitals and other institutions and then to those engaged in private practice in my judgment is neglecting our first duty." In reply to a question from Mr. Kitchin, as to why medical and surgical supplies were not included in the resolution, Mr. Kahn of California, the chairman of the committee on military affairs, said, "I understand that there has been no request made by the dentists for the sale of surgical supplies. The War Department has sent to the committee on military affairs a bill providing that surplus medical supplies be turned over to the Red Cross." Mr. MacGregor of New York asked for an amendment referring \$10,000,000 worth of medical supplies to the Red Cross given to the Red Cross by the War Department. Mr. Kahn replied that this concerned supplies in storage and that they had been turned over to the Red Cross by the War Department since the armistice. Mr. Kitchin offered an amendment to the resolution to include the sale of dental instruments to physicians, but the amendment was ruled out of order and the resolution was adopted.

#### FOREIGN

**Mme. Curie Returns to Warsaw.**—Some of our European exchange state that Mme. Curie has returned to her natal city, Warsaw, to assume the chair of radiology in the university there.

**Chair of Radiology.**—Prof. M. Bonzo, secretary of the Italian Radiologic Society, has been appealing through the columns of the *Informa Medica* to the authorities to found chairs of radiology in the universities.

**Deaths in the Profession Abroad.**—Dr. O. J. Engström, professor of gynecology at the University of Helsingfors, aged 66.—Dr. C. H. Hildebrand, professor of children's diseases at the University of Lund, aged 68.—Dr. R. Wurtz, agrégé professor at the University of Paris.

**Italian Colonial Institute for Hygiene and Biology.**—An institute with this name has just been organized at Naples by the initiative of Profs. I. Bandi and Franceschini, in connection with the Oriental Institute. There is a fine museum, and five traveling scholarships have been founded in cooperation with the Pasteur Institutes in Tunis and Algeria.

**Interallied Conference on the War Disabled.**—The third conference of this kind has just been held at Rome. The preceding ones were at Paris and London; the permanent seat of the commission is at Paris. Prof. Riccardo Galeazzi was in charge of the arrangements, and an instructive exposition of prostheses, of training methods and of men at work formed an annex to the conference. This exhibition is to be kept open for two months. The next conference is to be held at Brussels, and the *Polichinco* states that Professor Galeazzi was elected president of the permanent committee, which aims to study ways and means for "uncripping the war cripples," and to disseminate promptly any improvements realized anywhere.

**Italian Surgical Congress.**—The Twenty-Sixth Congress of the Società Italiana di Chirurgia convened in October at Trieste, with Professor Nicolich of Trieste in the chair, as Senator and Professor Durante, the president, was unable to be present on account of sickness. One of the vice presidents, Professor Grossich, of tincture of iodine fame, was also unable to attend, as he is president of the Consiglio nazionale di Fiume, and was detained at home. The society has held no meetings during the war, and this reunion was notable for many reasons, historical as well as scientific. The subjects appointed for discussion were war wounds of the peripheral nervous system, to be introduced by Professor Verga, and motor plastic amputations and prostheses, to be introduced by Professors Galeazzi and Putti.

**Italian Congress of Internists.**—The Twenty-Fifth Italian Congress of Internal Medicine followed the surgical congress at Trieste in the first week of October, with Senator and Professor Maragliano in the chair, and a large gathering of the leading internists of the country. In both these meetings the authorities, local and national, paid exalted tribute to the indefatigable devotion of the surgeons and internists during the years of warfare. The work of the Italian Red Cross was extolled in particular, and also the work of the women physicians during the war. A steamer in the bay was fitted up to offer hospitality to the visiting physicians. This use of a steamer for the congress members was also a feature of the recent meeting at Bilbao, Spain, of the Spanish Association for the Advancement of Science.

**Serologic Institutes in the Netherlands.**—The state has taken over Professor Spronek's bacteriotherapeutic institute at Utrecht in order to insure the continuance of this institution which has done such good service for twenty-five years. It will henceforth be known as the National Serologic Institute, and will continue its work in the preparation of vaccines and antisera and the teaching of serology. Professor Spronek has been appointed director, and he has petitioned to be relieved from his courses on general pathology and pathologic anatomy in order to devote all his energies to teaching serology. Another professor is to be appointed to the chair of pathology. The Utrecht institute is in charge of the labor department of the government, while the similar institute at Rotterdam belongs to the department of agriculture and commerce, and is designed for veterinary purposes only.

**New Fellows of the Royal College of Surgeons.**—The following have accepted the honorary fellowship of the Royal College of Surgeons of Edinburgh, awarded in connection with the termination of the war, 1914-1919:

British Empire.—Sir William Norman, K.C.B., R.N., late Director-General, Naval Medical Department, Sir Robert Hill, K.C.M.G., C.B., C.A.O., Director-General, Naval Medical Department, Lieut. Gen. Sir T. H. John Gouldwin, K.C.B., C.M.G., D.S.O., K.H.S., Director-General, Army Medical Department; The Hon. Major-Gen. William Rice Edwards, C.B., C.M.G., K.H.P., M.D., Director-General, Indian Medical Service; Major-Gen. G. L. Foster, C.B., Director-General, Medical Services, Overseas Military Forces of Canada; Major-Gen. Sir N. R. Howse, V.C., K.C.B., Director, Australian Army Medical Service; Col. W. H. Parkes, C.M.G., C.B.E., Director, New Zealand Medical Corps; Col. P. G. Stok, C.B., Director, South African Medical Corps.

Ally.—Rear-Admiral William C. Braisted, U. S. N., Administrative Head of the Medical Service of the United States Navy; Surg.-Gen. Merritt W. Ireland, United States Army Medical Corps. Medicine

Inspector-General Sieur, Member of the French Academy of Medicine and Professor of the Val-de-Grace Military Hospital, Lieut.-Gen. Leopold Melis, K.C.B., Inspector-General du Service de Sante de l'Armee Belge, attache a la Maison du Roi, Maggiore Generale Commentatore Lorenzo Buonomo, Attache to the Ispettorato di Sanita Militare, Rome, Surgeon-Director-General Professor Tadao Honda, Director-General Naval Medical Service (Japan).

**Pediatricists' Congress of the Northland.**—The First Nordiske Congress for Pediatricics was held at Copenhagen in August, with Prof. C. E. Bloch of Copenhagen in the chair. In his opening address he said that the desire to hold an independent meeting of pediatricists was not because they wished to pull apart from internal medicine, but pediatricics now is more than a mere subsection of internal medicine, the study of the growing organism under normal and pathologic conditions is such a vast field in itself. The first subject on the order of the day, the etiology and classification of acute digestive disturbances in artificially fed children, elicited a lively discussion with opposing views, some advocating the French classification and others the Finkelstein. The importance of infection as the factor versus the food elicited much discussion, as also the treatment of acute digestive disturbances, and of infantile tetany. A number of experiences were related showing the effects of war deprivations on children and how they were combated. The Nordisk Pediatric Association was then formally founded, with three representatives on the board from each of the Scandinavian countries, Pipping, Lovgren and Sourander representing Finland; Johannesen, Loof and Collet, Norway; Junell, Wernstedt and Lichtenstein, Sweden, and Bloch, Monrad, A. Meyer and C. Friederichsen, Denmark. The next congress is to be held at Stockholm in 1921. The meeting was attended by 25 pediatricists from Sweden, 16 from Norway 7 from Finland and 34 from Denmark.

#### LATIN AMERICA

**Dr. Vaz Appointed to Chair.**—Dr. Juvenal da Rocha Vaz has been appointed professor (*substituto*) of clinical medicine at the University of Rio de Janeiro.

**Physician Appointed Head of the National Education Board in Cuba.**—Dr. Gonzalo Aróstegui has been appointed by the president of the republic of Cuba secretario de instruccion pública y bellas artes, succeeding Dr. Dominguez Roldán.

**Organization of Puebla Academy of Medicine.**—On the initiative of Dr. A. Cabrera, who is governor of the state of Puebla, Mexico, thirty-three physicians of Puebla recently organized the Academia de Medicina de Puebla. They at once appointed a committee for collaborating in the research on typhus which has been inaugurated by the medical organizations of the City of Mexico. The officers elected include Dr. M. Vergara, president; Dr. F. Bello, vice president, and Drs. G. Vergara and P. Soto, secretaries.

**Yellow Fever on War Ship.**—Two cases of yellow fever on board the U. S. S. *Chicago*, both resulting in recovery, have been reported to the bureau of medicine and surgery of the navy department. The cases occurred during an outbreak of yellow fever at Amapala, Honduras, and the medical officer reports that in one of these cases the first treatment of anti-leptospira iteroid serum of Noguchi ever given to man was administered. The serum apparently had a very happy effect on the patient and seemed to turn a bad prognosis into a convalescence in his case.

**New Quarantine Station in Central America.**—The sanitary authorities of Honduras and El Salvador with a view of preventing the introduction of plague, cholera, yellow fever, etc., have recommended to the respective governments the establishment of an international quarantine station on one of the islands of the Gulf of Fonseca, to be administered jointly by both governments, with the government of Nicaragua joining if it so desires. Major-General William C. Gorgas has just completed a trip of inspection through El Salvador in connection with the recent occurrence of yellow fever in Nicaragua. He was accompanied in his trip by Dr. T. C. Lyster of the Rockefeller Foundation and Dr. W. Pareja of El Ecuador.

#### CORRECTION

**Ragweed Dermatitis.**—In the article of Dr. Richard L. Sutton, in THE JOURNAL, November 8, under Figure 2, the legend reads: "Giant ragweed replaces the common ragweed in most parts of the Eastern and Southern States." This should read in "moist parts."

## Government Services

### Personnel of the Medical Department

For the week ending November 14, there were in the Medical Corps 2318 officers on duty out of a total of 30,571 the maximum number on duty Nov. 15, 1918; the Medical Reserve Corps contained 3,879 officers, an increase of fifty-two from the previous week.

#### Personal

Frederick F. Russell, Col., M. C., U. S. Army, has been designated as official representative of the Medical Department of the Army in the government division of the National Research Council.

### Applicants Desired for Regular Army and Navy Medical Corps

With the discharge of numerous reserve officers from the military medical service, it is desired to again call attention to vacancies existing in both branches, Army and Navy. The Medical Department of the Army on November 15 contained 841 regular medical officers, and there were 710 vacancies. Since Nov. 11, 1918, 137 resignations have been tendered. The Medical Department of the Navy has at present 420 vacancies; 175 resignations from officers of permanent commission in this corps have been received since Nov. 11, 1918, and of those resigning 120 have already been discharged. The Navy is anxious to receive applications from younger medical men who desire to enter the medical service directly. For a number of years it has been the policy to recruit medical officers for the regular Navy Medical Corps from officers enrolled in the reserve force; but for a limited period it has been decided to offer opportunity to recent graduates to obtain a permanent commission directly from civil life. Graduates from reputable colleges between the ages of 21 and 32 years are eligible and, if interested, should address the Chief of the Bureau of Medicine and Surgery, Navy Department, Washington, D. C.

### Army Educational Service

Reports to the Surgeon-General on the activities of the educational services at fifteen Army general hospitals, and one base hospital for the month of September show that of 2,300 patients who received surgeon's certificates of disability, 2,209 were able to resume their old occupation, or were not in need of retraining, and only 130 were designated as unfit for their old occupation. November 7, there were 18,406 in sixteen Army hospitals in the United States.

### Bill to Reimburse Soldiers for Loss in Exchange

A measure of interest to all physicians and nurses who served with the American Expeditionary Forces who sustained losses by exchanging American money for the moneys of foreign countries has been introduced in the Senate by Senator William M. Calder of New York. The bill authorizes the War Department to pay to any officer, enlisted man, female nurse or civilian of the American Expeditionary Forces the sum equal to the amount of loss suffered by them, by reason of a fluctuation in the rate of exchange on any negotiable instrument received from an Army officer for pay, allowances or reimbursement. The measure is Senate Bill 3420 and has been referred to the Senate Committee on Military Affairs.

### Decorations for Foreign Officers

The Distinguished Service Medal has been awarded to Surg. Vice Admiral Sir Robert Hill, medical director general of the Royal Navy, and to Surg. Corp. E. Sutton, in charge of the Royal Navy Hospital, Haulbowline.

### Last Trip of Hospital Train

U. S. Army Hospital Train No. 4, operated by the Medical Department of the Army, left New York, November 4, on its last trip to Denver. The patients on the train were tuberculosis cases, invalids from the Zone, and have been

at Seaboard military hospitals, Otisville, N. Y. During the war more than 125,000 patients have been cared for by U. S. Army hospital trains, which have been under the charge of James S. Wilson, Col., M. C., U. S. Army, post surgeon at Holoken, N. J.

#### Decorations Awarded

The Distinguished Service Medal has been awarded to Charles N. Fiske, Capt., M. C., U. S. Navy, and to John J. Snyder, Com., M. C., U. S. Navy.

Dr. Franklin H. Martin, Chicago, formerly colonel, M. C., U. S. Army, had conferred on him the Order of Commander of Sts. Michael and George by the Prince of Wales, in Washington, D. C., November 14.

#### Citation for Bravery

Capt. Sydney S. Schochet, M. C., U. S. Army, Chicago, has received the following citation with award of the military cross from the British government: "For conspicuous gallantry and devotion to duty during operations east of Ypres, Belgium, September 28 to October 1. This officer during the action in which his unit was engaged displayed the utmost gallantry and devotion to duty. He continually went out into the heavy shell fire to attend and assist in removing the wounded, and repeatedly took risks which he would not allow his assistants to share in his anxiety to assure their proper care and removal. It was owing to his untiring energy and complete disregard for his own personal safety that under every adverse circumstance the wounded of his own and several other units were safely evacuated. This example which he gave of unbroken cheerfulness and courage throughout the whole of these operations was a valuable stimulus to all who came under his authority."

#### Citation for Colonel Seaman

The citation on page 12, G. O. 89, War Department, 1919, relating to Col. Gilbert E. Seaman, M. C., U. S. Army, Milwaukee, has been rescinded, and the following substituted:

Colonel Gilbert F. Seaman, M. C., U. S. Army, after serving with conspicuous success as division surgeon, 32nd Division, became chief surgeon 6th Army Corps and in this capacity was an important factor in the establishment of effective means for treating numerous sick and wounded.

#### Citation Changed

The citation in Par. 9, of G. O. 89, W. D., 1919, relating to Col. James A. McCoy, is rescinded and the following substituted therefor:

J. A. McCoy, Lieut.-Col., Medical Corps, U. S. Army. For exceptional merit in and distinguished services. He served with conspicuous success as commanding officer of American Red Cross Hospital No. 11, at Jussy-Morin, and Chateau Thierry, from June 1, 1918, to 1919. Although he was hampered with insufficient personnel and equipment, he nevertheless succeeded in caring for a large number of wounded men from the Marne thereby rendering invaluable service to the American Expeditionary Forces. Home address 299 Broadway, Paterson, N. J.

#### Woman Physician Decorated

In recognition of her work in the smallpox epidemic in Rumania, Dr. Margaret E. W. Farwell, Los Angeles, has been decorated with the Order of the Crown, 1st class, grade.

#### MEDICAL OFFICERS, U. S. NAVY, RELIEVED FROM ACTIVE DUTY

CHICAGO—M. G.	MILWAUKEE—M. J. SIPP

#### German Babies and Reparation

A memorial signed by leading public men, including Cardinal Bourne, the Archbishops of Canterbury and York, Sir William Osler and Sir Alfred Pearce Gould, has been presented to the reparation commission in Paris asking for consideration of the consequences of enforcing the provision in the peace treaty that Germany shall cede 140,000 milch cows and 10,000 goats. The memorial states that there is reliable evidence of terrible suffering among German children due to deficiency in the milk supply. The increase of tuberculosis has been immense, and in combating it, milk is a prime necessity. Any further reduction in the present deficient milk supply would have appalling consequences. Discussing this memorial, the *Times* says that throughout the war nothing has been so harrowing as the sufferings of the innocent, especially women and children. To end that suffering would fill the hearts of the Allied peoples with satisfaction. But German children are not the only children threatened with death and disease from shortage of milk. The children of the countries which the Germans looted and deliberately destroyed are suffering in the same way. Dr. Calmette has recently reported to the Académie de médecine that in Lille 8,000 out of 18,000 schoolchildren had to be sent to hospitals or convalescent colonies. On the ground of humanity, all babies have an equal claim; but justice must also be considered. The victims are equally innocent; but the sufferings of the French children are the direct consequence of the deliberately inhuman methods adopted by the Germans in an unjust war, while those of the German children are due to the misdeeds of their fathers. Justice requires that they shall make restitution.

#### Influenza

During the last few weeks there has been in the ninety-six great towns of England and Wales a slight but gradual increase in the number of deaths attributed to influenza and a coincident rise in the number of notifications of acute primary and acute influenzal pneumonia. The increase appears to have been associated with prevailing meteorological conditions, and does not apparently signify more than the usual variation in catarrhal and lung diseases generally which may be expected at this season of the year. While the possibility of a fresh outbreak of influenza cannot be excluded, the data available do not at present afford any indication of an immediate recrudescence of the disease in epidemic form.

#### The Red Cross in Peace

The work done by the British Red Cross in the great war is too well known to need commendation. It is now proposed to carry forward to the era of peace the benefits of that great organization. Its program is to promote the improvement of health, the prevention of disease, and the mitigation of suffering throughout the world whether in peace or war. Its work will be: (1) the care of the sick and wounded men of the army and navy whether still on the active list or demobilized; (2) such care as may still be necessary for prisoners of war; (3) the care of those suffering from tuberculosis, having regard in the first place to soldiers and sailors, whether they have contracted the disease on active service or not; (4) child welfare; (5) work parties to provide the necessary garments, etc., for hospitals and health institutions in need of them; (6) assistance in all branches of nursing, health and welfare work, auxiliary to the ministry of health; (7) Red Cross war and peace hospital library, and (8) home service ambulance work.

#### Preventive Medicine

One of the first acts of the newly established ministry of health was to call for a memorandum on preventive medicine from the chief medical officer, Sir George Newman. He begins a very able review of the subject with the statement that "the first duty of medicine is not to cure disease, but to prevent it," and goes on to define the objects of preventive medicine as: (1) to develop and fortify the physique of the individual and thus to increase the capacity and powers of resistance of the individual and the community; (2) to prevent or remove the cause and conditions of disease or of its propagation, and (3) to postpone the event of death and thus prolong the span of man's life. A great deal has already been accomplished; but though the death rate of England and Wales has fallen from 20.6 per thousand living in 1868 to 13.5 in 1917, and the infant mortality rates from 155 to 96 per thousand births, we still

lose in England every year upward of 235,000 lives by the deaths of persons under the age of 50, and upward of 64,000 infants and have many stillbirths. Moreover, the influenza epidemic cost 6,000,000 deaths in India and 100,000 in England and Wales.

At present we have an immense body of knowledge and experience old and new, "but there is lack of correlation of the knowledge, and there is lack of understanding of the precise problems to be solved, and of the ways and means by which they may be faced." In the first place, the new knowledge is insufficiently shared by the whole medical profession; in the second, the administration of the public health service, both central and local, is insufficiently coordinated and unified; and lastly, "There is all over the country inadequate treatment of the sick and incapacitated, in quantity and quality. The beginnings of disease are still almost entirely ignored. The treatment provided for the majority of the sick is insufficient and inadequate; it does not represent the best of present medical knowledge. Whole groups of disease are neglected, so far as prevention is concerned, for prevention has been too exclusively concerned with certain infectious diseases, and much disease is allowed to 'go by default,' untended and untreated. The provision of facilities for residential hospital treatment of patients requiring it (with the exception of the insane and the infectious) falls far short of what is necessary." Evidence of inadequacy is as follows: In 1918 there were probably 1,000,000 cases of measles in the country; tuberculosis claimed 92,000 fresh victims, and 6,500 newly born infants developed ophthalmia. Of the children at school in England a large number are backward, upward of 10 per cent are unclean, and 10 per cent are undernourished. Not less than half the school-children stand in need of dental treatment, and half a million at least are urgently in need of it. Upward of half a million are so defective in eyesight as to be unable to take reasonable advantage of their lessons. Another quarter of a million suffer from ear and throat diseases. At the examination for national service it was found that the number of recruits placed in the lowest categories of ill health or unfitness amounted approximately to not less than 1,000,000.

The present position is thus summarized: 1. There is a steadily falling birth rate, which in 1917 reached a figure (17.18) gravely affecting the source of the nation. 2. There is a death rate (13.5) which shows a steady decline at all ages (1841-1845 compared with 1911-1915), and there is an increased expectation of life from birth upward; nevertheless, nearly half the deaths occur under 50 years of age. 3. Although the infant mortality rate (96 per thousand) is one of the lowest recorded, there is still unnecessary loss of life in infancy and before birth. 4. There is a relatively light burden of epidemic and infectious disease, which, with certain exceptions, is steadily decreasing in incidence and mortality, an indication of the victory of preventive medicine over some infectious diseases. 5. Tuberculosis, measles, acute rheumatism and influenza are, however, still prevalent and, with venereal disease, lead to much disablement and mortality. 6. There has been in recent years remarkable and continuous improvement in sanitary environment, though the problem of insufficient and unsuitable house accommodation remains.

With regard to the lines of reform, medical education is dealt with. The basal sciences of medicine must be studied more deeply, and clinical training must be more thorough. Especially must the mind of the student be directed to the beginnings of disease, its earliest signs and symptoms, notably those symptoms which are subjective, "for no laboratory experiment or mechanical device can serve as a substitute for this knowledge to which they are ancillary and auxiliary." The practice of preventive medicine in all forms of clinical work must be insisted on, since prevention is concerned not only with the mass, but also with the individual. With regard to the physician, early specialism is condemned. The need for closer integration between preventive and curative medicine is emphasized. In all cases the cause of disease, not in the abstract alone, but in the particular patient, must be sought. Disease must also be considered in its ancestry, for example, tuberculosis following measles. An adequate medical service is necessary, and a systematic and coordinated attack on the problem of disease. A large number of separate departments must work together, and many aspects of the problem must be viewed at once. For example, there are the problems of heredity and of eugenics; there are alcohol, syphilis and tuberculosis. There is the care of motherhood; there is the welfare work for infants; there is the medical care of the schoolchild. Sanitation is related to all the above, and so is the vast problem

of industrial hygiene. Infectious diseases have to be fought, and noninfectious diseases must be prevented. Finally, research work must be carried on, and the people must be educated in hygiene.

The keystone of the new edifice must be the general practitioner. He is the foundation of any medical service, its "pivot, its anchor, its instrument." Means must be found to help him in carrying on his professional education, for the advance of medicine is continuous. He must also be given opportunities for carrying on his practice in an adequate manner. He must have laboratory facilities and consultant advice and assistance. Indeed, he must be helped to help himself.

## PARIS

Oct. 23, 1919.

### Meeting of Surgeons

The twenty-eighth Congrès français de chirurgie was held recently under the chairmanship of Dr. Wallther, surgeon of the Hôpitaux de Paris and agrégé professor at the Faculty of Medicine. In his opening address, the president reviewed the progress in surgery during the war. He also paid homage to the colleagues who had fallen on the field of honor.

Three subjects were discussed: internal traumatic lesions of the wrist; the treatment of cancer of the tongue by the surgical method, and paraneoplastic tumors.

#### INTERNAL TRAUMATIC LESIONS OF THE WRIST

Internal traumatic lesions of the wrist constitute a comparatively new chapter in pathology. As recently as twenty years ago this subject was unknown, and it is only owing to roentgenographic researches that it has been opened up. Dr. Jeanne, acting professor in the Ecole de médecine of Rouen, and Dr. A. Mouchet, surgeon of the Hôpitaux de Paris, emphasized particularly the part that roentgenography plays as an indispensable aid to clinical examination. In the unequivocal cases, roentgenography confirms and often completes the clinical examination. In the doubtful cases it reveals the lesion. This is especially true in the case of fractures of the semilunar bone, the os magnum, the ulnariform bone, etc., in which the signs are so vague. The roentgenographic examination is more to be relied on than the fluoroscopic, for fluoroscopy is entirely inadequate for the exploration of wrist lesions. At least two roentgenograms are always necessary: an anterior view and a lateral view. The two roentgenograms supplement each other. The examination of the plate is preferable to that of the print. The glass plate is, in fact, a more faithful reproduction than the print. The print, even though it has not been doctored, does not give as clear a picture as the plate, for the print varies with the time of exposure. An illuminating box is very useful in examining the plate. However, one must bear in mind that the interpretation of a roentgenogram of the wrist is not an easy matter and requires a long preliminary training. In very delicate cases it is advisable to roentgenograph also the sound wrist, for a comparison with the injured wrist will be very instructive. A comparison of this kind would be especially useful should there exist in a given subject marked variations from normal in the size and shape of the wrist bones.

Certain fractures of the carpal bones—compression fractures of the semilunar, and fractures of the os magnum and of the ulnariform bone—are often listed under such headings as "chronic rheumatoid arthritis," "tuberculous arthritis of the carpus," or "chronic synovitis of the wrist," since these bones present anatomic alterations that are rather distinct for an eye that is not trained to detect them. Furthermore, it is well to know that the e fractures are much more frequent than is commonly supposed. Another reason why they often remain long undiscovered is that they are frequently the result of very slight traumas that cause a little disturbance of function at least at the start. They are often regarded as sprains, so the patient resumes his work, and when later he is compelled to stop work and consult his physician, no account is taken of the former trauma, even if he remembers it, and the physician is liable to overlook the fracture of the carpus if he is not thoroughly familiar with the interpretation of roentgenograms of this region.

As regards treatment, Jeanne and Mouchet hold that the subacute luxation of the semilunar bone should be reduced promptly to avoid stiffness of the wrist and the nervous symptoms that are the inevitable consequence of leaving it to heal spontaneously. If a month has passed since the injury, the reduction should no longer be attempted. In such cases should proceed with the resection of the scaphoid, and in

case there exists a concomitant fracture of the scaphoid, the superior fragment of the scaphoid that is attached to the semilunar should be removed. An isolated fracture of the scaphoid justifies surgical intervention if vicious consolidation exists or if the lesion is painful; removal of the bone is indicated. This treatment is recommended also for fractures of the other carpal bones under the same circumstances.

In the course of the discussion to which the communication of Jeanne and Mouchet gave rise, Dr. Maurice Perraire, surgeon of the Rothschild Hospital in Paris, called attention to the excellent service that stereoröntgenography may render in the diagnosis and control of internal lesions of the wrist. He himself always had recourse to this method for the reason that it afforded a view of the antero-posterior relief and, by reversing the plates, of the postero-anterior relief.

#### MESSAGE IN FRACTURES

Dr. Petit de la Villeon of Bordeaux made the remark that while he served in the capacity of expert in industrial accidents he was struck with the bad results secured by the method that confines itself exclusively to massage. A large number of workmen treated in this fashion are afterward referred to the expert in industrial accidents. Dr. Petit de la Villeon was often impressed with the marked deformities resulting from the massage treatment which were frequently associated with notable functional weakness. He thinks that the method recommended by Lucas-Championnière has been much overdone. No doubt the fundamental idea of this method is perfectly correct, but it should be emphasized that the method is indicated only in fractures without displacement. On the other hand, if it is exaggerated to the extent that it is made a routine system, this method constitutes, as it were, a dangerous pitfall into which the general practitioner unobsciously glides whenever he is confronted with fractures presenting marked displacement; for such fractures, if treated by massage exclusively, heal with frankly bad results. Fracture of the radius with displacement, such as one encounters in adults, and, more particularly, in workmen who are the victims of industrial accidents, should be reduced at once, the reduction being done, if necessary, with the aid of general anesthesia. After the fracture is reduced, it should be immobilized by means of a light plaster splint that will keep it in the position of moderate palmar flexion and inclined toward the ulna. Only after immobilization for a period of from ten to fifteen days may the splint be properly removed and the treatment by means of massage and mobilization be begun. The results will be all the better for the fact that the reduction was well done in the beginning and the fracture kept immobilized in a suitable position. Dr. P. Barlaquin of Paris also expressed himself to the effect that the method of "immediate mobilization and massage without reduction" had been overdone in fractures of the radius. He recalled all fractures associated with displacement or penetration and immobilized them for from twelve to fifteen days in a plaster splint in the position of the classic flexion of the hand, with a deviation to the ulnar side.

Dr. J. Barard, professor of clinical surgery at the Faculty of Medicine of Lyons, declared himself an advocate of immobilization of all fractures of the radius, even though it should be for only four or five days and by means of a light splint. Contrary to the views of Jeanne and Mouchet, he took the question of irreducibility of the fracture as determined rather by the anatomic type of the fracture than by the age of the lesion. He also thinks that after several attempts at reduction under anesthesia the surgeon should resort to plaster only in order to reduce a fracture, especially in view of the fact that surgical intervention is easy and of good prognosis.

#### Medical Care for Military Pensioners

A decree has just been issued according to the terms of which the State will provide all soldiers and sailors who are pensioners under the civil and military laws, for the duration of their lives, with medical and surgical care (including pharmacy and medical material) necessitated by the wounds and diseases sustained or contracted in line of duty that constitute the cause for their discharge.

#### Personal

At one of its recent meetings, the Academy of Medicine chose three foreign correspondents in the fourth division (surgery, physics and chemistry) as applied to medicine and pharmacy. The correspondents chosen were M. Brusilovs, professor at the University of Louvain and president of the Academy of Medicine of Belgium; M. Paterno of Rome, and Dr. Machado de Lissabon.

## Marriages

ALBERT BOWEN, Capt., M. C., U. S. Army, Rochester, N. Y., to Dr. Amy A. Metcalf of Teichow, Shantung, China, at Lambeth, France, October 27.

HAMDEEN SINKEY LEWIS, Bay St. Louis, Miss., to Mrs. Corinne DeMontluzin Benedict of New Orleans, October 29.

HERBERT HERMAN SCUDENFELD, Washington, D. C., to Miss Martha Wills of Danville, Va., at New York, October 18.

FRED MERTEN ROTHOW, Ashland, Wis., to Miss Lucile Agnes West of Wheeling, W. Va., at Chicago, November 11.

JAMES WRIGHT CLARKSON, Hickory, N. C., to Miss Caroline Robinson Davis of Petersburg, Va., October 28.

LEROY LOREN BELT, Kenton, Ohio, to Miss Frances D. Jordan of Marblehead, Ohio, recently.

## Deaths

Charles Noah Dixon Jones, New York City; Long Island College Hospital, Brooklyn, 1882; College of Physicians and Surgeons in the City of New York, 1883; aged 62; a fellow of the New York Academy of Medicine, and a member of the Medical Society of the State of New York; surgeon to the Woman's Hospital, and gynecologist to the Southern Dispensary and Hospital, New York City; for many years connected with the health department of New York; died at the Lincoln Hospital, New York City, October 30.

Albert VanDevanter Braden, Ishpeming, Mich.; University of Virginia, Charlottesville, 1910; aged 31; a member of the Michigan State Medical Society; who served as captain, M. R. C., U. S. Army, during the war, and was chief medical officer of Evacuation Hospital No. 7, in France, and was honorably discharged, May 3, 1919; died in the Ishpeming Hospital, November 8, from pneumonia.

William Wallace MacFarlane, St. Louis; Washington University, St. Louis, 1866; aged 85; formerly of Auxvasse, Mo.; formerly assistant physician of State Hospital No. 1, Fulton, Mo., and superintendent of the Agnew (Calif.) State Hospital; a Confederate veteran; once surgeon to the Confederate Home, Mo.; died in the Masonic Home, St. Louis, October 30.

Stewart Alfred McComber, Schenectady, N. Y.; Detroit College of Medicine and Surgery, 1903; aged 48; associate director of athletics at Foyer du Soldat, Paris, since July, 1918; formerly physical director and professor of hygiene in Union College, Schenectady; died in the American Hospital at Neuilly, France, November 5, from cerebrospinal meningitis.

Ivan Dwight Hayes, Toronto, Ont.; University of Toronto, Ont., 1911; aged 35; who enlisted in the Royal Army Medical Corps in 1915; was invalided home from France the next year, and later reenlisted for home service, from which he was discharged in 1918, on account of heart disease; died, September 12, from heart disease.

Stephen Jackson Keefe \* Elizabeth, N. J.; University of the City of New York, 1889; aged 52; assistant surgeon of the Third New Jersey Volunteer Infantry during the war with Spain; coroner of Union County from 1895 to 1898; assistant surgeon to St. Michael's Hospital, Newark; died, about October 26.

Lewis L. Williams, Brazil, Ind.; Louisville (Ky.) Medical College, 1878; aged 61; a member of the Indiana State Medical Association; local surgeon of the Terre Haute, Indianapolis and Eastern Traction Company; secretary of the city board of health; was shot and instantly killed, in Brazil, November 3.

Trevanion V. Dupuy, Chicago; Miami Medical College, Cincinnati, 1889; aged 57; formerly safety director of Iron-ton, Ohio; was found dead in Jackson Park, Chicago, October 28, death being due to a gunshot wound of the head, self-inflicted, it is believed, while despondent on account of ill health.

Andrew J. Bennett, Busti, N. Y.; University of Buffalo, 1891; aged 59; a member of the Medical Society of the State of New York; health officer of Chautauqua County;

\* Indicates "Fellow" of the American Medical Association.

for four years supervisor of Busti; died in the Women's Christian Association Hospital, Jamestown, November 1.

**Richard E. Venning** \* Charlestown, W. Va.; University of Pennsylvania, Philadelphia, 1891; aged 51; once president of the West Virginia State Medical Association; founder of the Charlestown Hospital; died at the home of William O. Norris, Charlestown, October 31.

**Otto Ernest Plath** \* Phoenix, Ariz.; Miami Medical College, Cincinnati, 1856; aged 55; also a pharmacist; secretary of the Arizona State Medical Association in 1899, and president in 1907; local surgeon of the Santa Fe System; died, November 3, from acute bronchitis.

**Charles Frederick Sterling**, Warrenton, Va.; Pulte Medical College, Cincinnati, 1877; aged 73; once professor of diseases of the eye and ear, University of Michigan, and a member of the staff of Grace Hospital, Detroit; died, October 28, from cerebral hemorrhage.

**Orfila James Allen**, Arco, Idaho; Gross Medical College, Denver, 1896; aged 55; chief surgeon of several mining companies; once secretary of the Idaho State Medical Association, and state board of medical examiners; died, August 22, from carcinoma of the throat.

**William H. Ussery**, Lebanon, Okla. (registered, Oklahoma, act of 1908; aged 64; a member of the Oklahoma State Medical Association; a practitioner for twenty-four years; died in the Gainsville (Texas) Sanitarium, October 29, from cirrhosis of the liver.

**Samuel Belash Childs**, Brooklyn; University of the City of New York, 1869; aged 76; a member of the Medical Society of the State of New York; for fifty years attending physician to the Faith Home for Incurables; died, November 8, from cerebral hemorrhage.

**Frank Fulmer Castlebury**, Roaring Branch, Pa.; Jefferson Medical College, 1896; aged 57; a member of the Medical Society of the State of Pennsylvania; died at the home of his sister in Williamsport, Pa., October 28, from chronic parenchymatous nephritis.

**Aaron Boylan**, Milford Center, Ohio (license, Ohio, 1896); aged 80; for fifty-six years a practitioner; a veteran of the Civil War; a member of the Ohio State Medical Association; for many years local surgeon for the Pennsylvania System; died, November 4.

**Caleb William Sommerville**, Highland Park, Philadelphia; Medico-Chirurgical College of Philadelphia, 1902; aged 42; lieutenant, M. R. C., U. S. Army, and honorably discharged, March 27, 1918; died, November 4, from pneumonia.

**Farquard A. Mayes**, Hayti, Mo. (license, Missouri, 1876); aged 71; a member of the Missouri State Medical Association; a practitioner since 1872; also a druggist; local surgeon for the Cotton Belt System; died, November 4.

**James Henry Breen** \* Hudson, Mass.; Tufts College Medical School, Boston, 1906; aged 41; for several years town physician; dropped dead, November 3, near the railway station at Hudson, while running to catch a train.

**Abraham S. Brinkerhoff**, Brooklyn; New York Homeopathic Medical College, New York City, 1892; aged 63; a member of the staff of Flower and Bellevue hospitals; died in Miami, Fla., November 8, from heart disease.

**Edward L. Baker** \* Indianola, Iowa; Louisville (Ky.) Medical College, 1873; aged 65; medical director of the Order of United Craftsmen; secretary of the Warren County Medical Society in 1916; died, November 2.

**Robert Little Kennedy**, Royal Oak, Mich.; Detroit College of Medicine and Surgery, 1858; aged 45; formerly medical superintendent of the State Tuberculo-sis Sanatorium, Howell, Mich.; died, October 28, from myocarditis.

**John Abner Penton**, Goodwater, Ala.; College of Physicians and Surgeons, Baltimore, 1900; aged 49; a member of the Medical Association of the State of Alabama; died, October 17, from cirrhosis of the liver.

**James W. Smith**, Richmond, Mo.; Washington University, St. Louis, 1874; aged 71; a member of the Missouri State Medical Association, and president of the Richmond Exchange Bank; died, October 21.

**William Remma Ditmars** \* North Adams, Mich.; University of Michigan, Ann Arbor, 1872; aged 73; once president of the Hillsdale County Medical Association; died, November 2, from arteriosclerosis.

**Lewis Beecher Thomson**, Washington, D. C.; Maryland Medical College, Baltimore, 1905; aged 70; a member of the Medical Society of the District of Columbia; died, October 15, from angina pectoris.

**Frank O. Sherwin**, Duluth, Minn.; Rush Medical College, 1878; aged 65; formerly health commissioner of Duluth; for twenty years physician to the port of Duluth; died, October 24, from myocarditis.

**Whitfield Timlow Seeley**, Warwick, N. Y. (license, New York, 1901); aged 73; a member of the Medical Society of the State of New York; a practitioner for forty-four years; died, October 9.

**John Gygi** \* Big Falls, Wis.; Ohio Medical University, Columbus, 1906; aged 43; died, October 22, from an accidental overdose of chloroform taken for the relief of gallstone colic.

**Samuel Phillips**, Leavenworth, Kan.; University of Maryland, Baltimore, 1853; aged 89; at one time a surgeon in the army; died in St. John's Hospital, Leavenworth, October 31.

**Albert Henry Cox**, Stephens, Mo.; Missouri Medical College, St. Louis, 1882; Bellevue Hospital Medical College, 1883; aged 60; died, October 27, from cerebral hemorrhage.

**Abram Case Williams**, Springfield, Mass.; Yale University, New Haven, Conn., 1895; aged 50; a member of the Massachusetts Medical Society; died, October 25.

**Willis Swanner Anderson** \* Shelby, Ohio; University of Pennsylvania, Philadelphia, 1886; aged 53; health officer of Shelby; died, November 5, from septicemia.

**Gideon D. Spengler**, Allentown, Pa., and Philadelphia; Jefferson Medical College, 1878; aged 73; died in the Jefferson Hospital, Philadelphia, October 24.

**Charles D. Arnold**, El Reno, Okla.; University of Louisville, Ky., 1876; aged 73; a member of the Oklahoma State Medical Association; died, October 25.

**Mary Ann Armstrong**, Berkeley, Calif.; University of Michigan, Ann Arbor, 1879; aged 70; formerly a resident of Santa Cruz, Calif.; died, November 3.

**Oscar L. Nutty**, Turbotville, Pa.; College of Physicians and Surgeons, Baltimore, 1880; aged 58; died, November 11, from chronic interstitial nephritis.

**Clayton W. Carson**, Chicago; Rush Medical College, 1884; aged 59; died in his automobile, near St. Luke's Hospital, November 8, from angina pectoris.

**George W. Farver**, Hammond, Ind.; Indiana Medical College, Indianapolis, 1875; aged 69; died in Montezuma, Ind., October 21, from cholangitis.

**Charles Henry Hall** \* Hiron, S. D.; Hahnemann Medical College, Philadelphia, 1879; aged 73; died in a hospital in Minneapolis, October 30.

**Newton C. Fancher**, Kansas City, Kan. (license, Kansas State Board of Eclectics); aged 84; a veteran of the Civil War; died, October 20.

**Edgar Bertrand Doolittle** \* Hazleton, Pa.; University of the City of New York, 1882; aged 59; died, October 27, from bronchopneumonia.

**Edward Lewis Holtenstein**, Kutt-town, Pa.; Jefferson Medical College, 1886; aged 55; died, October 27, from carcinoma of the stomach.

**William John Humphrey**, Cherryville, Pa.; University of Pennsylvania, Philadelphia, 1872; aged 69; died, October 19, from nephritis.

**Alexander Bleecker Leggett**, Babylon, L. I., N. Y. (license, New York); a practitioner since 1858; aged 84; died, November 6.

**Major D. Sterrett**, Beckville, Texas; Atlanta (Ga.) Medical College, 1866; aged 79; a veteran of the Civil War, died, October 24.

**Pettygrew M. Eakes**, Philadelphia, Miss.; Kentucky University, Louisville, 1905; aged 41; died, October 21, from nephritis.

**Wesley Ivy Wimberly**, Hammon, Okla.; Tulane University, New Orleans, 1913; aged 31; died, October 24, from pneumonia.

**John William Respess Corlis**, Brooksville, Ky.; Medical College of Ohio, Cincinnati, 1855; aged 89; died, October 27.

**George W. Kern**, Elizabethtown, Pa.; Hahnemann Medical College, Philadelphia, 1878; aged 71; died, October 28.

**John Wesley Reading**, Marion, Ohio; Bellevue Hospital Medical College, 1895; aged 84; died, October 25.

**Edward Thomas Stevens**, Buffalo; University of Buffalo, 1899; aged 60; died, October 14, from pneumonia.

## The Propaganda for Reform

IN THIS DEPARTMENT APPEAR REPORTS OF THE JOURNAL'S BUREAU OF INVESTIGATION OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND THE ASSOCIATION OF LAWYERS TOGETHER WITH OTHER MATTER TENDING TO AID INTERESTED PROFESSIONS AND TO OPPOSE TRICKS ON THE PUBLIC AND ON THE PROFESSION.

### THE ELI PRODUCTS OF ELI H. DUNN

Physicians are receiving some miscellaneous advertising matter from a concern that seems to operate under various names such as "F. H. Dunn & Co.," "Eli H. Dunn," "Eli Laboratory," etc. The concern is located at 3820 Main St., Kansas City, Mo. One JOURNAL reader, who is evidently not greatly impressed by this material, forwards the stuff to us with the laconic request: "Will you please give me your opinion on this junk?"

The "junk" referred to comprised, in part, an advertising leaflet on "Eli 000 Capsules," another leaflet on "Eli Vaginal Capsules," and another on "Eli 'Vin' Restorative;" then there was reference to the inevitable nostrum for intravenous use: "Ampules Eli Venhydrarsen." A four-page leaflet, headed in large and very black letters "Confidential Guide to Live Wire Physicians Only," expressed its key-note in the opening paragraph:

"It is to make MONEY as well as REPUTATION in the treatment of all CHRONIC AFFECTIONS and all types, forms and sequella of VENEREAL diseases."

The "Eli 'Vin' Restorative" is said to be a "tonic aphrodisiac." The "action" of the product is to "Arouse Sexual Ardor and Desire. It flux blood supply to the genital organs." A poster to the "Guide" urges physicians:

"If you do not already use Intravenous Serums, by all means get on them, if for no other reason than to meet the popular DEMAND."

A "Special Note" in the "Confidential Guide" advises physicians who "have to deal with Hysteria" to "write the Author of this Guide, who will explain by personal letter a method of cooperation by which such Convulsions may be At Once and forever stopped. . . . There will be \$100 for You from every case treated." One physician wrote to the Author of this Guide—Eli H. Dunn, M.D.—asking for further information on this treatment for hysteria. He received in reply two letters both signed Eli H. Dunn; one was to be shown to the patient, the other was for the doctor's own information. The letter for the patient to see described the curative effects of "Dunn's Intravenous and Restorative Treatment" in hysteria and recommended it "with the utmost confidence in every case able to pay you the fee commensurate with the service you render." Then followed these paragraphs:

The cost of treatment when administered by yourself is \$300 AND WITH ORDERS which includes one complete outfit and serum for a month.

Should you call me personally in consultation an additional fee of \$100 per case covering the time I am away from my Kansas City office will be estimated and held until I arrive."

The letter that was intended only for the doctor's eye (colored):

"You are to pay \$100. (for the ) and \$70 of the per diem."

It explained that the "complete outfit" referred to in the "Special Note" would consist in part of a tube of intravenous "Restorative" and boxes of "Restorative Capsules" and "Eli 000 Capsules."

Eli H. Dunn seems to have had a somewhat varied and peculiar career. After being graduated in 1885 he apparently started practice in Orion, Ill. During the '90's he was practicing at Elma, Iowa, and about 1900 he seems to have moved to Kansas City, Mo. During 1906 and 1908 he also had an additional office at Denver, Colo. About this time he was experimenting "Dunn's Uterine Evacuant" which was "a strictly legitimate" product which could be injected within the uterus with perfect safety and immediate effect." This stuff was advertised both from the Kansas City and the Denver offices. The "Personal Column" of a Kansas City

paper in 1910 carried the message to "Ladies" that "Dr. Dunn" was a "Regular physician for women only." Dunn's violation of the postal laws in 1911 and of the federal Food and Drugs Act in 1912 need not be gone into at this time.

THE JOURNAL would feel like apologizing for devoting space to such a preposterous scheme were it not for the fact that physicians, being human, sometimes "fall for" preposterous schemes. Some, we know, have nibbled at Dunn's bait; others may do so. The gross commercialism that permeates the advertising matter sent out by Dunn again emphasizes the fact that the fad for intravenous medication offers an attractive field for those who would exploit our profession.

### OMISSION OF COTARNIN SALTS (STYPTICIN AND STYPTOL) FROM N. N. R.

#### Report of the Council on Pharmacy and Chemistry

The Council has authorized publication of the following report.

W. A. PUCKNER, Secretary.

Salts of the base cotarnin have been used as local and systemic hemostatics. The hydrochlorid was first introduced as "Stypticin," and is now in the pharmacopoeia as cotarnin hydrochlorid (*Cotarninae Hydrochloridum*, U. S. P.). The phthalic acid salt of cotarnin—cotarnin phthallate—was introduced as "Styptol." Both Stypticin and Styptol were admitted to New and Nonofficial Remedies. In 1918 the Council voted to omit Stypticin because the former American agents were no longer offering it for sale. Styptol was retained and is described in N. N. R., 1919.

As was pointed out in the description (N. N. R., 1918), the evidence for the usefulness of the cotarnin salts has been contradictory and unsatisfactory; but since the available data against the efficiency were at least equally unreliable, the Council deemed it best to retain them in N. N. R. pending a thorough investigation of the subject. This was undertaken by P. J. Hanzlik, at the suggestion of the Therapeutic Research Committee of the Council.

A reliable judgment of hemostatic efficiency can be formed only on a basis of strictly controlled conditions, which can best be furnished in the laboratory. Hanzlik repeated the principal experiments published by previous investigators, and applied a number of new or improved methods. The results (published in the *Journal of Pharmacology and Experimental Therapeutics* 10:523, 1918; 12:71, 1919) show the following:

**Direct Application to Wounds.**—The widely quoted results of the gynecologist K. Abel, on the footpad of cats, were found to be quite unreliable. When the experiment is properly controlled, the results are either negative or the bleeding may be increased. Quantitative experiments on wounds of the footpad of dogs showed that cotarnin invariably increased the bleeding. Equally negative or unfavorable results were obtained with wounds to the comb of roosters, and to the liver and spleen.

**Direct Action on Vessels.**—The results of perfusion experiments were variable, but, in general, showed a vasodilation action instead of constriction. This holds true also of the uterine vessels. The vessels in the living animal (rabbit's ear) were also unaffected.

**Systemic Administration.**—The bleeding from an irrigated wound was not modified directly by intravenous injection of cotarnin salts, but varied merely with the state of the blood pressure.

The evidence for the inefficiency of cotarnin salts as hemostatics seemed so conclusive as to warrant the Council in rescinding the acceptance of Styptol, and directing the omission of the general article on cotarnin salts and the description of Styptol from New and Nonofficial Remedies.

**The Frequency of Multiple Births.**—For a rough approximation, the order of frequency with which twins, triplets, etc., occur is, according to Knibbs, as follows: In a series of confinements 1 per cent. will present twins, 0.01 per cent. triplets, 0.0001 per cent. quadruplets and 0.00002 per cent. quintuplets.

## Correspondence

### A HYPOTHESIS BEARING ON DISEASE THERAPY

*To the Editor:*—I desire to advance a hypothesis as a serviceable conception of disease processes.

Certain organisms or the toxins elaborated by them or poisons otherwise produced initiate specific processes in certain structures. These processes, if unchecked, run a definite course, and tend to produce characteristic symptoms. In many individuals so afflicted there comes a time in which the injured structures are sensitized not only to the specific proteins elaborated by the causal organisms, but also to allied proteins elaborated by other organisms, and perhaps to allied bodies chemically produced. In such instances the structural change already initiated tends to run as it would if the controlled original cause were still acting.

Thus a tabetic, as a result of vigorous antisyphilitic treatment, may become symptomless, and his cerebrospinal fluid may be brought to normal; but if he should suffer from an infection, as acute appendicitis, the patient's chief and practically only complaint may be acute lightning leg pains. Or, on the other hand, vigorous antisyphilitic treatment may afford a tabetic little relief from such pains, while the removal of a focus of infection may lead quickly to their disappearance.

Or a patient with latent tuberculosis may complain of periarthritic pains due to a fibrositis, the result of infected tonsils. The removal of the tonsils may give speedy relief; but if the latent tuberculosis becomes active, the pains are likely to recur, to be again relieved by the abating or removal of the tuberculous focus.

Many similar instances might be enumerated, each one capable perhaps of other interpretation, but pointing in their summation to the hypothesis suggested.

The moral to be drawn is that a patient with a syphilitic or other infection should not only be treated for that particular infection, but also be rendered as free as possible of other foci, though they apparently have no bearing on his immediate symptoms; and in patients who do not get relief by the treatment of the initiating cause, we must consider the probability of secondary sensitization.

CHARLES MINER COOPER, M.D., San Francisco.

### "THE RANGE OF THE GENERAL PRACTITIONER IN PSYCHIATRIC DIAGNOSIS"

*To the Editor:*—I have just been reading the little gem by Dr. O. I. Hess (*THE JOURNAL*, Nov. 15, 1919, p. 1544), and thought that possibly I could inform him regarding the meaning of "somatopsychic." The term is such a common one and has so long been firmly embedded in psychiatric language that I had supposed every medical student would have heard it at least once. Certainly, no man can read a psychiatric textbook published in this country in the last fifteen or twenty years and not find the term.

It was originally proposed by Wernicke, whose contributions did so much to clear up the confusion that existed in certain fields in psychiatry. Wernicke divided delusions into three types: autosychic, autopsychic and somatopsychic. White's "Outline of Psychiatry" or any other standard book will give a good discussion of these terms. In fact, the terms themselves are so simply compounded that I am surprised to find that one who revels in the words "esoteric" and "pedantic" should have any difficulty in arriving at the correct meaning.

As for his discussion of the term "disoriented" versus "confused," I have only this to say, that if the questioner can define "confused" he will do more than any psychiatric writer I know, including Kraepelin; whereas, "disorientation" is a word which can be precisely defined and used by people in all parts of the world with exactly the same meaning.

It is regrettable, of course, that the doctor should have found his "ideation" and "orientation" somewhat befogged

by the use of these terms, but I am sure that we all find occasional words which we do not understand in the writings of specialists in other fields than our own. Of course, the question of terminology is an extremely important one. New words have as their greatest value that they can be precisely defined to convey a certain idea, whereas old words that have been in use for a long time have changed greatly in meaning from time to time, and very frequently no two persons can be found to agree on what is meant by a given term. The trouble is that the average man regards all efforts to improve terminology as pedantic, and dismisses the whole problem with no further effort to understand.

It is, accordingly, a good sign when one is interested enough to attempt to find out what a given word means. Let us hope there will be many more such inquiries.

LAWSON G. LOWREY, M.D., Boston.

Chief Medical Officer, Boston State Hospital,  
Psychopathic Department.

### THE USE OF ACRIFLAVINE

*To the Editor:*—Under the section devoted to N. N. R. (*THE JOURNAL*, Nov. 8, 1919, p. 1443), the action and uses of acriflavine are noted, with the fact that its clinical use has occasioned numerous and exceedingly conflicting published reports. My experience is that the preparation has no special virtue, compared to the usual nontoxic antiseptics, when employed in the cited indications. Acriflavine's chief value is its remarkable power to stimulate epithelial growth on healthy granulating surfaces. In cases in which Thiersch's method of skin grafting is indicated, as after amputation of the breast, I follow and recommend the practice of Mr. A. J. Couzens of London—wet eusol dressings for from twenty-four to thirty-six hours, then changing to wet acriflavine dressings, 1:1,000. Healing occurs with great rapidity.

MAXWELL QUACKENBOS, M.D., New York.

### EXPANSION OF THE WORK OF THE RED CROSS

*To the Editor:*—I have just finished reading Dr. Farrand's pamphlet on health centers as peace time activities for the great Red Cross organization. As near as I can judge, most of this work will be planned by laymen, and I can see in it, what every medical man will see on reflection, the possibility of sentimentality overriding common sense.

If this health work is to do any real good, it must be steered by wise counsel of the best men in the profession; and in my judgment it is of such importance that the problems should be handled by a special committee of the American Medical Association. It is possible that something of the sort has been planned.

Enthusiasts in health and welfare work find it easy to strike a popular chord and arouse enthusiasm in the lay mind over their theories, some of which would not stand analysis; and the thought occurred to me that one way our Association might help retain sanity in this field is to see that the medical profession, through well chosen speakers, has its views presented in the same way as those who bring out all this new propaganda.

Somebody in every community will have to sit on the lid.

W. S. CHASE, M.D., Akron, Ohio.

### "THE RELATIONSHIP BETWEEN HERPES ZOSTER, SYPHILIS AND CHICKENPOX"

*To the Editor:*—I have read your editorial on the relationship between herpes zoster, syphilis and chickenpox. The segmental distribution and spinal findings indicate that it may have a central causative factor, as distinguished from peripheral nerve irritations. Some time ago I had a case of gallstone disease in which occurred a marked herpetic eruption over the abdomen in the region of the gallbladder. At this time the patient was suffering from repeated attack of colic with marked jaundice, evidently due to common duct

blockage. I operated on her a few days later, the jaundice having cleared up considerably, and at that time found the cystic duct obstructed by a large stone, as well as a number of stones in the gall bladder. I have no doubt that in this particular case there was so much irritation about the gall bladder neck that a "reflex irritation" brought about the external herpetic eruption by way of the nerves from the duct region and thence along the segmental distribution. This case would seem to indicate that there may be other than purely "central spinal" sources for herpetic-like eruptions.

W. G. PARKER, M.D., Mount Vernon, Ill.

### Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be accepted. Every letter must contain the writer's name and address, so these will be omitted, on request.

#### URINARY TESTS FOR SYPHILIS

To the Editor—Will you kindly inform me whether the test in the enclosed "literature" is what it is represented to be?

CHARLES M. THOMAS, M.D., Sunbury, Pa.

ANSWER.—The "literature" referred to by Dr. Thomas dealt with the "Uri-Na Test" sold by the Standard Appliance Company of Philadelphia. There seems to be a strong family resemblance between this alleged test and that known as "Capell's Urine Test," which was discussed in the Propaganda Department of THE JOURNAL, Aug. 23, 1919. Of that THE JOURNAL said: "Unfortunately, its scientific value to the sufferer is negligible compared with its economic value to the exploiter. It is not so much a test for lues in the patient as of credulity in the doctor." The same may be said of the "Uri-Na Test." The facts are, there is no method at present known by which the absence or presence of syphilis may be determined by a simple color test of the urine.

#### USE OF MERCURIC CYANID PREPARATIONS SUBCONJUNCTIVALLY

To the Editor—Please give me the percentage of solution and indications for the use of mercuric cyanid subconjunctival injections; also the indications for normal salt solution in the same location.

F. C. McCLANAHAN, M.D., Tanta, Egypt.

ANSWER.—Both mercuric cyanid and mercuric oxycyanid, in solutions varying in strength from 1:40,000 to 1:2,000, are often found to be of signal value when used subconjunctivally, in hypopyon ulcer, and in other purulent or deep-seated infections of the eye. It must be remembered, however, that even in a thoroughly cocainized eye, these injections are extremely painful, and for this reason many eye surgeons do not wish to use this remedy. Physiologic sodium chloride solution is employed for the same conditions. From 0.5 to 20 minims of a 5 to 10 per cent. solution are injected, and repeated at two to three day intervals, according to the results obtained.

#### RADIUM SALTS

To the Editor—Please state what is the most effective radium salt for treatment.

GEOFFREY A. HERTLEY, M.D., Battle Creek, Iowa.

ANSWER.—Now and Nonofficial Remedies, 1919, recognizes the following salts of radium: radium bromid, radium carbonate, radium chloride and radium sulphate. The efficacy of these salts depends essentially on the percentage of radium which they contain, and accordingly all are sold on the basis of their radium content. The choice of one or the other depends on physical factors. Thus the bromid and the chlorid are commonly used in the applicators, whereas the insoluble sulphate is used in constructing an apparatus for the production of water charged with radium emanation.

For more complete details refer to New and Nonofficial Remedies.

### North Carolina June Examination

Dr. H. A. Royster, secretary of the North Carolina State Board of Medical Examiners, reports the oral, written and practical examination held at Raleigh, June 24-28, 1919. The examination covered 15 subjects and included 72 questions. An average of 80 per cent. was required to pass. Of the 68 candidates examined, 59 passed and 9 failed. Twenty-three candidates were licensed through reciprocity. Seven candidates were refused reciprocity certificates. The following colleges were represented:

College	PASSED	Year Grad.	Per Cent.
Emory University	.....	(1919)	80
Tulane University	.....	(1919)	84.5, 85.1, 81.7

## Book Notices

**THE ITINERARY OF A BREAKFAST.** A Popular Account of the Travels of a Breakfast through the Food Tube and of the Ten Gates and Several Stations through Which It Passes, Also of the Obstacles Which It Sometimes Meets. By J. H. Kellogg, M.D. Cloth. Price, \$1.60 net. Pp. 210, with illustrations. New York: Funk & Wagnalls Company, 1919.

The publisher has characterized this "popular account of the travels of a breakfast through the food tube" as being "as fascinating as a romance or a book of travels." The book is in popular language, the intestinal tube being considered as a road with ten gates, with numerous stations and obstacles. The reader is enlightened with regard to the method of overcoming the obstacles and the way in which the food passes through the gates. Some of the views held by the author are not those generally held; for example, that limitation to a single evacuation daily must be considered as constipation, and that from three to four evacuations constitute the normal mode of living. Most of the views expressed are, however, of a common sense, practical character and exceedingly instructive. Particularly interesting are Dr. Kellogg's views on the use of the roentgen ray and interpretations derived therefrom in connection with examinations of the intestinal tract:

A typo misinterprets what he sees. The minute indications of disease he overlooks, and unusual but perfectly normal appearances he mistakes for cancer or some other dreadful condition, for which he urges immediate operation.

Unfortunately the country is full of x-ray tyros, thanks to the commercial activity of x-ray machine manufacturers. It is safe to say that at the present moment the conclusions drawn from the majority of x-ray examinations of the colon are altogether unreliable and worthless, if not positively misleading, and a menace to the patient's welfare if made a basis for active treatment or operation.

Beware of the x-ray tyro. There are in the United States possibly one hundred x-ray specialists whose examination of the alimentary canal may be regarded as of value and whose conclusions may be trusted as fairly reliable; but the chances are very great that our estimate is far too large.

The book is one which the physician will read with interest and the layman with considerable enlightenment. Whether the neuroasthenic who is inclined to make a fetish of his intestinal evacuations can benefit from it seems doubtful.

**MAMMALIAN PHYSIOLOGY: A COURSE OF PRACTICAL EXERCISES.** By C. S. Shepperton, M.D., D.Sc., F.R.S., Waynflete Professor of Physiology in the University of Oxford. Cloth. Price, 12 shillings, 6 pence. Pp. 156, with illustrations. New York: Oxford University Press, 1919.

This is a laboratory outline of mammalian experiments given in a course of physiology at Oxford University. This course compares favorably with those of our better medical schools. Incidentally, the medical schools of Great Britain are handicapped, in teaching these sciences, in the restriction placed on the use of animals for teaching purposes. As the result, most of the experiments outlined in this book are done on decapitated animals. The book will be found helpful to teachers of physiology, pharmacology and physiologic chemistry.

**CEREBROSPINAL FLUID IN HEALTH AND IN DISEASE.** By Abraham Levinson, B.S., M.D., Associate in Pediatrics, Northwestern University Medical School. With Foreword by Ludwig Hektoen, M.D. Cloth. Price, \$3. Pp. 231, with 56 illustrations. St. Louis: C. V. Mosby Company, 1919.

In his foreword, Professor Hektoen states that he believes this to be a valuable little book in which the author has combined a true philosophic interest with a first-hand practical knowledge. Why say more?

**A TEXT BOOK OF BIOLOGY FOR STUDENTS IN GENERAL, MEDICAL AND TECHNICAL COURSES.** By William Martin Smallwood, Ph.D., Professor of Comparative Anatomy in the Lateral Arts College of Syracuse University. Third edition. Cloth. Price, \$3. Pp. 306, with 243 illustrations. Philadelphia: Lea & Febiger, 1918.

Biology is fundamental to all the medical sciences. Professor Smallwood presents the subject from the point of view of the comparative anatomist and, as in most textbooks of biology, the frog is selected as the type for complex animals. The first seven chapters cover its anatomy and physiology.

The second part of the book concerns the biology of unicellular organisms, taking up in turn the development of worms, plants, insects, biologic adaptations, bacteria, the biologic factors in disease, evolution, heredity and animal behavior. The book is excellently illustrated; the author has drawn on many sources for the pictures, and they help to make this an attractive textbook.

### Malpractice in Treating Injury to Brachial Plexus

(Tucker v. Stetson (Mass.), 123 N. E. R. 239)

The Supreme Judicial Court of Massachusetts, in sustaining exceptions to a verdict in favor of the plaintiff, says that he met with an accident whereby he sustained a broken collar bone and a severe injury to the brachial plexus. He was taken to a hospital, where he was treated by the defendant. During the time he was in the hospital his arm and shoulder were bandaged up. He could move his fingers a little, but could not move his arm; and since that time he has never been able to make any other movement with the fingers or arm. At the end of three weeks he left the hospital at the defendant's suggestion, the defendant directing him to see another physician every day or so, telling him he thought his arm would come on all right in a couple of months or so. The plaintiff went to the other physician every other day or so and had his arm rubbed with a liniment of some kind, and then put back in its bandage, the physician telling him to massage it himself once or twice a day, which he did, but noticed no change in the feeling or sensation of his arm as he followed this course of treatment. After six weeks of treatment his arm began to wither up. He then went to the Massachusetts General Hospital, and was operated on unsuccessfully. The arm at the time of the trial was useless.

The claim of the plaintiff, as set out in the declaration, was "that the defendant carelessly and negligently failed to operate on the injured parts of the plaintiff's body seasonably and that he failed to exercise that judgment which he professed to possess in the treatment of the plaintiff's injuries." At the close of the evidence the presiding judge refused to direct a verdict for the defendant; and this court thinks the ruling was right. The defendant testified that he had practiced surgery since 1895; in 1901 became examining physician and surgeon for important railroads; had done some postgraduate work devoted to surgery; had a large and varied practice; but "had never performed an operation to relieve any trouble with the brachial plexus, though he knew what it was and appreciated the effects of injury to it and considered himself competent to pass on whether the brachial plexus had been affected, and was satisfied in his own mind the following day after the accident that the plaintiff had trouble with the brachial plexus and treated him keeping that fact in mind." The evidence fully warranted the jury in finding that ordinary surgeons in the town where the defendant practiced his profession had the skill and ability to perform the surgical operation of "cutting down on the nerves and suturing or sewing them together as far as possible in their normal position." The conflicting testimony warranted a finding that such an operation, performed a few days after the injury, would probably have restored the use, or some of the use, of the arm. It also warranted a finding that the defendant did nothing for the plaintiff except to have a sand bag placed on his shoulder, have a roentgenogram taken, dress the arm with cotton bandages, and keep him in bed on his back during the time he was at the hospital, without advice that an operation was desirable or a suggestion that he could or should obtain the services of the best surgeons at the Massachusetts General Hospital. The foregoing facts, if believed, warranted a finding that the defendant was negligent in failing to operate or in failing to advise seasonably to procure surgical relief if the defendant felt himself incompetent to act.

But there was prejudicial error, the court thinks, in an instruction to the jury that it might take into consideration the possibilities of good results from an operation in determining whether the plaintiff had proved his case. The liability of the defendant was not to be determined by the jury on consideration of contingent, speculative and possible results of an operation which might be performed on the plaintiff to remedy or mitigate the consequence of the injury to the nerves, but on proof by a fair preponderance of evidence that it was reasonably probable that such a result would follow an operation, performed by the defendant with the ordinary skill and ability of surgeons practicing in towns similar to the one where he undertook to practice his profession.

#### Power of Personal Representative to Waive Privilege

(*Grieco v. Howard (Utah), 180 Pac. R. 423*)

The Supreme Court of Utah, in reversing a judgment that dismissed the complaint of the plaintiff, a special administrator, who sought to have a deed that had been made set aside on the ground of mental incapacity of the grantor and undue influence, says that it was held on the trial that a physician called by the plaintiff as a witness could not reveal matters which he had learned in his treatment of the grantor, who had died; and that the apparent conflict in the former decisions of this court in regard to the power of the personal representative of a deceased patient to waive privilege rendered it necessary to determine definitely the rule by which future cases should be governed in Utah. The exact question was: Can the personal representative of a deceased person, under the Utah statute, waive the privilege conferred by the statute, and demand that the physician who attended the deceased prior to his death be permitted to testify concerning information acquired necessary to enable him to prescribe or act for the patient? The statute reads:

There are particular relations in which it is the policy of the law to encourage confidence and to preserve it inviolate. Therefore a person cannot be examined as a witness in the following cases: (4) A physician or surgeon cannot, without the consent of his patient, be compelled in a civil action as to any information acquired in attending the patient which was necessary to enable him to prescribe or act for the patient.

The authorities are uniform, under all the statutes with which this court is familiar, that the patient can waive or withhold the privilege where the question arises during his life. But the question here was, Can his personal representative, after the death of the patient, waive the privilege the same as the patient could have done if living? The Utah statute and most other statutes are not express on this particular point, and for that reason there is considerable conflict of authority, not so much among text writers as among adjudicated cases.

The statute under consideration was adopted literally from the California Code of Civil Procedure as early as 1884 and *In re Flint*, 100 Cal. 391, 34 Pac. 863, decided in 1893, it was held that the privilege is personal to the patient, and after the death of the patient cannot be waived by his personal representative. But, after carefully considering the language of the statutes and the cases decided under them, referred to by the California court in the *Flint* case, this court enters its inability to understand on what authority the California court or any other court can consistently hold that the differences in the statutes justify the conflicting views in the conflicting opinions referred to. It seems to this court that it would be far more ingenious to admit that the statutes referred to, including the Utah statute, are all substantially the same in meaning and effect, and that the conflicting opinions of the courts are due entirely to conflicting views of different minds concerning the true intent.

In view of the state of the law as this court finds it, and this court's own convictions of what is most reasonable and just, this court is of the opinion that under the Utah statute the personal representative of a deceased person has the same right to waive the privilege given by the statute, after the death of the patient, as the patient would have had if living.

### CLINICAL CONGRESS OF AMERICAN COLLEGE OF SURGEONS

*Ninth Annual Meeting, held in New York, Oct. 20-24, 1919*

The President, Dr. William J. Mayo, Rochester, Minn., in the Chair

#### Gunshot Fractures of the Femur

SIR ANTHONY DOWLING, London, England: Gunshot fracture of the femur occurs in 1.5 per cent. of all wounded men. It is one of the most dangerous injuries of the war, the danger being proportionate to the extent and nature of the injury of the soft parts even more than to the extent of the bone lesion. With the adoption of the "Thomas outfit," the transportation of the patient to the casualty clearing station was greatly simplified. Pain was either altogether prevented or reduced to a minimum, bleeding was soon checked, and the steadying of the fragments effectually prevented further injury to the soft tissues and spread of sepsis. The conditions necessitating primary amputation are complete smashing of an area of bone; extensive comminution of the lower articular end of the femur; laceration of the femoral vessels; extensive destruction of muscles and skin, and gas gangrene. Primary amputation for fracture of the femur is attended with a much higher death rate than is amputation in the thigh for injuries of the leg, and also the higher up the limb is removed the greater the mortality. Primary amputation at the hip is so uniformly fatal that it would better not be performed at all. The apparatus employed should be a skeleton metal splint which permits traction to be applied either directly downward or else in various degrees of abduction and flexion. The direction of traction and the amount of flexion must be guided by frequent roentgenograms. Even when the fragments are separated by an interval of 1 or 2 inches, the gap will be completely filled in by new bone. Fixed extension proved not to be as good as continuous extension. Movements of the knee joint are begun early, and slight flexion of the knee is to be preferred to traction on the fully extended limb. When union is sufficiently advanced it is the custom to get the patient out of bed while maintaining the length of the limb by the application of "walking caliper splints" fixed to the heel of the boot. The question of the removal of bone was not entirely settled when the war ended. There seems to be no doubt that, on the one hand, the removal of all fragments which might necrose hastens the healing of the wound, while, on the other hand, the removal delays the healing of the fracture, and in the opinion of some has been responsible for permanent nonunion in not a few cases. In fractures of the shaft it is important to support the bone at the site of fracture so that the natural anterior curve of the femur is very fully maintained or even slightly exaggerated. Stiffness of the hip joint should never occur, except in cases in which the fracture involves either the neck of the bone or the trochanter. This can always be prevented if care is taken that the foot is not cramped in bandages. It has been the custom recently to remove sequestrums earlier than in former years.

#### DISCUSSION

SIR ROBERT JONES, Liverpool, England: In England we obtained an average of only one-fourth inch shortening in those cases treated with calipers. In our experience at Liverpool the average shortening was five-eighths inch. This carries an important lesson. All those patients were treated in the simplest possible fashion, with Thomas splints or those similarly made. None of these patients were subjected to internal splinting. In the early part of the war the men subjected to internal splinting all lost their limbs. When

caliper splints are worn, the patient with an ununited fracture can walk with ease. The patient with a gap in his femur can walk without limping. Deformity resulting from slight overlapping is not as bad as that resulting from a meticulous apposition. When there is deformity of the femur we do not operate if there is good function and good alignment, even if there is as much as one inch shortening. If one operates on a malunion there is often a greater stiffness of the knee than before. A knee at 5 degrees flexion is bandaged at 20 degrees; when the patient can lift the limb to 20 degrees of flexion, it is bandaged at a still greater degree of flexion. It is not advisable to attempt forcible movements.

DR. FRED N. G. STARR, Toronto, Ont.: Recently I came across the original article written by Thomas in 1875, in which he stated that the splint he had devised enabled one to "handle the patient as though he were a toy, without pain." I have seen that so often that I am thoroughly convinced of the value of the Thomas splint. All accident ambulances should be equipped with Thomas splints, and the men in charge should be taught how to apply them at the site of the accident.

#### Empyema: Its Pathogenesis and Treatment

DR. ALEXIS V. MOSCOWITZ, New York: Knowledge of the pathology and pathogenicity of empyema is necessary, in order to understand its treatment. The view has hitherto been held that the pleurae became infected by contiguity with the lung. That does not seem logical, because such a thing does not take place in other serous cavities. It seems as if contamination must occur from the pleura. In most cases a subpleural abscess is found connecting with the empyema cavity. This is the rule rather than the exception. There is a rupture of the subpleural pulmonary abscess. Irrigated by an irritating solution, a persistent cough is produced. The analogy between the pleura and the peritoneum is very close, differing only with the greater mobility of the lung, as compared with the sluggish peritoneal peristalsis. The stages observed are: Serous pleurisy is converted into exudate, then encapsulation occurs, which might be either diffuse, localized or multiple. Seropurulent pleurisy is not encapsulated, but purulent pleurisy is always so. An absolutely free empyema containing frank pus is an unknown quantity. Frank pus is usually an end-product. The reason why thoracotomy is not permissible in the early stage is this: The fluid runs out and atmospheric pressure, at 15 pounds to the square inch, rushes in, collapsing the lung. This is badly borne by the patient and causes fluttering of the mediastinum with rapid heart action. It pushes out the other lung and disables the heart. Thus early thoracotomy is attended by a terrible mortality. When the stage of adhesions has been reached, these form an anchor for the lung to the side of the chest. It is then safe to operate and evacuate the pus. An acute pyopneumothorax is different. These patients bear early operation. The statistics as to the use of surgical solution of chlorinated soda are rather rosy, but some patients remain cured. In cases in which a pneumothorax occurred, this tended to disappear. It is safe to sterilize the cavity and close it over a pneumothorax.

#### DISCUSSION

DR. JOHN L. YATES, Milwaukee: Anything foreign to the serous membrane is an irritant. This irritation provokes an acute serous reaction. Before adhesions form, the serous fluid has formed and penetrated the cavities. This is sufficiently irritating to provoke a serofibrinous reaction apart from bacteria, and secondary foci may become more acute than the primary one. The best prevention of empyema is in keeping the pleural serosa in constant apposition. Drainage should be done later, when the secretions have coagulated. Primary thoracotomy can be done only by maintaining pulmonary inflation.

DR. JAMES F. MITCHELL, Washington, D. C.: The profession has agreed that early operation is dangerous in streptococcal empyemas. It has been found that pressure in one side of the chest is not independent of pressure in the other. There is a definite relation between the opening and the amount of air in the lungs. When the lung is restricted by pneumonia, the size of opening compatible with life becomes smaller.

Adhesions render the opening safer. Attention to diet and early exercise are found to be most important therapeutic aids. Three points can be emphasized: (1) avoidance of early operation; (2) vigorous application of the Carrel-Dakin method; (3) attention to diet and exercise. Persistent cases should be subjected to roentgen-ray examination. Stereoscopic plates should be made both with and without bismuth, because the bismuth may obscure a foreign body. The chest wall may be closed regardless of an existing cavity, provided the latter is sterile. The cavity tends to disappear with expansion of the lung. The operation should be as simple as possible. Slough should be removed. Small flaps should be used to close the opening. Early exercise should be instituted. There are few cases that will not respond to comparatively simple operations. All the individuals we treated became able-bodied men, without subsequent deformity.

#### Surgical Treatment of Exophthalmic Goiter

DR. GEORGE W. CRILE, Cleveland: Of 2,250 thyroidectomies, 50 per cent. were subjected to ligations. In 333 cases, ligation was first done, then a thyroidectomy. Among 116 ligations, one death occurred in the stage of dissolution. In the first 100 cases the mortality was 16 per cent. With the use of gas and oxygen anesthesia this was reduced to 2.5 per cent. By the adoption of special management of cases, the mortality has been further reduced to 0.6 per cent. Since the war, special precautions have been added against postoperative hyperthyroidism due to excessive chemical activity and destruction by oxidation. With each degree of rise of temperature this chemical activity is increased 10 per cent. With a temperature of 105 F., metabolism is increased 70 per cent. Another point of importance was the discovery by the British research department that the wound can be left open in statu quo, by the use of a dressing of 1:5,000 flavine. This permits the surgeon to stop at any point at which he considers the patient is not enduring the operation well. Lobectomy is performed under analgesia, as the inhalation anesthesia interferes with internal respiration in a patient already suffering from suboxidation. Hypersensitiveness is sufficient to destroy the patient. Complete team work is essential to success. The operation is performed by the hospital and not by the surgeon. The differential diagnosis is greatly aided by the Goetsch epinephrin test and basal metabolism determination.

#### DISCUSSION

DR. DEAN D. LEWIS, Chicago: Tachycardia without exophthalmos does not differ from ordinary thyrotoxic goiter. Hyperplasia of the thyroid epithelium presents the four classical signs of goiter. Surgeons are likely to want to operate too soon. The exercise of judgment makes all the difference between one surgeon's success and another's lack of it. I have seen patients die after ligation. I have not seen anything that will control that.

DR. CHARLES H. MAYO, Rochester, Minn.: The Surgeon-General's report showed that 15 per thousand is the rate of goiter in the northern Pacific states. There is almost no goiter in New Hampshire and Vermont. There are perhaps more mistakes in diagnosing exophthalmic goiter than any other condition. The thyroid is not essential to life, but it is synonymous with making life worth living. The cell changes in the thyroid are due to increase of biochemical products by bacteria, coming from different parts of the body and acting on the thyroid. Two thirds of the cases are simple hyperplastic glands. A second type is caused by areas of degeneration throughout the gland. A hyperplastic gland sometimes goes with myxedema a sort of burned out condition. In hyperthyroidism there is a burning of fats, a rapid oxidation, and these people literally destroy their own cells. The thyroid gland bears relation to the elimination of nitrogen. Nitrogen, if retained, leads to tetany. Creatin and creatinin have almost the same chemical constitution as the thyroid secretion. There is, however, no positive determining factor to tell what is the controlling influence in thyroid action. We do not all agree as to methods, but the important point is that the mortality has been brought down

## MEDICAL SOCIETY OF THE STATE OF PENNSYLVANIA

Sixty-Ninth Annual Meeting, held in Harrisburg, Sept. 22-23, 1919

(Continued from page 1580)

### Prevention of Communicable Respiratory Diseases Based on Observations in U. S. Army Camps

DR. ORLANDO H. PETTY, Philadelphia: Personal hygiene was taught on all occasions. Special emphasis was placed on droplet infection, and the men soon learned to report their comrades for isolation on the evidence of acute colds. In the prevention of infection, the properly fitted gauze mask, exchanged when soiled, was probably the most valuable preventive agent. The value of bacterins in the prevention of communicable respiratory diseases has not been proved. Prevention is accomplished, not by the injection of polyvalent preventives, but by the tireless enforcement of the difficult procedures of sanitation, hygiene and preventive medicine.

#### DISCUSSION

DR. M. HOWARD FUSSELL, Philadelphia: There is no easy road to the prevention of respiratory diseases. So far as we know, the diseases which we can prevent most readily are smallpox, typhoid and, possibly, pneumonia. If we should promptly isolate cases of ordinary infectious colds we would greatly limit cases of respiratory disease. Dr. Petty's stand regarding bacterins is extremely sane. I myself am not sure that the bacterins are entirely harmless.

DR. CHARLES A. E. COGMAN, Philadelphia: The sanitation of the army camps is applicable to civil practice. The value of bacterins is yet to be demonstrated. The mask which seemed to us the most valuable was the ordinary chloroform inhaler, placed over the nose and fastened with elastic bands about the ears. Moistened with mercuric chlorid solution, it was efficacious.

DR. ARTHUR C. MORGAN, Philadelphia: The remarkable advance in the medical work of the army, made between 1898 and 1919, is not due to the regular army men alone, but in large part to the reserve corps men. The young members of medical detachments received lessons which should make them 100 per cent. efficient health officers. I would recommend that for a health officer a good young fellow be selected who has had his training in the medical department of the army.

DR. C. P. BROWN, Ambler: While it is not definitely proved that the pneumococcus vaccine is the answer to pneumonia, certainly it is entitled to much more extended use than it has received.

### Value of Early Diagnosis of Pleural Effusions

DR. S. A. SAVITZ, Philadelphia: To my mind, percussion is the dependable presence, and its variation on change in posture is the cardinal sign. Palpation and auscultation are of little value. The frequent use of the aspirating needle is important. An individual with a pleurisy who is discharged too soon, or with a pleurisy unrecognized, undoubtedly has a passive lesion which may become active. Too much emphasis cannot be laid on the importance of keeping such patients under observation for a long time. By doing so, especially in conjunction with the surgeon, tuberculosis will be diminished greatly.

#### DISCUSSION

DR. ARTHUR C. MORGAN, Philadelphia: Pleurisy with or without effusion does not mean the "predi position" to tuberculosis; it means that the patient is really the subject of tuberculosis. I have had remarkable results from auscultation of the chest in pleurisy with effusion.

DR. EDWARD H. FUNK, Philadelphia: That simple puncture is not attended with danger should be emphasized. We had 100 deaths from simple puncture at Camp Wheeler. Necropsy disclosed no other cause of death. Even if all cases of pleurisy are tuberculous, which I think is an overstatement, many cases of pleurisy can be tapped and the patient be healthy for a long series of years.

DR. CHARLES A. E. COGMAN, Philadelphia: The differential diagnosis between some pneumonias and pleurisies is extremely difficult. In diagnosis too great dependence must not be placed on one method. Percussion and auscultation

are most valuable, and at times it is essential to use the needle, the Roentgen ray and the fluoroscope.

DR. W. G. TURNBULL, Cresson: In tuberculosis, patients have developed empyema, not as a necessary part of pulmonary tuberculosis, but as the result of unwise aspirations of pleural effusions.

### Pulmonary Syphilis

DR. ELMER H. FUNK, Philadelphia: Syphilis of the lung commonly manifests itself as a gumma, usually near the root or in the lower lobes. These gummas may occasionally break down and form small cavities, or be converted into fibrous tissue, and the resulting contraction may distort the lung and give rise to bronchiectasis. The gumma may be latent and be found at necropsy. Syphilis of the lung occurs more often than the older observers would have us believe, and than postmortem evidence indicates. I believe that patients have perished from pulmonary syphilis improperly treated under a mistaken diagnosis of pulmonary tuberculosis or other condition.

#### DISCUSSION

DR. EDWARD J. G. BEARDSLEY, Philadelphia: In a case of seemingly advanced tuberculosis, sputum examinations had been negative for tubercle bacilli. The patient's blood gave a +++ + Wassermann test. On the forty-second sputum examination, myriads of acid fast bacilli were found.

DR. WILLIAM A. WOMER, New Castle: In a case in which repeated examinations for bacilli in the sputum were negative a history of chancre was obtained. After thorough antisyphilitic treatment, the condition cleared up, and the man today seems to be in perfect health.

### Cardiovascular Phenomena Associated with War Neuroses

DR. GEORGE MORRIS PIERSON, Philadelphia: Medical officers are in accord that chronic organic disease of the heart played an inconspicuous rôle among the medical casualties of the American Expeditionary Forces. Of 3,752 medical cases in one base hospital, only twenty-four were definite examples of organic heart disease. This incidence, however, by no means represented the number of apparently healthy soldiers in whom, from time to time, systolic murmurs were observed. Approximately 4,000,000 soldiers were examined by the cardiovascular boards, and about 38 per cent. of all rejections for physical disability in all the drafts was on account of circulatory disease. The weight of evidence strongly suggests that the symptoms of effort syndrome depend on a neurosis. An opinion held by neurologists is that effort syndrome is a neurosis in which cardiovascular manifestations predominate. It would seem justifiable, therefore, to regard effort syndrome as the result of the reaction of an unstable nervous mechanism to anxiety and overstrain, producing a neurosis associated with cardiovascular symptoms. After the signing of the armistice, effort syndrome was difficult to discover.

### Significance of Heart Murmurs

DR. EDWARD H. GOODMAN, Philadelphia: Murmurs are largely useful as a peg on which to hang a diagnosis. As an index of the degree of valve damage, they are worthless prognostically, except in mitral stenosis. Diastolic murmurs are always serious murmurs. Unless one recognizes the fact that the murmur is not always found, and unless one is able to suspect the diagnosis in the absence of murmur, many cases of stenosis will be pronounced sound. With systolic murmurs, diagnosis is more difficult. Many practitioners are stigmatizing individuals with such murmurs with the diagnosis of valvular heart disease and thereby condemning them to a life of semi-invalidism. While it is important to distinguish between the innocent systolic murmurs and those which are not, the greatest importance here as in diastolic murmurs attaches to the behavior of the muscle. By an estimation of its efficiency we shall regard murmurs in their true light.

#### DISCUSSION

DR. A. E. ROUSSEL, Philadelphia: Systolic murmurs have a relatively greater importance after than during the second and third decades of life. Presystolic and diastolic murmurs are important because they denote heart changes rendering

the subjects poor risks. No one has a right to call a murmur organic unless there are signs of compensatory hypertrophy. In mitral stenosis the amyloid nitrite test is of particular value. In the suspected case the patient breaks a capsule of amyloid nitrite and passes it in front of his face. In many instances the murmur comes out, whereas before it had been only suspected.

DR. CHARLES REA, York: In the difficulty of determining the presence of a presystolic murmur a helpful principle to me is that when there is uncertainty of just when the first sound begins, a presystolic murmur is present.

#### AMERICAN PUBLIC HEALTH ASSOCIATION

Forty-Seventh Annual Meeting, held in New Orleans, Oct. 27-30, 1919

(Concluded from page 1548)

##### Cure of Infected Persons as a Factor in Malaria Control

DR. C. C. BASS, New Orleans: Malaria may be eradicated either by destroying the mosquitoes capable of transmitting the infection or by destroying the infection in man, the only other host of malaria parasites. Theoretically, it would be possible to eliminate malaria from a region by disinfecting all infected persons in the region. This would result regardless of the abundance of mosquitoes, if all infected persons were cured. There would then be no malaria for mosquitoes to transmit. Practically all physicians relieve their patients of active clinical symptoms of malaria, but few actually disinfect their patients. In the experiments in Mississippi, the data obtained indicate that between 50.77 and 68.86 per cent. of all persons who have attacks of malaria during a given year have relapses and not new infections. The standard, practical method of treating and disinfecting persons who have malaria, adopted in the Mississippi experiments, is: under 1 year of age,  $\frac{1}{2}$  grain of quinin; 1 year, 1 grain; 2 years, 2 grains; 3 and 4 years, 3 grains; 5, 6 and 7 years, 4 grains; 8, 9 and 10 years, 6 grains; 11, 12, 13 and 14 years, 8 grains; 15 years and older, 10 grains. This treatment appears to disinfect more than 90 per cent. of patients.

If all persons who know they have malaria and treat themselves should employ a method of treatment which disinfects them, and if those who are treated by physicians are treated so as to disinfect them, we would have, theoretically, 55 per cent. of reduction in the prevalence of malaria each year. The only way by which all persons who have malaria in a given locality can be found is by intensive malaria surveys. Those who give positive histories during the previous twelve months should be considered probably still infected and therefore should take the necessary treatment to disinfect them. Experiments in malaria control were conducted in Bolivar County, Miss., under the auspices of the Mississippi State Board of Health, as a result of which, treatment and methods of carrying out this more or less intensive method of malaria control were worked out. The reduction indicated by a resurvey of a large part of an area of 100 square miles just one year from the first survey was 89.9 per cent.

##### Present Methods of Anopheles Drainage and Anopheles Control

MR. J. A. LEPRINCE, Memphis, Tenn.: It is to be hoped that, within a few years, communities desirous of freedom from malaria and the mosquito pest will install adequate permanent drainage systems. Where conditions are favorable, the drainage system should be planned to eliminate the necessity of supplementary measures, such as oiling and maintenance of open ditches. In many localities, effective screening of houses is the best preliminary procedure for malaria control; but it would be more economical and satisfactory to install permanent drainage systems and obtain permanent benefits at a reasonable cost.

##### Mosquito Work of the Bureau of Entomology

DR. D. L. VAN DINE, Mound, La.: In the summer of 1913, a project was undertaken by the bureau dealing particularly with the mosquitoes concerned in the transmission of malaria

in this country. A laboratory for the purposes of this investigation was established in the delta region of the Mississippi valley at Mound, La., where the anopheles mosquitoes and malaria are prevalent. One result of this project has been given in the conclusions on the loss in crop returns from malaria. The amount lost in crop returns is equivalent to a direct annual tax of \$3.88 per acre on the land under cultivation. It is estimated that the total average cost per acre to bring permanent swamp land into cultivation is \$17. The screening of dwellings has been an important factor in the reduction of malaria when the screening work has been done thoroughly and proper use has been made of the protection afforded. Dr. Howard estimates that the people of the United States spend \$10,000,000 every year for screening against flies and mosquitoes, and concludes that if this enormous expense is at all necessary, it should be done thoroughly. The individual use of mosquito bar over beds is a more promising protection against malaria infection than screening the house among the tenants. One careless member in a household will offset the care taken by all other members in a screened house; but the mosquito bar protects the individual. It also implies no reconstruction of buildings, and places no restrictions on the movement of individuals from point to point.

##### Resolutions

Resolutions were adopted opposing legislation prohibiting the use of dogs for scientific purposes; urging the appointment of committees in the several countries represented in the association by their federal governments to study existing methods for the preservation and improvement of health of the people, such as hospital facilities, public health activities, charitable institutions and compulsory health insurance, with the view of reporting some adequate plan for coordinating the already existing activities and for the existing application of scientific and social agencies for accomplishing the desired ends; urging the enactment of legislation which will increase substantially the pay of the officers of the U. S. Public Health Service; to set a national medical examination week during May, 1920; to cooperate with the U. S. Public Health Service in carrying out the provisions of the act to provide for the care of persons afflicted with leprosy and to prevent the spread of leprosy in the United States; to assure for the future a national health program and a coordinated federal health administration; to appoint a committee to study the needs of the national health situation and to confer with other agencies having the same object in view, and to secure the appointment of a special congressional commission for a survey of federal health activities along the general lines of the France-Denison resolution; to commend the work of the U. S. Army and Navy in combating venereal diseases during the war; and, in view of the importance of thorough eradication measures for the control of plague among the ground squirrels of the Pacific Slope, urging Congress to appropriate \$1,000,000 to be expended by the U. S. Public Health Service in this work.

##### Influenza Mortality Among Wage Earners and Their Families

LEE K. FRANKEL and LEE I. DUBLIN, New York: White rather than colored people were attacked by the pandemic of influenza, and the young rather than the old, a reversal of usual conditions. The 70,729 deaths included in this study were largely concentrated during October, November and December, 1918. October alone showed 34,471 deaths, or nearly one half of all the deaths in the entire period. In October, the death rate was 3,395 per hundred thousand; in November, 1,035, the figures declining rapidly thereafter, with a slight halt, however, in February and March. During the period 1911 to 1917, considering these seven years as a norm, there was an annual influenza pneumonia rate of 125 per hundred thousand. On the basis of the rate for the year ending September, 1918, there would have been only 13,891 deaths, as against the 70,729 that actually occurred. From 1911 to 1917, the mortality rate showed an excess of 18 per cent. males over females among white lives, and of 30 per cent. among colored lives. For the period from October, 1918, to June, 1919, the excess of males over females among the

whites was only 3 per cent., and there was no excess at all among colored lives. From 1911 to 1917, influenza pneumonia showed an excess of 72 per cent colored males over white males, and of 50 per cent colored females over white females. During the period of the epidemic, the situation was reversed. The colored males showed a rate of 1,522 per hundred thousand, as compared with a rate of 1,844 per hundred thousand for white males.

**Acidosis During Starvation.**—In his studies on acidosis during starvation, Asada used Van Slyke and Cullen's method for plasma bicarbonate determinations. On the first and second days of starvation the plasma bicarbonate in the arterial blood of rabbits showed a drop from the normal value. On the third day of the fast there was a second rather sharp fall, after which there was no change until the fourth day. On the tenth fasting day there occurred a third rather moderate fall, after which no further marked change took place until the end of life. Generally, the arterial plasma of rabbits has 55 volume per cent. of carbon dioxide, which may fall to about 5 volume per cent. the second day of the fast, to about 6 volume per cent. the third day, and to 7 volume per cent. the amount of carbon dioxide in the arterial plasma is influenced considerably by the condition of the animals. After one extraction of the arterial blood from the carotid, the acidosis seems to be considerably increased, because by the second extraction the amount of carbon dioxide is always less than that of the first extraction on the same fasting day. In the moribund rabbit a contrary result is obtained, i. e., the amount of carbon dioxide in the arterial plasma does not decrease but increases. This is also the case in the arterial plasma immediately after death. In Asada's opinion this increase is not due to bicarbonate, but rather to an accumulation of carbon dioxide caused by the failure of the circulatory as well as the respiratory functions. The rate of the loss of body weight is affected by wide individual fluctuations which may or may not be influenced by the blood extraction. The animals lived in the state of an absolute fast for from eleven to twenty days and at the end of life had lost from 27.69 to 52.37 per cent. of their initial weight. Microscopically, many organs showed cloudy swelling, vacuolization and

atrophy. There was invariably an intensive congestion in every glandular organ, but fatty degeneration was found almost in no case.

**Studies on Extract of Lung.**—The toxic action of lung extract and means for neutralizing this action were made the objects of Kakinuma's investigations. He found that intravenous injection of beef lung extract into guinea pigs invariably causes dyspnea and, in a majority of cases, convulsions as well. The minimal lethal dose of the beef lung extract for guinea-pigs on intravenous inoculation varied from 0.02 to 0.15 c.c. per 100 gm. of body weight. Glucose destroys the toxicity of lung extracts. Thus 1.0 c.c. of 10 per cent. glucose mixed with the minimal lethal dose of lung extract renders the latter inert. Hypodermic injection of epinephrin immediately before an intravenous lethal dose of lung extract was protective in effect. Intravenous injection of lung extract caused a slight increase in the blood sugar of rabbits.

**Vital Staining in Acidosis.**—The vital staining method by injection of lithium carmin solution into the ear vein of living animals was studied by Asada. He found that vital staining cannot be accomplished by a single intravenous or intraperitoneal injection of lithium carmin in subtoxic doses in a healthy animal. If, however, an acidosis be first established, a single injection of the dye will give a satisfactory stain. In animals which have been vitally stained, an actual decrease in plasma bicarbonate occurs. Hence, the conclusion is drawn that it is incorrect to predicate the existence of specific stain taking substances or granula in the cells. Rather, vital staining with lithium carmin is due to the development of an acidosis which so alters the function of the body cells that the diffusing dye is deposited in the granula. This deposition corresponds to the precipitation from colloidal solution of the dye when the normally alkaline solution is made acid *in vitro*.

**Studies in Secondary Traumatic Shock.**—Experiments were made by Gasser and his associates to determine the rôle that the absolute volume of the blood plays in the reduction of the effective volume in shock, and to evaluate the possible modes by which such a reduction might be brought about. Four forms of experimental shock were studied, namely, those produced by injections of massive doses of epinephrin; by clamping the vena cava above the liver for a period of three hours so that the general arterial pressure was 30 to 40 mm. of mercury; by clamping the abdominal aorta above the celiac axis for a period of three hours so that the distal pressure was 30 mm. of mercury and by exposure and manipulation of the intestines. The blood volume was found to be decreased in all forms of experimental shock studied and after all grades of damage. Red cell counts or hemoglobin determinations were of value in indicating blood volume only when no absolute stasis occurred and when no corpuscles were jammed in the capillaries. The effective volume of the blood may be reduced in the following ways: 1. By decrease in the volume of the blood as the result of: (a) transudation of plasma; (b) transudation of plasma and jamming of the corpuscles in the capillaries and venules, or the latter combined, with (c) absolute stasis in some part of the vascular system, and (d) hemorrhage into tissue, especially into the lumen of the intestines. 2. By dilatation of the capillaries and small veins with greatly decreased slowing of the circulation. This is always attended by some loss of plasma, but the latter may be relatively inconsiderable. The transudation of plasma is greatly opposed by the injection of 4 c.c. per kilogram of 20 per cent. acacia before traumatization. The mechanism of action is believed to be due mainly to the antagonism to filtration by the resulting increase in the osmotic pressure of the plasma colloids.

**Catalases of Blood During Anesthesia.**—Estimations of the catalases of the blood were made by Reimann and Becker before and after anesthesia. They were decreased in 65 per cent. of the cases and increased in 35 per cent. The methods for the determination of catalases have been criticised and the opinion expressed that they are inaccurate, and that no deductions can be drawn from them. The authors' results before and after anesthesia come within the experimental error. The functions of catalases in the body are unknown.

**Control of Pylorus.**—Evidence is presented by Luckhardt and others on the basis of experimental work on man and dog that there is a correlation between marked motor activity of the stomach (either as tonus changes or peristalsis) and an inhibition in tone of the pyloric sphincter. The intragastric contents issuing from the duodenostomy were usually acidic toward phenolphthalein but rarely showed presence of free acidity to dimethylamidoazobenzene or congo red. It seems probable to the authors that even under normal conditions the chemical control has been greatly overemphasized to the exclusion of other possibilities. Another important finding was the fact that vomiting is more easily induced by irritating the duodenal mucosa than by an irritation of the gastric mucosa.

**Effect of Surgical Procedures on Metabolites.**—A certain few surgical patients show uncompensated acidosis after anesthesia and operation. These studies were made by Reimann and Hartman to show, if possible, changes in the nitrogen metabolism. About ninety patients were observed. The urinary acidity was increased very definitely in every case until in some instances, almost half normal acid was excreted. The blood urea and nonprotein nitrogen were increased in every case. In the urine the general tendency of the ammonia was to increase, whereas the excretion of urea was either increased or diminished, with apparently no relation between the urea in the urine and in the blood. The question of retention or increased production suggested itself in the case of the increase in the blood urea and nonprotein nitrogen.

**Experimental Surgical Shock.**—All the more important methods of treating under standard experimental conditions a state that exhibits the clinical signs of surgical shock which is produced by the exposure of the abdominal viscera of a dog, under a constant ether anesthesia, until blood pressure decreases to the desired level, were tested by Mann. The therapeutic measures were tested after the viscera had been replaced and after determining the curve of the blood pressure. The value of the classical use of heat as well as the effect of cold in helping to produce the condition, was corroborated experimentally. Experimentally, rebreathing was not found to be of importance. None of the drugs usually employed in the treatment of shock were found to be very effective. The best results in the treatment of experimental shock were obtained by the injection of fluid media. The data of the experiments justify the conclusion that none of the artificial solutions give such good results as the use of blood. The so-called colloidal solutions and their various modifications give better results than physiologic sodium chloride solution, but their potency is certainly not equal to blood or blood serum and occasionally they might be harmful.

**Increased Intracranial Pressure and Elevation of Body Temperature.**—The results obtained by Moore in her experiments support the view that temperature regulation is dependent on physicochemical factors without the intervention of hypothetical "heat centers." The rise in body temperature and other symptoms attending increased intracranial pressure correspond so closely to those of "heat puncture" in which there is generally sufficient brain lesion to cause an increase in pressure in the brain cavity, and those of clinical brain lesions, that it seems possible to apply the same explanation to each of these cases. Moore thinks the rise in temperature which is reported by advocates of the "heat center" theory as being due to "heat puncture" can be explained in a like manner, as can also the rise obtained in 22 per cent. of her punctures and the fatal symptoms in a number of these and other cases.

**Gum Acacia in Secondary Traumatic Shock.**—Experiments were made by Gasser and Erlanger which had as their first object a detailed inquiry into the mechanism of why a concentrated solution of gum acacia tends to prevent the concentration of the blood which otherwise practically invariably develops while shock is being induced. When glucose in 18 per cent. solution is injected into the circulation of a normal animal the blood comes into osmotic equilibrium with the tissues within the first minute or two, the average

maximum dilution amounts to but half of the theoretical maximum, and the blood regains its normal concentration within from five to forty-five minutes. When gum acacia in a concentrated solution is injected the average maximum dilution of 41.7 per cent. of the theoretical maximum is attained within from twenty-five to fifty minutes; the decline of the blood volume to normal requires from two and one half to six or more hours. When the concentrated acacia is immediately followed by the glucose the maximum dilution is quickly attained and is much greater than that resulting from the injection of either of the two substances alone. The dilution is well maintained. Comparable results are obtained in animals in shock when a strong solution of gum acacia is followed by a solution of sodium bicarbonate that is isotonic to 18 per cent. glucose. With such a combination of solutions given in appropriate amounts, the blood volume, the blood pressure and the reserve alkali of animals in shock often can be brought to normal and held there for the usual duration of an experiment. Yet such animals, as well as shocked animals treated with other combinations of gum acacia and carbonate or bicarbonate, often died within twenty-four hours.

**Treatment of Traumatic Shock.**—Of animals traumatized by holding the arterial pressure down to 40 mm. Hg for two hours and fifteen minutes by partially occluding the inferior vena, 48 per cent. die within forty-eight hours. When treated with 6 per cent. gum in 2 per cent. sodium bicarbonate, 12 c.c. per kilogram of body weight, 45 per cent. die within forty-eight hours. When treated with 25 per cent. gum followed by 5 per cent. sodium bicarbonate, of each 5 c.c. per kilogram of body weight, 56 per cent. die within forty-eight hours. When treated with 25 per cent. gum followed by 18 per cent. glucose, of each 5 c.c. per kilogram of body weight, 45 per cent. die within forty-eight hours. When treated with 25 per cent. gum in 18 per cent. glucose, 5 c.c. per kilogram of body weight and hour, 24 per cent. die within forty-eight hours. Not only is the death rate increased by the third treatment, but death occurs earlier. These results are taken to indicate that bicarbonate and the high viscosity of a strong gum solution are somewhat harmful, at least, in traumatized animals; that the harmfulness of the strong viscous gum can be avoided, in part, through the osmotic action of hypertonic glucose subsequently injected, but not by bicarbonate; and that when the hypertonic gum and the hypertonic glucose are given simultaneously and slowly so as to avoid altogether the period during which the high viscosity of the gum is hampering the circulation, a maximum saving of life can be effected. The beneficial results presumably are due to the internal transfusion effected by the hypertonic solutions, to the maintenance of the increased blood volume through the colloidal and possibly other properties of the gum acacia, to the action of the hypertonic solution on the heart and blood vessels, and to the specific action of glucose on nutrition in general and on that of the heart muscle in particular.

**Hypertonic Gum Glucose in Secondary Traumatic Shock.**—According to these observations made by Erlanger and Gasser the use of hypertonic gum glucose solution is not contraindicated in the treatment of shock even when it is complicated by dangerous hemorrhage. The fact that the hypertonic gum glucose solution does not produce the recovery of animals from the effect of a hemorrhage that is apt to result fatally furnishes another proof of the innocuousness of this solution.

**Effect of Oxygen on Blood Volume in Lung Edema.** The continuous administration of oxygen to goats passed with chloroform did not inhibit the concentration of the blood. The percentage saturation of the hemoglobin with oxygen was normal even after a considerable concentration of the blood had occurred. The concentration of the blood is not caused by the imbibition of water by the tissue as the result of oxygen want. Wilson and Goldschmidt conclude, therefore, that the loss of water from the blood is due to the development of the edema of the lungs.

**Sympathetic Nervous Control of Thyroid Function.**—In one series of five rabbits given daily injections of about 10

mg of cocaine per kilogram body weight for eight days there was observed no change whatever in the microscopic appearance of the thyroid glands. A second series of three rabbits was run, each animal receiving from five to ten injections a day for eleven days, and again no changes in the glands were observed. Neither did the rate of growth or general appearance and behavior of the animals indicate any lasting results from the use of the drug. Since the strength or effectiveness of the impulses over the sympathetic fibers should have been greatly augmented by the continued use of cocaine producing symptoms of thyroid hyperactivity and morphologic changes in the gland, Mills concludes that the evidence from these experiments contributes to the indication of a lack of secretory function of the sympathetic fibers to the thyroid gland.

**Streptococcus Hemolyticus Carriers.**—Bacteriologic examination of a considerable number of excised tonsils has convinced Bryan of the futility of local treatment in attempting to eradicate *Streptococcus hemolyticus* from the tonsils. While it may be possible to sterilize the surface of the tonsil and remove the crypts there will nevertheless remain a number of deep crypts that are inaccessible to any chemical means of disinfection. Granting that all the crypts were accessible there still remains the possibility of still further disease in the deeper and more inaccessible parts of the gland. Therefore, all local treatment after the cultures show the presence of *S. hemolyticus* is not only deceptive but it is a waste of time. A complete enucleation of the tonsil is necessary. Any tonsillar tissue remaining after an incomplete operation harbors the organism and the patient continues to be a carrier.

**Bacteriology of Streptococcus Hemolyticus.**—In this paper are presented the facts obtained in a biologic study of *S.*

*hemolyticus*. By the reaction of agglutination four distinct immunologic types and a certain number of unclassifiable strains have been discovered among the 125 strains studied by Avery and his associates, Dochez and Lancefield. Individuals of the same type are closely related to one another immunologically, and the different types can be distinguished sharply one from the other. In addition to the four types, study of the reactions of which has been completed, there are in addition two other types, investigation of which is as yet incomplete. The authors found that by the immunization of sheep, a highly specific agglutinating serum is obtained, but that the serum produced from rabbits is not so specific and may show a wider range of crossing. Rabbit serums showing nonspecific cross agglutination reactions, in general fail to manifest corresponding cross protection reactions. Whenever it has been possible to raise the animal virulence of strains of *S. hemolyticus*, the evidence obtained from the agglutination tests has been confirmed by that gained from the protection reaction. In all instances in which this has been done, the one reaction has corroborated the findings of the other. The performance of reliable protection tests has been made possible by the production of sufficiently high titer antistreptococcus serum, and by the possibility of raising the animal virulence of a certain number of strains to a high degree.

This work has cleared up a number of points about *S. hemolyticus* which have been in dispute for many years. In the first place, *S. hemolyticus* of human origin is not a unit type, as was previously supposed, but probably consists of a number of types, at least four of which have been identified. Previous investigators have stated that freshly isolated human strains change their antigenic properties on animal passage, and that the latter procedure for the development of animal virulence gives a common antigenic character to all strains. The authors have found no evidence to support this contention—in fact, immune serums produced with human strains that have never been passed through animals afford a high degree of protection against strains that have received many animal passages. In addition, the antigenic differences between strains of *S. hemolyticus* which have been passed through animals are quite as distinct as those between strains which have not been so passed. The types of *S. hemolyticus* studied have been obtained almost exclusively from the respiratory tract and from a limited source of supply, and there is some reason to believe that those which produce cellulitis, erysipelas and septicemia may be of somewhat different character.

**Streptococcus Carriers in the Army.**—The available evidence presented by Blake would seem to indicate that the widespread streptococcus infections that have occurred in the army have, in very large part, been due to invasion of virulent streptococci in individuals rendered susceptible by predisposing diseases, chiefly measles, influenza and pneumococcus pneumonia through contact infection, either direct or indirect, and that autogenous infection has played an insignificant rôle in the production of these streptococcus infections. Their truly epidemic character and their strikingly selective incidence, Blake says, would seem to admit of no other interpretation.

**Nasal Sinus Disease in Infants.**—In all cases of infectious arthritis in infants and young children studied by Dean and Armstrong during the last eighteen months, the source of infection has been in the upper respiratory tract, in the nasal sinuses, or faucal or pharyngeal tonsils. In no case were the teeth, the gallbladder, appendix or the lingual tonsil the source of infection. The most common symptom has been sneezing. A condition characterized by listlessness, poor appetite, underweight, poor color, so commonly caused by diseased tonsils, which persists after the removal of the tonsils and adenoids, with negative report from the pediatrician so far as a systemic condition is concerned, is very suspicious of sinus disease. The diagnosis of sinus disease is very difficult. It is only by repeated examinations of the nose and careful study of the case from every angle, that a proper diagnosis can be made. The most important thing in the treatment of nasal sinus disease in infants and young

children is the removal of the adenoids and diseased tonsils, if present.

**Complete Extirpation of Larynx for Carcinoma.**—Hoshino has observed forty-one cases of laryngeal carcinoma, in sixteen of which a complete extirpation of the larynx was done, most often under local anesthesia. Hoshino describes the operation in detail. He says that better results are obtained when there are two flaps in the skin incision, each having its stalk in the side of the neck, than when there is only one large flap with one base. It is more successful to section the trachea below the larynx and arrange for safe respiration before removing the tumor. The pharyngeal wound is sutured with a double suture, but the mucous membrane is approximated in the submucous layer. Between the main laryngeal wound and the opening of the trachea should be a bridge of intact skin, as Grueck suggested. For the purpose of conversation after extirpation, a simple rubber tube is used by Hoshino, one end being introduced into the trachea while the other end is held in the mouth. This tube enables the patient to whisper with the help of his lips, teeth, tongue, palate and pharyngeal muscles. The tube is much easier to use than the modern complicated artificial larynx, and is better liked by the patient. The percentage of permanent cures in Hoshino's sixteen cases was 50, while there was also 50 per cent. recurrence, with no mortality during or following the operation.

**Conserving Mucoperiosteum in Maxilla Resection.**—In the case cited by Hoshino and Ota a tumor about the size of a hen's egg was situated on the left upper alveolar process. The tumor was chiseled away from the healthy bone, thus leaving only the mucoperiosteum for the floor and lateral wall of the nasal cavity. It was necessary to remove the anterior part of the alveolar process from the incisor tooth on the right side to the first molar tooth on the left side and also the anterior half of the hard palate. In addition, one third of the median wall of the antrum of Highmore was removed, but the mucosa of the sinus was not disturbed. The oral mucous membrane on the remaining portion of the hard palate, and that on the upper lip was loosened and then approximated to the edges of the wound. This left a small wound in the roof of the mouth which had to heal by a process of granulation from the surrounding edges of the mucosa, while the nasal cavity was covered entirely by the mucoperiosteum. The patient recovered in sixteen days without any complications. He is able to talk and to swallow food without any of it passing into the nares.

**Studies on Blood Sugar.**—Experiments made by Hamman and Hirschman showed that in normal persons the administration of a second dose of glucose immediately after the reaction to the first dose produces a much less marked reaction on the blood sugar than did the first dose. These experiments indicate that the mechanism of carbohydrate utilization once stimulated works more efficiently than when called on abruptly to manage large amounts of glucose. Probably to this fact is largely due the better utilization of sugar slowly absorbed, and the almost unlimited power of the body to utilize starch. In diabetics the same difference is observed as in normal persons, although the difference is

not so marked. It was found in testing several patients that they reacted to levulose in the same way that they did to glucose, only that the blood sugar rise was less marked.

**Chronic Benzin Poisoning.**—The symptoms complained of in a case of chronic benzin poisoning are referable almost entirely to the gastro-intestinal tract and the central nervous system. Haden describes them in detail as part of his case report. The factory at which the patient worked was visited. It was found that lithographing rolls were dropped into a trough, six feet long and one foot wide, filled with benzin, and scrubbed clean. About two gallons of benzin evaporated from the trough daily. The room in which the work was done was large, but from the nature of the lithographing inks it had to be closed tightly to prevent the ink from drying. The patient had worked for over a year, five hours daily, at this trough where he was continually inhaling the fumes.

**Reaction of Monkeys to Inoculation of Measles Blood.**—Blood from two early cases of measles in the pre-eruptive and later in the early eruptive stage was injected subcutaneously and intraperitoneally into two monkeys. One animal remained free from symptoms; the other developed a moderate leukopenia and later a slight rash. A portion of the same specimen of measles blood was injected subcutaneously and intramuscularly into two susceptible human volunteers. No symptoms resulted. A specimen of blood from the monkey which subsequently developed a rash was injected into a susceptible volunteer, but produced no symptoms. Normal serum injected into monkeys was followed by a very slight erythema appearing about eight to ten days after injection in four of ten animals. Sellards believes that the weight of evidence in these experiments is against the interpretation of the symptoms in this monkey as representing a reaction to the virus of measles.

**The Syphilitic Prostitute.** Goodman is in charge of the venereal service at Camy Las Casas, Porto Rico, and he here reports (in English) the results of clinical and serologic examination of 791 prostitutes in Porto Rico. His tables show that 139 of the 721 girls were under 17 years of age and 42 per cent. in this group had three or four plus Wassermann reactions; 15 per cent. had active infectious syphilitic manifestations. About 48 per cent. of the total were between 18 and 23 years of age; 50 per cent. of these gave a pronounced Wassermann reaction; 11 per cent. had active genital lesions of syphilis. Of the 147 women between 23 and 27 years of age 45 per cent. were serologically positive, and 11 per cent. had dangerous syphilitic manifestations. Only sixty-four women were in the age group 28 to 32 years, and 43 per cent. of these had three or four plus Wassermann reactions but only 4 per cent. had active lesions. In the three five-year periods above this, from 33 to 37, 38 to 42 and 42 to 56, thirty-six, twelve and five women of a positive Wassermann reaction was obtained in 38, 33 and 25 per cent. respectively. The series of prostitutes studied included 422 whites, 304 mulattoes and 65 negroes, but the proportion of positive Wassermann reactions was about 47 per cent. in each group. In the ratio of active syphilitic lesions, however, the whites gave 10 per cent., the mulattoes 13 per cent. and the negroes only 3 per cent. with infectious syphilitic manifestations.

 \*Treatment of "M" in Tuberculosis. R. W. Allen.—p. 70.  
 Allen's Report on Tuberculosis Subjects. B. Hudson.—p. 174.

**Tuberculin Therapy.**—Allen took several strains of living human tubercle bacilli, treated them carefully with various solvents for the fats and waxes, dried and weighed them and so injected them to the very slow action of dilute hydrogen peroxid until only a slight apparently insoluble residue was left. After careful neutralization this solution was diluted with physiologic sodium chloride solution containing 0.3 per cent. tricesoid until 1 c.c. contained 20 mg. of the original dry bacilli. By the addition to this of an equal bulk of tuberculin A. F. (albumose free) tuberculin "M" is constituted. It accordingly contains (1) any little exotoxin which the tubercle bacilli may form growing in a protein

free medium; (2) any endotoxin liberated by the autolysis of dead bacilli; (3) the broken down protoplasm formed by this autolysis; (4) bacillary protoplasm and endotoxin in considerable amount after lysis, oxidation and hydrolysis. It contains no products resulting from the action of the bacilli and protein nutrients, i. e., no non-specific toxins which may give rise to considerable constitutional reactions, while the bulk of the specific toxins have been subjected to oxidation and hydrolysis as must naturally occur in the body prior to the elaboration of specific anti-endotoxins. This tuberculin is, therefore, practically "atoxic" or "detoxicated," and can, therefore, claim precedence as such to any Thomson's detoxicated vaccines. Thus far Allen has given several hundred doses varying from 0.0001 c.c. to 1.0 c.c. in chronic and subacute cases, and has never seen any constitutional or general reaction result from a dosage of less than 0.4 c.c. other than a very slight feeling of malaise coming on within twenty-four hours. In every case he has been able to find a dosage, usually varying between 0.0001 c.c. and 0.001 c.c., which excites that mild degree of "focal" reaction which Allen considers as a highly desirable evidence of immunizing response, i. e., slight exacerbation of the signs and symptoms usually occurring within eight to twenty-four hours and thereafter passing away rapidly; in every case there has been steady improvement in the clinical signs and symptoms; in each case of completed treatment Allen has so far apparently induced the total disappearance of the tubercle bacilli; in one case, wherein for various reasons a complete course of treatment has been thrice interrupted, the tubercle bacilli, after having disappeared, have reappeared in about three months' time, again to disappear as tuberculin treatment was resumed. In view of these conclusions Allen feels justified in claiming after an experience of various tuberculins extending over nearly fifteen years, that in tuberculin "M" he has succeeded in elaborating a tuberculin which (1) is perfectly safe to use, being practically devoid of unaltered toxins; (2) which undoubtedly possesses power of inciting the formation within the body of the various antibodies necessary for the destruction of the invaders; and (3) which has an antigenic value far superior to any other tuberculin so far produced. For these reasons it is peculiarly adapted for the treatment of dispensary cases and of all such as are not resident in any institution. A safe initial dosage for an adult with chronic or subacute tuberculosis is 0.0001 c.c. The administration as regards dosages and intervals must be conducted under the control of observations of the reactions thereby induced; that an ultimate dosage of from 0.4 to 1 c.c. can and should, as a rule, be attained.

**Traumatic Aneurysm of Common Carotid.**—Jamison cites two cases. One was a case of gunshot wound of the neck causing an arteriovenous aneurysm of the left common carotid. The internal vein was enormously distended, having a diameter of 2 inches. There was a communication between it and the internal carotid just below its division. The vein was divided and tied. The common carotid was ligatured in two places and divided between them. The external and internal carotids were ligatured at their origin from the common trunk. The second case was one of gunshot wound of the neck causing a dissecting aneurysm of the left com-

mon carotid artery. The sac of the aneurysm was roughly fusiform, and extended from 1½ inches above the clavicle to somewhere about the level of the lower jaw. The sac was perilously thin, and appeared to consist only of some of the outer coat of the artery. The internal jugular and the common carotid were ligatured. During the process the sac burst spontaneously in its upper part. A swab was pressed on the hole and controlled the bleeding. The tying of the carotid was then finished. The sac entirely overlaid the external and internal carotids, preventing any search for them, so two swabs were placed on the hole in the sac and pressure maintained on them by sewing the inner edge of the carotid sheath firmly to the edge of the fascia covering the sternocleidomastoid. This proceeding stopped the hemorrhage and the wound was closed. The wound was reopened five days later and the swabs removed. The sac had been obliterated entirely and no hemorrhage occurred. The wound was reclosed. Both patients were young men and made uninterrupted recoveries.

**Traumatic Rupture of Subclavian Artery.**—In this case the rupture of the artery was caused by the pole end of a hoat hook which was pressed against the chest beneath the left clavicle. An operation was done at once. The proximal end of the artery was clamped. The distal end could not be found. The patient was very restless and would not keep his arm quiet. Further operative intervention was deferred until the patient's strength would permit it. He died on the ninth day from exhaustion. At the postmortem the subclavian artery was found completely severed, the distal end was full of firm clot. The vein was not torn. It is Fitzwilliams' opinion that this man's life might have been saved if he had been more reasonable and more amenable to treatment, in spite of the severe injuries he had sustained.

**Treatment of Incipient Mental Disease.**—Jones urges the establishment of psychiatric clinics because they would help to educate the public in matters of health, and certainly in respect of mental health. But besides their educational mission and their great therapeutic utility, they are urgently needed for the better education of medical practitioners and students and for research in psychiatry. Three universities in England have taken this matter into serious consideration.

**Absence of Uterus, etc., with One Large Central Kidney.**—Parakh's patient was 17 years of age. The vulva was perfectly formed, the pubis well covered with hair, and the breasts well developed. There was no vagina, except for about a quarter of an inch. On rectal examination a distinct tumor was felt a little above the closed end of the ill-formed vagina. This was believed to be the uterus, but neither tubes nor ovaries could be felt. On opening the abdomen it was found that the tumor felt from the rectum was a large central kidney, slightly horseshoe shaped, but placed low down. There was no ovary or tube on the right side, but a fairly large sized ovary was present on the left side, with a fallopian tube running down and disappearing into the upper end of the closed vagina. There were several small cysts in connection with the mesentery.

Case of Cholelithotomy: Patient Operates on Himself. J. A. Snel.—p. 454.  
Treatment of Malaria. R. V. Taylor, Jr.—p. 455.

**Anaerobic Conditions for Bacteria Cultures.**—The method described by Miles uses the hydrogen substitution process, and the apparatus consists of a flask fitted with a two hole stopper through one hole of which a thistle tube is inserted to the bottom of the flask, and through the other, a glass tube bent sharply in a short curve at the lower end, is inserted. Granulated zinc, or small squares of the metal, are placed in the flask. The other part of the apparatus is a beaker of about 500 c.c. capacity, half full of liquid petrolatum. Pre-

liminary to use, the flask and beaker are placed in a hot air sterilizer and heated to 150 C. for one hour. The culture of organisms is sowed on a freshly slanted agar tube; the tube is flamed well on the outside and inverted over the short tube end in the beaker of liquid petrolatum. Hydrochloric acid is added to the flask containing the zinc through the thistle tube; it is well to add also some water, and a little copper sulphate to act as a catalyzer. Hydrogen is evolved and in a short time it completely replaces the air in the culture tube. The tube is left in the oil and as many tubes are sowed as are needed. The beaker containing the culture tubes is then incubated, the liquid petrolatum effectually sealing the tubes against the entrance of air. One great advantage this method has over others is that the tubes are readily accessible for examination; they remain anaerobic so long as the open end is not removed from the oily liquid, and can be handled in examination. Further, the volume of air to be displaced is small in each tube and this increases the efficiency of the air substitution. Usually a few minutes will suffice to replace the air with hydrogen.

**Cholelithotomy Performed by Patient.**—Snell reports the case of a Chinese doctor who following an attack of dysentery had a very severe attack of pain in the upper right abdomen. This pain sometimes improved and then became worse. He had not noticed any jaundice or fever. About six months later a swelling appeared over the site of this pain. It was very tender and the patient had fever. The swelling took on the form of an abscess and the patient opened it himself with a knife. Some pus came away and later there was a watery, yellowish discharge which continued for several months. The wound did not heal. Four months later he noticed something dark and stonelike in the wound. On pressure out came two faceted stones. Twenty days later, four more were passed. The gallbladder was removed.

Quinin Metrorrhagia. A. J. Chalmers and R. G. Archibald.—p. 191

**Quinin Metrorrhagia.**—In the case cited by Chalmers and Archibald hemorrhage was due to quinin dihydrochlorid which the patient had been taking for several months as a prophylactic measure against malaria. The quinin was stopped and after a short interval the girl was placed on calcium lactate, 10 grains, twice daily. The metrorrhagia which had been going on for several months quickly ceased. There was, however, a slight recurrence with the next menstrual period, but this was quickly controlled by a few doses of the same mixture. The authors suggest that this line of treatment might be useful for controlling the metrorrhagia of the tropics when excessive.

Prognostic Importance of Tuberculosis of Larynx. S. Thomson.—p. 689.  
Ancylostoma Duodenale, with Pyloric Obstruction. H. K. V. Soltau.—p. 690.

**Serologic Racial Differences.**—The Hirschfelds point out that the highly interesting problem of a possible double origin of the human race has become a question which can be studied by means of serologic methods, and that experiments in immunization deserve to be made use of for the solving of anthropologic questions. A close cooperation would be necessary between anthropologists and serologists, and the researches should be conducted on an international basis. A series of important special researches, such as the examination of various stocks, primitive races, and anthropoid apes, should be begun without delay.

**Meningococcus Carriers.**—According to Embleton and his co-workers, the sites of carrying in the chronic meningococcus carrier are Luschka's tonsil, the fossa of Rosenmüller, the retronasopharyngeal wall, and the faucial tonsils. The anterior and upper parts of the nose and the nasal sinuses are not, as a rule, infected. The presence of lymphoid hypertrophy and nasal obstruction, although it may favor the production of a "chronic carrier," is not necessarily the cause. Meningococcus carriers are divided into two groups: (1) Acute or temporary carriers, those carrying under eight weeks; (2) chronic carriers, those carrying over eight weeks. Acute or temporary carriers remain infectious on an average for twenty-four days; the maximum discharge rate occurs during the third week. Chronic carriers remain infectious on an average for five and a half months, the longest carrying period found was 634 days, or one year and nine months. Eighty per cent of carriers are acute or temporary, 20 per cent chronic. The type of cocci carried rarely changes; in 985 carriers this was only observed to occur once. Treatment of the carrier appears to prolong the carrying period. The meningococcus remains in the "carrying site" until ousted by some other bacterium. A large number of nonagglutinable organisms, otherwise indistinguishable from the meningococcus, are probably altered meningococci. The best method of freeing a meningococcus carrier from infection is Nature, open air and exercise.

**Instability of Red Blood Cells.**—Dreyer and Gardner are convinced that it is not possible to obtain a standard suspension of red cells of constant sensitiveness to hemolysis by means of Rous and Turner's method. Therefore, the use of such suspensions as a standard unchanging material for experimental work or for routine complement fixation tests would necessarily lead to erroneous results.

**Ancylostoma Duodenale Causing Pyloric Obstruction.**—In the case recorded by Soltan pyloric obstruction was the obvious cause of the vomiting and a movable mass to the right of the median line suggested a new growth. A new feature was, however, presented when the patient passed large masses of the ova of *Ancylostoma duodenale*. Though the evacuation was not accompanied by any change in the tumor, the question arose whether there might not be ulceration caused by the ankylostoma with surrounding induration. Clinically, the mass resembled a pyloric cancer in outline, mobility, and situation, but might equally well be due to induration around an ulcer. The abdomen was distended. There was no free fluid in the general peritoneal cavity. Extending from the duodenopyloric junction toward the midline and involving the lesser curvature for about 2½ inches was a large mass firmly adherent to the liver, gall-bladder and pancreas. On the surface, and extending on to the anterior surface of the stomach, were many small, white, irregularly shaped patches resembling in appearance an actinomycetoma. These patches were not raised or hard. No enlarged gland were felt in the mesentery, but the glands in the lesser gastrohepatic omentum were palpable.

In order to relieve this obstruction a posterior gastroenterostomy was performed. The result was most encouraging. The patient improved steadily. The following points are of interest: The onset with dysenteric symptoms and incessant vomiting; the hematemesis two months later, which lasted for three days only and never recurred; the presence of a tumor, probably a direct result of the invasion of the intestinal wall by the hookworm causing obstruction; the character and character of the tumor; the amount of tumor which had to be given before a final negative result was obtained—two doses of 30 grains each are sufficient in most of the cases; in all cases, the similarity between the tumor and that of pernicious anemia; the diminution of weight and the hemocrit index, and marked improvement of the anemia as the result of the relief of the obstruction; the complete absence of eosinophilia.

\*Ligature of Uterus to Rest on Gonorrhoea. W. L. Potter.—p. 211.  
\*The Case of Oculomalingia. R. Pullen.—p. 217

**Influence of Treatment and Rest on Gonorrhoea.**—Potter is convinced that in the treatment of gonorrhoea want of rest and improper treatment, such as early urethrovaseal irrigation, will cause epididymitis to develop. Diet and medicine, he says, are of secondary importance. Prostatic massage and vaccine are not useful.

\*Probably Radical Cure of Mixed Psoriasis of Fourteen Years' Standing. A. Krakowsky.—p. 239.

**Treatment of Retroflexed Uterus.**—The operation of internal shortening of the round ligaments, such as the original Gilliam operation, or one of its modifications, is preferred by Ritchie for the treatment of retroflexed uterus. However, he says he does not deal with every case of simple retroversion or retroflexion by operation, but only with those which give rise to pathologic symptoms. Many uteri are retroverted or flexed to various degrees and give rise to no trouble. These should be left alone.

**Treatment of Salpingitis.**—Windeyer is convinced that many women will be spared from mutilating operations, especially as regards the ovaries, and a not inconsiderable proportion will be given the chance of becoming the mother of one or more children, if when dealing with patients with first attacks, we should wait for a longer period before considering operation and make more use of vaginal celiotomy in the acute "pus cases."

\*Supercute Pulmonary Edema. A. R. Southwood.—p. 284.  
\*Case of Symmetrical Dry Gangrene. E. J. Addison.—p. 285.

**Traumatic Ulceration of Bowel: Problem in Forensic Medicine.**—Ulceration of the ileum with other bodily injuries was found in each of three postmortem examinations made on persons dying insane. According to Lind the injuries in all three cases must have been produced by violence applied to the chest and abdomen, presumably by some one kneeling on the supine victims. On opening the abdominal cavity, in the first case there was found a general peritonitis in early stage, due to the rupture of an ulcer in the ileum, not far from the cecum. The ulcer was recent, solitary, round, about 5 millimeters in diameter and not associated with disease of the intestines. Diligent search for foreign bodies or hatpin stab in the abdominal wall was made with negative result. There was also no bruising of the surrounding parts. In the second case the ulcer was slightly larger than in the first case, otherwise it was similar. In the third case there was an ulcer about the size of a 3-penny piece, with a clean surface, not perforated, apparently ready to commence repair. In the absence of other disease, such as typhoid, tubercle, foreign body, or any other possible factor in ulcer formation, Lind claims that it may reasonably be said that the ulceration is the result of trauma.

### Tubercle, London

October, 1919, 1, No. 1

\*Endopleural Operations in Pulmonary Tuberculosis: Jacobaeus' Method. W. Holmboe.—p. 1.

\*Necessity for a Uniform Standard of Classification in Pulmonary Tuberculosis. J. Guy.—p. 9.  
\*Case of Innocent Tuberculosis. S. Thomson.—p. 13.

**Endopleural Operations in Pulmonary Tuberculosis.**—In Jacobaeus' method a thoracoscope is introduced into the pleural cavity. By means of the galvanocautery pleural adhesions are divided, the hand being guided by the eye. The purpose of these measures is to make it possible to collapse the lung. Holmboe calls attention to the dangers of Jacobaeus' method, such as hemorrhage, emphysema under the skin, elevation of temperature, pleural effusion and fistulas. He has employed the thoracoscope in twenty-seven

cases; among these there were nine in which cauterization appeared to be indicated. In five of these striking improvement was effected, and in two others there was some improvement.

**Necessity for a Uniform Standard of Classification in Pulmonary Tuberculosis.**—The classification used for official purposes in the public health service in Edinburgh is practically similar to that adopted by the sanatorium workers of North America. The basis is the Turban-Gerhardt classification and the time honored stages of 1, 2 and 3 are kept. In addition some indication has to be given of the general condition of the patient, and here Guy has adopted the threefold division of (a) good, (b) moderate and (c) bad. When cases are met with in which the lesion is quiescent, i. e., producing no disturbance, local or constitutional, or in which it has been quiescent long enough to apply the term healed to it, the anatomic classification is given and the word quiescent or healed is added, as stage 1, healed, or stage 2, quiescent. Grave difficulties are encountered when an attempt is made to define borderline cases before they are quite definite enough for stage 1a, or where they do not conform to all the requirements of that class. In order to complete the classification a further addition is required. All cases with a definite syndrome, all cases of hemoptysis, all cases of marasmic babies with a positive skin reaction, Guy says should be classified as stage A, thereby indicating that no local lesion was detected but that the diagnosis depended on constitutional symptoms and history alone. All cases in which the syndrome was incomplete, or where other factors, such as bad home hygiene, came in to confuse the diagnosis, might be classified as stage A suspect, or simply as suspect.

### Bulletin de l'Académie de Médecine, Paris

Oct. 7, 1919, 82, No. 30

- \*Heliotherapy after Pleurisy. P. F. Armand-Delille.—p. 156.
- \*Surgery of the Heart. H. Vaquez.—p. 157.
- \*Alcohol in Cerebrospinal Fluid. E. Lenoble and F. Daniel.—p. 160.
- \*Disease of the Nails. A. Sartory.—p. 162.
- Influenza in Strasbourg. Eugene Folly.—p. 163.
- \*Dispensary for Workers on Munitions. Paul Blum.—p. 165.
- Industrial Capacity of the War Crippled. Gourdon and Dijonnet.—p. 167.

**Preventive Heliotherapy After Serofibrinous Pleurisy.**—Armand-Delille emphasizes that in his experience nothing has proved so effectual as heliotherapy in warding off pulmonary tuberculosis after a spontaneously curable attack of tuberculosis of the serous membranes. This, he reiterates, is the more important because heliotherapy does harm rather than good when pulmonary tuberculosis is once installed. He has applied full sun baths in the treatment of convalescents from pleurisy, both adults and children. The results have been absolutely satisfactory, none having developed tuberculosis in the lungs or elsewhere, and the intervals since have been up to six and seven years. He applies the heliotherapy in the form of extensive sun baths, given progressively under attentive medical surveillance, and advises to keep up this treatment for several years, continuously or intermittently, a complete course at first, and then a supplementary course for a few months each year in favorable conditions in a southern or mountain climate or in the home city during a sunny summer. If the persons who have had serofibrinous pleurisy will do this they can lead otherwise an almost normal life, and, he asserts, need not fear the ulterior development of pulmonary tuberculosis.

**Surgery of the Heart.**—Vaquez reviews the new possibilities in surgery of the heart which recent research and the war experiences have opened up. Tuffier has specified the zones in the heart which it is extrahazardous to touch, and those which will bear handling. If physicians will determine the mechanism of valvular lesions, their pathologic physiology, and will point out those cases which might be remedied by an operation, surgeons could then study out the best means to accomplish this. Valvular insufficiency does not belong in this class as it is the result more of retraction of the columns than of loss of substance. Stenosis of the various valves offers a more promising field, as when aortic stenosis, for example, is inducing a considerable hyper-

trophy of the left heart, or mitral stenosis is causing great dilatation of the auricle. The prognosis then is extremely grave whatever the other symptoms may be. In a case of the kind some years ago the mitral stenosis in the young man had caused such high pressure in the lesser circulation that the second pulmonary sound at the base was so loud that it could be heard at a distance. Vaquez discussed with Tuffier the possibility of operative relief, but they did not dare to assume the risk, and the young man died in a few months with multiple infarcts in the lungs. He queries whether resection of the semilunar valves might not be possible and useful in such a case, assuming that the stenosis is not due to changes in the vessel itself. With mitral stenosis, some other intervention would have to be devised to meet the indications, and several methods can be imagined which might prove effectual, but Vaquez does not specify what those methods might be. The physician must indicate his preferences and it is for the surgeon to realize them. An encouraging element is the notable progress realized in operations on the heart in these years of warfare. Data have been accumulated which should be analyzed from the standpoint of the greater or less tolerance of different points in the heart. Study of such data, supplemented by the findings of persevering research on animals, opens a prospect of interventions on the heart for lesions of a medical type. When that day comes, the surgeon, blamed today for having too much confidence in them, will be censured for having refused the surgical resources at his command to a patient otherwise irremediably doomed.

**Alcohol in the Cerebrospinal Fluid.**—Lenoble found with the Nieuouw test applied repeatedly to eight men that the alcohol content of the blood after ingestion of alcohol varied within a wide range, but that the alcohol content of the cerebrospinal fluid kept at a constant figure. This figure was 0.02 per thousand after ingestion of 325 c.c.; 3 per thousand after 350 c.c.; 4 after 400 c.c. and 6 per thousand after 450 c.c. The proportion of alcohol in the urine is larger but the elimination here is more rapid. In the cerebrospinal fluid an average of ten days is required for its elimination or even longer, up to eighteen days, or more, with much alcohol; eight days seems to be the minimum. Acetone has to be excluded, as this gives a similar response to the Nieuouw test. An assassin claiming to have been intoxicated at the time of the crime can have his statements substantiated or refuted in this way. It has also cleared up the diagnosis in certain obscure morbid conditions, including coma from alcohol intoxication superposed on uremia, epileptic crises, intracranial hemorrhage, etc.

**Diseases of the Nails.**—Sartory examined twenty-one cases of hypertrophy of the nails and a large number of cases of mycoses of the nails, and found that some fungus growth was responsible for the abnormal conditions in every instance. With the trichophyton the nail grows thinner, but with the other fungi involved the nail grows thicker. The cases labeled onychogryphosis all belong therefore in the onychomycosis category.

**Dispensary for Munition Workers.**—Blum describes the work of a dispensary organized for the women workers on munitions. It was open for two hours every evening, and over 900 applicants were recorded each month. It has now 2,000 made-out cards, and has done a most important work in prophylaxis and treatment, especially in pathologic gynecologic conditions, in tuberculosis and pretuberculosis, in anemia, and in venereal diseases. Blum urges the necessity for maintaining this dispensary for women factory workers and founding others, as the women apply to it with greater confidence and in larger number proportionately than to the specialized tuberculosis or venereal disease dispensaries.

### Bulletin Médical, Paris

Sept. 21, 1919, 33, No. 41

- \*The Herd Wassermann Reaction. Jeanne and M. H. —p. 530.
- \*Responsibility of Physician when Weintraub is Infected by Syphilis.—Smolod, G. Thibierge.—p. 537.
- \*Abortion of Syphilitic Fetuses and Lactation.—p. 539.
- Inherited Syphilis of Endocrine System. R. Barthélemy.—p. 541.
- \*Syphilis and Immunity. Clément Simon.—p. 544.

**Interpretation of Wassermann Reaction.**—This entire number of the *Bulletin* is devoted to syphilis. Jeanseime and Bloch reiterate that the physicochemical modification of the serum in syphilitics which yields the Wassermann reaction is nothing specific, and differs completely from the so-called immunity reactions. It is mere chance, they say, that in our climate this modification occurs only in syphilis. The reaction can be induced in normal persons by intravenous injections of neo-arsphenamin, and this may happen also and more readily in syphilitics giving previously a negative reaction. The principle they advocate is that every patient with recent syphilis should be given arsenophamm treatment until the blood gives no Wassermann reaction. Then mercury can be given, but any return of the Wassermann reaction, even without manifest symptoms, calls for renewed vigorous treatment and continuation of the arsenic.

**Responsibility of Physician When Wetnurse Acquires Syphilis from Nursing.**—Thiberge cites some recent damage suits brought against physicians on these grounds, and he remarks that such suits will probably become more and more frequent in the near future. If the wetnurse was syphilitic at the time she was given the infant to nurse, or developed syphilis within the incubation period the physician is relieved of all responsibility. If he overlooked or misinterpreted syphilitic lesions on the child, the courts do not hold him responsible unless there is evidence of crass ignorance or carelessness. But if the physician recognized the syphilis, as evidenced by the prescriptions or directions he gave, and failed to warn the wetnurse, then he is assessed damages. In one case cited the sum was 8,000 francs and costs, and in the case of the infant of a medical student, 6,000 francs (\$1,200). If the wetnurse has herself consulted the physician, or if his oversight of the child is part of his public duties, he can be explicit in warning the wetnurse not to allow herself or the environment to become contaminated by the infant's secretions or soiled articles. If he is the physician of the child or the family, then he owes professional secrecy to them, and he must not tell the nurse that the child is syphilitic. Some damage suits have been brought against physicians, midwives and institutions because they handed over a foundling to a nurse without examining it for syphilis. Thiberge reiterates that the child of a syphilitic should never be given to a healthy wetnurse nor the child of a person seriously suspected of syphilis. Take from the healthy wetnurse at once every child with manifestations of or suspicion of syphilis, and in the latter case seek in every way to make the diagnosis sure as speedily as possible.

**Abortion of Syphilis.**—Lacapère and Laurent report a number of cases in which infants or adults had been exposed to syphilis, but vigorous arsenical treatment during the incubation phase seemed to eradicate the virus. They do not believe in starting vigorous treatment from mere syphilitic suspicion, but watch intently for some specific manifestation. At the first sign of this, there is still time to effectually abort the disease.

**Syphilis and Immunity.**—Simon says that we cannot speak of a natural immunity in syphilis. The organism during the syphilitic infection is in a state of allergy. There is a tendency to an incomplete immunity and also a tendency to sensitization, and the different phases of syphilis correspond to the periods during which one or the other of these gets the upper hand.

**Infections of Urinary Apparatus Originating in the Intestines.**—Coyon and Lemerre remark that in most of the cases of descending infection of the urinary apparatus, bacilli of the colon type are responsible. They published three years ago two cases of paratyphoid B pyelocystitis, and two of colon bacillus pyelocystitis. The clinical picture seemed to be identical in all. There was evidently septicaemia of intestinal origin, with descending infection of the kidney pelvis and bladder. Septicaemia probably occurs more frequently than is generally suspected after appendicitis and enteritis. Pregnancy pyelonephritis is generally preceded by gastrointestinal disturbance, followed by symptoms of general infection. Kowitz published in 1914 a compilation of cases of pyelocystitis in young children developing in the course of gastro-enteritis. He related that the colon bacilli and albumin in the urine always preceded the appearance of leukocytes in the urine. A more recent report mentions the finding of the colon bacillus in the blood of one among eight children with chronic diarrhoea, and a paracolon bacillus in another.

**Adiposogenital Syndrome.**—A case in a man of 33 and one in a woman of 40 are described, with the pathologic findings in the pituitary. The skin shows certain features suggesting that the thyroid may be at fault also. Both improved under pituitary treatment, the woman being given polyvalent glandular treatment. The infantilism in the man might be called reversible. Similar reversible changes in the genitals were reported by Frank and Marañón (1917) following bullet wounds of the pituitary. Several cases have been encountered at the Laeque Hospital within a year in which the patient's aspect suggested thyroid disturbance, but the loss of vision and manifest lesions in the sella turcica pointed to the pituitary as the primary gland at fault. Syphilis or tuberculosis may be responsible for this, and offer a chance for improvement under specific treatment. In the two cases reported here, inherited syphilis may possibly be incriminated. Along with the specific treatment, opotherapy may prove useful. The combination of pituitary and thyroid treatment has been particularly beneficial, the first patient having lost under it 5 kg. and the various subjective symptoms showing marked improvement. The pituitary treatment was given by the subcutaneous route.

**Pancreas Extract Treatment in Gastric Cancer.**—Summarized when published elsewhere; see page 1560.

**Scoliosis with Sciatica.**—Léri describes two cases of sciatica in young men who were unable to hold their spine straight. There was scoliosis first to one side and then to the other. One of the men could change it from side to side by hoisting himself with his hands, lifting up the trunk. There seemed to be an abrupt, springlike action as the spine changed over, and this was slightly painful. Radioscopic also confirmed the assumption that some rheumatismal deformity of vertebrae was responsible for the scoliosis in these cases. This probably occurs also in other cases of what is called sciatic scoliosis.

**Steeple Skull and Syringomyelia.**—Marie and Léri cite some cases in which syringomyelia or hydromyelia developed in consequence of abnormally high pressure in the brain from tumor. They describe a case in their own service in which symptoms of syringomyelia accompany abnormally high pressure in the brain, but the pressure in this case is from premature ossification of the sutures of the skull, causing pronounced steeple skull.

**The Kidneys at Onset of Acute Nephritis.**—Ameuille has been impressed by the difference between the soundness of the kidneys of patients dying early in acute nephritis and the extremely pathologic condition with old chronic nephritis. In the latter, the kidneys are practically all destroyed, but in the early acute cases the kidneys seem practically normal, and yet there is equal and intense retention of nitrogen and chlorids in both. He suggests that the pathologic changes in the kidneys may be the result of the wearing out of the kidneys from an excess of work when the kidneys were really sound at the beginning of the trouble.

**Lethargic Encephalitis.**—The clinical picture in the man of 27 resembled that described recently as lethargic encephalitis.

itis, but in reality it was a tuberculous meningo-encephalitis. The symptoms were explained by the localization of the infectious process.

**Cancer of the Sigmoid Flexure.**—Necropsy cleared up a puzzling case in which a man of 27 suddenly developed jaundice from retention, and this proved to be the result of compression from a tumor which was a metastasis from a large silent cancer in the sigmoid flexure region. The latter had given no signs of its presence except intestinal hemorrhage on two occasions. The diagnosis had been catarrhal jaundice.

**Hemorrhagic Purpura from Therapeutic Arsenic Poisoning.**—Labbé and Langlois report the outcome of one of the three cases recently published by Leredde in which hemorrhagic purpura developed under neo-arsphenamin (neo-arseno-benzol) treatment. One case was mild, one subacute and fatal, and the last one was acute and the young woman died the tenth day of the purpura. Her blood showed the characteristics of both purpura and hemophilia; the anemia from the hemorrhages had been reinforced evidently by a hemolytic process. The liver was hypertrophied. The chancre of the hip and swelling of glands in the neck, with rosella a month later, were treated with six injections of the neo-arsphenamin during one month; then an interval of a month during which influenza developed; then four injections, each inducing congestion of the face; then a rest of three weeks and one injection; a rest of two weeks, and then four injections at intervals of a week or two, each of which was followed in two hours by bleeding from the gums and nose. After the last injection this bleeding kept up for a week, and a few echymoses appeared on the legs and a patch of purpura on the shoulder. One more injection was then given, and the bleeding from the gums, tongue and nose reappeared after an interval, and symptoms developed resembling those of infectious purpura with high fever and death the tenth day. Fifteen injections of the drug had been made in the course of five months, the doses ranging from 15 to 90 cc., a total of about 8 gm. Bleeding from the gums and nose and patches of purpura during treatment with neo-arsphenamin should warn to stop the arsenic treatment once and for all. In the discussion that followed, Grenet remarked that he had often noted small hemorrhages from the gums, or hemoptysis with previously latent tuberculosis, but he had never had any serious hemorrhages under this treatment. He had been impressed, however, with the frequency of jaundice developing during the two or three weeks after the neo-arsphenamin administration. Garnier confirmed this, but in his experience there was usually an interval of three or four months before the azyretic jaundice developed. In all the cases the jaundice cleared up soon and the cure was complete.

**Splenectomy for Chronic Jaundice.**—In Gilbert's case the jaundice appeared at the age of 2, and at 16 the spleen was found much enlarged. Since then the jaundice has developed in waves, most intense during the colder weather. At 33 the disease had reduced the erythrocytes to 1,900,000, and the cholemia varied from 1:1,500 to 1:3,000. The spleen measured 22 cm. but the liver was not enlarged and there was no pruritus or bradycardia, but the blood was veering to the type of pernicious anemia. The spleen was then removed, and the jaundice disappeared and the blood picture returned to approximately normal in two months. In this and in another case the splenectomy restored the patients to clinical health.

- \*Influenza and Tuberculosis. C. Roulier. — p. 128. To be cont'd.
- \*Tuberculosis with Albuminuria. G. Tola. — p. 438.

**Irregular Onset of Gangrene from Embolus.**—Gallavarrin and Contamin relate that a woman of 54 had formation and thickening in the left leg; then there were a few cramps and the leg felt heavy. By the end of the third week the symptoms had become more pronounced, and in another week the

pains were intense. Ascending arterial thrombosis was demonstrated in the triangle of Scarpa at the amputation, and at necropsy six weeks later. In this and in two similar cases an embolus had evidently started the thrombosis. These experiences warn against delay in amputating in such cases, or the ascending thrombosis will extend too far for recuperation to be possible.

**Treatment of Tuberculosis with Albuminuria.**—In Tolot's case he disregarded the high albumin content of the urine, and gave every day the juice expressed from 150 gm. of beef or horse meat, as he considered that this was required for the pulmonary tuberculosis of the Landoiry typhobacillosis type, with recurring hemoptysis and asthma. As the general health improved under this, the albumin dropped from 1.10 gm. per liter to 0.60, to 0.10 and finally disappeared from the urine. Diphtheria antitoxin has been known to have a similar effect. High albuminuria in such cases calls directly for causal treatment, regardless of the albumin content of the urine which some might think contraindicates the antitoxin or meat juice.

- \*Incapacity from Ulnar Paralysis. J. Lévy-Valensi. — p. 277.

**Recent Progress in Neurology.**—Camus' review covers the last five years, and he comments on the great progress realized during the war, and the complete revision it has brought in our knowledge of section of the spinal cord.

**Criminal Responsibility.**—Laignel-Lavastine begins his study of this subject by repudiating the term "criminal responsibility" and using instead "penal capacity," analogous to the expressions earning capacity and civil capacity. He discusses this from various standpoints, reiterating in conclusion that the medicolegal expert does not have to pass judgment on the penal capacity. All he has to certify to is *l'normalité, la nocivité, l'impulsivité, l'indimidiabilité et la perfectibilité* of the accused. It is for the court to decide from these premises whether the penal capacity is normal, attenuated, or nil.

**Latent Meningitis in Syphilitics.**—Sézary has modified his previously published views on this subject as new facts learned have compelled their revision. He now explains the meningitis revealed by lumbar puncture in syphilitics as testifying to nervous lesions, but he emphasizes that it is not a factor in their production. It is merely the ordinary reaction of any serosa to the presence nearby of some nest of spirochetes and the consequent local degeneration of tissues.

**Abdominal Wall Sign of Location of Lesion Causing Spinal Paraplegia.**—Thomas noted at necropsy of men with complete spinal paraplegia that the injury of the spinal cord extended much higher than had been surmised from the symptoms. Study of the voluntary control of contracture of the muscles in the different segments of the abdominal wall and of the defensive reflexes in the same muscles has shown that these are modified in case of spinal cord lesions, as also the response to electric and mechanical stimuli, and that the limits of these segmental modifications correspond to the limits and gravity of the spinal cord lesion.

- \*Bony Arterial Aneurysm. F. M. — p. 277.

**Gunshot Wound of Aorta.**—The vein has demonstrated that certain trunk arteries may be wounded without entailing

the normal hemorrhage that was to be expected. In a case reported here, the bullet had passed entirely through the thoracic aorta from side to side, lodging finally in an intercostal space. The artery evidently contracted in a defensive spasm, and no blood escaped from it. The spasm relaxed at the seventeenth hour, and the blood then poured out and proved speedily fatal. The length of time the artery keeps to this defensive spasm in such cases is a guide to intervention in others.

**Cancer of Mouth and Throat.**—Moulik reviews the outcome in 28 operations for laryngo-pharyngeal malignant disease, and expatiates on the advantages of local anesthesia in such cases. He applied it exclusively in his last series of 10 cases which were all among the most extensive operations that can be done in the face and neck. Local anesthesia, he claims, amply suffices for pharyngotomy and is indispensable for operative bronchopulmonary disturbances that have not occurred under local anesthesia in his experience, so that he is inclined to attribute these complications to the alkaline anesthetic irritating the air passages and, by its noxious action on the liver, reducing the general defensive reactions. Observation of a single case under local anesthesia is the most convincing argument to prove its superiority. There is no spectacle more astounding, he remarks, than to see the patient after the vast mutilation of a pharyngotomy get up himself from the table and start unaided to return to his bed after the two hour or two hour and a half operation. The last 4 in this group did not even lie down for an hour during the rest of the day. Four of them required a second operation, excision of glands in the neck, and none asked for general anesthesia. The patients have to be trained beforehand to allow the operation without full consciousness, and the surgeon has to train himself to work slowly, anesthetizing the successive planes in turn and waiting a minute or two for the anesthesia, and not working toward the line of the injection. Demarcation of this is aided by adding a little blue stain to the anesthetic solution. He advocates section of the jaw or pharyngotomy; no tracheotomy for the anesthesia, it is necessary only to arrest direct hemorrhage; no preventive ligatures; a few whiffs of nitrous oxide for the most tumorous or for the most painful procedures, as in taking out bone. He gives an illustration of a man in good health to date five years after removal of an epithelioma of the velum, tonsils and base. There was an interval of three years and a half before recurrence in two other cases of cancer of the tonsil. These were the longest survivals.

**Inguinal Hernia.** Burian writes from Prague to comment on the large number of hernias that developed during the war, and the frequency of relapses after the routine operative treatment. In sixty-two cases of relapse of inguinal hernia after the Bassini operation, the breach was in the new location of the spermatic cord, which it is difficult to secure firmly. To remedy this, he trains the muscles for two or four weeks before the operation with active and passive gymnastic exercises of the abdominal walls, hips and legs, striving to strengthen the internal oblique in particular. The operation aims to close the hernial sac at the highest possible point; to aid in this he removes all the adipose tissue back of the aponeuroses. He closes the canal by reconstructing the anterior wall with a triple layer of aponeurosis. He passes the catgut through the aponeurosis of the internal oblique and also of the external oblique, back from the edge of each, and fastens them both to Poupart's ligament and to the side lip of the aponeurosis in such a way as to show, by illustrations, that the side portion of the aponeurosis laps over the median portion. This forms a strong third layer of aponeurosis, while the spermatic cord is left in its natural place. Experiences with this technique in hundreds of cases have demonstrated that it is simple, and applicable even to very extensive hernias. The Girard relapse is somewhat similar only that the muscle with this hernia is paralyzed by the suture threads which traverse and strangulate the muscle, and large patches lose their vitality in consequence.

**Loose Shoulders.**—Du-Sejour immobilizes the shoulder in a horizontal plane with the humerus, and has been quite successful with this method in treatment in thirty-two cases of the loose joint left after extensive resection of the shoulder. The immobilization was kept up for two months or more, and then the shoulder was massaged and the new pseudojoint cautiously exercised, with hot douches of the shoulder. The immobilization was kept up for two months with fine results when the deltoid was usable. To save this muscle, therefore, should be the special concern of the surgeon in operating in the shoulder region.

**Restoration of Spongiosa Tissue.**—De Gaulejac and Nathan refer to destruction of the spongiosa from a traumatic hematoma in the bone. Their anatomic and experimental research has demonstrated, they say, that the bone can repair itself at the expense of the fibrous tissue, the collagen of the latter becoming transformed into prebone tissue under the influence of the surrounding bone tissue.

**Restoration of the Parenchyma of the Shaft of a Long Bone.**—De Gaulejac and Nathan affirm that the middle layer, the Haversian layer, of compact bone is the fertile element. This reacts to trauma and inflammation by a return to an undifferentiated stage. If the restraining barrier is broken down, it is capable of proliferating into the adjacent connective tissue. Grafts in this fertile layer in the bone start rapid processes of repair. As the periosteum is so liable to have been injured in the cases of trauma, slices of connective tissue are generally more readily available, but periosteum is preferable on account of its two layers, the loose and the compact tissue.

**Improved Technic for Artificial Anus.**—Malespina remarks that the usual method of fastening the loop so that its branches lie together like the barrels of a gun, has several disadvantages. The feces are liable to get into the lower branch of the anus which the artificial opening aims to prevent. This can be avoided by making a double anus. An incision is made a fingerbreadth above the anterior-superior iliac spine, parallel to the crural arch and iliac crest. Two T incisions are then made at right angles to the first incision. They are 4 or 5 cm. long and 4 cm. apart. The flap of skin thus cut on three sides is drawn under the loop of intestine and sutured to the other lip of the incision, thus forming a bridge. Thirty-six or forty-eight hours afterward, the intestine is divided, and as the whole heals, the two openings into the bowel are separated by a distance of 3 or 4 cm. The rubber bag receptacle for the fecal matters has two openings to fit over the twin anus openings. In fifty cases in which this "bridge anus" technic has been applied in the last seven years, there have never been any by-effects or mishaps of any kind, and the terminal bowel has been left completely in place.

The Chloroform Controversy. W. Löffler.—p. 1553. Concl'n.

**Diseases of Deranged Metabolism.**—In the course of this review of his personal observation of cases of deranged metabolism, Gigon remarks that the calory requirements of the body in disease cannot be estimated from the requirements in health. One of his patients with cancer of gallbladder and liver lived for eight months on 600 or 700 calories, and did not lose very much in weight. She weighed 50 kg. to start with. One diabetic patient weighing 78 kg. gained 4 kg. and felt better on 2,000 calories than on a larger amount. The lesser need for calories in these cases is a phenomenon of the disease. In obesity, merely qualitative modification of diet may succeed, as in one case described in which vegetables and fruit were eaten in large amounts, with stationary weight. The woman did not begin to lose weight until the fruit was dropped and butter and three teaspoonfuls of oil taken instead. It is evident that pathologic qualitative

changes in the metabolism play an important part in the metabolism in the obese. The obesity may be of toxic origin, from alcohol, beer or overeating. This latter form is the most amenable to treatment, perhaps. Or, the obesity may accompany or follow some infection. Specific treatment as for syphilis, or a course of arsenic, may prove more beneficial than dieting. A third group is traceable to endocrine disturbance, and organotherapy and dieting are called for. In a fourth group, the central nervous system might be incriminated; psychoses may accompany obesity. Symmetrical deposits of fat in the upper arms, thighs and calves suggest a nervous origin. In a fifth group, the obesity is of the atonic type, with flabby muscles, and often with edema at the ankles, slight anemia, and blood pressure normal or below. Treatment in this form has little chance for success; thyroid treatment brings on heart disturbances. Muscular exercise must be cautious. A salt-poor diet with little fluids is usually helpful.

He declares that the pathologic condition which is exactly the reverse of obesity is as fully a morbid entity as the latter. To keep the balance in weight, an excess of calories is required, 4,000 instead of 3,000. The same causal factors may be involved as with obesity, but the cerebrum seems to be responsible for the graver cases of *Magrucht*—a term he has coined analogous to *Fettsucht*. The action of the brain on the metabolism is too often forgotten, and has not been studied enough. The brain via the liver or other glands with an internal secretion may derange the metabolism, inducing diabetes or obesity or its opposite. In the latter disease, copious drinking has proved very beneficial in certain cases. Whether this is due to washing out of toxins or to modifying the connective tissue so that it will take up fat better, or to other causes, is still a question. In three women there seemed to be an abnormal hydrophilia of the subcutaneous connective tissue, with remarkable dryness of the skin and tendency to chilblains. There was slight improvement under arsenic.

In referring to diabetes insipidus, he remarks on the frequency of psychoses with it. Cases are on record of diabetes insipidus with cerebral syphilis. In the case of one boy of 11, improvement in the diabetes insipidus was realized under long continued administration of one or two table-spoonfuls of cod liver oil. He saw no benefit from strychnin in his five cases. In the physiology of nutrition, albumin plays the most important rôle, but disturbances in the metabolism of albumin are insignificant, so far as we know to date. It is possible that rheumatism, migraine, skin disease and anaphylactic phenomena may be manifestations of something in this line. Scurvy, rachitis and osteomalacia may also belong in this category. This suggests treatment by measures to modify the metabolism.

**Aspiration Apparatus.**—Wild gives an illustrated description of a simple water-jet aspiration apparatus, with both water and mercury manometer, designed for slow prolonged aspiration with the lowest possible pressure under constant manometer control. It is especially useful for gentle aspiration of the pleura, nasal cavities and pharynx. He has special vacuum cups to fit over the tonsil.

### Chirurgia degli Organi di Movimento, Bologna

September, 1919, 3, No. 4

\*Wounds of Large Joints. Metella Francini, p. 441

\*Traumatic Aneurysms. Giovanni Morone, p. 463.

\*Osteoplastic Resection of Both Feet. Ugo Camera, p. 401.

\*Prosthesis after Edema. A. Serra, p. 407.

**Operative Treatment of Traumatic Aneurysms.**—Morone gives an illustrated description of five cases of aneurysm in after war wounds in which his operative intervention restored clinically normal conditions in the circulation. In a sixth case he merely ligated the popliteal vein as the false aneurysm was a complication of a suppurating process in the knee and fracture of the tibia. Gangrene developed, and the man died from septicemia a month afterward. Suture is preferable to ligation, especially of the "dangerous" arteries (main femoral, popliteal, axillary and humeral). One man with a saclike arteriovenous popliteal aneurysm was cured by resection of the whole, between four ligatures; another by mere excision

of a hematoma at the origin of the iliac artery, between clamps. Besides the aneurysmatic hematoma in the popliteal in another case, the artery was not treated with an embolus. The man recovered after amputation.

**Resection of Both Feet.**—The illustrations of Camera's case show the extensive wounds left by a tumor that had carried off both heel regions. He applied the Vladimiroff-Mikulicz osteoplastic technic with excellent results, the man being able to walk on the front fourth of the foot.

**Prosthesis After Osteoplastic Resection of the Foot.**—Serra gives illustrations of the case described in the last abstract after the man had been fitted with a contrivance which provides ample support for the feet, while ordinary shoes are worn just below the tip of the toes. The man is thus made a few inches taller, but there is absolutely nothing to show a trace of the deformity, the trousers showing nothing but the shoes below, and the man is now able to walk well and to dance. Both Camera and Serra regard the results obtained as far superior to those with amputation above the malleoli, the only other resource.

### Policlinico, Rome

July 27, 1919, 26, No. 29, 30

\*Antibacterial Action of Secondary Rays. F. Ghilarducci, p. 897.

\*Necropsy Findings in 200 Children with Influenza. Mancini, p. 848.

\*Syphilis of the Nervous System. Silvio Canestrini, p. 908.

\*Remedies Used in Influenza. Ignazio di Pace, p. 912.

\*Index of State of Nourishment. Alcaro Ceriali, p. 918.

**Antibacterial Action of the Secondary Rays.**—Ghilarducci reports experiments which show in the most evident manner the retarding or suspension of the development of bacteria under the influence of the secondary rays. Lead, tin and silver were the most active on the prodigious; copper a little less, iron still less, and aluminum had scarcely any appreciable action in this line. A thin sheet of cardboard interposed absorbed part of the active rays. These findings confirm his previous statements in regard to the bactericidal action of the secondary rays from bis-muth and silver salts in the rabbit stomach. The later research obviated the objection that the bactericidal action may have been due to the direct contact with the metal.

**Syphilis of the Nervous System.**—Canestrini remarks that if it were not for the ability of the pale spirochete for the nervous system, syphilis would not be such a serious disease. It is remarkable that this affinity of syphilis for the nervous system in the form of congenital cerebral syphilis, of tabes and general paralysis is not observed in countries with backward civilization, although syphilis may be widely prevalent there. Döring has related that in his many trips through Asia Minor he never met with a case of manifestations of syphilis of the nervous system among the 10,000 syphilitics he examined. But when these syphilitics from Asia Minor moved to Constantinople to live, a large proportion developed in time tabes or general paralysis. Some have found the cerebrospinal fluid normal only in 22 per cent of their cases of recent syphilis, and Königstein reported in 1917 that he had found this fluid pathologic in 41 per cent, during the second stage. These findings demonstrate the organic cause for the frequent headaches in recent syphilis. Canestrini called attention in 1911 to the way in which the fluid veered toward normal under arsenamine treatment of tabes and paralysis, although the subjective and objective symptoms showed no improvement.

From his own experience and review of the literature he is convinced that the action of arsenamine by the vein is no whit inferior to that of the Swift and Ellis lumbar puncture technic. He describes a number of unusual cases, among them that of an unruly boy of 10 with emurea and other signs of congenital cerebral syphilis. Under specific treatment the character changed and the symptoms all subsided, except the pupil reactions. He varied it to be included into giving specific treatment when tabes is merely the work of alcohol or tobacco poisoning. He had a case of the latter kind in a worker on tobacco. He also warns against iodid treatment when there is a possibility of hyperthyroidism, or we may encounter exophthalmic goiter superadded on

the syphilis. *Tabs dorsalis* may develop from inherited syphilis alone. Hirsch has decried a case in a virgin of 52. In conclusion Canestrini refers to a case in which a man of 35 had, with other symptoms of syphilis, hallucinations and delirium. After a week of arsenophenium treatment, febrile-hemolytic jaundice developed, and as this subsided in two weeks the hallucinations disappeared and the man was restored to comparative health, able to return to work. This intermission lasted for two years, when delirium returned and the man died in a few weeks. Canestrini suggests that the febrile jaundice from retention may have modified the spirochetes in this case, and queries whether it might not be possible to induce a therapeutic hemolytic jaundice by injection of meric acid or of sodium glycocholate or tartricholate.

**Index of State of Nourishment.**—Cerioli divides the weight in grams by the height in centimeters, and accepts the quotient as an index of the state of nourishment exact enough for many practical purposes. The average index from twelve men was about 400 and from twelve women 375.

- Comparative Growth and Pathologic Anatomy of Twins. Angiola Berrino.—p. 595.  
\*Localizations of Tuberculosis in Young Children. A. F. Canelli.—p. 533.

**Localization of Tuberculosis in Children.**—Canelli reviews the necropsy findings in regard to tuberculosis in 1,004 children. The findings were positive in 26.0 per cent. and in all but 10.8 per cent. the tuberculosis was directly responsible for the death. No signs of tuberculosis could be detected in 66.3 per cent. of the 766 nontuberculous cadavers. Cheesy or calcified tuberculous lesions in the tracheobronchial glands or in the lungs were evidently the primary localization of the tuberculosis in nearly every case, and in every case in infants under a year old. In only 72 cases was the tuberculosis restricted to a single organ or system, and in this group, to the brain or meninges in 1.9 per cent.; to the intestines in 0.3; to the mesenteric glands in 1.9; to the peritoneum in 1.1, and to the bones in 1.5 per cent. In 195, various organs or systems were involved, the intestine and mesenteric glands in 12 per cent.; the glands and meninges in 11.2; bones, lungs and glands in 3.8, and lungs, meninges, liver, spleen and glands in 17 per cent. A cavity had formed in the lung in 10.8 per cent. of the patients from 6 to 12 months old, and in 20 per cent. of the patients from 1 to 2 years old.

- \*Treatment of Myiasis. T. De Almeida Junior.—p. 496.  
\*Caution Necessary with Thermal Mineral Waters in Treatment of Disease of the Eyes. O. Correa Netto.—p. 504.

**Myiasis.**—De Almeida relates that inhalation of chloroform will expel maggots and other larvae that have found lodgment in the nose. Myiasis of the mouth, ear or other cavity is not infrequent in Brazil. In three cases among railroad construction workers in 1913, the symptoms caused by the unsuspected larvae in nose or ear suggested meningitis. One man was almost unconscious and could only groan and press his hands to his head. He was treated for meningitis but died the third day, just before death expelling thirty maggots from his nose. There had been nothing, no discharge from the nose, to suggest their presence before. In a second case the nose was edematous and there was a fetid discharge giving the clue. Under inhalation of chloroform and rinsing with diluted chloroform, over 100 maggots were expelled, some still lively, and recovery was complete. In the third case the larvae could be seen in the ear and they were finally driven out by chloroform on a cotton pledget. In another case a young woman complained for twelve days of headache, dizziness, fever and vomiting, and there was a discharge from the nose. On suspicion of a gonococcus process the nose was treated with potassium permanganate without relief, and finally the nasal discharge showed blood admixture. Treatment then with chloroform brought over 100 live larvae, but the maggots had destroyed the tissues so that the tip of the nose perforated, leaving a disfiguring defect. In the fifth case described, the man of 40 was found unconscious beside an empty liquor bottle. To rouse him, camphorated oil was injected and ammonia was held to his nose, and large larvae then began to crawl out of his nose.

- \*Surgical Treatment of Stomach Disease. V. Pauchet (Amiens).—p. 513.  
\*Gastric Chemistry. R. Luis y Yagüe.—p. 528.

**Surgery of the Stomach.**—Pauchet analyzes his experience with 1,200 operative cases of gastric and duodenal ulcer, cancer and gastroptosis. Treatment of gastroptosis, he says, requires the cooperation of the physician, the patient, the masseur and—of time, as it has to be a regular course of orthopedics of the abdomen, as with orthopedics of the limbs. In his 30 cases the attempt to cure the gastroptosis failed completely in 6 instances. He found that 75 per cent. of the gastric cancers were located at the edge of an old ulcer, and that 80 per cent. of all gastric cancers are at the pylorus end of the stomach. His experience confirms the advantages of gastro-enterostomy two or three weeks before the gastrectomy. It is better not to wait longer than this as the cancer may progress too rapidly. With movable cancers, the operative mortality after gastrectomy averages 5 per cent. He prefers gastrectomy for gastric cancer even when it can be only palliative. This raises the death rate to 25 or 30 per cent. but the postoperative course is better than after simple gastro-enterostomy, and the survival longer. He says of operative treatment of gastric ulcer that extensive gastrectomy is the preferable treatment, and simple gastro-enterostomy or excision of the ulcer alone is advisable only when there are contraindications to extensive gastrectomy. He describes in detail the technics he advocates for various pathologic conditions in the stomach, defining the indications for each.

**Dissociated Gastric Chemistry.**—Luis applies this term to certain conditions in the secretory functioning of the stomach which he has never seen described elsewhere. The gastric secretion, he explains, is not a simple but a complex activity, varying to adapt itself to the conditions prevailing at the time. There seems to be usually a constant relation between the free and bound hydrochloric acid and the total acidity, but occasionally the free hydrochloric acid is proportionally much above or below the usual standard. The total acidity may be at the normal figure but the proportion between the free and the bound acid may be very irregular and variable, and there may be dyspepsia of the so-called nervous type. The symptoms are those of nervous disturbances, but they

do not fit into the frame of any special neurosis. They render the prognosis more favorable than might otherwise be the case, as they demonstrate the neuropathic or endocrine basis, and guide to appropriate treatment.

**Hydatid Cyst of the Liver.**—Razetti comments on the case described by García Parra that it is the first hydatid cyst known in Venezuela, although hundreds of operative cases of amebic liver cyst have been recorded, and at 400 necropsies special search has been made for hydatid cysts, without results. García operated on the assumption that the cyst was in the ovary. The tumor had been slowly developing through five years, and yet had never caused severe local or general disturbances. The description by García is not very clear as to the hydatid origin of the cyst, and Razetti thinks that probably a cystadenoma was mistaken for echinococcus disease, as he has hitherto preached the clinical dogma that hydatid cysts of the liver or of any organ are unknown in Venezuela.

- The Surgery of 1918. J. M. Bartrina Thomas.—p. 482.
- Vaccine Therapy of Malta Fever. J. Durán de Cottes.—p. 495.

**Overvaluation of the Wassermann Reaction.**—Umbert reiterates that only minute clinical examination can be relied on for the diagnosis of syphilis. The Wassermann reaction may fail in the cases in which its aid is most needed, and we must bear in mind that not every affection in a syphilitic is necessarily of syphilitic origin. He lays great stress on the retrospective diagnosis of syphilis by clinical investigation, organ by organ, and examination of other members of the family. The Wassermann reaction generally proves superfluous when this is done.

**Treatment of Wounds.**—Bartrina reviews recent progress in surgery and his own experience in 657 various operations. An illustration is given of one young woman with a large gap in the outer ear wall. This he reconstructed with a wedge cut from the upper part of the ear. He says of Lugez's method that it is the perfecting of principles long cherished in surgery, but that its application requires great skill and perseverance. It is of transcendental importance in treatment of pleural empyema. Film treatment of burns, on the other hand, is pure empiricism, but its application is rapid, simple and effectual.

**Vaccine Therapy in Malta or Undulant Fever.**—Durán has applied vaccine therapy in over 600 cases of Malta fever since 1906, and states that vaccines should be the pivot for treatment except when the heart and kidneys are the seat of old pathologic processes. These contraindicate vaccine treatment, at least during periods of hemorrhage and extremely high fever. He gives the ether-killed vaccine by subcutaneous injection, usually repeating three or four times, aiming to aid in the complete immunization.

- \*Roentgen Treatment of Hypertrophied Prostate. J. and S. Ratera.—p. 816.

**Gastric Ulcer.**—Luis comments on the frequent absence of actual pain, vomiting and hematemesis with gastric ulcer. Pain in the stomach with digestive disturbance points to ulcer when it is intense and persisting. A boring pain is instructive but is seldom experienced, and then as a rule only with the so-called callous ulcers or those complicated with perigastric inflammation. Vomiting also generally accompanies only chronic ulcer with hyperchlorhydria, and preeminently those ulcers near the pylorus. In itself, vomiting has little diagnostic value.

**Pituitary Insufficiency and Diabetes Insipidus.**—Marañón and Gutierrez present evidence to prove that the cerebrospinal fluid is a factor in polyuria but not by its chemical ingredients—its hormone content, as some believe—but by a mechanical action from its high pressure. Among their arguments are that normal cerebrospinal fluid does not modify the output of urine, and neither does injection of this fluid from a person with diabetes insipidus. No influence on diabetes insipidus was observed after intraspinal injection of pituitary extract. If persons with diabetes insipidus were injected subcutaneously or intraspinally with normal cerebrospinal fluid instead of pituitary extract, this would be further evidence but no one has attempted this. The above testifies, they say, that the oliguria-inducing hormone does not pass into the cerebrospinal fluid, but withdrawal of some of the fluid to reduce its pressure favorably modifies diabetes insipidus. In one of their own three cases the output of urine dropped from 5,600 to 3,200 after escape of 40 cc. of lumbar puncture fluid; in the second case the output dropped from 12,000 to 8,700. In the third case, the drop was only 150 gm. If any oliguric hormone actually passed into the cerebrospinal fluid, the output of urine would naturally increase, instead of dropping, after withdrawal of a portion. The hypertension is the work of the pituitary tumor, but in turn it hampers the functioning of the still functionally capable portions of the pituitary, thus setting up a vicious circle.

**Ferrán's Vaccination Against Tuberculosis.**—See Madrid Letter, October 4, p. 1074.

**Roentgen Treatment of Hypertrophied Prostate.**—Ratera reports fifteen cases of hypertrophied prostate in which systematic deep roentgen treatment was followed by significance of the gland, even when it seemed to present features of an adenomyoma. He warns that cystitis may apparently develop under the treatment, but that this in reality is merely the breaking through of abscesses already in the prostate tissue. This was demonstrated beyond question in one of his cases. The best results are obtained when the bladder

s—retains normal contracting power. The exposure through the coccygeal region seems the preferable technique, alone or combined with exposure of the perineal region. The tissues are no thicker for exposures from two points, each side of the tip of the coccyx, than from the perineum, while the posterior aspect of the prostate presents a better surface for raying from the rear, instead of raying from pole to pole. In two of his cases transient retention of urine followed, evidently from the reaction of the prostate tissue, and the urine was turbid and bloody for some time. The usual dose was 5 H units per zone, once or twice a month, filtered through 3, 4 or 5 mm. of aluminum. In some cases they gave up to 10 or 15 units per field, with thick filters, but in this case the intervals had to be two or three months. No reaction in the skin was observed in any case.

 \*The Status Nerve with Constant Irregular Pulse. S. Yamada. p. 87.  
 \*Study of Pancreas Functioning. Z. Hattai and K. Marui. p. 121.

**Pathogenesis of Epithelial Cancers.**—The preceding research of Yamagiwa and Ichikawa has already been mentioned in these columns. At date of writing (April, 1918) they had a record of 16 well defined carcinomas developing on rabbits ears systematically painted with tar. In 20 other cases incipient carcinoma had developed, and in 23 others there was carcinoma in a transitional phase. The shortest interval before the well defined carcinoma developed was 103 days, and the longest, 565. In only 3 instances was the development of metastases noted. One important practical conclusion from their research is obvious, namely, that carcinoma does not begin as such but passes through the phases of atypical development of the epithelium, follicular epitheloma, and finally carcinoma, and also that the carcinoma may in time have to yield to encroaching connective tissue and thus be compelled to retrogress and heal. Their findings seem to show that the physiologic epithelium cells are like a newly born babe whose character can be trained to good or to evil according to the training and environment in which it grows. The repeated tar applications can influence the cell until it becomes malignant. The cell once becomes malignant cannot return to its former physiologic state but it may succumb to the encroachments of connective tissue.

**Action of Pituitary Extract on the Puerperal Uterus.**—Shiraki gives fourteen comprehensive full-page tables of his findings with over three pages of bibliography. Among the practical conclusions of his research are the warning that obstetrical treatment should not be given unless the fetal head is in a proper position to stand the resulting contractions of the uterine walls. The proportions between the size of the fetal head and the pelvis are comparatively normal; and unless the diameter is at least 7 cm. as otherwise the powerful spasmodic contractions of the uterus might strangle the fetus or rupture the uterus, especially as under the induced contractions it is a difficult matter to deliver the child rapidly when haste is imperative. As a rule, the success in the operation is the more certain the lower the fetal head is at the time.

**Changes in Mouse Mammary Glands Under Injections of Scarlet Red.**—Takeuchi found the changes much more pronounced in the male than in the female mamma, but no tendency to actual malignant transformation could be detected.

**Blood Sugar During Immunization.**—The twenty-two horses examined showed very little fluctuation of the blood-sugar content through the years, even when the horse was being used for production of diphtheria antitoxin. Similar

lack of fluctuation was noted in rabbits treated with diphtheria antitoxin.

**Constantly Irregular Pulse.**—Yamada tabulates the minute details, clinical and necropsy, in thirty cases, including four from his own practice, with seven photomicrographs of sections of the sino-aortic node. The latter was usually pathologic, but in 13.3 per cent. of the cases it seemed to be free from fibrosis.

- \*Sugar Content of Blood in Diabetes Mellitus. S. Lindblom. p. 753.  
 \*Polythemia and Enlargement of the Spleen. Harald Öhnell. p. 761.

**Mechanisms for Speech, Music and Calculation.**—Henschen presents arguments to prove that some psychic phenomena form to a certain extent an independent entity, a psychic functional complex. This has an anatomic basis, he explains, formed of certain cortical centers connected by association paths. Both anatomically and functionally one complex may drop out without influencing any of the other complexes. He cites numerous instances to show the interworking of the higher psychic coordinating centers with the lower mechanism, and the correlation between the different complexes, as, for example, between music and speech. A man may be able to sing to a melody certain words but is incapable of speaking the words separately. From the clinical and anatomic data on record in regard to aphasia, etc., Henschen deduces that the left hemisphere of the brain is chiefly responsible for elaborating into ideas the material accumulated by the senses. He suggests that this more complete development of the left hemisphere is an inherited property. He has noticed in ancient and modern art that the left half of the skull is often more prominent, as in the sculptured head of the Young Augustus. Comparison of sculptured heads suggests that the prominence of the left half of the skull testifies to the sculptor's having worked from a living model. It is important from the standpoint of physiology and heredity, he adds, to determine whether this hypothesis is correct. In conclusion he reiterates that study of aphasia and similar complexes allows us a glimpse directly into the mechanism of the mind, and offers a promising field for research on the psychic life.

**Sugar in the Blood in Diabetes.**—Lindblom theorizes that hyperglycemia to a certain extent is a useful phenomenon in diabetes. It serves to warn the sugar-forming and the sugar-destroying organs that formation of sugar must be reduced or the destruction accelerated to restore an approximate balance. The organs gradually become less sensitive to the hyperglycemia, while the ability of the kidneys to eliminate sugar grows less. The urine may be freed from sugar on a proper diet, not in spite of the hyperglycemia but thanks to this. But, of course, hyperglycemia is injurious on the whole, so that efforts to keep it down are indicated, and avoidance of carbohydrates is rational.

## DEFECTS IN THE TEACHING OF PATHOLOGY, AND THE LAY PROFESSOR

DOUGLAS SYMMERS, M.D.

Director of Laboratories, Bellevue and Allied Hospitals; Professor of  
Pathologic Anatomy, Bellevue Hospital Medical College

NEW YORK

Pathologic anatomy has to do with the structural rearrangements brought about by disease; and that individual who approaches the interpretation of any problem in medicine without a comprehensive knowledge of the normal and altered architecture of the tissues concerned, is poorly equipped for his task. The converse is equally true, namely, that individual who confines himself to the study of pathologic anatomy without attempting to bring it into harmony with the signs of altered function is intellectually blind in one eye.

### THE CAUSE FOR DEFECTS IN THE TEACHING OF PATHOLOGY

It is impossible to avoid the conclusion that in this country the teaching of pathologic anatomy is woefully defective, except, perhaps, in isolated instances. There is a disposition in certain quarters to shoulder the blame on the medical schools, and at first glance the stricture appears to be merited. As a matter of truth, I venture the opinion that the responsibility lies elsewhere. In New York State, where one rarely seeks in vain for signs of the New World's progress, the regulations governing the distribution of unclaimed bodies are such as might be expected in a community of avowed obstructionists—in the face of which it is proposed to finance a project to make New York City the medical center of the world! Unfortunately for this plan, the centralization of medical thought and action is a problem less simple than that of the expenditure of money. A medical center must be that place which furnishes the greatest opportunities for the exposure of disease in its anatomic nakedness, and certainly there is little promise of this in any city which consigns the vast majority of its unclaimed dead to a trench in potters' field, where they are abandoned to an end which has nothing to do either with our respect for death or with our regard for the rights of the living. The fault exists in many American centers of population. In these circumstances it is impossible for the schools to secure necropsies in numbers sufficient for the teaching of pathologic anatomy on a scale commensurate with its importance. The subject cannot be taught outside the necropsy room any more than botany may be studied to best advantage without resort to the things

that grow in the fields. The demonstration of museum preparations or of organs more or less freshly removed, while useful, conveys only a tithe of the meaning of pathologic anatomy.

The medical schools cannot be expected to send their graduates into action prepared to harmonize anatomic with clinical findings when it has never been impressed on them by other than the shallowest sort of precept that such correlation is essential to the interests of the sick, to the accuracy of vital statistics, and to their own intellectual well-being. Few interns come to us at Bellevue Hospital prepared, for example, to explain the physical signs of croupous pneumonia on the basis of the naked eye and histologic changes in the lung; and how many of these young men, most of them earnest and anxious students, would anticipate a stricture at the isthmus of the aorta when, on lifting the breast plate at necropsy, the distended internal mammary arteries are brought into view?

As bearing specifically on this phase of medical education, I addressed a questionnaire to the resident staff at Bellevue Hospital. Fifty replies were analyzed. They came from graduates of twenty-six different schools in fifteen different states. Of the fifty interns, twenty-nine (58 per cent.) had never performed a single necropsy previous to receiving the degree in medicine; twenty-one (42 per cent.) had never assisted at a necropsy, and nineteen (38 per cent.) had neither performed nor assisted at the performance of a necropsy. Of twenty-one who had performed necropsies before graduation, eleven (52 per cent.) acted in a voluntary capacity, so that of the fifty graduates only ten, or 20 per cent., had performed necropsies as part of their training for the degree in medicine—and these were done in hopelessly insufficient numbers. Of the fifty, all had witnessed necropsies, it is true. Some of these were provided by the schools as part of the required course in pathology, but attendance on by far the greater number was voluntary.

There was a time, still remembered by the older generation of physicians, when the state was obstinate in its refusal to legalize the dissection of unclaimed bodies for educational purposes. The objection was an emotional one—that dissection is a profanation. The schools were accused of body snatching, ghoulis trafficked in the dead, and every student of medicine was viewed askance as a sort of skulking felon who was unalashed either by the darkness of the churchyard or the sanctity of the grave. The legalization of dissection was finally brought about after numerous long and bitter fights. In Pennsylvania, if I mistake not, the contest was closed and won by the late William S. Forbes, the militant professor of anatomy in Jefferson Medical College, but only after

he had been systematically vilified by press, pulpit and populace.

#### OBJECTIONS TO NECROPSIES FOR EDUCATIONAL PURPOSES

In the new order of things, however, dissection of the dead was soon accepted as a matter of course. Any suggestion to suppress it now would be received as an indication of enfeebled mentality. Nevertheless, there still is a deep prejudice in this country against the performance of necropsies for educational purposes. In various parts of continental Europe the people have long since been convinced that postmortem investigation is a public service, an act to be commended for the welfare of humanity. It is taken as much as a matter of course as is scholastic dissection in this country at the present moment. It seems never to enter any one's head to object, although the continental laws specifically provide that the operation shall not be done if opposition be registered by the family. In this country, on the other hand, necropsy still is all too often regarded as an insult to the dead—a view founded partly on sentiment and derived partly from ignorance. Respect for the presence of death is deep in every one of us. In my own experience in the necropsy room, I have yet to witness a single act which could be construed as a sign of desecration. In seeking consent from responsible relatives, a declaration to the effect that postmortem investigation is a dignified ceremony—not a mutilation—and that the examination will be conducted in a spirit of reverence for the dead, often suffices to elicit a sympathetic response. Even among the more intelligent, such an explanation will be reassuring, but among the less intelligent it should never be withheld and should be emphasized by every force available.

In another and large group of cases, consent is refused because of superstitious religious interdictions. Among the Jews the belief that the Mosaic laws forbid the opening of the body after death is so widely prevalent that it seldom occurs to any one to question it. As a matter of fact, the Jewish religion interposes no objection, and the Jew who denies permission does so of his own election and not because his creed would otherwise be disregarded. He may not be aware of the truth of this statement any more than the Christian is aware of many things in his religion. In one of the large Jewish hospitals in the Middle West, the question of religious objection was met by the superintendent, who invited the heads of the Jewish community to discuss the matter with him. The importance of examination of the body after death was explained to them, and it was related that certain of their coreligionists had refused permission on the ground that the procedure was not sanctioned by ecclesiastical law. Many of the rabbis present were of the same opinion, but the matter was taken under advisement, and, at a second meeting, it was reported that diligent search had failed to uncover any provision which forbade the opening of the body after death.

The most formidable opposition to necropsy is to be found in the laws governing the distribution of the unknown dead. Particularly is this true of New York State. In other communities, notably Pennsylvania, Illinois, Ohio and Louisiana, the laws are more elastic. In Pennsylvania, all unclaimed bodies pass into the keeping of the State Anatomical Board, which appor-

tions them to the several medical colleges for purposes of dissection, and, in certain instances, to the hospital pathologists for instruction by necropsy. In the Philadelphia General Hospital, the chief resident physician informs me that there is a yearly average of about 300 unclaimed bodies. In the summer months, when the medical schools are closed, the State Anatomical Board concedes to the hospital pathologists the right of post-mortem investigation in 25 per cent. of the unclaimed bodies and in 35 per cent. during the winter, the Pennsylvania law requiring that every medical student shall have personally participated in at least seven necropsies before he is entitled to receive his degree. In Illinois the unclaimed bodies are cared for by the Demonstrators' Association. At the Cook County Hospital in Chicago, Dr. Fred H. Stangl, the resident pathologist, tells me that there are about 900 unclaimed bodies every year. The hospital has an arrangement with the Demonstrators' Association by which such bodies to the number of from 200 to 275 are given each year to the hospital pathologists for purposes of instruction by necropsy. From the Charity Hospital in New Orleans, Dr. Duval writes that about 1,000 dead are unclaimed every year. Each body at the end of twenty-four hours becomes automatically a subject for necropsy or dissection, depending on arrangements mutually agreed on by Tulane University and the hospital authorities. In Ohio the laws are equally liberal. Any individual who dies in a hospital, and whose body is unclaimed at the end of thirty-six hours, automatically becomes a subject for examination by the accredited pathologist to the institution, and the pathologist is entitled to retain such organs as he may desire for purposes of teaching or research. Under the provisions of this law, Dr. Woolley at the Cincinnati General Hospital tells me that he secures, on an average, 150 necropsies on unclaimed bodies every year.

In New York State things are different. For example, during the year 1918, in the city of New York alone, 7,245 unclaimed bodies passed through the mortuary (an increase of 400 over the previous year, due to the pandemic disease which raged during 1918) and every one of this tremendous number was buried in potter's field without the legal right of necropsy or dissection of any description, with the exception of 715, which were given into the hands of the Anatomical Board for the use of the medical schools. In Bellevue Hospital alone, between 800 and 1,000 bodies are unclaimed every year, and forty-eight hours after death every one of these passes automatically into the custodianship of the commissioner of public charities, who is charged with their burial in potter's field.

#### "LIVING" PATHOLOGY

An ingenious method of dissolving the difficulties of teaching pathologic anatomy was recently proposed by one of our surgical interns at Bellevue Hospital in an anonymous document which he posted, or caused to be posted, on the bulletin board. The copy which follows is a true one, faithful to the charm of the original. It is an excellent illustration of the necessity for the broader training of medical students in pathology:

#### FOOD FOR THOUGHT

Why is it that so many physicians will get up in the middle of the night and travel miles to see a postmortem examination, and yet, many of these same men, in their minds, will consign to eternal oblivion the very thought of taking the elevator to the fifth floor of this building where

they can witness several operations every day, each of which will demonstrate the same changes produced by disease in living tissue before they are obscured by terminal results?

Since the sponsor of this implied protest is unknown, I am quite unable to say whether the sentiment is original or whether the protestant is a disciple of that distinguished Philadelphia surgeon who, in a paper embodying certain observations on what he terms "living" pathology, closes with the delightfully naive decision that "only by standing at the elbow of the surgeon . . . can the internist hope to attain proficiency in diagnosis and proper conception of treatment . . ."! Parenthetically, is not all pathology "living," is there such a thing as "dead" pathology—is it not true that all pathologic phenomena cease with death? Is there a "living" and a "dead" physiology? As a matter of truth, pathology and physiology are mated, and both are living—the one has to do with normal and the other with perverted function. The study of diseased tissues after death is but an attempt to arrive at an intelligent explanation of those digressions which were present during life. The practice of representing pathology to medical students as something which has to do with the dead rather than with the living is pernicious.

#### THE SURGEON AND THE PATHOLOGIST

There are surgeons that are accomplished pathologists. It is to be feared, however, that the average surgeon is ill prepared to instruct the internist in other than manipulative procedures. Indeed, if a knowledge of pathology were more prevalent among the ordinary run of surgeons and even among certain surgeons of exalted rank, the pathologist would less often be called to the operating room to make a frozen section for the "rapid diagnosis," let us say, of breast tumors. The better trained surgeon knows the naked eye appearance of the benign tumors of the breast and their differentiation from the malignant. He also knows, for example, that adenofibroma of the breast is often a precursor of carcinoma, that not uncommonly an apparently innocent adenofibroma reveals evidences of cancer only after the microscopic examination of sections removed at different levels, and that the necessarily hurried and almost uniformly improper fixation of tissues for diagnosis by frozen section is dangerous. In fact, it was taught by Orth, I believe, that the only really safe method of excluding malignant changes in these circumstances is by serial section of the entire growth; and this, of course, is rarely practicable. Other examples could be multiplied beyond the reaches of this paper. Certain it is that the rapidly prepared frozen section reveals nothing of immediate worth that is not detectable by the properly trained naked eye at a saving of time which is valuable to the anesthetized patient. It is not to be understood that the naked eye interpretation of breast tumors and similar lesions is without its pitfalls; but the microscopic pronouncement of malignancy in rapidly prepared frozen sections, while it may impress the visitor to the clinic, is seldom of further value, although it does place a burden on the pathologist in the event of mistake; and this, from the standpoint of the surgeon, is not without comfort. However true all this may be, it is far from my remotest desire to decry the teaching of pathology by the use of tissues freshly removed at operation or by the observation of changes in the living body. The method is a splendid one, albeit of such limited appli-

cation to general medicine that the internist who confines his inquiries in pathology to the peregrinations of the surgeon's elbow will find himself searching, as it were, for a pot of gold at the foot of the rainbow.

#### THE LAY PROFESSOR

In addition, however, to inadequate facilities for the teaching of pathologic anatomy, there are other defects to be found in certain American schools of medicine and all of them bear directly on pathology. For example, there are schools in this country in which the teaching of physiology and physiologic chemistry is entrusted to men who have received no systematic training in medicine—masters of arts or doctors of philosophy or of science. The consequence is that the student is apt to gather the impression that these subjects are only remotely related to practical medicine—that they constitute a sort of mental hurdle to be leaped and left behind as soon as possible, not necessarily because the nonmedical professor in the medical school is lacking in abstract knowledge of the subject which he is delegated to teach, but because, in the absence of a broad training in theoretical and practical medicine, his sense of proportion, his appreciation of relative values, his perspective is ill adjusted to the remainder of the curriculum and to the labyrinth of medical problems beyond the classroom. Sometimes it happens, also, that the chair of pharmacology is filled by a man whose education does not include a composite training in medicine. In these circumstances the questionable propriety of selecting such a teacher finds little extenuation in the fact that pharmacology occupies a place of secondary importance in the curriculum. It is none the less strictly a medical subject and should be taught by medical men. Moreover, there are at least two representative schools in this country in which the chair of anatomy is filled by men neither of whom holds a degree in medicine. Both, it is true, are scholars of caliber. But anatomy, it seems to me, should be taught by some one who at every turn is able to point out to the student the application of anatomic facts to clinical medicine and surgery. At Guy's and, if I mistake not, in other London schools, anatomy is taught by men who are qualified for surgical rank. The benefits are manifest—the student receives practical instruction and the surgical staff is recruited from masters of anatomy. In an occasional American school the effort to effect a liaison between anatomy and surgery is attempted by special lectures; but, in the majority of teaching institutions, the interval is never bridged, and the student leaves the dissecting room in considerable doubt as to the application of the multitudinous facts which have been crowded on him. The teaching of embryology commonly is left to instructors few, if any, of whom are capable of vitalizing the intimacy between it and pathology, notably in the vast domain of tumors. The teaching of histology is all too often entrusted to an assistant with the alphabetical distinction of a bachelor's degree in arts or science, thus leaving another gateway to pathology guarded by an extramural sentinel. Small wonder is it that so many slip through who do not know the meaning of the structural differences between an artery and a vein, and how many times is just such apparently simple knowledge as this invoked, almost unconsciously it would seem, to help clarify the day's problems? Let

the teacher of histology confide to the student the merest intimation of the importance of the elastic tissues of the aorta in the genesis of aneurysm, and the association is likely to be stored away in anticipation of that day when his knowledge of aneurysm shall have acquired concrete form and practical significance. Otherwise, the student is tempted either to forget that the aorta has any elastic fibers or to wonder why Nature should have gone to the trouble of placing them there.

Then comes the course in pathologic histology—the *pons asinorum* of the curriculum, in crossing which the student wonders all the while by what extraordinary combination of circumstances the microscopic changes in diseased tissues could possibly have to do with the problems of bedside medicine. Later, he is taken to the museum and to him are demonstrated a number of relics, or, in the more highly favored schools, he is permitted to look on collections of discolored or partly decomposed viscera removed at necropsy a week before, and again he wonders why experience still leaves him in confusion.

In this wise it is brought about that in the most impressionable years of his training the student is presented with subjects of enormous importance, but the presentation is made to him in such a fashion that he cannot fathom the relationship that they bear to one another or to clinical medicine. In New York State, to make matters worse, he is permitted at the end of the second scholastic year to take the licensing examinations in the elementary branches—*anatomy, physiology, chemistry, etc.*—passing which he feels that a yoke has been lifted from his neck and that, like other forms of suffering, he is now entitled to forget them and to seek elsewhere for happiness. Thus, he commences the study of the so-called practical branches almost completely bereft of that most valuable working asset of all—an anatomic conception of disease, without which the philosophy of medicine finds itself in constant conflict with the sophistry.

Moreover, the lay professor in the medical school seems disinclined to fill his assistantships with young physicians who, potentially at least, are better qualified to teach a strictly medical subject than is the head of the department himself and who, as they develop, promise to command no small degree of attention from the students. The student reasons that if these branches of medical knowledge, the import of which he has so often heard described in the superlative, are taught by men of academic training, then, indeed, there must be some element of exaggeration in the tales which have been brought to him of their ponderous value in practical medicine. Perhaps the argument is lacking in logic, but at least it has the merit of being human.

The danger does not cease here. The lay professor, himself realizing the necessity for correlating the teaching of his subject with that of the more strictly practical branches, too often yields to the temptation to trespass on that incidental knowledge which he has gathered in his travels with the medical caravan. In this way the student not uncommonly is misinformed at a period of development when his mind is receptive to impressions rather than capable of directive thought, and the eradication of mental weeds often is a far more difficult problem than that of their implantation.

Finally, it is significant not only that the lay members of the medical faculty, by virtue of their votes

and influence, participate in shaping the policy of the schools to which they are accredited, but also that the destiny of the entire system of medical education is thus partially given into their keeping. Even now there are those physicians that profess to see in this an explanation of the present disposition on the part of certain schools to overemphasize the importance of laboratory procedures. This tendency, which is becoming more pronounced each year, appeals strongly to those faddists among whom any test which suggests an easy approach to the solution of any problem, or which promises a division or evasion of responsibility, is assured of a kindly reception. Whether its credentials are written in the language of science or in that of pseudoscience appears to make little difference. It panders to laziness, which is man's most easily accessible weakness.

#### THE GRANTING OF HIGHER DEGREES IN MEDICAL SUBJECTS

There are also those that see another menace reflected from the same source of influence. For example, several American universities are committed to the policy of granting higher academic degrees in pathology, bacteriology, psychiatry and other subjects whose application belongs wholly or largely to the field of medicine. Bacteriology in its commercial or agricultural aspects is an obvious exception. In one of the great American universities, the degree of Doctor of Philosophy is given in psychiatry and carries with it instruction to the effect that psychoanalysis is applicable to the treatment of the feebleminded. It is a striking illustration of the fact that psychoanalysis is a therapeutic explosive which is at once too valuable and too dangerous to be entrusted to amateurs in psychopathology.

#### CONCLUSIONS

1. Faultfinding, unless it be undertaken with a view to constructive suggestion, is at best, I presume, a doubtful virtue. In this paper I have ventured to register two complaints—one has to do with the selection of nonmedical men to teach medical subjects. The means of correction suggest themselves. It would tend to overcome the difficulty if the universities indulged in fewer architectural extravagances—if they exhibited less magnificence in the matter of buildings and more munificence in the form of salaries. The problem is one which strikes at the root of our system of university education, for, with the ceaseless expansion of industry, corporations are calling for trained men, and many respond who otherwise would elect an academic career, but who cannot sacrifice financial emolument to intellectual pursuits. For the same reason the medical schools cannot hope to attract and hold medical men as laboratory teachers at a wage which is incompatible with decent living, when consultations beckon with finger tips of gold.

2. The other complaint concerns the prejudice against using the bodies of the unclaimed dead for purposes of education by necropsy. The remedy is apparently one of legislation. The making or changing of anatomic acts is not an easy matter, although it is to be recalled that the older anatomists prevailed against odds which were terrifying, and our task would appear to be somewhat simplified by their accomplishments.

That state which countenances dissection of unclaimed bodies for educational purposes could not, without being inconsistent, deny the legalization of

necropsy on the unknown dead for the promotion of medical progress, although consistency in such affairs is a somewhat independent quantity. Assuming, however, that it would be practicable to reconstruct existing laws governing the distribution of the unclaimed dead, I believe that amendments should provide, among other things, that if a patient without friends or relatives requests that his body be not touched in the event of death, his wishes are to be respected. If the relatives of a person dying in a hospital or elsewhere are unable to provide for burial and request that the body thus left unclaimed be not touched, their wishes are likewise to be respected. If a patient be admitted to a hospital in an irrational or unconscious state and remain so, his body, in the event of death, although unclaimed, is to be untouched if for no other reason than that, in his last illness, the deceased was given no opportunity to express a desire as to the disposition of his remains. In addition, the law should make it more than ever mandatory on the hospital to exercise every precaution accurately to record the location of responsible relatives at the moment of the patient's admission, to investigate every available clue should the patient die, and to leave the remains intact if it be established that such relatives exist but are not accessible. In every case, at least forty-eight hours should elapse before the body is legally declared abandoned, and the hospital should be allowed to extend this limit if delay is deemed desirable in the interests of those who appear to have been forsaken in death.

## THE TREATMENT OF PERITONITIS\*

GEORGE W. CRILE, M.D.  
CLEVELAND

After exhaustion or shock due to the condition for which operation is performed; after starvation from cancer or obstruction; after hemorrhage from perforating ulcers, etc., or following the physiologic disturbance produced by an operation itself—for instance, resection of the stomach, of the gallbladder, of the intestine, etc.—the most common danger incident to abdominal operations is infection. In civilian surgery, the principal sources of abdominal infection are the appendix, the gallbladder, the tubes, ulcers, or the operation itself; while in military surgery, infection may be due to missiles, clothing, or the contents of the hollow viscera—especially the last.

It follows that a consideration of methods of prevention and treatment of abdominal infection has a direct bearing on every type of abdominal operation. The scheme of treatment to be presented is based on a total experience in all types of operations of my colleagues Dr. F. E. Bunts, Dr. W. E. Lower and Dr. H. G. Sloan, my associates at Lakeside Hospital and myself, including 13,145 laparotomies among which are: 6,820 operations for appendicitis; 1,261 operations on the stomach and intestine; 1,289 gallbladder operations, and 2,837 operations on the female pelvic organs. By the general management to be outlined in this paper, our mortality in all abdominal operations has been decreased 33¼ per cent.; in acute appendix operations alone, the reduction in mortality has been 67.6 per cent.

The presence of infection is readily determined by two characteristic groups of symptoms—general and local. The general symptoms—accelerated pulse and respiration, raised blood pressure, increased temperature and rapid loss of strength and weight—indicate the presence of some acid-forming activation. On the other hand, the local symptoms—pain, tenderness, distention, muscular rigidity, intestinal paresis, vomiting—indicate the protective response of the organism to the bacterial invasion—its effort to secure immobilization in order that the spread of the infection may be inhibited. This increased activation of the organism in its self-defense against the infection, and the acids formed by the infection added to those due to chronic disease, by so much lower the resistance of the patient.

The prime problem of abdominal infection, therefore, is the same as the prime problem of abdominal surgery in general—the reduced resistance and mounting acidosis of the patient.

These facts point the way to the two prime requisites in treatment: (1) the conservation of the remaining energy in the body against further depletion, and (2) the neutralization and elimination of the superabundant waste products. In the abdominal case in which immediate operation is not imperative, the vitality of the patient may be increased by obvious measures—diet, fresh air, and above all *rest and sleep*, until a favorable condition for operation is obtained.

In the soldier with perforated intestines, however, and in the starved civilian patient with partial obstruction, or with acute infection, operative measures cannot be postponed. In these cases the administration by rectum of a 5 per cent. solution of sodium bicarbonate with 5 per cent. glucose, and an immediate transfusion of blood may effect a sufficient restoration for the operation, or at least for the first séance of a two-stage operation under strict anociation—nitrous oxid-oxygen analgesia, local anesthesia, and the minimum amount of manipulation required to complete the operation; or in grave situations to make a sufficient anatomic adjustment to save the patient until an interim of rest and restoration has sufficiently increased his vitality to permit the performance of the second and major stage of the operation.

As for the technic of the operation, whether it be performed in one or two stages, whether it be the removal of an appendix or gallbladder, resection of the stomach or colon, removal of tumors of the ovaries or uterus, or, in the wounded soldier, the repair of intestinal rents or perforations, every step should be under complete anociation—nitrous oxid-oxygen anesthesia or analgesia, supplemented by ether only when it is necessary to secure increased relaxation during the exploration, procain infiltration, gentle manipulations and sharp dissection.

The essential points in the associated treatment of abdominal infection, therefore, are:

1. Nitrous oxid-oxygen.
2. Anesthetized incision.
3. Accurate, clean-cut operation to diminish both infection and shock.
4. Adequate drainage.
5. Fowler's posture.
6. Vast hot packs over the entire abdomen, spreading well down over the sides.
7. Five per cent. sodium bicarbonate, with 5 per cent. glucose by rectal tap, continued as long as it is tolerated.

\* Read before the American Association of Obstetricians and Gynecologists, Cincinnati, Sept. 17, 1919.

8. Primary lavage of the stomach, repeated only if indicated. (It will rarely be indicated if anociation is complete.)

9. From 2,500 to 3,000 cc. of physiologic sodium chloride solution administered simultaneously every twenty-four hours until the period of danger is past.

10. Morphine hypodermically until the respiratory rate is reduced to from 10 to 14 per minute, and held to this rate until danger is past. It should be noted, however, that morphine is not useful in a streptococcus peritonitis.

By employing water, hot packs, and morphine, the surgeon can play the patient almost at will. The control of the drive, as marked by the changes in the respiratory rate in particular, is dramatic. Morphine lowers the respiratory rate, decreases the peristalsis of the intestines, reduces pain and secures physiologic rest and sleep, the prime means of recuperation.

Under this combination of the anociation of peritonitis with the anociated operation, my associate Dr. Lower and I have performed 409 consecutive operations for acute appendicitis with or without generalized peritonitis without a death.

1021 Prospect Avenue.

### SUPERIMPOSED CAVITIES, THE POSSIBLE CAUSE OF CRACKED POT SOUND\*

JOSEPH WALSH, M.D.

PHILADELPHIA

Cracked pot tympany (*bruit de pot fêlé* of Laënnec) is so well known to clinicians that a special description is unnecessary. It was first called attention to by Laënnec about 1820, and in 1860 was so fully described by Walshe<sup>1</sup> that nothing has been added since. It is found under the following conditions:

Pulmonary cavities. Osler<sup>2</sup> says "only over tolerable large cavities with thin walls"; Fowler and Godlee,<sup>3</sup> superficial cavity with slightly yielding walls and free bronchial communication, the mouth being open at the time; Cornet<sup>4</sup> in Nothnagel's Practice, cavities, especially at the apex communicating by a narrow orifice with an open bronchus.

Pleural effusion (*skodak* cracked pot, though ordinary tympany or hyperresonance is much more common).

Occasional cases of pneumonia when the consolidation is at its height.

Occasional cases of bronchitis, especially in children. Normal lungs of crying children during expiration.

Cornet mentions relaxed or infiltrated or tuberculous lung, or open pneumothorax.

A similar sound can be produced by filling the cheek with the mouth open, or striking the back of the hands, loosely folded across each other, against the face, the contained air being forced out abundantly and quickly between the fingers at each blow, or by filling the hand with coins, shutting it tight enough to allow only a slight space for the coins to move, then shaking the hand.<sup>5</sup>

It is commonly thought that the larger the cavity, and the nearer to the anterior wall, the more likelihood of its production. Yet we often see cavities of the largest size immediately underlying the surface not producing it, so that these circumstances alone do not explain it. Walshe states that in a case showing it, it will cease to be produced if the mouth and nose be closed, though percussion will still show tympany. He contends that the fair interpretation of this fact seems to be that the sudden rush of air from the cavity outward, produced by the forcible blow on the yielding parietes in the ordinary open state of the mouth and nose, but completely prevented by their closure, is the real cause of the phenomenon. It has, therefore, been considered necessary for the cavity to connect freely with bronchi, thereby allowing the air in the cavity to be expelled freely and instantly. Yet we often find at necropsy large cavities apparently connecting freely with large bronchi without the sound having been produced (Case 439, U. S. Army General Hospital No. 17).

It has also been asserted that it depends on the collision of liquid and air in the cavity; but Walshe called attention to cavities which with fluid did not produce it and without fluid did produce it. In addition, in the case of filling the cheek there is no fluid to explain it.

It is ordinarily stated, therefore, that the pathologic conditions producing it are a large cavity communicating freely with a bronchus, and relaxation of the pulmonary tissue.

Dec. 1, 1918, Case 296 at General Hospital No. 17 showed cracked pot in the first interspace near the sternum on the left with dullness to the fourth interspace. December 5, it showed ordinary tympany in the first interspace and cracked pot in the third interspace  $1\frac{1}{2}$  inches from the sternum. A diagnosis of two cavities was made. The roentgen ray, however, showed the appearance of four cavities, two superimposed on two others.

The possibility was suggested that the double cavity might have some influence in the production of cracked pot, and further cases were sought. Only one (Case 17) was found. This manifested cracked pot in the first interspace on the left, and the roentgen ray showed again the appearance of two cavities superimposed. This patient is still living.

Subsequent examinations of Case 296 revealed the cracked pot tympany sometimes in one and sometimes in the other of the two previously mentioned places and sometimes absent in both. For instance, December 14, there was ordinary tympany between the first and second ribs, and dullness between the third and fourth. When present, the cracked pot sound could be elicited both with the mouth open and with it closed, though more satisfactorily when open. Closing of the nasal passages was not tried.

December 30, this patient died. The necropsy disclosed not four cavities, but three, yet so situated that the first underlay the second and the second the third. The first extended from the apex to the second rib, the second from the first to the third rib, the third from the second interspace to the fourth rib. In other words, though only three cavities were present, they were so placed that in the two situations in which cracked pot sound occurred, there was a part of a cavity superimposed on another. On the strength of this finding, the conclusion was reached that the superimposing of cavities may, at least, aid in the production of cracked pot

sound, and investigations were made by artificially introducing cavities into the removed lungs of animals.

It was found that percussion of two inflated bladders tied so as to prevent the escape of air, either introduced into an animal's lung, or placed over one another outside, gave tympany, but not cracked pot. In other words, communication with the air is evidently necessary; the mere rattling of cavities on one another is not sufficient. An open trachea was percussed both within and without the lung, and found to produce it, though not so typically as occasionally heard; two open tracheas, however, superimposed produced the sound exquisitely.

The application of these facts to its occurrence in pneumonia, above a pleural effusion, and in crying children, affords a more satisfactory explanation than the one usually offered, namely, relaxation of the lung. In pneumonia, the tissue is consolidated around the bronchial tubes, so that they act practically like superimposed cavities, sometimes open, sometimes occluded, only in the former event producing the cracked pot sound. Above a pleural effusion the normal lung is compressed about the bronchial tubes, and since there is no secretion to occlude them, the sound is very common, much more common, for instance, than in pneumonia.

An analogous condition prevails in crying children. Fluoroscopic examination reveals that if we exhale all the air possible and then cough several times, we can raise the diaphragm to the third and even occasionally the second rib, thereby compressing the lung to this extent. The effort of the crying child is practically entirely expiratory, producing a similar condition and one not unlike that above a pleural effusion. In addition, the bronchial tubes of the child are much larger in proportion to the lung space, and give the sound of cavity more evidently.

I have never heard it over pneumothorax, though I have examined and necropsied more than twenty cases, several of which (for instance, Case 210) communicated with the lung by large openings. Stanton<sup>6</sup> reports sixty-one cases without cracked pot ever being noted. With the idea of superimposed cavities in mind we would expect it only over a small pneumothorax communicating freely with the lung with a large cavity behind it.

**Importance of Rural Hygiene.**—Over 50 per cent. of the population of the United States is rural. Therefore, what affects directly and importantly the residents of our rural districts affects vitally the strength of our nation. The reference to my breakfast of this morning illustrates the close and important connection between the residents of our urban centers and the sanitary conditions of our rural districts. Thousands of city residents visit the country every day for business or social reasons. The vast bulk of milk and other fresh foods supplied to our large cities are brought in from farm homes. Most of the cities obtain their water supplies from open streams or lakes which receive drainage from extensive rural territories. Through any of these media—persons, food, or water—and also by flies and mosquitoes, infection spread from unsanitary rural premises may be conveyed to persons residing in the city. Thus the sanitation of the rural districts has a direct and important bearing on the health of the whole nation.—L. L. Lumsden, "Rural Hygiene," *Pub. Health Rep.*, Nov 7, 1919.

## A BACTERIOLOGIC INVESTIGATION OF AN OUTBREAK OF INFLUENZA IN AN INSTITUTION

THE INMATES OF WHICH WERE PREVIOUSLY FREE FROM THE INFLUENZA BACILLUS WHEN COMPLETELY VACCINATED WITH INFLUENZA VACCINE

AUGUSTUS B. WADSWORTH, M.D.

Director, Division of Laboratories and Research, New York State Department of Health

ALBANY, N. Y.

The New York State Training School for Girls at Hudson, N. Y., is located on the southern outskirts of the city. The population of Hudson was 11,544 in 1915. It accordingly ranks as a third-class city. Early in the influenza epidemic in this country there was an outbreak in Hudson, but the quarantine that was immediately established at the training school was so rigidly and so effectively carried out that no cases of influenza developed in the institution. In order further to safeguard the inmates, all were vaccinated. A vaccine prepared by suspending in salt solution the growth of fifteen strains of the influenza bacillus (a vaccine prepared by the central laboratory at Albany, and one used generally throughout the state) was the vaccine used. Three doses containing 1 billion bacilli per cubic centimeter were given, a first dose of 0.5 c.c., and the second and third doses of 1 c.c. each.

### A SUCCESSFUL QUARANTINE

At this time a bacteriologic investigation was conducted by bacteriologists from the research laboratory of Dr. William H. Park in New York City, in order to ascertain how many of the inmates harbored the influenza bacillus. The influenza bacillus was isolated from the throats of only three of the inmates, who numbered 461 in all. These bacteriologic investigations and the vaccination were completed, Oct. 31, 1918. The epidemic in the city subsided without any cases developing in the institution. It was not certain whether this was owing to the effect of the quarantine or to the complete vaccination of the inmates.

### LATER OUTBREAKS OF INFLUENZA

During the latter part of December, 1918, however, there was an outbreak of influenza in the institution lasting through January, 1919. Unfortunately, it was not possible to secure bacteriologic investigations of the cases early in the outbreak, but later Miss Ella Hoppe of the laboratory staff was sent to the institution to take cultures from the nasopharynx in thirteen cases that had developed. The influenza bacillus was isolated from four of the ten vaccinated patients who were examined, and from two of the three unvaccinated patients. At the same time, cultures were taken from five persons who had been vaccinated but who had not developed influenza. These girls were in the cottage that had the greater number of cases. The influenza bacillus was isolated from one patient.

In February a second outbreak occurred, making the total number of cases, for the two outbreaks, 166 among the vaccinated, and thirty-seven among the unvaccinated. These thirty-seven had doubtless been assigned to the institution after October 31, when the vaccination of the inmates was completed. After the

second outbreak, nasopharyngeal cultures were taken from thirty-eight cases. No negative cases were reported until three specimens had been examined. The influenza bacillus was isolated from thirty-two of the thirty-eight cases examined. Thirty cases developed among the vaccinated, and from these the influenza bacillus was isolated in twenty-six. Eight cases developed among the unvaccinated, and the influenza bacillus was isolated in six of these. At the same time, cultures were taken from five persons who had been vaccinated but who had not developed the disease. Two cultures of the bacillus were isolated. Of the three negative cultures, one had been positive when control cases were taken in January.

#### RESULTS OF THE INVESTIGATION

The results of this investigation are thus of interest in demonstrating not only how much more effective and efficient quarantine is in the prevention of the spread of influenza than the use of an experimental preventive inoculation, the practical value of which is wholly indeterminate, but also that, with changing personnel, a rigid quarantine for a sufficient length of time should be maintained to insure against subsequent outbreaks. It is also considered of special interest to record the observations of influenza and the very general distribution of influenza bacilli during the outbreak without attempting to draw any definite conclusions from these isolated facts.

While at present the dispensary is giving treatment in new cases of discharged soldiers and sailors at the rate of about forty per month, these being referred by the American Red Cross and by the U. S. Public Health Service, and while this organization had entered the field some time before the Social Hygiene divisions of the Army and Navy were established,

Figure 2 is a detailed treatment schedule form for early primary syphilis. It is organized into several horizontal sections, each with a grid of boxes for recording dates and findings. The sections include:

- APPROXIMATELY ONCE WEEKLY FOR SIX WEEKS:** This section has a grid with columns for 'Date' and 'Finding'. It includes sub-sections for 'APPROXIMATELY ONCE WEEKLY FOR 3 WEEKS' and 'APPROXIMATELY ONCE WEEKLY FOR 3 WEEKS'.
- MERCURY SUPPLEMENT FOR 6 WEEKS:** This section has a grid with columns for 'Date' and 'Finding'.
- MERCURY RUBS FOR 6 WEEKS:** This section has a grid with columns for 'Date' and 'Finding'.
- SPECIAL FLUID WASHINGTON'S:** This section has a grid with columns for 'Date' and 'Finding'.

Fig. 2.—Schedule of treatment in early primary syphilis. The original card measures about 5 by 8 inches.

the formation of these efficient bodies supplanted our work, in part, during the period of the war.

However, from the first, the civilian educational propaganda has continued, and it has been most active since January 1 of this year. During that month, the objects of the league were communicated to 5,000 different employers of labor, by means of a series of letters, three in number. Since then, the dispensary superintendent has given twenty-six lectures reaching a total of 9,550 persons at hotels, lodging houses, Y. M. C. A. buildings, and industrial plants. More than 16,500 pamphlets were distributed at these lectures, making a grand total of 113,500 pieces of literature distributed, so far, by the league. At the present time, the requests for talks and pictures are so numerous as to tax the strength of our staff severely.

The films "Fit to Win," "The End of the Road," and "Open Your Eyes," which originally were prepared for the U. S. Public Health Service, are being used and exhibited to excellent advantage. The first showing of "Fit to Win" and an explanatory lecture, at the employees' club house of the great McCormick Reaper Works to an audience of 500, brought such an enthusiastic response from both the officers and men of this concern that ten successive showings were arranged for at the same place, in order to bring the facts before every one of the 9,000 employees of the firm. As a result, arrangements were made to place 100 framed dispensary notices in as many washrooms of this great plant.

More than 1,200 dispensary notices have been placed in sixty of the largest department stores and industrial plants, including the Illinois Steel Mills; Hart, Schaffner & Marx; the great packing plants; the stockyards; bakeries, and so forth. Nearly every Y. M. C. A. building has a display. In addition, there are permanent exhibits, each comprising a set of twenty-four framed pictures, at the city hall comfort station and in twenty-four of the big industrial plants. Framed posters are being exhibited in washrooms in scores of shops and factories.

## THE VENEREAL DISEASE DISPENSARY

INCLUDING A REPORT OF THE WORK DONE AT THE  
ILLINOIS SOCIAL HYGIENE LEAGUE DISPENSARY  
DURING AND SINCE THE WAR\*

B. C. CORBUS, M.D.

Chief of Staff, Illinois Social Hygiene Dispensary  
CHICAGO

In the summer of 1915, a charter was applied for and obtained from the state of Illinois for the establishment of the Red League of Chicago, which is now known as the Illinois Social Hygiene League. A campaign was started immediately to enlist the aid of the general public in promoting the aims of this organization. In addition to popular education in social diseases (venereal diseases), their prevention and treatment were included in the objects of the league.

In order to ascertain the exact facilities of the Chicago dispensaries and hospitals for attending and housing patients with venereal diseases, a questionnaire was sent out, the results being compiled and published in a survey by Dr. Mary Lincoln of this city. Excepting a very few instances, both hospitals and dispensaries were found to be far below the standard that had been set for the dispensary of the league. It was the intention of the organization to open this dispensary in the spring of 1917, but war was declared and sufficient funds were not available until the following spring (1918.) However, during the first year of its activities, the league conducted an intensive educational campaign.

\* Read before the Section on Urology at the Seventieth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

\* Owing to lack of space, this article has been abbreviated for publication in THE JOURNAL. The complete article appears in the Transactions of the Section and in the author's reprints.

DISPENSARY ORGANIZATION

*The Civilian Drive.*—Having familiarized themselves with the venereal situation as it existed in the armies and among the civilian population of the United Kingdom, the directors of the league decided to concentrate their interest and activities in an effort to put into effect the venereal disease program as outlined by the Advisory Board to the Surgeon-General in relation to these diseases among the laity. Therefore, being convinced that the time had arrived to fight venereal disease openly, in the civilian population, they equipped and established the first dispensary of the Illinois Social Hygiene League, at 118 West Grand Avenue, Chicago.

Since the program of the league is not only a medical one, but affects the social and the economic life equally, the public was invited to join and contribute to the work of the organization. From May 1, 1917, to May 19, 1919, 436 members have made contributions to the expenses of the league.

*The Dispensary Staff.*—Eleven specially trained physicians are now on the staff of the Illinois Social Hygiene League. Of these, three are women who treat only women patients and young children. Several other physicians, at present, are receiving instruction and training; and their number will be increased as rapidly as an increase in the available space can be secured, as it has been found unwise to hold clinics crowded by both patients and medical men receiving instruction.

With a view to increasing the interest and the efficiency of the staff members, it was decided from the beginning to pay each attending physician a fee of \$5 for each period of attendance. Thus, if a staff physician serves in the clinic for three weekly periods, he receives about \$60 per month. This principle of remunerating physicians for their work in the clinic has proved highly successful, and the staff members are rarely absent from the clinics.

All staff members are required to sign a medical ethics standard.<sup>1</sup>

*Improvements in Dispensary Practice.*—Some of the things that have been accomplished in our work are as follows:

Frequent meetings of the medical staff to discuss details of treatment.

Fig. 7.—Schedule of treatment in late secondary syphilis, page 2

The development of a standardized technic of examination and treatment for syphilis; also a definite discharge technic.

The development of a standardized technic of examination and treatment for urethritis; also a definite discharge technic.

A plan of study of case records.

The evolving of a new social service record and the securing of a social worker for women patients.

Separation of syphilis and gonorrhea clinics; also of clinics for men and women.

The appointing on the staff of women physicians for women and children patients.

The devising of new medical charts and history cards calculated to secure the greatest possible efficiency in history records.

The reducing of the business management, the collection of fees, and the soliciting of funds to an efficient basis.

*Equipment.*—Being located in the north central section of the Chicago business district, the dispensary is easily accessible. It occupies a two-story building, the first floor being used by the executive staff, with private telephone communication to the dispensary operating room. In addition, there is a private reception room for women.

On the second floor, there is a large waiting room, well furnished, with attractive pictures on the walls, also a cystoscopy room, a women's treatment room, an irrigating room, and the laboratory. Most important of all is a room, fitted with a comfortable bed, where the patients may remain several hours after having undergone a spinal puncture.

The dispensary periods last from one to three hours according to the number of patients calling for treatment. There are fourteen weekly clinics held, covering separate syphilis clinics for men and women; separate genito-urinary clinics for men and women; all groups of clinics being served by one nurse.

The hours at which clinics are held are arranged suitably for working people; namely, early morning;

Fig. 6.—Schedule of treatment in late secondary syphilis, page 1.

The chief of staff is not paid for his services, nor are the physicians in training and the occasional volunteers. A social worker is paid by the Chicago women's clubs. Besides the superintendent, there are two clerks, as much of the superintendent's time is being devoted to educational work which soon will include the supervision of a second, or branch dispensary in the stockyards district. A laboratory was established recently with one technician in charge.

1. This appears in the author's reprints.

hours for night workers, evening hours for those who work during the day, and noon hours for working women. The clinics are held for charity patients and for those who pay a fee for services received. Such a mixed clinic has been proved quite feasible and successful in actual operation. While certain relatively high fees are charged for arsenamin treatments (\$5), for Wassermann tests (\$5) and for spinal punctures (\$5), these charges are regulated to meet the financial status of the patients. The average fees received amount to \$2.50. The fee charged depends on the patient's earning capacity, on the number of persons dependent on him, and on his savings. However, no patient is turned away because of lack of means, and discharged soldiers and sailors are treated free of charge regardless of their willingness or ability to pay.

Thus, there is no real competition with private practice; for capable specialists in venereal diseases charge fees far beyond the pocketbooks of married men earning less than \$100 per month. As the medical service in the dispensary is salaried, there cannot be a possible exception taken to this arrangement on the part of the medical profession.

An excellent feature of the system of the dispensary is that the physicians and the nurse have nothing to do with the collection of the patients' fees, this being attended to by the lay clerical and social service staff under the direction of the superintendent. Therefore, the staff members are obliged to treat pay patients and charity patients with the same care and efficiency.

It is of interest to note that, during the first year of operation, the dispensary received \$4,300 from patients, nearly \$3,000 of which was paid to the medical staff.

**Records.**—The card system of records in use in the dispensary is unique in some respects. The medical and social service histories are kept on separate cards

The record system is so arranged that all of the facts of statistical importance are easily and quickly summarized. Our state and city departments of public health require complete records, which are furnished promptly. Reports also are made to previous medical attendants. Finally, the records permit ready arrangement for the purposes of clinical study.

The follow-up system, referred to in the foregoing, assures the constant and regular attendance of the

Fig. 11.—Schedule of treatment in tertiary syphilis, page 2.

patients. If these are neglectful, they are reported to the department of health.

Most of the drugs required for treatment are supplied to the patients, and no extra charge is made for them except in the case of mercury rubs, for which a week's supply calls for a payment of 50 cents. Occasionally, however, a prescription is written that must be filled at a drugstore.

**Clinical Material.**—The patients come to the dispensary largely from these sources, named in the order of their importance:

1. Exhibit, public comfort station at the city hall.
2. Referred by patients or former patients.
3. Signs in washroom in shop or factory.
4. Referred by private physicians, hospitals, philanthropic agencies, other dispensaries, and, surprising to relate, by druggists.
5. Newspaper publicity.

Thus are indicated the most successful methods of attracting patients to the dispensary. The educational work of the Social Hygiene League is, therefore, organized to give its greatest attention to the following publicity methods, also named in the order of their importance:

1. Permanent exhibits, comprising framed photographs and posters in public places.
2. Installation of three stereomicrographs in public places, such as the municipal pier, public bathing beaches, amusement resorts conducted by private capital (White City, Riverview Park, etc.).
3. Dispensary notices and posters in washrooms of shops, stores and factories.
4. Newspaper publicity.
5. Lectures illustrated with slides and films, at which literature is distributed.

**Safety in Industry.**—Employers and state and federal departments and safety organizations are working for the decrease of danger. But it can never be entirely abolished. When the machinery is as safe as it can be made employees still cause injury to themselves and to others by carelessness or blundering.—Wright, "Industrial Nursing."

Fig. 10.—Schedule of treatment in tertiary syphilis, page 1.

but in the same folder, thus automatically providing for an effective follow-up system of delinquent patients and, at the same time, a record of fees paid and owed. A signal system indicates at a glance what cases have been discharged within the month. A separate discharge slip of distinctive color, which must be filled out and signed by the last physician on the case, is attached to the record and contains the discharge record, the technic of which must be carried out carefully; otherwise the superintendent will return record and patient to the physician.

## THE EARLY DIAGNOSIS OF SYPHILIS AND A COMPARATIVE STANDARDIZATION OF THE TREATMENT\*

E. B. TAUBER, M.D.  
CINCINNATI

In the problem of syphilis it is imperative to secure an earlier and more efficient diagnosis of the disease than is the case at the present and a more generalized effective treatment. This should be the keynote of our endeavors.

The early diagnosis of syphilis is an unknown quantity to many men who are practicing medicine in our times. To men who have the older ideas of the disease to guide them, ideas that are firmly planted in their minds by a couple of decades of practice, it seems almost sacrilege to insist that waiting for secondaries is a criminal action and that we lose the benefit of the one psychologic moment in the life history of syphilis when we can seize our real opportunity.

The definite diagnosis in the early primary stage before the spirochete has spread to the lymphatic system near the primary lesion and before the serologic reaction is positive is the one and only time that, taken advantage of, may lead to success; and it is the time for action instant and effective. This is the time for radical cure if such is possible. An injection of arsenphenamin here can put an immediate end to infectivity of the case. A sterilization complete and entire seems possible here. The suppression of the biologic and serologic evidence of the disease is possible and maybe probable here. This should be our treatment for paresis, tabes dorsalis, iritis, etc.

### PROPHYLAXIS OR TREATMENT THAT WILL PREVENT THESE CONDITIONS

The first week or so of the initial lesion, while syphilis is still a local condition, is the time that we should employ every energy and endeavor of our diagnostic and therapeutic armamentarium to cure, for never again in the picture of syphilis for the individual patient or the state will this moment return.

Our public health services, medical colleges, hospitals, and clinics must teach this point and ever impress it on all in contact with them; that is, the student groups, the nursing groups and the public in general, these facts and necessities.

The dark field examination must be a routine at the clinics, in the hospitals and in our private practice. The organism must be known and recognized by all.

The newer staining methods, such as the Medalia method, must be taught generally. There can be no valid objection to teaching the profession of the future and the present the only means of diagnosis for the period when the dangerous sequelae may be mastered and dominated by us.

Every sore, whether on the genitalia or elsewhere, is or should be open to a suspicion of chancre and should be repeatedly examined for *Spirochaeta pallida*. Every papule, nodule, crack, excoriation, and herpetic or other erosion should be viewed with the possibility of an initial lesion and should be examined for *Spirochaeta pallida*. Chancroids should not be accepted as

uncomplicated with syphilis; double infection is always possible.

Antiseptics applied, especially mercurials, make the finding of *Spirochaeta pallida* difficult or almost impossible; and because of this we should teach that no mercurial dressings, or better still, no antiseptics, should be applied to any lesions until the examination for *Spirochaeta pallida* has been made, and if any have been used, it should be made a routine to irrigate thoroughly with physiologic sodium chlorid solution and to apply a wet dressing of the solution for twelve hours or more before examining for *Spirochaeta pallida*. To obtain *Spirochaeta pallida*, a definite method is important. We have used in the Cincinnati General Hospital this method:

The surface of the lesion is wiped with a cotton sponge to remove superficial organisms. The wound may be rubbed or teased lightly, but one should not cause bleeding; just an oozing that will give serum to transfer to a new clean slide and slip should be produced. Immersion oil is put on both the under surface of the slide and upper surface of the cover. This will give a continuous airless medium from dark field to objective. A focus with fine adjustment should be secured until one gets a dark background with the glistening moving particles in white rings. Then a search for the twisting spirochetes may be instituted.

As a professional body, let us be honest and acknowledge we have not spread the vital importance of early diagnosis. It has taken a world war to impress on us that the modern conceptions of syphilis have not been taught in our medical colleges. We have zealously striven to whitewash the episodes occurring in the wrecks due to this disease. We have had clinical characteristics and endless discussions as to secondaries and tertiaries and neurosyphilis; forgetting that we were proving our guilt in this very manner; and now we must scrap our clinical differences and turn to laboratory diagnosis to the finding of *Spirochaeta pallida*. I do not mean here the serologic diagnosis, for then we are losing our great opportunity.

### TRAINING THE PROFESSION TO EARLY DIAGNOSIS

How can we create this? This is our tremendous duty. You must all aid this. We must aid all the men who will do dark-field work in the smaller towns and villages and show them and others by our support that we are back of them. The internist, the surgeons of the smaller localities must call on the man in that locality who has special knowledge of syphilis, and this will cause the demand to be supplied. We must send to Coventry the man who cauterizes or applies some medicament to the sore on the penis or other location before advice, and competent advice at that, is given and the dark-field tests are made.

In early syphilis, systematic treatment must be immediate and must be pushed vigorously; sledge hammer treatment here is indicated, not feather duster types of treatment. Syphilographers will doubtless agree that the effective time for arsenphenamin is early, before the serologic tests are positive. So, then, this places on us the burden of outlining a method or schema for treatment that shall be more or less standardized. Here I mean a treatment for the majority of cases, not for individual ones; also a treatment that will not be inflexible but one that has been tried over a long period of time in a sufficient number of cases to at least have the merit of being successful. The

\*Read before the Section on Urology at the Seventieth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

outline I wish to submit has been tried at the Cincinnati General Hospital, the outpatient dispensary, the night venereal clinic and in my private practice, all of which I have under my control, and our results have been very good. Our method is as follows:

#### A SUCCESSFUL METHOD OF TREATMENT

Courses of from four to six intravenous injections of arsphenamin of from 0.3 to 0.6 gm. at intervals of from three to seven days are given, combined with mercury. Here we may with one or two such courses effect a cure. But even with such vigorous treatment a second or third course of arsphenamin of the same type is advisable after a two months' interval, given with the same courses of mercury.

In all cases, after the Wassermann test is positive, I believe at least three such courses of both arsphenamin and mercury to be the minimum, and more can be given as indicated. I believe that mercury, given either by intramuscular injections of soluble or insoluble preparations or by rubs, is of great aid to our arsphenamin therapy, and in the rational cure of syphilis, mercury and arsphenamin must be combined.

The courses of mercury should be from ten to twelve injections, at weekly intervals, of an insoluble; or from twenty-four to thirty, given every other day, of a soluble, or thirty to forty daily injections. I myself believe in giving one course of each type of mercury with each course of arsphenamin. Serologic tests should be made once a month at first, and later at two month intervals, until the test seems to become permanently negative as shown by at least five unbroken negative tests, each six months apart, with no treatment and no clinical evidence of syphilis before we should become in the least optimistic in regard to the case as being checked or cured.

It is my opinion that provocative injections and spinal puncture with the colloidal gold test may be made; but there is a difference of opinion as to this need, except in cases that require these special methods.

In late syphilis, mercury and iodids should be pushed in courses with arsphenamin given in the same way.

In secondary syphilis, the first year, three courses as above outlined of from six to eight doses of arsphenamin in each course, combined with mercury, and not less than three of such courses are indicated.

The second year, if the Wassermann test remains positive or there is recurrence of any lesion, practically a repetition of the first year's treatment, as outlined, will be necessary.

If the Wassermann test is negative and remains negative and there is no recurrence of lesions, at least four doses of arsphenamin in conjunction with two courses of mercury are recommended.

The third year, if the Wassermann test remains negative and there have been no recurrences from the first year, a patient should pass into a period of observation with regular periods for a serologic examination. If there is any nerve involvement or tabes and paresis, the treatment will depend on the individual case and will be covered by any general methods; but treatment must be pushed for years.

Congenital or hereditary syphilis requires longer and more persistent treatment; but again more individual treatment is necessary and cannot be outlined in the same way that early acquired syphilis can be. To recapitulate, my outline is as follows as regards standardization for early syphilis:

Arsphenamin and mercury to be given combined, Arsphenamin, each course from four to six doses of from 0.3 to 0.6 gm. intravenously at three to seven day intervals. Mercury (insoluble), gray oil, mercuric salicylate, twelve doses at weekly intervals, dose from three to five minims.

Mercury (soluble), twenty-four to thirty injections of mercuric cyanid or mercuric chlorid, given every other day. Rubs, twenty-four to thirty given every day.

*First Year.*—First course of treatment, from two to two and one-half months. Rest, one month. Second course of treatment, from two to two and one-half months. Rest, two months. Third course, from two to two and one-half months.

*Second Year.*—If Wassermann is negative, rest after third course for four months; mercury, two months; rest, four months; mercury, two months.

If Wassermann is positive, rest, two months; course of arsphenamin and mercury, two months; rest, two months; arsphenamin and mercury, two months; rest, two months; arsphenamin and mercury, two months.

*Third Year.*—If Wassermann is negative, patient passes to period of observation with regular serologic examinations.

If Wassermann is positive, rest after last course, two months; arsphenamin and mercury, two months; rest, two months; mercury course, two months; rest, two months; arsphenamin and mercury, two months, and so on, being controlled by serologic findings.

It is not easy to state when a cure is accomplished; but, in general, we can only say, by intensive therapy safety can be secured and in most cases a cure can be effected. This may result in overtreatment in some cases, but it is better to err in this way than to undertreat a single one, and some cures require a definite amount of treatment on a definite basis, if the needed results are to be obtained. Therefore, before patients are told they are well, even after repeated negative Wassermann tests without treatment (for negative Wassermann tests during treatment only indicate that progress is being made), I consider it necessary that at least two or three years of negative serologic tests without treatment or recurrence of any symptoms indicative of syphilis shall elapse before we can even say that we think the pathologic condition is eliminated. In so brief a paper I could cover only majority cases, and no attempt has been made as regards treatment or outline for individual cases.

#### CONCLUSIONS

1. No single sign of improvement should be accepted as definite or final, and treatment should not be stopped at such indication. Only cessation of all around symptoms is indicative, and that only if it continues through years.

2. Arsphenamin therapy is necessary, since it controls infectivity and contagion. It yields quick results.

3. Mercury is essential but as a splint to our arsenic therapy and as an aid to permanence in cure.

4. Most syphilis is undertreated. Sledge hammer blows are indicated. Overtreatment is to be preferred to undertreatment.

5. It is better to be overconservative rather than optimistic in stating that a cure has been effected. Our modern therapy is still in too infantile a stage to justify anything but overconservatism.

I believe that specializing and efficiency tendencies can be obtained, and very ably, in the treatment of syphilis.

Hospitals and clinical centers in our larger cities can be used by smaller centers. The extension of wartime methods in the army to civil practice will and should come.

In a few words, I believe syphilis is as easily preventable as other infectious diseases. With syphilis an actual condition, it must be recognized early and treated early if its economic results are to be prevented. Thus our problem is early recognition and early treatment. The early period is its period of greatest transmission; also the period in which our chances of curing a patient are greatest. This places the burden squarely where it belongs, on us, the medical profession, and also on the public health service, medical schools, hospitals and clinics. These different agencies must individually disseminate knowledge, acquire competent teachers, and adequate equipment to give adequate treatment and to graduate competent physicians. This means that syphilis needs centralization, efficiency, control, and the teaching of the early diagnosis of syphilis and a comparative standardization of its treatment.

19 West Seventh Street.

### UROLOGY IN THE UNITED STATES NAVY\*

OSWALD S. LOWSLEY, M.D.  
NEW YORK

The most important problem which presents itself to any one in charge of groups of individuals, civilian or military, is the maintenance of the good health of such persons. It has long been recognized that it is much more economical and, in fact, much easier to prevent certain diseases than to cure them. Smallpox, typhoid fever and last, and probably most important, venereal diseases are the most spectacular representatives of this group.

The urologist, serving with the United States Navy in the world war, was occupied to a certain extent with so-called major urologic problems, such as instrumentation (cystoscopy, endoscopy, etc.), and major and minor operations. His most important duties, however, were concerned with the prophylaxis and treatment of venereal diseases.

#### VENEREAL DISEASE IN U. S. NAVAL HISTORY

One examines the history of prophylaxis against venereal diseases in the United States Navy with a certain amount of pride. Admiral W. C. Braisted,<sup>1</sup> Surgeon-General of the Navy, said in his last annual report:

The medical department of the Navy began fifteen years ago to apply prophylactic measures against venereal diseases, and since that time has steadily broadened its campaign into a well rounded program for the prevention and control of these diseases. In addition to purely medical measures, an increasing amount of attention has been given to the moral and educational phases of the problem.

As individual opinions vary widely as to what steps may be properly undertaken to promote upright living and prevent the incidence of venereal diseases, and as there may be some misconception in regard to the attitude of the Navy in this matter, it seems fitting to outline the position taken by the bureau. Medical officers, both afloat and ashore, are charged with the duty of warning all persons in the naval service and particularly the newer, younger men, of the

danger of acquiring venereal disease through illicit intercourse, and of the serious consequences of such disease. In the instruction given on health and personal hygiene they are required to emphasize the sin of impurity and the necessity of pure living for the fullest enjoyment of health and happiness and the best and most loyal service to the country.

As far back as 1905, a method of venereal prophylaxis was recommended for general use in the U. S. Navy by Medical Inspector Oliver Diehl.<sup>2</sup> Various methods of conducting the prophylaxis were instituted during the succeeding five years, reports of which were rendered from time to time. Surg. Raymond Spear<sup>3</sup> rendered an interesting report:

In 1905, while the U. S. S. *Baltimore* was on the Asiatic Station, preventive treatment was given the men after their return from liberty, with the result that although the ship visited the ports of Sydney, Melbourne and the Auckland for a month each, there were practically no venereal cases on board, and the crew was "clean." This happy state of affairs was brought about by an intelligent commanding officer, who aided the medical officer in all his recommendations. The English ships which were in these ports at the same time as the *Baltimore*, in most cases, had over 25 per cent. of their crews infected with some sort of venereal disease; so the nonexistence of venereal disease on the *Baltimore* was due to the preventive treatment entirely.

P. A. Surg. W. J. Zalesky,<sup>4</sup> while stationed in New Orleans, in 1908, instituted a system of prophylaxis. Of his experience there he said:

The personnel of the station consisted of eighteen sailor men and about sixty-six marines. During the fall of 1908 the men were given several talks as to precautionary measures, and urged to apply for prophylactic treatments at the yard dispensary. For three weeks following, twenty-three men applied for such treatments, but gradually the number of applicants declined, the men losing interest in the treatments. During these three weeks, no venereal trouble broke out, and with the decline of applicants the venereal cases again increased. Liberty was freely granted, the limits of the station ended nowhere. Under these conditions, control of the men was necessary, and in endeavoring to impress on them the importance of prophylactic treatments, the aid of the commanding officer was sought. The interview with this officer resulted in the publication and posting of the following order:

1. Men who have had intercourse or have been exposed to venereal infection in any way will report immediately on their return to the barracks to the medical officer or his assistant on duty, at the sick bay.
2. It is important that men so exposed report for a preventive treatment at least twelve or eighteen hours after contact, as a delay in treatment is less likely to prevent disease.
3. Men will be examined at frequent intervals by the medical officer, and any man found concealing venereal troubles will be reported to the commanding officer.
4. No reports are entered on the sickness and disability sheets of the enlistment records in carrying out preventive treatments.
5. Men are informed that by reporting promptly and cooperating with the medical department in receiving preventive treatment they stand little chance of contracting venereal diseases and keep their body, record and surroundings clean.

Signed.....  
Captain..... U. S. M. C.

Approved:.....  
.....Commandant.

\* Read before the Section on Urology at the Seventieth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1915.

<sup>1</sup> Because of lack of space, this article is abbreviated in THE JOURNAL. The complete article appears in the Transactions of the Section and in the author's reports. A copy of the latter will be sent by the author on receipt of a stamped addressed envelope.

<sup>2</sup> Braisted, W. C.: Annual Report, Surgeon-General U. S. Navy, 1918, p. 172.

<sup>3</sup> Diehl, Oliver: Venereal Prophylaxis on the Asiatic Station, U. S. Naval M. Bull., July, 1910, pp. 355-37.

<sup>4</sup> Spear, Raymond: The Prophylaxis of Venereal Diseases on the Navy, U. S. Naval M. Bull., April, 1910, pp. 146-15.

<sup>5</sup> Zalesky, W. J.: Venereal Prophylaxis, U. S. Naval M. Bull., January, 1910, pp. 3-3.

At the time that the order was published, all men were examined and carefully instructed as to the intentions of the order. During the first month after publication of the order, fifty-six out of sixty-six men took the preventive treatment, with no developing venereal trouble. This good record has continued, as I have been advised that up to September 1, following over 500 applications of the treatment, not a single case of venereal disease has developed or been detected on that station for the past five months.

#### PROPHYLACTIC METHODS NOW IN FORCE

The Reports on Venereal Prophylaxis<sup>5</sup> made by P. A. Surg. W. S. Pugh, Jr., P. A. Surg. W. A. Angwin, P. A. Surg. N. T. McLean, Medical Inspector J. M. Edgar, Surg. J. S. Taylor and P. A. Surg. F. G. Abeken were published in the *U. S. Naval Medical Bulletin* for April, 1910, and on every ship the results were so excellent that prophylaxis became general throughout the entire navy. Below is a description of the method in practice.

The following direct orders were given to the crew:

1. Liberty will be given daily from 1 to 5:30 p. m.; on Sundays, from 9:30 a. m. to 5:30 p. m. Chief petty officers have liberty until 10 p. m. This applies to Central American towns.

2. All men who have been exposed to venereal disease will report at the sick bay and be given prophylactic treatment.

3. Those men who have not reported and then develop venereal disease will be punished for disobedience of orders.

4. A member of the hospital corps will be on duty for supervision of the treatments from 4 until 10:30 p. m., and from 7 to 9 a. m.

**Immediate Precautionary Measure.**—It was recommended to the men to use tablets of mercuric chlorid ashore directly after intercourse, and I have learned that a number of them did so.

**Preventive Treatment in the Sick Bay.**—The subsequent preventive measures to be taken in the sick bay, in guarding against infection, are these:

1. A thorough cleansing in hot soap and water must follow urination.

2. The external genitals are washed with a 1:1,000 mercuric chlorid solution. (Despite the experiences of others, I have never seen this strength produce irritation).

3. An injection of 2 per cent. protargol is given, about 5 c.c. being used. It was found in the use of this injection that the great difficulty was in getting the men to hold it five minutes, to do so, apparently, being too much trouble. To overcome this difficulty and have some of the solution retained, even if only for one minute, I decided to add 20 per cent. of glycerin to the solution. This did not prove to be an extra irritant, and it made the substance adhere, even when held only for a few minutes. I later found 15 per cent. of glycerin to be sufficient. The injections, in all these cases, were supposed to be held for five minutes.

4. Following the injection, calomel ointment (Metchnikoff's formula) was used. When first starting our crusade the foregoing ointment was made up with equal parts of benzoined lard and petrolatum as a base, but experience demonstrated that equal parts of lanolin and petrolatum were more tenacious, and had greater penetrating powers; at present the latter combination is used. After the penis is thoroughly dried, this ointment is spread over its entire surface from the external meatus to the root at the symphysis pubis. It is then thoroughly rubbed in and left on for two hours. A number of men have left it on all night with no evil effects.

Medical Inspector Oliver Diehl tabulated for the Asiatic Station the data which appear in Tables 1 and 2.

<sup>5</sup> Reports on Venereal Prophylaxis, U. S. Naval M. Bull., April, 1910.

The figures in Tables 1 and 2 are for the entire year of 1909. During the last six months, the cases of venereal disease have been further classified thus: The total number of cases during this period was 373, of which 246 were gonorrhoea; 108, chancroid, and 19, syphilis. They are subdivided, with reference to cause, as is shown in Table 3.

The number of men reported here as going on liberty, 70,954, does not include every man. But it

TABLE 1.—RESPONSE OF MEN TO PROPHYLACTIC TREATMENT

Classification	Number	Per Cent.
Men who went on liberty	70,954	100.0
Men who reported on return from liberty	65,655	92.5
Men who failed to report on return from liberty	5,319	7.5
Men who admitted exposure and received treatment	21,166	32.2
Men who denied exposure	43,469	67.7
Total number of primary venereal admissions during 1909 (gonorrhoea, chancroid or syphilis)	609	
Percentage (based on number of men going on liberty)		0.84

covers most of the liberty given by ships during the year, and the number (exceeding the average strength of the Navy and the Marine Corps) is considered sufficiently large to serve as a basis for a fair estimate of the value of the scheme.

Dr. Diehl calls attention to the prevalence of venereal disease in the navy in these words:

The extent to which venereal disease has caused damage to the service may be gathered from the following: In his last annual report, the Surgeon-General gives the following

TABLE 2.—TOTAL NUMBER OF CASES OF VENEREAL DISEASE (FIVE HUNDRED AND NINETY-NINE) CLASSIFIED WITH REFERENCE TO THE PROBABLE CAUSE OF DEVELOPMENT OF INFECTION

Probable Cause of Development of Infection	No. of Cases	Per Cent.
Failure to report	113	18.86
Denial of exposure	85	14.19
Overstaying liberty	85	14.19
Extended liberty	140	23.37
Failure of treatment	176	29.58
Failure of treatment (based on total number of men admitting exposure)		0.83

as the number of admissions in the entire Navy and Marine Corps during 1908; gonorrhoea, 3,015; chancroid, 665; syphilis, 1,001; total, 4,681. This, based on the average strength, which is given as 50,984, makes a ratio of 91.8 per 1,000. The venereal admissions constituted 17.76 per cent. of the total admissions for all diseases, and caused a total of 106,526 sick days. In his report for 1907, it was also stated that if applied to the force afloat, venereal disease alone

TABLE 3.—PROBABLE CAUSES OF DEVELOPMENT OF INFECTION IN SIX RECENT MONTHS

Probable Cause of Development of Infection	Gonorrhoea	Chancroid	Syphilis	Totals
Failure to report	48	13	5	66
Denial of exposure	23	17	3	43
Overstaying liberty	33	10	—	43
Extended liberty	70	30	6	106
Failure of treatment	72	38	5	

would have operated to render entirely inactive for over a month three battleships with a complement of 1,000 officers and men each.

From these early experiences, the present method of venereal prophylaxis has evolved and has become general, not only in the Navy but in the Army as well; and a decided effort is now being made to have the civilian population receive the benefits of the valuable lesson learned in the various branches of the service.

At the present time, the men in the Navy are given systematic education on the subject of venereal dis-

case, personal hygiene and the high value attaching to continence. By posters on shipboard and at training stations, by moving picture exhibits, by lectures and informal talks, everything possible is done to create proper sentiment on these topics as well as to warn against the danger of venereal infections. Men returning from liberty after incurring the risk of infection are urged to avail themselves of prophylaxis, for which facilities are provided at the sick bay under a trained attendant. They wash the genitalia with soap and water. Protargol, in a strength of from 0.5 to 2 per cent. is then injected into the urethra and held for a period of at least five minutes. Thirty per cent. calomel ointment is then rubbed on the penis and left on all night.

Men who contract a venereal disease are reported for misconduct and isolated. This means that they lose their pay until they become noninfectious.

Syphilitics have the subjoined abstract attached to the health record which follows them throughout their service, and hence does away with any possibility of the disease being neglected in the Navy:

Exposed at [city]; primary on [site]; spirochetes ———; Wassermann ———; luetin ———; secondaries ———; tertiary ———.  
Description ———.  
Signature of medical officer making diagnosis.  
Serum reactions: where made; date; reactions.

PREVALENCE OF DISEASE IN 1918

The statistics given in Table 4, concerning venereal diseases in the Navy for the six-month period ending June 30, 1918, were compiled from Form F cards received in the bureau. Only original admissions are included.

TABLE 4. VENEREAL DISEASES IN THE NAVY FOR THE SIX MONTHS' PERIOD ENDING JUNE 30, 1918

Estimated average complement	322,270
Total admissions for gonorrhoea	12,752
Number of days lost	88,820
Average number of days lost	7.0
Annual rate per thousand	63.96
Total admissions for syphilis	1,110
Number of days lost	6,333
Average number of days lost	5.71
Annual rate per thousand	3.44
Total admissions for chancroid	2,810
Number of days lost	29,000
Average number of days lost	10.32
Annual rate per thousand	18.14
Total days lost, all venereal diseases	125,153
Average number of days lost, all venereal diseases	9.50
Annual rate per thousand, all venereal diseases	41.30

The wonderful work done in venereal prophylaxis has written a page in medical history which will live forever. We of the Navy point with a certain amount of pride to the fact that it was the Navy Medical Corps which first brought out the efficacy of prophylaxis along venereal lines. It was so thoroughly done and was so convincing that the entire medical profession has adopted the methods developed. Every credit must be given the Venereal Prophylactic Department of the Army for its extensive and efficient campaign for the protection of our soldiers, which has attained the same perfect success that characterized the original work done by the Navy.

ESTABLISHMENT OF A UROLOGIC CLINIC

The United States Navy has always had a reputation for speed and efficiency, and the establishment of a urologic clinic at the Pelham Bay Naval Training Camp bears out this reputation.

After being in the camp doing influenza work for a few days, it seemed to me that there was decided need for a urologic clinic. A building was therefore found which was being held in reserve for the observation of suspected contagious cases. Rough plans of the changes desirable in the building to make it suitable for a clinic were prepared by a sailor. A list of the physicians and hospital apprentices needed was then made out. Finally, a complete list of all equipment and instruments necessary to the proper conduct of an up-to-date, scientific clinic was compiled. Armed with this material and a letter describing my ideas on

TABLE 5.—TABULATIONS BY DEPARTMENT OF SERVICE SHOWING A COMPARISON OF THE PREVALENCE OF GONORRHEA, SYPHILIS AND CHANCROID IN THE NAVY FOR THE SIX MONTHS' PERIOD ENDING JUNE 30, 1918

VENEREAL DISEASE	REPORTED FROM THE FLEET			Total for Six Months' Period
	First Quarter (Jan. and Feb. and March)	Second Quarter (April, May and June)

Average days lost, all venereal diseases	7.54	5.12	6.42	

the subject, the senior medical officer, Commander B. L. Wright, was interviewed. Within one week's time after the senior medical officer had approved the suggestions made, the clinic was in full swing; the building had been reconstructed; all equipment was in place and in working order, and all instruments were at the clinic or on the way there.

Rooms suitable for cystoscopy, urethroscopy, minor operations, irrigations and other treatments were provided. In addition, there was a large writing room with a recorder's desk, a ward containing four beds, a utility room, a small kit bin, and a room for men on night duty.

The floor plan (Fig. 1) is self-explanatory.

The personnel of the clinic comprises nine persons, three lieutenants (one the director and the other two his assistants), five hospital apprentices, and one orderly.

The patients were all referred to the clinic by medical officers in the regimental infirmaries. At the first visit, each patient had a card made out, on which was recorded his name, age, race, location and the date on the top line. Below that was a brief outline of the patient's history, including his chief complaint, the symptoms, their duration, the source of infection, the previous venereal history, and the present condition.

capacity. A space was provided for a record of the findings at examination, for the final diagnosis, the medicine and an outline of his treatment. On each patient's first visit, his card was made out, as far as possible, by the recorder. He was then passed on to one of the medical officers, who completed the history taking, and gave the patient a thorough examination, taking as much time as necessary for this purpose. The form of the card used for the patients appears below.

The clinic was thoroughly equipped for accurate work, and there was intimate cooperation between the camp laboratory and the roentgen-ray department at the base hospital. The clinic gave us every modern aid necessary in arriving at a correct diagnosis.

TABLE 5.—TABULATIONS BY DEPARTMENT OF SERVICE SHOWING A COMPARISON OF THE PREVALENCE OF GONORRHOEA, SYPHILIS AND CHANCEROID IN THE NAVY FOR THE SIX MONTHS' PERIOD ENDING JUNE 30, 1918—Continued

Average number of days lost.....	9.51
Annual rate per thousand, all venereal diseases.....	99.67

The general plan followed was for the medical officer to give as much time as necessary to each patient, in order that a correct diagnosis might be made. To this end, the hospital apprentices were trained to give the usual type of treatments, such as prostatic massage, bladder irrigations, sounds, the administration of arsphenamin, and the injection of mercury. After the patient was started on his treatment, he might not see the medical officer for a period of a week or ten days, unless he expressed the desire to do so, or the hospital apprentice in charge considered the interview necessary.

At the morning clinic, appointments were made with patients in need of cystoscopy, urethroscopy, minor operations, major operations, and various other procedures, which required the time of the medical officer.

Here is an outline of the week's work: The clinic's duties began at 8:30 a. m. daily. Passing sounds and

other instrumental work was done at 10 a. m. Mondays and Thursdays, at 1 p. m., cystoscopy and urethroscopy were performed, on Tuesdays and Fridays, at 1 p. m., minor operations. Wednesday was arsphenamin administration day. Saturday afternoon and Sunday, only routine treatments were given.

Through the kindness of Commander P. T. Desze, the medical officers of this clinic were permitted to do certain necessary investigative work in the hospital roentgen-ray room, such as passing of lead ureteral catheters, immediately followed by roentgenoscopy and the giving of injections of thorium, sodium bromid, etc. Authority to operate in major operative cases discovered in this clinic was granted by the base hospital officers.

Acute venereal diseases and infectious skin diseases were definitely diagnosed and sent to the base hospital in the usual manner, through the regimental surgeon, who made out the health records in accordance with the findings of this clinic.

Charts were kept for the pathologic condition of each anatomic structure. These were kept up to date by the recorder, who made them out at the end of each

clinic day. There were special charts for syphilitic cases, chronic prostatitis and minor operations.

A perusal of the statistics proves to be very illuminating. Before discussing these in detail, attention is called to the fact that Pelham Bay Naval Training Camp is changed somewhat in its character. During the war, it was almost entirely a training camp for officers and petty officers. Therefore, the men comprising it were picked men, both as regards their intellectual capacity and their physical ability. In addition to the men in the training school, there have been stationed here a number of orchestras, bands, groups of athletes, actors and the usual number of mechanics, yeomen, and the like.

As soon as the armistice was declared, a large majority of the men originally in the camp were graduated from the schools, or discharged from the service. More recently, the camp has been utilized as a point for the physical examination and discharge of sailors, particularly those who have been abroad.

the remainder were infections of the skin of the scrotum. The hydrocele and varicocele patients were operated on under local anesthesia and then kept in bed for a period of four days. Drainage with rubber

TREATMENT PRACTICED

The attendance of the clinic was very gratifying, indeed. The total daily attendance averaged 141 (Table 6). The clinic was used largely in a consultative capacity. Patients requiring treatment, such as urethral injections, daily, have been referred to the regimental infirmaries and do not appear on the list.

The types of cases treated included practically every lesion of the genito-urinary tract. Because of the fact that most of the men were young, healthy adults, there were very few cases of major lesions of kidneys, ureters, etc.

All of the phimosis patients were operated on under local anesthesia in the clinic, 0.1 per cent. cocaine being the drug used. It was our practice to put such patients to bed in the clinic for a period of from one to three days, after which they were returned to their barracks.

Lesions of the scrotum were fairly rare, only fourteen instances having been noted. Of these, five were varicocele; four were hydrocele; three, hernias, and

tubing was employed in the hydrocele cases.

By far the greatest number of individual cases for any lesion were the cases of chronic prostatitis. These patients varied in age from 18 to 31 years, the average being 23 years. Fifty-two of these patients complained of morning drop; forty-one complained of more or less continuous mucous discharge; six complained of pain; ten had dysuria; four had nocturia, and one complained of premature ejaculation.

All chronic prostatitis patients were treated by rectal massage, followed by irrigations of permanganate or silver nitrate. Sounds were passed at intervals. The prostatic fluid was examined in a fresh state with a microscope at regular intervals. No patient was discharged as cured until all pus had disappeared from the prostatic fluid. Most chronic prostatitis patients were subjected to both a cystoscopic and an endoscopic investigation at some time during the course of their treatment.

We found numerous cases of enuresis, in practically every one of which we were able to discover, by the use of the cystoscope and the endoscope, a lesion of the prostate or of the posterior urethra, or both. These patients were subjected to treatment of the prostate by massage, etc., and by application of cauterizing agents

LESIONS OF KIDNEYS

through the endoscope, and were practically universally cured.

We had two cases of stone in the ureter, in both of which operations were performed in the base hospital. We had one case of bilateral renal hemorrhage, which cleared up after rest in bed, hot applications and uri-

nary antiseptics. We had no cases of tuberculosis of the genito-urinary tract.

An interesting fact was brought out in the treatment of acute gonorrhoea. It was found that a cessation of the discharge was brought about in three weeks from the onset in the average case. Several cases were aborted, being cleared up within a week. On the other hand, a few cases persisted for about six weeks. These cases were all treated according to this routine: Inter-

## PREVENTIVE MEDICINE AS APPLIED TO VENEREAL AND SKIN DISEASES\*

HUGH HAMPTON YOUNG, M.D., D.C.M.

BALTIMORE

General Gorgas said early in the war:

Veneral diseases present the most serious communicable disease problem of the war. . . . The army loses more days of service from its men on account of venereal disease than from any other cause. During the twelve months ending September, 1918, there were 170,000 cases of venereal disease in our army (in the United States). This means a loss of approximately two and a quarter million training days in a year. Add to this the cost of medical care and hospital equipment, and the loss of possible relapse later and you commence to see what venereal diseases cost a nation at war. . . . During the period from Sept. 2, 1917, to May 31, 1918, the annual rate per thousand for our troops in the United States was 102.3 per cent.; the rate from all other communicable diseases, 29.4 per cent., pneumonia, scarlet fever, typhoid and paratyphoid (measles not included).

En route to France, by request of General Pershing I spoke to his officers and men on the S. S. *Baltic*, June 3, 1917, on the army venereal problem. In this lecture I presented a chart to demonstrate the excellent progress that had been made in the reduction of infectious diseases in the United States Army from 1906 to 1916 (Fig. 1). As shown here, a most remarkable result had been obtained in the practical eradication of typhoid fever and a great reduction in malaria. Alcoholism had been reduced to a third of its previous frequency.

After the introduction of prophylaxis in 1911, venereal disease had dropped from 155 per thousand per year to 84. I expressed the hope that it would

### LESIONS OF SCROTUM

nal medication, acid sodium phosphate or sodium benzoate, 10 grains before meals; hexamethylenamin, 15 grains after meals. Local treatment, 10 per cent. silver protein compound of the argyrol type injected for five minutes three times daily.

Cases in which the disease had become posterior were treated by irrigation of potassium permanganate once daily and injection of a silver protein compound of the argyrol type twice daily.

We were not able to obtain any acriflavine, and were therefore unable to try out this drug, which, according to some reports, has been remarkable in its cure of acute gonorrhoea.<sup>6</sup>

### STATISTICS ON VENEREAL DISEASES IN U. S. NAVY<sup>7</sup>

The annual venereal disease rate in the Navy during the eight years previous to the war was without appreciable variation, as follows:

Syphilis	42.97 per 1,000
Gonorrhoea	90.36 per 1,000
Chancroid	33.31 per 1,000
Total	166.54 per 1,000

During the fiscal year, July 1, 1917, to July 1, 1918, the period during which educational and preventive measures were introduced into naval training camps, methods practically parallel to those adopted in Army camps, and developed through the Navy Department's Commission on Training Camp Activities, the rates were decreased by 60.75 per cent. In figures the rate for this year is as follows:

Syphilis	12.28 per 1,000
Gonorrhoea	69.59 per 1,000
Chancroid	24.10 per 1,000
Total	105.79 per 1,000

Furthermore, according to latest reports, this rate still continues to decrease, reaching in August, 1918, an average of 80.34. The annual rate is obtained in the following way: The figure representing the total original admissions to the sick list during the week is multiplied by 1,000 and divided by the complement of men. The quotient is then multiplied by 52.

<sup>6</sup> In addition to the references already given, the following will be found of interest:

Confidential notes on Preventive Medicine for Medical Officers, U. S. Navy, Nov. 15, 1918.

<sup>7</sup> From the Social Hygiene Monthly.

Fig. 1.—Decrease in infectious diseases in the United States Army during the ten-year period from 1906 to 1916.

be possible to better these figures considerably in the American Expeditionary Forces. It will be subsequently seen how this prophecy was fulfilled. In this lecture, stress was laid on the value of education as to the frequency and danger of venereal disease.

\* Read before the Section on Urology at the Seventieth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

<sup>8</sup> Owing to lack of space, this article has been greatly abbreviated in THE JOURNAL by the omission of tabular matter, reproduction of official orders, etc. The complete article appears in the Transactions of the Section and in the author's reprints.

1. Venereal Disease, No. 11, U. S. P. H. S.

I dwelt on the fact that continence was quite compatible with sturdy health in young men leading active outdoor lives, and called attention to the excellent results that had been obtained on the Mexican border by closing houses of prostitution, and driving out all clandestine

phenamin had been given. During the years 1915-1916, this hospital had given treatment in 22,596 cases of gonorrhoea, which totaled for the patients 1,082,621 days in hospital, an average of forty-eight days per patient. Sixty per cent. of these cases presented complications, usually prostatitis, and epididymitis, and 17 per cent. of the patients were readmitted for relapse of the disease after being discharged as cured. In addition, all patients lost from one to two weeks each in travel to and from the hospital.

*The French Army.*—No accurate statistics were obtainable as to the amount of venereal disease in the French army, partly owing to the fact that uncomplicated gonorrhoea is treated by the French in the regimental organizations. Thibierge,<sup>2</sup> however, estimated that up to the end of 1916 there had probably been 200,000 cases of syphilis in the French army. These were treated in about twenty hospitals varying in capacity from 100 to 800 beds, each patient remaining in hospital for from four to seven weeks. The French had established throughout their country "Centres dermatovénérologiques" at which patients with venereal disease, in both the civil and military population, are under treatment at clinic and as bed patients.

Fig. 2.—Venereal rate per thousand per year for each week from September, 1917, to January, 1919, in both the American Expeditionary Forces (solid line) and in the troops in the United States (broken line).

prostitutes and saloons in nearby towns. Emphasis was also laid on early prophylaxis, and the remarkable results obtained by it.

Then and afterward General Pershing evinced the keenest interest and knowledge of the subject of venereal disease as an army problem.

Arriving in England, I was assigned to the study of the venereal problem there with three other officers, namely, Capts. L. C. Lehr and M. L. Boyd and Lieut. H. L. Cecil. We reported to the British authorities in England, June 8, 1917, and devoted about a month to the study of the treatment of venereal diseases in England and with the British troops on the continent. Numerous hospitals in England and France were visited, and the routing of venereal patients was studied from their diagnosis in the various organizations to their admission to the hospitals. A second month was then spent in the study of the methods employed in the hospitals attached to the French army, and an extended tour was made with Captain Lehr and Médécin-Major Simon of the French army, during which the Second, Fourth, Fifth, Sixth and Eighth Armies were visited and sanitary organizations were studied and followed from base to trenches in various places.

VENEREAL DISEASES IN BRITISH AND FRENCH ARMIES

*The British Army.*—It was found that during the year 1916-1917, treatment was given in 112,259 cases of venereal diseases in the British army hospitals. Of these, 52,495 were treated in fourteen hospitals in England and 59,764 in five hospitals in France. The capacity of these hospitals varied in England from 100 to 1,500 beds, and in France from 500 to 3,500 beds. The largest of them, with a capacity of 3,500 beds, had given treatment, up to the end of September, 1917, in 55,634 cases of venereal disease, among which were 12,000 syphilitics, to whom 94,021 injections of ars-

RECOMMENDATIONS FOR UROLOGIC SERVICE

August 6, 1917, I reported to the chief surgeon of the American Expeditionary Forces, and was requested

Fig. 3.—Efficacy of venereal prophylaxis. The percentage of infections (or failures) gradually rises from 0.08 per cent. during the first hour after sexual contact to 1.57 per cent. after four hours, and reaches 7.4 per cent. after ten hours.

to prepare recommendations for the organization of a urologic service of the American Expeditionary Forces.

2. Thibierge: Syphilis et Pirmée.

In a preliminary argument the disadvantages of the methods employed in the French and British armies were briefly detailed, particular stress being laid on the absence of educational propaganda, of prophylactic

sent there as "division urologist," to put the new methods in operation, and was given the most hearty cooperation by the division surgeon, Colonel Ashford. The effects of the methods adopted soon began to show themselves.

In September the venereal rate was 80, but by October 26 it had fallen to 54 per thousand per year. In November, however, came a terrible increase in the venereal rate, which rose rapidly to 201. Investigation revealed that men in the new divisions that had begun to arrive through the Port of St. Nazaire had become greatly infected there.

I received orders to investigate the situation. It was found that this small seaport was utterly inadequate to take care of the ships arriving from America. As a result of this, it would often be many days before the soldiers could be debarked, and during this time the men were given shore leave for the purposes of exercise, relaxation and amusement. St. Nazaire was a typical dirty seaport town with numerous grog shops and many houses of prostitution, and was inadequately policed.

In a camp near by, many thousand soldiers were detained while waiting to be dispatched to training areas which were being organized to receive them in eastern France. The soldiers had free access to the town, and as a result there was much drunkenness, and the houses of prostitution did a flourishing business, the adjacent streets being blocked by hundreds of soldiers, and the individual women taking on from thirty to sixty men each in an afternoon and evening. Men returning to the ships found no prophylactic stations, and those in the town and camp were inadequate. The sudden rise in the venereal rate was thus immediately explained.

The following memorandum was presented:

Paris, Oct. 20, 1917, a memorandum for a cable to Secretary of War given to General Pershing.

Fig. 4.—Record of prophylactic treatments at Rennes.

methods, the disadvantage of moving men from the front to hospitals far distant for treatment of venereal diseases, the inadequate treatment obtained owing to the inability to treat the patient more than a limited period of time, and the bad effect on morale in removing from the front men with venereal disease.

Steps were at once taken to make the necessary preparations for inaugurating the plan which had been adopted.

A set to be known as the "regimental infirmary urologic set," with a splendid equipment of glass syringes, platinum needles and other instruments, necessary for syphilis and minor genito-urinary work, was devised and ordered in quantity in Paris.

A simplified standard treatment for syphilis was devised, namely, special ampules of neo-arsphenamin; ampules of bidistilled sterile water, 2 c.c. (the solution to be made direct in the ampule of neo-arsphenamin); 1 c.c. ampules of 1 per cent. mercuric cyanid, and ampule syringes of 40 per cent. mercurial (gray) oil (mercury for intramuscular injections).

INAUGURATION OF PLAN IN THE DIVISIONS

The first division had already arrived in France and was encamped in the training section of which Gondrecourt on the Meuse River, about 20 miles from Toul, was the headquarters. Capt. M. L. Boyd was

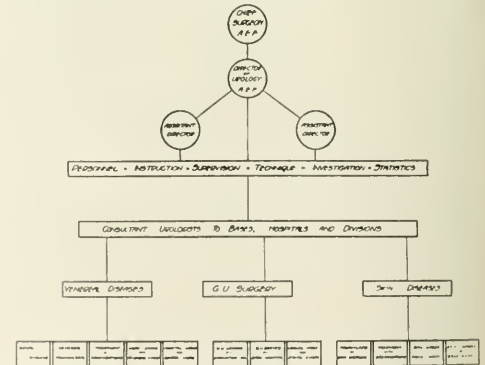

Fig. 5.—Graphic outline of the organization of the division of urology and its activities.

Commanding and medical officers should give more attention to the instruction of men on venereal diseases and their prevention.

Incoming troops show evidence of contracting venereal disease while on leave just before embarking.

Equipment for the treatment of venereal disease on shipboard has been very inadequate. Cases developing on sea, especially syphilis, have gone untreated. Transports should be thoroughly equipped for all this work.

Regiments have arrived without proper equipment and drugs for prophylactic stations at their camps, and for the treatment of venereal disease.

Officers do not seem to be sufficiently impressed with the gravity of the venereal situation in Europe, of the especial danger to incoming troops, and of the great loss of effectiveness which has been produced by venereal diseases.

*Comment.*—During the months of August, September, October and the first half of November, the houses of prostitution flourished and were filled with soldiers. November 15, rigid orders were issued placing these houses out of bounds, and the immediate result was a great reduction in the number of sexual contacts, as shown by the number who took venereal prophylaxis. As a result, there was a steady decline in venereal infections among resident troops, and the monthly rate per thousand, which in October reached 16.8, dropped in January to 2.1 among the white troops. During the same period there was an even more startling drop in the venereal infections among the negro laborers, the percentage dropping from 108.7 per thousand per month to 11 per thousand. No statistics could speak more eloquently for the doctrine of closing the houses of prostitution. Our studies had previously shown numerous infections coming from houses regularly "inspected" three times a week.

As a result of the measures that were taken, there was a continued decrease in the venereal rate of the American Expeditionary Forces, which, according to the statistics of the Surgeon-General's Office, fell to 16 per thousand per year in October, 1918, as shown in Figure 2. In the meantime the army had been growing rapidly, and the personnel of the division of urology had greatly increased.

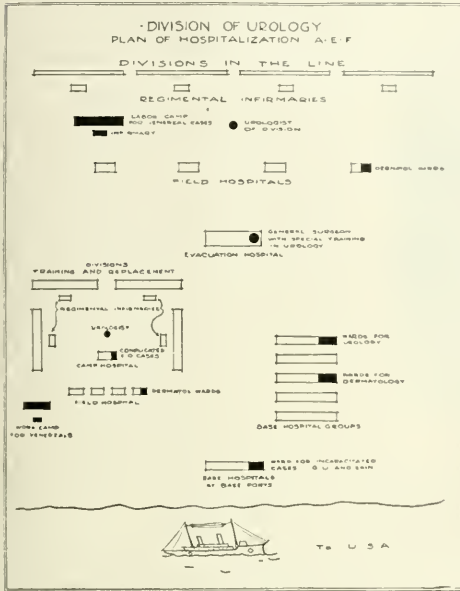

Fig. 6.—Plan of handling venereal and urologic surgical cases in the American Expeditionary Forces.

Information, instruction and advice, by means of cards, leaflets and posters, as well as by lectures delivered on shipboard, would be very helpful.

On arrival of transports, shore leave should not be given to troops, and they should be kept in camp pending their transportation to training camps.

HUGH H. YOUNG,  
Major, M. R. C., Consultant Urologist, A. E. F.

In addition to the foregoing memorandum a detailed report on the situation at St. Nazaire was presented and as a result General Pershing made a special trip to St. Nazaire and promulgated General Order 77, which is one of the most notable of army health orders. This general order put the houses of prostitution out of bounds, stopped the sale of strong liquors, and confined the troops on transports until ready to be debarked.

The stringent provisions of this excellent order, particularly the provision that the "venereal reports be filed at these headquarters with personal records of organization commanders, and will be used in determining a commander's efficiency and suitability of continuing his command," produced a profound impression and stimulated both line and medical officers to keep down the venereal rates in their organizations. The immediate effect of this order was seen in the venereal reports of the troops permanently stationed in St. Nazaire, as shown in Table 2.

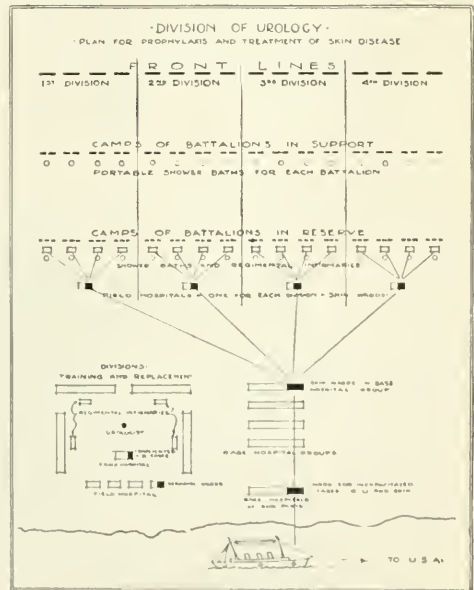

Fig. 7.—Plan for the prophylaxis and treatment of skin disease in the A. E. F., by bathing, disinfecting and laundries. The special wards in base hospitals never became necessary.

FEATURES OF THE CAMPAIGN AGAINST VENEREAL DISEASE

The campaign against venereal disease in the American Expeditionary Forces consisted briefly of the following:

1. Social hygiene, which had for its purpose the minimizing of the number of sexual contacts.

2. Prophylactic treatment, bi-weekly examinations, the object of which was to detect venereal disease and to institute prompt and efficient treatment, in order to reduce the number of days sick, and to restrict leave in order to combat the spread of infection.

3. Repression of prostitution by placing houses out of bounds.

4. The reporting of sources of infection and dispensary treatment of the civil population.

Fig. 8.—The Foden-Thresh steam disinfecter in operation at bathing establishment of the Twenty-Sixth Division within 1 mile of front-line trenches.

5. Enforcement of laws relating to alcoholism.

6. Court-martial for venereal disease.

7. Treatment of venereal disease with the organizations, in order to reduce the loss of effective strength and to avoid making venereal disease an excuse for escaping duty.

#### SEXUAL CONTINENCE

In various general orders and circulars, sexual continence was urged on the troops of the American Expeditionary Forces. Is this in any way possible in armies?

The total number of men covered by Table 3 was 7,401; the average length of stay in France was seven weeks; the total number taking venereal prophylaxis was fifty-six. Among these 7,000 men, during a period of almost two months, only one new case of venereal disease was discovered after four careful physical examinations were made. This record, of course, is remarkably good—probably better than that of the army as a whole, but these organizations are cited as evidence that sexual continence can be followed by large bodies of troops for a considerable period of time.

This long drawn-out war of the trenches has exploded another old-time fallacy, namely, that the soldier must be a libertine in order to be a good fighter.

#### EFFICACY OF PROPHYLAXIS

The army statistics for sixteen years have effectively demonstrated the excellent results that can be obtained by prophylactic treatment in preventing venereal disease. One of the most careful studies on the subject is that contained in a recent report of Riggs (Fig. 3). Riggs has shown that if given during the

first hour after sexual contact, the failure of prophylaxis was less than 0.1 per cent., and during the first four hours was less than 1 per cent. After that it rose rapidly to 7.5 per cent. after ten hours. Study of the medical records of the American Expeditionary Forces testified to the accuracy of Riggs' statistics. Among 100,000 instances of prophylaxis given in Bordeaux, the percentage of failure was 1.7. An analysis of the conditions among the troops in Paris showed that the failure when prophylaxis was taken in three hours or less was 0.5 per cent. (785 cases).

#### RESULTS OBTAINED

The plan of keeping and treating men with venereal diseases within their organizations was followed to the end of hostilities. As long as the troops were in training areas or in very quiet sectors, little difficulty was experienced in treating men at regimental infirmaries; but when an active sector was occupied, the medical officer was so busy with other duties that it became necessary to organize venereal labor camps at which all the cases could be concentrated within the division, only a little more remote from the front lines. This plan was first promulgated by Major L. C. Lehr, in the First Division, and was afterward amplified by Major H. L. Sanford, in the Forty-Second Division.

Owing to the small amount of venereal disease present, none of these divisional venereal camps exceeded 180 men, even though certain cases of chronic gonorrhoea and latent syphilis were taken for treatment. From 60 to 80 per cent. of these men were on a full duty status doing important work for the division, such as repair of roads, stone crushing, erection of barracks, horse lines, sanitary work, carpenter work and general mechanical work. It was shown that com-

Fig. 9.—French movable steam laundry, with compact, modern machinery driven by gasoline motor; hot-air drying room; capacity, 2,000 suits per day (service de santé type).

plications were not more frequent here than with men who had been hospitalized, and the active exercise and outdoor life had a wonderful effect in maintaining health and morale. Of great importance was the opportunity afforded to bring back to these divisional camps cases of syphilis for successive courses of treatment as the months passed by. In periods of great activity, and when an offensive was planned, these men were often sent forward to do their bit with their com-

rades, being allowed to return afterward to complete their treatment. Many of them made the supreme sacrifice, but there was no evidence to show that they did not fight as well as the others.

Fig. 10.—Number of cases of skin disease in field hospital, Forty-Second Division, A. E. F., during the months of April, May and June, 1918, showing rapid decrease when general bathing and early diagnosis and treatment were vigorously pushed.

Figure 5 shows graphically the organization of the Division of Urology, American Expeditionary Forces, and Figure 6 shows the plan adopted for the treatment of venereal diseases and urologic surgical cases in the American Expeditionary Forces.

In many of the divisions, particularly those at the front, the amount of venereal disease contracted monthly was astonishingly small. The Forty-Second Division had only six new cases in one month and eight in another month among 26,000 men. When, however, troops were allowed to go on leave, the venereal rate often increased considerably. During the last stages of the great conflict, when the divisions were being rushed forward into battle, almost continuously for several months, the maintenance of the venereal labor camps was quite difficult, and it was proposed to organize army venereal labor camps to which all cases incapable of being handled with divisions would be sent. These were to be situated not too remote from the front, at places where work companies were needed for employment in useful occupations and as much as possible on a full duty status. The sudden ending of the war made it unnecessary to organize these army camps. In the depot or replacement divisions venereal camps handled the problem among replacement troops very effectively.

General Pershing's interest in the venereal problem was actively maintained throughout the war, as evinced by the frequent orders, memoranda and bulletins that

he issued from time to time. His letter to Lord Milner shows his deep interest in the subject. This letter was incorporated in Bulletin 54, which was drawn up at his request. Although engaged in one of the great battles of the war, General Pershing took the time to review the manuscript and give his personal approval to it.

RESULTS

The figures as officially announced to the entire American Expeditionary Forces by the Surgeon-General of the United States Army, are shown in Figure 2. As seen here, after the early rise, the result of the bad conditions at St. Nazaire, there was a steady decline until Nov. 1, 1918, when the rate reached 16 per thousand per year. Since the signing of the armistice there has been a slight increase, the rate during December and on January 1 being 28 per thousand per year, less than one third of the rate in the regular army in 1916. In Figure 2 is also seen the venereal rate of the United States Army stationed in the United States. As seen here in September, 1917, there was a rapid increase of the venereal rate due to the men coming in with the draft from civil life. From 1 to 8 per cent. of these men were infected with venereal disease (average: white men, 5 per cent., negroes, 15 per cent.), and the annual venereal rate of the army took a sudden great rise to 200. During the winter months of 1917 there were fewer drafts, and the curve fell; but during the spring and summer of 1918, with the huge increase from civil life, the venereal rate rose steadily until it presented the monthly rate of 228 per thousand per year, and one week it reached the great height of 342 per thousand per year. With the cessation of hostilities and the stopping of the draft, the rate rapidly dropped to 72, December 1.

Fig. 11.—Field hospital devoted to treatment of skin cases of the Forty-Second Division, near Bacarat, on the river Meurtre. This hospital was better known among the doughboys as "Scratchville by the Sea."

Statistics show that for every case of venereal disease acquired in the Army in the United States, five were acquired from civil life and brought in with the draft.

A recent report shows that "in slightly over a year and a half, since the first drafted men were mobilized,

there have been reported to the Surgeon-General over 225,000 cases of venereal disease among all troops in the United States. Approximately 200,000 of these cases were contracted in civilian life."

Experiences obtained in the American Expeditionary Forces, in which the venereal rate had been reduced to such a low figure (16), testify to the great value of the army methods for combating venereal disease, and the splendid effect of military discipline and the well ordered life of the soldier.

#### HOSPITALIZATION

Following advices from other armies in Europe, preparations had been made by the Surgeon-General's Office to provide one base hospital of 1,000 beds for venereal diseases, alone, for every 100,000 troops sent to France. Personnel and equipment of many of these hospitals were organized and dispatched to France, but venereal diseases had been so effectively combated, and the measures for their treatment with the organizations in the divisions and in the depot labor camps had been so effective and satisfactory, that it was decided not to use any of these hospitals for venereal disease, and they were promptly turned over to the treatment of the wounded and the sick.

In October, 1918, when the hospital resources in the American Expeditionary Forces were terribly taxed to take care of the wounded and sick, it was extremely gratifying to realize that of the twenty base hospitals which it was planned to provide for an army of two million men, according to the original intentions of the War Department, none were required for the treatment of venereal disease, and that every one of them was in use for other purposes and was available for the treatment of the wounded at that most trying time in the medical history of the American Expeditionary Forces.

## PART II

### SKIN DISEASES

Circular No. 2, chief surgeon's office, Nov. 9, 1917, provided for eight professional divisions in the medical department, and named the director for each division. In the fifth division, venereal, skin and genito-urinary surgery were grouped together and placed under a "director of urology."

An investigation was at once made as to the frequency of skin disease, and the best methods for its prevention and treatment that had been evolved in the French and British Armies. A memorandum was then sent to the office of the chief surgeon, American Expe-

ditionary Forces, calling attention to the fact that trench fever, scabies and inflammatory processes in the skin had caused 90 per cent. of all the diseases of the British armies in France and that, being largely due to pediculosis and scabies, they were almost entirely preventable; that it was of utmost importance that every effort should be made toward prevention of skin diseases, namely, provision of requisite facilities for bathing, disinfestors and adequate supply of underclothing; that since the beginning of the war great improvements have been made in bathing apparatus, steam and hot air disinfestors and movable laundries, and that every effort should be made to obtain these in as great quantity as possible from France and England, as it was evident that with the great difficulties of transportation from America we would certainly be faced with a considerable shortage.

On Jan. 8, 1918, the Manual of Military Urology, which had been prepared by the division of urology, was presented and approved for publication by the chief surgeon and the commander-in-chief. In this manual skin diseases and their prevention were discussed at length and a "plan for the prevention and early treatment of dermatologic cases" was announced.

General Order 38, American Expeditionary Forces, Sept. 17, 1917, delegated to the engineering corps the furnishing and installation of bathing apparatus, and General Order 13, Jan. 21, 1918, delegated to the quartermaster corps the furnishing and installation of laundries and sterilizers and the provision of a supply of clean underclothing.

General Order 18, American Expeditionary Forces, Jan. 31, 1918, held the town major responsible for the location and maintenance of baths, washing and incinerating facilities. The medical department was not authorized to take part in the management of the bathing, disinfesting or laundering for the troops. In compliance with the directions embodied in a letter of Feb. 21, 1918, from the chief surgeon, American Expeditionary Forces, to Major Hugh H. Young, a report on the prevention of skin diseases in the American Expeditionary Forces was made by a board consisting of Majors Hugh H. Young, Hans Zinsser and Haven Emerson.

It is possible to give in THE JOURNAL only the headings of this official report, namely: The great frequency of disease due to vermin, especially skin diseases; methods of disinfestation, its relation to position of troops; choice of methods; relative value of steam, hot air, chemicals; laundries; repellants; scabies stations; proposed organization.

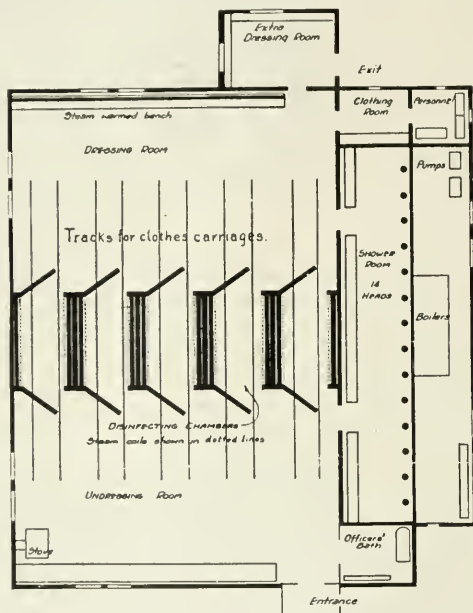

Fig. 12.—Plan of an excellent German steam bathing and disinfesting plant, captured in the Argonne.

The splendid work and remarkable ingenuity of certain division urologists in improvising apparatus and in bathing and disinfesting their troops under great difficulties deserve extended notice; but unfortunately our time is too short and space does not admit of even mentioning their names. These men struggled at all times with great problems of preventive medicine, and obtained results in the prevention of skin and venereal disease that were indeed remarkable. When the divisions were engaged in combat they were allowed no rest, but took active part in the operations, sometimes as battalion surgeons, at other times with the ambulance or triage, in the shock wards, or as operators in the divisional hospitals for the desperately wounded. The debt of gratitude that I owe these faithful assistants, whom I delighted in visiting, as frequently as possible, up and down the front, could never be repaid. The results obtained by them is forcibly shown by the fact that their work in preventing diseases of the skin and in sterilizing those patients who were early brought in to the field hospitals devoted to skin diseases were so effective that it was very rarely necessary to evacuate patients with skin disease out of the divisions, and in an exhaustive report made by Major Knowles, assistant consultant in dermatology, it is shown that in October there were probably not more than 100 cases of pyoderma in the entire American Expeditionary Forces. As a result, it was never necessary to organize a special hospital for skin diseases, and our only clinic was a small one in Paris. Instead of 90 per cent. of the evacuations for disease from the organizations being the result of vermin, as reported to have been the case in the British Army, it is safe to say that a very small percentage of the cases of disease evacuated from the American Expeditionary Forces was due to such causes. These magnificent results were obtained under most trying circumstances, with great shortage of apparatus, with equipment of varied character, and confronted by the necessity of improvising all sorts of crude methods in order to bathe and disinfect the troops. Had it been possible to have twenty portable shower baths, two portable disinfestors and two portable laundries per division with the proper personnel and transportation, no difficulty would have been encountered in practically eliminating lousiness and scabies from the troops.

In the most active period of warfare, that of the great battle of the Argonne, the need of army and corps supervision of bathing and disinfesting equipment was shown, and provisions were made for a corps urologist to carry out this work for the divisions as fast as they come out of the lines to rest. But space does not permit reference to the detailed plans that were finally adopted to insure the proper functioning of the sanitary measures. In this last phase of the war the advance was so swift that it was necessary to make use of captured German bathing establishments, one of which is shown in Figure 12.

#### ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. CORBUS, TAUBER, LOWSLEY AND YOUNG.

DR. ABRAHAM L. WOLBARST, New York: With reference to the standard treatment of syphilis, it is easier to speak of it than to carry it out in actual practice. Strictly speaking, there is no standard treatment for syphilis or any other disease, because there are no standard human beings, and we must treat the individual and not the disease. If we

start out on the assumption that syphilis requires so many arsenamin injections, and so many mercury injections, we are going to strike a snag. We must study the individual, and unless we do that we are not going to cure him. I regret that the author did not say anything about the clinical aspects of syphilis, and especially the primary lesion. We are attaching altogether too much importance to the laboratory findings and giving not enough attention to the clinical features. It is the fashion in some quarters to make the diagnosis of syphilis on a positive Wassermann reaction, even though clinical data might be absent. I think this is a serious error. We should be able to recognize a chancre when we see one. It is far better to let a man with syphilis go untreated until he shows definite clinical symptoms, than to take a man who has chancroid or something of that sort and treat him for syphilis just because a laboratory found a positive Wassermann. I do not wish to underrate the value of the Wassermann test; but I believe it means nothing unless it is employed intelligently in conjunction with the clinical aspects of the case. Different laboratory workers get contrary results on the same serum taken at the same time. How, then, can we rely implicitly on such a test? You have no moral right to convict a man of having syphilis unless the positive Wassermann is corroborated by clinical data supporting such a diagnosis. Another expedient of great value is the excision of venereal ulcers whenever it can be done. If the lesion is on the foreskin, I invariably circumcise the patient, thus removing at one stroke the foreskin as well as the ulcer. If it be a chancroid, we have an immediate cure; if it is a chancre, the future course of the disease is greatly modified for the better by this excision of the infecting focus. As to the arsenamin technic: I have given over 1,700 injections in my office without a single severe reaction of any kind. I think this is due to the water which I use. I use an "aerated distilled water" (made by an old established mineral water manufacturer in New York). I have found this water much more satisfactory in every respect than the pure distilled water. The manufacturer informs me that the water contains (per 100 volumes) 0.70 volumes of oxygen, 1.26 volumes of nitrogen and 0.06 volumes of CO<sub>2</sub>. Those gases are forced through distilled water under high pressure. I am of the opinion that the oxygen in the water may possibly have some stimulating effect by oxygenating the red blood cells and thereby overcoming any possible toxic effects of the arsenamin in the blood. In cases in which arsenamin and mercury do not give the desired results, I recommend pituitary extract. It has been pointed out by eminent students of endocrinology that syphilis is essentially a pituitary disease and that syphilis has a very distinct and close bearing on the pituitary. A man deficient in pituitary extract is more easily infected than a normal man, and once such a man is infected, it is harder for him to get rid of his infection than for a man with normal pituitary substance. Small doses, almost homeopathic in character, have been of great service in such cases.

DR. HARRY W. PLAGGEMEYER, Detroit: With regard to the urologic school at Fort Oglethorpe, I do not think that Dr. Timberlake has sufficiently brought out just what was done there. I am not saying that critically. Possibly it is a matter of bashfulness. I had the privilege of being a "rookie" in Oglethorpe and, of course, like many of the rest of us here, I slept in the barracks, and I heard the same talk, and one of the chief sources of conversation was the urologic clinic, at the time I got there, and the work that Dr. Timberlake was doing. The point is that although he has given us a rather amusing sketch, and made a bit light of his endeavors there, I think that from a practically inchoate mass he developed one of the finest and best organizations in the way of teaching, in concentrated form, that I have ever seen; and the point I want to bring out is this, in case of possible argument: I heard some remarks, after I came away from Oglethorpe, against the dangers of so-called tabloid teaching. At Oglethorpe, in addition to engendering in the minds of all the men in the barracks, a kindly democratic feeling, he inspired them with a very

healthful fear of their subject, which is the beginning of wisdom. I am sure that he has sent out from that school hundreds of men, who otherwise would probably have dabbled in urology, who have been given not only a fundamental training in details, but an atmosphere on the subject which will redound to the glory of this section in the future. The school of urology at Oglethorpe, as conducted by Major Timberlake, is a lasting monument to his work.

DR. V. D. LESPINASSE, Chicago: Germane to Dr. Young's paper in regard to reconstruction work, I would like to mention an apparatus for reconstruction of the penis. This apparatus was designed originally to help the condition of a very undeveloped penis. In answer to the patient's appeal I developed an appliance and fitted it to his penis. This appliance was used with satisfaction and has also been used on one case where the shaft of the penis was about two-thirds gone.

DR. ANTON G. RYTINA, Baltimore: I would like to say a few words about the clinic we established in Baltimore, which is known as the U. S. government night clinic. We have sufficient funds available to conduct the clinic along very highly efficient lines, but the main thing I want to bring out is the connection therewith of the detention ward, and I think the influence of this organization, and all organizations, ought to be along the lines of controlling prostitution by the establishment of detention wards. We have, in connection with our clinic, this detention ward, which is made very efficient by the splendid cooperation we have in the Baltimore police department and the city courts. There is a statute on the books of Maryland which states that any individual who is suffering with an infectious disease can be detained, or can be quarantined, and these women are picked up off the streets and are brought to us. We detain them for arsenphenamin treatments as long as we think it is necessary, and it is surprising to see the wonderful work we are doing. The only opposition we have been receiving has been on the part of the suffragists. They cannot see why we should detain women and not men, and in conversation with one of these women I told her it was an economic problem entirely; that in Baltimore about the most infections that a man could give in one evening would be one or two; whereas we have women brought in who sometimes infect as many as forty men a night. I remember one woman especially who had extensive condylomas of the vulva, and she told us confidentially that she had been having intercourse with about forty soldiers every evening. We have about twenty-five beds. We ought to have about five hundred. A civic organization has just been established, and I feel it is going to accomplish a lot, and be very successful, because Dr. Young is going to head it.

DR. WILLIAM E. KEANE, Detroit: I would like to bring out a method used in the outpatient department of St. Mary's Hospital, where we are unable to secure the serum from the sore for the dark field, and where we are unable to diagnose the chancre clinically, and it is too early for the blood tests—cases where the foreskin cannot be retracted and yet the diagnosis should be made as quickly as possible. We have circumcised the patient and in several cases were able to grow a serum in artificial serum and demonstrate spirochetes in the dark field within a day or two and, of course, proceed with specific treatment. This is a distinct advantage in all doubtful cases it certainly is justifiable to take such means to enable us to make a very early diagnosis. I certainly agree that the time to treat syphilis is in the very early stage, and the earlier we can make our diagnosis, the more we are going to do for the patient later on. The excision of the sore certainly seems to be rational treatment. Not only that, but where for reasons we are unable to excise the sore, we should direct treatment particularly locally, with the cautery, or with mercurial ointment, because it is a distinct advantage to do as much as possible to eradicate the focus of infection.

DR. JAMES R. DILLON, San Francisco: I agree with Dr. Tauber that every venereal sore should be examined for syphilitic infection, such as herpes, simple ulcers, chancroids or hard chancres. Frequently the spirochetes are not found in

the first examination, especially if the patient has used a mercurial preparation. If the lesion is treated with a mild boracic solution, or with a physiologic sodium chlorid solution, the spirochete may reappear in three or four days. Regarding standards for arsenphenamin treatment in primary syphilis, I followed a series of cases at the Stanford medical school, taking the blood Wassermann twenty-four hours after each arsenphenamin injection, and found some cases in which the provocative Wassermann was positive where the chancres were only two weeks old; in other cases, after the second or third injection the Wassermann became positive, where it had previously been negative. You cannot limit treatment to any particular number of injections. In some cases it will take as many as ten or twelve, with mercury, to render the provocative test negative. Another thing, there is undoubtedly a specific strain of spirochete that enters the blood stream and attacks the nerve centers early, even in the first few days of the primary sore. Occasionally, a positive spinal fluid is found in the early stages of primary and secondary syphilis and in spite of intensive antisyphilitic treatment in the early stages, with blood tests to guide the treatment at intervals of from six months to a year, for two or three years afterward, the blood Wassermann would return positive. Possibly the only way of curing such patients is by the Swift-Ellis method or other intraspinal injections. Ordinarily, I give at least three additional injections after the provocative Wassermann has become negative.

DR. P. A. JACOBS, Cleveland: I have listened with a great deal of interest to the various methods of standardization for the treatment of syphilis. It is my opinion that the standardized treatment for syphilis cannot be accomplished. What I would suggest, first, is that some standardized method for the carrying out of the Wassermann reaction be first instituted. No two serologists perform the Wassermann test or technic alike. One uses an alcoholic extract, and the other cholesterin, or what not. If I am not mistaken, the British have at this time a commission for the purpose of bringing about a standardization for the performance of the Wassermann test.

DR. ELMORE B. TAUBER, Cincinnati: In Ohio we have a law which is even a little bit better than that of Maryland, I believe. If there is a reasonable doubt that a person has venereal disease, we have the right to put him in detention. So at the present time we are arresting both men and women on the streets of Cincinnati. We have eighty beds for women and thirty-seven for men at the present time at the Cincinnati General Hospital, and we are getting remarkably good results in this way. We are taking these women (they usually come in negative, as they have had a douche, or something of the sort to make them negative) and their first slide is negative as regards gonorrhoeal diseases usually, and the Wassermann is taken immediately. But after being there for twenty-four or forty-eight hours you would be surprised at the 95 to 98 per cent. of positive slides that we get. We only discharge them after they have three negative slides, without any treatment. In regard to Dr. Wolbarst's idea of the serum, I was not speaking of the condition when the serologic test becomes positive. My method is entirely directed to try and standardize, and as Dr. Corbus said, we must arrive at some method of standardization. My method is directed purely at the early diagnosis, and the treatment under those conditions, before the serologic condition is positive. Because without that we are in a deplorable state. While it may not do anything it is at least a step forward in the right direction. Dr. Keane's method of circumcision and growing a culture seems to be rather logical, and one I will be glad to try out.

DR. HUGH H. YOUNG, Baltimore: This question of standardization is an extremely important one. It was absolutely necessary in the A. E. F. to suggest a thorough method of treatment of syphilis. We did not lay down any fixed law as to how the disease should be treated, but we standardized more or less the drugs to be used, because it was impossible to have everything. Mercury and arsenic were given simultaneously during the first course, and in the after courses neo-arsphenamin was preferred to arsenphenamin. You

do not have to have Dr. Wolbarst's special water, aerated with certain gases, and things of that sort; just a little tube of ordinary sterile water was all that was necessary, and you could entrust it to men who had little experience before. I am a strong believer in an effort to get at what might be called an ideal treatment for syphilis, rather than a standard treatment. The work these men are doing in Chicago, Cincinnati and elsewhere is bound to spread. We studied the whole question of infection of prostitutes very carefully with the French. I saw at St. Nazaire prostitutes who had infected our soldiers, and yet it was impossible to see that they had any venereal disease at all. We got a lot of syphilis in one house, and yet you could find no syphilis among those women. We investigated further and found that not infrequently the prostitute transmitted the diseases, not because she herself had it, but because she simply was a carrier from one man to another. Where a woman would have intercourse with from fifty to one hundred men in an evening, if one fellow came in whose secretion was filled with staphylococcus, the woman might easily, if she did not wash, transmit the infection to the men who followed. We found one house where eighteen men got venereal disease, and one of the women had as a helper a small boy who opened the door and welcomed everybody. He had a large chancre on his penis and would reinfect her two or three times a day, and she spread it to the soldiers who came along. There is no question about it that one of the greatest dangers in houses of prostitution is lack of cleanliness, and the fact that these women transmit disease by being just temporary carriers of deposits left by applicants for her favor.

DR. BUDD C. CORBUS, Chicago: In regard to the standardization of treatment, especially in regard to syphilis. Looking up our army records, and every record that was available, there was no definite standard set for the treatment of this disease, that could be followed with any degree of accuracy. By standardization I do not mean that every case is going to measure up to this one standard and be treated that way. Ordinarily there are certain salient features that stand out in the treatment of syphilis, that are not adhered to. We have attempted to standardize the treatment of syphilis. Our standard is not perfect, but it is flexible, and is an attempt at something ideal. If it is imperfect, we can regulate it some time later. Systematic standardization in the treatment of syphilis is universally needed.

**On Teaching Hygiene.**—No greater service can be rendered the college youth than requiring him to devote some time to the conscientious study of both personal and public hygiene. This is so universally accepted by academicians that it would be but useless repetition to present arguments in its behalf. That universities regard hygiene as an essential subject is demonstrated by a perusal of their catalogues. A criticism called forth by the average course in hygiene, however, is the half heartedness or laxness with which it is conducted. . . . Hygiene, both personal and public, can be made one of the most interesting subjects in the college curriculum. Is it not true that people are fundamentally interested in health? It has been stated that matters relative to health and physical well-being make up the bulk of the laity's conversation. If this is true why not by education substitute facts for the world of harmful misstatements and prevalent superstition?—John Sundwall, *Pub. Health Rep.*, Nov. 7, 1919.

PATHOLOGY AND OPERATIVE TREATMENT OF CONTRACTURE OF NECK OF BLADDER\*

LEO BUERGER, M.A., M.D.  
NEW YORK

We may apply the general term "contracture of the neck of the bladder" to designate all those pathologic processes involving the region of the internal vesical sphincter and the adjacent periurethral tissues of the prostatic urethra that do not belong to the class of true neoplastic formations, and that result in a greater or less coarctation, rigidity or distortion of this portion of the urethrovesical canal. The fibromas or adenomas that may be located in this region are usually grouped in the category of so-called "hypertrophy of the prostate," although, correctly speaking, fibro-adenomas of the prostate would be a better appellation. When the latter are unaccompanied by fibrotic and inflammatory lesions leading to stenosis of the vesical sphincteric ring, they make a variety quite distinct from what we wish to term "contracture of the neck of the bladder."

The appellation "median bar" should not be employed because its application is confusing, for the term is not sufficiently comprehensive to include all the lesions that belong to this class of cases. Although it is an accompanying objective manifestation of some lesions of contracture of the neck of the bladder, it is frequently absent, and can in no sense be regarded as a primary lesion. Nor is it for the most part responsible for the clinical symptoms. Its use, I believe, should be discarded in this connection.

Fig. 1.—Fibrotic lesions.

It was the pathologic study of cases that gave the clinical symptoms of contracture of the neck of the bladder, cases that did not belong to the class of adenomas, that led me to adopt a more extensive operative procedure than that which merely has for its purpose the removal of a small portion of tissue from the floor of the sphincteric region. These pathologic investigations on material obtained by a wide excision of tissue from the affected region have brought me to the conclusion that, although no single lesion may occur to make up the complex of contracture of the neck of the bladder, nevertheless, the anatomic alterations which lead to the narrowing of the bladder outlet are so extensive and deep that the radical surgical procedure suggested should give better results than some of the methods applied heretofore.

My pathologic studies of seventeen cases have brought to light that we are dealing here with single lesions in some cases and with a combination of changes

\* Read before the Section on Urology at the Seventeenth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

in others, always, however, representing invasion of the sphincteric and periurethral tissues extending far beyond the mucous membrane. These lesions may be

Fig. 2.—Arteriosclerotic sphincteric fibrosis showing multiple enlarged sclerotic vessels.

a simple fibrosis of the sphincter without evidences of a previous inflammatory process, the fibrosis being of varying depth or there may be fibrosis accompanied by an inflammatory process; or there may be submucous and periurethral inflammatory lesions involving the sphincteric region and posterior urethra extending centrifugally for a variable distance into the surrounding tissues, forming an inflammatory fibrosclerotic sheath of varying thickness; or, there may be diffuse glandular invasion of the sphincteric region with or without periacinar inflammation associated with more or less sphincteric fibrosis; and, finally there may be mixed forms in which any of the foregoing changes may be accompanied by the accidental formation of small adenomas or fibromas.

It must be well understood that any observations on the nature of nonneoplastic lesions at the neck of the bladder are open to fallacious interpretation, in view of the fact that the very incipience of the process can rarely, if ever, come to our notice. What can be submitted for histologic section are tissues which represent results of more or less chronic processes, that may have taken on new aspects by virtue of the advent of secondary complications, as well as secondary mechanical distortions. On the one hand, chronic cystitis, with or without pyelonephritis, vesical calculus, and chronic inflammation of the prostate may be responsible for alterations in the neck of the bladder that are quite distinct from the original lesion, causing confusion in our subsequent estimations of the pathology; and, on the other hand, distortions of the bladder, the mechanical effect of the distention of chronic retention, may

bring about pseudovalves or bar formations at the vesical neck that are in reality not the cause but the result of a number of anatomic, mechanical and pathologic factors.

A critical analysis of the dignity of all the elements concerned in the pathology of each of my own cases, however, has enabled me to come to certain conclusions that are somewhat at variance with the observations of those whose investigations are based for the most part on necropsy material. Although such work as that of Randall and the anatomic studies of Lowsley are exceedingly valuable in demonstrating beyond peradventure that vesical obstructions other than the pure adenomas and so-called hypertrophies frequently exist, nevertheless, my own clinical and pathologic observations seem to be in accord rather with the occasional clinical findings of other authors, who report true stenosis of a fibrotic nature at the internal urethrovesical outlet. Although other forms have been encountered, they all have this in common: that an essentially fibrotic or inflammatory fibrotic lesion occupying the internal vesical sphincter, and the periurethral intraprostatic region is always present, even though accompanied by other changes.

I do not feel at liberty to express myself definitely regarding the etiology, nor do I wish to discuss in detail the nature of the processes, whether they are purely recessive and of the involution type, degenerative, or arteriosclerotic in cases of the fibroses, or induced by contiguity from the prostate and sexual adnexa, or by metastatic paths in the cases of the inflammatory varieties.

My purpose is rather to demonstrate how extensive is the involvement of adjacent parts in these sphincteric lesions, and to show what varieties of pathologic processes are encountered, for the reason for the surgical

Fig. 3.—Inflammatory type of contracture.

operation that I recommend is wholly based on the nature of my pathologic findings.

#### PATHOLOGIC CLASSIFICATION

A simple and satisfactory grouping of my seventeen cases divides the material into three classes: (1) fibro-

sis (eight cases); (2) fibrosis and inflammation (four cases), and (3) fibrosis associated with adenomas or fibromas, or with infiltrating adenomas (five cases).

Fig. 4.—Inflammatory sheath formation plus fibrosis.

*The Fibroses.*—At operation, with the bladder opened suprapubically, we encounter the following evidences of regional alterations in and about the internal sphincter:

Visually, the striking abnormalities are an unusually small internal vesical orifice, and the presence of a horizontally situated transverse prominence (median bar) in the situation of the postero-inferior lip of the sphincter, neither of these being essential for the existence of a contracture of the neck of the bladder, since the latter may occur in the form of extensive and diffuse rigidity of the sphincter and prostatic portion of the urethral channel, the sphincteric ring being seemingly patent. When a bar is well developed, it may be exaggerated by edema or by enormously congested capillaries and veins, or it may involve merely the floor of the vesical orifice or extend laterally for varying distances, in some cases being truly eccentric and almost laterally placed.

Often a distinct shortening of the sagittal trigonal distance, with transverse plication of the retrosphincteric area will be appreciated, a furrow separating this interureteric bar from the vesical orifice. When the median bar is well developed, or when edema and marked vascularization are intense, the aspect of a congested and inflamed vaginal cervical ostium is simulated.

In other cases when a diffuse fibrosis of the prostate is an attendant lesion, in the group that is often suspected as prostatic carcinoma, there is on the contrary

a distinct mound in the distal trigonal area, although no true fibro-adenomas or even fibromas may be present.

The tip of the index finger introduced into the internal vesical orifice finds a hard, infiltrated, annular band or fibrous ring, effectually preventing its introduction into the urethra. When force is employed, the engagement of the posterior urethra is at once followed by tearing of the outlet, most frequently at the roof of the neck.

When the coarctation of the sphincter is but slight or doubtful, the tissues of the posterior urethra as well as the sphincter will be appreciated as having been converted into a fibrotic, hard sheath that reveals none of that resilience and elasticity so characteristic of the normal urethrovaginal outlet. Or, in addition to these lesions, small areas of increased density may be palpated, these being manifestly due (as sections show) to multiple discrete fibromatous nodules.

As to the situation and extent of the lesions, these may be described as being the submucous tissue of the internal sphincter, the sphincteric muscle itself and the periurethral tissues of the posterior urethra usually behind the verumontanum. The depth or amount of centrifugal involvement varies considerably, so that histologically, as well as objectively with the palpating finger, we can readily detect a superficial and deep form, depending on whether the structure of the pros-

Fig. 5.—Chronic inflammatory sheath.

tate itself and the tissues even beyond the sphincter suffer in the process. In a sense and in truth, all the "contractures" may be regarded as being deep lesions, since the submucosa and sphincteric muscle are always affected. But when, in addition to this, tissues at a

considerable distance from the urethra are inseparably bound up in the pathologic lesion, the unusual extent of infringement on the integrity of the vesical outlet can be both histologically and surgically recognized.

Fig. 6.—Inflammatory sheath plus hypertrophy.

*The Microscopic Lesions.*—The material obtained for study comprised a pyramidal piece (or wedge) of tissue excised at suprapubic operation in such a fashion as to ablate the greater part or whole of the floor of the internal sphincteric ring, the apex of the pyramid lying in the prostate, its distal end just above the verumontanum, and its proximal side being cut transversely just beyond the sphincteric margin in the trigon. It was attempted to obtain as large a section, in a sagittal sense, as possible, one border of the section being covered with mucous membrane.

*Lesions in the Pure Fibroses.*—In making arbitrary divisions for purposes of clarity and possible clinical grouping, it must be again emphasized that we may be dealing with histologic pictures that, although seemingly of degenerative, involutive or atrophic type, are in reality in some, or possibly in all instances, the end-product of antecedent active inflammatory processes. This is not at all likely in view of the histories, the clinical course, the cystoscopic and urinary findings, and the microscopic architecture of the tissue; still, it is a possibility that cannot be excluded in all cases.

Fibrosis, as seen in the sections of our cases of contracture of the neck of the bladder, is of various types. It may be described, according to its disposition and its relation to the muscular bundles, as perifascicular

or intrafascicular. We may consider it, according to the type of tissue, as either represented by well developed connective tissue in the intermediate stages of maturation, or as evidenced by the presence of an inflammatory process.

In general, the fibrotic replacement of muscle fibers of the sphincter is striking, the latter muscle being normal in thickness, hypertrophied or atrophied. Usually the diffuse nature of the process is noteworthy, the muscle bundles being often widely separated by either dense or at times edematous connective tissue. The latter type is more frequently disposed in the neighborhood of the mucous membrane. Figure 1 illustrates the extensive invasion of the muscle with connective tissue in a case of true fibrotic contracture, there being nowhere any evidences of inflammation, the sphincter tearing when the finger was forcibly made to enter.

Atrophy, disappearance of, and degeneration of muscle fibers can be observed going on *pari passu* with the proliferative process of the connective tissue. The process usually implicates the greater part of the sphincter, but may be associated with evidences of recent inflammation (secondary) or with deep fibrosis, much of the prostate gland being invaded, or with the formation of a sheath of sclerotic tissue extending far distally in the urethra (even beyond the verumontanum), or finally with multiple minute submucous or intraprostatic fibromas.

For the most part, it is the sphincteric disorganization that makes for the coarctation of the urethrovesical outlet in these cases; but there is the interesting type just referred to, in which a veritable sheath of fibrotic tissue lying between the mucosa of the supramontane urethra (between the sphincter and the verumontanum) forms a cylindrical narrowing in this region.

Fig. 7.—Diffuse glandular infiltration of sphincter with fibrosis (mixed form).

Associated with this lesion, multiple minute fibromas, submucous and intraprostatic, may give the palpating finger the impression of a carcinomatous prostate.

Another striking example of atrophic prostate associated with arteriosclerotic fibrosis of the sphincter is

well depicted in Figure 2, in which the proliferation of sclerotic vessels is a feature.

Summing up briefly the types of fibroses, we find the pure fibroses of the sphincter, those accompanied

Fig. 8.—Intense fibrosis with glandular infiltration (mixed form).—

by some recent inflammation, those with deep fibrous involvement of the prostatic tissues, those complicated by a sclerotic connective tissue submucous sheath in the posterior urethra, by fibromas, and the arterio-sclerotic variety (Table 1).

*Fibrosis and Inflammation.*—Is it in this variety particularly that it is difficult to find convincing argument for or against the primary nature of the inflammatory process. Careful pathologic and clinical study has given justification for the assumption that an inflammatory process is responsible for many of the cases of contracture, and that fibrosis of the sphincter and prostatic region may be the sequence of such lesion. Nevertheless, I feel assured, too, that this fact in no way precludes the possibility of the simultaneous occurrence of both lesions, namely, the pure fibrosis and the inflammatory changes. In four of the cases, the predominance of the inflammatory process was noteworthy. Figure 3, taken from a case of marked stenosis of the vesical orifice, demonstrates the extensive inflammatory infiltration of the muscle, and the

destruction of the sphincteric fibrosis, proving conclusively the rôle that inflammation plays in the destructive process that disintegrates the muscle, thereby impairing its functional activity. In this case, acute and subacute as well as chronic types of lesions were all exemplified in different sections. Even a cursory glance at Figure 3 leaves a strong impression as to the intensity of the destructive process that has affected the musculature of the sphincter. The sparsity of the muscle fibers standing out prominently against the infiltrating inflammatory background, and the large amount of older connective tissue in other sections afford exquisite demonstrations of the lesions.

In this case we found, first, large zones in which no sign of muscle tissue could be detected with a low power magnification, inflammatory tissue and disintegrated muscle fibers being the substituting elements; secondly, areas in which muscle fibers were widely separated by larger collections of inflammatory cells, and, thirdly, areas of old connective tissue which indicate an old process and which separate the bundles rather than the individual muscle fibers.

In cases such as these, there can be no question as to the inflammatory nature of the lesion.

Another variety of inflammatory contracture is illustrated by three other cases (Figs. 4, 5 and 6), in which

Fig. 9.—True fibroma and adenoma, the sphincter being involved.

we can study the formation of the sclerotic inflammatory ring (Fig. 4) or of a dense fibrous sheath of greater tubular extent.

In Figure 4 both the recent inflammatory, as well as the old sclerotic, process can be seen side by side. Two types of lesions, chronic and active proliferative, are

presented here, the former manifesting itself in a finished connective tissue product, the latter in an active inflammatory lesion destroying the muscle elements. From a study of the material in this case it would appear that the inflammatory process has had exacerbations and remissions leaving their early recognizable imprint on the musculature.

Even more exquisite an example of inflammatory sheath formation with sclerosis of the sphincter and the development of a fibrotic periurethral envelop between verumontanum and vesical outlet is that depicted in Figure 5. Here, too, there are active and chronic lesions, a slowly developing fibrotic lesion involving the whole sphincteric muscle, a more recent productive inflammation in the muscle, and a still more recent (acute) lesion which may be an extension from the mucous membrane. Just how much influence the process in the mucous membrane has on the production of the deeper lesions it is hard to say. It is conceivable and highly probable that in some of these cases recent infection may add just enough additional infiltration to occlude the sphincteric orifice and produce complete urinary retention.

Another excellent example in which an extensive rigid periurethral and sphincteric inflammatory infiltration is associated with marked muscular hypertrophy is offered in the section photographed in Figure 6.

**Mixed Forms (Fibrosis and Adenoma, or Fibrosis with Glandular Infiltration).**—There is another most interesting complex of lesions at the vesical neck that may readily be confused with the so-called hypertrophies of the prostate, which should, however, be separated into a special class, both from the clinical and the pathologic standpoints, namely, the group in which concomitant glandular infiltration or submucous adenomas play an important part in the pathologic product. These may be divided into one variety with discrete fibro-adenomas, and another in which there is a diffuse infiltration of the muscle of the sphincter, either with glandular proliferations from the middle lobe or of subcervical origin.

**Fibrosis with Discrete Adenomas.**—At first glance, it would appear difficult to meet the criticism that fibrosis with discrete adenomas is pathologically equivalent to and indistinguishable from the so-called hypertrophies or adenomas. A study of the cases in point reveals, however, that both clinically and histo-anatomically there is enough difference to warrant the division into separate classes. Occurring frequently in very young adults, the contractures associated with minute precocious adenomas are characterized histologically by a preponderance of fibrosis with but minute adenomatous proliferations, the latter being in my experience of

unusually insignificant size, even though the material was obtained from elderly individuals. That the extensive fibrosis also present may be a deterrent to the rapid growth of the adenomas seems possible and even likely. Theoretically, it is conceivable that a case of contracture of long standing, with small precocious adenomas in a young man could develop subsequently a picture in which adenoma and contracture play an equal rôle. Only a few such cases have come to my notice. When the two lesions have progressed hand in hand for years, we regularly find at the operating table that the fibrosis predominates, so much so that I do not hesitate to group these cases with the contractures.

The fibroses with discrete adenomas do not, in my experience, tally with the subtrigonal and subcervical glandular hypertrophies of other authors (Lowsley and Randall). For I find, first, that the fibrotic sphincteric alterations are the essential lesions, and, secondly,

that the adenomas are irregularly distributed under the mucosa, in the posterior urethra or prostatic region, or at any portion of the sphincteric ring. Hypertrophies of Albarran's and Holmes' glands do occur, it is true; but unless associated with marked sphincteric fibrosis, they must be relegated to the class of hypertrophies or adenomas of the prostate. In short, localized glandular neoplastic formations which complicate sphincteric fibrosis may form a part of the total lesion, may exaggerate the rigidity of the vesical outlet, and may even contribute in offering an additional obstacle to the outflow of urine. *They must not be regarded as the essential lesions.*

**The Infiltrating Adenomas.**—Finally, I may call attention to another variety

Fig. 10.—Elevation of bar prior to excision.

of mixed lesion, which, as far as I know, has not been described, namely, a diffuse glandular invasion of the sphincter by noncircumscribed elements. Considerable disorganization of the muscle may be caused thereby, and there is regularly associated with it a very marked fibrotic process, often with periacinar inflammation (Fig. 7). An example of more intense connective tissue change coupled with infiltrating adenoma is depicted in Figure 8, in which there were also some minute discrete adenomas. Interesting for comparison is the photomicrograph shown in Figure 9, which is a sagittal section through the floor of the sphincter and prostatic urethra in a case of true adenoma or "hypertrophy." Here the sphincter, although compressed and displaced, is still intact and is not fibrotic, the neoplastic formations being represented by a beautifully encapsulated fibroma, and another adenoma arising in the middle lobe region. Under the mucosa of the posterior urethra are two minute fibromas.

THE AUTHOR'S OPERATION FOR CONTRACTURE OF THE NECK OF THE BLADDER

Although the mere ablation of a subperival adenoma would suffice to cure such a condition, the lesions in cases of contracture are too extensive and deep to be materially influenced by anything but a more radical operation. With a view to relieving the stenotic sphincter and to enlarging the rigid inflammatory sheath, the following simple operation was devised and carried out with some beneficial results during the last three or four years. Possibly similar procedures have been used now and then by other surgeons:

The bladder neck is exposed in the usual way by the suprapubic route. The peritoneum is pushed well out of the way and an adequate vertical incision is made into the anterior wall of the bladder, but no larger than is necessary for the proper introduction of retractors and for the exposure of the sphincteric region. With adequate illumination, the sphincteric region is found. It is first viewed carefully, the presence of the transversely placed ridge or bar being noted. Such bars may be true bars, owing to the invasion of this region by glandular and fibrotic or inflammatory tissue, or pseudobars, due to edema with inflammation of the mucous membrane and dilatation of large veins. A small submucous adenomatous lobule should not be regarded as a true bar.

One then attempts to insert the finger, or at least to measure the size of the internal sphincteric ring, which in most cases will be found to be sclerotic, tightly contracted, too small for the tip of the finger to enter. If possible, the finger is forced through the sphincteric ring, which procedure is usually followed by the tearing of the anterior commissure, the latter being involved in the sclerotic and inflammatory process in most of the cases. The inferior or posterior lip of the sphincteric region is then grasped (Fig. 10) with long angulated many-toothed volsella or fixation forceps, drawn upward and toward the head of the patient, the floor of the sphincter being thus put on the stretch, and brought into better view. The amount of tissue that is thus grasped should depend on the nature of the lesion. When the lesion is very deep, when there is a great deal of fibrous tissue possibly accompanied with some adenomatous infiltration, a larger bite will have to be taken than when we are dealing with a case in which an inflammatory sheath surrounds the sphincteric region. It is well in most cases to obtain a sufficient amount of tissue in the grasp of the forceps, so that the next step can be carefully carried out without losing the grip on the tissue that is to be excised.

A long, sharp knife is then employed to remove a large pyramidal piece of the sphincter. The base of the pyramid is formed by a portion of the bladder floor extending from the inferior sphincteric margin backward for a centimeter along the apex of the trigon. Its lateral walls are limited by the lateral margins of the sphincter, and its apex lies in the fossula prostatica not far from the verumontanum. The incision is carried downward for at least 1.5 cm. or more, through the sphincter and into the prostate. The excision can usually be made so as to remove an intact piece, if a sufficiently sharp knife is at hand, and if the traction on the sphincteric region is not too great.

The finger is then made to enter the sphincter once more, in order to dilate this as well as the supramontane urethra, a careful exploration being made for the presence of any complicating adenomatous or fibrotic neoplasms.

Sounds are then passed through the urethra, the dilatation being carried to at least 32 French.

If the bleeding is active, a small packing may be placed into the sphincteric region and posterior urethra, and carried through the suprapubic wound alongside of the drainage tube. When the bleeding is profuse, it is best to place one or two catgut hemostatic sutures through one or both lips of the wound area, inserting the needle so that the edges are not brought together. The mucosa must not be included,

the stitches entering and emerging on the same side of the divided area. The bladder is then closed over a moderate sized suprapubic rubber drain.

OPERATIVE RESULTS

Of the seventeen cases in which the diagnosis was confirmed by thorough pathologic studies, there were thirteen good results. Two could be regarded as failures, one in a case of complete retention of urine, and the other in a highly neurotic individual. Two other patients were merely improved, although one of these is almost free from symptoms. The first, a man with intense chronic symptoms has observed marked diminution of his urinary frequency, although he can in no sense be regarded as cured, while the condition of the second patient is distinctly ameliorated (Table 2).

TABLE 2.—RESULTS OF OPERATION

Name	Age	Date of Operation	Result
A. S.	29	7-17	Excellent
B. M.	67	1-30-18	Excellent
I. W.	50	1-29-19	Good
J. A.	38	6-13-18	Excellent
M. A.	59	3-11-18	Good
M. R.	62	10-6-17	Excellent
L. H.	57	4-16-19	Improved
S. S.	62	12-7-17	Excellent
J. S.	62	1-2-18	Good
M. M.	50	7-7-17	Excellent
A. S.	52	11-14-17	Poor
M. F.	48	2-4-18	Improved
J. B.	40	9-15-17	Excellent
M. S.	28	4-18-17	Poor
S. S.	60	1-26-18	Excellent
G. H.	41	9-8-15	Excellent
J. B.	69	1-28-19	Good

In short, there were at least thirteen good results out of seventeen, or about 75 per cent. Most astonishing was the "cure"—for thus the patient styles it—obtained in a man (J. A.) who had had complete urinary retention for five months, who had been pronounced as having a paralytic bladder and regarded as incurable by competent urologists, and who acquired complete restoration of function after the excision of the inferior sphincteric margin.

ABSTRACT OF DISCUSSION

Dr. HEN H. YOUNG, Baltimore: We are indebted to Dr. Buerger for a very clear presentation of this very important subject. Attention was called to this condition by some of the very early urologists in America, but for many years it was lost to sight, except, perhaps, to a very few men. It is unquestionably a far more common condition than is usually thought to be the case. Many young men do not realize that they have obstructions from which they get great relief after operation. The condition, as we have found it, is more varied and more multiple than has been described by Dr. Buerger. In more than 200 cases we have operated and found lesions exactly such as he found, and many other types of lesions besides. We found cases that are congenital, unquestionable muscular hypertrophies, in addition to the fibroid type. More important than all is the fact that we found them situated in other places, around the prostatic orifice, and not posteriorly, so that the operation suggested here would not, in my opinion, rectify many of the cases one sees. It has been a mooted question for many years what we should call this condition. All sorts of names have been suggested. No one name will cover all conditions. Contracture of the neck of the bladder certainly does not meet the emergency. Whether an enlargement is a contracture or not I cannot say. Dr. Buerger has devised the best way of getting specimens. He has given us a good pathologic study. As to the necessity of doing that operation, I am in doubt, because removing the posterior part, and possibly part of the

trigon, of that region, will not cure the condition in many cases. We have to make multiple excisions, very frequently anterior, not infrequently posterior, and laterally as well. The punch operation, has been very satisfactory in a large majority of cases, but more than one cut is necessary, and an anterior cut is often as necessary as the posterior. The amount of tissue that can be removed in that way is really very extensive. It is certainly better than the rongeur operation done through the suprapubic region. Recently we modified the operation somewhat by the use of a spear which is first introduced and prevents the tissue from slipping out. That has made the operation more effective where there is a bar, enlargement, hypertrophy or valve. A careful cystoscopy, feeling with the finger in the rectum, is very important in diagnosis. Of course, the punch operation may be followed by hemorrhage. It is possible to stop it by the use of a retention catheter.

Dr. WILLIAM C. QUIMBY, Boston: I have been studying the material from this type of case by means of special staining methods in an endeavor to differentiate the pathologic elements present, and from this I quite agree with what Dr. Buerger says in regard to the wide variation of pathologic tissue found in the region of the internal bladder sphincter. The symptom which this difficulty causes is almost invariably of an obstructive nature. It is rare, in other words, to find symptoms due to inflammatory processes, of which dysuria is a prominent example. Nevertheless, I feel from examination of the histologic material that the most probable cause for the sclerosis and fibrous tissue present is a previous inflammation. For, as Dr. Buerger has shown, one does not get the material until the inflammation has passed, when all that remains is the result of the storm that has gone before. Those cases where glandular elements and hypertrophies are found are not under consideration for the moment because these are more analogous to the middle lobe hypertrophies. In regard to operation: I have recently been following the type of operation which Dr. Buerger described. I have used Dr. Young's punch, and also Dr. Braasch's punch, and while by both of these instruments the punch can be made well, my endeavor has been actually to palpate the condition at the neck of the bladder and see by ocular inspection what it is. An operation may then be planned according to what is found. I came to this conclusion independently, finding, as Dr. Young has said, that frequently these obstructive conditions are not on the floor of the urethra, or in the prostatic urethra, but are either lateral or anterior. I feel that I can do much toward freeing the neck of the bladder if, after dilatation of the posterior urethra, I can feel the tissues between the index finger and thumb, and thus estimate the degree of distensibility of the internal bladder sphincter. When it is definitely indurated and sclerotic, I remove it. Sometimes this may only involve one small area, such as would be represented by one centimeter or one half a centimeter; sometimes the necessary removal is more extensive. Therefore, I feel that until I learn more about what the exact underlying pathologic condition is, I prefer to see it and examine it by the suprapubic operation rather than through an intra-urethral instrument.

Dr. OSWALD S. LOWSLEY, New York: I wish to congratulate Dr. Buerger in calling our attention to this procedure. In the past we have paid too little attention to the small stricture at the vesical orifice. Dr. Buerger's operation is especially applicable to those cases in which we formerly used Chtwalsky's operation. By this procedure you do not destroy the sphincters. One sphincter can be destroyed, provided the other is not injured; then no incontinence will result. Destruction, even temporary, of both sphincters, may result in permanent incontinence. Dr. Buerger recently reported a case of stricture following his operation. We had one at Bellevue Hospital following an operation by Dr. Keyes. I imagine that stricture occurred because Dr. Buerger injured the neck of the bladder up after his operation. If not, I would like to have him explain the reason. The stricture we had was very tight, and quite a serious affair. It required a great deal of effort to relieve the situation. Dr. Keyes removed a sclerotic prostate. We do not yet know

whether the man is cured. I operated on one patient, using this method, with rather a bad result, but that was not entirely the fault of the operation; it was probably the fault of the bad general condition of the patient. The wound did not heal rapidly and broke down suprapubically repeatedly, in spite of the fact that the drainage tract was high. This patient should not have been operated on by this method. I am still very enthusiastic about the Young punch operation. I think in most cases, except a few selected ones, the punch does all that is required, whether the tumor be situated on the floor of the vesical orifice or in the roof.

Dr. H. G. HUGBEE, New York: About eight years ago I attempted to burn out this constricting tissue with the high frequency spark and found that when the stricture was caused by fibrous tissue it took too long a time to carry out this method and that the incisions were not deep enough. For the past three or four years I have been using the punch with complete satisfaction. I have had two recurrences. I did not make enough excision. The second time I took out sections anteriorly, and distinctly felt the ring give way. In both cases we have obtained excellent results. Several of these patients had such a hard prostate that I felt, before operating, that they probably had a carcinomatous ring, but the pieces we removed with the punch showed only fibrosis. The punch is an exceedingly satisfactory operation, in these cases where the constriction is due to a ring of hard fibrous tissue. I have not had any serious complication from hemorrhage. I use a large lisle thread, straight or single catheter, and I occasionally clear out the catheter during the first twenty-four hours. This is all that is necessary. I rarely leave it in three days.

Dr. ALEXANDER RANDALL, Philadelphia: Dr. Buerger's illustrations picture very accurately the fibrosis and the changes it occasions at the vesical orifice, with the contracture, the drawing together, or pinching together, of the vesical trigon, and that deep cleft formation across it. This is one form of obstruction. But there is a second direction in which this same fibrotic process can exert itself, and this he does not picture. This second form seems to exert its influence entirely within the prostatic urethra. The same contracture occurs with, however, a shortening of the distance from the vesical orifice to the verumontanum. The trigon is unchanged, and the suprapubic picture is unchanged, which is probably the reason Dr. Buerger has missed it. It is best appreciated by the study of postmortem specimens, and when once understood can be diagnosed clinically by cystoscopic study. Dr. Quimby's remarks about the careful study of the orifice before deciding on the form of operation are pertinent, though I feel that this is done better by careful cystoscopic study before operation is considered, than at the time of operation. Dr. Buerger's glandular hypertrophy type of obstruction, which his illustrations show very clearly, is the third form of obstruction, and as he has said originates from an entirely different pathologic process. In speaking of the difficulty of selecting a name for this clinical condition, whose pathology is so varied, and yet whose symptomatology is always the same, we must be careful not to select a name essentially descriptive of some special pathologic process, such as "contracture" or "sclerosis," which does not cover the need when we know that frequently inflammation or hypertrophy are the causative factors. For this reason I have always adhered to the original title given by Guthrie of "median bar formation," a clinical, not pathologic, term under which the various known types or forms can be grouped. Zuckerkandl often spoke of these conditions as prostatic hypertrophy in miniature. I realize that Dr. Buerger has purposely passed over the question of the cause of this fibrosis, however, I would like to ask him if he will give us his ideas as to why it takes on this peculiar, localized, limited pathologic process, and whether he has found it associated at any time with fibrotic changes elsewhere in the body.

Dr. LEO BUERGER, New York: I am sorry that some of the speakers still retain the impression that I believe that neoplastic tissue forms an obstacle and that this is the cause of the symptoms in these cases. On the contrary, I believe that

the clinical and secondary pathologic phenomena are produced by coaction of the sphincter, and that complicating fibro-adenomas obstructive lesions play but a subsidiary rôle. I wish to emphasize that the presence of a bar, or fibro-adenomatous nodule is not essential, for neither lesion is present in some of the worst cases. The essential thing is the fibrosis, be it inflammatory, involuntional or arterio-sclerotic in nature in and about the sphincteric region and adjoining prostate. I believe there is often a fibrosis of this whole sphincteric and prostatic region and it is this that permits urine to leak into the posterior urethra and give symptoms of urinary frequency. When doing my operation by which the sphincteric floor is excised not because it presents an obstructing obstacle but because it is anatomically the only mobile part of this region that lends itself to attack, you will find that as soon as you force your finger into the sphincter, a tear will occur which is not so in the normal. The sphincter floor is the proper place for excision also, because it gives access to the fibrotic prostate and permits of the removal of adventitious small prostatic adenomas and fibrotic tissue. Regarding Dr. Randall's question as to the nature of fibrosis, I believe that the true fibroses are of two kinds pathologically, primarily inflammatory and primarily fibrotic. The first are the result of old or still active inflammatory processes, the second are due either to arterio-sclerosis or the accompanying degenerative alterations that go with the involution changes occurring in this region.

TACHYCARDIA FOLLOWING INFLUENZAL PNEUMONIA \*

FRED M. SMITH, M.D.  
CHICAGO

In many of the patients at Camp Travis, the pulse rate increased from 80 to 100, or even 120, per minute during the convalescing period of influenzal pneumonia. The pulse curve in these men showed that this increase in pulse rate began at the time they were first allowed on their feet. Frequently it was so marked that they were ordered back to bed. Others who had been discharged from the hospital to quarters or duty were returned for observation. Some complained of shortness of breath, weakness, dizziness, and palpitation of the heart on exertion. The point of especial interest was whether the influenza had produced some organic disease of the heart, such as myocarditis, or had merely served to bring into the open tachycardias that otherwise might have gone unnoticed. This report is based on the study of ninety-five such men. They were observed from the standpoint of (1) the myocardium and (2) the autonomic nervous system.

METHOD OF STUDY

The histories of the men were carefully taken down. The points considered were (1) the family history, as relating to alcoholism, neurosis, insanity and tuberculosis; (2) general health in childhood, as pertaining to illness with acute infectious diseases, and response to games; (3) occupation in civil life, whether sedentary, light, moderate or heavy, and its effects; (4) military training, in respect to its duration, and the men's response to drill, hikes and double time, and (5) the present symptoms, with regard to their date of onset and the occasion under which they arose. The taking down of the history was followed by a physical examination and the routine laboratory work. In the physical examination, special attention was given to the condition of the lungs and the heart. Those men in whom there were evidences of delayed resolution were trans-

ferred to other wards and not included in our figures. In none was there any departure from the normal in the urine, blood counts (including the differential) or in the blood pressure readings.

ANALYSIS OF CASES

*Irritable Heart.*—Thirty-six patients (37.8 per cent.) of the ninety-five studied gave a history of having had the symptoms of an irritable heart prior to their entrance into the army. In every instance these symptoms had been markedly aggravated by their recent illness. They were the men who, after having been discharged from the hospital to quarters, were returned because of the marked tachycardia, shortness of breath, weakness, dizziness, and palpitation of the heart on exertion.

These men were analyzed from the standpoint of possible etiologic factors that existed in civil life. The results are shown in the accompanying table. Twenty-one (58.3 per cent.) were, or had recently been, hookworm positive. Four (11.1 per cent.) had the physical and the roentgen-ray findings of a chronic inactive pulmonary tuberculosis. Two of these tuberculous men were also positive for hookworm. Two (5.5 per cent.) gave a history of having had malaria practically every fall of their childhood life. They stated that they had always been weak. Three (8 per cent.) had the physical and the roentgen-ray findings of chronic bronchitis. This condition, from the history, had been present for years; tuberculosis was suspected but not proved. Five (13.9 per cent.) had families in which two or more members were highly neurotic.

TABLE 1—HISTORY OF THIRTY-SIX PATIENTS WHO HAD HAD SYMPTOMS OF AN IRRITABLE HEART

Affection	No. of Cases
Hookworm	21
Chronic inactive pulmonary tuberculosis	4
Chronic malaria in childhood	2
Chronic bronchitis	3
Alcoholism	1
Neurotic families	5
Total	36

*Hypersensitive Nervous System.*—Thirty-eight (40 per cent.) of the ninety-five men studied had what may be called a hypersensitive nervous system. We were unable to find a physical basis for their tachycardia. They were of a nervous temperament and responded readily to any external stimuli. They had a marked vasomotor instability, perspired freely, and in all respects, from a physical standpoint, presented the symptoms of an irritable heart, except that they had a greater tolerance for work. A majority of them had, to their knowledge, a rapid pulse in civil life. Not a few of them had been held up temporarily by the examining board at the time of their entrance into the army. They, however, had had no symptoms following strenuous exercises and had been admitted. They had all responded well to their military service. Following influenza, however, a few complained of weakness, shortness of breath, and palpitation of the heart on exertion, for a period of from five to six weeks.

*Hyperthyroidism.*—Twenty (21 per cent.) of the ninety-five patients studied are under observation for hyperthyroidism. The results of this work will be given in a later report.

*Organic Heart Disease.*—The diagnosis of acute myocarditis was made in only one instance in the ninety-five cases studied. The course and physical findings of the patient differed markedly from that of

\* From the Medical Service, Base Hospital, Camp Travis, Texas.

the other men. He had a pulse rate of 140 per minute, a definite cardiac enlargement, and a blowing systolic murmur at the apex which was transmitted to the axilla. These findings were associated with shortness of breath, palpitation of the heart, and a feeling of exhaustion on exertion. These symptoms disappeared on rest in bed. The left cardiac border receded to the midclavicular line, the murmur decreased in intensity, and the pulse rate came down to normal.

This was in sharp contrast to what occurred with the remaining ninety-five men. In them the pulse rate did not decrease with rest in bed, nor did their symptoms improve under these circumstances. They were given graded exercises regardless of their tachycardia. Had their symptoms been due to a weakened myocardium, it hardly seems possible that they would have subsided on the type of exercises that was given; for a man's response to exertion may be regarded as the best test of his cardiac efficiency. The fact that the pulse rate of these men decreased on exercise, and that there was no change in the cardiac findings from the standpoint of murmurs and enlargement, justified us in believing that there was no organic heart disease.

#### GRADED EXERCISES

All the men except the one with acute myocarditis were given the graded exercises, as outlined by Lewis.<sup>1</sup> They were assured that they had no cardiac disease and would in time be as strong as ever. At the end of four weeks, all with the exception of four were getting a thirty-minute period of strenuous exercise twice daily, and in addition doing from a 3 to a 4 mile hike. They contended that they felt as well as ever. The pulse rate had decreased, and all had gained in weight. Some were heavier than they had ever been before in their lives. Those men who had had irritable hearts in civil life gained the most slowly. Greater care was taken in advancing the grade of their exercise. The four men who had the physical findings of a chronic inactive pulmonary tuberculosis were even slower than the rest in regaining their tolerance for work. Possibly, in many of these men there would have developed a severe type of irritable heart had they not been carefully handled. In this connection it should be added that those men who had recently been hookworm positive had had treatment. This might have been a factor in the rapid increase in strength of some of these men.

#### REPORTS FROM OTHER CAMPS

The necropsy reports from other camps are in accord with our findings. They are uniform in that few cardiac complications were observed. Hall, Stone and Simpson,<sup>2</sup> at Camp Logan, reported no cardiac complications in thirteen necropsies. Blanton and Irons<sup>3</sup> observed one case of acute myocarditis and three of acute dilations in 123 necropsies at Camp Custer. Synnott and Clark,<sup>4</sup> at Camp Dix, noted no cardiac complications other than a slight dilatation of the right heart. The number of necropsies was not given. Friedlander, McCord, Sladen and Wheeler,<sup>5</sup> at Camp

Sherman, reported twenty-three necropsies, noting slight dilatation of the right heart as the only cardiac complication. Nuzum, Pilot, Stangl and Bonar<sup>6</sup> saw one acute dilatation of the right heart in forty necropsies at the Cook County Hospital, Chicago. Strouse and Bloch<sup>7</sup> reported 500 cases, emphasizing the infrequency with which the myocardium was involved, as judged by clinical evidence; The reports of a detailed study of the morbid anatomy by a number of German authors,<sup>8</sup> based on the study of 174 necropsies, bear out the findings in this country. Twenty-five necropsies were performed at Camp Travis. Dilatation of the right heart was recorded in six instances, and in these hearts there was also hypertrophy of the left ventricle. This would indicate that previous damage to the heart muscle existed. The objection might be raised that microscopic examinations were not reported. It is possibly true that pathologic changes sufficient to cause serious disturbance in later life could have been easily overlooked by the naked eye. Those hearts that we studied microscopically at Camp Travis showed no significant pathologic condition.

#### ATROPIN TEST

The inhibitory action of the vagus was tested in fifty men by the administration of atropin. This was given in doses of  $\frac{1}{33}$  grain, as described by Morris,<sup>9</sup> and later by Mason,<sup>10</sup> in their work on typhoid. The patients were put to bed in a quiet room and allowed to remain until the pulse rate became constant. They were then given  $\frac{1}{33}$  grain of atropin in sulphate hypodermically in the upper arm. The reaction began usually within from fifteen to twenty minutes, and lasted from forty to sixty minutes. The height of the reaction was reached about forty minutes following the injection. Mason states that in most normal persons the pulse rate increases from twenty to forty per minute following the administration of  $\frac{1}{33}$  grain of atropin. Nineteen of the fifty men given the test had an increase in pulse rate of from 1 to 12 over the initial rate; twenty-one, from 20 to 30, and the remaining ten, from 30 to 40. According to the work of Morris and Mason, the results in the nineteen instances possibly suggest a hypotonic vagus nerve. Some of these men, however, had had, to their knowledge, a rapid pulse in civil life. In these cases we are not justified in assuming that the recent illness had had much influence on the action of the vagus nerve. Even in the remaining cases we have no basis for assuming that the action of the vagus nerve resulted from the influenzal pneumonia. It might have resulted from some infection in childhood, as diphtheria, or even have been a normal response for them.

#### EPINEPHRIN TEST

The same fifty men were given threshold doses of epinephrin. The method employed was that devised by Goetsch.<sup>11</sup> The men were put to bed in a quiet room. The pulse and blood pressure readings were taken

until they became constant. An injection of 5 c.c. of a 1:1,000 solution of epinephrin was made into the deltoid muscle. Records were made of the pulse and the blood pressure every two minutes for ten minutes, and then every five minutes for one hour. Following this, observations were made at intervals of ten minutes for one-half hour.

A reaction was not considered positive unless there was an increase in the pulse rate and the blood pressure of more than from fifteen to twenty points, accompanied by marked tremor of the hands, nervousness, palpitation of the heart and increased arterial pulsation.

Twenty-five of the fifty men were sensitive to small doses of epinephrin. These men had given what is considered a normal reaction to the atropin test. The same factors should be taken into consideration in the explanation of the results of the epinephrin test, as in explanation of those from the use of atropin. The fact that we do not know the reaction these men would have given prior to the influenzal pneumonia will not permit us to draw conclusions from the test as to the effects of this illness on the sympathetic nerve.

SUMMARY AND CONCLUSIONS

1. Ninety-five cases were studied. The diagnosis of acute myocarditis was made in one instance. As far as we were able to determine, organic heart disease was not the basis of the tachycardia in these men.

2. Thirty-six men (37.8 per cent.) gave a history of having had an irritable heart in civil life. These symptoms were aggravated by their recent illness. A possible etiologic factor was found in thirty-one of these cases.

3. In thirty-eight men (40 per cent.) no physical basis was found for the tachycardia. A majority had, to their knowledge, a rapid pulse in civil life.

4. Twenty men (21 per cent.) are under observation for hyperthyroidism. The results of these observations will be given in a later report.

5. Fifty men were given the atropin and the epinephrin tests. The results in nineteen suggest a hypotonic vagus nerve, and in twelve a hypersensitive sympathetic nerve. These men might, however, have given the same reaction to these tests prior to their influenzal pneumonia.

6. The graded exercises were of distinct value in estimating the state of the myocardium and in improving the general condition of these men.

122 South Michigan Avenue.

**Deer Fly Fever, or Pahvant Valley Plague.**—In recent years there has occurred among the rural population of Millard County, Utah, a disease initiated (according to popular belief) by a fly bite on some exposed surface of the body and manifested by the enlargement of the lymph glands which drain the bitten area and by a fever of a septic type lasting from three to six weeks. The site of the bite and the affected lymph glands become tender and inflamed, and they commonly suppurate. There is marked prostration and the patient is confined to his bed. The first case known to have terminated fatally was reported in 1919. The Surgeon-General of the U. S. P. H. Service detached Dr. Edward Francis to investigate this new disease. Cultures made on ordinary laboratory mediums from the lesions of animals dying from the disease were negative; but cultures made on coagulated egg yolk yielded a growth of a small nonmotile coccobacillus. These cultures reproduced the lesions of the disease in guinea-pigs. It is believed that this organism is the *Bacterium tularence*, first described by McCoy and Chapin in 1912.

TOXIC JAUNDICE FOLLOWING "INTENSIVE" ANTISYPHILITIC TREATMENT

THOMAS J. LYNCH, M.D.

Major, M. C., U. S. Army  
ST. JOSEPH, MO.

AND

SOLOMON F. HOGE, M.D.

First Lieutenant, M. C., U. S. Army  
WAYNESBURG, PA.

With the advent of the so-called intensive treatment of syphilis by the administration of arsphenamin, the subject of toxic jaundice has become one of practical importance. This is particularly so, in view of the fact that, while many hundreds of doses of the drug may be given without apparently the slightest ill effect, there do appear to be conditions under which the drug has a powerful toxic action on the liver cells, and an intense degeneration occurs with fat deposit in the liver and kidneys in fatal cases.

After the administration of arsphenamin, some slight symptoms due to the direct toxic action of the drug are generally produced, such as nausea or vomiting, transient diarrhea, and a temperature rise of 1 or 2 degrees. These symptoms usually last for a few hours, and no others occur. Very infrequently, however, after a period of three or four days, symptoms of a profound toxemia develop. The patient presents an abnormal mental condition: irritability and delirium rapidly progressing to unconsciousness, with perhaps convulsions and Cheyne-Stokes respiration. Jaundice may or may not appear. Death usually results in from two to three days. This accident is liable to occur following a single dose of the drug. This condition is explained by William H. Wilcox,<sup>1</sup> in his Lettsomian Lectures on jaundice, as undoubtedly due to an auto-intoxication such as occurs in acute yellow atrophy of the liver. This group of apparently delayed symptoms should be carefully distinguished from those of acute arsenical poisoning, in which we have vomiting, diarrhea, skin rashes, etc. When these symptoms occur after the giving of arsphenamin they are probably caused by impurities in the product or by its decomposition.

There is an additional class of cases whose frequency of occurrence we are now recognizing. These occur at variable lengths of time following the administration of large doses of the drug with a short interval of time between doses. In the so-called intensive treatment, from 0.4 to 0.6 gm. are given at weekly intervals over a period of from six to eight weeks. After a rest of one month, the course is repeated.

During the past few weeks we have been able to observe three cases of toxic jaundice, one of which was fatal, following the intensive administration of arsphenamin. All of them occurred in young adult males. All three patients gave a negative history of previous liver involvement, and each was surrounded by every safeguard possible, namely, physical examination, including urinalysis previous to each injection

REPORT OF CASES

**CASE I.**—*History.*—Private P, enlisted in the army at Jefferson Barracks, Mo., Sept. 26, 1916. The date of his exposure to syphilis is not definitely known. The date of the primary lesion is Dec. 25, 1915. Jan. 1, 1917, there is

1. Wilcox, W. H. Brit. M. J. 1:439 (May 24, 1919).

a record of multiple sores on the foreskin of the penis. There is no record of any secondary lesions. The serum reactions as recorded on the syphilitic register are shown in Table 1. The treatment given, as recorded in the register, is shown in Table 2. The mercurial medication was:

Jan. 1 to April 5, 1917, mercurial unctio, dose 5 gm., time 115 days. During the months March and April, 1919, the patient had thirty rubs of mercurial ointment. The amount in each rub is not given. The arsenic preparation

TABLE 1.—SERUM REACTIONS IN CASE 1

Date	Place	Reaction

used was that put out by the government under the name of "arsenoloid" or "arsphenamin."

The patient was admitted to the post hospital, Fort Sill, Okla., May 2, 1919, aged 23 years. Time of service, two and one-half years. Feb. 6, 1918, a gun exploded and one of the missiles struck the patient in the lumbar region. This produced a severe contusion. The convalescence continued over a period of six months. During this time he complained of pain in the back which was worse at night and when he stooped over. He noticed a decrease in lifting power. The pain had never entirely disappeared. At the end of six months spent in quarters the patient went to work, but kept complaining of pain in his back. From July, 1918, till his admission to the hospital he had in a way been able to stay on duty.

**Physical Examination.**—On entrance into the hospital, the general condition was good, and aside from a slight tenderness on each side of the second, third, fourth and fifth vertebrae, the patient was marked negative. Temperature, pulse and respiration were normal. The roentgenologic examination of the kidneys, the ureters and the lumbar vertebrae failed to demonstrate any definite pathology.

**Clinical Course.**—From May 2 to 7, 1919, the patient was under observation on the medical service, and a provisional diagnosis of myalgia of the lumbar muscles was recorded. About May 8, the patient began to complain of severe pain in the left renal area with radiations down along the course of the ureter. A tentative diagnosis of pyelitis was recorded. With the exception of May 4, when the temperature was recorded at 100, there was no rise of temperature till May 23.

May 21, the patient complained of loss of appetite and some nausea, but did not vomit. The pain in the left upper

quadrant remained unchanged. May 22, the condition was recorded as unchanged. May 23, the temperature was elevated, a. m., 99.2; at 4 p. m., 103; at 7 p. m., 103.3. The patient complained of a chilly sensation, and was more nauseated than on previous days. The patient did not vomit. Other signs and symptoms were negative. May 24, the temperatures recorded were: 6 a. m., 100; 10 a. m., 101; 1 p. m., 103; 4 p. m., 102. May 25, there was no change in the general condition of the patient. The temperature was a little lower than the previous day, a very slight jaun-

dice appearing. May 26, the jaundice was noted as rapidly increasing in intensity. The patient vomited about 6 ounces of dark coffee-ground vomitus. From then on till death the patient continued to vomit at various intervals. The time between the intervals was usually about three to four hours. The amount of the vomitus varied from 4 to 6 ounces. It had the same characteristics as the first specimen. During the morning of May 27, there was no change in the general condition of the patient. The vomiting, however, continued and toward evening the patient started to hiccup. May 28, the jaundice increased and the vomiting was unchanged. The patient complained that he was unable to see more than 3 or 4 feet and distinguish objects definitely. His mentality became sluggish. Now and then, periods of delirium intervened. The patient vomited and hiccuped almost continuously. Blindness became complete. Cold perspiration stood out over the entire body. The patient was in a dying condition. On the morning of May 29 the patient was wildly delirious and completely unconscious. This continued till about 1 p. m., when he died.

The record of the urinary findings on the various dates is shown in Table 3.

The special tests carried out on the urine after the patient developed the jaundice all betrayed the presence of bile. The tests that were carried out for the presence of arsenic were all negative.

**Necropsy.**—The pathology will be touched on only as it is considered of a positive nature and in relationship to the diseased condition. Externally there was nothing noticeable except the deep jaundice. On opening up the abdomen it was seen that most of the viscera were studded with small hemorrhagic areas. They varied in size all the way from that of the head of a pin to that of a dime. In the intestine they were beneath the serous coat, while in the kidney and the liver they were beneath the capsule. None had discharged their contents into the abdomen. The liver was about normal in size and of a yellowish mottled appearance much like the so-called nutmeg liver. It was fairly firm, and cut with leather-like resistance. The cut surface oozed blood freely. The capsule was not wrinkled. The left kidney showed an area about the size of a silver dollar that was deep red and contained many coalescing hemorrhages. The stomach, the heart and the lungs were studded with the same type of hemorrhages.

To give in detail the histopathology of the various structures examined would yield very little additional information to that which may be gained by detailing the changes that occurred in the viscera most violently attacked, namely, the liver, and by simply naming the conclusions drawn from the study of the various structures that showed lesions.

The entire structure of the liver was involved to such an extent, and the architecture was so much distorted, that it was difficult to distinguish clearly the various structures concerned in the make-up of the hepatic lobule. It was seen

that certain areas, or rather holes in certain areas, were set off at varying distances from each other. The membrane lining these holes or probable vessels was frayed out and indistinct. Immediately adjacent to this vessel was a zone of rather homogeneous substance that bore a semblance to hepatic tissue. Surrounding this zone was still another zone in a much more advanced stage of degeneration. Leucin and tyrosin crystals were numerous. The interlobular connective tissue presented only indefinite lines that held together the remnants of the hepatic lobule.

The vessel was thought to be the interlobular or afferent vein. The farther away from this vessel one studied, the more necrosis was found. This would yield a picture suggestive of that indefinitely defined group of hepatic changes

TABLE 5.—SERUM REACTIONS IN CASE 2

classed with the acute yellow atrophies. A study of the cells under higher magnification disclosed many of the cells with a poorly stained nucleus and a finely granular cytoplasm. Other cells showed the more advanced stages of degeneration. Sections were stained with the special stains for fat. The attempt to demonstrate the presence of fat was not successful.

A section of the liver was subjected to the various tests for the presence of arsenic. Both this laboratory and the department laboratory failed to demonstrate the presence of the metal in the tissue examined.

*Conclusions Drawn from the Various Pathologic Findings*

Spleen: (a) Acute splenic tumor; (b) diffuse pigmentation of the spleen.

Kidney: (a) Acute tubular nephritis; (b) hemorrhagic nephritis (multiple foci).

Liver: (a) Massive necrosis of the liver cells (acute yellow atrophy); (b) diffuse pigmentation of the liver tissue.

Heart: Localized myocarditis.

Stomach: Hemorrhagic gastritis (multiple foci).

Mesentery and Omentum: Multiple hemorrhagic foci.

Lungs: (a) Hypostatic congestion; (b) hemorrhagic pleurisy (multiple foci).

CASE 2.—*History*.—Private O. P. entered the service, April 13, 1917, at Fort Sill, Okla. His previous history was neg-

*Clinical Course*.—The patient was admitted to the hospital at Fort Sill, Okla., May 13, 1919, aged 24. Length of service was two years. Six days before coming to the hospital the patient traumatized his penis. The injury was not very painful, so he postponed coming to the hospital as long as convenient. On examination he presented a slight tear of the foreskin. This was the only mark on the penis. The patient was kept in the hospital for treatment. May 22, which was about thirteen weeks after the course of treatment, the patient developed jaundice. According to the notes on the physical examination taken at this time, the chest was negative. The abdomen was soft. There were no masses; there was no tenderness and no rigidity. The liver appeared normal in size. There was no tenderness over the liver area. The spleen was not palpable. The clinical course of this case was a close parallel to the one already described in detail, except that the vomiting and hiccuping stage was not reached, as the patient recovered. The jaundice was as deep as in the first case. The convalescence was sluggish but was not interrupted by recrudescence or relapse. The patient was discharged from the hospital, July 1, 1919, apparently well. The jaundice having faded away entirely, he was considered over the attack.

A daily examination of the urine was made and recorded, but in this brief summary it is not necessary to enter it. The albumin finding was positive on every analysis. Sugar was never found. Bile was found in all the examinations except the last four. White blood cells were found constantly. Pns cells were present occasionally. Hyaline and granular casts were present in variable numbers through the entire course.

The blood findings are shown in Table 7.

TABLE 7. BLOOD FINDINGS IN CASE 2

Date	White Blood Cells	Hemoglobin (Per cent.)
6-31-1919	8,600	75
6-13-1919	7,200	75
6-16-1919	8,800	80
6-4-1919	6,300	85

Special tests were being tried again and again to demonstrate the presence of arsenic in the urine, but without success.

CASE 3.—*History*.—Private J. B. entered the hospital, May 14, 1919, complaining that he had been suffering for the previous week with a dull aching pain in the lumbar region, the legs and the arms. The pain was of a continuous nature and worse at night. Along with the pain there had been much headache, nausea and dizziness. The patient was held under observation, as it was thought that there was a possibility of a beginning case of cerebrospinal syphilis. Subsequent study did not substantiate this hypothesis. This obscure condition changed very little between May 14 and 23, May 24, however, the patient developed a slight jaundice. The course from then on was more definite. The jaundice rapidly deepened. The nausea gave way to a few paroxysms of vomiting. Dizziness was very pronounced, and vision became clouded. The patient remained in this condition for about ten days, when he began to improve. The nausea ceased. The pain in the back, arms and legs subsided. The headache stopped. The appetite returned and the jaundice began to fade. The eyesight cleared up and the patient was better in every way. The convalescence was not rapid, nor was it stormy. July 1, he was discharged to quarters to complete his convalescence. The jaundice was not entirely gone from the skin.

*Urinalysis*.—The urine was analyzed every other day over a period of more than a month. During all this time the albumin factor was constant. Never was there a trace of sugar present. The analysis of the urine for bile was started, June 1, and continued to June 27. During this time bile was a constant factor save for the last four analyses. Urinary casts in this case were not a constant factor. When they were present they belonged to the hyaline and the granular variety.

ative for syphilitic taint in every form. There was no history of illness referable to hepatic origin. The patient was exposed to syphilis some time in March, 1918. About a month later he noticed a little insignificant painless ulcer on the dorsum of the penis. In May, 1918, secondaries appeared in the nature of skin rashes over the arms and the chest.

Serum reactions as recorded on the syphilitic register are shown in Table 5. The treatment given as recorded in the register is shown in Table 6. During the months of May, June and October, 1918, and January, 1919, the patient received injections of mercurial ointment in dram doses daily for periods of thirty days.

The blood study was repeated again and again, but at no time did the white blood count go above 8,200 and no time below 6,000. The hemoglobin ranged between 60 and 85 per cent.

The arsenical treatment in Case 3 is shown in Table 8.

The mercurial treatment consisted of forty-two rubs prior to March 1, and twelve rubs during the second course of arsphenamin. The special tests that were carried out in this case to demonstrate the presence of arsenic were unsuccessful.

## COMMENT

This completes the record, in outline form, to be sure, of the three cases that it has been our privilege to study.

A survey of American literature for a case or cases similar to those described and from which some suggestions or conclusions could be drawn was not rewarded with success. A survey of the British literature gave a record of three cases. Veale and Wedd<sup>2</sup> reported a case of fatal jaundice and discussed its relationship to the antisyphilitic treatment administered. Fenwick, Sweet and Lowe<sup>3</sup> reported two fatal cases of icterus gravis following injections of neo-arsphenamin.

It seems that the best method to follow in summing up the data of the literature would be to pick out the points of similarity and dissimilarity in the cases reported. All the patients were adult men with a record of previous good health and without previous history

increased rapidly till it attained a deep yellow tinge. The urine in the cases of this series was dark brown, and gave positive findings for the presence of bile. Marsh's test for arsenic, repeated again and again on the urines, failed to demonstrate the presence of the metal. The cases reported by Fenwick, Sweet and Lowe failed to show the presence of the metal when tested by the Marsh, the Reinsch, and the Nordent-Koch methods. The patients in this series who recovered were studied over a period of about three weeks, and during that time there was not the slightest trace of the metal demonstrable.

The fecal examinations showed the stools pasty, of light color, and very slightly greasy. Analysis showed the presence of fat. The bile test was negative. The test for occult blood was positive.

The vomitus was of the coffee-ground type, and when analyzed it showed macroscopic blood, low acid content, much mucus, many epithelial cells, and even flakes of gastric mucosa.

Postmortem revealed hemorrhagic phenomena in one or more of the viscera of all the bodies. In one of the cases the petechial hemorrhages were present in almost all the viscera, but especially in the walls of the stomach and the small intestines. There were a few points of hemorrhage in the kidney and the visceral pleura. The other cases showed the walls of the stomach and intestine deeply injected. The pancreas seemed to be free from gross pathology. Microscopically the kidneys showed a type of tubular nephritis much like that seen in cases of mercurial poisoning. This nephritis was localized rather than diffuse, and unilateral rather than bilateral. The liver was small and mottled. It did not favor identically any of the more common types of cirrhosis. There was little or no fatty degeneration in any of the specimens examined. None of the tissues subjected to the various tests for arsenic gave positive findings.

From the brief summary of the one fatal case in this series and of the three fatal cases of the British literature, together with the two cases that ran a similar course with recovery, it seems justifiable to put them into a separate class and to treat them as an entity not included in any of the three classes referred to in the beginning of this paper. The etiology is not established beyond the question of doubt, but the light of present scientific investigation points in accusation against the antisyphilitic treatment. Whether or not we can charge the unfortunate results to the number of full doses of medication as prescribed in the course of intensive treatment; or whether they be due to a combination of the arsenical and mercurial medication; or whether they be due to a selectivity on the part of certain tissues, especially the liver, such that an overwhelming dose should start the degenerative process; or again, whether there could be a visceral syphilis, especially of the liver, that should prove a point of lowest resistance in the defense of degenerative changes, would be beyond the realm of our present knowledge.

The microscopic study of the kidney showed a tubular type of nephritis entirely compatible with that seen in mercurial poisoning. The hepatic findings, however, which are paramount in this series of cases, hurl a discordant note into any mercurial etiology alone. To conclude that negative chemical tests for the presence of arsenic should eliminate this drug from any etiologic responsibility would be hasty and unwar-

of hepatic illness. All gave positive Wassermann blood findings prior to the administration of the antisyphilitic treatment. All received intensive treatment, which included one of the standard arsenical preparations and some form of mercurial medication. The particular preparation of mercury depended on the choice of the medical officer. All patients showed a period following the discontinuance of the intensive treatment that could well be called negative as far as symptoms or signs of arsenical poisoning are concerned. Then followed a brief and rapid onset of a group of symptoms that were for the most part entirely similar. The appearance of rapidly increasing jaundice without apparent cause was one of the early signs. In the three cases of this series, and in the one reported by Veale and Wedd, the patients complained of crippling pains in the right lumbar region. The condition of the patients in all those cases having a fatal termination became rapidly worse. All suffered intensely from the paroxysms of vomiting that occurred shortly before death. Delirium was a more or less constant symptom.

The objective symptoms showed the liver decreased in size in four out of the six cases. All patients complained of liver tenderness, the intensity of which depended on the stage of the disease. The jaundice

<sup>2</sup> Veale, R. A., and Wedd, B. H. J: A Case of Fatal Jaundice, Brit. M. J., 2: 341 (Sept. 20) 1918.

<sup>3</sup> Fenwick, P. C.; Sweet, G. B., and Lowe, E. C.: Icterus Gravis after Narsenobillon, Brit. M. J., 1: 448 (April 20) 1918.

ranted. To say that the nephritis was due directly or indirectly to the mercurial medication, which would of itself hamper the chief avenue of elimination of the arsenic and its toxins, and to suggest that this factor, plus the toxicity of the arsenic already in the system, had overwhelmed the hepatic tissue instigating the necrotic process would be compatible with the findings and in harmony with the clinical picture of the case.

## IRRITATIVE URETHRITIS

CREIGHTON BARKER, M.D.  
NEW HAVEN, CONN.

Nonspecific urethritis has been defined by Keyes as "an acute urethritis due neither to the gonococcus nor tubercle bacillus and usually excited by no known cause other than sexual excitement or contact." He states further that it is almost, but not quite, universally true that the normal male urethra is immune to infection by any bacterium except the gonococcus. The observation of the bacteriologic findings in a vast number of cases of urethritis, and the not infrequent occurrence of cases in which the discharge failed to show the presence of gonococci, prompted a careful study and analysis of such cases.

Just how frequently this condition occurs is rather difficult to state, since no record of the total number of cases examined is available; however, the twenty-eight cases presented herewith appeared in two different localities during a period of slightly less than five months, and were encountered during the examination of approximately 500 separate cases.

In studying these cases the points considered were: (1) etiology, (2) symptoms, (3) bacteriology, and (4) clinical course.

The etiologic factor which seemed to be constant was an irritation of the urethral mucosa caused by the administration of the venereal prophylactic that is required in the army. All of the patients included in this series received the prophylactic and it may be assumed that the urethritis in all cases, except one, was due to this cause.

The standard American prophylactic, a 2 per cent solution of protargol, was not a frequent offender, and it was usually found in cases in which the urethritis developed following the use of a prophylactic provided by themselves. One group of cases was of particular interest in that British individual prophylactic packets were used, and three of seven men using them developed a urethritis. The identity of the material in that particular lot of prophylactic could not be determined and inquiry of two battalion surgeons of the British Expeditionary Forces disclosed no evidence that severe urethral irritation following the use of their prophylactic was common among their troops.

### IMPROVISED PROPHYLAXIS

The greatest number of cases followed the use of what it has been chosen to call "improvised" prophylaxis, that is urethral injections provided by the soldiers themselves and usually obtained from a French apothecary, who no doubt had a secret formula of his own. It was obviously impossible to determine the content of all the solutions thus dispensed; but potassium permanganate, mercuric chlorid and zinc sulphate were identified beyond doubt in addition to the silver salts.

Clinically, all of the cases showed great similarity, onset from twenty to forty-eight hours after use of the prophylactic, slight pain and burning during urination, and a varying amount of discharge, at first clear and glairy, later creamy and distinctly purulent. Microscopically, this discharge showed many epithelial cells, an increasing number of pus cells with a preponderance of the mononuclear types, and a varying bacteriologic picture.

The course of the disease, that is, the time from the appearance of the discharge to the disappearance of all symptoms, varied from two to eleven days; and in one case a recurrence was noted seven weeks after the patient was discharged as cured.

### BACTERIOLOGIC STUDY OF CASES

The bacteriologic study of these cases revealed no single organism as the causative agent, but did bring to light one striking fact, namely, that the use of urethral injections of bactericidal substances rendered the urethral canal sterile for varying lengths of time.

### STATISTICAL DATA IN SERIES OF URETHRITIS CASES

Case Number	Incubation, Hours	Duration, Days	Prophylactic Used	Organism
1	27	2	Improved	Gram-positive diplococcus

19	36	1	"result"	Many forms
20	28	2	U. S. A.	None
21	28	2	Potassium permanganate	None
22	30	3	Mercuric chlorid	None
23	18	1	Silver salt	None
24	21	2	Silver salt	None
25	36	3	Zinc sulphate	Gram-positive diplococcus
26	27	1	Improved	None
27	40	1	Improved	None
28	48	4	Potassium permanganate	Gram-positive diplococcus

\* Recurred after seven weeks with out further sexual contact.

Seventeen, or 60 per cent, of the cases showed no organism in the examination of gram-stained smears, and fifteen, or 50 per cent, of the cases, showed no growth after seventy-two hours' incubation of plain agar and hydrocolloid fluid agar. Eight cases, or 28 per cent, showed the presence of a large gram-positive diplococcus, which grew profusely on ordinary mediums and was also cultivated from three out of ten normal urethras. The three remaining cases presented the greatest interest. One showed a mixed infection with *B. coli* and *Staphylococcus albus* which disappeared after three injections of 10 per cent. argyrol. One showed a short chain streptococcus mixed with the gram positive diplococcus mentioned above and ran a very protracted course. In this case, after much questioning, it was learned that the patient had taken no prophylactic, and eighteen months before had had an obstinate posterior urethritis and *syphilis*. The last case followed the injection of a dilution of a popular cresol-disinfectant; the discharge was scanty and soon disappeared. The patient gave a history of a recent

gonorrhoea three years before, and smears of the pus showed a diversified bacterial flora of more than a dozen forms.

The entire series is given in the accompanying table.

#### TREATMENT

The treatment in these cases presented no difficulty. As soon as it was determined that the discharge was not due to infection with the gonococcus, local treatment was stopped, copious drafts of water were recommended, and alkalis were administered. So long as urethral irritation was continued by injections of antiseptic solutions, the discharge persisted.

#### CONCLUSIONS

A consideration of the information presented by these cases prompts these conclusions:

1. The injection of irritating bactericidal substances into the urethra not infrequently causes a urethritis which may easily be confused with the true gonorrhoeal infection.

2. Such injections render the urethral canal sterile for a considerable period of time.

3. In prescribing treatment in such cases of "irritative" urethritis, the local application of antiseptics is to be avoided.

4. Purulent discharges from the urethra should not be considered gonorrhoeal until the gonococcus has been unmistakably demonstrated in the smears.

322 George Street.

### DELAYED DEATH IN CORONARY THROMBOSIS

R. B. ACKER, M.D.  
NEW ORLEANS

That thrombosis in the coronary arteries does not invariably cause sudden death has been recently emphasized.<sup>1</sup> It is possible that fairly frequently in lesions of this sort, life is prolonged a considerable space or that the establishment of a compensatory circulation is accomplished with a complete or nearly complete return of full heart function. It is undoubtedly true that this condition many times goes without diagnosis, and in the absence of a necropsy the true state of affairs is not recognized.

An interesting and important feature is the intense abdominal pain that may be present. This has an important surgical bearing; as, given a sudden, very severe abdominal pain, with tenderness to palpation, which may even be accentuated over appendix or gall-bladder, a laparotomy may be seriously considered and in some instances, probably, logically performed. An interesting question of differential diagnosis is thus raised.

Herrick gives a tentative classification based on the clinical picture of cases of coronary thrombosis:

1. Cases of instantaneous death in which there is no death struggle, the heart beat and breathing stopping at once.

2. Cases of death within a few minutes or few hours after the obstruction.

3. Cases of severity in which death is delayed for several hours, days or months, or recovery occurs.

1. Herrick, J. B.: *Thrombosis of Coronary Arteries*, J. A. M. A. 72:197 (Feb. 8) 1919.

4. A group that may be assumed to exist embracing cases with mild symptoms; for example, a slight precordial pain ordinarily not recognized, due to obstruction in the smallest branches of the arteries.

The case herewith presented falls under Group 3 in the foregoing classification.

#### REPORT OF CASE

A sailor, aged 34, was suddenly seized, January 25, while on board ship, with a severe pain in the left chest, axilla and upper arm. There was some pain in the abdomen. The pain was accompanied by a pronounced feeling of weakness and what he termed "shortness of wind." He was nauseated and vomited several times. He was compelled to stop work and take to his bunk. The following day he felt much better, but the pain persisted. In a few days he was able to be about, but was unable to work and still complained of the constant pain in his chest, arm and abdomen. January 31, he was brought to the hospital.

He had had no attacks similar to this previously. He denied having had pains of any sort in the chest or elsewhere. He states he had taken care of himself and not dissipated and had always been well. He denied any venereal infection.

On admission he complained of pain in the precordium, left shoulder, upper arm and abdomen. He was noticeably weak; the pulse was 88 and small in volume. There was no marked increase in the area of heart dullness. The urine contained considerable albumin and some casts.

His condition improved considerably. Weakness became less marked. The pulse became stronger. Pain in the chest diminished. February 3, the tenth day, he sat up in a chair and even walked about the ward a bit, without discomfort. February 4, his condition was still improved, though dull ache persisted in the precordium and left arm. February 5, he began complaining more of the pain in the abdomen and complained less of the chest and arm. This increase in pain in the abdomen came on rather suddenly and seemed very severe. He was nauseated and vomited. It was necessary to give morphin. February 6, pain in the abdomen still persisted and had grown worse. The patient seemed in agony. He was with difficulty relieved by morphin. On two successive palpations of the abdomen he localized the greatest point of tenderness first over the appendix and next the region of the gallbladder. Repeated examinations failed, however, to substantiate the localized tenderness. The abdomen was not rigid. It was not distended or tympanic. The patient had difficulty in telling exactly where the pain was, but localized it most often in the epigastrium and below the costal margin on both sides.

On the evening of February 6 he suddenly died.

The heart was normal in size and somewhat pale. External examination revealed very little abnormality. There was a partially organized thrombus in the ramus descendens anterior of the left coronary artery. The heart muscle at the apex of the left ventricle and at the lower part of the interventricular septum was soft, very pale and friable.

The anterior papillary muscle was in similar condition. There was no evidence of arteriosclerosis in the aorta or elsewhere. Except at the extreme tip of the ventricle, the anemic area was confined to the inner one half to two thirds of the ventricular wall. The outer shell of muscle immediately beneath the visceral pericardium was not affected. The kidneys had marked interstitial changes. There was a moderate passive congestion of the liver. There were no other pathologic changes in the abdomen.

#### COMMENT

In this case the patient lived for a period of thirteen days from the onset of first symptoms.

The interesting distribution of the anemic infarct, confined almost entirely to the inner portions of the cardiac wall, I have not seen described before.

Massachusetts General Hospital

BOSTON

The treatment of exophthalmic goiter and other forms of thyrotoxicosis by the roentgen ray was recommended as early as 1905, and a considerable amount of literature on the subject has since accumulated. In 1916, Pfahler was able to collect seventy-six papers on the treatment of exophthalmic goiter by the roentgen ray. Nevertheless, outside of a few clinics, no general attention has been given to this subject. During the past five years we have treated, in the roentgen-ray department of the Massachusetts General Hospital, 262 patients for thyrotoxicosis. The results of this work have been sufficiently encouraging, we think, to warrant a more general use of this agency in the treatment of thyrotoxicosis.

Experimental and investigative work has shown that it is possible to destroy the glandular structures by subjecting them for a sufficient length of time to the roentgen ray or to radium. It is also generally known that the action of this form of light is most destructive on the higher organized type of cell and that the tissues of the lymphatic system are particularly vulnerable.

Anatomically, the thyroid gland is somewhat allied to the lymphoid structures, and change in it is often accompanied by an enlargement of the thymus. (Koehler found the thymus enlarged in 50 per cent. of his operative cases.)

If these statements are true, and the amount of irradiation sufficient to destroy the thyroid gland is not greater than that which will produce an injurious effect on the skin, we should be able to remove part or all of the gland by means of irradiation and produce results similar to those of surgery without the dangers incident thereto.

A REVIEW OF THE LITERATURE

A review of the literature would seem to prove that such results can be obtained. In 1913, Dr. Florence Stoney reported forty-eight cases of exophthalmic goiter treated by the roentgen ray, in fourteen of which complete cure was effected, and in twenty-two great benefit was derived, so that the patients were able to resume the ordinary habits of life. Four patients derived no benefit; seven quit too soon for any opinion as to the result, and one patient, in whom the pulse rate fell from 136 to 112 after treatment, died twelve hours after operation. Pfahler and Zulick, after a careful review of the literature and a study of their own cases, reach these conclusions:

1. We believe that the trial of treatment for one series with an interval of waiting of one month is justifiable in all cases, for if operation is decided on nothing is lost, and many operations can in this way be avoided.
2. Treatment should be directed toward the thyroid and the thymus glands.
3. Increase in weight and decrease in pulse are the first signs of improvement and are practically always found.
4. Treatment must not be prolonged over too long a period or hypothyroidism may be produced.

5. The goiter and the exophthalmos are the last to show improvement, and in many cases show no change.

Means and Aub<sup>1</sup> base their observations on a considerable number of cases treated medically, surgically and by roentgen ray, and these are their conclusions:

1. The general metabolism shows a characteristic increase in hyperthyroidism.
2. This rise may be used as a functional test of the thyroid activity or as an index of the intensity of the thyroid intoxication.
3. An extended study of the metabolism in various types of toxic goiter shows that:
  - (a) Rest alone usually causes a marked decrease in toxicity.
  - (b) Drugs in addition to rest do not materially accelerate this decrease.
  - (c) The roentgen ray, in some cases, produces a definite improvement, while in others it seems to be quite without effect.
  - (d) The usual immediate effect of surgery is a marked decrease in toxicity, but there is a very definite tendency toward a subsequent recurrence.
4. The lesson in therapeutics to be drawn from these results we believe to be about as follows:
  - (a) Complete rest in bed plus irradiation should be continued until the metabolism reaches a level.
  - (b) If rest and the roentgen ray fail to restore the metabolism to within 20 per cent. of the normal, it is proper to resort to surgery, unless there is some definite contraindication. Among contraindications a rising metabolism, in spite of complete rest, seems to be very important.
  - (c) Following operation, if the metabolism again increases, further active treatment should be carried out. The observations in the cases that we have followed for a long time emphasize the importance of keeping cases of exophthalmic goiter under observation for months rather than weeks, and preferably years rather than months.

ARRANGEMENT OF CASES IN GROUPS

After a study of the case histories of our series, we have arranged the cases into four groups:

1. Patients in whom very definite benefit ensued, apparently as the result of the treatment, and are clinically well.
2. Patients in whom there was definite improvement but who still manifested some evidence of disease.
3. Patients in whom there was no change under treatment or who became definitely worse.
4. Patients in whose cases fairly complete data were obtained, at least one basal metabolism record was made, and sufficient time had elapsed to warrant a definite opinion as to the final result. The cases in this group are selected from the other three.<sup>2</sup>

In addition to the cases grouped, there were 133 patients who received one or more treatments but have not been included because of insufficient data.

DISCUSSION OF THE VARIOUS GROUPS

In Group 1 (patients apparently well), there were thirty-four patients, ten of whom were over 35 years and five under 20 years of age. Three were males and thirty-one were females. Two of the patients had been operated on without complete relief of symptoms. In some instances the histories were incomplete, but the

<sup>1</sup> Means, J. H., and Aub, J. C. A Study of Exophthalmic Goiter from the Point of View of the Basal Metabolism. *J. A. M. A.* 60:33 (Feb. 7) 1917.  
<sup>2</sup> The basal metabolism determinations were made by the indirect calorimetry with the Bland apparatus. The results are reported as a percent variation from the normal, but possibly per cent of body surface area. For a more detailed description of the work done adapted by the Russell Sage Institute. The full details of this work will be published elsewhere by Means and Aub. *Connecticut A. M. J. C.* and *The Boston J. of Clinical Chemistry*, XIX, Feb. 1, 1917. *Metabolism*, J. C. M. A. Vol. Ten, No. 1, 1917 (May) 141.

present condition of the patient is known. In some of the cases exophthalmos persists, but the patients are free from symptoms of thyrotoxicosis. The number of treatments received by each patient ranged from three to thirteen, the average number being about seven. The greatest duration of treatment was thirty months, and the shortest four, while the average time was eight months. When a record of the metabolism was made, it showed a sharp drop in most cases. This was true of the pulse also. But in some who never had a high metabolism the pulse remained high, and in these there is some doubt in regard to the diagnosis. In typical thyrotoxicosis the pulse usually follows the metabolism. Seventeen of the number showed a gain in weight; six a loss of weight, and in the remainder the records were incomplete.

In Group 2 (cases improved), there were sixty-eight, thirteen of whom were 36 years of age or older; nine were under 20 years, and the others ranged between 20 and 35 years. Three were males and sixty-five were females. In many of the cases part of the data are missing, owing to the fact that complete records were not kept of the early cases. In a few the diagnosis may have been incorrect, but all of the cases were referred from the medical department for treatment for hyperthyroidism. The opinion as to the result of the treatment is based on a study of the clinical records, and the statement of the patient at the time of the last visit. They were under observation for from three months to two years and a half. The average time, however, was rather less than in Group 1. The average number of treatments received was also less.

In Group 3 (unimproved or bad results), there were fourteen patients, five of whom were over 35 years of age, while there were none under 20 years. All were women. In the case of two of the patients the diagnosis was probably incorrect, as tuberculosis was suspected in one, and the other never had a high metabolism. One died following operation. This patient had received one treatment a few days previously. Two died during the period of treatment from intercurrent disease; six had less than the required number of treatments, making a total of ten in which failure to obtain relief was not due entirely to the method of treatment. In the three remaining cases, two patients showed only slight improvement after prolonged treatment and may definitely be classed as failures (they were comparatively young patients, between 25 and 30 years of age). In the remaining case, myxedema developed, possibly as a result of overtreatment. The number of treatments in Group 3 averaged the same as those of Group 1, but the duration of treatment was rather longer.

Group 4 comprises a fairly complete study of thirty-six cases, in all of which at least one metabolism test was done, while in some the metabolism was determined before and after treatment. In a few of these cases the record was made too soon after treatment to show the best results. In all of them the final observations were made by a disinterested clinician. The comparison of cases in this group is much the same as in the others, eleven patients being over 35 years, only three under 20 years, and the others ranging from 20 to 35 years. Seventeen of the patients were perfectly well, while thirteen were improved, making a total of thirty who were definitely benefited by the treatment. In four of the cases the diagnosis was incorrect, as proved by the metabolism determination and the future

course of the disease. One patient was operated on without relief; two had recurrence of symptoms that responded to future treatment, and in one case myxedema developed as a result of overtreatment. One patient died from unknown cause during the course of treatment. The accompanying table presents the results of treatment in this group.

#### METHOD OF GIVING ROENTGEN-RAY TREATMENT

The method of giving the treatment varied somewhat in the first two years. During the last three years, however (in which the greater number of treatments were given), it has been fairly constant. Most of the work was done with an interrupterless machine, Coolidge tubes being used. The parallel spark was approximately 8 inches. The rays were filtered through 4 mm. of aluminum and 1 mm. of leather. The target skin distance was 8 inches. Three areas were treated at each sitting, each area receiving two thirds of an erythema dose.

The treatment should be applied to both the thymus and the thyroid regions. Fairly hard rays should be used, and the treatment should not be repeated until three weeks have elapsed. After a series of three treatments, there should be an interval of three months before resuming treatment; then a second series of three treatments should be given. If the symptoms have not sufficiently disappeared at the end of this period a third series should be given, making nine treatments in all. Consequently, during this time, the patient will have been under observation about one and a half years.

#### DANGERS INCIDENT TO THE TREATMENT

The dangers and unsatisfactory results incident to this form of treatment are less severe than those of surgery, but they do exist. It is probably true that the function of the thyroid gland may be destroyed and hypothyroidism produced. This is more likely to result if treatment is pushed and the interval of two or three months between each series is omitted. A reexamination in the early cases convinced us that changes go on for some time after treatment is discontinued, and that it is not necessary to have complete cessation of symptoms before stopping treatment.

Another undesirable feature is that of telangiectasis and atrophy in the regions treated. These patients are especially susceptible to changes of this kind, and as the majority of them are young women, when such changes do occur, the resulting disfigurement is of considerable import. These changes are more likely to occur when unfiltered rays are used or an erythema is produced. By using heavy filters and keeping well below the erythema dose, such untoward results can usually be avoided.

The toxemia may be increased to a dangerous degree by the first treatment. This must be guarded against by starting with small doses, preceded by rest in bed until the symptoms are reduced as much as possible. In cases in which surgical treatment has been employed but no complete cure effected, the treatment should be given with the utmost caution, as the danger of hypothyroidism is then greater. Treatment should not be commenced too soon after the operation, and should never be prolonged.

#### DIAGNOSIS OF TYPE OF GOITER

In selecting patients for treatment, it is of first importance that a definite diagnosis of the type of

goiter be made, as on this depends the treatment to be adopted. Should the case not be one of thyrototoxicosis, harm may result from the irradiation. These cases should be studied by a competent clinician and metabolism tests made before treatment of any kind is instituted.

Nonmalignant goiters may be divided into simple or colloidal, cystic and toxic goiters. Toxic goiters may be further subdivided into exophthalmic goiter and adenoma. In the first two forms there is no evidence of hyperplasia of the gland and no toxic symptoms; therefore, radiation would only tend to destroy what remained of the normal gland and would hasten hypothyroidism, producing no effect whatever on the size of the tumor. If pressure symptoms are present, surgical treatment should be given in such a case. In the toxic type, whether exophthalmic or not, there is an

exophthalmic goiter is a self-limiting disease, and that in from 60 to 70 per cent. of the cases, spontaneous cures are recorded at the end of five or six years.

If these reports are accepted, the percentage of cures must be high or prompt relief of symptoms must be obtained, in order to show that any form of treatment is a source of definite benefit to the patient.

In most of the cases reported in this paper, decided improvement was noted twelve months after treatment was begun. In some of these, however, the symptoms had been present for a considerable time, and it is possible that the disease had nearly run its course before treatment was begun. Nevertheless, it is our opinion and that of the associate clinicians, that in cases taken early in the disease a more ready response to treatment was noted and more satisfactory results were secured.

RESULTS OF TREATMENT IN GROUP 4

Number	Sex*	Age	Duration of Treatment, Months	No. of Treatments	Metabolism		Pulse		Weight, Kg.		Tumor		Exophthalmos		Duration of Symptoms before Treatment	Final Note

¶ After four roentgen-ray treatments, metabolism was .45.

increase in the structure of the gland and in its activity, both of which are affected by irradiation; hence it is in this type of case that roentgen-ray treatment is indicated.

To obtain a fair estimate of the value of any form of treatment it is necessary to know and consider the percentage of patients suffering from the disease who recovered without treatment. Hale and White followed eighty-seven cases of exophthalmic goiter treated at Guys Hospital, London. After a number of years it was found that sixty-one of these patients were cured, twenty-one decidedly improved, and only five of the eighty-seven cases unimproved. Staunton, after a rather extensive experience in the treatment of goiter and after a review of the literature concludes that

SELECTION OF PATIENTS FOR TREATMENT

We cannot emphasize too strongly the importance of careful diagnosis and the selection of patients to be treated. If the case is one of thyrototoxicosis, after the second or third treatment the patient usually expresses a feeling of relief from the disagreeable nervous symptoms, the pulse rate becomes lower, and there is a gain in weight. About a year after treatment is begun there should be considerable diminution in the size of the thyroid gland. Exophthalmos never entirely disappears. Except in the more severe cases, the patients have continued their usual habits of life, but we believe that it is of definite advantage to have the treatment supplemented by rest, as in this way the duration of treatment will be shortened. Usually, at the end of six

mouths the patients are sufficiently relieved to resume their ordinary occupation without difficulty or discomfort. To be sure, the relief from symptoms is not so quickly obtained as by surgery, but the dangers are less, and in the milder cases it obviates the necessity of interfering with the daily life of the patient. These are factors that should be considered when deciding as to the form of treatment.

If relief is not obtained by roentgen ray after nine treatments, or if, for any reason, it is desirable to hasten results, surgery may be recommended. The previous treatment by roentgen ray will be of benefit, as it reduces the operative risk by destroying the thymus gland. After roentgen-ray treatment some operators have complained of adhesions and increased bleeding at time of operation; but such has not been the experience of the surgeons in this clinic.

#### SUMMARY

1. It is possible to decrease the activity of the thyroid gland and probably to destroy its glandular structure by exposure to the roentgen ray.

2. Roentgen-ray treatment when applied in cases of thyrotoxicosis produces a relief of symptoms and shortens the course of the disease.

3. A study of the basal metabolism before, during and after treatment is of the greatest importance both as a means of diagnosis and as a check on the amount of treatment to be given.

4. The roentgen ray, accompanied by rest, should be tried in all cases of thyrotoxicosis and should be continued for a sufficient length of time to destroy at least the thymus before resorting to surgery.

## Clinical Notes, Suggestions, and New Instruments

### FRAGILITAS OSSIUM WITH BLUE SCLEROTICS

WALTER D. WISE, M.D., BALTIMORE

This case is reported, not because it is an exaggerated example of the type, but because the type is interesting and rather rare.

Charles W., aged 5, was seen at the South Baltimore General Hospital, Aug. 4, 1919. His mother stated that he had been playing on the floor when suddenly he complained of his leg and began to cry, refusing to put weight on the foot. He did not fall, and had not been engaged in any game or been doing anything that would have been likely to cause an injury. The leg was swollen and tender. There was a slight deformity just above the ankle. A roentgenogram revealed a fracture of the lower third of the tibia, and the upper part of the fibula. The child was well nourished, fairly well developed boy with no signs of scurvy, rickets or any constitutional disease. However, it was noted that his sclerotic were of an azure blue. It was then seen that his mother had sclerotics of the same color. She gave a history of having such in her life, three fractures of the right humerus and two of the left, all from trivial causes. The mother's father was reported to have the same type of eyes and to have had fractures of the clavicle and humerus, but apparently from rather severe falls. The patient's two brothers had blue sclerotics, but had had no broken bones. One sister with the same colored sclera had sustained a broken forearm as the result of her mother's having fallen with her—presumably a legitimate cause.

The leg united in the usual length of time without deformity or any unusual feature.

1800 North Charles Street.

### A CASE OF TRYPANOSOMIASIS

HAROLD B. ADAMS, U.S., NEW YORK

*History.*—A young seaman, aged 26, white, was admitted, August 13, to the wards of Roosevelt Hospital for observation, with the diagnosis of sleeping sickness made by a physician in West Africa. He weighed 140 pounds and was 5 feet 8 inches in height. He was born in Baltimore, but was raised in England. He had been a seaman all his life.

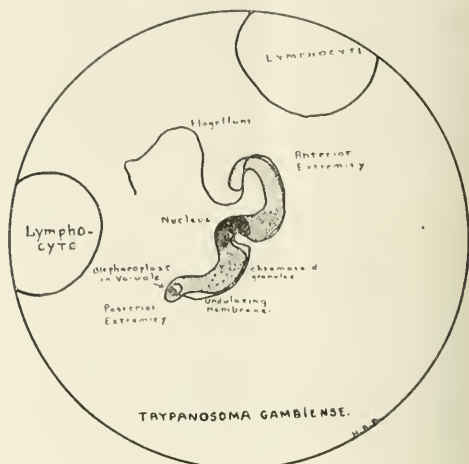

Fig. 1.—*Trypanosoma gambiense*: nomenclature, and size as compared with lymphocytes.

The patient complained of extreme weakness amounting to feebleness, constant dull headache, intense itching of the arms and legs, and swelling of both sides of the neck.

The family history was negative. The patient had always been healthy until his present illness. Sixteen months before he had gone to Sierra Leone, West Africa, where he worked on a development project for nine months. In January, 1919, after he had been in Africa eight months, he was taken to the company hospital with a high fever, intense headache and recurring chills. There was a general erythematous rash over the entire trunk and upper extremities, accompanied by intense itching. The rash and the itching were ascribed to poisoning by a mangrove dye.

The physician in charge, while looking for malaria, discovered trypanosomes in the blood. He immediately placed the patient on sodium arsinitate, 2 grains every other day. A diagnosis of double tertian malaria was also made, and quinin was administered. One month later, February, the patient left Africa and returned to England, where he received treatment at the Seaman's Hospital in London. At this time he had an eruption, described as round red spots 5 or 6 inches in diameter, shaped more or less like a horse-shoe, on his chest, back and face. They persisted until just before his entrance to this hospital when there was still a slight suggestion of an annular erythematous patch on the right cheek. He was discharged, relieved, from the London hospital, but was advised to continue treatment for at least two years. He was supplied, by a private physician, with several hypodermic syringes and sodium arsinitate, which he injected intramuscularly into himself in varying doses at even more variable intervals over a period of five months. During the past sixteen months he has lost about 50 pounds.

When on shore, his habits are alcoholic. Five years before, he had had gonorrhoea, and a chancre in May, 1919.

*Physical Examination.*—The results of examination of the eyes, ears, nose and mouth were negative. His speech was unaffected. On each side of the neck, posterior to the

sternomastoid muscle, was a chain of hard lymph nodes. They were discrete, showed no tendency to suppuration, and were not tender.

The heart was slightly hypertrophied, and there was a faint blowing systolic murmur, heard best at the apex, and transmitted to the axilla. Tachycardia was present. There were many hard, discrete nodes in each axilla. Posteriorly, there were a few maculopapular eruptions averaging about 5 mm. in diameter.

The abdomen was negative except for a slightly enlarged spleen and inguinal nodes.

The genitals showed evidence of a chancre.

There were no tremors, local edema or abnormal reflexes of the extremities. Both epitrochlear nodes were enlarged, hard and firm. There was a peculiar hyperesthesia of the upper extremities which was demonstrated by slightly pinching the arm.

The patient is now apparently in the apyretic stage of the disease. At no time since his arrival has he had a temperature over 101, but he often has a subnormal temperature reaching as low as 96.4. The evening temperature is always higher than the morning temperature, and all the subnormal falls have occurred between 8 and 9 o'clock in the morning.

The pulse is easily excited and jumps to 110, slightly more or less, under the least provocation.

The urine is negative.

The blood findings are: hemoglobin, 85 per cent.; red blood cells, 4,600,000; white blood cells, 5,000; polymorphonuclears, 46 per cent.; lymphocytes, 54 per cent.; Wassermann reaction, negative when admitted, three weeks later, + + + +; malaria parasites, not found; nonprotein nitrogen, normal. The patient's blood was examined for trypanosomes twice daily for one week unsuccessfully. Animal inoculation has been tried but has not yet proved successful.

**Treatment and Results.**—A cervical lymph node was aspirated with an ordinary 10 c.c. Luer syringe, and a watery substance extracted. Only about enough to fill the needle of the syringe was secured. A smear was made and stained by Hastings' method. *Trypanosoma gambiense* was found in fairly large numbers. The patient was placed on arsenic treatment in the form of sodium arsenite, 3 grains every other day. He was also put under vigorous antisyphilitic treatment. At one time, about a week after the sodium arsenite was started, he complained of a smarting sensa-

tion have almost disappeared. He is stronger and has been allowed to leave the hospital on pass without any harm. There is no more itching, and the rash has gone from his back. However, he still complains of neuralgic pains in the limbs and is sometimes irritable and often discouraged.

COCCIDIOIDAL GRANULOMA: REPORT OF A CASE

GORDON F. HELSLEY M.D., REDRESSA, CALIF.  
Senior Physician, State Prison at Folsom

**History.**—A negro, aged 32, seen on entrance to the prison, Dec. 20, 1918, had a large tumor in the left lumbar region which had first been noticed in March, 1917. At no time was the mass painful. The patient was born in Maryland, where he lived eight years; he then lived fourteen years in Oklahoma, and since then in California (ten years) in the Sacramento-San Joaquin Valley. He had been a waiter; he had never been around live stock. He had a sore on the glans penis in 1906 (supposedly chancre). He had a bubo in 1909, which was never opened. There was a swelling in the right supraclavicular region in 1917 at the same time as the lump in the back was first noticed. Following the diagnosis of cervical lymphatic tuberculosis, an operation was performed, after which there was a sinus for several months.

**Examination.**—The patient was of healthy appearance and well nourished. There was a scar of operation above the right clavicle. The inguinal glands were enlarged, both sides. A scar was situated on the lower surface of the glans penis. In the left lumbar region was an irregularly shaped mass about 16 cm. in breadth and length and 8 cm. thick. The skin over it was normal and movable. The mass was somewhat fixed to the deeper structures, however. Its edges were poorly defined, especially to the left. To the right it was closely adjacent to the spinous processes. It was soft, somewhat fluctuant and not at all tender to pressure. It was considered to be a deeply situated lipoma or a benign cyst. The patient's temperature was normal throughout the day. The Wassermann test of both the blood and the cerebrospinal fluid was negative.

**Operation and Result.**—Feb. 24, 1919, under local anesthesia, removal was undertaken. The mass was found to be a thick walled sac extending to the spinous processes on the right and beneath the latissimus dorsi muscle on the left. The sac was opened, and a large quantity of thick yellow fluid was drained out. A portion of the sac was removed and a rubber tube inserted. The wound was closed.

Microscopic examination of the tissue was done by Dr. William Ophüls, who reported: "Sections show fibrinous wall covered on inside with caseous material. At edge of caseous masses epithelioid cells and very large multinucleated giant cells. In some of the latter spherical parasites with double contoured capsule. Coccidioidal granuloma, abscess of back."

March 1, under spinal anesthesia, the previous incision was reopened and enlarged, the latissimus dorsi muscle cut across, and the entire sac removed. The sac was adherent to two of the lower ribs (the tenth and the eleventh). The eleventh rib was rough, but showed no sign of active osteomyelitis. Some old cicatricial tissue could not be removed. The wound was swabbed out with tincture of iodine, the muscle repaired and the wound closed.

There was considerable drainage from the wound, but it was entirely healed by April 8. In May the operated area began to swell, and, May 15, purulent fluid broke through the old incision. By June 16 the wound was again entirely healed, without swelling, and dressing was discontinued.

March 1, the patient was put on potassium iodid, 30 minims of the saturated liquor three times a day, which was rapidly increased until March 26, when he was taking 1 ounce three times a day, or 1,440 grains of potassium iodid daily. This rather large dose was continued until May 24, when the patient's condition was so much improved that the therapy was reduced to 15 drops of tincture of iodine in milk three times a day, which dosage was changed to 30 drops three times a day, June 1. He is still receiving the latter medicine

Fig. 2.—Temperature for first sixteen days of disease; \* indicates time node was aspirated.

tion in both eyes. Examination disclosed a circumcorneal injection and a marked photophobia, but no other symptoms. The following morning he had apparently recovered. Reading made his eyes feel tired, but by the next day there were no further eye symptoms and there has been no recurrence. Since the condition cleared up without stopping the arsenic, we think it was due to the trypanosome.

Positive findings which led to the diagnosis of trypanosomiasis were: Subjective: neuralgic pains in arms, legs and back; hyperesthesia; headache; intense itching, and transient eye symptoms. Objective: trypanosome found in material from aspirated node; loss of weight; mild tachycardia; enlarged spleen; polyadenitis; subnormal temperature and the maculopapular eruption on the back.

After six weeks of treatment the patient is obviously much better than when he was admitted. The cervical glands

tion. At no time has the patient manifested any symptoms attributable to iodism.

At the present time, three months after the wound finally closed, the patient appears to be in perfectly good health, and there is no evidence of a recurrence of the disease either at the previous site or elsewhere.

AND OTHER REMEDIES IN THE TREATMENT OF DISEASE.

### USE AND ABUSE OF CATHARTICS \*

(Continued from page 1613)

#### CASTOR OIL

The "soothing purgative"<sup>1</sup> is probably the best sobriquet by which to characterize the therapeutic qualities of this old reliable agent of notoriously nasty taste. Were it not for this unique combination of action it would probably have long ago been consigned to the limbo of the abandoned scourges of the ill. It is the fact that it is the least irritant of the powerful and reliable cathartics, the most potent of the evacuant oils, that renders it still indispensable.

To be a reliable purgative, a substance must produce a certain degree of irritation in the intestine, hence the term "soothing purge" may appear paradoxical. As is well known, this oil, bland and soothing in itself, yields an irritant—ricinoleic acid—on digestion in the intestine. Accumulation of this irritant, with possibility of excess of irritation, does not occur, partly because of the powerful peristalsis it provokes, which pushes it on and on, so that the small intestine empties itself into the colon in two hours instead of the normal eight, but chiefly on account of the fact that this unsaturated fatty acid is absorbed and assimilated, and capable of serving as food for man. Castor oil, be it remembered, is an article of diet in China, which goes to prove the saying, "De gustibus non est disputandum." Demulcent up to the moment of its digestion, the portion that is split up becomes momentarily irritant, to be reconverted into the soothing triglyceride of ricinoleic acid—or castor oil—on absorption through the intestinal mucosa.

From this it is easy to understand that the action of castor oil is, to a certain extent, independent of dose, and that the dose is not much influenced by age. An infant may safely be given a teaspoonful or two—a dose that will usually physic an adult. The reason is that castor oil becomes activated in proportion to the amount of digestive juices available; and, of course, the larger the intestine the more juice there is. The quantity of oil that exceeds the digestive capacity is passed through unchanged, acting merely like so much petroleum. Excessive action is therefore an impossibility. True, the usual dose for an adult is from 1 to 2 teaspoonfuls, and it must be admitted that such a dose is more reliable and thoroughly active

than that of a teaspoonful or two. When, however, there is difficulty in administration, on account of the taste, the knowledge that a teaspoonful may suffice for an adult is of importance.

Because of the thoroughness and reliability of its action, and the impossibility of excessive effect, it is the purgative of choice for delicate invalids, infants, in pregnancy, and in patients with hemorrhoids or anal fissure.

For the reasons given, castor oil produces little griping; indeed, it is a good remedy in the treatment of intestinal colic. "The castor oil cure"—a course of daily doses of castor oil—has relieved many an obscure case of abdominal pain, and incidentally made the diagnosis.

In cases of abdominal pain in which an intestinal obstruction is suspected, castor oil is probably the least objectionable of the reliable cathartics. Here, too, it has diagnostic importance: for, if a liberal dose fails to act, more drastic cathartics will probably also fail, and ought not to be employed.

This oil is notorious for its tendency to leave the bowel sluggish after it has produced an evacuation; hence it is one of the worst drugs to give in the treatment of chronic constipation. On the other hand, in view of its soothing qualities, it is a cathartic to use during the cleaning-out phase of the treatment of acute diarrhea. Regarding its use in chronic diarrhea, Brunton writes: "Sometimes a teaspoonful of castor oil, given every morning, will do more for a chronic diarrhea than anything else I know."

I. A. Abt found, however, that even castor oil is not absolutely harmless, at least in children, as he discovered evidences of irritation in the last stools when teaspoonful doses were given on three successive nights. Single dram doses produced no irritation; and, as compared with magnesium sulphate and calomel, it seemed to have the least irritant action.

A dose of castor oil usually acts in from four to six hours; hence it should be given so that it will produce its effect while the patient is awake. Like other oils, it has a tendency to delay gastric evacuation, and therefore it is best given on an empty stomach an hour before breakfast.

It is possible to so refine this oil, that, provided it is protected from the influence of the air, it is almost devoid of odor and taste. Such oil is obtainable under the trade name of Kellogg's "Tasteless." Squibb's, or Allen & Hanbury's, are very similar. It should be procured in small bottles and used while fresh, the bottle being kept carefully corked.

A good way to prescribe castor oil is in elastic capsules, the 2.5 c.c. size being none too large for the average adult. To make such capsules go down easily, it is well to advise that they be dipped in water for a minute before taking them, and to remind the patient to look down while swallowing, just as he does when he swallows food. Holding the head up while attempting to take pills or capsules is one of the chief causes of inability to swallow them. Two of these capsules often suffice for a satisfactory result. If a much larger amount is required, it is best given floating, in the form of the so-called "sandwich" dose. If the following directions are carried out, the dose can be swallowed without tasting the oil:

In a small tumbler or medicine glass is placed a layer of thick syrup of any flavor desired. The glass is inclined in such a way as to coat its inside almost up to the rim. Then

\* This is the seventh of a series of articles on the pharmacology, properties and practical application of the common laxatives and cathartics. The first article appeared October 15.

1. We must differentiate between a purgative and a laxative. A laxative is an agent that produces formed stools, and is incapable of causing acute irritation in any dose. The oils previously discussed are typical laxatives. A purgative is an agent capable of causing profuse evacuation of the bowels, but which does not act as an irritant poison in any dose. Castor oil belongs to this class of cathartics. A drachm is an active cathartic which in overdoses acts as an irritant poison.

the oil is poured into the center of the glass, care being taken that it does not run down the side. This is topped with a layer of pleasantly flavored alcoholic fluid, such as aromatic elixir. While the dose is being taken, the edge of the glass should be placed on the lower teeth, so as to avoid straining the oil through the teeth, to which some of it might adhere. When correctly taken, the oil follows the alcoholic fluid, gliding down the tongue on the surface of the syrup, without at any time touching the gustatory membrane. Of course, the patient must take the whole dose at one gulp.

The small infant needs no disguise for castor oil. Taste sensation is not sufficiently developed for it to object to so bland a thing as this oil. It will lick the oil from the spoon. As soon as taste sensation asserts itself, however, we should do something to disguise the dose for the child, unless we deliberately inflict it on the youngster as a punishment. As such, by the way, it is used as a remedy, prophylactic as well as curative, for the little fellow who habitually over-eats, or the school child malingering because of a dreaded examination. In both instances, a day of fasting is a good adjunct to the dose of castor oil. However, because of the prejudice against medicine in general which such practice is likely to engender, it is questionable whether some other method of punishment could not be easily found that would be less detrimental, just as threatening to call a physician when the child does not behave makes the youngster afraid of the doctor, when it would be to the child's interest to cultivate the feeling in the little one that the physician is the children's friend, the best friend a sick child can have.

Sweetening the castor oil and making it aromatic is a good way of disguising it for the child. By means of saccharin (0.05 per cent.) dissolved in alcohol (3 per cent.), castor oil can readily be sweetened. When this is flavored with aromatics (vanillin, 0.1 per cent, coumarin 0.01 per cent) and volatile oils (oil of cinnamon 0.3 per cent, oil of clove 0.1 per cent.), we have the aromatic castor oil of the National Formulary (*oleum ricini aromaticum*, N. F.), which is palatable excepting for the acidity left after it is swallowed. This can be eliminated by using a non-acrid oil, such as Kellogg's "tasteless." Children, however, take aromatic castor oil readily, even when made from ordinary oil, as they usually do not associate the after-sensation with the dose that has been swallowed. We may, therefore, consider the problem of the administration of castor oil to children solved by this means.

In view of the N. F. formula, which can be compounded by any pharmacist, it is hardly necessary to specify a proprietary preparation. Should such specifying seem expedient, *oleum ricini dulce*, marketed by the Pitman-Moore Company, Indianapolis, might be mentioned as an example of such a preparation on the market.

The following method is also of practical value, as it enables one to administer a "tasteless" castor oil without the patient's knowledge, and is useful, therefore, for those children who unreasonably object to medicine of any kind. By vigorously shaking "tasteless" oil, with a liberal excess—at least four times as much—of hot milk, in a bottle which they do not more than half fill, and then having the dose taken immediately, the mixture will be found scarcely distinguishable from rich milk. Such oil might also be given floating on hot soup. However, a protest should be

entered here against administering ordinary castor oil mixed with an important food. This might create in the child a disgust against this article of diet that may last for years.

Thorough emulsification lessens the activity of castor oil, probably because in this form it is too rapidly digested and assimilated. A 35 per cent. emulsion of castor oil can readily be prepared and made palatable. A formula for such a one is to be found in the National Formulary under the name of *emulsum olei ricini*, N. F. It is flavored with tincture of vanilla. The British Pharmacopoeia has a similar formula of different flavor (orange flower and cinnamon) under the title *mistura olei ricini*, B. P. However, as a babe might require a tablespoonful, and an adult a wine-glassful or more, of such emulsions, these preparations are not economical ones, to say the least.

Medicine is still one of the dreaded bighorns of childhood, and castor oil is a leader of these. Let us admit that it is poor technic to insult the palate—the sensitive guardian of our system against chemical injury—when medicine is to be given. It is no longer necessary, and certainly inexpedient. The patient may take the dose; but he does so with open or smothered revolt.

(To be continued)

## New and Nonofficial Remedies

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

W. A. PECKNER, SECRETARY.

**Pituitary Solution-Hollister-Wilson.**—Liquor Hypophysii, U. S. P.—A sterilized solution of the water soluble extract of the posterior portion of the pituitary glands of cattle, preserved by the addition of chlorbutanol, each Cc. containing 0.095 Gm. It is standardized according to the method of Roth (Bulletin 100, Hygienic Laboratory, U. S. P. H. S.).  
*Actions and Uses.*—See New and Nonofficial Remedies, 1919, p. 204.

*Dosage.*—From 0.3 to 1 Cc. to be injected intramuscularly or subcutaneously. May be increased or diminished according to indications.

Manufactured by the Hollister-Wilson Laboratory, Chicago. No U. S. patent or trademark.

*Ampoules Pituitary Solution-Hollister-Wilson 1 Cc.* Each ampoule contains a pituitary solution. Hollister-Wilson U. S. P.

Posterior lobes of the pituitary body of cattle are dried and fattened and then extracted with highly acidulated water, the solution boiled and filtered. The resulting extract is sterilized and then adjusted so as to correspond with the Pharmacopoeia standard.

Pituitary solution Hollister-Wilson is a transparent liquid, colorless and having a faint characteristic odor.

**Cancer.**—Posters to warn the public against the danger of delaying operation in cancer cases have been prepared and circulated recently to the number of 4,500 among the largest industrial plants in Massachusetts. Through the cooperation of the Associated Industries of Massachusetts and the Retail Trade Board of the Chambers of Commerce the cancer posters have been displayed on the bulletin board of 1,100 of the largest factories and fifty of the largest department stores in the state. The posters offer free information regarding cancer to all who write to the Massachusetts Health Committee, 525 Boylston Street. The inquirers promptly receive the latest cancer circulars of the State Department of Health and the American Society for the Control of Cancer—*The Commonwealth* 6:121 (May/June), 1919.

## THE FUNCTIONS OF THE THYMUS

To the scientific investigator there is something tantalizing in the existence of anatomic structures for which no clear-cut function is demonstrable. There are in the body numerous organs that are indisputably indispensable to life. Whenever they are extirpated experimentally or destroyed by disease, the loss of something that they contribute to bodily well-being manifests itself, and death ultimately ensues. Removal of the pancreas, the pituitary or the suprarenals affords an illustration of the fact that these structures are necessary to the organism. Other organs, such as the stomach and salivary glands, can be extirpated without untoward outcome. Their function is replaced to a certain sufficient extent by the action of other glands, although the contributory advantage of the removed tissues becomes evident in the modifications of physiologic performance that their loss entails. Without gastric secretion, alimentation may still proceed satisfactorily; but the danger of undue bacterial action in the absence of the antiseptic hydrochloric acid of the stomach is always imminent, and the need of careful selection of foods that can be managed by the enteric tract without preliminary gastric digestion is recognized. If not indispensable, this function is at least absolutely useful.

In contrast with these instances of physiologically necessary or desirable organs is the existence of other tissues that baffle the observer. No one can longer confidently maintain that the spleen is indispensable; nor, on the other hand, is the physiologist willing to admit that this large, conspicuous organ, which is so intimately connected with vital abdominal structures, is essential. Equally undetermined is the rôle of the thymus in the organism. It is known to undergo a normal involution in the earlier years of life; consequently the possibility of some interrelation between the thymus and growth (which likewise ceases in the course of a few years) has long been kept in mind by investigators. Thus it has been reported that in cases of arrested development or of general weakness in young persons, the thymus has been found to be persistent. However, so many factors are concerned in

the complex changes attending growth that chance parallelisms of the sort just indicated have little if any significance to the critical student of the subject. Extracts of glands, as in the case of the pituitary and suprarenals, sometimes display physiologic potencies indicative of a special function. So far as is known, extracts of the thymus do not differ in effect from those made from other common cellular organs.

The extensive literature on the physiology of the thymus gland is peculiar in that it seems to represent a series of more or less conflicting personal impressions. The eagerness to find something tangible in the activities of the thymus has led investigators to grasp at almost any deviation from the normal that an observer has chanced to note whenever the structure has been interfered with. This is particularly true of extirpation experiments. We agree with a recent reviewer who remarked that it is doubtful whether an unprejudiced person, reading for the first time the literature on experimental extirpation of the thymus, could obtain from it any clear conception as to what the effects of removal of the thymus actually are; probably he would be at a loss to know whether to regard the thymus as essential to life or as an organ devoid of function, or at least of function demonstrable by extirpation.

The choice of experimental animal has not always been fortunate. For instance, Park<sup>1</sup> concluded that in all probability the thymus cannot be extirpated completely from the guinea-pig and, consequently, that the guinea-pig is an absolutely unsuitable subject for thymus extirpation, if it is desired to remove the entire gland. His work makes it appear that the thymus extirpations performed on the guinea-pig by all other investigators were partial and should be so regarded, as none of them examined their animals to make sure that remnants were absent, and that their conflicting results must be considered and interpreted in that light. Again, the severity of an operation that involves the opening of the thorax and extensive dissection from the beating heart in animals at an early age is such that some retardation of growth after thymectomy may naturally be expected apart from any function of the removed tissues themselves. Such factors have rarely been adequately controlled.

In view of this uncertainty, we welcome an excellent contribution, both critical and experimental, that has been made to the subject of thymus function from the departments of pediatrics and surgery at the Johns Hopkins University by Park and McClure.<sup>2</sup> They have performed the important service of pointing out the incongruities in the literature of the subject and the inadequacies of many experiments so limited, often, that chance variation or dietetic or environmental influences cannot be excluded as the controlling factors.

<sup>1</sup> Park, E. A.: Extirpation of the Thymus in the Guinea-Pig. *J. Exper. Med.* 25:129 (Jan.) 1917.

<sup>2</sup> Park, E. A., and McClure, R. D.: The Results of Thymus Extirpation in the Dog. *Am. J. Dis. Child.* 18:317 (Nov.) 1919.

In addition, the Baltimore investigators have made a large number of carefully controlled experiments in thymectomy on young dogs. An illustration of the sort of conception heretofore held is found in the publications of Basch,<sup>3</sup> for example. He concluded that the thymus is not essential to life but exercises a transitory function corresponding to its own life history; that its function is concerned especially with the growth and development of bone, and intimately connected with the process of calcification. He suggested, at least, that growth bears some relation to the size of the thymus, supporting the theory by necropsy findings in a litter of three animals which, having exhibited in life great differences in size, showed at the post-mortem correspondingly great differences in the size of their thymus glands.

Park and McClure are convinced that thymus function is absolutely unessential to life. In contrast with such contentions as have just been mentioned, they defend the thesis that extirpation of the thymus produces no detectable alteration in the hair, teeth, contour of the body, muscular development, strength, activity or intelligence of the experimental animal. Extirpation of the thymus probably does not influence growth or development. However, the possibility that it may cause retardation in development and delayed closure of the epiphyses cannot be excluded absolutely. Extirpation of the thymus probably produces no alterations in the organs of internal secretion. However, with commendable scientific caution the authors say it is possible that extirpation of the thymus produces well marked changes in the organs of internal secretion in the period immediately following thymectomy which was not covered by their experiments.

There has of late been a popular impulse, so to speak, toward classifying the thymus as an organ producing an "internal secretion." As Hoskins<sup>4</sup> has recently contended, the proof of this has never been furnished. He himself considers that the thymus functions as a lymphoid organ in infancy and childhood when a large number of lymphoid cells and leukocytes are needed, and involutes, like an enlarged tonsil, when its presence no longer is necessary. Whatever the facts are, we may hereafter insist, thanks to the excellent American studies of Parks and McClure, that the preconceived ideas of investigators shall no longer dominate the teaching with respect to thymus function; and that positive conclusions hereafter shall be drawn "only from evidence that is overwhelming."

## AN ENGLISH EXPERIMENT IN SOCIAL MEDICINE

In England, the medical profession and the public are apparently in a state of readjustment. Social insurance in the four years preceding the war, the needs and emergencies of war times, and the discussion of the last year culminating in the creation of a national health ministry, all have combined to arouse and concentrate interest and discussion on the improvement of medical services. An experiment now being carried on in Glasgow is, therefore, of special interest. Dr. David McKail, lecturer on public health at St. Mungo's College, and Mr. William Jones, clerk and treasurer of the Glasgow Insurance Committee, have worked out a plan for a public medical service as a substitute for the social insurance scheme now in operation. Beginning with a criticism of social insurance, which they condemn for failure to provide any form of institutional treatment and for furnishing medical services to only about one third of the total population, they propose to build up a complete medical service, furnishing unrestricted treatment to every citizen needing it, and involving the enrolment of the medical profession and the public control of all general hospitals and infirmaries.

The proposed plan is founded on the experience gained in efforts to meet war conditions, when for a time dispensaries were established in Glasgow for centralizing the patients of absent physicians. The city was divided into districts, and a consultation center established in each. The Bridgetown District, with approximately 100,000 inhabitants, is taken as a convenient unit for study. The volume of sickness as shown by the number of dispensary visits is found to be 3.11 per person per year, varying from a maximum of 7.5 visits for the first year of life to a minimum of 1.32 for ages from 15 to 25. House visits are found to amount to one fourth of dispensary visits. This amount of professional work would require twenty-seven physicians, working thirty-three hours a week. A 25 per cent. addition for seasonal increases would necessitate a staff of thirty-three physicians, each of whom would have an annual vacation in the summer or fall. Births would average nine or ten a day, requiring four obstetricians. Minor surgery and various specialties would require six, making a total staff of forty-three medical men, exclusive of institutional and consultant service. These men are to be graded in three classes, according to age, experience, etc. Each junior would be allowed time and be required to do graduate medical work and special study with a view to his advancement in the service. Salaries would range from \$1,500 to \$2,000 for juniors, \$2,500 to \$3,500 for middle grades, and \$4,000 to \$4,500 for seniors. Provision is also made for dentists and for dental treatment. It is estimated that the expenses of such a medical service could be defrayed by a tax of 1s. 10d.

in the pound, imposed in the same manner as the public health assessment, and that the entire expenses of operation could be supplied at an individual cost below the seven shillings capitation basis on which social insurance is now being conducted.

An interesting side light is thrown on the provision for free choice of physicians, under the social insurance plan now in operation. A careful study of the district shows that since the introduction of social insurance and the panel system in Glasgow, those affected have not made an effort to exercise any choice in the selection of physicians, but have gone to the nearest and most conveniently located physician. The advantages for the physician of the proposed public medical service are the limitation of working hours, the guaranteed adequate income, the avoidance of waste of time and energy, the opportunity for increased income, the accumulation of experience, and the opportunity for graduate and special work for every practicing physician. The advantages claimed for the individual are better treatment at a much less expense and for the community, economy of administration, and the prevention of a large amount of disease. The *London Lancet*,<sup>1</sup> in commenting on the proposed plan, expresses the hope that the authors may have an opportunity of testing it, as success or failure would alike afford much needed experience.

#### MEASURING METABOLISM

The estimation of the basal metabolism of man as an index to the existence of certain pathologic manifestations of the bodily functions is becoming quite common as a result of the improvement of respiration apparatus which enables suitable experimental observations to be made with relative ease by a trained clinician at the bedside. The history of medicine affords many other interesting illustrations of the readiness with which the physician appropriates, to diagnostic use, instruments of precision and methods of analysis that are practical in form and execution. The clinical thermometer, the sphygmomanometer, the serologic tests for syphilis, the quantitative determination of gastric and duodenal secretory factors—these and numerous other illustrations of the prompt adaptability of the alert physician to the possibilities of better diagnosis testify to the tendency of exact science to replace empirical judgment whenever circumstances make it worth while.

An indispensable feature involved in the use of any method of precision in medicine is the establishment of normal values. What is the normal range of body temperature? What are the limitations of blood pressure estimations? How are they affected by physiological or environmental factors quite apart from disease processes? Such inquiries must be answered clearly

before aberrant values can lay claim to correct diagnostic significance. In the case of the basal metabolism, likewise, it has become essential to have standards by which the data obtained may be evaluated. Size, age and sex must be taken into account. To the establishment of the foundations of calorimetric research, American investigators, notably at the Carnegie Nutrition Laboratory in Boston and the Russell Sage Institute of Pathology in Bellevue Hospital, New York, have made fundamental contributions, many of which have been specifically reviewed from time to time in *THE JOURNAL*. We shall not discuss the still debated questions, such as the relative significance of body surface and weight, in the calculation of units of metabolic performance. More important for the clinician is the fact that body weight, stature and age of the subject must be considered in predicting basal metabolism.

With this conviction in mind, Harris and Benedict<sup>1</sup> have recently issued standard "multiple prediction tables for normal basal metabolism" in both man and woman. In accord with what has been asserted in the past, the use of the standards shows the existence of a well marked differentiation in the level of metabolism of men and women, and shows that the differences are persistent throughout adult life instead of disappearing in later years as maintained by Sonden and Tigerstedt. There is no evidence for such differentiation in newborn infants. The average woman shows a daily heat production about 300 calories less than the average man. If correction is made for body size by expressing heat production in calories per kilogram of body weight, she shows an average heat production of about 1.2 calories per unit of weight less than the man. If body surface is used as the basis for comparison, the woman shows daily heat production approximating 76 calories per day per square meter less than that of man.

Data recently secured by the Food (War) Committee of the Royal Society of London substantiate this general outcome. Thus Rosenheim<sup>2</sup> concludes, starting from the contention that the unit of surface area eliminates the same amount of heat in the normal adult, that the figure for women is about 7 per cent. lower than that for men. The energy expenditure of women in various activities has likewise been ascertained by the English committee in order that they might be assured of a fair assessment of their share in the available food supply during the period of food stringency. The outcome determined under conditions of factory work shows the following increments of heat production during work and walking: light work, 72 per cent.; medium hard work, 109 per cent.; hard work, 181 per cent.; walking, 274 per cent. It may come as a surprise to learn that the energy expenditure

<sup>1</sup> Harris, J. A., and Benedict, F. G.: A Biometric Study of Basal Metabolism in Man, Pub. 2-6, Carnegie Institution of Washington, 1919.

<sup>2</sup> Rosenheim, D.: A Preliminary Survey of the Energy Expenditure of 12,000 Requirements of Women Workers, Proc. Roy. Soc., Series B, 91:44 (Aug. 6), 1919.

<sup>1</sup> An Epitome of the Public Medical Service, *Lancet* 2:649 (Oct. 11) 1919.

during one hour's horizontal walking is in all cases higher than that of even the hardest work on the lathe. Women expend about the same amount of energy as do men in horizontal walking, the "maximal economic velocity" being about 3 miles an hour (or 80 meters a minute). As has been demonstrated in the case of athletes, training works for economy of energy expenditure. A waitress is likely to walk with greater physiologic economy than a person of sedentary habits. It is known that during adult life the basal heat production of the adult continuously decreases. This is one of the accompaniments of age. Perhaps the failure of rejuvenescence in the human individual is associated with his inability to speed up metabolic performance at a juvenile rate. Pulse rate, which is in some degree an index of metabolic rate, normally decreases with age. Statistics gathered by Harris and Benedict<sup>1</sup> express the relationship between age and metabolism in terms of an actual decrease in daily heat production per year amounting to about 7.15 calories in men and 2.29 calories in women. The decrease in heat production per kilogram of body weight is more nearly identical in the two sexes, namely, 0.112 calory in men and 0.124 in women. Such tests of the rate of change as have been made throughout the age range of adult life indicate that it is essentially uniform. Senescence and metabolism are thus interrelated.

---

### HEALTH LEGISLATION IN CONGRESS

After a continuous session of exactly six months, the first session of the sixty-sixth congress has adjourned without enacting any beneficial public health legislation; nor was any legislation detrimental to public health enacted. The Senate made progress with some measures of interest to the medical profession, while practically no consideration was given to any of this legislation by the House. This is due primarily to the fact that the Senate has a committee charged with the consideration of medical legislation, known as the Senate Committee on Public Health and National Quarantine, while the House has no such committee, nor any committee that corresponds to it. The Senate committee considered and reported favorably a bill to provide \$1,000,000 for the study and treatment of influenza and kindred diseases, introduced by Senator Harding of Ohio; a bill to establish a division of tuberculosis in the United States Public Health Service, introduced by Senator Randsell of Louisiana; a bill making appropriations for the care and treatment of drug addicts, introduced by Senator France of Maryland, and a bill to admit government employees suffering with tuberculosis to army, navy and Public Health Service hospitals. All of these measures are now on the Senate calendar, having been reported favorably, and are in line to be called up at the beginning of the next session, Monday, December 1. The Senate

passed a bill providing for the retirement of female army nurses, introduced by Senator Wadsworth of New York, and this measure will be before the House at the coming session for final action. The House Committee on Pensions favorably reported a bill to pension members of the Female Nurse Corps of the war with Germany, introduced by Congressman Fordney of Michigan. The regular governmental appropriation bills, including the necessary appropriations for the Medical Corps of the army, navy and U. S. Public Health Service, were passed. A number of other medical measures were introduced in both the Senate and the House, but no action was taken on them. Some relate to the establishment of the Department of Health in the federal government, and have been referred to in *THE JOURNAL* from time to time, while others provide for the establishment of bureaus of rural sanitation and maternity, and infancy hygiene in cooperation with the state governments. It is quite evident to those who have watched, or who are interested, in medical and health legislation, that, so far as congressional legislation is concerned, one of the big needs of the time is the creation of a committee on public health in the House of Representatives of the United States Congress. —

### DRUG POTENCY IN WAR-STRICKEN POPULATIONS

Almost every physician has seen, at times, in individual cases, surprising and unexpected pharmacologic responses to the administration of certain drugs. He charges to obscure idiosyncrasy the unanticipated effects of substances that have a well known potency in standard dosage. Progress in the study of pharmacology and therapeutics tends to reduce the number of instances in which ignorance of the cause of either hypersensitiveness or resistance to a drug, as the case may be, must be veiled by the word "idiosyncrasy." The phenomena of tolerance to drugs are gradually becoming unraveled and explicable; the limitations of dosage are being rationalized because the scientific spirit of our times is no longer content to accept vague or meaningless phrases in place of lucid explanations. On several occasions *THE JOURNAL* has stated that the war-time diet with its attendant undernourishment had brought about pathologic conditions in indirect ways in some places. The incidence of certain diseases has evidently increased because of a lowered resistance on the part of a food-impooverished population. Other maladies, such as cancer and diabetes, have become less conspicuous. Several clinicians have recently recorded a greatly increased sensitiveness of persons in the undernourished districts to the effects of commonly administered drugs.<sup>1</sup> Treatment with mercurials and arsphenamin in usual doses in cases of syphilis has resulted in increased instances of mercury poisoning. Icterus is reported more frequently as an undesired manifestation of this therapy. A profound narcotic effect has followed the use of small doses of

<sup>1</sup> J. Zernik, F. Kreuzunterernehmung und Arzneimittelwirkung. Deutsch. med. Wochenschr., July 31, 1919, p. 858. Rumpel, Kreuzwirkung auf die Ernährungverhältnisse, Monatsh. u. J. Med. Ch. dtd., June 19, 1919, p. 204.

paralytic which were commonly employed with ordinary anesthetic outcome in prewar days. Patients who formerly tolerated much larger doses of morphin derivatives without untoward symptoms succumbed to the customary prescriptions with signs of profound narcosis. The objectionable cutaneous manifestations of certain drugs have become conspicuous in the war-stricken population. Such instances suffice to show the unanticipated, but by no means inexplicable interrelations of widespread undernourishment and practical therapeutics.

#### FINDING THE PROVERBIAL NEEDLE

Under General News last week was an item to the effect that an investigator of stammering desired to secure a stammerer whose skull had been trephined. He wished to determine whether or not there was any relation between stammering and cerebral congestion. While there are thousands of stammerers in the United States, and an unknown number of persons whose skulls have been trephined, it seemed extremely unlikely that the combination might exist in any considerable number of cases. The request was published with small hope of response. But the first mail on Monday morning brought the name and address of such a person. The legendary difficulty of finding a needle in the haystack is thus shown to be not such a difficult matter after all, providing the right method—or, as in this case, the right medium—is employed.

#### UNTOWARD REACTIONS AFTER ARSPHEN-AMIN ADMINISTRATION

The exact nature of the reaction due to individual idiosyncrasies that sometimes follows the administration of certain drugs is perhaps not always the same. In some ways these reactions resemble, at least superficially, the phenomena of anaphylaxis, or hypersusceptibility. Very few of the drugs concerned, however, are protein bodies, and anaphylaxis strictly speaking is hypersusceptibility to foreign protein. It has been suggested that these reactions be described as "anaphylactoid reactions." That such reactions occur after arsphenamin administration was first noted by Hoffman. The phenomena usually result after repeated intravenous injections of the drug. There is a sudden congestion and swelling of the face, or a cyanosis of the face with a feeling of congestion in the head. The patient complains of a feeling of oppression in the chest, with cough, dyspnea and pain in the back. Frequently mental anguish is present. These symptoms usually develop usually during the administration of the drug, and disappear when this is stopped. Hirano<sup>1</sup> has been working on this problem in Kitasato's laboratory for two or three years. He concludes that so far as anaphylactoid reactions to arsphenamin are concerned, the phenomena are connected with the action of the drug on the suprarenal glands. He points out that Brown and Pearce showed experimentally many years ago that arsenic has a selective action on the suprarenals. His experiments show that large doses of arsphenamin or of neo-arsphenamin lead to a

marked reduction in the chromaffin substance of the suprarenals, and that the epinephrin content both of the blood and of the gland itself undergoes a marked diminution after the injection of even therapeutic doses of arsphenamin. He thinks that the anaphylactoid symptoms are produced when this sudden reduction in the epinephrin content of the blood is so great that a fresh supply cannot be furnished promptly by the suprarenals. If these observations are correctly interpreted, they point directly to the treatment of anaphylactoid phenomena after arsphenamin administration by the intramuscular injection of epinephrin. Hirano's results and those of Pearce and Brown are also suggestive as throwing light on the possible cause of the pigmentation of chronic arsenic poisoning. May it not be that this pigmentation is not directly associated with the drug itself but is an indirect effect produced by its action on the suprarenal glands?

### Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST; SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

#### COLORADO

**Testimonial to Health Officer.**—Dr. George B. Gilmore, who served as health officer of Colorado Springs during the influenza epidemic last year, was presented by the city council with a framed copy of a resolution adopted by that body. Mayor C. E. Thomas made the presentation address.

**Personal.**—Dr. M. Ethel V. Fraser, Denver, who received a decoration from the French government for her work in the Chateau Thierri sector, has returned from France.—Dr. Frost C. Bichtel, Denver, who has been seriously ill, has gone to Hot Springs, Ark., for his convalescence.—Dr. Charles Fox Gardiner, Colorado Springs, has been reelected chairman of the Pikes Peak chapter of the American Red Cross.

#### ILLINOIS

**Hospital Notes.**—Christian County has voted in favor of levying a tax for the building and maintenance of a county tuberculosis sanatorium.

**Central Illinois Physicians Meet.**—At the annual meeting of the District Medical Society of Central Illinois, held in Pana, October 30, Dr. Henry E. Monroe, Shelbyville, was elected president; Dr. Robert L. Morris, Decatur, vice president; Dr. Franklin A. Martin, Pana, secretary, and Dr. Lotharo L. Morey, Vandalia, treasurer.

**Personal.**—Dr. Josephus J. Brown, for nearly forty-one years a practitioner of Troy, has disposed of his business and property interests and announces his retirement. He expects to reside in California.—Dr. Frederick D. Culbertson, Rushville, has let the contract for the erection of a new medical and surgical institute at Rushville, to be known as the Culbertson Hospital.

#### Chicago

**Deaths from Denatured Alcohol.**—The coroner's office states that fourteen deaths, from the use of denatured alcohol as a substitute for whisky, have been reported since September 15. Many cases of blindness have also been reported which are attributed to the use of denatured alcohol as a beverage.

**Low Death Rate.**—In spite of the estimated increase in population of a quarter million, since 1915, the death rate of Chicago is lower than far, this year, than it was four years ago. During the same period in 1916, 31,205 deaths were reported, in 1917, 33,281; in 1918, 37,679; and in 1919, up to November 15, only 29,983.

**Dr. Emerson in Chicago.**—At the November 19 meeting of the Chicago Medical Society, Dr. William R. P. Emerson, professor of pediatrics in Tufts Medical College, Boston, pre-

<sup>1</sup> Hirano. Kitasato Arch. Expt. Med. 3:1, 1919.

sented the results of some of his researches on nutrition.—Dr. Emerson also addressed the Chicago Pediatric Society, November 18, on the subject of "The Malnourished Child."

INDIANA

**Personal.**—Dr. Richard C. Mackey, Hobart, superintendent of schools, suffered a cerebral hemorrhage, November 2.

**Hospital Site Purchased.**—The county council of Vigo County has approved the plans of the county commissioners for the purchase of the farm of Dr. Joseph Frisz, 8 miles north of Terre Haute, as a site for the county tuberculosis hospital, and has appropriated \$22,275 as the purchase price.

**Mental Hygienists to Meet.**—The annual meeting of the Indiana Society for Mental Hygiene will be held at the Hotel Severin, Indianapolis, December 15, under the presidency of Dr. William L. Bryan of the University of Indiana. At this meeting the urgent needs of the state in the matter of care for its mental defectives will be presented.

**Hospital Items.**—It has been announced that the proposed \$100,000 sanatorium for the disabled and retired Presbyterian ministers of the United States will be located on a site 10 miles east of Evansville, adjoining the Thornton Home for retired ministers.—The Kosciusko county memorial committee reached the decision that a hospital would be a most practicable memorial to the county sailors and soldiers.—Construction work has been started on the new Methodist Hospital, Gary.—The new Bloomington Hospital, erected by the local council of women of the city at a cost of about \$75,000, was open for inspection November 7, 8 and 9, and patients, November 11. The present hospital building is to be used as a home for nurses.

IOWA

**Smallpox Increasing.**—Fourteen cases of smallpox have been reported in Davenport, since November 5. Four of these were in one house.

**Personal.**—Dr. Charles E. Block, Davenport, has been appointed physician of Scott County, succeeding Dr. Sidney G. Hlands, resigned.—Dr. John W. Watzek, Davenport, has been elected treasurer of the Crossett Timber Company.

KANSAS

**Personal.**—Dr. William V. Tucker, Elkhart, representative for Morton County in the legislature, has retired and moved to his farm in Oklahoma.

**Reception to Service Men.** The meeting of the Barton County Medical Society at Great Bend, October 16, was devoted to honoring the ten of the twenty-four practitioners of the county who entered the army and saw active service during the war. The welcome home address was delivered by Dr. Horace C. Embry, Hoisington, and Dr. Elmer E. Morrison, Great Bend, officiated as toastmaster.

LOUISIANA

**Physicians Injured.**—Drs. Adolph Jacobs and David Adiger, New Orleans, formerly house physicians of Charity Hospital, were injured, November 14, when an automobile in which they were riding was overturned on Gentilly Road. The injured physicians were taken to Touro Infirmary.

**Bubonic Plague.**—The outbreak of bubonic plague at New Orleans is said to be under control. Up to date, five cases have occurred with two deaths. The dock board has begun the ratproofing of the river front, and the railroads are undertaking the same work at their terminals. All ships are being fumigated and the fending-off and rat-guard ordinances are being strictly enforced. Since November 1, 3,497 rats have been trapped. Of these, twenty-eight were found to be infected with plague and sixty-four more are under suspicion.

MAINE

**Physicians' Licenses Revoked.**—An official report shows that at its meeting, held November 12 and 13, the Maine State Board of Registration in Medicine revoked the licenses of Drs. Dennis J. O'Brien of Portland and Lemuel F. Noble of Boston on the ground that they had been convicted in the federal court, under the Harrison Narcotic Law, of illegally dispensing drugs.

MARYLAND

**Personal.**—Dr. Elijah J. Russell, Baltimore, has been appointed surgeon to the Baltimore City Fire Department

**Tuberculosis Campaign.**—Tuberculosis caused an economic loss in Baltimore last year of approximately \$3,500,000, according to Mr. A. E. Sinks, executive secretary of the Maryland Tuberculosis Association, who is making a survey of health conditions in the city and state, preliminary to the health campaign by the National Tuberculosis Association.

**Herter Lectures End.**—The final lecture of a series under the Herter Foundation was given at the Johns Hopkins Hospital by Dr. Henry Hallett Dale, director of the department of biochemistry and pharmacology, Medical Research Committee, National Health Insurance, London, England. His first lecture was on "Capillary Poisons and Shock." In the second he discussed "Anaphylaxis," giving the theory of action of drugs in general and the results of personal research. The third lecture was devoted to "Chemical Structure and Physiological Action," in which the results of the most important research work being conducted in England were given.

MISSOURI

**Personal.**—Dr. David F. Morton, Perryville, is ill in a hospital in Rochester, Minn.—Dr. Oliver C. Gebhart, St. Joseph, was elected president of the Visiting Nurse Association of St. Joseph, at the annual meeting, October 27.

**Base Hospital Reunion.**—A reunion banquet of the officers and enlisted personnel of Base Hospital No. 28 was given at the University Club, Kansas City, November 6. About thirty-five were present, and Dr. John F. Binnie officiated as toastmaster.

**Red Cross Appropriation for Clinic.**—The executive committee of the American Red Cross has appropriated \$5,000 to the state board of health for venereal disease control work, with the understanding that a venereal clinic be established in St. Joseph.

**Unlicensed Practitioner Fined.**—Dr. Carl E. Schulte, St. Louis, is said to have pleaded guilty in the St. Clair County Court, October 31, to the charge of practicing medicine in Illinois without a license, and to have been assessed a fine of \$50 and costs.

**Endowment for Pharmacology.**—Authentic reports show that Washington University Medical School has received \$300,000 to endow its department of pharmacology. Half of this sum was given by the general education board and the other half was raised by the medical school.

**Conservation of Vision.**—The bill providing for the compulsory use of a prophylactic in the eyes of the newborn failed of passage at the last session of the legislature, and the Missouri State Association for the Blind has already opened its new campaign looking for the presentation of the bill at the next session.

**Obstetricians Resume Session.**—The first session of the Kansas City Obstetrical Society since the United States entered the war was held, November 4. Dr. Palmer Findley, Omaha, gave an address on "Venereal Control of Women in Detention Homes, in War and Peace," and Dr. Grandison D. Royston, St. Louis, presented a paper on "Complications of Pregnancy and Labor." An informal dinner was given to the speakers at the Kansas City Club.

**Kansas City Veterans of the World War.** Ex-officers of the Medical Corps of the U. S. Army and Navy organized the Kansas City Medical Veterans of the World War, November 3. The object of the association is for the promotion of fellowship, the preparation and recording of history, and the perpetuation of memory of the days of service for the benefit and improvement of the local medical profession. Dr. George E. Bellows was elected president, Dr. John F. Binnie, vice president, and Dr. Ernest G. Mark secretary-treasurer.

NEW YORK

**Personal.**—Dr. Francis F. Fromczak, health commissioner of Buffalo, was elected president of the All Polish Convention, November 10.—Dr. Frank H. Lutton, Alton, has been elected a member of the lower house of the New York legislature.—Dr. George W. Lane was reelected mayor of Corning, November 4.—Mr. H. Bartlett Cleveland, who has been connected with the sanitary engineering department of the New York State Department of Health for fourteen years, has resigned his position as principal assistant engineer to enter consulting and designing engineering practice in New York City.

**Joint Clinics for Mental Diseases and Defects.**—A program for a state wide system of joint clinics, under the

clinics of the State Hospital for Mental Diseases and the State Commission for Mental Defectives, is being worked out. The purpose of these clinics is to provide, in the various communities, facilities for the examination of patients with nervous and mental disorders, and to supply expert advice and suggestion as to treatment. The first of these clinics was opened recently at Watertown, through the cooperation of Dr. William C. Sandy and Dr. Paul G. Madden, superintendent of the St. Lawrence State Hospital, Ogdensburg, and plans are under way for the establishment of two additional clinics, one in cooperation with the Binghamton State Hospital, Binghamton, and the other with the Willard State Hospital, Willard.

**New York State Society Condemns Health Insurance.**—A special meeting of the House of Delegates of the Medical Society of the State of New York was held at Albany, November 22, to consider the report of the Committee on Compulsory Health Insurance. Dr. Harvey R. Gaylord of Buffalo, chairman of the special committee, presented a report, stating that the essential components of all compulsory health insurance schemes are the payment of a cash indemnity during a relatively brief period of incapacity due to illness, and provision for medical, dental and nursing care and attendance, hospital accommodations, maternity care and medicines during illness. The advocates of social insurance make two main assertions, that a large amount of poverty is due to illness causing unemployment and loss of income, and that a large number of people receive inadequate and insufficient medical attendance. The remedy proposed is the establishment of a state administrative machinery to administer a system of compulsory state health insurance. The committee is of the opinion that the belief that a large amount of poverty is due to unemployment caused by illness is based on a *a priori* reasoning, and that the preponderance of evidence is against this assumption. The statistics of the Labor Bureau of New York City show that disability from all causes is responsible for only 5.7 per cent. of unemployment. The committee is unable to find any reliable evidence showing that medical attendance in the state is either deficient in quantity or defective in quality and is not convinced that the proposed plan of compulsory health insurance would benefit or improve the quality of medical services, while the inquisitorial powers proposed for the state industrial commission and the local boards of directors would tend to submerge and nullify the activities of the present state department of health. The committee is of the opinion that the relative morbidity, mortality, infant mortality and maternal mortality rates have been much more materially reduced in the United States in the last twenty years than they have been in those countries in which compulsory health insurance prevailed. The committee, therefore, finds: first, that there is no necessity for social insurance in New York; second, that in those countries where it has been in operation for many years, it has caused a deterioration in the standard of morale and medical service, and that it would have the same effect in New York; third, that in comparison with those countries where social insurance has been in operation, the United States has shown a more marked reduction in both mortality and morbidity; fourth, that there is no need of social insurance, if adopted, gradually undertaken, as an extremely valuable function of the state department of health. In view of the paucity of accurate and reliable vital data, the committee recommends that the Legislature should be requested to appropriate enough money to make a study of the amount and character of illness in the United States and its economic relation to the community. It is recommended that if additional legislation is to be considered, it should provide for a greater development of the present county health departments and the wider utilization of the present hospital facilities for the diagnosis and treatment of diseases. The committee, therefore, recommends that the House of Delegates and the Medical Society of the State of New York should formally oppose the enactment of any law instituting a system of compulsory health insurance against illness. Dr. S. S. Galvater presented a minority report consisting of twenty-one resolutions which would be observed in any social insurance legislation. The majority report of the committee was unanimously adopted.

#### New York City

**Personal.** Dr. Russell Pemberton sailed for Washington, October 9, as ship's physician and observation officer of the magnetism ship *Carnegie* for a cruise in the South

Atlantic and Indian oceans.—Dr. Thomas F. Reilly has been appointed visiting physician to St. Vincent's Hospital.

**Hygiene and Preventive Medicine Department Organized.**—The organization of the new department of hygiene and preventive medicine at Cornell University has been completed, and the following appointments to the staff have been made: Dr. Haven Emerson, professor of hygiene and preventive medicine, and director of the department; Dr. James Stevenson Allen, Geneva, assistant professor of hygiene and preventive medicine and assistant director of the department, and Dr. Frank C. Balderrey, medical advisor.

**School for Crippled Children.**—The Free Industrial School for Crippled Children, 471 West Fifty-Seventh Street, has opened its fall term with a full attendance. This school embraces the Lulu Thorley Lyons Home for Crippled and Delicate Children, Claverack, N. Y., where the children spend the summer after the close of the school year. The children taken by this school are not eligible for public school life as they are not physically able to attend, but here are enabled to pursue the same course of studies. A special study is made of the case of each child who receives such medical and surgical attention as is required. The school provides hot lunches, autobus transportation, and clothing when necessary for the children. The joint societies celebrated their twentieth anniversary by beginning a drive for \$100,000 for their permanent fund.

#### OHIO

**Banquet to Service Men.**—The Medical Society of Logan County made the chief feature of its annual dinner at Bellefontaine, November 7, a welcome to the members of the society who had been in active service during the world war. Dr. Robert H. Butler, Bellefontaine, acted as toastmaster.

**Personal.**—Dr. John R. Pipes has been elected mayor of Avon.—Dr. Robert Longfellow, Toledo, has been elected dean of the staff of the Ohio Soldiers' and Sailors' Home, Xenia, succeeding Dr. Charles J. Shepard, Columbus.—Dr. John C. Larkin has been made a member of the volunteer visiting and consulting staff of the home.

**University of Cincinnati Notes.**—At the meeting of the board of directors of the University of Cincinnati, October 14, a donation of \$5,000 for a scholarship in the college of medicine, by Mrs. Isaac A. Wyler, was announced. This scholarship is given in memory of her son, Dr. Jesse S. Wyler, Cincinnati, who died from influenza during the epidemic last year.—Dr. John C. Oliver was appointed acting dean of the medical college during the illness of Dr. Christian R. Holmes, both of Cincinnati.—Dr. Clarence W. Betzner, Cincinnati, was appointed attending orthopedist to the Cincinnati General Hospital.

#### OKLAHOMA

**Laboratory for Medical Society.**—At the recent meeting of the Washington County Medical Society it was decided to purchase equipment at a cost of \$1,000, and to establish a bacteriologic laboratory for the use of the physicians of Bartlesville.

**Clinic Organized.**—The Oklahoma City Clinic has been organized by Drs. Abraham L. Blesh, William W. Rucks, John Z. Mraz, David D. Paulus, Marvin E. Stout, and others. The clinic has purchased Wesley Hospital which has a capacity of sixty-five beds.

**University Hospital Dedicated.**—Thursday, November 13, the regents and faculties of the University of Oklahoma held special exercises dedicating the new State University Hospital which has just been completed in Oklahoma City. The hospital contains 175 beds, including twenty-five in private rooms. The building cost approximately \$200,000, and the equipment, \$76,000. Approximately \$200,000 per year will be required for maintenance. The dedicatory address was given by Dr. Jabez N. Jackson of Kansas City, Mo.

**Tablet to Staff Members Unveiled.**—In memory of Major Robert Lord Hull and Frank Bruner Sorgatz, both of whom died in military service during the influenza epidemic, the sisters of St. Francis and St. Anthony's hospitals, Oklahoma City, erected a bronze tablet which was unveiled at a memorial service. Dr. Robert M. Howard presided. Dr. John W. Riley spoke of the life and work of Dr. Sorgatz, and Drs. Arthur B. Chase and George A. LaMotte, spoke on Dr. Hull. The tablet was unveiled by Dr. H. Coulter Todd.

## PENNSYLVANIA

**Personal.**—Dr. Theodore L. Hazlett, Pittsburgh, has been appointed medical director of the Mont Alto Sanatorium, succeeding Dr. Frederick C. Johnson, Mont Alto, who has been on leave on account of illness.

**Schools Teach Diet.**—Classes in "eating" will shortly be established in three schools and include a course of study for both parents and pupils in the causes of malnutrition. There will be nurses in charge of each school and a dietitian. Intensive health work along this plan is to be conducted at the Campbell School, Eighth and Fitzwater streets, the Hawthorne School, Twelfth and Fitzwater streets, and the Meredith School, Fifth Street above Fitzwater. Each of these schools will be equipped with scales and other special apparatus necessary for the work. The weight of the children will be recorded, and a health card filled out for them. Under the new plan of health education, which it is hoped eventually to extend to other schools, a pupil's health card will follow him through all his public school career. Malnutrition, the school medical inspectors state, is not due entirely to poverty. Causes which contribute are improperly prepared food, too much candy and eating between meals.

## Philadelphia

**Personal.**—Dr. Charles Lincoln Furbush, sanitation expert, was decorated with the order of Companion of St. Michael and St. George by the Prince of Wales, November 22.—Dr. Howard S. Anders sustained a fractured rib, when a trolley in which he was riding collided with another car.

**War Physicians Dinner Guests.**—Sixty physicians who served in the army or navy during the world war were the guests of honor at a reunion dinner given by the Homeopathic Medical Society at Philadelphia at the Adelpia Hotel, attended by 160 physicians. Dr. Gilbert J. Phalen was toastmaster.

**Graduate School of Medicine Opens.**—The Graduate School of Medicine of the University of Pennsylvania opened in October, and according to George H. Meeker, dean of the University of Pennsylvania, there are sixty-three physicians in actual attendance, about thirty have been turned away because of the present limited accommodations, and nearly fifty are already applicants for the courses of the next semester, which begins Feb. 9, 1920. The general plan for the University Graduate School of Medicine is as follows: A central university organization as now or to be constituted, having as its special business graduate medical education. The cooperation of other university groups, especially the Undergraduate School of Medicine. The cooperation of the hospitals of Philadelphia generally, not as integral parts of the university, but affiliated through their staffs and clinical and physical facilities, in this important movement for Philadelphia, under the educational control of the university. This general hospital cooperation is still in its beginnings. The cooperation of public and private philanthropies, in contributing toward the large funds without which the goal will be difficult or impossible to reach. In 1916, a merger between the University of Pennsylvania and the Medico-Chirurgical College of Philadelphia was effected. By the conditions of this merger the Medico-Chirurgical College became an integral part of the University of Pennsylvania as its Graduate School of Medicine and the heads of the clinical departments were constituted a nucleus for the faculty of the new school. By merger with the university in 1918 the Philadelphia Polyclinic and College for Graduates in Medicine, with its facilities for graduate medical instruction, was further added as the "Polyclinic Section" of the Graduate School of Medicine constituted as above. On this foundation, and with some valuable assistance from the Undergraduate School of Medicine and a few of the hospitals of Philadelphia, the work of the new school has been started.

## SOUTH CAROLINA

**Hospital Items.**—The Darling Hospital Association has been incorporated at Darlington, with a capital stock of \$100,000.—The Ferguson Private Sanatorium, Gaffney, was opened for the reception of surgical cases, October 1.

**Fire at Camp Hospital.**—The total loss caused by the fire which destroyed the officers' quarters at the United States Public Health Service Hospital, Camp Sevier, Greenville, is estimated at about \$10,000. There were about 750 patients at the hospital at the time of the fire, forty officers, more than 100 women, nurses, aides and stenographers, and about 150 civilian employees.

**Personal.**—The charge of manslaughter brought by William M. Graydon, a lawyer, against Dr. Julius H. Taylor, Columbia, on account of the death of Graydon's son, following an operation, was dismissed in court, October 30.—Dr. Carl A. West, Columbia, has been appointed health officer for Lexington County, succeeding Dr. Boldridge E. Kneecr.—Dr. William D. Simpson, Abbeville, has resigned as a member of the state board of charities and corrections.

**Public Health Work.**—Dr. G. E. Neal of the state health department, who established a clinic in Newberry, has gone to Anderson to establish a similar clinic there. In connection with this work a state advisory board will be established consisting of one member of the state board of health, one member of the federal board of health, one member to be recommended by the legislative delegation, and one by the city council, either mayor or chairman of the city board of health.—The United States Public Health Service is sending an investigator to look into the conditions in Newberry County with regard to trachoma. At St. Luke's School there are said to be five cases of trachoma, at Monticello School, five, and at Saluda, three cases.

## WASHINGTON

**Red Cross Clinic Opened.**—The junior Red Cross Clinic was opened in the Horace Mann School, Spokane, during the week of November 14. Drs. Oliver T. Batcheller, Ronald A. Greene, Elmer E. Langley, Carroll L. Smith and Fred G. Sprawl were in charge of the eye, ear, nose and throat clinics, and Drs. Earl H. Current and Peter D. McCornack in charge of the medical clinic.

**Personal.**—Dr. William L. Hall, Spokane, recently returned after years of service as a medical missionary at Szechwan, China.—Dr. Thomas C. Barnhart, Spokane, has succeeded Dr. Albert E. Stult as physician of Spokane County.—Dr. William O. Wisner has been appointed assistant to Dr. Thomas C. Barnhart.—Dr. Frank S. Miller, Spokane, has been elected medical director of the Edgecliff Sanatorium.

## WISCONSIN

**Increase in Smallpox.**—Up to November 12, 133 cases of smallpox have been reported in the state. The so-called normal for Wisconsin for November is 113, but if the high record is maintained, the high mark of 196 reported in 1914, will be exceeded. The state board of health gives its usual warning regarding vaccination.

**New Officers.**—At the annual meeting of the Wisconsin Anti-Tuberculosis Association, October 30, the following officers were elected: president, Dr. John W. Coon, Stevens Point; vice presidents, Dr. John R. Curries, Two River, and Mrs. Ben Hooper, Oshkosh; secretary, Dr. J. Gunney Taylor, Milwaukee and treasurer, John H. Kromer, Milwaukee.—At the annual meeting of the Milwaukee Physicians' Association, Dr. Arthur R. F. Galt, was elected president; Dr. Edward M. Rice, vice president, and Dr. H. P. Seckert, secretary-treasurer.—At the annual meeting of Wisconsin Women's Medical Society, held in Milwaukee, October 1, Dr. Belle P. Nair Wimbago, was elected president; Dr. Ada B. Chandler, Pardeeville, vice president, and Dr. Bertha A. Thomsen, Oshkosh, secretary-treasurer.—The Wisconsin Branch of the Medical Veterans of the World War was organized October 1, at Milwaukee. Dr. H. M. Chester Brown, Milwaukee, was elected president, Dr. L. Reek Steverson, Wausau, secretary-treasurer, and Drs. John M. Dodd, Elkhart, Gilbert E. Swann, Milwaukee, and James R. Langley, Fond du Lac, a committee to complete the organization.

## CANADA

**University Buildings Burn.**—The main buildings of the University of Montreal better known as Laval University, including the medical department, were destroyed by fire November 22. The loss is estimated at \$400,000, which is said to be covered by insurance.

**Saskatchewan University News.** Several weeks ago the University of Saskatchewan was closed, pending an investigation into the affairs of that institution. Four university professors were dismissed, and now an investigation is being held with the Chancellor, Sir Frederick H. Brown, in the chair. Dr. A. McKay, one of the dismissed professors, proposes that a controller be appointed, which would leave the president free to direct the more important policies of the institution.

**Personal.**—E. L. Brinkhwaite, M.B., Ph.D., late professor of the Western University, London, Ont., has been appointed

national organizer of the Inter-Church Forward Movement. — Dr. George R. Pirie, some time on the staff of the Hospital for Sick Children, Great Ormond Street, London, England, has returned to Toronto and commenced practice in diseases of infants and children. — Dr. Frank S. Park, Toronto, has gone to England to report on conditions regarding the emigration of children to Canada.

**Smallpox Situation in Toronto.**—Smallpox still continues to spread in Toronto, although the daily incidence of cases has not been so marked during the past week. The total has now risen to 518 cases and the number of persons quarantined something like 1,500. The antis held a mass meeting the other evening, but were only able to muster some 400 citizens. Altogether there have been more than 100,000 vaccinations. Col. J. W. S. McCullough, Toronto, provincial medical officer of health, has stated that of the 600,000 vaccinations in the Canadian army, there were recorded no untoward results. The Ontario law makes vaccination compulsory.

**Hospital News.**—During the war period there was a large falling off of promised subscriptions to the Toronto General Hospital, and now the trustees find themselves faced by a serious situation. There are three interests involved in that institution, namely, the city of Toronto, the University of Toronto, and private benefactors. In order to clear the hospital of an indebtedness of over \$600,000, the trustees are asking that the city and university each put up \$125,000, and then the trustees will engage to secure \$500,000 from among themselves and by private subscription. It has been said that the hospital, having secured business management, has recently been running without any deficit on maintenance account.

#### GENERAL

**Southern Gastro-Enterologists Elect Officers.**—At the annual meeting of the Southern Gastro-Enterological Association, held in Asheville, N. C., November 10, Dr. Sidney K. Simon, New Orleans, was elected president; Dr. George M. Niles, Atlanta, Ga., vice president, and Dr. Marvin H. Smith, Jacksonville, Fla., was reelected secretary-treasurer.

**New Officers for Railway Surgeons' Association.**—At the annual meeting of the Surgeons' Association of the Western Division of the Southern Railway, held in Louisville, Ky., October 23, Dr. John F. Weathers, New Albany, Ind., was elected president, and Dr. Fred R. Gobbel, English, Ind., secretary-treasurer. The meeting for 1920 will be held in West Baden, Ind.

**Meeting of Southern Medical Association.**—The thirteenth annual meeting of the Southern Medical Association was held in Asheville, N. C., November 10 to 13, under the presidency of Dr. Lewellys F. Barker, Baltimore, Louisville, Ky., was selected as the place of meeting for 1920, and the following officers were elected: president, Dr. Edward H. Cary, Dallas, Texas, and vice presidents, Drs. Henry H. Bridges, Asheville, N. C., and Alired L. Gray, Richmond, Va. The association approved the recommendation of the Southern States Association of Railway Surgeons that the general association take up with the government of the sixteen southern states, the matter of securing specific legislation to prevent grade-crossing accidents.

**Sale of Ambulances.**—The director of sales announces that the Surplus Property Division, Office of the Quartermaster-General of the Army, is offering for sale to specified welfare organizations and charitable institutions, 100 new G. M. C. ambulances, located at Jeffersonville, Ind. These ambulances are to be sold at government cost. This offer to charitable institutions will be effective until Dec. 20, 1919. The following organizations may take advantage of this offer: The Boy Scouts, the Girl Scouts, Camp Fire Scouts, Navy Scouts, and other societies doing war camp community service only, the Y. M. C. A., the Y. W. C. A., the Y. M. H. A., the Knights of Columbus, the Red Cross, Salvation Army, charitable institutions which shall have been vouched for by their local chambers of commerce, public hospitals which are not operated for private or corporate gain, R. O. T. C. schools, provided the schools use the equipment purchased for military purposes, the committee on special war activities of the National Catholic War Council, educational institutions which are not self-sustaining but are dependent on voluntary subscription or government assistance, municipalities and states of the United States, and the hospitals, insane asylums and other institutions having need for ambulances which are operated by the cities and states.

#### FOREIGN

**Typhus in Siberia.**—Newspaper advices from Omsk say, since January 1, of this year, there have been 120,000 cases of typhus fever in Siberian troops, and that new cases are being reported at the rate of 1,000 daily.

**Nobel Prizes to Germans.**—The Nobel Prize for Physics for 1918 has been awarded to Prof. Max Planck of Berlin, and that for 1919, to Professor Stark of Greifswald, Germany. — The Nobel Prize for Chemistry for 1918 has been awarded to Prof. Fritz Harber of Berlin.

**Death Losses of Armenian Physicians.**—Since the opening of the world war, 67 Armenian physicians are said to have been killed, and 52 died from typhus; of Armenian pharmacists, 54 were killed, and 18 died from typhus; of Armenian dentists, 10 were killed, and 4 died from typhus, and 15 medical students were also said to have been killed.

**Charges Against Turkish Physicians.**—In a pamphlet entitled "Persecution Directed Against Armenian Doctors in Turkey During the World War," published by the union of Armenian physicians at Constantinople, it is charged that Turkish physicians not only plotted against the lives of the Armenian population, but directed a special campaign against their Armenian colleagues. These charges are said to be substantiated by the testimony of prominent Turkish physicians. Some of the criminals have fled from the country and others are now awaiting trial.

**Red Cross Home Opened.**—The American Red Cross Maternity Home Hospital, at Coatbridge, Scotland, established through a gift of \$10,000 from the American Red Cross, was dedicated with impressive ceremonies under the auspices of the Town Councils of Coatbridge and Airdrie, recently. This is one of the five similar institutions founded in Great Britain. These institutions are devoted to helping the mothers and children of England and Scotland, where the infant death rate has been appalling, due largely to housing conditions which have made it impossible for mothers to give proper care to their children.

**American Red Cross Activities.**—During the first ten days of September, 269 men, sick and wounded soldiers, went through the American Red Cross at Irkutsk, Siberia, in order to be transported to local hospitals from the station. Besides this, three sanitary cars have been fully equipped by the American Red Cross, under the supervision of Dr. Charles S. Brady. From September 10 to October 1, 905 ambulatory and ninety stationary patients were treated at the dressing station. The total number of typhus patients was 804, and there were also 460 sick with different diseases, making a total of 1,264. Those in need were equipped by the American Red Cross with warm underwear, shoes and clothing.

#### LATIN AMERICA

**Plague in Paraguay.**—In connection with the appearance of bubonic plague in Paraguay, the department of public health has just announced that several new cases have developed, including one in the capital itself, Asunción. The department announces that all sanitary measures have been taken to prevent the spread of the disease.

**New Sanitary Code of São Paulo.**—The state of São Paulo, Brazil, has just adopted a new sanitary code which is considered the best, and in fact the first of its kind ever adopted in Latin America. The code is the compilation of all previous sanitary legislation with the modifications that seemed necessary to bring it up to date. The man in charge of its preparation was Dr. Arturo Neiva, one of the most prominent physicians of Brazil.

**Sanitary Commissions at El Salvador.**—The consul-general of El Salvador announces that the government of that country has decided to appoint a number of scientific commissions for the purpose of conducting campaigns against the various diseases that affect that country. The first commission appointed is for the prevention of yellow fever and sufficient funds will be provided to conduct an antimosquito campaign throughout the country. The government has also decided to establish several quarantine stations provided with the necessary facilities for the disinfection of ships and the consul-general is now making inquiries in this country in regard to the necessary apparatus.

#### CORRECTIONS

**Mercurochrome-220.**—In the article by Young, Swartz and White in THE JOURNAL of November 15, the foot note at the end of the article states that "Mercurochrome-220" is being used in 25 per cent. solution in the urethra. Dr. White

informs us this should read "25 per cent." which is the strongest solution used.

**Officers of American Public Health Association.**—The announcement of the new officers of the American Public Health Association, which was published in THE JOURNAL, November 8, contained certain inaccuracies. The corrected list of officers is as follows: president, Dr. Watson S. Rankin, Raleigh, N. C.; vice presidents, Dr. Alexander J. Douglas, Winnipeg, Man.; Samuel L. Jepson, Charleston, W. Va, and William H. Robin, New Orleans; secretary, A. W. Hedrick, C.P.H., Boston, and treasurer, Dr. Guilford H. Sumner, Des Moines, Iowa.

## Government Services

### Personnel of the Medical Corps

For the week ending November 21, the Medical Corps of the Army contained 2,318 officers from a maximum of 30,591 on duty Nov. 15, 1918. The medical reserve corps contained 3,858, an increase of sixty-nine from the previous week.

### Contract Surgeons Entitled to Discharge Button

The general staff of the army has decided that all contract surgeons serving during the recent war are entitled to the discharge button, and also to the Victory Medal. They may be obtained from any recruiting station or from the Depot Quartermaster, Washington, D. C.

### MEDICAL OFFICERS, U. S. NAVY, RELIEVED FROM ACTIVE DUTY

long as possible in order to furnish the necessary leverage. In the arm a stump 15 cm. in length below the acromion is necessary. At the time of amputation such matters should be carefully considered, and, if need be, it is better to leave less of covering than to cut the bone too short. If the amputation must absolutely be done higher up, the question is in order whether disarticulation would not be more suitable. In the lower third of the arm the supracondylar amputation is excellent, as it furnishes good bearing for the appliance and frequently does away with the necessity of suspension from the shoulder. Disarticulation of the elbow-joint is bad, as the stump is too long and it is more difficult to provide the proper covering. Furthermore the stump does not furnish a good bearing for prosthetic apparatus.

The separate movements of the forearm—flexion, pronation and supination—must be considered. In order that the appliance may have proper flexion, a stump 9 cm. in length from the joint-line is required, or, if the elbow is considered as being flexed at an angle of 90 degrees, 4 cm. below the insertion of the tendon of the biceps will suffice. A stump shorter than this does not give proper flexion, but it may nevertheless be useful as the support of prosthetic apparatus. Pronation is an important matter for consideration, as it is the source of the prehensile movements to be performed with the artificial appliance. Theoretically, if amputation below the insertion of the pronator teres has been made, pronation is preserved, but from a practical standpoint amputation must be performed below the junction of the middle and lower third in order to assure effective pronation. Amputation in the lower third of the forearm is much to be preferred to disarticulation at the wrist-joint, for this is often associated with radio-ulnar arthritis, which inhibits the movements of pronation, and then again, it leaves too long a stump.

In case of the lower limbs, the main consideration is to amputate at a site that will give good support. The bearing may be directly on the end of the stump, or it may be indirect. The American prosthetic apparatus, which can be readily adapted to any stump, gives good results with indirect support. However, direct support has some advantages; namely, no waste of strength and the feeling of ground support, which is more easily obtained if the leverage is secured nearer the ground. The Germans attach great importance to this feeling of ground support.

Amputations in the middle third of the thigh give excellent results; in fact, this is the most favorable site. It gives a leverage quite sufficient for the operation of an artificial limb. If the stump is too long, a pendulum-like movement is set up, which causes ulceration through chafing; the thigh socket is also unduly large, and it is more difficult to adjust the artificial knee-joint. With the exception of a few rare cases, all used the indirect support. In the upper third of the thigh, from 6 to 8 cm. below the trochanter should be preserved, for as long a fragment of bone as possible is left in order to be able to attach properly the prosthetic apparatus. In the lower third of the thigh it is rarely possible to secure direct support, as the stump would thus become too long.

In the lower leg we must relinquish the amputation that has heretofore been regarded as the amputation of choice, which was adopted because the end of the stump was expected to bear all the weight of the artificial leg, for it is no longer expected to do so. Amputation at the middle third of the leg is the most favorable site. In order to furnish leverage to swing the artificial leg, a stump 10 cm. in length from the joint-line is required, or, if the knee, flexed at a right angle, is taken as a basis of measurement, 6 cm. below the insertion of the tendons of the semitendinosus and the semimembranosus will suffice.

In the case of the foot, the total amputation by Sayre's procedure is unanimously regarded as excellent, for it gives a firm stump with good covering and causes no after-pain if the malleoli have been properly removed. The articular end of the tibia is preserved as this permits the use of an appliance without a socket.

In the discussion of the partial amputations of the foot there was a divergence of opinion. In regard to the amputation of anterior portions of the foot there is common agreement: removal of all the toes en masse, the lateral operation, with or without the chevron line, is a good operation if the flap is large enough to allow bringing the scar on the back of the foot. In the posterior portions of the foot the results are less satisfactory. The latter procedure is prevalent that after the necessary repairs would not be agreed to. Broca remarked that the value of amputation

Foreign Correspondence

PARIS

Nov. 6, 1919.

Meeting of Orthopedists

Owing to the important place that orthopedics has come to occupy during recent years, orthopedic surgeons were beginning to feel themselves somewhat restricted at the meetings of the Société française de chirurgie, at which only one session devoted to orthopedic surgery was accorded them. Following the example, therefore, of the urologists, they conceived the plan of founding a separate society, to hold its annual meeting concurrently with the congress of surgeons. The subject was first brought up in 1904, and, owing to the stimulus that the war has given to orthopedic surgery and to prosthesis, the plan has at last been realized. In 1918 the Société française d'orthopédie was founded, and it already counts among its membership a large number of French orthopedists and a considerable representation of foreign associates. October 10, this new society held its first meeting, under the chairmanship of Dr. Kirmisson, surgeon of the Hôpital de Paris and professor of clinical pediatric surgery on the Faculty of Medicine.

Amputations in Relation to Prosthesis

In his communication on the subject of amputations in relation to prosthesis, Dr. Nové-Josseland, surgeon of the Hôpital de Lyon and agrégé professor of the Faculty of Medicine of Lyons, emphasized the fact, for which the experience of the war furnished abundant evidence, that it is not sufficient, when we perform an amputation, to concern ourselves solely with the shape of the stump, but that the character of the service to be rendered and the kind of work to be done by the subject must also be considered. As for the upper limbs, the prosthetic appliances render little service in the liberal professions, for very few persons wear their appliances. In the case of workmen, however, especially agricultural workers, the movements that they perform and the tools that they use being simple, appliances are found to give good results if the stumps are left long and motile. It is desirable that the stumps should be as

tions could not be judged by the results secured during the war. The exigencies of the case governed our actions, frequently. It was often necessary for physicians to impersonate surgeons. The relative skill of the operator must be considered, as well as the character of the operation. Krimsson remarked that we should not be too ready to form conclusions from the results of the war, for here operations were often performed on feet that had been supporting for a long time, with neuritis and deep scars sometimes present. It would be inconsistent to compare, from the standpoint of prosthetic appliances, the results in such cases with those secured under normal conditions.

#### Surgical Congress

At the twenty-eighth congress of French surgeons, a partial report of which was given last week, two of the subjects discussed were: the surgical treatment of cancer of the tongue, and paranephric tumors.

##### SURGICAL TREATMENT OF CANCER OF THE TONGUE

In his communication, Dr. Pierre Sebileau, professor of clinical otorhinolaryngology at the Faculty of Medicine of Paris, emphasized particularly the necessity of the extirpation of cancer as soon as it appeared. Unfortunately, it rarely happens that surgeons have an opportunity of seeing a cancer of the tongue in its initial stage. This is partly owing to the patient's indifference, since the cancer develops from an old leukoplakia that has been for a long period benign, and is partly ascribable to the fact that the physician frequently fails to recognize the syphilitic origin of the leukoplakia. Sebileau holds that the only proper treatment consists in surgical extirpation. Electrocoagulation and the use of physical remedial agents in general have failed utterly. Radium of itself is incapable of causing a cancer to disappear, and can only be regarded as exerting a supplementary action. As regards the limitations of operability, Sebileau regards the following conditions as contraindications: (1) extension of the cancerous growth to the glosso-epiglottic sulcus and to the epiglottis; (2) invasion of the faucial pillars and of the tonsils; (3) profound infiltration of the mandible; (4) involvement of the two lateral halves of the tongue at the base, and (5) glandular hyperemia of the diffuse, inflammatory type. Before answering the question whether cancer of the tongue is curable or not, we would call attention to the fact that in speaking of cancer it is always hazardous to talk of a cure. It is estimated that 40 per cent. of cancer patients operated on early survive beyond the three-year period. In old cancers and in those operated on by parietal or mandibular route, the percentage of recoveries is much smaller. However, even under these conditions some do recover, and though the number be small it is the duty of the surgeon to persevere in this line of surgery, notwithstanding the fact that it is, as Sebileau admits, full of disappointments.

Dr. Vallas, agrégé professor at the Faculty of Medicine of Lyons, considers the surgical as the only method that has accomplished definite cures. In the opinion of Vallas, it is impossible to say as yet whether radiotherapy should be classed among the palliative or among the curative methods.

Dr. Abouker of Algiers expressed his opinion to the effect that general anesthesia is the most serious factor in connection with operations for lingual cancer. According to his view, local anesthesia can and must suffice in all cases. In a series of eighteen pharyngectomies for cancer performed under chloroform, the mortality was deplorably high, namely, 55 per cent., whereas in another series of ten pharyngectomies under local anesthesia, no deaths resulted. Another uses the Reclus solution, which consists of proparal, 1.20, with a drop of epiuphrin added to each cubic centimeter. From 30 to 40 c.c. are sufficient for the longest operations. It is well to color this solution with methylene blue in order to indicate to the eye the extent of the anesthetized area. If properly used, this method of local anesthesia permits operations in the cases of numerous cachectic, varicose, and diabetic patients who would not be able to withstand chloroform narcosis.

Dr. E. F. Jéze, professor of clinical surgery at the Faculty of Medicine of Montpellier, called the attention of the congress to a recent method, recommended by Delmas of Montpellier, which may prove to have merit: the method of general rachianesthesia, in which it is necessary, to use highly purified cocaine, which is injected brusquely in small doses into the spinal column, being first mixed with cerebrospinal fluid (a considerable quantity of which, from 30 to 50 c.c., has previously been withdrawn), not stopping until the patient complains of a severe headache.

#### PARANEPHRIC TUMORS

Paranephric tumors are retroperitoneal tumors that present intimate anatomic relations with the kidney, which remains otherwise intact, and that appear to have developed either at the expense of the capsule or of the perirenal fat. The communication of Dr. Paul Lecécne, surgeon of the Hôpital de Paris and agrégé professor at the Faculty of Medicine, is based on 113 authentic observations, ninety-six of which were operative cases and seventeen were necropsy reports. These tumors are found indiscriminately on the right and on the left side, and at every age, but predominantly in the fifth decade. They are also relatively frequent in young subjects, and they appear to affect more particularly the feminine sex (70 per cent. is the proportion). Their functional symptomatology is almost negative. Their evolution is slow, insidious and almost always entirely painless. There are few or no signs of compression, except in the advanced stages, during which there is a decline in general health, and at times short febrile attacks appear. Only the physical examination reveals the true state of affairs. The tumor is most frequently paramesial and appears as a multilobar mass—flabby, fibrous or pseudofluctuant, but never seeming to slip out from under the palpating finger, as is the case with cysts. Although generally only slightly movable, it always presents lumbar contact and even *ballotement* if its volume is not too great. On percussion the tumor sounds flat, with or without a resonant note in the anterior portion.

From a diagnostic standpoint it is important to determine the anatomic seat of the tumor and the functional activity of the kidneys. As regards the anatomic seat, careful percussion, dermatographic tracings, and, especially, the location of the tympanic note of the overlying colon (for which it will be well to have recourse to insufflation) will permit one to locate, at first approximately and finally more precisely, the retroperitoneal seat of the neoplasm. As for the testing of the functional activity of both kidneys, this is very important, not only from a diagnostic standpoint, but also as regards surgical interference, for it goes without saying that one will frequently be compelled to sacrifice the kidney. In the absence of operative intervention the evolution of the tumor proves fatal sooner or later. The tumor grows steadily larger, and death supervenes from cachexia or from concomitant complications (uremia, pneumonia, phlebitis, etc.).

From the standpoint of operative technic, transperitoneal laparotomy is preferable to the ilioabdominal or the extraperitoneal route, the latter being too obscure or too narrow to permit the enucleation of large tumors. Once the tumor has been enucleated, preferably by progressive delobulation, it is well to establish lumbar drainage. This procedure is much to be preferred to marsupialization, which necessitates delayed closure of the wound and causes a weakening of the walls.

The operation is a serious one (the mortality running about 40 per cent.), especially if the tumor is large and the patient is much weakened. As for the end-results, they are difficult to evaluate, as only one patient has survived long enough to permit a definite judgment (six years without recurrence).

#### BUENOS AIRES

Oct. 11, 1919.

##### Bubonic Plague

The appearance of several foci of plague in some places of the provinces of Santa Fé, Santiago del Estero, and Tucumán y Córdoba, compelled the national department of hygiene to carry out a campaign of prevention and treatment. As the authorities realize the existence of sporadic foci in different places of the country, the chief source of which are the rodents of the port of Buenos Aires, they have decided to solve definitely this matter by ordering the compulsory eradication of rats throughout the country and the careful deratization of all ships coming from abroad.

##### Appointment of Professors

The unexpected and troublesome interference that some groups of students are trying to exert in the appointment of professors reached its climax lately. A committee appointed by the students' association called on the president of the republic to ask him to appoint the candidate favored by them. The president stated that while the law permitted him to select any of the three persons whose names appeared on the list submitted by the faculty, he nevertheless wished to respect the autonomy of the universities, and therefore would select the first candidate on the list.

### University Discipline

The present university ordinance which provides that the board of directors of the faculties be elected by an assembly, composed in equal numbers of professors, assistant professors and students, has worked very poorly. These elections are now practically controlled by the students, who vote only one ticket, while the professors scatter their votes. On the other hand, there are always some professors who ask the students to vote for them or to have their names placed in the students' tickets. In order to obtain this they are compelled to make such concessions that the school discipline and the examinations suffer from it. In addition, this system creates antagonism between students and professors; and when the former do not win an election, as happens quite often, they incite disturbances, as those that took place last year in the school of medicine and in the law school lately. What makes matters worse is that the students do not know the history and qualifications of the candidates, and therefore they allow themselves to be manipulated and show very little discrimination, guiding themselves largely by the leniency shown by the professors in the examinations. Unless this system is changed, university discipline in this country is going to be seriously affected. Probably the only immediate solution is to permit the students to elect a candidate every year and have the others appointed by the professors.

### LONDON

Nov. 5, 1919.

#### Prevention of Tuberculosis

After an interval of several years, due to the war, the National Association for the Prevention of Tuberculosis has resumed its annual conference. A number of distinguished foreign physicians, including Dr. Linsly Williams, Prof. William C. White, Dr. David Lyman and Dr. C. J. Hatfield, of the United States, were present. Dr. Addison, minister of health, delivered an address. He said that the war had added, from the ranks of those who had served with the forces, to the number of tuberculosis patients. In consequence of the necessary suspension of many of our activities, the absence of many skilled men from the tuberculosis service in the ranks of the army medical corps, and the entrance of a large number of women into industrial service, there had been an increase in tuberculosis in some directions, notably among women. It was one of the functions of the ministry of health to try to secure that its efforts to deal with these great problems were not disjointed and fragmentary. As he had so often said, we had suffered in this country a great deal from failing to have a considered body of policy, and this applied with singular aptness to tuberculosis. We were likely to deal with these matters piecemeal—sometimes necessarily so. Unless a big program of rehousing and the clearance of slums should be carried out, combative efforts would be largely in vain. That was why the first action of the ministry of health was to promote the housing act. The millions of money now being spent in our manifold health services were largely wasted, because we had never had the foresight and the courage to tackle the capital expenditure necessary to remove the causes of disease. Education and enlightenment he placed only second in importance to housing. As long as we had millions of people who never opened their bedroom windows, the efforts of health workers would be largely stultified. The information for the public which he had in mind need not be of a highly professional kind, couched in technical phraseology. It needed to be sound knowledge and good common sense. Housing and the spread of information naturally went hand-in-hand with research. The war had shown that a good deal of the expenditure of sanatoriums might be fruitless unless the arrangements were supplemented by others. In many cases it was of no use to send a man to a sanatorium if, on emerging, he returned to an insanitary home. Again, the monotony and dreariness of long life in a sanatorium was a human factor of great importance. Many men who had been in sanatoriums ought never to return to their former occupations. Arrangements for industrial training, linked to the sanatorium system, were necessary. The ministry of health, in conjunction with the ministry of pensions, was arranging for the provision of 1,000 training places in connection with sanatoriums. They will have to be linked up with village settlement centers. Any attempt to have a sort of tuberculosis colony was doomed to failure, for sufferers from tuberculosis wanted to live among their fellow citizens and not to be marked out. He would not be a party to branding the tuberculous person as a leper. Facilities for

early diagnosis and consultation for early cases was one of the most important works laid before them.

#### The Annual Meeting of the British Medical Association

The next annual meeting of the British Medical Association will be held in the University of Cambridge at the end of June under the presidency of Sir Clifford Allbutt. It was intended to hold the 1915 meeting at Cambridge under his presidency, but the war intervened and he has remained president of the association ever since. During the war no scientific meeting took place until that of last year, which was held in London much earlier than usual, in order to enable the medical officers of the dominions and the United States who were still in Europe to take part. The coming meeting will be held a month earlier than usual, in order to coincide with the time when the university buildings will be vacant. The number of sectional meetings will be considerably reduced. There will be four principal sections, namely, medicine, surgery, physiology and pharmacology, and neurology and psychiatry, each of which will meet on three days. But the other sections, namely, pathology and bacteriology, obstetrics and gynecology, tropical medicine, naval and military medicine, radiology and electrotherapeutics, venereal disease, medical sociology, and medical education, will meet only on one day. This reduction of the sectional meetings seems to have been due to the success of the last meeting when, owing to the influence of the war, most of the special sections were omitted and greater prominence given to demonstrations. It is intended to make the Cambridge meeting as objective as possible by numerous afternoon demonstrations for which the splendid laboratories of the university are well suited.

#### Industrial Hygiene

The new ministry of health is about to devote great attention to industrial hygiene, which the experience of the war has shown to be an important part of preventive medicine. In this country there are 130,000 workshops and 150,000 factories, in which 12,000,000 people spend a third of their lives. Sir George Newman, chief medical officer of the ministry, proposes to deal with the following points: (1) the careful selection of workers on engagement, and periodic supervision (including observation as to output, lost time, sickness, physiologic requirements, etc.); (2) the hours of employment—shifts, breaks, spells, pauses, holidays, Sunday work, night work and overtime; (3) the factory or workshop environment—design, structure, sanitation, cleanliness, heating, temperature, ventilation, lighting, sanitary accommodation, washing facilities, cloakrooms, seats, restroom and surgeries; (4) the personal well-being of the worker—the industrial employment of women, incentive, food supply, drinking water, canteens, protective clothing, lifting weights, welfare conditions, rest and recreation, and (5) the effect of occupation on health—fatigue (due to excess in duration of labor, specialization, repetition, strain or speed), sickness, injuries, accidents and industrial disease (poisoning by lead, phosphorus, arsenic, mercury, anthrax, dust and fumes).

#### The Treatment of Crippled Children

Sir Robert Jones has made an important proposal for the treatment of crippled children. He finds that rickets and surgical tuberculosis account for 40 per cent of crippled children. These diseases are preventable, but the remaining 60 per cent of the causes of crippling, too little is known to expect prevention. Under present conditions some of the children die, and others become cripples, yet many are fully curable; but the country has made no effort to face the problem. He proposes to graft the work of caring for these children on the orthopedic hospitals now conducted by the ministry of pensions for disabled soldiers. The machinery exists; it is only necessary to enlarge its scope. The country would be divided into districts similar to those established by the ministry of pensions. In each district there would be an open air country orthopedic hospital and a system of outpatient clinics. Specially trained nurses and physicians will be necessary; but these are already in existence owing to the work for soldiers. It is proposed that the ministry of health should take action in the matter and make its plans in advance so that the staff of the hospitals may not be dispersed as the pension work diminishes. Sir Robert Jones is confident that if in an organization is set up, many thousands of children otherwise doomed to the life of a cripple will be released to lead a normal life, though not fully cured, enabled to be self-supporting citizens and given far greater possibilities of activity and happiness.

## Marriages

GOUVERNEUR VINCENT EMERSON, Major, M. C., U. S. Army, to Miss Marie V. McLaughlin of Jersey City, N. J., at the country home of the bride, Milford, Pa., November 2.

LOCKRAT DAVIS ARBUCKLE, Lieut., M. C., U. S. Navy, to Miss Gladys Whitehead, at Olangapo, Sambales, P. I., August 25.

HARRIET MARION JERYAIS, Roxbury, Boston, to Lieut.-Col. William Higgins, R. N., at Belgrade, Serbia, October 4.

HARRY ROLAND KENNER, Washington, to Miss Margaret Clare Warfield, at Woodbine, Md., November 3.

JOHN ALBERT BERCHARD LOWRY, Crewe, Va., to Miss Mabel Johnson of Harrisburg, Pa., September 3.

THOMAS M. McMILLAN, Mobile, Ala., to Miss Julia T. Talcott of New York City, November 12.

## Deaths

Charles E. Cantrell \* Greenville, Texas; well known surgeon of the Southwest; a member of the House of Delegates of the American Medical Association from 1906 to 1909, and a member of the Board of Trustees from 1909 to 1913, inclusive; died, November 20. Dr. Cantrell was born in Lead Hill, Ark., March 15, 1859; he was a practitioner of Arkansas from 1885 to 1893, and was graduated from the medical department of the University of Arkansas, Little Rock in 1893. He located in Wolfe City, Texas, in 1893, and six years later moved to Greenville, where he and his brother founded Cantrell's Hospital. Dr. Cantrell was at one time president of the State Medical Association of Texas, and was for several years local surgeon of the St. Louis and Southwestern Railroad. On the entry of the United States into the world war, Dr. Cantrell was commissioned major, M. C., U. S. Army, and was on duty at the General Hospital, Corpus Christi, Texas, and was honorably discharged, Dec. 3, 1918. On July 31, 1919, he was appointed inspector-instructor, United States Public Health Service, and placed in charge of the Fourteenth District, comprising the states of Texas, Oklahoma, Arkansas and Louisiana, with station at Corpus Christi. While engaged in this duty, he was exposed to the tropical storm, which devastated Corpus Christi in September last, and his fatal illness followed this exposure.

Allan McLane Hamilton, Great Barrington, Mass.; College of Physicians and Surgeons in the City of New York, 1870; aged 71; a widely known alienist and specialist on nervous and mental diseases; died suddenly, November 23. Dr. Hamilton, a grandson of Alexander Hamilton, was born in Brooklyn. After his graduation in medicine, he settled in New York City, where he resided until his retirement, about two years ago. At his graduation he received the first faculty prize on his theses on "Galvanopuncture," and was also awarded the Harsen prize medal. He was professor of mental diseases in Cornell University Medical College from 1909 to 1903; statistical secretary of the New York Academy of Medicine in 1874; secretary of the New York Society of Neurology in 1875; and at one time editor of the *Journal of Psychological Journal*. He was lecturer on nervous diseases at the Long Island College Hospital, Brooklyn; chief surgeon to the Epileptic and Paralytic Hospital on Rockwell's Island, and later physician in charge of the New York State Hospital for Diseases of the Nervous System. Dr. Hamilton wrote many books on mental diseases, the most recent of which was his "Recollections of an Alienist," which appeared in 1916. He was also the author of "Intimate Life of Alexander Hamilton," which was published in 1911.

Floyd Milford Crandall \* New York City; University of the City of New York, 1884; aged 61; for many years a member of the House of Delegates of the American Medical Association, and since 1913 secretary of the Medical Society of the State of New York; a member of the American Pediatric Society; president of the New York County Medical Society in 1909; and of the Society of Alumni of Bellevue Hospital; lecturer on diseases of children from 1889 to 1893, and adjunct professor of diseases of children since that time in the New York Polyclinic; secretary of

the section of diseases of children of the Pan-American Medical Congress in 1893; surgeon of the New York Skin and Cancer Hospital from 1890 to 1898; consulting physician to the Infant's and Children's hospitals; state medical examiner since 1907; assistant editor of the *New York State Journal of Medicine*; died, November 19.

Preston Heath Bailhache \* Surg., U. S. P. H. S., Orange, N. J.; Pennsylvania Medical College, Philadelphia, 1857; aged 85; surgeon, Fourteenth Illinois Volunteer Cavalry, during the Civil War; and later associate editor of the *Quincy (Ill.) Whig*; who was appointed an assistant surgeon in the United States Marine Hospital Service, Aug. 20, 1873, and was retired, Nov. 1, 1909; died, October 28. During his forty-six years of connection with the United States Public Health Service, Dr. Bailhache assisted in revising the regulations of the service; was a member of the National Board of Health from 1879 to 1885; was on the board for selecting national quarantine stations in 1880.

William Grosvenor Bissell \* Buffalo; Buffalo University, 1892; aged 49; in charge of the bureau of bacteriology in the department of health of Buffalo since 1894; president of the State Board of Medical Examiners; president of the New York State Sanitary Officers' Association; for twenty years major and surgeon of the 74th Infantry, N. G., N. Y.; a member of the American Public Health Association and Association of Military Surgeons of the United States; who had conferred on him the honorary degree of Doctor of Public Health by the University of the City of New York in 1919; died, November 14.

John Hey Williams \* Asheville, N. C.; College of Physicians and Surgeons, Keokuk, Iowa, 1863; aged 77; once vice president of the Medical Society of the State of North Carolina, and president of the Buncombe County Medical Society; formerly surgeon-general of the National Guard of North Carolina; a member of the staff of the Clarence Barker Memorial Hospital; one of the most prominent surgeons of North Carolina; died, November 14, from cerebral hemorrhage.

Nathaniel Gildersleeve \* Philadelphia; University of Pennsylvania, Philadelphia, 1900; aged 48; a member of the American Association of Pathology and Bacteriology; professor of microbiology and bacteriopathology in the school of dentistry of his alma mater; Thomas A. Scott Fellow in hygiene; pathologist of the Bar Harbor (Me.) Hospital, where he conducted a laboratory in the summer; died in the University Hospital, Philadelphia, November 11.

Richard Coe Newton \* Montclair, N. J.; College of Physicians and Surgeons in the City of New York, 1877; aged 68; a specialist in tuberculosis; surgeon in the United States Army from 1880 to 1889; formerly a member of the New Jersey State Board of Health; editor of the *Journal of the Medical Society of New Jersey*; a member of the staff of Mountainside Hospital, Montclair; died in that institution, November 13, from cerebral hemorrhage.

David Hayes Strickland \* Erie, Pa.; University of Pennsylvania, Philadelphia, 1863; aged 80; a life member and once vice president of the Medical Society of the State of Pennsylvania; local surgeon of the Pittsburgh and Lake Erie system; consulting surgeon to St. Vincent's Hospital; a veteran of the Civil War; during which he served as surgeon of the 111th Pennsylvania Volunteer Infantry; died, November 10, from pneumonia.

Enoch Hunt Jones, Murfreesboro, Tenn.; University of Louisville, Ky., 1892; aged 67; a member and for two terms president of the Tennessee State Medical Association; secretary of the Rutherford County Medical Society in 1916 and 1918; for many years health officer of Murfreesboro; died in St. Thomas' Hospital, Nashville, Tenn., November 3.

George Duffield \* Detroit; Detroit Medical College, 1882; aged 60; professor emeritus of clinical medicine in the Detroit College of Medicine and Surgery; attending physician to Harper Hospital; consulting physician to the Woman's Hospital and Infant's Home, Detroit; died in his office, November 12, from heart disease.

Lena Grace Spring, Hollywood, Los Angeles; Herring Medical College, Chicago, 1904; aged 49; once professor of physiology in the College of Medicine and Surgery, Chicago; at one time physician for the Mexican Central Railroad; died in an ambulance while being taken from her home to a hospital, November 2.

Adolph Hoerr \* Mamaroneck, N. Y.; University of the City of New York, 1896; aged 50; at one time county physician of Westchester County, justice of the peace, and

\* Indicates "Fellow" of the American Medical Association.

a member of the staff of the United Hospital, Port Chester; died, November 12, from arteriosclerosis.

**Arthur Winter**, Cleveland; Cleveland College of Physicians and Surgeons, 1896; aged 52; died in Mt. Sinai Hospital, Cleveland, November 8, from the effects of wounds of the lung inflicted with an ice pick by the enraged husband of a patient a week before.

**James Robert Lancaster**, Granbury, Texas; University of Louisville, Ky., 1876; aged 71; a member of the State Medical Association of Texas; a practitioner since 1869; assistant surgeon in the Confederate service during the Civil War; died, November 3.

**Matthias Higgins**, Newport, Ky.; American Eclectic Medical College, Cincinnati, 1889; Cincinnati College of Medicine and Surgery, 1892; aged 58; coroner of Campbell County for three terms; died in his office, November 4, from heart disease.

**Lemuel Stephen Coplan** \* Wellington, Kan.; University of Illinois, Chicago, 1897; aged 51; captain, M. R. C., U. S. Army, and honorably discharged, Dec. 12, 1918; died in Chicago, November 17, from atrophic cirrhosis of the liver.

**George Edwards Richards**, Boston; Harvard University Medical School, 1883; aged 73; a member of the Massachusetts Medical Society; at one time a member of the staff of the Boston Dispensary; died, September 8, from myocarditis.

**James B. Williams**, Chicago; University of Pennsylvania, Philadelphia, 1880; Hahnemann Medical College, Chicago, 1890; aged 62; a member of the Illinois State Medical Society; died, November 18, from arteriosclerosis.

**Paul White Abell**, Charlton, Mass.; College of Physicians and Surgeons in the City of New York, 1893; aged 52; died in the Memorial Hospital, Charlton, October 28, four days after an operation for the removal of gallstones.

**Dennis Church**, Churchville, N. Y.; College of Physicians and Surgeons in the City of New York, 1872; aged 69; from 1890 to 1892 in the chemical manufacturing business; died, November 16, from heart disease.

**Paul Faver**, Atlanta, Ga.; Medical College of Virginia, Richmond, 1868; Bellevue Hospital Medical College, 1872; a Confederate veteran; once a member of the Georgia state senate; died, November 12.

**Alonzo L. Hurd** \* Somers, Conn.; University of Vermont, Burlington, 1891; aged 61; once president of the Tolland County Medical Association; died, November 9, from pernicious anemia.

**Edward S. Zieber**, Philadelphia; Jefferson Medical College, 1880; aged 60; teacher of mathematics in the high schools of Philadelphia for thirty-five years; died, October 30, from bronchiectasis.

**Edwin I. Thorne**, Salt Lake City; Medical College of Ohio, Cincinnati, 1869; aged 72; a member of the Utah State Medical Association; died, November 3, from chronic rheumatism.

**Edmund Bailey Frye**, Boston; Dartmouth Medical School, Hanover, N. H., 1880; aged 63; a member of the Massachusetts Medical Society; died, October 23, from angina pectoris.

**William T. Herndon**, Ashboro, N. C.; Louisville (Ky.) Medical College, 1874; aged 78; died at the home of his daughter in Winston-Salem, N. C., November 1.

**Aaron M. Sherman**, Pasadena, Calif.; Western Reserve University, Cleveland, 1851; aged 93; for many years a practitioner of Kent, Ohio; died, about November 2.

**William H. Landis**, Buchanan, Mich.; Starling Medical College, Columbus, Ohio, 1885; aged 61; died in his office, October 7, from cerebral hemorrhage.

**John Jefferson Kackley**, Chetopa, Kan.; Washington University, St. Louis, 1871; aged 92; died at the home of his daughter in Chetopa, November 4.

**Samuel DeLancy Hicks**, Richmond, Va.; University of Berlin, Germany, 1884; aged 50; died at Bethel, Conn., September 18, from heart disease.

**Thomas DeHaven Blodgett** \* Tulare, Calif.; Cooper Medical College, San Francisco, 1894; aged 51; died, November 10, from septicaemia.

**Joseph Rollin Sook**, Newark, Ohio; Cleveland University of Medicine and Surgery, 1887; aged 53; died, November 4, from nephritis.

**William Bradley Towler**, Los Angeles; Victoria University, Toronto, Ont., 1869, aged 76; died, August 12, from heart disease.

## The Propaganda for Reform

IN THIS DEPARTMENT APPEAR REPRINTS OF THE JOURNAL'S BUREAU OF INVESTIGATION, OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORY, TOGETHER WITH OTHER MATTER TENDING TO AID INTELLIGENT PRESCRIBING AND TO OPPOSE FRAUD ON THE PUBLIC AND ON THE PROFESSION

### MICAJAH'S WAFERS AND MICAJAH'S SUPPOSITORIES

#### Report of the Council on Pharmacy and Chemistry

"Micajah's Medicated Wafers" and "Micajah's Suppositories," sold by Micajah & Co., Warren, Pa., are declared inadmissible to "New and Nonofficial Remedies" because (1) their composition is essentially secret (Rule 1); (2) the name of neither of these mixtures is indicative of its composition (Rule 8); (3) of exaggerated and unwarranted therapeutic claims (Rule 6), and (4) the therapeutic advice which accompanies the trade packages constitutes an indirect advertisement to the public (Rule 4).

W. A. PICKNER, Secretary.

Micajah's Medicated Wafers (formerly called "Micajah's Medicated Uterine Wafers") were analyzed in the A. M. A. Chemical Laboratory in 1910. They were found to consist essentially of dried ("burnt") alum, boric acid and borax, in approximately the following proportions:

Alum, dried .....	59.86 per cent.
Borax, dried .....	15.62 per cent.
Boric acid .....	5.67 per cent.
Water of hydration .....	18.85 per cent.

There are a number of drugs that are more or less effective in the treatment of local lesions of mucous membranes and the skin. They are classed as astringents. Among these are included alum, borax and boric acid. Every physician has used them. To say that a wafer consists of alum, borax and boric acid inspires but little awe. But there is something much more mysterious and impressive in declaring that a wafer "consists of an astringent and antiseptic base, in which are incorporated certain medicaments which both locally and after absorption, contribute to the astringent, antiplogistic, depletive, soothing and healing action of the product." This gives the impression that some powerful and almost incomprehensible factors are at work. Yet, after all is said and done, the substances contained in Micajah's Medicated Wafers are just the homely old alum, boric acid and borax.

In addition to "Micajah's Medicated Wafers," Micajah & Co. also put out "Micajah's Suppositories for Hemorrhoids." These have been examined in the A. M. A. Chemical Laboratory and, like the "Medicated Wafers" have been found to contain alum, boric acid and borax—and these substances practically alone incorporated in cocoa butter. The company claims that "to these have been added Ammonium Icthyosulphonate, Balsam of Peru, Ext. Belladonna." The A. M. A. chemists report, however, that if extract of belladonna is present at all it is in amounts too small to be detected by the method commonly employed in the chemical examination of alkaloidal drugs. The chemists report further that while ammonium ichthyosulphonate and balsam of Peru both have a decided odor and are dark in color, the suppositories have but little color and the odor of the cocoa butter that forms their base is not covered by these drugs; obviously, therefore, if ammonium ichthyosulphonate and balsam of Peru are present at all it is in amounts utterly insufficient to exert any therapeutic effect.

It would be hard to find better examples of mischievous proprietary medicines than these two products of the Micajah Company. "Twins of Efficiency," they are called in an advertising pamphlet. The composition is not stated. A physician using the "twins" does so absolutely in the dark. To him they are secret preparations. He is encouraged to use them in a great variety of conditions in which other drugs are much more useful. Inevitably, physicians using

them will be likely to overlook, or pass over, new growths, specific infections and diseases that require radical removal measures.

In addition to misleading and exaggerated claims, there is a reference to a report from the usual "well-known and reliable bacteriological laboratory." The excerpts published from this report at an unnamed laboratory are sufficiently vague to incriminate no one.

From time to time it is worth while to emphasize facts regarding proprietary medicines that while obvious are sometimes forgotten. For this reason attention is directed to Micajah's Uterine Waters and Micajah's Suppositories.

## Correspondence

### LIPOVACCINES AS A PROPHYLACTIC IN INFLUENZA

To the Editor.—In THE JOURNAL, Oct. 25, 1919, appeared a letter from Surgeon-General Blue, U. S. Public Health Service, relative to statements in the above subject made by me. To this letter I reply because Dr. Blue makes certain incorrect statements.

In a letter dated October 17, Dr. Blue sends me his letter to THE JOURNAL accompanied by a letter in which he states that my article contains "a number of misstatements," whereas, in the article for publication which he headed "Correction of Erroneous Statements in the Chicago Daily Tribune," he describes my article "as so misleading." He brands two of my statements as misstatements. A third statement made by me he pronounces correct in his letter to me.

The several other statements are not touched on. Even though he had made his point, the headlines and his several characterizations would not have been justified, and he himself might be accused of attempting to mislead, especially in view of his own statement that the principal object of his letter was to justify the action of the Public Health Service in its action on lipovaccines.

First, let me briefly discuss the statement relative to the use of lipovaccines by the army. Frankly, I did not know of the War Department March circular on lipovaccines until I received Dr. Blue's letter. However, I now have a copy of the circular before me, and I find that the facts are not in all accord with Dr. Blue's statements. I refer to "S. G. O. 442, Surgeon-General's Office, Mar. 12, 1919," signed S. C. R. Correll. Dr. Blue says: "The fact is that the army discontinued distributing lipovaccine some months ago, and withdrew that which was outstanding." The circular reads: "Lipovaccines were adopted as a war measure on account of their obvious advantages and have served their purpose. The present method of manufacture, however, needs further improvement,

and the duration of their protective power as compared with that of saline vaccines needs further investigation. Saline vaccines, therefore, will be used as a routine, and lipovaccines will be reserved for emergencies."

The second charge of error is flimsy. My article related to measures of control of influenza. Among other methods I referred to the use of vaccines. Six paragraphs were given to discussion of vaccination. A part of the discussion of vaccines was devoted to lipovaccines. In giving the evidence for vaccination I cited the two army experiments, inadvertently referring to the work at both Upton and Wheeler as having been done with lipovaccines. As is well known, the vaccination at Wheeler was with lipovaccines; that at Upton with saline vaccines.

Dr. Blue writes:

The chief objection raised is the coupling of the refusal of the U. S. Public Health Service to license lipovaccines with the statements which imply that for this reason people are being deprived of a valuable prophylactic agent.

He justifies the action of the service by the statement:

The lack at present of satisfactory potency and sterility tests for lipovaccines has led the bureau to decline to license such vaccines for interstate sale, and the evidence at our disposal indicates that a saline vaccine containing pneumococci is at least as effective as an oil suspension of the organisms.

I say the Public Health Service has made it impossible for most of the people to get influenza-pneumonia vaccines and (human nature being as it is) practically speaking, to prevent influenza-pneumonia vaccination. Dr. Blue says that at least the first part of the statement is correct, the Public Health Service having gone to the limit of its powers to make lipovaccines unavailable. I said that people who can get lipovaccines are lucky. Dr. Blue denies this and justifies the action of the service on two grounds—lack of confidence in the sterility of influenza-pneumonia vaccines and lack of faith in their efficacy. Here, as Dr. Blue says, is the real point of controversy, the chief reason, for his open letter.

First, as to sterility: I assume that what Dr. Blue meant to say is that it is difficult to sterilize lipovaccines. Lipovaccines made according to the older method were in fairly wide use in the army last winter. I have not seen any reports of any great harm due to lack of sterility. However, a simpler method of manufacture has been in use for more than six months. It was described by Rosenow in June last, and the description appeared in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION shortly thereafter. Using this method, it is just as easy to make sterile lipovaccine as to make sterile saline vaccine, and far easier than to make sterile smallpox vaccine—a product licensed by the U. S. Public Health Service.

Second, as to potency: I am not certain what potency tests Dr. Blue refers to. He may refer to lack of laboratory demonstration by the McCoy test or to lack of clinical proof of potency. This objection to influenza-pneumonia vaccines was raised frequently in October, 1918. Without going deeply into it, it seems to me that so far as the pneumococcus is concerned the evidence is very good that it can be used, in the laboratory, to produce specific antibodies and, clinically, to produce immunity as to streptococcus. The evidence is fairly good that it produces specific antibodies in laboratory animals. There is lack of agreement as to the degree of effectiveness in antibody formation with lipovaccines as compared with saline vaccines.

As I understand it, the position taken by Dr. Blue is that if the service were to permit the manufacture of lipovaccines, it would be in the position of guaranteeing their efficacy to an extent. This he declines to do. May I ask him: Does the Public Health Service guarantee the efficacy of saline vaccines against influenza?

I have before me catalogues of biologic products used for children and a variety of disorders put out under license of the U. S. Public Health Service. Does the service guarantee the efficacy of each case? Or does it stand behind them in the sense in which it declines to stand behind lipovaccines? The latter half of the sentence quoted is: "The evidence at our disposal indicates that a saline vaccine containing pneumococci is at least as effective as an oil suspension of the

present method of manufacture, however, needs further improvement, and the duration of their protective power as compared with that of saline vaccines needs further investigation. Saline vaccines, therefore, will be used as a routine, and lipovaccines will be reserved for emergencies."

and the evidence at our disposal indicates that a saline vaccine containing pneumococci is at least as effective as an oil suspension of the organisms.

I say the Public Health Service has made it impossible for most of the people to get influenza-pneumonia vaccines and (human nature being as it is) practically speaking, to prevent influenza-pneumonia vaccination.

Dr. Blue says that at least the first part of the statement is correct, the Public Health Service having gone to the limit of its powers to make lipovaccines unavailable. I said that people who can get lipovaccines are lucky. Dr. Blue denies this and justifies the action of the service on two grounds—lack of confidence in the sterility of influenza-pneumonia vaccines and lack of faith in their efficacy.

Here, as Dr. Blue says, is the real point of controversy, the chief reason, for his open letter. First, as to sterility: I assume that what Dr. Blue meant to say is that it is difficult to sterilize lipovaccines. Lipovaccines made according to the older method were in fairly wide use in the army last winter. I have not seen any reports of any great harm due to lack of sterility. However, a simpler method of manufacture has been in use for more than six months. It was described by Rosenow in June last, and the description appeared in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION shortly thereafter. Using this method, it is just as easy to make sterile lipovaccine as to make sterile saline vaccine, and far easier than to make sterile smallpox vaccine—a product licensed by the U. S. Public Health Service.

organisms." Suppose we ask, on the basis of this statement, Why license the one and refuse to license the other?

The point made in favor of lipovaccines in my article was that, using lipovaccines, vaccination can be done at one sitting, whereas three sittings extending over three weeks is required for vaccination when done with saline vaccines. Vaccination at three sittings is possible in military life. In civil life it does not work. In ordinary times for the civilian life, for the uses of municipal and state health departments, the only vaccination worth talking about is one-sitting vaccination.

Now, Dr. Blue may be right as to a laboratory proposition that a saline vaccine containing pneumococci is at least as effective as an oil suspension of the organism; but when it comes to fighting pneumonia and influenza among civilians, he is just about as wrong as a man could be. His action is equivalent to saying that influenza-pneumonia vaccination shall not be done generally. I do not think this a wise decision.

W. A. EVANS, M.D., Chicago.

COMMENT.—Dr. Evans' letter was referred to Surgeon-General Blue, who replies: "As Dr. Evans acknowledges the accuracy of my criticisms concerning his citations of the Army use of lipovaccines, and as nothing in that portion of his letter concerning the refusal of the U. S. Public Health Service to license lipovaccines requires any comment in addition to that found in my original letter, no further reply seems to be necessary."—Ed.

### THE EIGHT HOUR DAY

To the Editor:—I have translated the following statement from the issue of *La Presse médicale* just received. I believe it might well be published in THE JOURNAL.

#### THE EIGHT HOUR DAY—A FRENCH MEDICAL INTERPRETATION

"No sound comes from the press. In parliament an individual rises and says, 'The Labor Party desires an eight hour day.'

"Immediately deputies, senators, they of the left, of the center, of the north, they who follow the red flag and they of the tricolor, all cry with one voice, 'Demos has spoken! What he wishes shall be done.' 'Amen,' says Clemenceau. And the law is voted.

"The vote is characteristic of the psychology of modern parliamentarism. Political science, difficult and understood only by economists and by the wise, demands reflection, calculation of the moral and economic consequences which a law will effect and provision in it against counter-strokes and reaction. But politics is no longer the key which opens enlarged vision nor has politics become more democratic. Parliament is democratic and it is charged with the making of laws, but it merely churns them up. Modern parliaments cast laws into the clouds, just as a child might sow seeds, without knowing whether the plants which would arise would be weeds or wheat, a poison or a cure.

"It is impossible to think of a law more inopportune, or one more capable of increasing expenses, diminishing production, paralyzing commerce and industry, and delaying the reconstructions so necessary for our country.

"The ministries and the administrative officers of the state continue to recruit new employees by thousands upon thousands. Evidently this is a clever policy of dealing with the demobilized soldiers without dismissing those who have held office during the war. Evidently the process prevents the advancement of the old employees. The whole is a powerful machine which drains away the labor necessary for the farm and for productive industry.

"One has not yet observed the consequences of this interperate law. Who would dare to say that before this law was passed there existed any group of overworked laborers in France? On the contrary, rail transportation has become less reliable and more expensive, the ports of the country are tied up, the construction of houses is absolutely at a standstill and indispensable undertakings are postponed until the Greek Kalends.

"For example, the directors of our hospitals are anxiously demanding how they can recruit, pay, lodge and provide food for the additional hundreds of supplementary employees whom the law makes necessary. Are the patients better

cared for? No. The chiefs of service must wait for their necessary laboratories; the tuberculous must wait for their sanatoria.

"Unless the popular good sense does not immediately remedy the error of our legislators, we will soon be at the red dawn of a day without bread. For why should a farmer work longer than a hospital attendant? Why should the little guardian of turkeys in the pasture worry over them for longer hours than her sister who is in the beautiful bureau of Monsieur the Minister?

"Oh Parliament, be logical and apply the eight hour day to the workers in the field. Then the citizen will search the market in vain for an ounce of butter or a slice of bacon, even as a young man now will search Paris in vain to find a dwelling place in which to shelter his head and his illusions.

"The demagogue smiles at these miseries. What does he care for the cost of living? If bread fails he will eat cake, famine may overtake the vulgar, but in *centres d'ores* there are always truffes."

GRAHAM LUSK, New York.

## Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

### HARTMAN STILL WORKING THE PROFESSION

To the Editor:—The matter I am enclosing looks so much like a "work-the-doctor" game that I thought you might be interested to find out about it. Is it genuine or a collection agency follow-up scheme and is it being worked generally?

H. Z. FRISBIE, M.D., Elkland, Pa.

ANSWER.—The material sent in by Dr. Frisbie is a typewritten letter addressed to "Minister of the Gospel or Town Physician, Elkland, Pa." The letter was signed "Myrtle Moore" and accompanying it was a stamped envelope addressed "Myrtle Moore, 3925 Wentworth Ave., Chicago." The body of the letter was to the effect that Myrtle had recently written to a man (name given) in Elkland, Pa., but her letter had been returned undelivered. This fact led Myrtle to believe that the family had moved without letting her know. Then Myrtle continues:

"If it is not asking too much of you, I assure you it would be a great favor if you could advise or find out for me without putting yourself to too much trouble where a letter can reach this party. It is a matter of considerable importance."

The facts are, there is no Myrtle Moore, 3925 Wentworth Ave.—for the very good reason that 3925 Wentworth Avenue is a vacant lot. In the adjoining lot, however, 3923, is the "Administration Building" of the Hartman Furniture and Carpet Company, a concern that sells furniture and house furnishings on the instalment plan. This scheme on the part of the gospel as unpaid collection agents was exposed editorially in THE JOURNAL, August 23, last. At that time we showed that doctors in various parts of the country were receiving letters from "Myrtle Moore," "Helen Taylor" and other more or less hypothetical individuals asking similar questions about the present whereabouts of some individual and enclosing stamped envelopes that were addressed to a location in Chicago that did not exist. There is nothing fraudulent about the scheme, as the postal authorities notified us when we took up the matter previously. Nevertheless, it is a cheap and petty piece of unworthy misrepresentation and deceit. It reflects credit neither on the furniture concern that perpetrates it nor the postoffice authorities by whose assistance it becomes effective.

### ACRIFLAVINE IN THE TREATMENT OF GONORRHEA

To the Editor:—In THE JOURNAL, Nov. 8, 1919, under the heading New and Nonofficial Remedies, I notice a description of acriflavine. I have been told that this was used extensively in France in the treatment of gonorrhoea with very good results during the time that argentol is employed, that is an injection in the strength of 1:1,000. Please give me more information on this subject, and advise me through whom the drug may be obtained.

C. W. SHARPELORD, M.D., Fair Hill, Md.

ANSWER.—A review of the literature on the therapeutic use of acriflavine and proflavine has been prepared by the Council on Pharmacy and Chemistry. The report of the

Committee reviewing this abstract appeared in THE JOURNAL, Nov. 15, 1919, p. 1443, with the announcement that the complete report will be sent on receipt of a two-cent stamp. A further report on the use of acetylamine in the treatment of gonorrhoea was published in the U. S. Naval Medical Bulletin 13:859, 1919. Young, White and Swartz (THE JOURNAL, Nov. 15, 1919, p. 1483) also report on the value of acetylamine in the treatment of gonorrhoea.

TREATMENT OF PNEUMONIA

To the Editor: The pneumonia ser. is approaching and we are all anxious to be able to combat this dreaded disease as successfully as possible. Please inform me: (1) Is any serum or vaccine treatment better than the expectant plan? (2) How about antipneumococcus serum? (3) pneumoniae phylacogen (Parke, Davis & Co.), or (4) pneumococcus antigen (Elli, Lilly & Co.), as devised by F. C. Rosenow? I am anxious to do my patients justice.

B. O. LeBivace, M.D., St. Gabriel, La.

ANSWER.—1 It has not been demonstrated that any serum or vaccine treatment, used alone, is better than symptomatic treatment.

2. The serums against infection with Type I organisms appear to produce good results in the treatment of pneumonia caused by Type I organisms. The use of this depends on correct diagnosis of the type of infecting organism, for which good laboratory assistance is required. Polyvalent serums for use in pneumonia are on the market, but the evidence is not conclusive as to their efficiency. It must also be borne in mind that patients may be harmed by the intravenous injection of 100 or more cubic centimeters of horse serum.

3. Parke, Davis & Company's phylacogens, it is generally understood, are the filtered products of several bacterial species. Any results which follow their administration represent the reaction of the patient to the bacterial proteins. There is no reliable evidence that any of them has any specific virtues in pneumonia. Again it must be remembered that these protein reactions are by no means free from danger.

4. The pneumococcus antigen must be regarded as in the experimental stage.

Louisiana July Examination

Dr. E. W. Mahler, secretary of the Louisiana State Board of Medical Examiners, reports the written examination held at New Orleans, July 1-3, 1919. The examination covered 12 subjects and included 100 questions. An average of 75 per cent was required to pass. Of the 71 candidates examined, 68 passed and 3 failed. Ten candidates were licensed by reciprocity. The following colleges were represented:

Table with columns: College, PASSED, Year Grad., Per Cent. Lists various colleges and their performance in the Louisiana July Examination.

Massachusetts July Examination

Dr. Walter P. Bowers, secretary of the Massachusetts State Board of Registration in Medicine, reports the oral, written and practical examination held at Boston, July 8-10, 1919. The examination covered 13 subjects, and included 70 questions. An average of 75 per cent was required to pass. Of the 58 candidates examined, 45, including one osteopath, passed, and 13, including 2 osteopaths, failed. The following colleges were represented:

Table with columns: College, PASSED, Year Grad., Per Cent. Lists various colleges and their performance in the Massachusetts July Examination.

Dr. Bowers also reports that three candidates were licensed by special examinations held July 1 and July 31, 1919. The following colleges were represented:

Table with columns: College, PASSED, Year Grad., Per Cent. Lists three colleges and their performance in special examinations.

## Book Notices

**A MANUAL OF EXERCISES FOR THE CORRECTION OF SPEECH DISORDERS.** By May Kirk Scripture, B.A., Instructor in Speech, Columbia University (Extension and Summer Session), and Eugene Jackson, B.A., in Charge of Speech Correction at the University and Bellevue Hospital Medical College Clinic, New York City. Cloth. Price, \$2 net. Philadelphia: F. A. Davis Company, 1919.

This book is intended to embody the vocal materials and methods which the authors make use of in their work of speech correction. The material is presented in the form of fifty lessons, each lesson being intended to develop some especial phase of the work. The lessons are augmented by forty-six illustrations and considerable explanatory matter. The book seems to be intended for use in classes of the public schools, for example, and its aim to present underlying methods and materials that may be employed in the pedagogic treatment of speech disorders in general, and for the improvement of carelessness in speech. It is the first book of its kind to appear in America. The danger in the speech situation at this time is superficiality and mechanicalness of procedure. What is needed in speech work is a book of this general character that makes every proposed procedure rest solidly on physiologic foundations. Viewed from this standpoint, the book, while it contains much useful material, seems vague as to both physiology and methods. But if the teacher has been well grounded in principles, she would be able to adapt much of this material to her own independent needs.

**A TEXTBOOK OF PHYSIOLOGY.** By Martin Flack, C.B.E., M.B., B.Ch., Research Staff, Department of Applied Physiology, Medical Research Committee, and Leonard Hill, M.B., F.R.S., Director of Applied Physiology Department Medical Research Committee, London Hospital Medical College. Cloth. Price, \$8.50 net. Pp. 800, with 485 illustrations. New York: Longmans, Green & Co., 1919.

This book has been written "with the primary object of giving to the student, in an easily understandable form, the fundamental facts and theories of physiology, bearing in mind the limitations necessary in the student's textbook." It compares favorably with a number of standard textbooks of physiology published in the United States and Great Britain, for the use of medical students. The illustrations are excellent, the paper and print good; but in a number of the chapters the subject matter is not brought up to date. There is no reference to literature, an omission that detracts from the value of the book in the hands of the medical student. In some of the chapters, notably those on general dietetics, diet under various conditions, etc., some of the nutrition experiences of the recent war are brought in.

**THE NERVOUS HEART: ITS NATURE, CAUSATION, PROGNOSIS AND TREATMENT.** By R. M. Wilson, Captain, R. A. M. C., and John H. Caffery, Major, M. C., U. S. Army. Cloth. Price \$2.50. Pp. 136. New York: Oxford University Press, 1919.

In this volume the authors view the problem of heart disease from a new angle—that of the nervous system. Especially in their explanation of functional heart disease is emphasis laid on the influence of the vagus depressor and the sympathetic nervous system. Etiologically infectious-toxic agents are believed to play an important part. There is a good outline of the well-known symptomatology, prognosis and treatment of the so-called irritable heart. The theories underlying the views expressed in this work, which are an outgrowth of the views expressed by Wilson in his "Hearts of Man," are interesting and stimulating, but need further study before being generally accepted.

**INDUSTRIAL NURSING FOR INDUSTRIAL, PUBLIC HEALTH, AND PEOPLE NURSES, AND FOR EMPLOYERS OF LABOR.** By Florence South Wright, R.N., Bureau of Child Hygiene, New Jersey State Department of Health. Cloth. Price, \$1.25. Pp. 179. New York: The Macmillan Company, 1919.

With the aid of many industrial nurses, the author has prepared a brief outline of what is relatively a new field. She states that the trained nurse was probably first employed in industry in 1895, but that it is only within the last decade that the real development in this field has taken place. She

points out that in addition to a good preliminary education and hospital training, the industrial nurse requires a working knowledge of psychology, and of civic, industrial, social and relief problems. The book discusses the work, presenting typical forms and blanks for practical use. There is a good analysis of the relations of the nurse to her fellow employees. In an appendix are a brief outline of first aid methods and a list of sources of information relative to national social organizations, and, finally, a brief bibliography for special reading.

**ATLAS OF OPERATIVE GYNECOLOGY.** By Barton Cooke Hirst, M.D., Professor of Obstetrics, University of Pennsylvania. Cloth. Price, \$7 Pp. 292, with 210 illustrations. Philadelphia: J. B. Lippincott Company, 1919.

The author describes the technic of gynecologic operations, on the basis of a large experience, selecting in each case the operation which he believes best suited to the woman's subsequent life history. The text is brief, being wholly subordinated to the full-page illustrations of operative technic. The illustrations are so numerous and so excellent that they are almost an equivalent to standing at the side of the operator and witnessing the operation.

## Social Medicine, Medical Economics and Miscellany

### FIFTY-ONE DAYS FOR KILLING

Mrs. Emma D. Simpson, who shot her husband in court last April, was adjudged insane by a jury, September 26, and was thereafter sent to the Elgin State Hospital for the Insane. On Friday she was adjudged sane by a jury of experts and released. "The Elgin city court was packed with a sympathetic crowd," says the report.

She was fifty-one days at the institution. Her remark on regaining her liberty is significant. "I did not do the right thing—absolutely not," she said. "I could not have done such a thing had I been in my right mind. But until the last hour of my life I'll believe my husband wanted to kill me and marry a bad woman."

After the shooting she buoyantly said to the *Tribune* staff photographer, "When I go to court for this, I will defend myself. I will need no attorney; the new unwritten law, which does not permit a married man to love another woman, will be my defense. I will tell my whole story to the jury and they will free me."

The *Tribune*, in comment on this breezy announcement, said, "They probably will. What is law, what is a human life to the sloppy sentimentality of the juries which sit in these cases?"

Mrs. Simpson's optimism and our prediction have been essentially justified. She did not try her own case. The unwritten law she relied on was not formally pleaded. But the conventional plea of temporary insanity was, and there were learned experts to support it. The jury did not set her free. It compromised by setting her on the road to freedom. She was solemnly adjudged insane and sent for treatment.

Forecasting the outcome, the *Tribune* at the time of the trial said:

"Pity is at work for Mrs. Simpson, but we hear of little for the husband she slew in a public courtroom. She is said to be nervous. Nervous women should not carry firearms. Mrs. Simpson may be demented; if so, she should be placed in an asylum for life; not only until she makes a surprising recovery."

The recovery is made, but it is not surprising. This tragic comedy, beginning with the slaying of a human being by an infuriated woman, proceeding through the elaborate drama of the American criminal trial, and ending with the solemn farce at Elgin, develops as inevitably as an Hsien play.

Sentimentality is lawless. The disease in America is endemic. We need some drastic moral therapy—Chicago *Tribune*.

## Medicolegal

### Refusing to Submit to Roentgen-Ray Examination

*Re: Desmond Charcoal & Chemical Co. et al. (Mich.) 172  
N. W. R. 175*

The Supreme Court of Michigan, in setting aside an order of the industrial accident board denying a petition by an employer and an insurance company for permission to cease payments to an employee who tripped while wheeling ashes and tore ligaments on the kneecap, holds that it could not be said that the evidence was conclusive establishing the fact that the employee had recovered from his injury. It must be said that there was some, if slight, evidence supporting a contrary conclusion. It tended strongly to prove that he was recovered. But the doubt which is left in the mind was a small one, and his refusals to submit his person to expert roentgen-ray examination demanded suspension of his right to compensation, under the provisions of the workmen's compensation law. This was the order which the board sought to have made in the premises. The court does not intimate that it was its opinion that the employee had not had expert roentgen-ray examination, which was some time in the year 1915. But it was a fair consensus of the opinions expressed by the medical witnesses that any doubts now existing about his condition might be resolved by an expert roentgen-ray examination made presently. He had only to give his time in order that such examination might be made, the petitioners having offered to pay therefor.

### Medical Practice Act Constitutional—Chiropractor

*People, for Use of State Board of Health v. Kane (Ill.),  
125 N. E. R. 265*

The Supreme Court of Illinois, in reversing a judgment rendered for the plaintiff and remanding the cause, says that the defendant was charged with practicing medicine without a license from the state board of health, the action being brought under the act of 1899, as amended in 1917, which authorized a recovery of \$100 for the first offense and \$200 for each subsequent offense. The offense defined by the act consisted in practicing medicine or surgery or treating human ailments with out a certificate issued by the state board of health. The offense did not consist of treating some individual, but for practicing medicine generally by treating the public, so that a first offense meant a first conviction. There could not be a judgment for five first offenses, and the judgment must be reversed for that reason.

The statute was enacted in the exercise of police power, for the protection of the lives and health of the people. The state has a right to regulate any and all kinds of occupations for that purpose, and all measures and regulations for the protection of the public health, not intruding on constitutional rights, are within the scope of the police power. The right of a citizen to follow any legitimate occupation is subject to the paramount power of the state to impose such regulations as may be required to secure the people against deception, misadventure, deception or fraud in the practice of medicine, so long as they are not such restraints as are imposed by the constitution.

Section 7 of the act provided that any person should be regarded as practicing medicine, within the meaning of the act, who should treat or profess to treat, operate on or prescribe for any physical ailment or any physical injury to the members of another. The defendant was a chiropractor, his practice consisted in adjusting the vertebrae of the spinal column. That method of treating physical ailments, known as chiropractic, is not within the common meaning of the term "practicing medicine," but the general assembly had a right to define the practice of medicine for the purposes of the act so as to include that method. Within constitutional limits, the general assembly is the sole judge of what laws shall be enacted for the protection of the public health. In every citizen has a right to be governed by fixed rules, and cannot be subjected to the will or caprice of an administrative board.

The act provided for examinations of persons applying for licenses to practice medicine, and, as to those desiring to practice medicine and surgery in all its branches, prescribed general rules for an examination. As to those who desired to practice any other system or science of treating human ailments, who did not use medicines internally or externally, or practice operative surgery, it required that examinations should be of a character sufficiently strict to test their qualifications as practitioners. That provision, standing alone, conferred on the state board of health arbitrary power to grant or refuse licenses in its own discretion and on its own judgment as to what examination would be sufficient to test the qualification of each applicant for a license. It furnished no standard and no guide and no security to an applicant by which the courts could determine whether the requirements of the board were reasonable or not. The act, however, provided that all examinations should be conducted under rules and regulations prescribed by the board, which should provide for a fair and wholly impartial method of examination. Such rules and regulations, if made, would be subject to review by the courts to determine whether reasonable or not. Considering the provision of the statute for the adoption of rules and regulations subject to judicial review, under which examinations should be made and licenses issued, the statute did not violate any constitutional right.

### CLINICAL CONGRESS OF AMERICAN COLLEGE OF SURGEONS

*Ninth Annual Meeting, held in New York, Oct. 20-24, 1919*

*(Continued from page 1653)*

### Stiff and Flail Joints

SIR ROBERT JONES, Liverpool, England: One of the common products of the results of war injuries was the flail joint. The greater number of these disabilities were the direct results of excisions deliberately performed at casualty clearing stations or base hospitals in order to save the limb from amputation or the patient from death by minimizing local sepsis and preventing general sepsis. Cases in which so-called limited section was performed have resulted in better function than was obtained in those cases in which the excision was very extensive. Moreover, cases in which sepsis has been overcome and bones allowed to remain in position have sometimes resulted in a very good firm ankylosis with excellent function, if the position of election has been maintained. The treatment of a flail joint consists in the removal of necrotic bone and scar tissue, correct position, operative attempts at improved pseudarthrosis, production of ankylosis, and retention in mechanical apparatus. Ankylosis should be aimed at rather than mobility. In limiting the extent of excision, muscular attachments should be preserved. The rule should be that as soon as the surgeon can do so he should place the bones as nearly together as he can and in the best position for future functioning, whether a pseudarthrosis or an ankylosis occurs. Bone grafting, as generally understood, is of very limited application in injuries of the upper part of the shaft of the femur. Ankylosis in the case of limited excision of the hip is of no advantage and certainly does not justify the severe operation which it necessarily entails. The only practical treatment of a flail knee is ankylosis, and if the ends are in good position nothing is needed but to saw the ends and fix them with screw or nail. When there is a wide

separation associated with sinuses, it is necessary, after sawing the ends of the bone, to bring a bulky sliding graft from the tibia or femur and wedge it in at right angles to the line of the joint. A flail ankle is so rare that I do not recall an instance of it as a result of a war wound. Many operations for fixation of the shoulder have failed because the surgeon has been content to bare the glenoid and freshen the humerus. This is quite insufficient. It is important, before the arm is ankylized, to ascertain whether the scapula is mobile and whether it retains its normal position with regard to the humerus. If the scapula is fixed and the arm abducted, the patient will have a fixed abducted shoulder with an arm that he will not be able to lower.

DISCUSSION

DR. JOSEPH A. BLAKE, New York: If the treatment of the articulations is properly carried out, a stiff joint rarely occurs, unless there is disease. If one wishes to conserve the motion of a joint, he should never allow it to be lost. This means motion from the time of the injury, not several times a day, but some arrangement whereby unconscious movements may be made at any time. It is desirable that the patient should make the motions himself, since active motion not only maintains the functions of the muscles but also makes new bone conform to the architecture of the joint. Not only does active motion prevent deformity, but it favors healing by improving the nourishment of the parts. In a joint already stiffened, one is confronted with two problems: permanent ankylosis or a return to motion by proper treatment. The practice of breaking up a stiff joint under anesthesia is utterly and absolutely reprehensible and should never be done.

DR. JOHN L. PORTER, Chicago: In some cases of flail shoulder and flail elbow which I saw, the articular ends of the bones had been shot away, the wounds had become infected, and scar tissue had formed in the gaps. We devised a special wire splint for these cases which held the bones at the shoulder and elbow together and secured sufficient fixation, though not ankylosis, to make the joints useful. When healing was complete, active and passive motion were instituted. In the treatment of stiff joints it seems as though we are in danger of losing sight of the fact that stability must be preserved if the joint is to be useful. The results of arthroplastic operations on the knee joint are, as a rule, disappointing, as they leave the patient with neither a flail nor a stable joint, and often with 35 degrees of motion instead of 90 degrees. With such a knee a man cannot go up or down stairs, and is much more disabled than with a stiff knee fixed at an angle of 10 degrees. A stiff shoulder is very disabling if it is fixed close to the body; but if the arm is in the position of election—a slight abduction—one can get along quite comfortably.

DR. JOEL GOLDBERGER, Boston: A flail joint is rarely seen in civil life, but stiff joints are quite common. It is a simple matter to mobilize a stiff joint, but the procedure must be designed with a view to the ultimate usefulness of the limb. The shoulder in the proper position is much better stiff than flail. A flail elbow is better than a stiff joint. The knee joint should never be mobilized when once it is completely ankylized. The hip joint is fairly easy to mobilize, and many times the patient is better off if this joint is mobile. Fingers are very easy to mobilize.

The Physician and Surgeon in the Industrial Era

DR. OTTO P. GELBER, Cincinnati: Is it right that the physician who has a close view of the living and thinking of the people should play so small a part in their lives? Are we doing all we can to bring about health and sanity which are basic at all times to the national welfare? Workmen's compensation laws and group insurance schemes are being promoted without seeking the guidance of those best fitted to inspire and direct such undertakings. As a consequence of neglect to take cognizance of these things on the part of the leader of the medical profession, we have the general practitioner tinkering with industrial injuries with the result that disability is prolonged and there is a greater loss of time and wages to the

workman, and a loss of time and money to the employer, with consequent decreased production, and to society a greater burden. In President Wilson's industrial conference the medical and surgical profession had no representatives. If the profession does not awaken from its social, or rather unsocial, torpor, legislation will be passed to suit labor or capital, but it will have no consideration for the interests of the profession. Do these facts suggest why we have been unsuccessful in our demand for a federal department of health? The properly trained physician and surgeon should be taken out of his office where his services reach mainly only the rich or, through dispensaries, hospitals and clinics, the poor, and placed in group diagnostic clinics where his services will be at the disposal of the laborer. Our usefulness in the discussion of social problems has not thus far been noteworthy. During the last decade there has developed, in response to the demand of industry, the industrial physician, who is desperately trying to cope with industrial problems, which are quite different from the problems the physician meets ordinarily. He must be familiar with all the factors affecting the health of employees, with the sanitation of factory and home, with the workman's food and his habits, with the occupational diseases, and with the effects of fatigue and long working hours. Provision should be made for the special training of physicians and surgeons through the establishment of university departments, graduate courses, and endowed research institutes. The industrial physician must be attentive to the rising standards of medicine, for he is the molder of opinion in behalf of preventive medicine.

DISCUSSION

DR. JOHN MOORHEAD, New York: The problem is largely one of education, of direction given primarily in the medical college, transmitted by the visiting staff to the hospital intern, and made the subject of clinical demonstration at surgical meetings. Several of the colleges have already inaugurated special courses in these branches. Let us realize that this is a problem on the road to becoming a specialty, one demanding a training and experience that makes of its possessor a teacher, a leader. One concrete suggestion is offered, namely, that this congress establish a counterpart of the interrelated surgical conference.

DR. WILLIAM O'NEILL SHERMAN, Pittsburgh: The psychologic time has arrived for scientific medicine and surgery to take its place in industry. There are at least 500,000 industrial accidents in the United States annually, and 90 per cent. of all employees need medical or surgical care in the course of a year. The vast majority of industrial injuries are minor wounds that may easily be converted into serious wounds if not cared for intelligently. Industrial injuries are responsible for the loss of many millions of dollars annually. This loss can be diminished greatly by applying military surgery to industry. The problems of military and industrial surgery are similar, except for the presence of war and foreign bodies. Men trained for this work may be secured through the establishment of courses of military and industrial surgery, medicine, surgery and hygiene, with provision for graduate work in these branches.

DR. JONATHAN M. WAINWRIGHT, Scranton, Pa.: It does not matter just how large or small the casualty list in industry is, it is large enough to demand the most careful attention. In this field much may be done in the way of reconstruction. This we have learned and all the methods of physiotherapy are being employed. The dispensary is economically and industrially more important than the hospital, and should be provided with the best trained talent.

MR. K. M. LITTLE, Safety Institute of America, New York: There are 2,000,000 industrial accidents in the United States annually, the larger percentage of them minor injuries. More than 700,000 industrial workers lose more than four weeks' time annually as the result of industrial accidents. There are at least 22,500 industrial deaths annually in this country, and our industries turn out each year 15,000 workmen suffering from permanent disability. The loss of nine days annually (the estimate of the United States Bureau of Labor) by each of 50,000,000 workers on account of sickness means a tremendous industrial and economic loss. It is imperative that

the knowledge of the surgeon be brought to bear practically on the problem of the tremendous national loss due to sickness and disability among those engaged in industry. Every medical school must soon have a chair of industrial medicine and surgery so that medical students may be trained for this industrial service. If the physician and surgeon are to succeed they must have the industrial point of view.

(To be continued)

## MEDICAL SOCIETY OF VIRGINIA

Regular Annual Meeting, held at Richmond, Oct. 28-31, 1919

The President, DR. ENNIX G. WILLIAMS, Richmond,  
in the Chair

### SYMPOSIUM ON GASTRIC AND DUODENAL ULCER

#### Etiology and Symptomatology

DR. CHARLES R. GRANBY, Norfolk: There has been a radical change in our views in the last few years. Abrasions occur in the mucosa without causing ulcer. Hyperacidity is now considered an effect rather than a cause. Septicemia is not entirely proved to be the cause, but is largely so considered. We were formerly not diagnosing the great majority of these cases. The diagnosis is best made by careful attention to the history.

#### Diagnosis and Medical Treatment

DR. EDWARD MCGUIRE, Richmond: Too much appreciation cannot be given to the roentgen ray, but at the same time roentgenologists are prone to furnish a diagnosis without always furnishing roentgenographic proof. Formerly we attached much importance to gastric neuroses; now we look for more definite lesions.

#### Surgical Treatment

DR. STEPHEN WATTS, Charlottesville: It is of importance to continue medical treatment after surgical treatment. The best surgical procedure is destruction of the ulcer by cautery, excision and cautery, plus a gastro-enterostomy. Excision and destruction should be practiced if not too dangerous to the patient. A specimen may be examined for malignancy before using the cautery. Shock is not a contraindication to operation in cases of acute perforation. My experience in operating for hemorrhage is an unhappy one.

#### DISCUSSION

DR. SHELTON HORSLEY, Richmond: The chief thing we expect by any treatment is the relief of pain. The patient may not have pain for years and yet the roentgen ray shows ulcer still existing. When the ulcer reaches the muscular layer there is pain. Pain is due to pressure, and this is due to hyperperistalsis. Gastro-enterostomy relieves the excessive peristalsis. Hyperacidity causes hyperperistalsis. Gastro-enterostomy, if carefully followed up, will not give the fine results claimed for it. Symptoms of all sorts are not entirely relieved.

DR. D. C. VAN DERHOF, Richmond: In determining on the method of treatment there are three principal factors to consider, first, the location of the ulcer by roentgen-ray methods, and the age of the patient; second, complications such as ulcer perforation, located within the abdomen, and third, the temperament of the patient. Medical treatment must be carried out with pertinacity, over a period of sixteen months or two years. When the patient gets free of pain he is likely to neglect the treatment. The best argument for medical treatment is the result of surgical treatment relieving the hyperacidity.

DR. J. K. HILL, Richmond: I do not believe that there is anything as a medical cure of ulcer. There may be a mitigation of the symptoms for fifteen or twenty years, and the ulcer still be in existence.

DR. A. M. WILLIS, Richmond: Ulcer in the stomach is always the beginning of carcinoma of the stomach. If there be any virtue in medical treatment, of how much more value it is if the ulcer has been excised.

#### Hemoptysis

DR. E. E. WATSON, Salem: The treatment is prophylactic, immediate and posthemorrhagic. Codein, in one-quarter grain dose, quiets the patient and controls the pulse. I advise against the use of morphin. It predisposes to bronchial pneumonia. The nitrites cause general vascular dilation. The effect of nitroglycerin, one one hundredth grain, under the tongue, lasts for forty-five minutes; then sodium nitrite should be used. The patient should be propped up at 30 degrees or lie on the side. I cannot see that atropin and emetin have been of any value. Horse serum or diphtheria antitoxin has been beneficial, as has also been strapping the chest. We use artificial pneumothorax. No walking should be allowed for two or three weeks, and the patient should be cautioned against lying with the arms above the head. Furthermore, overtreatment should be avoided.

#### Home Treatment of Pulmonary Tuberculosis

DR. W. E. BROWN, Catawba Sanatorium: A large number of these patients are benefited by home treatment, and many cases are arrested. It is a case of home treatment or no treatment for the great majority of persons. Sputum cups and gauze handkerchiefs that can be burned should be used. Nothing should be placed in the mouth except toothbrush, food and drink. Cough can be controlled largely by will power. Cough is sometimes a reflex from wax in the ears, or from enlargement of the lingual tonsil. Vasomotor depressants, such as nitroglycerin or sodium nitrite, should be given for hemoptysis. Three substantial meals, with a glass of milk at each meal, and one between meals, should be given. The patient can do as well in his own climate as in any other, if he is properly cared for. The patient should study constantly how to relax completely. Recovery may be expected in 75 per cent. of incipient cases by strict attention.

#### DISCUSSION

DR. CHARLES R. GRANBY, Norfolk: For control of cough I have been using inhalations of chloroform. I have it mixed with creosote and alcohol so that it can be left with the patient.

DR. B. B. BAGBY, West Point: Personal experience convinces me that patients sleeping outdoors should have on more underclothing. I use two good suits of heavy underwear and two pairs of yarn socks. Also, the bed should be warm when the patient gets into it. The old fashioned bed warmer made of a slab of soapstone well heated and placed in the bed is excellent. Another thing is the matter of cleansing the teeth; stress should be laid on this.

#### Group Medicine and Its Feasibility and Value to Patients and Physicians

DR. J. ALLISON HODGES, Richmond: Physicians should learn from the industrial world as to the value of organization, not for gain but for service. The very rich and the very poor get the advantages of specialists, but the great rank of the people do not. The general practitioner needs the specialist and vice versa. It is feasible in any community of 3,000 or more to use team work. When this is established and in working order, medicine will have an impetus it has never had before.

#### Bladder Diverticulum

DR. R. L. PAYNE, Norfolk: Bladder diverticulum should be suspected in all cases of persistent cystitis with foul urine. The diagnosis is suggested by the clinical features, but is made definitely by the cystoscope, lead catheters and cystograms. As a last resort we may fall back on an exploratory incision. In cases of small multiple diverticula, especially in women, weak silver irrigation should be employed. Most men use it too strong. I use from eight to fifteen drops of a 25 per cent. solution in a pint of water.

#### DISCUSSION

DR. S. N. MICHAUX, Richmond: The cystoscope is a very unreliable means of diagnosis. We frequently find the orifice very small, almost occluded. Unless we are equipped with multiple cystoscopes we shall not be able to explore

the entire globe of the bladder. Cystograms may not divulge the diverticulum. All means of diagnosis should be used. Cystograms are often unreliable. The bladder is often not sufficiently distended. If the patient is narcotized with morphin, more distention will be permitted. One of the most significant symptoms is finding a profuse discharge of blood or pus after the bladder has been emptied with the catheter. The reason the operation mortality is high is that few patients have adequate preliminary treatment; they are septic when the operation is begun.

DR. T. J. HUGHES, Roanoke: It is essential to use pre-operative antiseptic treatment. I should like to have Dr. Payne tell us how to proceed if the diverticulum is at or very near the ureter. Some competent urologists advocate the removal of the kidney, but I do not agree.

DR. W. H. RIBBLE, Wytheville: I should like Dr. Payne to compare argyrol with silver nitrate, as an irrigation.

DR. R. L. PAYNE, Norfolk: I have never seen any irritating effect from sodium bromid. I have used thorium and potassium iodid. I have seen irritation from the potassium iodid. The most dependable thing for last resort is a lead catheter. If the catheter should enter the diverticulum a lead catheter should be inserted and the roentgen ray used. The bladder should be washed out with a 1:250 hydrochloric acid solution. I do not use argyrol any more. I think silver nitrate is better if used weak enough.

## Current Medical Literature

### AMERICAN

Titles marked with an asterisk (\*) are abstracted below.

#### American Journal of Diseases of Children, Chicago

November, 1919, 18, No. 5

\*Results of Thymus Extirpation in the Dog. Review of Experimental Literature on Thymus Extirpation. E. A. Park and R. D. McClure, Baltimore.—p. 317.

**Thymus Studies.**—Park and McClure report in detail a critical review of the literature on thymus extirpation and the results of their own observations made on dogs. They believe they have shown that thymus function is absolutely unessential to life; that there are other explanations than deprivation of thymus function for the symptoms and pathologic changes which have been reported in thymectomized animals, and that those explanations must be considered seriously in the interpretation of all positive experimental findings, and, further, that for the interpretation of the positive experimental findings reported by some investigators these explanations become absolutely essential. In putting valuations on the results which have been obtained by means of thymus extirpation, the greatest importance must be given to the fact that the symptoms and pathologic changes which have been ascribed to deprivations of thymus function are almost without exception the symptoms and pathologic changes which occur in laboratory animals as the result of confinement, improper food, unhygienic conditions, bacterial and parasitic infections and are identical with or closely related to those which have been reported after the removal of at least two organs of internal secretion in addition to the thymus, after excision of the carotid bodies and after a number of different abdominal operations. The authors were unable to affirm the claims of other workers that extirpation of the thymus produces any detectable alteration in the hair, teeth, contour of the body, muscular development, strength, activity or intelligence of the experimental animal. Extirpation of the thymus probably does not influence growth or development. The possibility that it may cause retardation in development and delayed closure of the epiphyses, however, cannot be excluded absolutely. Extirpation of the thymus probably produces no alterations in the organs of internal secretion. It is possible that it produces well marked changes in the organs of internal secretion in the period immediately following thymectomy which was not covered in these experiments.

\*Comparison of Certain Antigens Used in Complement Fixation Tests in Pulmonary Tuberculosis. H. C. Young and J. P. Givler, New Haven.—p. 476.

Employment of Rest and Exercise After Tuberculous Patients have Returned to Work. H. M. Kinch, Saratoga Lake, N. Y.—p. 487. Food Results of Employment of Ex-patients to Tuberculosis Sanatorium. H. L. Barnes, Wadum Lake, R. I.—p. 491.

\*Condition of Patients Twenty Years After Discharge from Trudeau Sanatorium. F. H. House, Trudeau, N. Y.—p. 497. Ancient Hindoo Knowledge of Tuberculosis. W. F. Petersen, Chicago.—p. 500.

**Acid Fastness of Tubercle Bacilli.**—Suyenaga reports experiments to influence the acid fastness of tubercle bacilli by cultivation. He grew a comparatively avirulent strain on several mediums; and finds that rapid transfer and rapid growth of the younger border of colonies did not noticeably affect acid fastness, the younger cultures were not much less acid fast than older ones. On a nonnutrient medium of agar in water, acid fastness was greatly reduced but not absolutely destroyed. Within wide limits the reaction of the medium had no marked effect on acid fastness.

**Comparison of Various Antigens Used in Complement Fixation.**—Young and Givler made tests on a large number of serums with three antigens, namely Cooper's antolysate, Petroff's methyl alcohol soluble antigen and Wilson's. The three antigens did not differ greatly in the percentage of positive findings in known cases of pulmonary tuberculosis (Petroff's 66 per cent.; Cooper's 63 per cent., and Wilson's 57 per cent.). The positive findings in the various classes of cases for the three antigens was 11 per cent. for clinically normal individuals, 58 per cent., questionably tuberculous; 56 per cent., incipient; 64 per cent. (66 per cent., sputum positive), moderately advanced, and 71 per cent. far advanced. Moribund cases, 44 per cent., gave lower percentage than the definite cases. Fifty to 60 per cent. of positive syphilitic serums gave cross fixation with the three antigens. The serum of only one out of seven guinea-pigs (of a total of seventy-five) proved unsuitable for complement fixation tests.

**Rest and Exercise for Tuberculous Patients Who Have Returned to Work.**—Kinch pleads for the importance of a more or less systematic regimen for tuberculous patients who have ceased active treatment and have returned to work. He outlines measures that should be employed for several years after an arrest or "cure" has been established. Among other measures which he is convinced would make for better ultimate results in tuberculous therapy he mentions a much longer period of sanatorium treatment, more thorough employment of rest at the house or heavy manual work, and greater care of patients after discharge. Patients should never be allowed to return to hard manual work, but should be placed in a suitable locality and at occupations that do not call for muscular work.

**Condition of Patients Twenty Years After Discharge from Trudeau Sanatorium.** The Trudeau sanatorium has succeeded in tracing 814 patients, who have been discharged from the institution twenty years or more. Of these 666 or 81.8 per cent. are dead, while 148, or 18.2 per cent. are alive. Heise further notes that of those discharged with the one case active, 4 per cent. are now known to be alive and 15 per cent. are alive of those who were classified as "inactive" on discharge.

**Spleen in Resistance to Infection.**—In order to arrive at some definite conclusion as to the importance of the spleen in opposing infection, rats were splenectomized by Morris and Bullock. From a similar number of control rats one testicle was removed. Both sets of animals were then exposed to chance laboratory contagion with the bacillus of rat plague. The results showed in a very definite manner that while these animals may get along fairly well without the spleen in the absence of any infection, the reverse is the case when the organism is put to the strain of resisting acute bacterial invasion. Under the circumstances, the authors feel compelled to infer that the spleen normally aids tremendously in resisting infectious processes in rats, and that its removal temporarily robs the body of its resistance until such a time, at least, as compensatory processes will have had a chance to reestablish this. Bearing this in mind, some of the fatalities following splenectomy, especially where death was attributed to infection, may find a ready explanation and tend to increase caution in the removal of this organ.

**Life Expectancy After Gastric Ulcer Operations.**—Of a series of 2,431 patients operated on for gastric and duodenal ulcer in the Mayo clinic between 1906 and 1915, all but 108 were traced. The figures quoted by Balfour show that the operative mortality from all causes in 545 cases of gastric ulcer in which operation was done during this period was 4.5 per cent., while in 1,684 cases of duodenal ulcer the operative mortality from all causes was 2 per cent. Gastric ulcer carries, therefore, twice the operative risk of duodenal ulcer. Five hundred and twenty-one gastric ulcer patients were under observation on the average of 3.6 years, and in that time 88 (17 per cent.) died from all causes. One thousand six hundred and fifty-one duodenal ulcer patients were under observation on the average of 3.4 years, and in that time 85 (approximately 5 per cent.) died from all causes. Ninety-one gastric and duodenal ulcer patients were under observation on the average of 3.8 years, and in that time 9 (10 per cent.) died.

**Operative Treatment of Peptic Ulcer.**—Deaver has done fifty-six operations for peptic ulcer with two deaths. In all but two of the entire series, closure of the perforation followed by gastro-enterostomy was the method used.

**Condition of Appendix in Laparotomies.**—One hundred and sixty-seven, or almost exactly one third of the patients operated on in the gynecologic service at the Boston City Hospital and whose histories were analyzed by Williams and Slater showed changes in the appendix. In sixty-four instances the condition demanding operation was inflammatory disease of the uterine appendages. In the majority of these cases the involvement of the appendix was secondary to the pelvic process. This leaves, however, 103 abnormal appendices not associated with any inflammatory process in the pelvis and producing no symptoms or signs which could be brought out by a careful history or a thorough abdominal and vaginal examination. Perhaps, two or three of these were cases in which the appendix was found adherent to a fibroid of the uterus or a cyst of the ovary. In the remainder, approximately 100 cases, the appendix condition cannot

be ascribed in any way to pelvic disease, and, therefore, a coincidence so far as any gynecologic cause is concerned. With few exceptions the lesions of the appendix were chronic in nature.

**Lymphosarcoma and Hodgkin's Granuloma.**—Levin's experience has shown that the results of the radium and roentgen-ray treatment of Hodgkin's disease are extremely encouraging, and therefore he feels that these agents should be employed in every case as soon as the diagnosis is made. However, the treatment must be conducted with great energy; half measures are less than useless.

**Benign Xanthic Extraperiosteal Tumor.**—Seventeen cases of benign xanthic extraperiosteal tumors of the extremities containing body giant cells examined in the Mayo Clinic are analyzed by Broders. The upper extremities were involved in ten cases; the lower extremities in seven cases. A history of injury was given in six cases, a local excision of the tumor was done in twelve cases; amputation in three cases. Fifteen patients were traced. Fourteen are living. There have been no recurrences. The patient reported dead died from general decline at the age of 73. There had been no recurrence of the tumor more than seven years after local excision.

**Glioma of Buttock.**—Kimpton reports two cases of glioma of the buttock. Both patients were 14 weeks old. In one case the cyst extended upward in front of the vertebra to the first lumbar vertebra. It had had apparently some connection with the spinal canal from the side of the coccyx and the anterior surface of the sacrum. On the inner side of the sac was a large, red, soft, cellular, infiltrating mass. In the other case the tumor was adherent to the rectum for about two and one-half inches. When the pedicle was freed, except for final attachment, it was found to come from the inner surface of the coccyx, the lower end of which was removed with the tumor.

**Results of Experimental Resection of Knee-Joint.**—Ely claims that after a fracture or a resection the whole tendency of the resulting process between the bones themselves, unless they are held firmly together without motion, is the separation of the bone ends by fibrous tissue and fibrocartilage, with a new joint, before the bones can unite. In order for bony union to occur, the bone ends must be held in contact, absolutely immobile. In the ordinary fracture, nature provides the immobility by a bony callus outside the cortex, in the periosteum. In those situations where the bony callus is not laid down, a false joint usually results unless complete immobilization is maintained until actual union of the bone ends occurs. In resections the external bone callus does not form. Hence, unless the mechanical requirements of complete rest can be answered, resections of joints are not followed by bony ankylosis.

- Surgical Risk and Preoperative Treatment. F. H. Washburn, Holden, Mass.—p. 585.

**Silent Renal Calculi.**—In nearly 4,000 necropsies at the Massachusetts General Hospital disclosing stone in the kidney or ureter, there was only one case with a completely negative history and urinary findings and a normal kidney macroscopically and microscopically; but there were four cases without symptoms and with a negative urine; six cases without any damage to be demonstrated at necropsy; and fifteen cases where the damage was too slight to compromise the integrity of the kidney. Two patients with stones in the calices known to have been present for at least six or seven years, who had had repeated attacks of renal colic, showed one a normal and the other an essentially normal kidney. Young says that stones in the ureter more surely do kidney damage than do stones in the pelvis or calix, and a small stone, if arrested in the ureter, may do as much

**Diagnostic Serum for B. Diphtheriae.**—The diagnostic serum used by Mason was developed in a rabbit, its titer being positive in 1:320. This was developed with strain No. 1. All cultures were isolated in pure culture by plating onto the original throat culture on Loeffler's blood serum coagulated in Petri dishes. Agglutination reactions were run with fresh saline suspensions treated at 62 C. for fifteen minutes, it being found that a lower temperature for that time would not kill the majority of the strains. After setting up, the reactions were run in a water bath at 56 C. for four hours, then kept in an icebox over night, being read in the morning. Controls were run with normal rabbit's serum, dilution 1:20 and with saline. Virulence for a guinea-pig was determined with a limited number of the strains, it being impossible to determine it in all cases due to a shortage of animals. These tests were performed by the subcutaneous method. Ten strains of organisms, morphologically diphtheroid, isolated from various sources, in no case gave any agglutination with the diagnostic serum prepared with strain No. 1 (*B. diphtheriae*). The controls in these cases were also negative. In only one case out of the sixty-five strains examined did the organism fail to agglutinate and none of the strains showed any agglutination in normal rabbit's serum in dilution of 1:20 or in saline.

**Basal Metabolism in Exophthalmic Goiter.**—About sixty determinations of basal metabolism have been made by Christie on patients with various forms of goiter. The majority of these determinations have been on patients who have shown ample clinical evidence for a diagnosis of exophthalmic goiter. Christie has established definitely in his own mind that an increase in metabolism is a most constant symptom of exophthalmic goiter, and that the degree of this increase is a very constant quantitative measure of the severity of the disease, and that other forms of goiter do not give values which are above normal and that there are doubtless many border line cases which, without a quantitative measurement of the metabolism, could be looked on with perfect justice as cases of exophthalmic goiter without increase in metabolism. Furthermore, Christie says, the simple portable apparatus described by Benedict is entirely feasible for the average clinic, because it is simple to manipulate, cheap and gives very accurate results.

**Obstetrics.**—Denison points out that the conscientious general practitioner must realize the necessity of prenatal care; must be able to diagnose and handle the usual and even

more complicated presentations; must be judicious enough to determine the indications for forceps or cesarean section. He must know how to handle placenta praevia and postpartum hemorrhage; as well as how to repair lacerations and obviate or treat infection. Those who will not give obstetrics the attention it deserves should leave it alone, while those who have a liking and facility for it should not hesitate to specialize, as there is a big field for their efforts.

\*Cutaneous Anthrax. E. F. Neve—p. 559.

Rupture of Large Intestine: Operation; Death. E. Huntley—p. 559.

**Advantages and Disadvantages of Gauze Packing.**—In Maylard's opinion the disadvantages of gauze packing would seem to so greatly outweigh the advantages that but one conclusion appears warranted—that gauze packing should be avoided, except under definite and clear limitations. These limitations may be thus expressed; the use of as small a piece of gauze as possible and for as short a time as possible, which equally comotes the avoidance of large packs retained for several days.

**Cutaneous Anthrax.**—The treatment adopted by Neve in these cases is very thorough cauterization with a red hot button cautery. Excision and incisions he regards as almost equally dangerous, tending as they do to open up fresh planes of communication, and thereby promote systemic infection. The natural local reaction to the pathogenic irritant is very strong. There is most vigorous leukocytosis. As a rule, the blood is not infected. The cautery, while destroying the virus, also increases the local reaction. Clinically, Neve's records point to this as the most satisfactory method of local treatment. Sclavo's serum has been recommended. But most of these patients, when they come under treatment, must have already produced their own anti-toxins; those who have not and are almost or quite moribund are hopeless. Seven of a series of seventy-five cases terminated fatally, giving a mortality of 9.3 per cent.

\*Tannin Alcohol as Disinfectant of Skin. T. Orimo—p. 1.

Influence of Reduction of Oxygen in Air and of Atmospheric Pressure on Blood Pressure, Respiration, Pulse and Grasp. H. Hara—p. 2.

\*Case of Arsenophanin Injection Followed by Jaundice and Pigmentation of Skin. U. Nagai—p. 3.

**Tannin Alcohol as a Disinfectant of Skin.**—Tannin alcohol (10 parts of a 20 per cent. watery solution of methylene blue added to 100 parts of 20 per cent. tannin alcohol) recently recommended by Wederhake as a useful skin disinfectant is said to be as effective as iodine tincture, without any irritating effect on the skin. Orimo established the following facts: (1) that staphylococci, streptococci, *B. coli* and *B. pyocyaneus* were killed within thirty seconds in vitro;

(2) that the sterilization of threads impregnated with suspensions of the above mentioned microbes took place in from one to ten minutes, while it was affected within one minute by iodine tincture; (3) that the surface of the normal skin painted with this disinfectant, though not sterile, was almost free from pus forming microbes, as seen in the case of iodine tincture application; and a small portion of the skin, comprising all its layers, when put into a suitable culture medium, generally had growths of microbes belonging to the groups of *B. subtilis* and staphylococci, this also being the case for iodine tincture; (4) that this disinfectant was unable to penetrate as deeply into the skin as iodine tincture; (5) that in twenty-seven cases in which operation was done aseptically by this method of skin disinfection, all the wounds showed primary healing; (6) that this disinfectant was absolutely nonirritating to the skin.

**Arsphenamin Injection Followed by Jaundice and Pigmentation of Skin.**—Nagai's patient received an intravenous injection of a diluted solution of 0.3 gm. arsphenamin, and one week later a second intravenous injection of a concentrated solution of 0.6 gm. of neo-arsaminol was given. The jaundice and black pigmentation of the skin developed in about two weeks after the second injection, and the patient had the appearance of one suffering from Addison's disease, though he complained of no subjective symptoms. The jaundice disappeared in three months, and the black pigmentation of the skin, although much improved, was still traceable from deposits of pigment, after seven months.

Cancer of Esophagus. T. Iriwawa.

**Cholesterin Content of Blood in Kakke, Anemia, Syphilis and Hemiplegia.**—Yamakoshi reports that the cholesterin content of ten normal Japanese varied from 130 mg. to 160 mg. in 100 c.c. of blood plasma. The cholesterin in forty cases of kakke disease was generally decreased but the decrease is by no means specific. The cholesterin was also decreased in cases of anemia and syphilis. Three cases of hemiplegia were examined. In all there was a remarkable increase in cholesterin.

**Relation Between Perforation of Heart and Death.**—Ando states that the length of the wound bears an important relation to the time of death. An oblique wound through the cardiac muscle layer causes a more delayed death than does a perpendicular wound. By tamponing the heart, a more speedy death occurred. If the wound involves the cardiac nerves, death occurs more rapidly than otherwise. If the wound is present in a more actively motile portion of the heart muscles, a more sudden death occurs than when it is present in more sluggish portions.

**Reaction of Bacteriologic Mediums.** McIntosh and Smart claim that failures to adjust the reaction of a bacteriologic medium correctly arise chiefly from the use of unsuitable indicators, difficulty in judging the indicator "end point,"

titration at the boiling point, and the hydrolysis which occurs during the process of sterilization. The chemical titration method has been found to be quite a reliable means of adjusting the reaction in routine practice, and by the procedure described the authors find that it is quite easy to adjust with considerable accuracy the reaction of a culture medium to the desired point. By means of specially prepared graph the Eyre system will, with certain precautions, indicate  $pH$  values. In the colorimetric method the preparation of the accurate standard solutions required is much more difficult than is usually believed, and the error in the reaction is often quite appreciable when tested against the hydrogen electrode. The ideal method of adjusting the reaction would be by the hydrogen electrode, but the use of this apparatus requires a technical skill and knowledge which places it at present beyond ordinary laboratory application.

**Traumatic Rupture of Intestine.**—It used to be taught that the most fixed part of the intestine, being unable to escape the compressing force, was the part most frequently ruptured. In theory this seems probable, but in actual fact the reverse is true. The most fixed parts of the intestinal tract are the duodenum and parts of the large intestine other than the cecum, the transverse and pelvic colon, and the rectum. Experience shows, however, that the most movable parts of the large gut—the cecum, the transverse colon, and pelvic colon—are the most frequently ruptured, in that order. The coil of intestine nearest the abdominal wall at the point struck is usually the coil in which rupture takes place, and in so far as the first few feet of the jejunum and the last few feet of the ileum before the ileocecal junction are usually in this position they will tend to be injured. The mechanism is simple. If the abdomen is struck above the umbilicus the force is transmitted to the first few feet of the jejunum. The mobility of this coil allows it to be pushed back till it is checked ultimately by the vertebral column, and between the latter and the moving body it is crushed and ruptured. The frequency with which one finds a small tear in the posterior parietal peritoneum close to the summit of the vertebral column would suggest this mechanism, also the bruising and laceration at the tear. A parallel situation occurs at the ileocecal junction. There is no sure and invariable sign or symptom, or group of signs or symptoms, which render the diagnosis certain. Occasionally, a group of symptoms such as rapid pulse, marked abdominal rigidity and extreme tenderness, with the history, and with visible bruising and fracture of the ribs, makes rupture of the intestine almost a sure diagnosis; while, on the other hand, the absence of these signs and symptoms makes such a diagnosis improbable. The only two signs which appear of real use in diagnosis are cutaneous hyperesthesia and edema in the left flank. The difficulty of diagnosis thus makes it clear that if there exists in the mind of the surgeon a suspicion that the intestine is ruptured, the right procedure is to open the abdomen and see, providing the patient can stand the added shock of the operation.

**Celiac Disease or Boric Acid Poisoning.** In Forsyth's case the poisoning was due to the milk fed this 8 months old baby. It contained boric acid to the amount of 5 grains to the pint—i. e. the child had been taking from 75 to 10 grains of the preservative daily. With no other change in the treatment than a new supply of the cow's milk the aggravation of the symptoms ceased, and within a couple of days the child began to get well, though it was some months before she was herself again. The symptoms never recurred.

**Vaccine in Influenzal Pneumonia.** The vaccine used throughout was the official army formula (30 million *B. influenzae*, 100 million pneumococci and 30 million streptococci, in 9 mmims). The dosage used was at first 3 mmims (and later 5 mmims) for the first dose, 5 mmims (and later 8 mmims) for the second. No bad effects were observed, the condition being unaltered in the few cases where it was not improved. The vaccine was only administered in severe cases with definite lung signs, actually in thirty-five cases out of a total of 216 cases of influenza. Out of the thirty-five cases there were three deaths. One patient had only one small and late dose and had rather

mitral stenosis, the second and the third patients appeared overwhelmed by the infection on admission; one patient had much hemorrhage from the lung, the other suffered from malarial debility of long standing. Each of these patients had two small doses of vaccine but died in a few days, without favorable response. Milne and Rogers are convinced of the improvement in general condition, in character of the sputum, and feeling of well-being of the patients that followed the injections in the majority of the cases.

**Hypertonic Salt Solution in Treatment of Tuberculous Abscess.**—To obtain a lymphatic current in the abscess cavity from the circumfoveal area, Durante uses a sterilized hypertonic salt solution composed of magnesium chlorid, 2.5 gm.; distilled water, 100 c.c.; liquor formaldehydi, 0.5 c.c. The treatment of tuberculous abscess with hypertonic salt solutions is carried out in the same way and on the same indications as treatment with iodine solutions; but the abscess cavity should be emptied, washed out and filled with salt solution every four days. This frequency of treatment is called for by the fact that the quantity of lymph collected in the abscess cavity by osmotic pressure is great and produces a slight distension of the tissues, and, that this distension, united with active hyperemia, causes a feeling of pain. The quantity of liquid that Durante leaves in the cavity varies from 10 to 40 c.c. according to (1) the capacity of the cavity, and (2) the greater or lesser degree of vascular action, which varies with the individual.

Perforation of Cecum by a Pin: Death from General Peritonitis. J. A. Maeween.—p. 785.

**Serum Treatment of Bacillary Dysentery.**—According to Klein antidysentery serum should be given in large doses, from 60 to 100 c.c. It is best given intravenously. It is most efficacious when given early in the disease. From the point of view of serum treatment a severe case of bacillary dysentery may be considered in three stages: (a) From the onset of the illness to a period somewhere about the fifth or sixth day. During this stage antidysentery serum (especially if given intravenously) has a most favorable effect, both as regards averting a fatal result and hastening recovery. A minority of cases fail to respond even to this early treatment. (b) An intermediate stage, from about the sixth to the tenth day. A patient having reached this stage is likely either to die or recover, irrespective of serum treatment. Nevertheless, the rate and completeness of recovery may still be affected by serum, especially if given in large doses, such as 100 c.c. (c) A third stage—the stage of "dehydration and profound intoxication"—generally starting about the tenth day. During this phase of the disease serum treatment is practically useless. A minority of patients who have survived to the tenth day or beyond it (without passing into the third stage) are still benefited by serum given in sufficient amount. In a series of 973 cases of bacillary dysentery, true dysentery arthritis occurred in eight instances. The arthritis has no relation to the arthritis of serum sickness, five of the eight patients had not received serum. Neither had the arthritis any relation to previous injury. Clinically, it might have been mistaken for gonorrhoeal arthritis, but in no case was there a history of such infection. The treatment consisted in immobilizing the joint by the application of a McIntyre's splint and the removal of some of the fluid to relieve the pressure; from 60 to 100 c.c. was removed, generally much to the relief of the patient.

**Serum Treatment of Bacillary Dysentery.**—The statistics given by Waller tend to show that in cases in which serum was used early, the acute stage is of shorter duration, the tendency to chronicity is less, and convalescence is more

satisfactory than when the serum was used late in the course of the disease, or by alternative methods. As a routine, in fairly severe cases as soon as the diagnosis had been made on clinical grounds, 140 c.c. of serum was given in three subcutaneous injections at eight hour intervals during the first twenty-four hours, while in cases of less severity 100 c.c. in two subcutaneous injections only was given during this period.

**Experimental Edema in Monkey.**—Harden and Zilva describe some preliminary experiments instituted with the object of studying the influence on monkeys of a diet free from the fat soluble A factor. As an antiscorbic, lemon juice, from which the acids had been removed according to the method of Harden and Zilva, was employed, a dose equivalent to 4 c.c. of the original juice being administered daily to each animal. The diet was, therefore, complete in every respect, except that it lacked the fat soluble A factor and was low in fat. All the animals had been kept for 198 days on the experimental diet before it was modified by the addition of butter fat and olive oil. During the whole of that time, although they did not grow, they showed no signs of ill health.

**Antistreptococcus Serum in Influenza.**—Hughes is convinced that antistreptococcus serum aborted or considerably shortened the course of the disease in ordinary cases that were seen early. Whether any of these patients would eventually have developed pneumonia if they had not been given serum is, of course, impossible to say. The fact, however, that the serum was proved to have a beneficial effect in pneumonic cases justifies Hughes in thinking that it sometimes aborted a potentially pneumonic one. The value of the serum, speaking generally, depends on whether a streptococcus is implicated in any case, and on the treating of the patient in the early stages of the disease. In those very virulent and fulminating pneumonias characteristic of the epidemic the serum was disappointing. In the very grave pneumonic cases the danger of anaphylaxis or an unreliable serum should be considered carefully.

\*Primary Pulmonary Tuberculosis in Children. R. G. Canti.—p. 71.  
Certain Phenomena Associated with Protein Shock Reaction and Intravenous Vaccine Therapy. A. E. Gow.—p. 82.

**Treatment of Malaria.**—Experience has convinced Cowan and Strong that many cases of "malaria" are really suffering from quinin poisoning. The amount of quinin that is administered is often large, and the smaller doses are continued for too long. In consequence, a condition of debility is induced, which, as its cause continues, also persists. Heroic doses of quinin do not cure chronic cases. The sheet anchor in chronic cases is arsenic. It, too, should be given in courses of from three to six weeks. It may be given by the mouth and pushed to full doses. If it upsets digestion, or fails to produce definite improvement, the next course should be given intravenously. Its special indication is anemia, in particular of the pernicious type. But all drugs are of little value if attention is not paid to rest and next protection from the sun and chill. Without attention to these apparent details all treatment is unlikely to produce rapid or permanent results.

**Pulmonary Manifestations in Malaria.**—Although malaria is frequently complicated by pneumococcal infection, Falconer maintains that numerous cases occur in which there are notable changes in the lungs without any evidence of superadded infection. These may present the physical signs of bronchitis, pulmonary congestion with more or less definite evidence of consolidation, or massive collapse of the lung. In many cases the symptoms at first are almost

entirely pulmonary and the malaria infection may be entirely overlooked. Its recognition at the earliest possible moment is important, as untreated with quinin there is a great liability for the lung to become secondarily infected with the development of true inflammatory changes.

**Blood Pressure in Right Ventricle in Pleural Effusion.**—In these experiments the blood pressure in the right ventricle was measured by passing a hollow needle through the skin and thoracic wall into the ventricular cavity, and connecting the needle to a Hürthle manometer by pressure tubing. Continuity between the blood in the ventricle and the tambour membrane of the manometer was established by filling the rubber tube and tambour with a 10 per cent. solution of sodium citrate. Pleural effusion was produced by infusing a quantity of defibrinated blood from another animal of the same species into one or other pleural cavity, usually the right. The most important change observed in all the experiments was the rise in mean diastolic pressure in the right ventricle. This was found at the first examination after the pleural effusion had been produced, and in two instances it was maintained at eighteen and at sixteen and one-half hours, respectively. It had subsided at twenty-three hours in one animal which was recovering, and also at twenty and one-half hours in another animal, which was dying. It was only in the first goat, which received the largest volume of fluid, that there was any considerable rise in the mean systolic pressure, which must represent the pressure in the pulmonary artery. Here is evidence that the bulk of fluid in the pleura was sufficient to cause actual obstruction to the pulmonary circulation.

**Primary Pulmonary Tuberculosis in Children.**—The findings of eighty-four necropsies made on children up to 10 years of age, carried out by Canti are recorded. Sixteen (19.05 per cent.) showed tuberculous lesions. The lung focus was found to be most often the size of a pea. Single lung foci were found on eight occasions. Two foci, apparently about the same age, were found in one case, and in one case showed more than two foci, of which one, being cavernous, appeared decidedly older than the remainder. In the majority of cases the focus was caseous or fibro-caseous. In one case it was calcareous, in one case liquefying, and in one case there was cavitation. In all cases the lung focus was situated just beneath or involving the pleura. In the cases where only one lung focus was present it was situated in the left lower lobe in three cases, in the right upper lobe in two, in the left upper lobe in two, and in the right middle lobe in one. Tuberculosis of the mediastinal glands, other than acute military tuberculosis, was found in twelve cases. Tuberculous lesions of the intestines were found in four cases. Tuberculous mesenteric glands were present in seven cases. Broncho-pneumonic changes in the lung tissue, due apparently to the direct spread from a tuberculous lesion, were found in three cases. Military tuberculosis was found in five cases where a lung focus was present, and in two cases where no lung focus could be found. From these findings it would, therefore, appear highly probable that tuberculosis of the mediastinal glands is secondary to a focus in the lung, and, further, that the focus in the lung is primary and not secondary to a focus elsewhere.

**Bulletin Medical, Paris**

Oct. 15, 1919, 33, No. 44

\*The Polymorphism of Tuberculosis. Emil Sergent—p. 579

**The Polymorphism of Tuberculosis.**—Sergent emphasizes that the disease in adults is the flaring up of infection acquired in childhood or reinfection after partial immunization. This flaring up or reinfection is announced by a set of disturbances and symptoms which are usually called "pretuberculosis" but which had better be called the "pre-relapse of tuberculosis." He declares that it is wrong to say that tuberculosis is the most curable of diseases; the cure of tuberculosis is exceptional. But a first attack confers a relative immunity. To maintain this immunity the resisting powers must be kept at a high level. Tuberculosis cannot progress—in the adult at least—if the soil is

unfavorable. Prophylaxis must combat weakening of the race and of the individual. Treatment must combat the bacillus (serotherapy), and tone up the organism until the soil becomes unfavorable for it (repose, fresh air and nourishing food, and medication to restore minerals and especially calcium).

- \*Nystagmus and Nodding Spasm. C. Lafon—p. 404
- \*Advisability of Wearing Light Gauze Underwear Inside Flannel Underclothing. Rymaillac—p. 416
- \*Medical Impressions of America. Béguin and Piquet—p. 407.

**Aviators' Neurosis.**—Cruchet explains aviators' neurosis as merely ordinary neurasthenia and psychasthenia but colored by the reactions special to aviation.

**Association of Nystagmus and Nodding Spasm.**—Lafon saw a boy of 12 with rotatory nystagmus who in early childhood had had nodding (bowing) spasm. He has also seen horizontal nystagmus in youths and soldiers and in one man of 30, accompanied in all with nodding spasm, but without isochronism, except that the nystagmus usually appears only as the nodding ceases. He theorizes to explain the mechanism.

**Impressions of the United States.**—In this further installment of their report, Béguin and Piquet describe their impressions of the hospitals in this country, saying in conclusion that America leads the world perhaps in surgery of the duodenum and of goiter. "But," they add, "more than the importance of the men and, generally speaking, of science in America, is the abundant resources at its command and the collective discipline which enables the chief and the personnel to accomplish the maximum of work. The abundance of resources allows organization of a scope unknown in France but which singularly facilitate the task. The assistance from a numerous personnel allows the chief to accomplish what he does without exhausting fatigue. *Richesse et organisation, voilà, with initiative in action, the points in which America seemed to us actually superior.*"

- \*Infant Welfare Work During German Occupation of Lille. M. Hretou, H. Poncet, L. Ducano and J. Vanvers—p. 71
- \*Malaria in Infants. Henri Lemaire—p. 78
- \*Soapy Stools. E. C. Avrainet and H. Deroy—p. 81

**Restricting an Infant to Water.**—Marfan ascribes to A. Luton of Reims in 1874 the first systematic use of the *diète hydrique* as a therapeutic measure in intestinal disease at all ages. Restriction to water rests and soothes the digestive apparatus, and probably molifies the intestinal flora while replacing the fluids lost in the diarrhea, and washing out the system by flushing the kidneys and the sweat glands, with the secondary effect of combating retention of heat. The water should be plain pure water, directly from the spring, or boiled. The quantity should be about that of the food the child has been previously taking. A good rule is about 125 gm. of water per kg. of weight, up to one year. Above one year, a liter of water per day will do. Unless this much is taken, the *diète hydrique* fails of its purpose. If the child does not care for the water, it can go from six to ten hours without even water. The best way to get the child to take the water is by a teaspoonful at a time. Two teaspoonfuls every half hour for the first two hours; then four teaspoonfuls every half hour for two hours, and then six teaspoonful every half hour for two hours. Then eight teaspoonfuls every hour and the ten every hour and a half. The last third of the first twenty-four hour the child can be given more than a nursing bottle of 100 gm. of water. Water is very curative, and uncontrollable vomiting a teaspoonful of water every fifteen minutes may be preferable to giving medicine drops slowly, instilled in the mouth of the child.

every five or ten minutes. This water diet should never be kept up for more than three days, or the child will have to contend with the effects of inanition in addition. A breast fed child very rarely requires restriction to water for more than twelve hours. The resumption of ordinary feeding should be gradual and progressive, as he describes in detail. The ordinary food can be resumed more or less promptly according to the digestion, temperature and pulse findings. In favorable cases, about the twentieth day, the child is ready for the standard feeding for its age and weight.

**Principles for Infant Welfare Work.** Breton and his co-workers describe the work of the well baby clinic and the dispensary at Lille during the German occupation. As the Germans carried off all the cows, no milk was available, and, as the factories were not running, the women could not find wage-earning work and had to stay at home. The consequence was that the women were driven to suckle their infants, and that the infants had their mothers with them at home, and the infantile death rate was far lower than ever known before in the town. The conclusion seems inevitable that distributing milk stations are an evil. The mothers rely on them and do not suckle their children, and the death rate keeps high. They urge the suppression of the milk stations or *gouttes de lait*, as they are called in Latin countries. That they are unnecessary is proved by the infinitely small number of women who are actually incapable of nursing their child when circumstances compel. Another lesson confirmed by the Lille experiences is the necessity for an adequate dietary as well as repose during the last months of the pregnancy.

**Soapy Stools.**—Aviragnet and Dorencourt devote twenty-two pages to the results of research on the pathogenesis of soapy stools, and comment on the numerous points that are still waiting for solution as well as on the facts apparently established to date.

### Paris Médical

Oct. 11, 1919, 9, No. 41

\*Vaccine Treatment of Osteomyelitis. R. Grégoire.—p. 285.

\*Phlebitis of the Basilica. G. Milan.—p. 295.

\*Treatment of Laryngeal Tuberculosis. E. Halphen.—p. 296.

**Vaccine Therapy in Osteomyelitis.**—Grégoire refers to acute staphylococcus osteomyelitis and describes eight cases in infants and older children which, he remarks, upset all preconceived ideas as to the course and treatment of acute osteomyelitis in children. Treatment was with a regional staphylococcus stock vaccine until the autogenous vaccine was ready, so as to waste no time. This proved so effective that in some of the cases the regional stock vaccine was continued to the complete cure. The dose seemed to be important; at first only 0.1 c.c., representing 200 millions of the killed micro-organisms. From two to seven injections were made, the intervals guided by the reaction on the part of the heart and kidneys. The pulse runs up in eight or ten hours and keeps high for two or three days. Albumin appeared in the urine but only in minute proportions and transiently in all but one case, in which it persisted for twenty-seven days. The vaccine proved futile in the two cases with septicæmia already installed, and both children died. There is no hope from vaccine therapy if the general system is endangered too much, and the general symptoms were half-way healed. In the six other cases the children began to feel better in twenty-four or forty-eight hours. The pain subsided and they ate and slept well and within fifteen, twenty or thirty days the child was using his limb without pain. During the four months to date there has been no tendency to exostoses or sequestræ.

**Phlebitis from Infection of Skin.**—The basilic vein in Milan's case became inflamed by extension of a trichophyton lesion on the wrist. He has encountered some cases in which pustular scabies was responsible for the phlebitis.

**Laryngeal Tuberculosis.**—Halphen appeals to practitioners in general to relieve their patients with tuberculous laryngitis by blocking the superior laryngeal nerve and thus doing away with the painful dysphagia. In his extensive

experience at the Lariboisière Hospital with this class of patients, the relief has been constant, and the injection of alcohol to block the superior laryngeal is simple and easy, owing to the superficial course of this nerve. The nerve is located by the cornua of the thyroid and of the hyoid bone, and the injection of a few drops of alcohol along its course blocks it completely, and in some cases definitely. There is a sharp pain at once, especially if cold alcohol is used, but it subsides in a few seconds as the nerve becomes blocked. The edema and infiltration retrogress and the patient can eat without dread of pain. A single bilateral injection answered the purpose in some cases; others required a new injection in five or ten days, but permanent anesthesia was finally realized after a few injections. Seven was the maximum in his experience. With the patient seated in front of him, Halphen pushes with two fingers the larynx toward the right with the left hand, and explores with his thumb the groove between the thyroid and hyoid bone on the right side. Holding the thumb there, he introduces the needle on a line joining the two cornua, first perpendicularly, then parallel to the hyoid bone, 1 cm. toward the median line. The thumb feels the needle making its way under the skin between the two landmarks. Then the needle is lightly pushed in deeper as the plunger is worked. A sharp violent pain shows that the nerve has been reached. The cricothyroid membrane must be left unmolested. Others may prefer to reach the nerve by starting from the median line, following the upper margin of the thyroid and then passing upward until the nerve is reached.

\*Surgery of the Large Intestine. J. Okinczyk.—p. 581.

\*Early Symptom of Rabies. L. Robert.—p. 584.

Transactions of French Surgical Congress.—p. 585. To be Cont'd.

Oct. 15, 1919, 27, No. 59

Transfusion of Citrated Blood. R. Lewisohn (New York).—p. 593.

**Surgery of Large Intestine.**—Okinczyk protests against the general assumption that the death rate with operations on the large intestine is necessarily extremely high. The technic is difficult but not necessarily more dangerous than with operations at other points in the intestine. Among the features which render the operation difficult is the extreme thinness of the walls of the large intestine. This compels the use of fine needles and still finer suture material, and making the incision always lengthwise in the region of the straight bands, where the wall is reinforced, rather than in the rounding protruding part of the wall. Another special feature is the scanty vascularization which renders it necessary to spare and save all the vessels. Only at the angles is there anything approaching the rich vascularization of the small intestine, and the anastomosis should aim to avoid the regions where the blood supply is scantiest. The large intestine is also partially fastened to the posterior parietal peritoneum, but cleavage is easily realized as, originally, the large intestine was as freely movable as the small. He gives ten illustrations to show different points in the technic. He advocates an artificial anus beforehand as a useful preliminary and he warns that the feces in the left half of the colon are comparatively solid as a rule while the contents of the right half of the colon are more fluid. This renders it unwise to use a Murphy button in the colon, at least in the left half, as the button is so liable to become obstructed. He expatiates on the indispensable usefulness of the valve of Bauhin; the waves of antiperistalsis seem to stop here. When this ileocecal valve is lost, the subject is tormented by the distention from the reflux of gases.

**Early Symptom of Rabies.**—In the eight cases of rabies encountered by Robert in Siam, he noted the constant appearance of intense pruritus as the first and most reliable symptom of the rabies. The region of the bite was all that itched at first, but then the pruritus spread to the entire body and persisted till death. The premonitory phase is characterized by irritability, depression, weeping and this pruritus. Other writers have mentioned the pruritus but none have emphasized its diagnostic importance.

- Prophylaxis and Treatment of Nontuberculous Vertebral Disease. A. Aimes.—p. 366.
- Medicine in Persia.—p. 368.

**Morally Abnormal Children.**—Paul-Boncour is chief of the Vitry Institut Médico-Pédagogique and he says that his seventeen years of living among abnormal children has demonstrated that they can be classed in five categories: the simply unruly; the delinquent unruly, led into vagabondage and thefts by bad companions; the backward heedless, affectionate truants; the unruly who have been led into vicious practices by others. Their perversion is pronounced and numerous delinquencies are credited to them. They may belong to criminal gangs, and they may have been trained to crime, but change of environment before the age of 13 may rescue them completely. Their moral sentiments are only temporarily perverted, and it would be inhuman to exclude these unruly delinquents from normal life. He adds, however, that after the age of 13 the character is so settled that there is not much hope of reform, and he refuses to admit to his school an *instable vicie* of this type if he has passed his thirteenth year. The fifth and last group comprises the actual pervers or vicious unruly. These are vagabonds and thieves like those of the fourth group, but there is a malignancy, a cruelty which colors their actions and has always accompanied them. This perversion is constitutional. By the fifth or sixth year this perverse instinct can be recognized. One of the first evidences of it is the lack of sympathy and affection for parents or friends. These children may display an insensibility to the pain of others, or a cruelty without regret for the sufferings they cause, or an actual fondness for inflicting pain on others. These constitutional pervers are the more dangerous the more intelligent they are. They are unsocial and do not join loyally in play with their mates, and yet they may be good students. Time is the best aid for classifying abnormal children, and observation for a few weeks may be the only means to distinguish between the naturally vicious and those merely trained to viciousness. The constitutionally vicious should be detected and classified by the medical school inspectors.

**Diabetes Insidipus and the Pituitary.**—Lereboullet in the course of his regular lecture on this subject describes the case of a man of 50 who had had syphilis at 18 and at 31 a protracted pneumonia, after which there was retrogressive infantilism, impotence, asthenia, falling of the hair and tendency to obesity. There was also polyuria. Treatment of various kinds proved futile until pituitary treatment was given, and then the output of urine dropped from the 7 or 8 liters, which had been the average for ten years, to the normal figure as long as the pituitary treatment was kept up. The extract from the posterior lobe alone was most effective.

- \*Recent Progress in Malaria. Paiseau.—p. 384.
- \*Serum Sickness in Diphtheria. L. Ramond.—p. 387.
- Blanders in Radiology of the Wrist. P. Japart.—p. 391.

**Pyloritis.**—Loeper describes the gastritis limited to the pylorus region. In three typical cases the microscope showed the changes in the mucosa: hypertrophy of the foveolae, lymphocyte reaction and diapedesis—all restricted to the region close to the pylorus. In many cases of dyspepsia, gastritis can be invoked and among these pyloritis is frequent, and is revealed by the presence of small round cells in the stomach content. Whether they are lymphocytes or not is immaterial. There is no blood with it, and no large cells. The pains are tardy; they may be attenuated by dieting, and there are no true or persisting attacks of pain. There may or may not be nausea and vomiting, but they are rhythmical like the pains. Hyperacidity is less common than with ulcer. The pyloritis may in time encender ulceration. Treatment consists in alkalines, fasting for three hours after

meals. Milk should be the only food; addition of sodium citrate will prevent its clotting and thus ward off mechanical injury as it passes the pylorus. Bismuth is as useful as with ulcer, and an alkaline citrated solution before meals rinses out the stomach and pylorus.

**Malaria.**—Paiseau reviews the experiences and publications on malaria during the war, concluding his analysis with the statement that to date no means is known that will permit definite sterilization of an organism infected with malaria parasites. He adds that arsenical treatment as an adjuvant to quinin seems to be coming into favor.

**Serum Sickness.**—The young woman recovered promptly from a mild attack of diphtheria. She had been given three injections of antitoxin in five days and was apparently convalescing when fever returned, with extreme prostration, a nonitching eruption and polyarthrits including even the vertebrae, intensely painful at the slightest movement, but she rapidly recovered. There is danger of mistaking this for meningitis or for a relapse of the diphtheria or of a meningitis. This might have serious consequences if more of the antiserum were to be injected on this mistaken basis. Lumbar puncture may be the only means to exclude meningitis by the lack of turbid fluid and of numerous damaged polynuclears. He discusses serum mishaps in general, and adds that prevention is as effectual as treatment is futile, with the serum sickness once under way.

- \*Inflammation Around Achilles Tendon. Peter Ryhiner.—p. 1507.
- Colloidal Silver in Cystitis. H. Koller.—p. 1511.

**Microsporon Epidemic.**—Winkler relates that there have been a number of brief epidemics of microsporon infection at different points in Switzerland. At Lucerne vigorous measures were taken, the children affected were segregated in a special school, and radiotherapy applied so that the infection was stamped out with only twenty-four cases.

**Embolism of Retinal Artery.** Strehel has had three patients with obstruction of the central artery of the retina. Obliterating arteritis was evidently to be incriminated in two cases, and no relief was to be hoped for. The other patient had an old cardiac defect and the artery became suddenly obstructed by an embolus. He punctured the anterior chamber with a broad short lancet and massaged, and in less than a month the scotoma had disappeared and the field was normal for white and all colors. The consistency of the embolus and the degree of obstruction determine whether clinically normal conditions can ever be restored. There are only fifteen cases on record of cure of embolism of the central artery of the retina. In Strehel's two other cases there was arteriosclerosis, and the retinal embolism was the precursor of cerebral hemorrhage.

**Peritendonitis.**—Ryhiner remarks that inflammatory processes in and around the Achilles tendon, as well as all other pathologic conditions in the feet have become very rare since more attention has been paid in military circles to the shoes and care of the feet. This renders the more remarkable a small epidemic of 17 cases of inflammatory processes around the Achilles tendon which developed in the course of two weeks in his battalion. There had been no marching and the shoes could not be incriminated, but all the men involved had just been under treatment for adenoiditis sore throat. The salivates seemed to act favorably in some cases, associated with the usual measures for tendonitis. A purely palliative but quite effective measure was to fasten a wooden block, 3 or 4 cm. thick under the heel of the shoe, thus relieving the strain on the tendon. Men could go on marching without special pain when the heel was thus raised.

**Empyema of the Chest.**—Constantini thinks he is justified in a favorable prognosis in cases of postinfluenzal empyema, as he was successful in curing his twenty-five patients in this category. All were cured in an average of forty days. Most of the patients were children, but one was 60 years old. He resected ribs and evacuated pus and fibrinous masses, all under local anesthesia, noting at most a little fever five or six days later, and a little dyspnea and cyanosis when the pleura was opened, and some coughing after the cavity had been cleared out.

 \*The Lenticular Nucleus. Antonio Jappelli, p. 834.  
 \*Hemolysis with Urine. G. Molinari, p. 837.

**Amebic Dysentery.** Boeri declares that emetin not only serves to differentiate and cure amebic dysentery in its acute form, but it is able to eradicate the disease even when the amebas are in the encysted form if systematically and perseveringly pushed. It may likewise arrest and cause the retrogression of liver amebiasis progressing toward an abscess. The abscess once formed, however, will scarcely yield to emetin alone. In prophylaxis, it is important to discover and cure all healthy carriers.

**Pluriglandular Disturbances.**—The young man in Farmachidis' case presented symptoms showing deficient functioning in several of the endocrine glands, the suprarenals in the lead. The Wassermann reaction was repeatedly negative, and there was no history of venereal disease, but under tentative mercurial treatment all the symptoms gradually disappeared and earning capacity was permanently regained.

**The Urine Hemolysis Coefficient.**—Molinari cites some recent research by Amati which confirms that physiologic urine has no hemolytic action but it seems to make the erythrocytes increase in size a little. Even when the specific gravity of the urine is very low, it does not injure the blood corpuscles. This suggests that the urine in health must contain some antihemolytic substance, and the absence of this in kidney disease and with cancer may serve in differential diagnosis from the resulting hemolysis. The latter does not seem to obey the laws of osmosis, and the hemolytic action of the urine does not necessarily parallel the hemolytic action of the blood serum. The substance in the urine causing hemolysis is apparently not modified by heating to 50 C. for half an hour.

As a distinctly hemolytic urine is rarely encountered, Amati has been studying the phenomenon from another standpoint, namely, he has been investigating physiologic urines for their content in the hypothetical antihemolytic substance, testing them with a hemolytic substance, that is, distilled water. The amount of distilled water that has to be added to the nonhemolytic urine before hemolysis is observed is thus an index of the content in antihemolytic substance. Healthy urine has to be diluted with 5 parts of distilled water to one of the urine before hemolysis occurs. Taking this figure, 5/6, as the average and almost constant index, the physiologic range seems to be from 4/6 to 10/11. When the index is lower, however, hemolysis may be induced with an index of 1/11, and an index of 1/11; 1/6 or 1/3 may be obtained.

We have found a differential sign which may prove important in certain cases. Amati found the index within normal range in pathologic conditions outside of nephritis and cancer, but his experience has not been very extensive. He distributes the urine in 8 test tubes commencing with 6 c.c. and reducing by 0.5 c.c. in the different tubes. The first tube serves for control. To the others are added the distilled water in amounts increasing from 0.5 c.c. to 5.5 c.c. in the last tube. A drop of blood from the same person whose urine is being tested is added to each of the tubes. A control set of tubes is prepared in the same way but the drops of blood used are from another person. After the sets of tubes have been incubated for a sufficient time, the

least dilution with which hemolysis is observed is the index of the content of the antihemolytic substance, that is, the urohemolytic coefficient of the urine in question.

 \*Infant Feeding. Infection and Constitution. Ohnd. Chaffarelli, p. 156. Cont'n.

**Remote Paralysis.**—Enjolas Vampré describes the case of a man shot through the chest who developed paralysis with vasomotor and trophic lesions in the left hand and arm. He compares the case with similar ones on record, and theorizes to explain the mechanism. His theory is based on the anatomy and physiology of the nerves involved, with the physiopathologic and clinical data—all demonstrating that the *paralysis a distancia* depends on a reflex paralysis in the true Babinski sense. The flagrant contrast between the localization of the wound in the chest and the diffusion, and the ascending course of the paralytic and trophic disturbances in the arm are special features, as also their tenacious course refractory to intensive and protracted treatment.

 \*The Indin Reaction in the Urine. L. Tejero y Ruiz and Celestino Moliner, p. 420.  
 \*Prophylaxis of Child Abandonment. G. Araoz Alfaro, p. 424.

**Suppurative Kidney and Bladder Disease in Children.**—Lozano and Ruiz give full details of 25 cases, all but 5 in girls. Most of the children (10) were between 2 and 5; six less than a year old; four between 1 and 2, and four between 5 and 13. The colon bacillus alone was found in 25 per cent., and associated with other germs in 33 per cent. The disease was primary in less than 15 per cent. In the others, it followed gastro-intestinal disease in about 33 per cent., measles in 25 per cent. and infectious sore throat in about 10 per cent. High fever is usually the first symptom to attract attention, remittent or irregularly intermittent, often accompanied by chills and sweats. Cystitis is less liable to be accompanied by fever, especially in older children. The pallor, disturbances in micturition, possibly pus in the urine confirm the diagnosis. The discovery of renal cells points to the kidney; both kidney and pelvis as well as the bladder may be involved at the same time. The absence of bacteria from the urine suggests possible tuberculosis, but they had one case with negative findings in which the pyelitis seemed of toxic and nontuberculous origin. There was no mortality in their 25 cases except in 3 tuberculous children. They emphasize the necessity for surveillance of the kidneys during acute infectious disease, giving fluids in abundance. Small doses of hexamethylenamin may be useful. The genital organs should be kept scrupulously clean, and phimosis, etc., corrected. During the febrile period the child should be kept in bed and fed only on milk with large quantities of water. If it does not like to drink, the water can be given in enemas or through a tube in the esophagus. Alkalines are said to render conditions less favorable for the colon bacillus, but large doses have to be given usually for this, every two hours, for eight or ten days, and their experience with this has not been very brilliant. Salol is irritating to the kidneys, and should not be given if they are involved. Epinephrin has proved very useful in their hands. It is especially potent in pyelonephritis cases. They give from 4 to 6 drops per year of age approximately, of the 1 per thousand solution, along with 0.75 to 2 gm. of hexamethylenamin, keeping up the latter until the pus disappears from the urine. If this treatment does not suffice, they advocate an autogenous vaccine. In one case of colon bacillus pyelonephritis that had lasted for four months, the cure was soon complete under the vaccine therapy, as also in a case of lactic aerogenes pyocystitis, which had been flaring up repeatedly for fifteen months. In the other case treated with the vaccine, merely improvement was observed.

Local treatment of the bladder is rarely needed. Pain is relieved by hot applications and sitz baths.

**The Iodin Reaction in the Urine.**—Tejero and Moliner have been testing Pezetakis' iodine reaction, and never obtained positive findings in normal subjects. The test has no diagnostic value in tuberculosis, but it is a sign of bad omen as the majority of those giving a strongly positive reaction died within six weeks. The test is merely the addition of 2 or 3 drops of an alcoholic 5 per cent. solution of iodine to 15 or 20 c.c. of filtered urine in a test tube. The wall of the tube is tapped a few times to mix the fluid. With a positive reaction the urine turns a golden yellow. The presence of quinin and certain other drugs impedes the reaction. In thirty-seven tuberculous children followed for three months all of the seventeen giving a negative reaction are living, as also seven with a slight reaction. Of the eight giving a moderately positive reaction, only five are still living.

\*Brain Tumors in Children. R. A. Rivarola.—p. 316

Treatment of Infected Abortion and Delivery. L. O. Romero.—p. 314

Tuberculosis. J. José Vitón.—p. 338. Cont'd.

**Bone Complications of Diabetes.**—Bonorino Udaondo has recently encountered two cases of diabetes in men of 48 and 50 in which the bones had become very fragile in the protracted course of the disease. Fracture occurred at the slightest provocation, one man having thus fractured the upper third of the left humerus, the patella and the lower

third of the same humerus. The fractures in the other man were in the left tibia and fibula and the right humerus at the middle third. Consolidation took long and the callus was always extensive. No other cause for the fractures could be found except the chronic, almost constant glycosuria accompanied with moderate acetouria. Similar spontaneous fractures have been observed in three of four rabbits given injections of sugar for one to three months. In nearly all these animals the bones became abnormally flexible and more transparent under the induced hyperglycemia. Acetone seems to promote the rarefaction of the bone tissue and the consecutive dystrophy. The dental caries in his two cases may be ascribed to the same factors as the fractures. Treatment was mainly dietetic, supplying food rich in calcium or Ferrier's recalcifying dietary.

**Cystitis with Incrustation.**—Castaño reports successful surgical treatment in two cases of cystitis with ulceration and deposits of calcium phosphate on the ulcerations. The aspect is that of a calculus, usually multiple, and adherent to the wall of the bladder. Both his patients were women, and the symptoms in one were those of simple cystitis. In the other, there was intense hematuria in addition. Pyelonephritis and pyonephrosis developed in this case. In women, these incrustations can be scraped off, unless they are so extensive that the bladder has to be incised, as was necessary in one of his patients.

**Sign of Cancer in Chest.**—Novaro found in three cases, with necropsy control in one, that the sternum was pushed over to the other side with a neoplasm encroaching on the pleura, lung and mediastinum. Pitres called attention some time ago to the similar pushing aside of the sternum by an effusion in the pleura, but in this case the deviation of the sternum is toward the side of the effusion. As the pleura is distended, the sternum is drawn toward that side. With a neoplasm, on the other hand, the reverse occurs; the neoplasm pushes the sternum over to the other side. The lung on the comparatively sound side expands and thus draws the sternum toward it, so that this inverted Pitres' sign may prove an aid in differential diagnosis of neoplasms in this region. The comparatively sound lung has to work extra hard to compensate for the damage of the other lung, and this entails the inversion of Pitres' pleural effusion sign.

**Brain Tumor in Children.**—Rivarola's conclusions are based on fifteen cases of brain tumors in children and considerable experimental work with paraffin tumors in dogs. The cerebellum is the usual site of tumors in children, and aside from syphilitic tumors (which are exceptional in children) and tumors forming during the last stage of generalized tuberculosis craniotomy is imperative, removing the tumor if this is possible. To permit the operation, the tumor has to be located, and the general condition must be good. The very early symptoms from the lesion may permit more exact localization than later, when the tumor has grown larger. When only a small zone feels the injury from the tumor, the local symptoms are most instructive. Months and even years may elapse without general disturbance, or only headache and convulsions. The diagnosis should be made then, without waiting for choked disk, vomiting and vertigo. If the convulsions are clearly localized, this suffices, and operations in this stage are usually successful.

In his cases and in those on record the clinicians and surgeons and specialists kept waiting and waiting for more definite signs of the location of the tumor, and postponed the operation until it came too late to save the child, as a rule. The retrospective diagnosis usually shows, however that the child early presented symptoms which, if heeded in time and the child placed at once on the table, might have permitted the eradication of the neoplasm. His clinical and experimental experience has demonstrated, he reiterates, that incision of the cortex with the bistoury, allowing exploration of the subcortical tissues and white substance through a linear or crucial incision, does not entail permanent injury, not even when it impinges on the parietal lobe, the seat of the sensory-motor centers. Operating at this stage, with a good general condition, there is no need to operate at two sittings.

- \*Leprosy in Uruguay. J. Brito Foresti.—p. 1.  
 \*Torsion of Ovarian Cyst. C. A. Nario.—p. 39.  
 \*Ferrán's Theory of Tuberculosis. A. María Oyuela.—p. 41.  
 \*Cancer of Vulva. C. Stajano.—p. 61. Con'd in No. 2, p. 166.

**Leprosy in Uruguay.**—Brito Foresti discusses the prevalence and the clinical forms of leprosy in Uruguay from the earliest times to date. He remarks that except for Chile, where leprosy is rare, all the South American countries suffer more or less from this scourge. There have been 215 known cases in Uruguay during the last twenty years, and 180 are still under observation, in a population of about 1,315,714. He regards chaulmoogra oil as the most effectual treatment but the intolerance for it by the mouth and the occasional suppuration when injected subcutaneously have compelled him to discard it, and he now prefers ichthyol. This has materially benefited many but not all, and there was no intolerance and no protests against even its prolonged use. He gave it in 0.30 gm. capsules to a total of 2 or 2.50 gm. daily for twenty days and then kept repeating this course with ten day rests. During febrile periods, sodium salicylate was very effectual. An antiserum did not display any benefit. Colloidal chaulmoogra oil is now being tried. The youngest victim of leprosy was a boy who was 7 when the first manifestations of the disease appeared; the oldest was a man of 70. No race, nationality nor social position seems exempt, but he never happened to see a negro leper.

**Torsion of Ovarian Cyst.**—In Nario's two cases the clinical picture was complicated by simultaneous torsion of the appendix. The latter had twisted close around the pedicle of the cyst in one case, the tip adherent. In the other the appendix had twisted twice around the long pedicle, like a vine around a tree. In both, the mucosa of the appendix was still smooth and velvety. These and analogous findings in cadavers demonstrate that a twisting cyst is liable to draw into its twist any loose organs or tissues around. The traction from the torsion may be felt at quite a distance, even in the retroperitoneum. He suggests in conclusion that this may be a factor in ptosis.

**Ferrán's Vaccination Against Tuberculosis.**—Oyuela discusses Ferrán's theories and deplors the skepticism with which his revolutionary ideas have had to contend. See Madrid Letter, Oct. 4, 1919, p. 1074.

**Cancer of the Vulva.**—Stajano tabulates the details in 30 cases of vulvar cancer of four different types. Four of the 40 women had never borne children and another woman of 31 was a virgin. The details in regard to child bearing were not known in 8 other cases. All the 18 others had borne from one to fourteen children. The neoplasm was marginal in 22 cases, in the clitoris region in 6, and around the meatus in 2 cases. He gives a chart to show the complications liable with these four types. With the marginal type, the lymphatic and paracervical glands are involved from the very beginning, and may be glands in this region. Not only the lymphatic glands but also the corresponding infiltration are characteristic. The treatment is to be traced in all with cancer in the clitoris or clitoris region. This patient had had a painless small scapular tumor for months, never in the line several pregnancies. An ovarian cyst had had just a pruritus for seven years and the vulvar cancer developed. Both presented typical cancer. The need for successful intervention was long felt when pains and discomfort drove them to seek medical aid.

In conclusion Stajano emphasizes the analogy between cancer of the vulva and cancer of the mouth so far as the prognosis and the treatment are concerned. Seven of his 30 patients are known to be still in good health. All these were marginal cases. All the other patients are known to

have died except 6 that could not be traced. He warns that an incipient cancer in the vulva, without glandular lesions, will probably disappear under roentgen treatment but that this disappearance is deceptive, the lesion usually recurring and often in inoperable form. This, he adds, is particularly liable in hospital and country patients that cannot be kept under supervision. Raying was regarded at first as a valuable aid in inoperable cases, but experience soon showed that these cancers soon became refractory to the rays, or seemed to progress under them, thus displaying marked difference in the response to that presented by cancer in the uterine cervix, although the two points are so near together. These deplorable results from raying vulvar cancers have been a great disappointment; they harmonize however with the experiences with raying of cancer of the lip, tongue and floor of the mouth. The only resource is complete and ample excision of the vulvar cancer, with all the inguinocervical glands on each side and, in case of clitoris cancer, also of the retrocervical glands and connecting lymphatics. He details the minute technic of the three kinds of operations required for the three groups, and insists on postoperative raying as an important adjuvant.

**Bacillary Dysentery in Uruguay.**—Cuervo reports experiences which testify that *Y bacillus dysenteriae* is common in Uruguay, and that this bacillus is responsible for many cases of intestinal disease, resembling dysentery, in children.

**Mucocele in Frontal Sinus.**—Alonso reviews some cases in the literature and compares them with an operative case in his own practice in which a mucocele cyst was found in the frontal sinus. In his case there was an extensive destructive process, but in Avelli's case the mucocele was sterile.

**Weber's Syndrome.**—Pelfort reports a case in a boy of 4 presenting total paralysis of the left side with paralysis of the oculomotor nerves on the other side and positive tuberculin skin reaction. The spinal fluid seemed normal and the Wassermann reaction was negative and there were no symptoms suggesting involvement of the cerebellum.

 \*Fluorene as Reagent for Aldehydes. J. A. Sánchez.—p. 103.  
 \*Tetanus in Argentina. E. R. Conti.—p. 104.

**The Wassermann Reaction in Breast Milk or Colostrum.**—Rojas reports a frankly positive Wassermann reaction in the breast milk and in the blood in 7 of 28 women; in 3 of the group the reaction was more pronounced in the milk than in the serum. In 6 the reaction was negative in the serum and positive in the milk. It was absolutely negative in the milk or colostrum only in 6 of the number, and was negative also in the blood in 4 in this group. Seventeen of the women had been delivered within five days; 11 were in the last two months of pregnancy.

**Tetanus in Argentina.** Conti states that in the six years before 1917 there were 10,868 deaths from tetanus in Argentina, including 8,347 in the newly born; 1,292 under 10, and 1,129 above this age. The ten years before 1878, tetanus was responsible for about 9.2 per cent. of the total mortality at Buenos Aires, but in the last ten years the proportion has dropped to 2.9 per thousand.

- Colloidal Iodin in Treatment of Acute Influenzal Meningitis. C. Heuer.—p. 129.
- Appendicitis as a Manifestation of Rheumatism. G. Giacobini.—p. 129.

**Polycythemia.**—The case of Vaquez' disease reported in detail by Goyena and Masoch was peculiar in that great enlargement of the spleen was the first sign of trouble in the woman of 30. Three years later she developed typical erythremia and while in the hospital on this account polycythemia became manifest, the erythrocytes running up from 4,510,000 to 8,400,000.

**Diathermy in Obstetrics.**—Beruti expatiates on the theoretical advantages of diathermy to influence atony of the uterus. The technic is not perfected enough yet to be applied directly to the gravid uterus, but applied at a distance it might tone up the physiologic processes in the uterus. It is possible also that it might aid in eclampsia, in asphyxia neonatorum, and to warm up the prematurely born, and in obstetric shock, and in rigors. He merely suggests these possible applications, not having had any experience with them. But he has found heat applied to the legs by the ordinary technic very useful in aiding the obstetric uterus to recover tone and energy.

**Giant Ovarian Cysts.**—Pelliza relates that in Caballero's service an ovarian cyst which weighed 55 kg. was removed from a woman of 52 in 1906. In another case, in 1914, the cyst weighed 59 kg.; this patient was a woman of 22. Gallo drained 80 kg. of fluid from a similar case. Pelliza then gives an illustrated description of a case in a woman of 49 who measured 1.43 meters around the waist. She weighed 96 kg. before the cyst was removed and 57 kg. two weeks later. Recovery was smooth, but the microscope revealed sarcoma in the ovary.

- \*Traumatic Shock. J. Segovia y Caballero.—p. 841. Cont'n.

**Necropsy Findings in Influenza.**—Cerdeiras describes the postmortem findings in seventy-nine influenza cases at Basel. This group of fatal cases formed 15 per cent. of the total pneumonic cases. The constant finding of lesions in the lungs confirms that influenza is preeminently a disease of the respiratory passages.

**Treatment of Vertebral Tuberculosis.**—In this instalment of his long article, Decré emphasizes that we should aid Nature's processes of healing instead of trying to make Nature work in our way. Necropsy of persons with healed Pott's disease has shown ossification of the anterior ligament and this, he thinks, is the model which we should imitate. Nature provides curves and compensations which enable the organism to balance its forces and adapt the organs to new conditions. Our task is to detect the disease early. He refers to Albee's method, saying that the latter claims that secondary operations are not necessary with his technic. "But," he adds, "Albee is not sincere, as, after making these claims, he goes on to speak of the satisfactory findings when the implant was inspected at a second operation. Why should he do a second operation? Surely not merely for the purpose of inspecting the graft, as radiography will supervise this."

**Traumatic Shock.**—Segovia here concludes his long article begun in No. 3431. It is based mainly on war experiences and he remarks that toxic shock is rarely encountered in peace times. Surgical measures are not needed so imperatively with peace time wounds. Nervous shock and hemorrhagic shock directly contraindicate operative measures beyond what is necessary to control hemorrhage.

- \*Induced Pneumothorax. B. H. Vos.—p. 713.
- Hysteria. T. Meinema.—p. 730.

**Treatment of Cardiospasm.**—It is evident from the experiences Benjamins reports that a different mechanism may be responsible for the spasm in different cases, but that usually the spasm is in the lowest segment of the esophagus and not in the cardia itself. General measures to reduce the tendency to spasm should be supplemented by systematic dilatation under esophagoscopic control. If this has been given a thorough trial and failed, an operation should be recommended. In 2 of his 3 cases of simple spasm, it was overcome by a single introduction of the olive tipped catheter. In the third the simple spasm passed into a phase of spasmodic contracture. There is a sensation of oppression, generally ascribed to the stomach itself. The lively antiperistalsis causes the food accumulating in the esophagus to be expelled, especially when aided by retching movements. In 5 of his patients the retention caused great distention of the esophagus, and in 2 others cicatricial degeneration had actually closed the lumen, compelling an operation. Guisez had 15 cases of cardiospasm in persons from 60 to 89, and 2 of Benjamins' patients were men of 54 and 64. Radioscopy with the contrast meal and with a small metal ball is usually instructive, but esophagoscopy is conclusive. In one man of 73 with symptoms of cardiospasm, not until the sixth examination did the catheter slide into the stomach and allow the discovery of a nodular cancer in the upper portion. Treatment should be that of spasm in general; the recovery in all his cases confirms that there was no paralysis. The tube is sometimes gripped by a spasm, and spasms elsewhere in the body may accompany the cardiospasm. He dilated the cardia with a set of olive tipped sounds passed through the esophagoscope tube. The irritation from imperfectly chewed food may be the cause of the spasm. In 4 of his 9 patients he found a large chunk of meat or of some fruit in the esophagus content. But there is probably some predisposing factor besides. The exaggerated reflex irritability is combated by passing the sound through the cardia, training the latter to allow the passage of other substances, so that it does not react with the spasm to the passage of food.

**Pernicious Anemia.**—Rombach relates experiences which confirm that pernicious anemia is not a morbid entity but merely a set of phenomena which may occur with any one of a number of actual diseases.

**Artificial Pneumothorax.**—Vis describes fifteen cases of induced pneumothorax in the last seven years. The immediate effects were excellent, but the ultimate outcome was far from satisfactory. The long rest of the lung did not seem to have improved the general condition on the whole, and the disease finally progressed as in cases in which this collapse therapy had not been applied.

### Acta Medica Scandinavica, Stockholm

1919, 52, No. 11

- Gastric Ulcers and Reticular Niche. H. Öhnlöf.—p. 1  
 \*Studies on the Concentration of Indifferent Naresites in Blood and Serum. F. M. P. Widmark.—p. 87  
 \*The Treatment of Alopecia Areata. J. Strandberg.—p. 165  
 \*Pulse and Electrocardiogram with Change of Position. H. Engström.—p. 175  
 \*Research on Motor Systems in the Abdomen. G. Söderbergh.—p. 211.

**Internal Treatment of Gastric Ulcer.**—Ohnell reports experiences which differ from the usual in that gastric ulcers showing a tongue like pocket or niche with the contrast meal healed definitely under internal treatment alone. The niche is usually accepted as an indication for operation. In 36 certain and 2 probable cases the narrow pocket disappeared as the ulcer healed. In 3 other cases, the pocket grew very much smaller. There has been no recurrence in any instance during the six to eighteen months since. The reason why internal treatment does not give such good results in the hands of others, he explains, is probably because the treatment is not kept up long enough. The different features of the 56 cases are tabulated under twenty-six headings, and the roentgen findings in each are reproduced. The tests for occult blood were negative, as a rule, in the cases in which the niche disappeared under internal treatment. The smallest niche shadow was 4 by 3 mm.; the widest 55 by 16, and the deepest 6 by 28 mm. The niche region was tender before or during the treatment but not in any case after completion of the course of treatment. Radioscopy of the stomach with the patient in different attitudes shows the widely different positions assumed by the stomach, with consequent traction, and on this account he keeps the patient absolutely still in his back for four weeks, and keeps him in bed for a further two weeks.

If the patient wearies of lying on his back and finds it difficult to sleep in this position, he gives a little sedative by the rectum the first few nights. This aids further in relieving paritosis during the first three or five days in a week, nothing is allowed by the mouth, and the extremely moist atmosphere of food thereafter. Most heat is applied as a counteraction for about a month; then he changes to warm, and when the patient gets up this is changed for an abdominal band. Fluids are supplied copiously by the rectum, 100 cc. of grape sugar solution, 6 per cent. honey, or 0.9 per cent. sodium chloride. He began with 400 gm. three times a day, reducing the amount proportionally as feeding by the mouth is resumed, never letting the fluid intake drop below 1 liter a day. To ward off thrombosis, the patients are made to massage the position of their legs repeatedly. Hygiene of the rectum is enforced. He had no paritosis develop in any case.

The bowel movements are promoted by an enema of olive oil. The patient is warned not to strain. It is better to let feces accumulate than to strain and hinder healing of the ulcer. The diet is 30 gm. milk seven times a day, 100 gm. of fresh egg yolk plus the yolk of an egg. But 100 gm. of grape sugar solution are given by the rectum three times a day from the first day on. Then two rectal injections are made, and the seven milk feedings total 630 gm. with two yolks. On the fourteenth day the rectal injections are dropped and 200 gm. milk is fed seven times, plus two yolks. On the nineteenth day 210 gm. of milk seven times a day and five yolks, and after this two to five soft boiled eggs, zwieback and butter are given with up to 1,500 gm. milk or five to six eggs. The course takes a full month. His experience confirms that a rictogenin he may be due to a determined but not ulcerated part of the gastric mucosa. The article is in German.

**Acetone Concentration in the Blood and Tissues.**—Widmark has been able to deduce certain general laws which seem to

regulate the concentration of acetone and other "indifferent" narcotics. He writes in English.

**Thyroid Treatment of Alopecia.**—Strandberg now has a record of nine cases in which endocrine disturbances seemed to be responsible for malignant patches of alopecia. All were in men except 3 but there was nothing to indicate positively endocrine disturbance. Two of the patients had dementia praecox and one signs of syphilis. Thyroid treatment was applied in every case but only briefly in 2; in 3 of the cases the hair grew again under the thyroid treatment. In one man with dementia praecox the hair began to grow in as the mental condition improved. One woman who was not benefited by the thyroid had her hair drop out again during a pregnancy, and also when menstruation returned. The article is in German.

**Action of Passive Change of Position on Pulse Rate and Electrocardiogram.**—Engström found a slowing of the pulse when the subjects were changed from a horizontal to a vertical position, the head down, while an opposite effect was apparent in rapidly changing the subject to an upright position. He theorizes to explain the mechanism of this. The article is in German, and the pivoting table is illustrated.

**Root Motor Innervation of the Abdomen.**—Söderbergh here presents his eighth communication on the motor disturbances in the abdomen which can be traced to spinal roots. The motor anomalies may reveal the point where the root lesion is located. The article is in French.

\*Forceps with Transverse Presentation. S. Lange-Nielsen.—p. 1045.  
 \*Inhibition Phenomenon in Antiserums. T. Thjotta.—p. 1051. Cont'n.

**Forceps with Transverse Presentation.**—Lange-Nielsen gives an illustrated description of what he says is a new method for introducing the anterior blade of the forceps. He introduces it over the back of the head with the convex edge forward. He says that this seems awkward, but in reality it permits better the *tour de spirale* which brings it up better in place with less danger of injury of the head.

**Inhibition Phenomenon in Immune Serums.**—Thjotta here concludes his long study of the nature and significance of the inhibition phenomenon described by Neisser and Wechsberg in 1901. It seems to be decidedly specific, becomes more pronounced as immunization progresses, and was found particularly intense in dysentery immune serum. The inhibition is the work of immune substances which develop during immunization or in the course of natural infection. But these immune substances are not identical with the ordinary immune agglutinins, bacteriolysins or precipitins. These special substances in the serum probably combine with the antigen to form a molecule complex which adsorbs the complement and thus keeps it away from the bactericidal substances in the serum. It is possible, he adds, that they may reduce or annul the action of antibacterial therapeutic serums, especially meningococcus antiserum. It is important therefore to determine this inhibition titer for each meningococcus antiserum, and, before using it, to dilute it proportionately with fresh complement-containing serum from the patient himself.

## CREDULITY AND CURES

FREDERICK PETERSON, M.D.

NEW YORK

The psychology of credulity is the main theme of this article—not credulity in general as applied to various religions, philosophies and political tenets—but credulity as related to the treatment and cure of disease, to the art and science of medicine. Why do people believe in "patent medicines," in all sorts of systems of healing, and quite generally also in doctors of medicine? Why do physicians often pin their faith to special methods and special medicaments? The general principles that govern faith, opinion, conviction, act also here; but an unusual factor in the field of medicine is the extraordinary complexity of the human body and mind. We often compare the organism to a machine; but even the most intricate machine is simplicity itself compared to the human body. On the one hand, we have metals and mechanics that almost any one can understand, adjust, repair and run; on the other, we have such a combination of sixteen elements in the greatest of chemical and physical laboratories, such complexity of anatomy, such intricate processes of physiology, and the whole permeated by spirit, by psychology and the mutual reaction of body and mind—all having occupied nature a hundred million years to build—that it is small wonder that even the greatest students and experts in this field of work cannot grasp it all, are dismayed at the difficulties they meet, and rejoice if a lifetime of work may chance to wrest one tiny fragment of new and permanent knowledge from the great mass of the still unknown. The healthy organism is difficult enough to know and to understand, but when we have added to this the innumerable diseases that develop within the body and the scores of invisible and intangible enemies that attack it from the outside, the problem grows colossal, and it is no wonder that people in general, no matter how erudite in other directions, have not the smallest conception of the problem of medical therapy.

The more one knows of a subject, the more critical, even skeptical, one becomes. If one knows nothing of a subject, the soil is prepared for faith, preconception, conviction. The great majority of illnesses are temporary, selflimited, and tend to recovery by nature unassisted. It is not surprising, then, that when an intelligent professor or learned clergyman happens to take during such a spell of illness a packet of cottage cheese, carefully powdered, with a long Greek name, his prompt recovery should fill him with a profound conviction of the value of

the remedy. He has this one convincing case, and its being his own lends a strong personal note to his recommendation of the agent to his friends. In fact, he becomes an authority by a single case, commends it to others, and even writes letters of his experience for use by the advertisers.

The physician works differently. If he observes good effects from a remedy in one case he tries it on others, and if it works well on twenty or thirty or perhaps fifty patients he will call it to the notice of other physicians by publication in a medical journal. Others are thus led to try it, some with similar success, some with critical reservation based on exceptional experience and conditions. Gradually, after use in thousands of cases and perhaps through the years by thousands of physicians, a new remedy takes its place in the pharmacopeia with a record of all the facts as to its utility and its limitations. It is thus that the hard won truths in regard to our small armamentarium of really useful therapeutic agents have been wrested from the years<sup>1</sup>

## CREDULITY AMONG THE LAITY

General intelligence, even great scholarship in all directions outside of medicine, is no criterion for judgment in the matter of means and methods for curing disease. Of Berkeley, one of the greatest minds of England, a philosopher, a scholar, it was said, "Ancient learning, exact science, polished society, modern literature, and the fine arts, contributed to adorn and enrich the mind of this accomplished man." He was a distinguished bishop as well as an illustrious scholar. But he discovered an elixir of life made by mixing a gallon of water with a quart of tar, leaving it for forty-eight hours, and pouring off the clear water. One of his essays which ran through many editions was "On the Virtues of Tar Water." Having tried it on himself and his family he was so sure of its efficacy that he felt it a duty to announce the wonderful discovery to the suffering world. Twenty-five fevers in his family were cured by this medicinal water. He recommended it as a preventive and alleviator of smallpox. It would cure impurities of the blood, coughs, pleurisy, pneumonia, erysipelas, asthma, indigestion, hysteria, dropsy, scurvy and hypochondria, and was of great use in gout and fevers, a preservative of the teeth and gums, and a substitute for all diet drinks and mineral waters. He forestalled criticism by saying, "Effects misimputed, cases wrong told, circumstances overlooked, perhaps, too, prejudices and partialities against truth, may for a time prevail," and furthermore, "Men may

<sup>1</sup> This is the normal progress of a useful drug, and of course I refer only to remedies not controlled by special interests. Unfortunately, at times, an agent does not follow this normal growth and evolution, but is imposed on a too credulous profession by powerful propaganda and suggestive advertising.

measure and object as they please, but I appeal to time and experiment." It is needless to say that the appeal of this wise and great man has been answered. Far water is forgotten. I merely refer to this shining example because the same psychologic reaction to cures for diseases has been manifested often since the time of Berkeley.

Even at this moment, a quite new method of therapy is being widely exploited by distinguished scholars, who if not as able as Bishop Berkeley, still have immense influence on the academic circles of their time. An Australian music teacher by the name of Alexander has adopted a system of cure of diseases in general which would seem to be a cross between massage and chiropractic. He has written a book entitled "Man's Supreme Inheritance," describing his theories and results, and this book is now having a huge circulation in this country. Prof. John Dewey, one of the most distinguished educators in the world and a professor of philosophy in Columbia University, writes a laudatory preface to the book. The *Atlantic Monthly* in its April number this year gave the method seven pages of free advertising in the shape of an article by Prof. J. H. Robinson, professor of history in Columbia University, entitled "The Philosopher's Stone," which he found in the Alexander method after "a lifelong personal experience of physical and mental depression." He says:

I am not telling my plain tale because I happen to have been redeemed in body and soul through Mr. Alexander's method, or because I have known others to be so redeemed. I think his ability to straighten out adults and give them new energy and courage is very important, but by no means so important as the possible application of his theories in the field of education by which it seems as if it might be possible to raise the whole race to a far higher plane than it now occupies.

Now, what is the method? A careful search through the book affords no clear account of what the author does or how he does it, but leaves the reader naturally to infer that the only way to recover from his malady is to consult the author himself, who practices in London six months and in New York six months.

From this book of well over 300 pages, one obtains with difficulty a limited general outline of the method of the new cult. I judge it is not intended that any but the writer should be able to employ this new cure, so that the patient to obtain his supreme inheritance would have to pay doubtless a considerable inheritance fee. However, one gathers by careful reading that the first principle is to establish a normal kinaesthesia by placing the patient in a position of mechanical advantage which induces a perfect system of natural massage such as has never before been attained by ordinary methods, and which is extraordinarily beneficial in breaking up toxic accumulation, in alleviating evils arising from auto-intoxication (This is always a word for word). By the use of his special technique, the author claims to have cured paralysis, erysipelas, tuberculosis, asthma, adhesions of the lungs, hemorrhage, congenital and other malformations, cerebral infantile paralysis, many varieties of throat, nose and ear trouble, hay fever, chronic constipation, chronic appendicitis, and colitis. I quote his own list. He anticipates the regeneration of mankind through his scheme of physical therapy.

Thus, we see that the assertions of an authority carry conviction to hundreds of listeners and thou-

sands of readers, and establish credulity in mankind. It does not matter whether the authority be an expert in philosophy, religion, education or history, what he says about a panacea for disease believed in by himself will induce belief in others. The assertion of authority is a powerful suggestion to believe, but a bare *assertion* by any one, even by a newspaper advertisement or the label on a bottle of "patent medicine," acts also as a suggestion to arouse credulity, as psychologic experts in advertising have been delighted to find.

Another factor in credulity is that we are so constituted as to be tremendously inclined to believe in what we would like to believe. When a man is ill there is nothing he desires more than to get well. This predisposes him at once to faith in any promise of cure.

And still another feature in cures is mystery. The commercial and therapeutic value of a "patent medicine" is secrecy as to its ingredients. Tar water was too plain and simple to live long. If it had had an incantation said over it, if it had had to be concocted at the conjunction of some planet with the moon, if it had had some high-sounding name, like Golden Discovery or Sanatogen, it might be alive today. This is true not only of medicines, but also of other methods of cure. The religious mystery associated with Christian science and the phenomena at Lourdes, the elaborate psychologic discussion in connection with "new thought" and mind cures, the anatomic dissertations on the spine and circulation in the advertisements of osteopaths and chiropractors, the rodomontades of men who write books like "Man's Supreme Inheritance," all these dealing with the mysterious, the occult and the unknown, make a wonderful appeal to that instinct of faith in those who are utterly ignorant of the significance of the theories suggested or terms used; and if one recovers by employing one of these methods, as often happens, since most diseases are self-limited and get well of themselves, the personal experience fixes a faith in the means that cannot be shattered. If you add to this personal experience the psychologic fact that once a conviction is firmly established in the mind of a grown man, it is almost hopeless to dislodge it, one learns to understand the credulity and gullibility of the race in the matter of panaceas for its ills. No one will easily give up an opinion when it will show him to have been wrong, even foolish. No amount of argument could have upset the belief of the brilliant Berkeley in tar water, nor could we swerve Professor Dewey or Professor Robinson one iota from their faith in a "readjustment which will establish a normal kinaesthesia" in their anatomies.

Now, I do not believe the medical profession has any quarrel with all these cults and methods, certainly not as to the good they may accomplish in some instances, but only so far as they may be hurtful or pernicious or untrue. We do object to the sale of secret "patent medicines" to the gullible public, even though they too may cure at times, because they have often contained dangerous ingredients such as morphin and alcohol, and because they too often lure the people into false hopes and to cruel disillusion. This is especially true of the much advertised tuberculosis, cancer and epilepsy cures. We do not object to cures by Christian science—we welcome cures by any method whatsoever, so long as they are cures—but we do object to the denial of the existence of disease and interference with its prevention in such disorders as smallpox, diphtheria and typhoid fever. It would be

idle to deny the recovery of patients under treatment by osteopathy and chiropractic, knowing what we do of self-limited diseases and the power of faith; but we have all encountered the evil results of their indiscriminate use, and deprecate their employment as a panacea by the unskilled and the ignorant. In the matter of the new cult of "readjustment to establish a normal kinaesthesia," the physician cannot accept as evidence the testimony of its one practitioner, or any of the evidence of those who claim to be cured by it, as decisive of a new advance in therapy—for all this evidence is combated by ages of experience in similar exploitations. The truth is that medicine is a great and difficult and progressive science, and that its truths are the results of the sifting of the centuries. No doubt all the cults and fads and fancies that have had and are having their day contribute something to the sum total of medical knowledge. Homeopathy, which is now little practiced, doubtless helped to diminish drugging. The numerous mind cures have done good by awaking the profession to a greater realization of the importance of the mind in every therapeutic procedure, though this idea is not new, having been well described by Plato in his *Charmides*. The various schemes of manipulation of the body by massage, osteopathy, Zander apparatus, etc., have made valuable additions to our knowledge of physiotherapy.

#### CREDULITY IN THE MEDICAL PROFESSION

Now, after this résumé of the many features of credulity among the laity, I approach with some trepidation and a feeling of delicacy the subject of credulity in the medical profession itself. We, above all others, should be hypercritical, should make a cult of skepticism in therapy. But do we? No one knows so well the extraordinary progress in all branches of medicine, especially during the past fifty years; no one knows so well the tremendous difficulties and complexities encountered, the mistakes made, the old paths retraced or abandoned, the amazing vistas opened. All these experiences should make the doctor of medicine, in particular, a profound skeptic, and happily also we may well believe an optimist.

I am afraid, however, that we too—just because dazzled by the effulgence of so many new discoveries—share, in a measure, the credulity of the public in remedial agencies. We see their errors plainly, and sometimes they see ours; but do we see our own? The same psychologic factors are at work in us as in the general public for the creation of faith in the new drug or in the new method. We do not know enough about it to be sufficiently critical. This ignorance of ours prepares the ground for the new belief, the new conviction. Its value is asserted by authority. And we are eager to believe in the new hope of help held out to us for the healing of the sick. Then, again, there are the marvelous mysteries behind all the new names—hormones, opsonins, endocrines, amboceptors, etc.—such a wide field for new facts, such a vast horizon for new theories. We can hardly be blamed for not being always able to get our bearings in these uncharted seas.

It has interested me to go over in this connection some of the therapeutic measures heralded to the profession with more or less vehemence of assertion during my own day. Some of these have already passed into oblivion. When I began practice, clitoridectomy was a reputed cure for many nervous disorders. One

scarcely hears of it now. About that time, too, surgeons were competing for their first hundreds in ovariectomy, an operation often then performed not because of ovarian disease, but for some theoretical relation to epilepsy, insanity and the psychoneuroses. Around that period the rhinologists came into their own with the turbinated bone obsession. I suppose the reason one hears so little of it now is that most of the turbinated bones of our generation were removed. Turbinated bones have gone out, and submerged tonsils have come in. In Vienna many cases, especially those of nervous disorders, were cured by magnets applied to the spine. Electricity had a great vogue, and large static and other machines were a part of office equipment. One rarely sees them now. For a time, suspension of patients with locomotor ataxia on the theory that stretching the spine affected favorably the fibers in the posterior roots had vogue, and it was rather startling to enter a clinic, hospital or doctor's office and see one man or several men hanging by the head from a miniature gallows. The passing of urethral sounds for the cure of locomotor ataxia had a brief but meteoric career. There was a good deal of trephining for microcephalia, under the impression that the brain would grow if it was given more room; and trephining was done for a time in general paresis but abandoned for good reasons in the course of time. The rest cure had a comparatively long life among remedial measures, and it had behind it great authority and much good logic; but as a cure it owed its success chiefly to the psychotherapeutic genius that launched it into existence. Except for the reverberations of his dicta in remote places, it is not employed nowadays, the antipodes of his teachings, namely, exercise and occupational therapy, taking its place. I suppose very few drugs have had such a rapid rise and sudden drop into the medical limbo as croctalin, exploited for epilepsy. It ended like the sky-rocket. Perhaps I should mention here in connection with croctalin, *Bacterium cinccinnaticum*, which caused so many epileptics to have their colons reduced to semicolons by operation. This germ is extinct, along with the general paresis germ discovered in Scotland some years ago. I presume many recall a series of volumes entitled "Biographic Clinics," by which the enthusiastic author, an ophthalmologist, sought to prove that the majority of diseases were due to eye strain and could be corrected by prisms. He was very bitter against certain of his confrères who believed in the same etiology of human illnesses, but who insisted quite violently on the cutting of eye muscles by a long series of delicate operations to remove eye strain. The originator of the latter method was awarded a prize by a distinguished foreign medical society for his great contribution to science!

Our past experience should lead us to be extremely cautious and skeptical in the presence of many of the therapeutic measures before us now. Leaders, despite their great intelligence, and high position, often stam pede the rank and file of us like sheep. Our leaders are very human and subject to the sway of the personal equation. I know one general consultant who seldom makes a diagnosis of anything except hypothyroidism or hyperthyroidism; in fact, I believe that he must in his mind have classified the whole human race as superior and inferior thyroids. I know another who does not see ordinary things in the ordinary light of day, but by a prismatic light; he sees them through the

rinow of the endocrines. Surely, so much pulling at teeth, so much removal of submerged tonsils, is not justified by results. At least I feel so from the many cases of psychoses, nervousness, sciaticas, neuralgia, spinal pains, cervicobrachial neuritis, and the like which have come under observation after such treatment had proved futile.

I am glad to see a growing skepticism with regard to Wassermann tests. They are of real value as corroborative of clinical findings, but when these are in doubt, the Wassermann tests should be controlled by reports from three different laboratories. It is not long since a single laboratory test was considered final, and that despite the presence or lack of clinical evidence.

#### PSYCHANALYSIS

I shall close with a few words as to psychoanalysis, on which subject I am qualified to speak, for I know Freud and Jung personally, have examined the method theoretically, and have or have had a number of practitioners of this cult as my friends. It has taken a considerable hold in America—though not so much in Europe—and owing to the fact that many reporters and writers are psychopaths and have undergone treatments by psychoanalysis, these doctrines are now frequently encountered in editorials in newspapers, magazine articles and a few books by mediocrities. The theories of Freud and Jung are to psychology what cubism is to art, new, sensational and rather interesting. If they were not so pernicious in their application, as well as untrue in psychology, I should say nothing of them, but let them take their place in our historical medical museum along with all the other fancies which the centuries have accumulated. In a few years they will be catalogued in that museum. I doubt if any persons have been benefited by this treatment. It requires months or years of work over each case and it is very expensive. I have, on the other hand, seen very bad results from the psychoanalysis of young women and men, permanent insanity, even suicide—and if it were not destined to be so short lived, I should advocate a law to prevent its employment in the treatment of young people.

There is only time to touch on one or two of the more salient features of the freudian theories. One of the most prominent is, for instance, that every dream is the fulfilment of a wish. This is a kind of turning back in a very crude way to the philosophical speculation on the world as will and presentation of ideas men as Berkeley, Schopenhauer and von Hartmann. If there is one clear fact in the psychology of everyday life it is that the essential function of the mind is its ability to deal with the future. It is anticipation of the future that guides our conduct, plans for our actions, distinguishes the right paths from the wrong paths that we are to follow, and the ways that are readily to progress from those that are unfavorable. Our memories are our experience on which we base our life; by the present is a point, the future is our goal. This is true especially of youth, which is full of anticipation of the future, a long preparation for all that is in store. Hence our minds are always full of anticipations in our waking life—hopes, desires, wishes, plans, ambition, aspirations, as well as fears, timidity, anxiety, dread, suspense. Naturally, our dreams, which are a sort of uncontrolled replica of waking thought, but with a wider horizon of memories,

reflect in a moonlight kind of way the thinking processes of our day. These anticipations come to us in our dreams. Sometimes they are pleasant; sometimes, anxious and apprehensive. Now, Freud, observing that his children usually dreamed of pleasant things anticipated, the theater, toys, country trips, quite arbitrarily jumped to the conclusion that a dream is the fulfilment of a wish. Then he said all dreams were a fulfilment of a wish, and as the obsession grew in his mind, he decided it must always be a sexual wish, however disguised. When confronted with fear and anxiety dreams he had to invent words like distortion, displacement, etc., to twist around an easily explicable dream, easily explicable by study of the normal anticipations of the mind, to make such a dream in some extraordinary manner fulfil a wish. When a friend of his, after hearing him lecture on this subject, came to him triumphantly with a fear dream, wholly opposed to his theory, Freud suddenly exclaimed exultingly, "You had this dream just to confute my theory. That was the hidden wish." The freudians will talk to you much about an elaborate symbolism which is wholly their invention. There are no symbols in anybody's dream life which were not first present in their conscious life. The freudian makes the claim that all the arts, and in fact all our civilization, had its origin in one drive, the sublimation of the sexual. The reader will remember that Rabelais had Pantagruel meet one Gaster in his travels who claimed that all the arts, powers, accomplishments of our civilization were the sublimation of the desire of the stomach. One theory is as good as the other. They are both rabelaisian. If one reads the analyses made by the psychoanalysts, one will find a complete revelation there of the type of mind of the analyst himself, his intelligence, his logic, his symbolism, his character; indeed, one will learn much more of him in this way than one will of the unfortunate patient the analyst thinks he is studying.

#### CONCLUSION

Most of these methods of cure are in the past. They are a part of our experience, and of certain value as such, although mostly of a negative value. Of course, this has been more than counterbalanced by enormous accessions of positive value during the same period of time. But these errors have a lesson for us today. We must try to take a middle path, if that is possible in the presence of new theories, to be broad enough to know that there are great mysteries in our complex organisms and all the sciences that have to do with them, to feel that precious discoveries are always before us awaiting some Cortez or Columbus, and therefore not to be too prejudiced to weigh, ponder and examine; and at the same time we should cultivate the critical faculty.

20 West Fifth Street.

**Import of Mental Deficiency.**—People speak of "mental deficiency." They seem to mean by that always "intellectual deficiency," or "cognitive deficiency." I think there is far too little attention paid to deficiency in feeling, or emotional deficiency, and to the deficiency in volition or conation. The feelings and the will are just as much parts of the mind as the intellect is a part of the mind, but the term "mental deficiency," as it is often employed, nearly always refers merely to the intellectual or cognitive side. In my opinion, we see just as many, or more, defects on the emotional and conative side as we do on the intellectual or cognitive side.—Dr. Lowells F. Barker, *New York State Journal of Medicine*.

PRESENT STATUS OF THE DEFINITE  
TREATMENT OF THE  
PNEUMONIASOBJECTS, INDICATIONS, AND METHODS OF USE  
OF QUININ, PITUITARY PRINCIPLE  
AND DIGITALISSOLOMON SOLIS COHEN, M.D.  
PHILADELPHIA

The definite plan of treating pneumonia is so called because it uses definite agents for definite objects, on definite indications. It does not exclude, but definitely includes, rest, diet, fresh air (the open air if possible, but with regulated temperature), and all other methods of good nursing, together with the free use of water and alkaline-saline drinks (chlorids, citrates, carbonates, bicarbonates).

Its pharmacodynamic center is quinin, and the principal pharmacodynamic aids are solution of hypophysis and digitalis. These substances are not "specifics" and are not advocated as such; but their use under definite indications is of special advantage. The indications are the important elements. They constitute the plan of treatment. The drugs are merely the present means of carrying out the purposes for which they are respectively indicated, and might be superseded by other agents found by experience to be superior, without affecting the fundamental principles involved. Thus far, however, I have found no other agents equal to them; except—within limitations—the specific Type I serum in Type I cases and mixed (polyvalent) pneumonia bacterins in other cases. The serums and bacterins may some day displace drugs in the treatment of the pneumonias; but that day has not yet come. For the present the two classes of agents may usefully supplement one another. As for the watchful waiting of the "expectant" plan of treatment, that is confessedly bankrupt. "Nature cures," it is true; but in the pneumonias, nature needs the guidance and assistance of scientifically minded art.

Auxiliary agents under special circumstances are oxygen, atropin, camphor, musk, strychnin, etc., and auxiliary measures of great importance are counter-irritation at the beginning, warmth to the chest throughout, and bleeding when indicated. These need not be discussed here.

PURPOSE OF QUININ, AND INDICATIONS  
FOR ITS USE

Quinin is not employed for the purpose of reducing temperature, but to combat bacteria, bacterial poisons and tissue poisons. Reduction of temperature, however, is an incident of its action, and thus affords a convenient index to its pharmacodynamic effect. The temperature curve is therefore taken as a guide for dosage, both as to quantity and frequency. Commonly the temperature, if above 102 F., is brought to or below that figure within three or four hours after the administration of the drug in sufficient quantity. A persistent tendency to reascend is the indication for continuing or increasing the medication. Cases of moderately high temperature, that is to say, from 104 to 105 F., in which quinin sufficiently and persistently used, fails to make a decided impression, are rare, and the failure is of bad omen. So far as I have been able to have such cases typed, the sputum contains, either singly or in

addition to other types, the organism of Type III, or of what seems to be a particularly virulent variety of Type IV. Among typed cases of resistant temperature, I have not seen any instance in which Type I or Type II was found alone. Many, perhaps the majority, of such cases have been seen late, and have given evidence, either antemortem or postmortem, of extensive suppuration, pleural or pulmonary. Various streptococci and staphylococci, sometimes Friedländer's bacillus, Pfeiffer's bacillus, *Micrococcus catarrhalis*, etc., are likewise found, but these are present also in cases that do not resist quinin. So far as my own studies go, however, quinin has no special influence on streptococci poisoning—its virtue is against the pneumococcus. This long-standing clinical observation has been verified experimentally through a series of studies by Drs. Kolmer, Heist, Steinfeld, Weiss and myself.<sup>1</sup>

## COMPOUND USED, AND DOSE

The preferable salt of quinin for administration by mouth is the dihydrobromid; for intramuscular injection, quinin and urea hydrochlorid; for intravenous injection, either of these, or the dihydrochlorid.

Massive dosage is commonly needed. The larger the quantity that can be taken in the first twenty-four hours, the better the prospect of recovery.

By the mouth, from 25 to 35 grains are given to begin with, and later, according to effect, from 5 to 15 grains every two, three or four hours. When the drug is given by the mouth, it is well to keep the temperature index down to 100 F. or less; and even should it fall to normal, there is no occasion for alarm, in the absence of severe symptoms of cinchonism—such as sweating, amblyopia, or tintinnus aurium. I have not, myself, encountered any instance of untoward cinchonism, the extreme tolerance of pneumonia patients to quinin being, indeed, one of the evidences of its antitoxic virtue. Two instances of transient amblyopia have, however, been reported to me. In this respect the unmodified quinin molecule differs very much from optochin (ethylhydrocuprein), whose toxicity is so great as to render it unsafe for internal use, although unequaled for local applications in pneumococci infections. The common practice, which may be used tentatively in any case, is to make the second dose of the quinin salt 15 grains, and the third dose 10 grains, and after that to keep up doses of 10 grains every fourth hour (during the waking hours) for a day or two, and then reduce the quantity to 5 grains every fourth hour. This plan, however, is not a rigid one and is subject to considerable modification, both as to quantity and frequency, according to the reaction and progress of the individual patient. Even in cases of quinin idiosyncrasy, it will be found that quinin in large doses is well tolerated during the progress of an acute lobar pneumonia—probably in other forms of pneumococcus infection as well, although it so happens that I can speak from personal observation only of that first mentioned. I have seen six such cases, and they have furnished six instances of recovery from the infection, without injury by the drug.

By intramuscular injection, the practice originally was to give 1 gm. (about 15 or 16 grains) as soon as the patient was seen, and to repeat this every third hour until the temperature persistently remained below 102 F. Later observation would point to 100 F. as a better index point. Also, it has been found that

<sup>1</sup> Summarized by Cohen, S. S. Penn. M. J. 22: 596 (May) 1919.

an initial injection of 1.5 gm. (say from 20 to 25 grains) is well borne, and that it may be followed by administration by mouth with almost equally good result as the continuous intramuscular injection. Thus the physician who sees his patient only once a day may make an injection at that visit and have even unskilled attendants continue to give the drug in capsule, in doses of from 5 to 15 grains every third hour, or every fourth hour, according to effect. If the intramuscular route is used continuously, the doses are continued at 10 or 15 grains every three or four hours until the temperature keeps at 100 F. or less. The solution is best made with boiling water, extemporaneously, and may be from 25 to 50 per cent. The skin must be painted with iodine, the injection given deeply, the needle emptied before withdrawal, and the point of puncture sealed with collodion. This averts local irritation and necrosis.

*Intravenous injection.* The initial dose has thus far been 1 gm. or less (from 10 to 15 grains) in 100 c.c. of physiologic sodium chlorid solution. At first, the attempt was made to make the solution neutral by the use of monosodium phosphate and disodium phosphate in physiologic proportions. An elaborate formula was worked out, and when the manipulations were carefully made, precipitation did not occur and the result was satisfactory. While this refinement was necessary to eliminate certain sources of error in some of our experiments on animals, it is unnecessary in the therapeutic use of the drug. No harm, local or general, results from the slight degree of acidity of the 1 per cent. solution in saline. It is rarely necessary to repeat an intravenous injection. The temperature commonly falls rapidly to normal or a little below, and in the course of a few hours returns to a moderate elevation. Sometimes it is not necessary to give the drug again at all; in other cases, administration by mouth in doses of from 5 to 10 grains every fourth hour suffices.

Observations concerning the bactericidal properties of the blood and serum of cinchonized animals and those on pneumococcus cultures *in vitro* have demonstrated that the power to kill or inhibit the pneumococcus is retained much longer when quinin is given in moderate doses, not more than three, or at most four hours apart, than when it is given in much larger doses, but with greater intervals. The frequency of repetition therefore is important, irrespective of the size of the dose. Small doses, however, are sufficient, even when repeated as often as every two hours. The first dose must always be from 10 to 20 grains by mouth or vein, or from 25 to 35 grains by vein. After that, not less than 5 grains, and as much as 15-20.

#### GRAPH OF SOLUTION OF HYPOPHYSIS, AND INDICATIONS FOR ITS USE

Solution of hypophysis is used to sustain blood pressure and prevent profligate eutery-paralysis. Gibson has observed the great prognostic omen, in acute lobar pneumonia, of a fall in systolic blood pressure to a point at which the number of millimeters of mercury is less than the number of pulse beats per minute. The arithmetic relation is purely accidental, but is convenient for the plotting of curves. The fundamental fact of vagus and vasomotor depression shown by these curves is of high importance. Although the accuracy of Gibson's interpretation has been denied by

many good observers, it has been confirmed by others, equally good; and the phenomenon described may be accepted as indicating a condition sufficiently serious to call for therapeutic correction—which is all we have to do with at present.

After considerable experimentation with various pressor agents—atropin, cocain, ergot, epinephrin and the posterior pituitary principle, in particular—the last named was chosen for routine administration for several reasons. Its action is less prompt than that of epinephrin, but equally powerful, and much more lasting. Cocain is equally lasting, but not so marked in result, and no more prompt. Atropin is as prompt as epinephrin and somewhere between epinephrin and solution of hypophysis in staying power, but no more marked than cocain. Hence solution of hypophysis excels all others in that it possesses both of the most important requisites, namely, intensity of action and duration of effect. In addition, it has the great virtue, in most instances of its continuous administration, of preventing that paralytic dilatation of the stomach and intestine which frequently accompanies the general vasomotor and cardiac depression indicated by the fall of blood pressure; both being the result, no doubt, of the action of the pneumonic poisons on the autonomic-sympathetic nerve system. When solution of hypophysis does not prevent dilatation, it frequently overcomes that untoward symptom.

The rule of practice is to inject 1 c.c. of any good commercial extract of the posterior pituitary body every third hour, until the systolic blood pressure in millimeters of mercury exceeds by five points or more the frequency of the pulse in beats per minute, and to continue its use as long as needed, in order to maintain this relation. Irrespective of pulse rate, the systolic pressure should not be permitted to fall below 90 while fever persists. In conditions of urgency, solution of hypophysis is repeated hourly, or is aided by one of the other agents (as, cocain, epinephrin [adrenalin] or atropin) given at alternate hours. When dilatation of the stomach threatens—as shown by tympany beyond the midaxillary line on percussion of the left lower thoracic region, or as indicated by other symptoms—solution of hypophysis should be given hourly for three hours, independently of the effect on blood pressure; and if the symptom is not then overcome, should be continued every two hours, with physostigmin (eserin),  $\frac{1}{60}$  grain (1 mg.), alternated hourly, as long as necessary.<sup>2</sup>

#### PURPOSE OF DIGITALIS, AND INDICATIONS FOR ITS USE

Apart from the ordinary pharmacologic action of digitalis, it appears to have, in lobar pneumonia at least, a special usefulness not explicable by anything known concerning its action on the nervous or muscular mechanism of the heart. Concerning this unknown factor, naturally, nothing definite can be said.

The purpose of the administration of digitalis, then, be stated as the support of the cardiovascular action, particularly as evidenced by the relation of the

<sup>2</sup> When gastric dilatation, not having been thus anticipated and prevented, occurs, the stomach should be washed out, and solution of hypophysis and physostigmin should be administered in the manner stated. When intestinal paralysis is shown by tympanites, the same are as to be made of solution of hypophysis and physostigmin; added to hot turpentine-stupe to the abdomen, perhaps the use of turpentine by mouth, the insertion of a rectal tube, and, if necessary, by a hot enema of a-safedid and alum. No degree of tympanites is slight enough to be neglected, but the activity of treatment will, of course, be regulated by the severity of symptoms.

diastolic blood pressure to the respiration frequency. By an arithmetical coincidence similar to that which underlies the Gibson pressure-pulse relation, it can be affirmed that whenever the diastolic pressure in millimeters of mercury falls to within less than ten points of the respiration frequency in excursions per minute, the prognosis tends to become grave; and that so long as the interval of ten points or more is maintained, the prognosis remains fairly good.

Furthermore, a drop of diastolic pressure below 60, irrespective of the respiration rate, if occurring before fever ends, is potentially of unfavorable import. Consequently, either rise of respiration rate or fall of diastolic pressure so far that the two curves fail to show an interval of ten points or more, or a tendency of diastolic pressure to fall and remain below 60, constitutes the definite indication for the production of full digitalis action. The effect is best measured by the rise of diastolic pressure,<sup>3</sup> which is a much more trustworthy and significant index than the pulse rate. Numerous charts in my possession, some of which have been published, exhibit this fact beyond contravention; and recent observations directed solely to this point, on patients with lobar pneumonia and on patients convalescing from lobar pneumonia, exhibit the digitalis effect on diastolic pressure in a marked degree, while as yet pulse rate and systolic pressure are influenced but slightly. I would invite confirmatory or connective clinical studies by others.

There is one practical point, however, which needs repeated emphasis: Even when a good preparation of digitalis is given hypodermically or intramuscularly and in full dose,<sup>4</sup> say the equivalent of 3 grains of the leaf, at least four hours elapse before a marked rise of diastolic pressure can be noted; sometimes it is eight hours or more. This interval can be shortened by previous sensitization of the heart to digitalis. At least, it is shorter when digitalis in moderate doses has been previously administered for two or three days. Hence it is well to give the digitalis from the beginning, in small doses—about 5 minims of a good tincture, by mouth three times a day, ordered as soon as one sees the patient—irrespective of the symptoms presented. Such dosage does no harm, in any event. The malady may run its course to recovery without any definite indication for full digitalis action being presented; but the drug is continued in these small doses, nevertheless. If, however, the indication for digitalis arises, as shown by the approach of the respiration and diastolic pressure curves, the drug is then immediately given hypodermically in full dose and repeated every four hours so long as necessary to maintain diastolic pressure at the height indicated. Should symptoms of digitalis poisoning occur, judgment would have to be used as to the continuance or discontinuance of the drug, or the modification of quantity or interval. It is only right, however, to say that digitalis poisoning has not been observed in my experience, in this manner of using the agent; and this, like the parallel quinin tolerance in pneumonia, calls attention to an obscure point in the study of toxemias of infection and drug-antidotism, that is well worth the attention of clinicians and experimenters. My own studies have made only a beginning. Additional and independent work is much needed.

1525 Walnut Street.

## CAROTINEMIA: A NEW CLINICAL PICTURE\*

ALFRED F. HESS, M.D.

AND

VICTOR C. MYERS, PH.D.

NEW YORK

About a year ago one of us (A. F. H.) observed that two children in a ward containing about twenty-five infants, from a year to a year and a half in age, were developing a yellowish complexion. This coloration was not confined to the face, but involved, to a less extent, the entire body, being most evident on the palms of the hands, which showed also distinct signs of desquamation. The sclerotics were not at all affected. The urine was amber, and the stools normally yellow. For a time, we were at a loss to account for this peculiar phenomenon, when our attention was directed to the fact that these two children, and only these two, were receiving a daily ration of carrots in addition to their milk and cereal. For some time we had been testing the food value of dehydrated vegetables, and when the change in color was noted, had given these babies the equivalent of 2 tablespoonfuls of fresh carrots for a period of six weeks.

It seemed as if this mild jaundiced hue might well be the result of the introduction into the body of a pigment rather than the manifestation of a pathologic condition. Attention was accordingly directed to the carrots, and the same amount of this vegetable was added to the dietary of two other children of about the same age. In the one instance, after an interval of about five weeks, a yellowish tinge of the skin was noted, and about two weeks later the other baby had become somewhat yellow. There was a decided difference in the intensity of color of the four infants, indicating probably that the alteration was in part governed by individual idiosyncrasy. On omission of the carrots from the dietary, the skin gradually lost its yellow color, and in the course of some weeks regained its normal tint.

The subject was pursued farther, and blood was aspirated to ascertain whether it contained the pigment, and more particularly to determine, if such were found to be the case, whether the nature of the coloring matter could be identified. In the two instances in which blood was withdrawn, the serum, as well as the plasma, was found to be distinctly yellow, much like that which is obtained in cases of jaundice. Various tests were carried out in order to determine the solubility of the pigment. They may be summarized by the statement that it was found to be soluble in purified petroleum benzine. To test its solubility, the plasma was first allowed to stand for a short time in contact with plaster of Paris; a few drops of absolute alcohol were added, and it was then extracted by means of a large continuous extractor (of the same pattern as was employed by Myers and Wardell<sup>1</sup> for cholesterol, only about seven times larger) for about eight hours. The extract had a very definite yellow color, whereas subsequent ether extraction proved negative. This is the test which has been devised by Willstätter and Mieg<sup>2</sup> to determine the presence of carotin.

\* Presented before the American Society for the Advancement of Clinical Medicine, Atlantic City, N. J., Jan. 13, 1919.

<sup>2</sup> Willstätter and Mieg, *Ann. d. Chem.*, **355**: 1, 190.

<sup>3</sup> The diastolic pressure is taken at the time of the disappearance of the sharp sound, not at the time of the last faint pulse.

<sup>4</sup> I have never used in pneumonia the "Bagleston method." It might be well to try it out. I am not prepared to say.

It was evident that we were dealing with a systemic condition brought about by the introduction of an excess of carotin in the food. A search through the literature failed to reveal a description of this condition, either in children or in adults. It is probable that von Noorden had this pathologic condition in mind when he described a "peculiar canary yellow tint of the epidermis, which appears especially in the nasolabial folds, on the palms of the hands and soles of the feet," which he had observed in diabetes, especially in those who are youthful. He regarded this peculiar alteration as the manifestation of some metabolic disturbance and termed the condition "xanthosis diabetica," reading a paper under this title before the International Dermatological Congress in Berlin (1904).

Excellent studies, however, have been carried out on animals in the last few years by Palmer and Eckles<sup>1</sup> and by Palmer as to the relation of fodder to the carotin content of the tissues. It was found, for example, that green feeds greatly increase the color of the butter fat of cows, mainly because they contain carotin, which accompanies chlorophyll in green plants. The body fat of the animal, the blood serum and the corpus luteum all depend for their intensity of color on the pigment of the food. This pigment, furthermore, is of two kinds: carotin, having the solubility mentioned above, and the xanthophylls, which are distinguished as being insoluble in purified petroleum benzine but soluble in 80 to 90 per cent. alcohol. In some animals, xanthophyll was found to be absorbed in by far the greater ratio, as, for example, in the hen, which, when deprived of this pigment in its food, has produced eggs having almost colorless yolks;<sup>2</sup> in others, as in the cow, carotin predominates in the tissue pigment. In still other animals, in the sheep and the goat, neither pigment is absorbed, so that we observe the colorless fat in so characteristic of these species. We are informed that in man "the relative proportion of carotin and xanthophyll is much more nearly equal than in the fat of cow's milk."

These pigments are very widely distributed among our foodstuffs, and it is probable that they frequently play a rôle in coloring the skin. As they are nontoxic<sup>3</sup> and lead to no physiologic disturbance, the discoloration usually overlooked or attributed to some minor impairment of the liver or of the intestinal tract. The discoloration may be brought about not only by carrots but also by any food which contains the carotinoids in high degree—we have seen it follow when the dietary included two oranges a day, or the yolk of one egg in the diet for a period of two months, or 2 ounces of egg yolk daily for one month. It is the pigment of the hemolytic and of the highly colored colostrum, and they will play a part, although a minor one, in the coloring of the raw horn.

It is probable that there will be found to be considerable individual variations in regard to the absorption of these pigments. Such was found to be the case to a marked degree in relation to another vegetable pigment which we are getting to, namely, that in beets. In certain children, a diet containing a moderate amount

of beets will lead to the occurrence of a red coloring matter in the plasma and in the urine, which may excite alarm. In others of the same age or younger, extraordinary amounts of beets or beet juice, as much as 8 ounces a day, may be given without any change in the body fluids.

#### EFFECT ON THE URINE

There is quite another aspect of this subject which is of interest: In the course of subcutaneous injections of an extract of carotin,<sup>4</sup> carried out in order to note whether an alteration in the color of the plasma could be occasioned by this means, it was noted that not only did the plasma become yellow but that the urine was changed in color. Following these general observations the urine was collected, evaporated to a very small volume, and extracted with purified petroleum benzine as in the case of the plasma. An extract of a definite yellow was thus obtained. In order to substantiate this result, concentrated carotin was given by mouth, and careful note was made as to whether the color of the urine was thereby heightened. The total amount of carotin in carrots is surprisingly small, less than 2 gm. per hundred pounds, and it is very difficult to obtain in a pure state. For our purpose it seemed adequate to follow the same procedure employed for the subcutaneous injections, to extract a considerable quantity of carrots with purified petroleum benzine and take up the residue with olive oil. In this way we obtained finally 15 c.c. of a preparation which represented about 10 pounds of carrots. To one infant, aged a year and a half, 5 c.c. of this carotin extract were given by mouth, and to another, twice this amount. The urine was collected previous to giving the extract and every half hour subsequently for a period of eight hours. This test definitely showed that the urine becomes yellower within three quarters of an hour after giving from 5 to 10 c.c. of concentrated carotin, and that this increased color persists for about six hours. Eighteen specimens, in all, were obtained from each case, and there could be no mistaking the intensification of color and the subsequent return to an almost colorless urine.

This pigmentation of the urine is perhaps of theoretical rather than of practical or clinical importance. Textbooks and physiologists teach that the urinary pigment is urochrome, and that it is a decomposition product of bile. If our observations are correct, it would seem that pigments derived from the blood likewise play a rôle in coloring the urine. In this way we may account for the characteristic light color of the urine in infants, compared to that of older children and of adults who are on a more liberal diet, containing a larger amount of vegetable pigment. This factor should be borne in mind in considering the nature of highly colored urines, which are now attributed solely to the absorption of bile and its derivatives.

#### CONCLUSIONS

We have shown that a diet rich in carotin (carrots, spinach, egg yolks, oranges, etc.) will bring about a yellow discoloration of the skin, a condition resembling mild jaundice, except for the noninvolvement of the sclera. This pigmentation, no doubt, has been frequently overlooked, confused with mild grades of icterus, or attributed to some obscure metabolic disturbance. It

7. A very large carrot was dried and completely extracted with purified petroleum benzine. The liquid was allowed to evaporate, and the carotin was taken up in olive oil. One and five tenths c.c. of this preparation were injected.

cannot be of rare occurrence, as carotin is widely distributed throughout our diet, being a constituent of almost all our vegetable foods. It is a disturbance which, therefore, will occur most readily in those subsisting on a dietary containing a large quantity of vegetables. The discoloration of the skin is accompanied by a similar yellow tingeing of the blood serum and the plasma. The pigment in the blood was identified as carotin.

In cases of carotinemia the urine was colored yellow as well as the serum. When a small quantity of concentrated carotin was ingested, the pigment appeared rapidly in the urine. These observations are of interest in view of the fact that clinicians as well as physiologists consider that the urinary pigments are formed solely from bile or its derivatives.

## VENEREAL DISEASE REPORTING IN MINNESOTA

### A STATISTICAL STUDY

L. W. FEEZER

Assistant Director, Division of Venereal Diseases, Minnesota State Board of Health  
MINNEAPOLIS

Until very recently, statistical statements relative to venereal disease have been largely guesses; and in case a definite basis was present, the material has been of very fragmentary nature. The only figures available have been gathered from hospital or institutional surveys and from men living more or less permanently under military discipline. No one knows how much venereal disease exists in this or any other country. Various estimates by capable men place the syphilitic portion of the population at from 3 to 15 per cent.

#### THE VENEREAL DISEASE RATE IN THE ARMY

The induction of several million men into naval and military service revealed on their examination an apparently larger venereal disease rate in the civilian male population than among the men in the regular army. The annual rate per thousand for the regular army in 1917 was 88. The computed annual rate for the draft army at one time shortly after the first draft went into camp mounted at one time to 388 per thousand.<sup>1</sup>

The second million men were more carefully examined than the earlier draft increment, and the records were more carefully kept. These men were examined at mobilization camps, and these examinations revealed that 5.4 per cent. of this million men, in all 108,000, between the ages of 21 and 31, had on the date of examination a venereal disease. How many of these men had previously had a gonorrhoeal or syphilitic infection that was entirely cured, or at least could not be detected in the army medical examination, it is impossible to say.

The percentage of soldiers with venereal disease has been worked out, not only for the entire group, but by state of residence. This percentage runs as low as 1.3 per cent. in some states (Vermont), and as high as 15.6 per cent. in others (Florida). All the states showing a rate in excess of 6 per cent. have a large negro population. The rate for Minnesota is 2.31 per cent.

#### THE VENEREAL DISEASE RATE OF THE CITIES

The rate was similarly worked out for the principal cities of the country. This rate ran as high as 27 per cent. in some of the Southern cities and as low as 2 per cent. in some of the New England cities. In all sections the urban rates were higher than the general rate for the state. The rates for the principal Minnesota cities were: Minneapolis, 4.09 per cent.; St. Paul, 3.98 per cent., and Duluth, 4.37 per cent. The general rate for cities was found to be 5.8 per cent.<sup>2</sup>

This short explanation is given chiefly for the purpose of showing Minnesota's relative position with reference to the prevalence of venereal disease, so far as we are able to consider the figures for the army an index of the condition of the civilian population. It is not unreasonable to believe that it is at least a fair index of the relative venereal disease incidence in the several states. Other data that will be presented in this paper indicate the draft age period as the one for which the venereal disease rate is highest among civilians. Therefore, it is not safe to assume that the percentages shown above are correct for all ages. However, we may go so far as to assume that a state having a relatively high percentage of young men with venereal disease has also a relatively high percentage of venereally infected persons in all age groups, and the comparison of ratios in different states may be the means of arriving at other conclusions of value in studying the distribution of venereal infections in our own state.

#### REPORTING OF VENEREAL DISEASE IN MINNESOTA

The regulation of the Minnesota State Board of Health requiring the reporting of venereal diseases was put in operation, Aug. 1, 1918. The fiscal year of 1918 ended June 30, 1919. During the eleven months of this fiscal year, 6,777 cases of venereal disease were reported. These reports, by disease and by month, are given in Table 1.

The Minnesota report card calls for certain medical and social data regarding patients with a view to furnishing material for statistical studies and, if possible, to assist in getting at the actual source of the particular infection.

Physicians have not been required to report venereal infections by the patient's name but are given the option of using the number printed on the card, as the identifying designation of the case. In spite of this option, a very considerable proportion of cases have been reported with the name of the patient, and a great number of physicians have been successful in getting at the name of the person who was the source of infection. This information has led to the apprehension of many dangerous and careless carriers of these infections by the social service investigators of the board.

The percentage of cases in which the name of the patient has been given is 62.5, leaving 37.5 per cent. reported by number. These percentages, which represent all cases reported, include, of course, the many cases reported by clinics, which always give the patient's name.

There were reported from the smaller towns of the state and from Duluth, exclusive of the clinic at Duluth, 1,611 cases. All these reports were made by private physicians, yet the reporting by name continues

1. Circular C 02, War Dept., Commission on Training Camp Activities.

2. A. D. Parke of the U. S. P. H. S. reports that a complete report of the Surgeon General on the physical condition of the second million men has not been made available for publication at the date of this paper.

high, namely, 48 per cent., leaving 52 per cent. reported by number. These figures go far toward refuting the often propounded argument that a law requiring venereal disease reports cannot be enforced. In short, the physicians of Minnesota, outside the Twin Cities at least, are voluntarily reporting the names of patients in approximately one half of their venereal cases.

#### THE MARITAL STATUS OF PATIENTS

One of the questions asked on the report card refers to the marital status of the patient, namely, whether

TABLE 1.—REPORT OF VENEREAL DISEASES IN MINNESOTA FOR THE PERIOD AUG. 1, 1918, TO JUNE 30, 1919

	Gonorrhoea	Syphilis	Chancroid	Total
August, 1918	296	372	18	683
September, 1918	230	331	22	673
October, 1918	40	295	16	701
November, 1918	34	263	12	629
December, 1918	96	264	10	560
January, 1919	316	246	21	583
February, 1919	115	229	16	360
March, 1919	46	223	8	284
April, 1919	27	220	8	249
May, 1919	27	207	14	689
June, 1919	27	205	9	280
Total	1,772	1,961	174	6,778

married, single or widowed. Under the last expression are included divorced persons. As was expected, the majority of infections were reported among single persons, the married and the widowed combined being less than the single. It was to be expected that the percentage of widowed persons would be small because this group is a comparatively small percentage of the population and is a status that is not commonly reached until long after the age at which exposure is most likely to take place. The result of this tabulation was: single, 3,932, or 60.7 per cent.; married, 2,260, or 34.9 per cent., and widowed, 285, or 4.4 per cent.

The question of source of infection is, of course, one of the most important concerning which information is desired by the state board of health. The question on the report card, "Source of infection?" is supplemented by "Commercial or clandestine?"

Physicians have not only indicated whether the source was a clandestine or a commercial prostitute, but have indicated when the spouse (husband or wife) of the patient was the source of infection and when

TABLE 2.—MANNER OF REPORTING VENEREAL CASES IN MINNESOTA

Manner Reported	No. of Cases	Percentage
By Name	772	48
By Number	809	52
Total	1,611	100

the case was congenital (syphilis) or accidental. These last two classifications, being relatively infrequent, have been grouped together. The percentages are shown in Table 3.

It should be noted that a very considerable portion of the cases in which no data as to the source of infection were available are tertiary syphilitics whose infection dates back some time, but who are now being reported because of the short time that has elapsed since reporting began. It is highly probable that in the "unknown" cases the infection was acquired in the same ways and in somewhere near the same proportion as those for whom the sources were given.

A table has been prepared from which the "unknowns" have all been dropped. Out of a series of 3,710 cases, in which the reporting physician has very clearly answered the question as to the nature of the source of the infection, we have, therefore, been able to determine the corrected percentages that fairly represent the actual ratio in which these various classes of sources are responsible for the spreading of venereal disease in Minnesota (Table 4).

#### RELATIVE PROPORTION OF CLANDESTINE AND COMMERCIAL PROSTITUTES

It is interesting to note the fact that there were 6.5 per cent. more cases reported as infected by clandestine prostitutes than by commercial prostitutes. While this does not necessarily prove that clandestine prostitutes are quite as likely to be infected as the professional sort, it does tend to bear out similar observations that have been made before. The accidental infections are so few in number that they were grouped with the congenital syphilis cases. The 4 per cent. indicated in this group are almost all cases of congenital syphilis. It may be stated as an item of interest that a majority of them were reported by the Mayo Clinic at Rochester.

TABLE 3.—STATISTICAL DATA ON THE SOURCE OF VENEREAL INFECTION

Reported Source	No. of Cases	Percentage
Not reported or indicated as unknown	2,870	42.4
Commercial prostitute	1,604	23.7
Clandestine prostitute	1,861	27.5
Spouse	318	4.7
Congenital and accidental	108	1.6

TABLE 4.—THE SOURCE OF VENEREAL INFECTION, THE "UNKNOWN" CASES BEING OMITTED

Reported Source	Percentage	No. of Cases
Clandestine prostitute	46.8	1,736
Commercial prostitute	40.3	1,495
Spouse	8.9	331
Congenital syphilis and accidental	4.0	148
Total	100.0	3,710

The person who was the source of the infection was given in comparatively few cases, only 7 per cent. of the entire number reported. This number, about 450, would constitute about 11 per cent. of the cases in which any information at all is available regarding the source of the infection. It would seem that with thousands of cases very recently infected by prostitutes, in addition to the cases in which the spouse is the source and known by name to the physician, more of this valuable information could be secured. It is on the basis of this information that much of the most valuable work of the board in eliminating carriers can be accomplished.

#### DISTRIBUTION OF CASES ACCORDING TO AGE GROUPS

One of the most interesting studies in connection with these cases has been their distribution into age groups. It should again be kept in mind in this connection that the groups of cases studied include a considerable number of long-standing syphilitics under treatment at dispensaries and therefore do not show really accurately the age of infection. It does show, however, that the approximate age at which the venereal patient finds himself in the hands of a reputable physician or institution is between 32 and 33 years. A study was made of the average ages by

location of cases. For certain months the patients from outside the Twin Cities, so far as this point was studied, appear to be of the average age of 27 years. The latter cases do not include so many old syphilitics as the reports from the cities, which include clinic cases and many others coming to city specialists for the treatment of advanced conditions; but even this figure is probably too high to represent the true average age at which infection with venereal disease takes place.

Table 5 gives the age grouping in 5,683 cases. This table was made up before all cases, reported up to

TABLE 5.—THE AGE GROUPING IN 5,683 CASES OF VENEREAL DISEASE

Ages	Number of Cases	Percentage
20 years and under.....	842	14.8
21 to 25 years inclusive.....	1,295	22.7
25 to 30 years inclusive.....	910	16.0
31 to 35 years inclusive.....	640	11.4
36 to 40 years inclusive.....	525	9.2
41 to 45 years inclusive.....	400	7.0
46 to 50 years inclusive.....	335	5.9
over 50 years.....	736	13.0
Totals.....	5,683	100.0

July 1 and indicated in Table 1, had been tabulated. It has been noted that the age grouping has been fairly constant from month to month.

SUMMARY

The following points in particular have been observed in studying case reports of venereal disease in Minnesota for the past year:

1. Of all cases, 62.5 per cent. were reported by name, and only 37.5 per cent. by number. This includes a large number of cases reported by clinics. Of cases seen by physicians in private, practically 48 per cent. were reported by name, and 52 per cent. by number.

2. Of all cases reported, 61 per cent. were single persons, 35 per cent. married, and 24 per cent. widowed or divorced.

3. Of all cases reported, 27 per cent. are females, and 73 per cent. are males. Among those cases in which the report card contained any statement whatever regarding the source of infection, 87 per cent. were stated to be pro-titutes. Of these 47 per cent. were clandestine, and about 40 per cent. were commercial prostitutes. The name of the person who was the source of the infection was reported in 7 per cent. of the total number of cases.

4. A larger number of patients fell in the age group from 21 to 25 years than in any other. The next largest group was from 25 to 30 years. This group comprised 16 per cent. of the total, and was very slightly larger than the total for all ages under 20.

**Is Your Community Fit?**—What is being done to protect the babies in your community? Have you a baby health station? Do you supervise the work of midwives? Do you make provision for expectant mothers in your community who are in need of advice and supervision? Proper organization for prenatal care, with sufficient bed space in maternity wards, and a baby health station should be provided if the financial condition of your community is at all able to support such expense. If your community is small, at least one full-time public health nurse should be employed for the instruction of mothers in the care of themselves and their babies. You owe this to the mothers.—*Pub. Health Rep.*, April 25, 1919.

ACUTE NEPHRITIS IN CHILDHOOD\*

LEWIS WEBB HILL, M.D.

Junior Assistant Physician, Children's Hospital; Alumni Assistant in Pediatrics, Medical School of Harvard University  
BOSTON

At the Children's Hospital we have been for several years especially interested in nephritis. This paper is a brief exposition of our experience with the acute cases.<sup>1</sup>

ETIOLOGY

It is now generally recognized that the vast majority of cases of acute nephritis are of infectious origin. In the older textbooks, cold and exposure are given as perhaps the more important causes, and it is undoubtedly true that these factors may have something to do with certain cases. In chronic nephritis in older persons, the wear and tear of life, especially on the blood vessels of the kidney, is often of great importance etiologically; but as far as children are concerned, micro-organisms or their toxins may be said to play the main etiologic rôle. It is well known that in many diseases (pneumonia, typhoid fever, etc.) there is enough irritation of the kidney to cause small amounts of albumin and a few blood cells to appear for a few days in the urine; and although this has been called "acute degenerative nephritis" by some authors, I believe it is best to speak of it as "acute renal irritation," and to reserve the term "nephritis" for those cases in which the inflammatory condition of the kidney is more lasting, and is the dominant feature in the disease picture.

Scarlet fever has long been regarded as the most important cause of acute nephritis, but I believe far more cases are secondary to tonsillitis than to scarlet fever. At the Children's Hospital we take no contagious cases, and would therefore naturally see little acute scarlet fever nephritis; and in our series of chronic cases we have seen, in the last three or four years, only four or five cases due to scarlet fever. Almost any acute infectious disease in a child may bring

TABLE 1. ETIOLOGY OF ACUTE NEPHRITIS

Disease	Number of Cases

about nephritis, but tonsillitis is by far the most important of them, as Table 1 will show. Whether it is the toxins of the organisms causing the primary acute disease which cause nephritis as they are excreted through the kidney, or whether the kidney is itself invaded by micro-organisms, is not certain.

The reason so many cases are classed as of unknown etiology is that in most of these instances the patients entered the hospital some time after the nephritis started, and in many it was not possible to get an accurate history. I believe there is no question, how-

\* From the Method Service, Children's Hospital.  
1 For more detail paper, see Hill, L. W., Nephritis of Childhood, *Am. J. Dis. Child.* 14: 67 (Oct.) 1919, and 173: (Nov.) 1919, *M. Clin. N. America*, July, 1919.

ever, that many of these unknown cases were secondary to mild throat infection. It is quite characteristic of those cases secondary to tonsillitis that the nephritis does not appear during the period of sore throat and fever, but usually a week or so after the patient is up and around, and apparently well.

#### DESCRIPTION OF TYPES

There have been many complicated pathologic classifications of acute nephritis, but for many reasons a simple clinical classification seems best, and I have therefore suggested dividing acute nephritis in children into two groups, according to the clinical picture: (1) acute hemorrhagic, and (2) acute exudative.

1. *Acute Hemorrhagic Nephritis*.—This is a type of nephritis occurring especially in children, although it is seen occasionally in adults. Its chief characteristic is a very bloody urine containing very few casts. The urine may be so bloody as to resemble clear blood, and sometimes several specimens of sediment may have to be looked over before any casts are found. The urine is not diminished in amount, and there is usually no edema. The various tests for renal function usually show a moderate impairment of kidney efficiency, but never the severe impairment that is often seen in the clematous cases with scanty urine containing many casts. The blood pressure is occasionally somewhat elevated, the highest we have ever seen being 140 mm. of mercury, but it is more likely to be normal than high. The subjective symptoms are insignificant, and we have never seen uremia in this type of nephritis. The urine usually contains blood for from six to twelve weeks, and in many cases may contain microscopic blood over a period of several months. Occasionally, a urine which shows no albumin will show a considerable number of blood cells in the sediment when examined microscopically. The prognosis is, as a rule, good, and we have seen no child die with this type of nephritis. Usually the process clears up entirely and leaves a perfectly good kidney behind it, but in a few cases chronic nephritis unfortunately develops.

2. *Acute Exudative Nephritis*.—The second type of acute nephritis, which we have called "acute exudative," presents a somewhat different picture. Edema is usually marked, and is sometimes extreme in degree. The urine output is very scanty during the early stages, and as the kidney begins to recover there is a polyuria. The urine is likely to be brownish red, with a heavy sediment of disintegrated blood, and contains a large amount of albumin. Microscopically, it shows large numbers of granular or cellular casts, and considerable numbers of blood cells. The child is likely to become more ill in this type of nephritis than in the acute hemorrhagic type. The blood pressure is usually elevated, there may be headache and convulsions, and occasionally a patient dies in uremia. The renal function tests, as a rule, indicate considerable impairment of kidney efficiency. Most patients recover, however, and usually without the development of chronic nephritis. Two patients out of twenty-four with this type died during the acute stage.

In our series of forty-nine cases of acute nephritis there were twenty-five of the "hemorrhagic" and twenty-four of the "exudative" type. In most of the hemorrhagic cases, tonsillitis was the etiologic agent, as it was also in the "exudative" cases; but far more of the exudative cases were of unknown etiology than were cases of the "hemorrhagic" type.

#### TREATMENT

Acute nephritis of either type should always be regarded as a serious disease. It seems rather unnecessary to say this, but I have seen a number of patients without edema who were allowed up and around, although the urine contained a large amount of blood.

It is especially important to keep a child with acute nephritis warm, and at the Children's Hospital we always have these children wrapped in an extra blanket, and take especial care to keep them out of drafts. It goes without saying that bathing and proper care of the bowels are of great importance. In the cases without edema we use licorice powder as a laxative, and in those with edema, when free watery catharsis is desired, magnesium sulphate. It is surprising to see how well most children take magnesium sulphate; they do not seem to object to it as much as do adults. Sometimes the best results can be obtained with it if it is given in small, frequent doses, that is, 1 teaspoonful every hour for five or six doses. Diuretics play a very small part in the treatment of acute nephritis, and most authorities are agreed that the stronger diuretics, such as the caffeine derivatives, may do more harm than good in this condition. There is no objection, however, to giving such mild diuretics as potassium citrate or cream of tartar. Iron is always indicated in acute nephritis of any type, as there is a considerable daily loss of blood in the urine, and anemia rapidly develops. For children, we prefer the saccharated ferric oxid in doses of from 3 to 5 grains three times a day. We have used the hot pack, or hot air bath, to promote sweating, in a few cases with extreme edema, but in the vast majority of patients the edema can be controlled by dietary measures and purgation. In severe cases, the hot air bath is used as an adjunct to these. Drugs, with the exception of laxatives and cathartics, are of comparatively small value in the treatment of acute nephritis, and far more important is the general care of the patient, particularly as regards the diet and the water intake.

*Diet*.—In acute nephritis we are dealing with acutely inflamed kidneys. It should be our aim, in accordance with general therapeutic principles, to rest these irritated organs as much as possible, and to protect them from the irritating end-products of metabolism. Food-stuffs may be divided into four groups: fat, carbohydrates, protein and salts. The fats and carbohydrates are not excreted through the kidney, but are burned in the body; therefore, free administration of fat and carbohydrate is permissible in acute nephritis. The kidney's chief function is to excrete the end-products of protein metabolism and some of the salts, particularly sodium chlorid. Consequently, in any dietary measure designed to spare the kidney, it is necessary to consider these two substances.

*Protein*: It is not desirable to put a patient with acute nephritis on a strictly protein free diet, which would probably do him more harm than good, as a certain amount of protein is necessary to repair the wear and tear of body tissue, and to keep the patient in nitrogenous equilibrium. Not a great deal is known of the exact protein requirements of children, but probably the old figure of from 1.5 to 2 gm. protein per kilogram of body weight is near enough to the actual requirement for practical purposes. The child should have, then, not more than 2 gm. of protein per kilogram of body weight. For practical purposes, in many cases, it is quite sufficient to omit meat, eggs, fish and

meat soups from the diet, and to make it up of cream, milk, cereals, bread, potato, etc. In the hospital we usually roughly calculate the protein and caloric value of the diet, according to the accompanying table of values (Table 2).

Table 3 represents an actual diet given during the acute stage to a boy, aged 5 years, with acute hemorrhagic nephritis.

Salt: In the cases without edema, it is quite sufficient to prohibit any salt cellar on the tray. The bread and butter does not need to be salt free, nor is it necessary to omit salt when cooking the vegetables and cereals. In the edematous cases, a more rigid salt restriction is necessary, as the most generally accepted view of edema in acute nephritis is that it is brought about by a primary salt retention with secondary water retention. In this group of cases the butter should be unsalted, and the bread, cereals and vegetables should

a day. If the patient handles water well, and there is no increase in weight or edema, the fluid intake may be gradually raised. It is important to weigh these patients every day, as often there will be an increase in weight, due to waterlogging, that is not apparent on the surface of the body. It is also important to keep a daily record of the fluid intake and output, and to observe closely their relationship.

EDEBOHLS' OPERATION\*

This operation consists in stripping the capsule from the kidneys, and should not be considered except in extreme cases, when there is a large amount of edema present which will not respond to ordinary measures of treatment, or when the patient is in such a severe state of uremia or anuria that the prognosis is very bad.

This operation has been used more in chronic cases than in acute, but we have had it performed in three of our acute cases with these results:

1. In a case of severe acute exudative nephritis, the operation undoubtedly saved the child's life; the child recovered completely.

2. In a case of severe acute "exudative" nephritis, the operation saved the child's life temporarily, but did not prevent the development of a chronic process.

TABLE 3.—ACTUAL DIET GIVEN IN ACUTE STAGE TO BOY, AGED 5 YEARS

Food and Amount	Calories	Protein, Gm.
Oatmeal, 2 tablespoonsful	70	0.3
16 per cent. cream, 2 ounces	107	1.8
Sugar, 4 drams	100	...
Bread, 3 slices	225	0.9
Butter, 2 cubes	450	...
Peas, 1 tablespoonful	49	0.3
Potatoes, 1 tablespoonful	70	0.2
Custard, 2 tablespoonfuls	110	0.5
Orange juice, 6 ounces	78	...
Ice cream, 2 tablespoonfuls	77	0.9
	1,327	24.7

3. In a case of subacute hemorrhagic nephritis, the operation did no good.

CARE DURING CONVALESCENCE

The child should not be allowed out of bed until the urinary sediment is practically free from blood. By this I mean 3 or 4 red blood cells to a high power field. A small amount of albumin may persist intermittently for months, and is not a contraindication to a moderate amount of activity. If the amount of blood increases when the patient gets up, as it does in some cases, he should be put to bed again. During the ambulatory stage of convalescence, it is especially important to avoid over-exertion and chilling of the body. The patient should be kept under observation for at least a year, and the urine examined every month or two. It is not necessary during convalescence to keep the child on as strict a diet as during the acute stage, and meat or eggs may be allowed once each during the day. It is especially important to guard the patient against throat and respiratory infections, as often if one of these occurs there is an acute exacerbation of the nephritis.

If the tonsils were apparently the original source of the disease, they should be removed as soon as the character of the urine has begun to improve, usually before the patient has been out of bed. If there are any dental pus pockets, the offending teeth should be extracted.

be cooked without salt. Such a diet is called a "salt free" diet, but the designation is not strictly accurate, as most of the ordinary foodstuffs contain a small amount of salt. This is not enough, however, to do any harm. The employment of a "salt free" diet is one of the most effective methods we have of getting rid of nephritic edema, especially when its use is combined with free catharsis and fluid restriction.

Water: In the nonedematous cases no restriction of water is necessary, and indeed it is desirable to give a reasonably large amount of water, as it helps in diluting and eliminating toxins. In these cases the kidney is usually able to handle water, and about 48 ounces of fluid a day is what we like to have the patients take. If the urinary output becomes much less than about two thirds of the intake, and the patient begins to gain in weight, the amount of water should be reduced.

The edematous patients need to be restricted considerably as regards the fluid intake. It is rarely advisable to try to give less than 12 ounces of fluid a day, as there is too much suffering from thirst. Most children, in ordinary weather, can get along very well for a limited period of time on from 16 to 20 ounces of fluid

THE OMISSION OF DRAINAGE IN  
COMMON DUCT SURGERYH. M. RICHTER, M.D.,  
AND  
J. R. BUCHBINDER, M.D.  
(CHICAGO)

Too little attention has of late been devoted to the possibility of a cleaner and safer technic in common duct surgery, namely, the tight closure of the duct following exploration, and closure of the abdominal incision without the use of drainage material of any type. This technic was attempted and abandoned in the early days of gallbladder surgery because of disastrous results, which we feel now can be avoided. Most theses on the surgery of the biliary tract emphasize two points essential to a safe outcome: (1) that the common duct itself should be well drained by placing a tube either within it or to it, and (2) that the abdomen should be drained down to the line of suture. It has been pointed out: (1) that the infected ducts should be drained as infection elsewhere is drained, and (2) that closure of the common duct is not without dangers of the leakage of infected bile.

Contemporary literature contains few references to any attempts at radical changes in common duct surgery. Most surgeons feel that when the common duct has once been opened, the safety of the patient lies in free drainage. But we feel that several important factors in details of technic have been overlooked, the observance of which will make the procedure we wish to suggest almost universally applicable.

The patent common duct, lined with mucous membrane, is a suitable drainage tube in itself and offers an ideal method of draining the affected parts above. If its patency is assured, it may be opened and sutured with impunity, as we would suture the intestine. The means used of assuring ourselves of its patency will be described.

We explore all ducts that show obvious pathologic changes. These changes include either enlargement or the palpatory findings of stone or the presence usually of numerous small stones in the gallbladder when there is any suggestion either of enlargement of the duct or a clinical picture of common duct involvement. We open most ducts showing enlargement, since this usually denotes obstruction due either to stone, to stricture, or to a thickened sphincter. Enlargement is, however, often associated with a functionless, shrunken gallbladder. We open the ducts in all jaundiced cases. A large proportion of these ducts carry infected bile, and this undoubtedly is an important factor in the greater mortality that accompanies common duct exploration over that of simple cholecystectomy.

If the detail of technic rather than any new operative procedure that we wish especially to emphasize; The duct is exposed in the usual manner; a variety of procedures may next be indicated. It is palpated for stones, no complete exploration, mobilization of the duodenum may or may not be necessary. The duct is then incised in the supraduodenal portion. This we have found to be more satisfactory than exposing through the cystic duct, because in cases in which it is necessary to extend the incision, it is difficult to get a tight suture line at the juncture of the two ducts. Furthermore, the inadequacy of exploration through

the stump of the duct must be obvious to any one accustomed to a free incision in the common duct.

The use of the silver probe or sound is an unreliable method of determining the patency of the duct, since by this method a stone of sufficient size to obstruct the free flow of bile may be overlooked. For determining the patency, a scoop or curet is more satisfactory and should be passed through the duct into the duodenum. Transduodenal cholecystectomy remains, however, the safest method of determining the condition of the distal end of the duct, when there is doubt concerning its condition. The biliary orifice is readily found, the sole cause of difficulty probably being an incision placed too high on the duodenum. When in doubt, the location of the end of the duct may readily be determined by passing a probe down the duct from above. That is, a supraduodenal incision is always made in addition to the transduodenal exploration. The orifice having been found, it is slit open to permit the removal of stone or to correct a stricture. It should be emphasized that opening the duodenum is a relatively safe procedure, and should be resorted to more frequently. An overlooked obstruction in this portion of the duct would be a fruitful cause of back leakage through the line of sutures in the duct above.

The patency of the duct being thus assured, and only under these conditions, the common duct is carefully sutured with the finest needles and suture material obtainable. Here lies the crux of the situation; capillary leakage through the line of the suture must be a constant accompaniment of the use of ordinary suture materials. In 1913 Courtenay,<sup>1</sup> working under the direction of one of us (H. M. R.), demonstrated that the finest suture materials that could be handled gave the nearest to ideal results in intestinal suturing. Thus human hair, used with the finest cambric or bead needles, obtained the conditions most to be desired in intestinal suturing: 1. The immediate strength of the line of suture as determined by hydrostatic tests was greater than when a heavier suture was used. 2. There was no capillary leakage along the needle perforations. 3. The histologic sections showed the minimum amount of scar, an ideal condition.

We have used two layers of such sutures, one uniting the free edges, the other burying the first row. In one case, the duct appeared not to be large enough to permit of its inversion in this way, and a single layer of sutures was used with perfect success. An essential part in the suturing of the duct is to include its peritoneal coat. No drain of any kind is placed in contact with the suture line any more than would be done in the case of a sutured bowel. The analogy is exact. The suggestion of E. Wyllis Andrews to drop the omentum down between the liver and duodenum to prevent postoperative adhesions is well taken.

Closure of the duct in this manner, avoiding the use of any foreign body for drainage material, is accompanied by a minimum of peritoneal traumatism. In previous articles<sup>2</sup> we have called attention to the ability of the peritoneum to care for infection. The soiling by infected bile, that may occur during exploration, caused practically no postoperative clinical reaction. In the absence of drainage, postoperative adhesions are reduced to a minimum. The extensive postoperative adhesions, following gall tract operations, are

<sup>1</sup> Courtenay, G. T.: Illinois M. J., 23:443, 1913.  
<sup>2</sup> Richter, H. M.: Surg., Gynec. & Obst., 28:399 (April) 1919; Buchbinder, J. R.: Ibid., 29:70 (July) 1919; Richter, H. M.; Ibid., 29:445 (Nov.) 1919.

due much more to the gauze drains than to any other factor. An analogy may be found in the postoperative adhesions in the female pelvis following prolonged drainage. The omission of drainage results in the omission of adhesions.

We have carried out this technic in consecutive operations only in the past three months, during which time we have operated on eleven patients, with one of whom only did we vary the technic by placing a piece of rubber dam down to the duct. In the ten cases, there was prompt recovery with a convalescence that was exceptionally smooth. In the one case, in which the rubber dam was used, an accumulation of purulent bile developed on the third or fourth day and was evacuated, after which recovery was prompt.

We began this practice following five years' experience in closing without drainage in our cholecystectomies during which, in a considerable series of cases, we have had no occasion to regret our action. As in the case of cholecystectomy, we do not feel that every common duct operation should be completed without drainage. It would not be safe in the presence of a virulent infection with severe inflammatory reaction present. It cannot easily be done when the duct is small. The frequency of the need of drainage is possibly illustrated by this series in which it was used once in eleven consecutive cases. A condition that occasionally requires gauze packing is oozing from the liver surface. This is unusual and did not occur in the series, though the gallbladder was removed in each case.

We offer these suggestions with a feeling that the one radical improvement in the technic of gall tract surgery is the omission of external drainage, and that a wider use of this method will demonstrate not only its feasibility, but also its comparative safety.

### RENAL FLUOROSCOPY AT THE OPERATING TABLE\*

W. F. BRAASCH, M.D., AND R. D. CARMAN, M.D.  
ROCHESTER, MINN.

Surgical treatment of renal lithiasis is rendered unsatisfactory by complications as follows:

1. The difficulties of an exact interpretation of the roentgenogram.
2. The difficulty of locating the stone.
3. Inability to find the stone.
4. The possibility of overlooking one or more stones when multiple stones are present.
5. The possibility of having fragments of stones broken off or loosely connected with the original stone.

It is true that a large number of renal stones are easily diagnosed and removed. This is particularly true of stones with a diameter of two or more centimeters, situated in the pelvis. When the stone is small and flat, however, or when it is deep in the calix, projecting into the cortex, palpation of the stone may be impossible, even when the kidney is brought out of the incision. The possibilities of error in diagnosis have been greatly reduced through the aid of cystoscopy and pyelography. Nevertheless, it may be quite impossible (1) to differentiate extrarenal

shadows which are obscured by the renal pelvis outlined in the pyelogram; (2) to identify small stones in the kidney that have not caused any pathologic changes in the outline of the renal pelvis, and (3) to recognize calcareous patches which are occasionally found in the kidney cortex and differentiate them from actual stone.

The preoperative localization of the shadow has been made fairly accurate (1) by interpretation of the size and shape of the shadow; (2) by the relation of the kidney to the shadow, and (3) by means of pyelography. Stones with a triangular or branched outline are almost always situated in the pelvis. If the outline of the kidney is definitely determined by the roentgenogram, the position of the stone may frequently be approximately inferred. Although pyelography will usually afford even more accurate data in the localization of the stone, it may also be inexact. It may be impossible to determine whether the stone is free in the upper calix, impacted in the end of the calix, or projecting partially or wholly into the cortex.

Nothing is more disconcerting than the inability to find a stone in the kidney when the various methods of clinical examination have definitely shown it to be there. In the presence of a hydronephrosis, particularly when the dilatation is largely confined to the calices, a stone of fair size may be secreted in the bottom of a calix and defy discovery by the palpating finger. A stone lodged in the end of a calix which is shut off from the pelvis by inflammatory or cicatricial change may escape palpation. When the stone is in the cortex, the venous congestion of the kidney consequent to delivery may render its palpation exceedingly difficult. Needling, while occasionally of aid, is more often of doubtful value, and since it causes considerable damage to the kidney tissue, should be discouraged. Cortical incision, when extensive and multiple, is objectionable because of consequent destruction of renal tissue and the danger of subsequent hemorrhage.

It may be very difficult to determine, from the roentgenogram, the number of stones in a kidney. The shadow may appear to be single when in reality it represents two stones which either overlap or are closely approximated. What appears to be a single branched stone may be made up of several distinct stones. The shadow may be misleading when it has a projecting branch which is seemingly explained by irregularity in the stone removed; a second small stone which actually caused the shadow may be easily overlooked. On the other hand, the shadow of an irregular stone may assume an outline and consistency suggestive of several stones. When only one stone is found at operation, the surgeon, after persistent search with more or less damage to the kidney, is still in doubt as to a remaining stone.

On the removal of branched stones, fragments are easily broken off, particularly when the ends are impacted in minor calices. Examination of the stone removed may show this, but more often it cannot be determined definitely. Rough stones that are extracted with difficulty may have a soft fragment wrenched off. Occasionally soft stones have a putty-like mass of crystals adjacent to them which may later form the nucleus of another stone.

Because of the difficulties in interpreting the roentgenograms and determining the number and location of stones, surgery for renal lithiasis is frequently an unsatisfactory procedure. Many so-called cases of recurrences of renal lithiasis are due to the fact that

\* From the Section on Urology and the Section on Roentgenology, Mayo Clinic.

the stone or stones have not been completely removed at the time of operation. Whether or not stones or their fragments have been overlooked may often be determined by a roentgenogram made following convalescence from operation. This may give the desired information; but if a shadow persists, the patient's condition will not be improved, and the surgeon is then faced with the awkward necessity of being obliged to advise either an immediate or a postponed operation. An immediate operation is rendered difficult by the patient's condition, by changed conditions of the peritoneal tissues, the possibility of renal hemorrhage, and so forth. If the operation is postponed, the patient may neglect the condition until the kidney becomes seriously damaged.

Realizing the difficulties involved, it is apparent that a more accurate method of examination of the kidney at the time of operation is desirable. Unfortunately, the usual roentgenographic examination at the operating table is an awkward procedure and requires too much time. It would seem that if fluoroscopic examination when the kidney is brought out of the wound could be made practical, the various difficulties surrounding lithotomy would be readily overcome. Taking advantage of the recent improvement in fluoroscopic apparatus and simplification of roentgenographic machines, we have employed the apparatus described herewith.

#### APPARATUS

The apparatus used for making fluoroscopic observations of the kidney at the operating table is essentially the same as that used in the base and field hospitals of the army, but with certain minor changes which make it adaptable to civilian practice.

Such instruments (machines) consist of a transformer and autotransformer enclosed in a metal cabinet mounted on large casters for portability. To the cabinet is attached a tube stand with a horizontal arm having universal joints for supporting the tube. The tube is of the Coolidge radiator self-rectifying type, mounted in a lead glass shield.

The unit is small and compact, requiring less than 20 square feet of floor space. It is of light weight, portable, and has no moving parts which might cause noise and vibration. The current is turned on and off either by a hand or a floor switch. These portable units may be operated from the ordinary lamp socket without special wiring.

#### TECHNIC

As an essential preliminary, the roentgen-ray operator should wear goggles of smoked glass for about fifteen minutes before the observation is to be made so that he may have the necessary dark-accommodation and retinal perception. The roentgen-ray unit should be placed as close to the operating table as possible, and the rays focused through a small diaphragm so that they will pass through the delivered kidney on the fluoroscopic screen. When the fluoroscopic is ready to make the roentgenoscopic examination, the hooded screen held in the left hand is placed over the eyes, and the goggles are removed. The current is turned on by means of a foot switch. In the right hand is held a sterilized metal-tipped rod 18 inches long with which the fluoroscopist accurately points to the stone shadow in the kidney. The exposure is short, requiring little more than a flash. The various details can be easily arranged so that there is no interference with surgical asepsis.

## A CARDIOPLEURAL SUCCUSSON SIGN\*

W. S. DUBOFF, M.D.

EDGEWATER, COLO.

The object of this report is to describe and explain a most unusual—and to us, new—physical sign.

#### REPORT OF CASE

A man, aged 21, was admitted to the sanatorium, June 11, 1918, with a history of two years' illness. Because of repeated, large hemoptyses, in the presence of a unilateral left-sided tuberculosis, pneumothorax was induced, July 25. Moderate amounts of air (about 500 c.c.) were injected at intervals varying from a few days to four weeks, without reactions. November 1, he developed a spontaneous pneumothorax with an effusion two weeks later, at first serous but rapidly becoming purulent. Because of pressure symptoms, he was aspirated, April 9, 1919, 900 c.c. of purulent fluid being removed and replaced by 600 c.c. of air. This was repeated, September 4.

June 20, 1919, the patient complained of a constant noise in his chest which seemed worse at night and prevented sleep.

Physical examination revealed a left-sided pyothorax to the clavicle, with a clear right lung and cardiac displacement to the right. The apex of the heart was neither visible nor palpable. The left border could not be percussed out because of flatness due to the effusion, while the right border was about 3 cm. to the right of the right sternal margin. The heart sounds were regular, clear and without accentuations. A distinct, short splash could be heard at each systole over the entire precordium. The splash could be heard easily without a stethoscope by placing the ear before the open mouth of the patient. It was audible to the patient himself.

The explanation of this peculiar sign was not obvious roentgenologically until September 6. Fluoroscopy at this time disclosed a conical accumulation of fluid at the left base, apex down, with a fluid level above, pulsating distinctly with each heart beat. The lung was well collapsed, except at the base, which explained the conical appearance of the fluid. The heart was displaced moderately to the right. The right diaphragm was freely movable; the left diaphragm was immobile, the outer half being lost in the fluid shadow.

#### COMMENT

A splashing sound synchronous with the heart beat is described by the French as the "bruit de moulin" and is supposed to be characteristic of hydropneumopericardium.<sup>1</sup> It occurred in nineteen out of thirty-eight cases collected by James, who also mentions it as occurring conceivably in hydropneumothorax, but cites no case. Speaking of pneumopericardium, Babcock<sup>2</sup> says, "Finally, the confounding of this disease with the presence of air and fluid in the pleural cavity is scarcely likely, if one will bear in mind that in pneumothorax the succussion sound is only obtained when the patient's body is agitated, while in the affection under discussion, the peculiar sound is present even when the patient is at rest."

This statement is not necessarily true. In our case pneumopericardium could be definitely ruled out by the fluoroscopic examination alone, while the history and physical signs do not in the least suggest such a possibility. Obviously, our patient had a pericardial-pleural adhesion which set the fluid in the pleural space suddenly in motion at each cardiac contraction.

RATIONAL SURGERY OF VISCEROPTOSIS  
BY THE CORRECTION OF  
MALFUSION\*

ROLAND HAZEN, M.D.  
PARIS, ILL.

This paper is based on observation and treatment of many nonoperative cases of visceroptosis, and on careful examination within the abdomen, and operation for its cure, in 116 cases. After-results are based on questionnaire returns from eighty-five patients, who were operated on more than one year ago. The first operation was performed eight and a half years ago.<sup>1</sup>

It is generally accepted that the most rational plan of relief for visceroptosis consists in its treatment by means of belts, postures, calisthenics and fattening. There are cases, however, which under the most painstaking attention to these principles fail to respond in a satisfactory degree. It is only in such cases that the assistance of surgery should be employed.

MALFUSION

To go back to the beginning, there is an embryologic basis for the congenital type of visceroptosis, which is more common than the acquired, being 96 per cent. in our series. This consists in certain defects in the process of agglutination and fusion of the peritoneum

Fig. 1.—General visceroptosis: ptosis of flexures and consequent ptosis of transverse colon with secondary atony and elongation; ptosis of right kidney; axial rotation of liver and stomach, with prolapse of liver and pylorus.

of the back with that of the cecum, ascending colon, hepatic flexure, splenic flexure and descending colon.

\* Read before the Section on Obstetrics, Gynecology and Abdominal Surgery at the Seventieth Annual Session of the American Medical Association, Atlantic City, June, 1919.

<sup>1</sup> Because of lack of space, this article is abbreviated in THE JOURNAL. The complete article appears in the Transactions of the Section and in the author's reprints. A copy of the latter will be sent by the author on receipt of a stamped addressed envelope.

<sup>2</sup> A preliminary report was read before the Illinois State Medical Association, and published in the Illinois Medical Journal in December, 1912.

These errors in fusion are harmful, when later they result in ptoses, angulations, constrictions and traction strains; and we shall consider them under the general term "malfusion." Thus, malfusion constitutes the fundamental pathology in visceroptosis.

The prevailing operations, of suspension, plication, colectomy, colostomy, etc., are not universally accepted. We see in them a basic objection in that they do not strike at the source. They do not correct the mal-

Fig. 2.—Ptosis of colon, involving the hepatic flexure and transverse colon; such findings may mean much or little, depending on the location of traction strains.

fusion, nor do they restore the static equilibrium of the abdominal viscera one to another, and, therefore, they can scarcely be expected to give uniformly good results.

Rational surgery, as herein described, is a constructive procedure, as the ptosis subject is virtually rebuilt, after the pattern of the normal subject. The principles involved are, primarily, the replacement and retention of the colon, by producing fusion at the back of the bowel, where fusion should originally have occurred.

Special attention to anatomic accuracy in the region of the flexures is necessary, as the position of the flexures is of vital importance to the re-establishment of visceral equilibrium. With the fundamental or primary defects thus repaired, attention is directed to the individual correction of various secondary results of malfusion.

Malfusion is encountered in two forms: (1) hypofusions, and (2) hyperfusions.

HYPOFUSION, AND THE HEPATIC FLEXURE  
SEQUENCE

Hypofusion, or laxity of attachment, permits prolapse of the colon, resulting in abnormalities in the position and relation of the viscera.

In our series of cases, ptosis of the hepatic flexure was found to be equally as frequent as that of the cecum and ascending colon (89 per cent. in each instance). It is my object here to show that the position of the hepatic flexure is the vital point, and constitutes the key to the situation.

If, primarily, the hepatic flexure is permitted to come downward, forward or inward, the transverse colon

will necessarily be carried with it and allowed to sag, so that ptosis of the hepatic flexure is always accompanied by ptosis of the transverse colon. Furthermore, a

elevated and brought further to the right, and the span of the transverse colon will be lengthened, and it will again hang as a festoon between the two upright fixed portions of the colon.

#### HYPERFUSION, AND TRACTION STRAINS

Hyperfusions are localized adhesion formations, usually having their origin in certain vestigial embryonic membranes. Fibrous hypertrophy, and later contraction, may occur as a result of the intermittent traction of a loose segment of the bowel. These formations will then produce constrictions and angulations of the colon, and traction strains at both ends of their attachment.

The finding by roentgen ray or otherwise, as in Figure 2, may mean much or little. The patient may enjoy perfect health, or may be an invalid. This depends on whether the malfusion is so formed as to afford easy, uniform and regular support, throughout the length of the colon, in its faulty position; or whether the support is irregular, holding under local tension at one point, with marked slackness at other points, thus producing local traction strains, as seen from the interior in Figure 3.

Here we see the cecum and part of the ascending colon in normal position. There are two small but firm bands of adhesion at the bend of the ascending colon, one passing beyond the longitudinal muscle bun-

Fig. 1.—Malfusion: hyperfusion with prolapse of hepatic flexure and transverse colon; hyperfusion, or adhesion formation, from hepatic flexure to gallbladder and liver; and from bend of ascending colon to flank, producing angulation and traction strains.

primary ptosis of the hepatic flexure will be followed by a definite sequence of secondary changes in the position of the other viscera, constituting general visceroptosis (Fig. 1).

The hepatic flexure sequence is as follows:

The hepatic flexure, coming out of its housing beneath the liver, produces a vacancy in the upper abdomen. As a consequence, the liver will rotate inward or forward to occupy this space, producing ptosis of the liver, and the costal margins will collapse. The axis of the liver now assumes an oblique direction. If the spleen also prolapses, the liver rotation is further exaggerated.

The forward rotation of the liver carries with it the greater end of the stomach, which now assumes a position near the median line at a much lower level than formerly, constituting ptosis of the stomach. The main axis of the stomach is now nearly vertical. If the splenic flexure also prolapses, this change in the stomach axis is exaggerated.

The transverse colon often loses its sacculations, owing to atrophy of the longitudinal muscle bands, and in addition to its ptosis is thereby actually elongated.

It is evident, thus, that if the ribs are lifted and the flexures are now replaced in the upper abdomen, deep in the flanks, under the liver and stomach, and retained there, the liver and stomach rotation will be prevented. The pyloric outlet of the stomach will be

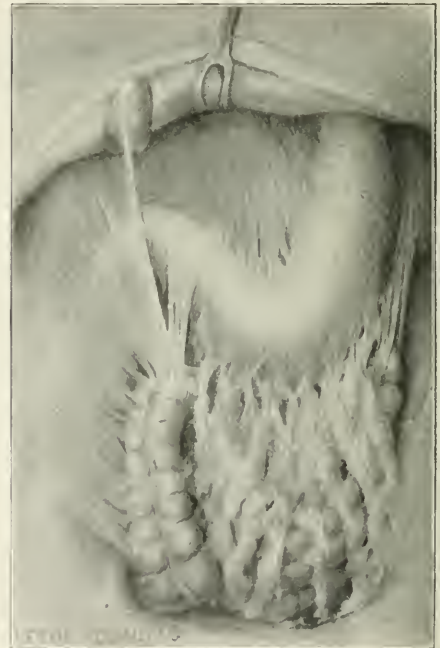

Fig. 4.—Malfusion: hyperfusion with prolapse of ascending colon, hepatic flexure and splenic flexure, with consequent prolapse of transverse colon; hyperfusion, or adhesion formation from hepatic flexure to gallbladder and pylorus, and from splenic flexure to spleen and flank, producing angulations and traction strains.

de, and so placed as to produce an angulation, and to take the strain of bearing part of the weight of the upper half of the ascending colon. The hepatic flexure

is downward and inward, and rather evenly supported by a fairly uniform, but very long mesocolon. The end of the hepatic flexure, and beginning of the trans-

Fig. 5.—Operation: mesocolon of the hypofused ascending colon and hepatic flexure, held in position for the application of sutures, which are to obliterate it and fuse the bowel to the flank.

verse colon, is supported in an angulated position by a large, firm band, attached to the gallbladder and to the liver. The effects of physical exertion, producing traction strain, on the gallbladder and bile ducts, as well as on the colon, in this case are evident.

Figure 4 shows the hypofusion and prolapse involving the cecum, ascending colon, hepatic flexure and splenic flexure, with consequent sag of the transverse colon. Hyperfusions are also well illustrated. Note the restraining bands, which, suspending the colon at the flexures, produce traction strains on the gallbladder and pylorus on the right side, and on the spleen and flank on the left.

In our series of patients operated on, we found irregular and abnormal adhesions of this type in the region of the hepatic flexure, in 67 per cent. of the cases, as compared with adhesions of the ascending colon in 53 per cent. of the cases. Harvey<sup>2</sup> found, on postmortem examination of 105 new-born children, thirty cases of adhesion in the upper region, and thirty cases in the lower region. It is evident, therefore, that the importance of the hepatic flexure, in relation to its hyperfusions, is equal to, if not greater than, that of the cecum and the ascending colon.

REPORT OF A CASE

CASE II.—Mrs. H. H. P., aged 39, had suffered for twenty-five years from fatigue, jolting, and dragging pains through-

out the right side of the abdomen, and occasionally in the splenic region. Moderate exertion would cause physical incapacity for several days at a time. For ten years she had been totally incapacitated for household work; for six years, attacks of persistent vomiting had followed any moderate exertion. During the previous year her condition had been deplorable. She was a woman of intelligence, and had consulted many physicians, and had received many diagnoses, and but little benefit. When she first consulted me, she had just completed a course in bed, with treatment for gastric ulcer. Her symptoms were better in bed, but returned as soon as she got up. She was thirty pounds below her best weight, and extremely anemic.

Under rest, postural and supporting treatment, for six months, she managed to retain enough nourishment to gain a few pounds in weight, and her hemoglobin increased from 55 to 70. She had not gained any during the past two months. As she had thus evidently reached her maximum improvement, an operation was performed for the cure of her visceroptosis. The following conditions were found:

Ptosis of the entire right side of the colon was present. The cecum was in the pelvis, being suspended by a band of adhesions, 1 inch wide, extending from the front of the ascending colon to the flank. The hepatic flexure was very movable and displaced downward and inward, and was supported by a span of adhesions, suspending it from the pylorus and duodenum. It was also kinked by a band of adhesions, uniting it to the transverse colon.

The splenic flexure was in normal position, but sharply angulated by a band of adhesions, attaching it to the spleen

Fig. 6.—Operation: sutures applied and the first two flexures and the bowel wall suspended to the flank by means of sutures. Note the location of the renal and gastroduodenal arteries.

and to the left flank. The transverse colon was markedly prolapsed, and exerted a pull on the adhesions at the flexures. On division of these restraining bands, the hepatic flexure and the ascending colon presented a free range of motion, the width, permitting a very free range of motion. The hepatic

2. Harvey, S. C.: *Ann. Surg.* 58: 641 (June) 1918.

flexure could be displaced to the normal region of the splenic flexure, without traction. The technic described below was employed for the correction of the ptosis in this case.

This patient made an uneventful recovery, has not vomited since the operation, which was performed five years ago, and

Fig. 7.—Operation: The posterior or fusion sutures are tied. Note the gastrocolic flexure and the location of the gastrocolic sutures. Omental sutures for support of transverse colon are also shown.

gained 35 pounds in weight during the first seven months, and retains this weight now. She does all her housework and is 100 per cent. physically efficient. She enjoys better health than she had ever known before the operation (Figs. 14, 15 and 16).

Fig. 8.—Operation: repair of the transverse defect; completed normal flexure, suspended with ligatures, flexure well up and back, maintaining normal visceroperitoneal relations. Transverse colon, also, is here suspended.

#### TECHNIC OF THE OPERATION

1. *Repair of Primary Defects.*—The abdomen is opened in the median line, and a thorough inspection is made of the position of the viscera, and the location of

the adhesions. The colon is then lifted out, by intestinal forceps, which grasp the anterior longitudinal muscle bundle. Its posterior attachments are now systematically inspected for areas of loose attachments, for irregular formations of constricting or restraining adhesion bands, and also for the finer strands of fibrous fasciculi, which are found in the outer layer of the mesocolon, and most numerously at and below the flexures.

This inspection, which is assisted by the palpating finger, passing along the outer aspect of the colon attachments, includes the entire colon, starting at the cecum and proceeding up the right side and down the left, with particular attention to its attachments in the kidney, hepatic, pyloric and splenic regions.

Adhesion bands are divided, when found to be harmful, and the colon is always freed of any constricting bands that are found to pass over the anterior longitudinal muscle bundle, at any point.

Figure 5 shows the ascending colon and the hepatic flexure freed of adhesion bands, and its mesocolon, containing numerous fibrous fasciculi, held in position ready for the application of the sutures.

Fig. 9.—Operation: Secondary elongation of transverse colon; suture applied which, on tying, shortens the longitudinal muscle band, reproducing its sacculations.

Figure 6 shows a number of parallel sutures introduced into the mesocolon, beginning at the cecum. The needle at no place enters the bowel wall itself, but picks up the mesocolon close to the bowel. Thence, the needle is reintroduced several times, picking up all the fibrous fasciculi possible until the posterior wall of the flank is reached. At this point, a deep stitch is taken, which must include the firm iliac fascia below and the lumbar fascia above. The capsule of the kidney is included in the stitch coming from the beginning of the hepatic flexure. This stitch starts the forward curve of the flexure. When these sutures are tied, the mesocolon will be obliterated, the bowel will be replaced in its normal position, and firmly, evenly and uniformly attached to the flank.

In order to insure an easy, forward and inward curve to the hepatic flexure, a suture is now inserted in the edge of the gastrocolic omentum, and thence into the lateral abdominal wall, just beneath the liver. Similar sutures are placed at the splenic flexure, and descending colon, if needed.

It is an advantage, also, to take up any slackness of the transverse colon that may remain, either by plication of its mesocolon, or suspension by the hammock opera-

tion of Coffee. This guards against injury in the event of vomiting, and makes for better retention during the period of muscular adjustment, which follows, in the upper abdominal walls.

Figure 7 shows the position of the posterior stitches after tying, and of the gastrocolic and omental sutures, ready to be attached to the abdominal wall.

Figure 8 shows a side view after the stitches have been tied. This completes the repair of the primary and fundamental defects, by converting the malfusion into normal fusion, as it secures the uniform and even attachment of the portions of the bowel that normally should be fused to the back. Notice the posterior slant of the flank, and the colon lying firmly and evenly attached. The hepatic flexure now lies well back and high up under the liver, and curves smoothly and evenly over the lower pole of the kidney and duodenum as it passes forward and inward, to become the transverse colon, which is now seen in its normal position.

The static equilibrium of the abdominal viscera is now restored. Intra-abdominal pressure will exert its

obliterating the opening in its capsule, through which its lower pole must descend and turn inward as it comes down:

A deep suture on a large needle is passed backward, through the peritoneum, close to the inner side

Fig. 11.—One year after operation: good position of both flexures and transverse colon, with easy curve and absence of filling defects at flexures.

of the lower pole of the kidney, down to and including the lumbar fascia, then outward and forward, close to the outer side of the lower pole of the kidney, and emerging from the peritoneum. On tying this suture, the opening in the capsule of the kidney is obliterated and, the kidney having been well replaced before applying the suture, the strands of the nephrocolic ligament of Longyear are secured to the lumbar fascia. This also aids in maintaining the proper position of the ascending colon.

Fig. 12.—Marked ptosis of stomach, and rotation of pylorus to median line.

Fig. 10.—Ptosis of both flexures and transverse colon; filling defects at flexures.

force obliquely on the ascending colon, which tends to retain the hepatic flexure in this position. The flexure now acts as a wedge lying beneath the liver, and tends to prevent its prolapse with consequent prolapse of the pylorus.

**2. Repair of Secondary Defects.**—If the transverse colon is atonic and much elongated, with the obliteration of its sacculations (Fig. 9), fine silk intestinal sutures may be inserted at intervals in the longitudinal muscle band, in such a manner, that on tying them, this band will be shortened by 2 inches with each stitch, with a reproduction of the sacculations.

Forward and downward rotation of the liver is a vital menace to our results, and must be corrected to insure proper space for the hepatic flexure replacement. It is remedied by its replacement and retention by means of two mattress sutures passing through its lower border and suspending it to the anterior abdominal wall.

Undue relaxation of the stomach may call for suspension, preferably by the operation of Rovsing.

We have devised a procedure by which ptosis of the kidney can be repaired from within the abdomen, by

#### RESULTS OF OPERATION

The average final results are among the most striking we encounter in surgical practice. Not only are the active symptoms relieved, but these patients are virtually reconstructed, physically, mentally and func-

tionally. Physical inefficiency and invalidism are replaced by ability to do work; fatigue and neurasthenia, by sound mind and nerves; constipation is improved, and the sallow complexion is replaced by the pink glow of good health. Many report a vigor

The changes in bodily poise and outline following operation are well illustrated in the photographs of Case 11 (Figs. 14, 15 and 16). (See report of case above.)

QUESTIONNAIRE REPORTS

A questionnaire covering general improvement, as well as a detail report, was sent out to all patients whose operation had been performed more than a year ago, from which returns the deductions presented in Table 1 have been made.

Eighty-eight per cent. of the patients report a gain in weight since operation. While seven patients report

TABLE 3.—RESULTS IN THE CASE OF SEVENTY SEVEN PATIENTS ARRANGED IN GROUPS ACCORDING TO TIME SINCE OPERATION

Group	Years Since Op.	No. Cases	Results Satisfactory, %		Results not Satisfactory, %	
			Cured	Much Imp.	St. Imp.	Not Imp.
1.	.8½ to 3½	27	81.5	+ 15 = 96.5	3.5	+ 0 = 3.5
2.	.3½ to 2	25	60	+ 40 = 100	0	+ 0 = 0
3.	.2 to 1	25	28	+ 44 = 72	16	+ 12 = 28

FIG. 11.—One year after operation: stomach at good elevation, and pylorus correctly located to right.

and stamina which they never before had known, even in their earlier days.

The typical roentgen-ray findings, before and after operation, are well illustrated in a case as follows: Figure 10 shows the colon before operation, in which is seen a sharp angulation, ptosis, and filling defects, at both flexures, also marked ptosis of the transverse colon. Figure 11 shows the roentgen-ray examination

loss in weight, this loss was due chiefly to other illnesses. The net results of sixty patients who reported their weights show an average gain for the entire group of 15½ pounds per patient. One half of these patients gained an average of 14 pounds over their best former weight. This gain in weight is a striking evidence of the improvement that has occurred in this group, as a whole.

PHYSICAL EFFICIENCY

Before operation, the average degree of this incapacity, per patient, was 45.7 per cent. The questionnaire returns show an average incapacity, per patient, of 0.09 per cent. since operation. In other words, the physical efficiency of the entire group has been almost completely restored.

That the improvement in these patients is often slow, but that their ultimate cure is permanent, is demonstrated by Table 3, which divides the cases into three

TABLE 1—QUESTIONNAIRE REPORTS

of the colon one year after operation. The entire colon is seen to be in good position, with a free, smooth and easy turn at both flexures, absence of angulation and of filling defects, and good position of the transverse colon.

The stomach of this patient (Fig. 12) before operation is very low, and its outlet is in the median line. The examination of this stomach one year after operation (Fig. 13) shows it to be up in good position, and the pyloric outlet is located to the right, as it should be. This patient has enjoyed a complete symptomatic cure.

FIG. 14 (Case 11).—Before, three weeks after, and seven months after operation. Note improvement in weight, widening of costal angle, and collapse of right costal margin, after the malfusion has been corrected.

groups, of equal number, according to the time since operation, and compares the results in the different groups.

This table shows that practically all of the unsatisfactory results are found in the group of patients most recently operated on, being 28 per cent. in this group. After the two year period, however, the table shows that the unsatisfactory results amount to an average of only 1.75 per cent. Furthermore, the number of

absolute cures increases progressively with the increase in the time since operation, as seen by comparing the more recent with the older groups; the largest percentage of cures, 81.5, occurring in the oldest group of patients.

The questionnaire returns further show that 81.5 per cent. of the patients consider themselves as still improving; 18.5 per cent. consider themselves as sta-

operate as I did not believe I could do any good; however, I had a suspicion of an inclusion of the iliac hypogastric nerve within the scar of the kidney operation as causing the pain in the lower abdomen. The patient was a young woman and she and her aunt both persuaded me to operate on her. At operation I found the cause of the pain to be as I had anticipated, the inclusion of the nerve. She had complete relief. I put her on the treatment she should have had in the first place and a diet adapted to her gastrointestinal functions. She improved rapidly and in six months she had gained in weight so that she weighed 130 pounds.

Dr. J. SHELTON HORSLEY, Richmond: The results obtained by Dr. Hazen have been excellent. It seems to me the reason all these patients are not cured is that toxic substances are absorbed and in the course of years this has a degenerating effect on nerve tissue, possibly on the sympathetic ganglions. Even after you effect a cure in the bowel function the changes in the sympathetic ganglions may be so great that the patient still has some of the neurasthenic symptoms; just as late operation for lesions of the brain does not cure epilepsy. I take it for granted that every case of stasis should be treated by a good medical man for at least six months before any operation is done. Should the patient not be cured, operation may be necessary. Coffey has demonstrated that the peritoneum is the strongest support within the abdomen. I have been doing a simple operation in cases of gastroptosis, a modification of Beyea's method. I start the suture on the left side, near the stomach wall, carry it up on the left side and return on the right side in a reverse direction and tie. This makes a purse string suture in strong tissue and avoids the thin peritoneum in the center of the gastrohepatic omentum.

Dr. CHARLES P. NOBLE, Philadelphia: There is no question that practically all these patients with ptosis are instances of arrested development from environmental causes. They are a separate group in the human family, and unless we look at them from that standpoint we fail to meet the situation. In a certain percentage of them mechanical surgery may afford relief from certain symptoms, but it does not alter the constitutional nature, and in order to secure good results in general they must be treated along physiologic lines. The general method is medicinal treatment followed by physical cul-

Fig. 15 (Case 11).—Before, three weeks after, and seven months after operation. Note improved vigor, posture and poise, and the filling out of the hollow upper abdomen. Visceral equilibrium is restored.

tionary in their improvement, and none of them consider themselves to have been made worse through having undergone the operation.

#### ABSTRACT OF DISCUSSION

Dr. ROBERT T. MORRIS, New York: In order to discuss intelligently the subject of visceroptosis we must divide it into its various categories and consider the features of each. We are dealing with a group of defective patients, those who present stigmata, objective signs of arrested development of structure. It is almost impossible to place these patients back in good position as a unit in the social system, no matter what we do for them surgically or medically. Such patients have eyestrain, nonerupted molars, nasal hypertrophies and other sources for peripheral irritation. Another group represents changes in the anatomy because of the circumstances brought to bear. Structures develop resembling the kinks which Lane described, for example. Disturbances of the sympathetic ganglions of the autonomic and sympathetic systems which conduct digestion constitute a fourth category, perhaps, cases of psychoneuroses, mental depression and insanity; in fact, various end-results of conditions which are anatomically and functionally wrong. If the work which has been done by Dr. Hazen relieves a certain percentage of these patients let us do that work. For instance, I often fix the loose kidney. These patients have the sagging colon because of loose kidney. It can be fixed in ten or fifteen minutes so that it will stay in place permanently but it must be done in the right way. If you do not do these various operations as well as Dr. Hazen has done them, you are simply adding to the patient's troubles.

Dr. J. J. GILBRIDE, Philadelphia: It would not be possible in Philadelphia to operate on so large a number of patients as reported by Dr. Hazen because we know how to treat them better. Occasionally, some of our professors are misled into operating in some of these cases with disastrous results. I recall a patient complaining of severe pain in the right lower abdomen. She weighed about 95 pounds. One professor had taken out her appendix, another professor fixed the kidney and another professor did a curetette, while still another operated on her nose. Later, she consulted another professor and, of course, he dodged and recommended electrotherapeutics. Of course, she was an invalid. I did not want to

Fig. 16 (Case 11).—Before, three weeks after, and seven months after operation. Note improvement in constriction of the upper abdomen and prominence of the lower abdomen.

operate and outdoor life, and particularly the restriction of their activities within a much smaller amount of effort than is entirely physiologic for a normal individual. Unless that is done these people are always feeling sick. If the trouble is not in the intestine it is in the nervous system, and the varying symptoms simply show that they are expending more energy than they should. In other words, they are drawing on their potential nerve supply for ordinary use.

Dr. REYNOLD HAZEN, Paris, Ill.: I realize that visceroptosis is a complicated condition to handle. With the male in the

upright position there has been delay in the fastening of the ascending and descending colon to the back. It is a change due to our change of state. The female has not followed that quite as perfectly; first, because of the primary law that the female does not follow change of structure; and, second, that her pelvis is larger than that of the male and her symptoms do not usually appear until a certain time. All this time the colon has been loose. The condition is similar to that of a man with a broken arch; he may not have symptoms until he is on his feet. He may have been doing desk work and is without symptoms until he is required to be on his feet. The general psychic and peripheral symptoms referred to are important and I have thought of the relation of the sympathetic ganglions with a bowel that is down and pulling on the sympathetic nerves. The wonder is that we do not have more reflex symptoms. In treatment I did not intend to advocate operation for every patient whose colon is down. Almost all these patients are patients referred by physicians who have done their best. We do not advocate operation. In fact, I should not want to advocate operation for general use. It should be done only by men particularly interested in this field of work because the general conception of the whole abnormality of the anatomy is so complicated that we cannot make the repair with any one method of operation. As Dr. Gilbride told us there is too great a tendency to operate without study. Thirteen per cent. of the patients in our series had had operations before we saw them, without relief. To repair a gastropnoxis many factors have to be correlated to produce a satisfactory result.

## AMPUTATION ABOVE THE LEVEL OF ARTERIAL OBSTRUCTION

### IN ARTERIOSCLEROTIC GANGRENE

DANIEL N. EISENDRATH, A.B., M.D.

AND

RALPH B. BETTMAN, A.B., M.D.

CHICAGO

The tendency of the majority of surgeons in selecting the level at which to amputate in arteriosclerotic gangrene is to be guided by the extent of the area of gangrene. Not infrequently, the amputation is followed by extensive sloughing of the flaps and either death follows from sepsis, or, as in a case recently observed by us, the opposite limb becomes involved as the result of the extension of the thrombosis from the femoral to the iliac artery and then across to the opposite iliac artery. We have felt that the ideal method of choosing the level at which to amputate would be to expose the femoral artery at the middle of the thigh and to follow it in an upward or downward direction until a level was reached at which the thrombotic occlusion of the artery ceased, and distinct pulsation could be observed in the vessel. We have reported this plan in a recent case with very gratifying results.

#### REPORT OF CASE

A man aged 56 was admitted to Michael Reese Hospital with marked evidence of arteriosclerosis and an area of gangrene involving the entire dorsum of the foot. There was an absence of pulsation in the arteries of the limb as high as the upper femoral region. An amputation through the lower third of the thigh by the Grutter-Stokes method was decided on. On exposure of the femoral vessels at the middle of the thigh for purposes of preliminary ligation, we were greatly surprised to find the femoral artery completely occluded by a thrombus. Following the vessel in an upward direction we were unable to find any pulsation until close to Poupard's ligament (Fig. 1). At this level, the artery was ligated just above the occlusion, that is, through the lower-

most pulsating portion. An amputation was performed at this level, and the patient, who had been extremely septic, made an uneventful recovery. In spite, however, of the high level at which the amputation was performed, there was moderate gangrene of the skin flaps. Dissection of the arteries of the limb revealed many calcareous areas in the femoral artery and a firm clot completely occluding its lumen (Fig. 2) up to a point close to the femoral canal. The clot was firmly adherent to the intima in many places and extended from the femoral into both tibial arteries. The veins were normal.

Fig. 1.—Extent of thrombosis in femoral and tibial arteries. Arrow points to level at which femoral artery was ligated proximal to upper level of thrombosis.

Fig. 2.—Femoral artery showing complete occlusion by thrombus, the upper level of which is at the dotted line. The thrombus extends into both tibial arteries. The arrow points to calcareous plaques on intima of artery.

#### COMMENT

We believe that exposure of the femoral artery in order to determine the upper limit of the occlusion is the simplest and most accurate method of deciding on the level at which amputation should be performed.

**The Child's Food.**—A growing child requires far more food than its weight would indicate. For, in the first place, its intake must exceed its expenditure, so that it may grow.—Julius H. Hess.

## THE COURSE OF THE BLOOD CHANGES IN A CASE OF APLASTIC ANEMIA\*

JOHN J. O'MALLEY, M.D.

Lieutenant Commander, M. C., U. S. Navy

AND

HENRY B. CONRAD, M.D.

Lieutenant, M. C., U. S. Navy

WASHINGTON, D. C.

Aplastic or aregeneratory anemia is the term applied to a well marked type of anemia due to decreased blood formation. Clinically it is marked by anemia, a pronounced tendency to hemorrhage, and a rapidly fatal course. Despite the severity of the anemia there are none of the evidences of bone marrow regeneration, such as megaloblasts, normoblasts, anisocytosis, and stippled or basophilic erythrocytes in the circulation. At necropsy the red marrow is found to be aplastic, showing an increase of fat and a diminution in megaloblasts and normoblasts.

The disease is not so rare. Musser<sup>1</sup> collected reports of fifty-nine cases, including twenty-four of Cabot, and added another, which is probably the best studied case that has been reported.

The case that we present is reported on account of the remarkable opportunity it afforded for observing the progressive changes in the blood during the disease.

### REPORT OF CASE

*History.*—L. H., man, aged 67, white, admitted to the hospital, July 15, complaining of weakness, had always enjoyed good general health except for constipation, for which he had taken cascara once or twice a week since youth. He had been a moderate drinker for many years. There had always been a tendency to bleed for long periods of time from cuts and scratches, but there had been no serious hemorrhage.

In 1910 he suffered from a "nervous breakdown." The systolic blood pressure was then 176. At that time exertion would occasionally bring on pain over the sternum which would run down the right arm, never down the left. During the illness he frequently took sulphonal. He made a perfect recovery.

Several years previous to his entrance into the hospital he suffered from glaucoma and the right eye was enucleated. Pilocarpin had been administered three times a day in the left eye since that time.

In March, 1919, four months before the present admission, the patient was in the hospital four weeks with "indigestion." The leukocyte count was 6,750. There was no marked pain. The roentgenogram was negative save for stasis in the large intestine. He apparently recovered from the indigestion, but became nervous and sleepless. He was still nervous and sleeping poorly at the onset of the present complaint. During the whole of this time, about four months, he took from 5 to 20 grains of barbital every night. His appetite was good. He urinated once at night; there was no obstruction.

*Present illness.*—For about three weeks before admission, the patient had noticed that he was more easily tired by walking and climbing steps than formerly. July 14, he walked three or four blocks to dinner. On returning, which was slightly up hill, he became exhausted and had to rest several times on the curb. He was admitted to the hospital on the following day.

*Physical Examination.*—The patient was a rather old man, lying quietly in bed with a definite appearance of weakness.

There was no emaciation. There was a very distinct pallor but no yellow tint to his skin. His musculature was extremely flabby. His speech was somewhat "thick." He was mentally active and alert.

Head: The right side of the face was distinctly smoother than the left, and his mouth was drawn to the left. However, he could whistle, and there appeared to be no weakness of the right side. The left pupil was small and did not react to light or accommodation (pilocarpin). The teeth, on which much dental work had been done, were in poor condition.

Glands: The posterior cervical and submaxillaries were palpable; the gland at the left angle of the jaw was enlarged. The axillaries were about the size of lima beans. The epitrochlears were not palpable, nor were the inguinals enlarged.

Chest: On percussion the lungs were found to be clear except at the right base, where the liver dullness was increased. The lower lung borders descended on inspiration, the left about 2½ fingerbreadths, the right somewhat less. The breath sounds were everywhere harsh. Crackling rales were present at both bases, more marked on the left. The cardiac dullness extended from the third rib above to just outside the midclavicular line. The point of maximal impulse was in the fifth interspace, a little outside the midclavicular line. At the apex the first sound was muffled and followed by a blowing murmur. The systolic murmur was present also at the base, but not transmitted. The pulmonic second sound was clear and not accentuated. The aortic second was clear and a bit accentuated. The pulse was good and could be felt equally at both wrists.

Abdomen: The abdominal wall, like that of the chest, was flabby, and the pressure of the bell of the stethoscope left a slight imprint.

Lower extremities: The musculature was flabby.

Rectal examination: The prostate was slightly enlarged. There was normal resiliency.

Nervous: There was lateral nystagmus; the eye movements were otherwise good. In other respects the examination was negative.

Blood: The blood was pale. At the prick of a needle the patient bled very freely. The red cell count was 2,240,000; the color was good; there was no anisocytosis or poikilocytosis. There was no stippling, polychromatophilia, or nucleated forms. Only four or five platelets were seen in a smear. The hemoglobin was 55 per cent (Tallqvist). The leukocyte count was 3,000; polymorphonuclears, 43 per cent; eosinophils, 2 per cent; lymphocytes, 53 per cent; large mononuclears and transitionals, 2 per cent.

Urine: The urine was pale; the specific gravity was 1.013. There was a faint trace of albumin. There were a few granular casts and cylindroids; there was a little mucus, and an occasional white cell.

*Clinical Course.*—The disease was rapidly progressive. The patient became weaker and weaker. He slept considerably and was irritable when awake. On the second day after admission, petechial hemorrhages appeared on the legs. They increased on the following day, but quickly cleared up after the first transfusion. Two transfusions of 600 c.c. and 550 c.c., respectively, were made by the citrate method, on the seventh and twelfth days after his admission. There was a febrile reaction after each of the transfusions; the temperature was 102.5 F. after the first transfusion and 101.5 F. after the second, but he had no chill. When the patient had recovered from the reaction, he said he felt better for about twenty-four hours, but there was no visible improvement. Five days after the second transfusion, petechial hemorrhages again appeared over the body as well as over the extremities. On the following day, the sixteenth day after admission, the temperature rose from normal to 101 F. and there was considerable bleeding from the gums. The temperature continued between 101 and 102 F., and bleeding from the gums continued until the patient's death. He was never ataxic and was rational almost to the last. On the day of his death there was a slight hemorrhage from the rectum. He died on the nineteenth day after his admission.

\* From the Naval Hospital and Medical School.

<sup>1</sup> Musser, J. H., Jr.: Study of a Case of Aplastic Anemia, *Arch. Int. Med.* 14: 275 (Aug.) 1914.

**Laboratory Examinations During Stay in Hospital.**—The blood culture and Noguchii reactions were negative. The sputum was constantly pale and contained no blood, fibrin, or hematosporin on repeated examination. There was usually a trace of albumin.

**Blood.** The duration of bleeding from a prick of the finger was longer than normal. After transfusion, this was not so. Toward the last, slight pinching of the toe of the foot resulted in a laceration.

Coagulation time, tested in capillary pipets, was within normal limits. From ear puncture it was two and two thirds minutes, from a vein it was nine minutes.

Hemoglobin estimations made with the Tallqvist and Sahli methods showed considerable variation, probably due to the low amount considered. Two estimations were made by the Van Slyke method for determining the oxygen carrying capacity of the blood. The first, made the seventh day after admission, gave 30 per cent, estimating 14 gm. per hundred c.c. as normal, and a color index of 0.84. The second, made the

seventh day after admission and four days after the first transfusion, gave 30 per cent and a color index of 0.74.

The quality of the red corpuscles, tested with hyperchrome estimations, showed no decrease. With the patient's corpuscles, hemolysis began at 0.44 per cent, and was complete at 0.34 per cent; with the control's corpuscles, hemolysis began at 0.46 per cent and was complete at 0.34 per cent.

The results of the chemical examination of the blood on the twelfth day after admission per liter (c.c. were: total solids, 21 mg.; urea nitrogen, 50 mg.; urea carbon, 1.7 gm.; creatinin, 4 mg.; plasma carbon dioxide, 48.1 per cent (Van Slyke); plasma, no bilirubin, no indican.

The variation in the number of red cells is shown in Chart 1 (upper division).<sup>2</sup> It varied widely between 2,400,000 and 110,000. After each transfusion there was a marked increase which lasted about one day. Probably as a result of the transfusions there was no general trend downward. The day before death, the count was not so low as it had been in the earlier days of the disease.

There were never at any time abnormal forms of red cells present. There were no polikaryotes, and no anisocytes. Occasional cells had diameters of 6.5 microns in diameter and have been reported as 8.5 microns, but no greater variations. There were no spherocytes, no stippling, and no nucleated forms observed. On the second day of admission, four of the leukocytes were seen in each blood smear. After that day, leukocytes were absent.

There was a marked leukopenia, the leukocyte count varying widely between 2,000 and 650. The leukocyte curve is shown in Chart 1 (lower division). It began with a count of 1,100,000 and a count of 1,250. Its abnormal form of leukocytes were present at all. Practically all fell into the general leukopenia. The course of the differential counts is shown in Chart 2 (upper division). At the beginning, the polymorphonuclear cells and the lymphocytes were present in about equal percentages. The percentage of lymphocytes

steadily increased, while that of the polymorphonuclear cells steadily decreased so that toward the last the lymphocytes reached 92 per cent, and the polymorphonuclear cells dropped to 6 per cent.

**Necropsy.**—Only a partial necropsy was obtained. The liver was enlarged and hard, and sections showed cloudy swelling with a slight increase of connective tissue. There was considerable bile pigment, but special staining failed to demonstrate hemosiderin. The rib, when cut across, showed a small area of light red marrow. Smears from this showed few cells, mainly small mononuclears and red cells. Sections showed large vacuoles, formerly occupied by fat, with narrow strands of marrow tissue between. The marrow tissue was composed mainly of small mononuclears (lymphocytes) with a few non-nucleated red cells and an occasional myelocyte. No mention is made of the predominance of the lymphocytes in most of the necropsy abstracts reported, but it was observed by Hirschfeld.<sup>3</sup> Compared with the marrow of a normal rib, there did not appear to be an increase of lymphocytes but rather a marked diminution of myelocytes and nucleated red forms with a tremendous increase of fat, while the lymphocytes were unaffected and remained in normal numbers.

#### COMMENT

The value of the case in the study of aplastic anemia may be briefly discussed.

**Etiology.**—In the fifty-nine instances that Musser<sup>1</sup> collected, the great majority of the patients were under 35 years of age; he doubts the authenticity of a case at 68. That aplastic anemia may occur at a more advanced age is verified by the present case at 67. There were no evidences of intestinal parasites, as in the case reported by Stitt,<sup>4</sup> nor of benzene poisoning, as in the cases reported by Selling,<sup>5</sup> nor of suppuration, as in the cases reported by Dalton.<sup>6</sup> Of other factors

present, sulphonal, barbital, alcohol and chronic constipation, none could be implicated in an etiologic rôle. As in the vast majority of cases of aplastic anemia, in this case no exciting cause could be found.

**Course and Complications.**—Four months before the patient's admission nothing in his general condition suggested anemia, but the leukocyte count was on the lower level of normal, 6,750. From the patient's history the duration of the disease was probably between five and six weeks. Certain it is that the disease was not very evident clinically for more than three weeks.

The significance of the fever is uncertain. Fever is given as quite a prominent symptom of the disease by

Chart 1.—Variations in the red cell count (upper division) and in the absolute numbers of the different leukocytes (lower division) in a case of aplastic anemia; parallel lines indicate total leukocytes; solid line, polymorphonuclears; line of dots and dashes, lymphocytes; broken line, eosinophils and basophils.

Musser,<sup>1</sup> while less stress is laid on its occurrence by Cabot<sup>7</sup> and Lavenson.<sup>8</sup> In the present case, fever was present only during the last four days of the disease, and the temperature was never above 102 F. The persistence of râles at the bases of the lungs during the latter part of the disease would suggest a terminal pulmonary infection. If the resistance to infection were reduced *pari passu* with reduction in the number of polymorphonuclear neutrophils, it must have been exceedingly low when they were present in less than 5 per cent. of their normal numbers. The fever had no effect in increasing the leukocyte count.

Subcutaneous hemorrhages and hemorrhages from the mucous membranes are characteristics of the disease rather than complications.<sup>9</sup> Both were evident in the present case, but were not so severe as to affect either the clinical course or the blood picture of the disease.

*Pathogenesis.*—The absence of immature red cells in the circulation and the absence of bile pigments in

the skin, urine, and blood plasma, and the absence of hemosiderin in the liver tend to confirm the prevalent conception that the anemia is due to failure in formation and not to abnormal destruction of red blood cells.<sup>10</sup> The persistence of the red cell count at about the same figure as on admission, despite the rapid progress to fatal termination, is not a constant feature of the disease. In the case of Stitt,<sup>4</sup> the red count fell to 490,000 on the day of death. In the present case, the red count was probably kept up by the transfusions. According to the work of Ashby,<sup>11</sup> transfused cells live and function, and are therefore of value to the general body economy. Such persistence of the red cell count raises doubt as to the anemia being the essential factor in the disease. Cabot<sup>12</sup> raises a similar query in regard to pernicious anemia. The other bacteriologic and chemical examinations, blood culture, blood sugar, nonprotein nitrogen, urea nitrogen, creatinin and carbon dioxide content of the blood plasma, gave no lead.

The estimations of hemoglobin were made on the oxygen carrying capacity of the blood and therefore approach accuracy. At the two estimations the hemoglobin was about the same, but the color index fell from 0.84 to 0.74. This was associated with quite definite progress in the disease and is of interest in

contrast to pernicious anemia, in which the color index rises as the disease progresses.<sup>13</sup>

The leukopenia in the present case is quite a constant feature of the disease. In Chart 1 (lower division) the course of the leukocytes, the lymphocytes and polymorphonuclears in actual numbers per cubic millimeter is shown. The total leukocyte curve shows marked variations that can be divided into those due to the transfusions and those due to the course of the disease. After the first transfusion there was an increase of about 600 cells per cubic millimeter, due mainly to an increase in polymorphonuclear neutrophils. But this increase was extremely transient, lasting only twenty-four hours. Possibly a similar increase occurred after the second transfusion but was not detected, as no count was made within forty-eight hours.

The downward course of the leukocyte curve is independent of the transfusions. This progressive decrease is in contrast to the red cell curve, as shown in Chart 1 (upper division) which, probably on account of the transfusions, maintained its height to the end. This feature of the leukocytes can be seen to be entirely due to a progressive reduction in the polymorphonuclear elements of myeloid origin, for, if the temporary drop which occurred between the transfusions is ignored, the lymphocytes maintained quite a constant level to the end. The drop in the leukocytes which occurred after the first transfusion and was partially recovered from before the second transfusion is likewise, in all probability, due to the disease and independent of the transfusions. It was due partly to a diminution in lymphocytes, but mainly to a diminution in polymorphonuclears. After it the polymorphonuclears continued to decrease rapidly and progressively, while the lymphocytes made a rapid and good recovery, which they maintained.

The course of the differential counts did not confirm the prevalent opinion that the cells of myeloid origin are the only ones to suffer.<sup>14</sup> To ascertain how each cell had suffered it was necessary to compare the actual number per cubic millimeter present in the disease with the actual number per cubic millimeter present in normal blood. The only previous count which we had of the patient was a leukocyte count of 6,750. If that is taken as normal, and the normal percentages as given by Sydney Miller<sup>15</sup> are assumed—polymorphonuclears 64.2 per cent.; eosinophils and basophils 3.4

Chart 2.—Variations in the relative leukocyte counts (upper division): solid line, polymorphonuclear neutrophils; line of dots and dashes, lymphocytes; broken lines, eosinophils and basophils. Various blood cells in percentages of the normal (lower division): parallel lines, red blood cells; solid line, polymorphonuclear neutrophils; line of dots and dashes, lymphocytes; broken line, eosinophils and basophils; line of dashes and hollow dots, large mononuclears and transitionals.

per cent.; lymphocytes 22.5 per cent., and large mononuclears and transitionals 10.8 per cent.—the following numbers represent 100 per cent. in Chart 2 (lower division): for polymorphonuclear neutrophils, 4,331; for eosinophils and basophils, 230; for large mononuclears and transitionals, 729; for lymphocytes, 1,518; and for red cells, 5,000,000. It will be seen that every type of cell suffered, but the lymphocytes suffered least. The polymorphonuclear cells, including the neutrophils, eosinophils and basophils, suffered markedly and progressively. The platelets were absent except at the earliest observation.

#### THERAPY

The patient was transfused twice. The petechial hemorrhages cleared up after the first transfusion, but there was no other benefit evident clinically. Each transfusion increased the red cell count, which did not return to its former level for five days. The transfusions probably account for the way in which the red counts maintained their level; but they were at no time followed by evidence of bone marrow stimulation. The effect of the transfusions on the white count was extremely transient. The effect on the downward course of the polymorphonuclear cells was of little consequence, an elevation after the first lasting forty-eight hours, but none after the second.

#### SUMMARY

In a case of aplastic anemia, the diagnosis was based on the anemia, the absence of abnormal red cells in the circulation, and the aplastic red marrow at necropsy. There was no evidence of increased hemolysis.

The red cells were reduced to about 1,800,000. They were only temporarily increased by transfusions, and they continued in about their original numbers to the end. The platelets were practically absent.

The color index was below 1, and dropped as the disease progressed.

There was an actual reduction in all the leukocytic elements of the blood, more marked in those of myeloid origin. Those of myeloid origin were the only elements to show progressive diminution in numbers.

**China Medical Board Report.**—The fourth annual report of the Board for Education, China Medical Board, for 1918 contains the report of the trustees of the Peking Union Medical College and the Shanghai Medical School of the Rockefeller Foundation. During the year, construction work on the buildings of the Peking Union Medical College went forward, the total number of members of the faculty proper being increased to thirty-four, and contributions were paid to numerous hospitals, three medical schools, and sixty-five dispensaries. The two colleges at Shanghai have been incorporated into the year 1918 of the Peking School, on account of the increased cost of living and the increased cost of building materials. A gift of \$500 is reported from the Harvard Medical School in China to be used toward the maintenance of the Shanghai Medical School. Payment have been made to the Chinese government for the medical faculty of Fuhai, St. John's University, and Shanghai Christian University. The largest appropriation of the year amounted to \$21,148.88 from the Board at Nanking. Appropriations have also been made for the Foreign Christian Missions Society at London. The total expenditures of the Board for the year amounted to \$2,131,588, distributed as follows: administration, \$48,676; Peking Union Medical College, \$1,735,983; Shanghai Medical School, \$114,261; apparatus for missionary hospitals, \$123,686; appropriation to other medical schools, \$67,549; fellowships at 100 hospitals, \$51,575; and miscellaneous, \$2,757.

## INFLUENCE OF PITUITARY EXTRACTS ON THE GENITAL TRACT\*

ROBERT T. FRANK, M.D.  
NEW YORK

During the course of an investigation of the physiologic properties of the lipid constituents of the various endocrine glands, a study of the effect of the anterior lobe of the pituitary body on the growth of the genital tract was undertaken. This work was completed in 1917, but for extraneous reasons has not been published until now.

Various investigators have obtained diverse results from the feeding of the anterior lobe extracts to different varieties of animals, such as rats, rabbits and dogs. Among these investigators may be mentioned Sandri, A. E. Schaefer, T. B. Robertson and E. Goetsch. Robertson and Goetsch, the former using a purified extract which he denominates tetelin, and the latter the dry extract of the anterior lobe, claim to have obtained increase in body growth and stimulation of the genital tract in animals. The growth-producing effect of hypophysis extract appears to have been generally accepted in the literature, and the extract has been applied in some instances to the treatment of human beings. It seems well worth while to publish the results obtained by a series of experiments conducted with all due precautions on white rats.

Considering it likely from the perusal of the literature that anterior lobe extracts actually cause increase in growth and stimulation of the genital tract, a series of experiments was conducted in order to determine what constituents of the pituitary extract produced these phenomena. Through the kindness of the laboratories of Parke, Davis & Co., four extracts were obtained. These consisted of the following portions of the gland: Extract No. 1 of anterior and posterior lobe in proportion of 1 to 6 desiccated; Extract No. 2 of pituitary free from fat soluble substances; Extract No. 3 of pituitary containing only fat soluble substances; Extract No. 4 of anterior lobe only desiccated and diluted with lactose to prevent decomposition.

Six litters of white rats raised in the laboratory were used in the course of these experiments. The rats were 3 weeks old when the experiments were begun. Litters 1 and 2 were composed of six sisters each; Litters 3 and 4 of five sisters each; Litter 5 of three sisters, and Litter 6 of four sisters. In each litter at least one animal was selected as control. For thirty-five consecutive days each animal (except the control) was fed with 0.05 gm. of pituitary, given in a bolus composed of meat, egg and cream cheese, which was eagerly taken. In order to round out the diet, the animals were also fed with milk, greens and oats. Throughout the experiments all the animals, except No. 4 of Litter 6, showed progressive increase in growth.

At the necropsy, it was found that no concordant increase in size or in general body weight, or in the genital organs ascribable to the glandular feeding was present. Irrespective of whether experimental animal or control, certain rats showed a greater increase of weight, the presence of corpora lutea in the ovaries, and enlargement of the other internal genitals.

\* From Columbia University, George Crocker Special Research Fund, G. Wood director.

According to Goetsch's report, animals of this age (56 days) should show no corpora lutea unless stimulated by the extracts. Possibly his results were accidental, as the individual series contained few animals; or possibly the season of the year may have had some influence, because in his experiments most of the animals were fed during the early months of spring; or, again, possibly individual breeds show premature maturity.

#### CONCLUSION

It may be said that more extended experiments along these lines will be necessary before stimulation of the sex organs, at least of the female sex organs, can be ascribed to the use of pituitary extracts. The practice of at once applying unconfirmed results obtained in the laboratory to clinical practice is pernicious. In no field has it been more abused than in that of "endocrinology." If this practice continues unchecked, organotherapy will fall into disrepute both in the opinion of the medical profession and in that of the public.

### THE SPINAL FLUID IN PRIMARY AND SECONDARY SYPHILIS

JOSEPH McIVER, M.D.

Instructor in Neurology, University of Pennsylvania School of Medicine;  
Assistant Neurologist, Philadelphia General Hospital

PHILADELPHIA

This study was undertaken with the idea of determining so far as possible what percentage of cases of primary and secondary syphilis would show infection of the cerebrospinal fluid as might be demonstrated by the usual laboratory methods.

The tests made on each specimen of spinal fluid were the Wassermann reaction, protein determination and cell count. In every case, comparison of the blood Wassermann has been made with the findings in the spinal fluid. The duration of the disease, the present signs of syphilis and previous treatment have also been taken into consideration.

These studies were made in a series of ninety-one cases. The majority of the patients were either in the primary or the secondary stage of syphilis. The lesions manifested varied from early chancre to a fading secondary rash. A few of them, however, were well past the secondary stage. There was only one out of every four or five cases in which any previous treatment had been given, and that was usually a very small amount.

All of these cases gave a +++ Wassermann reaction of the blood serum, as this was one of the determining factors whether or not studies be made of the spinal fluid.

The cell count was made immediately on removal of the spinal fluid. The average number of cells per cubic millimeter was nine. No effort was made to classify them. The greatest number of cells per cubic millimeter for any one specimen was seventeen. One of these was a case presenting a chancre of the lip with marked glandular involvement but no secondary rash. The others were cases of well marked secondary syphilis. If a cell count of five per cubic millimeter is taken as the average in normal spinal fluids, practically all of these cases showed a slight abnormality. The percentage of cases of secondary syphilis showing changes in the spinal fluid has been given as from 10

to 90. If we may consider a slight increase in cells an abnormality, then undoubtedly a large number of the primary and secondary cases of syphilis would show abnormal spinal fluid. This, however, must be regarded as only of suggestive significance, as there are a number of conditions that may produce an increase in cells. Then, again, we have to admit that cell counting is subject to error.

Only two of these cases showed a slight excess of protein in the cerebrospinal fluid, and curiously enough one of these was in the chancre stage. The other was one of two years' duration. Very little treatment had been given in either case.

In performing the Wassermann reaction of the spinal fluid, 0.6 c.c. was used, 0.2 c.c. being the usual amount. The increased amount of fluid had no effect on the reaction.

I might say at this time that the vast majority of these patients suffered from lumbar puncture headache despite the fact that they remained in bed from three to four days following the operation. The amount of fluid withdrawn never exceeded from 3 to 4 c.c. The intensity and duration of the headache varied a great deal in different persons. Although this was troublesome and annoying, no serious complications followed.

It might have been more interesting if we had made more than one examination of the cerebrospinal fluid at different periods of the disease. However, I did not feel justified in doing this, considering the discomfort that it caused the patient and what it promised in return.

In making the lumbar puncture, 2 per cent. cocaine was used to anesthetize the skin. This was a great help in reducing the immediate discomfort of the puncture. The introduction of physiologic sodium chlorid solution into the spinal canal to replace the amount of spinal fluid removed was considered but was not done.

What percentage of those infected with syphilis will develop symptoms of the nervous system has been a field of much speculative theorizing and has been variously estimated at from 9 to 25. A great deal of time and energy have been spent trying to determine the class of cases that will develop neurosyphilis and at what time in life. The explanations that have been offered are familiar to us all.

It has been said by some that the papular variety of syphilis was more likely to give a positive Wassermann reaction of the spinal fluid. This has not been true in my series.

Others have thought that there must be a difference in the virulence of the spirochete flourishing in different parts of the world. In this series a number of countries were represented, namely, England, France, Ireland, Italy, Portugal, Wales, and all parts of the United States. Notwithstanding the number of places from which the infections came, there was no noticeable difference in them so far as the laboratory studies were concerned. Clinically, the cases from abroad usually presented more marked secondary manifestations, but as a rule they had gone longer untreated.

#### CONCLUSIONS

1. There is a slight increase of lymphocytes in the cerebrospinal fluid in the majority of cases of primary and secondary syphilis.
2. The increase in protein content does not appear as early as the increase in lymphocytes.

3. In this series not a single  $+++$  was observed. A Werhmann reaction was obtained on the spinal fluid in primary and secondary syphilis.

4. It does not seem reasonable to conclude that we can determine by the examinations of the cerebrospinal fluid in cases of florid syphilis just who is going to develop symptoms of the central nervous system.

424 Chester Avenue.

## Clinical Notes, Suggestions, and New Instruments

### A SIMPLIFIED METHOD FOR INDUCING THERAPEUTIC PNEUMOTHORAX\*

ROSENBLATT, M.D., BOSTON, MASS., N. Y.

The usual procedure employed in the induction of therapeutic pneumothorax consists of two steps: First, a local anesthetic is injected into the skin, subcutaneous tissue, and pleura second, a special needle is inserted through which the gas is introduced.

About four years ago, Dr. Alfred Meyer suggested that the operation could be much simplified by introducing the gas through the same needle with which the local anesthetic is injected. He accomplishes this by connecting the syringe from the needle and slipping the rubber tubing leading to the gas apparatus onto the hub of the needle, or by attaching the rubber tubing to the needle by means of an adapter. Following under the direction of Dr. Meyer we have been using this method for some time in primary operations as well as in refills, and it has proved to be quite satisfactory. The only Gussone's and others have reported that they have been using this method in refills with satisfac-

tion. An objection that has been raised is that the method is that while the syringe is being detached from the needle and the rubber tubing attached to the hub of the needle is the short time exposed to the atmosphere such some air enters the pleural cavity. Another, and more serious, objection for forced ejection is that should the point of the needle happen to be in a pulmonary vein, where a retrograde, negative, some air may be aspirated into the vein, and the lower end of the needle is exposed to the atmosphere and air entering the entire

#### AUTHOR'S METHOD

In order to avoid the above objection and at the same time make the operation much simpler and easier I have devised a method by which the gas can be introduced through the same needle through which the local anesthetic is introduced. The method consists in inserting between the syringe and needle the adapter for introducing the local anesthetic. A diagram illustrating the method is given in the accompanying illustration and a description of pleural effusions. One end of

this stopcock has the point of the syringe and the other end fits the needle. A branch extends from the side of the stopcock to which can be attached the rubber tubing leading to the gas apparatus. The stopcock is also provided with a two-way valve so arranged that when the valve is turned one way, the needle communicates with the syringe for drawing up and injecting the local anesthetic, and when it is turned the other way, the needle is communicating with the side-branch leading to the gas apparatus. The stopcock can be made to fit any type of syringe and needle, but we found it best to use an all glass Luer syringe and a sharp steel needle,  $1\frac{1}{4}$  inches long and from 21 to 22 gage.

The technic is very simple. First, the stopcock is set so that the needle is communicating with the syringe, and the local anesthetic is drawn up and injected in the usual manner. When the operator thinks he has pierced the parietal pleura, the rubber tubing leading to the gas apparatus is connected to the side-branch of the stopcock, and then a quarter turn of the stopcock valve puts the needle in communication with the rubber tubing leading to the manometer and gas bottle, so that the manometer can be read and the gas introduced.

The syringe may be left in place, but we found it advisable to withdraw partly the piston of the syringe as soon as the anesthetic is injected, so that the fluid that remains in the lumen of the needle is aspirated back into the barrel of the syringe, leaving the needle clear. Moreover, this simple procedure of partly withdrawing the piston of the syringe frequently gives us valuable information as to where the point of the needle is located. If the point of the needle is engaged in tissue, as soon as the piston is released it will be drawn back forcibly into the barrel of the syringe, as if the finger were held over the point of the syringe while the piston is withdrawn. This usually indicates that the needle is not deep enough. If the piston falls back by gravity, the point of the needle is in a free space, either in the pleural cavity or in the lung, and if satisfactory manometric oscillations cannot be obtained, the indications are that the needle is too deep, and it should be withdrawn somewhat. Should blood come up into the syringe when the piston is partly withdrawn, the point of the needle is in a blood vessel, and then it is best to withdraw the needle and insert it in another place.

We have been using this method for about two years in primary operations as well as in refills, having performed thirty-five primary operations and about 350 refills, and we have found it perfectly satisfactory. Among the primary cases, we had a number that were very unpromising from the standpoint of physical signs and roentgenographic findings; yet we have been successful in all but one case, and in the great majority we succeeded in inducing pneumothorax with the first attempt.

There are two objections that might possibly be raised to this method as well as to other methods in which a small, sharp needle is used. First, some claim that a sharp needle is more likely to penetrate and wound the lung than a large, blunt needle, secondly, this needle has no obturator and one may think that it is easily blocked up. As a matter of fact, however, even if a small needle should pierce the lung substance, it is very unlikely that lung tissue will be damaged or that spontaneous pneumothorax will result, while a dull, heavy needle is more likely to cause laceration if it pierces the lung. Furthermore, even those who use a large needle for introducing gas also use a small, sharp needle for injecting the anesthetic, and this is practically what the entire operation

Syringe for use in artificial pneumothorax. A, syringe, stopcock and needle ready for use. B, valve of stopcock arranged for injection of a local anesthetic. C, valve turned for introduction of gas.

\* From the Department of Surgery, Country Synagogue, Belford Hill, New York, and the Department of the Jewish Charitable Relief Society, New York.

1. Meyer, A. Tr. Nat. Anest. Study & Prev. Tuberc. 11: 702, 1917.  
2. Gussone, H. Tr. J. Exp. Med. 14: 1, 1917. Reprint in Artificial Pneumothorax, J. A. M. A. 72: 4 (March 20, 1919).

consists of with our method. As to the absence of an obturator, if the needle is small and sharp it is not likely to be blocked up with tissue, especially in this case in which the anesthetic fluid, being forced through the needle, acts like an obturator. Should the needle become blocked up with a drop of blood, it can easily be dislodged by moving the piston gently up and down, or a small amount of anesthetic fluid may be retained in the syringe and then forced through the needle whenever it becomes necessary to clear it. At any rate, we hardly ever had any trouble due to a blocked needle.

ADVANTAGES

The advantages of this method over the two-puncture method are obvious:

1. The operation is rendered much simpler and easier.
2. The amount of trauma to the pleura is greatly minimized, and so pleural shock is less likely to occur. Though the cause of pleural shock is not well known, yet judging from what is known about shock in general, it is reasonable to suppose that pleural shock is less likely to occur when the pleura is punctured with a small needle than when it is pierced with a dull trocar and cannula.
3. Subcutaneous emphysema is less frequent.
4. The patients do not dread the operation so much when this method is used, as they consider it of a minor character, and it is well known that the state of mind of the patient is an important factor in the success of the treatment.

INFLUENZA AND EPILEPTIFORM ATTACKS

L. PIERCE CLARK, M.D., NEW YORK

Since no case has yet been recorded in which epilepsy or epileptiform attacks have apparently been initiated by influenza, a case of this type may be worthy of brief mention. It is the only one of which I am aware.

REPORT OF CASE

A boy, aged 2 years, with an unimportant family and personal history, contracted a severe attack of influenza in January, 1919. He had a temperature as high as 104. The disorder was initiated by general convulsions which endured for several hours. The fever lasted four days. A week later, after a normal temperature for two days, he again had a fever of from 104 to 106 but without convulsions, and pneumonia developed. He was ill ten days, and two weeks after recovering he began having almost daily both grand mal and petit mal attacks. He had a persistent cough and was physically prostrated for several weeks. He slept poorly, was irritable, and did not gain in weight. The convulsions seemed to have been rendered worse by the advent of dentition. When this was completed, in July, however, the attacks began to appear daily (as many as fourteen a day) in spite of fair physical health, and without any other obvious cause. The whole mental development ceased at the onset of the influenza and pneumonia. Even some words already learned at that time, as well as his ability to creep and walk with slight support, were lost. Since the latter part of July, during which time this boy has been under my observation, he has had a decreasing number of petit mal attacks until now, when slight ones appear only at weekly intervals. The treatment has been hygienic, dietetic and moral. He is gaining in weight. Mental development is progressing normally although still somewhat retarded for a boy of 2 years, it being about equal to that of a child of 1 year.

COMMENT

While one may not say positively that the influenza and pneumonia caused the epileptic attacks in this child, the latter condition was certainly precipitated by this infectious disorder, and the sequential convulsions bear the earmarks of epilepsy in that there has been tongue-biting and voiding during attacks. The prognosis would seem to be favorable, although an entire arrest cannot be predicted from this short period of treatment.

20 West Forty-Eighth Street.

SIMPLIFIED APPARATUS FOR OBTAINING ARTERIOGRAMS\*

ARTHUR N. DONALDSON, A.B., M.D., LOMA LINDA, CALIF.

In the use of the polygraph we have found that unless plenty of hands are available, the application and operation of the sphygmograph is a trial to the patience of both patient and technician. Some time ago R. H. Halsey<sup>1</sup> described the use of an Erlanger capsule for obtaining a brachial arteriogram, which we tried with indifferent results. We were unable to obtain a bulb of just the right elasticity to transmit

Fig. 1.—Capsule used for obtaining brachial arteriograms: A, cylinder, 5 cm. wide and 9 cm. long whose ends are plugged by rubber corks, each perforated by a single opening; B, Marey tambour glued in hole of one cork; C, short glass tube connecting capsule with recording tambour of polygraph; D, one thickness of ordinary dental dam on Marey tambour.

properly the pressure changes. We believe we have found a substitute for the Erlanger capsule that will serve all purposes admirably, and that can be inexpensively put together in any laboratory.

A graduate, about 5 cm. in diameter, may be used and cut so as to secure a cylinder, 9 cm. long. The two ends (Fig. 1 A) are plugged with rubber corks, each perforated

Fig. 2.—Polygraphic tracing; arteriogram produced by use of the apparatus described, showing extrasystole.

by a single opening. Glued in the hole in one cork is the stem of an ordinary Marey tambour (Fig. 1 B); in the other cork is a short glass tube (Fig. 1 C) to connect the capsule with the recording tambour of the polygraph. On Marey's tambour is used one thickness of ordinary dental dam (Fig. 1 D). This holds the pressure in the cuff and responds readily to brachial pulse changes.

With this arrangement and a pressure equal to the diastolic pulse in the cuff, the delicate recording tambour of the poly-

Fig. 3.—Tracing obtained with cuff over sleeve on woman.

graph responds with a gratifying amplitude; and we have no fears of any interruption in our tracing when dealing with a nervous patient who may find it hard to keep quiet.

#### BRAN

That constipation is a disease of civilized man and due to the use of too concentrated food is a bromide commonplace, the truth of which might, however, be challenged. If the food of savage man represents a more advanced stage of evolution than the bulky food of early man, then our still more concentrated diet must be considered a further step in advance. It is true that the progress of civilization has been accompanied by a refinement of food and elimination of indigestible residue, chiefly cellulose, as to lead to the production of a smaller quantity of fecal matter and to less frequent bowel evacuation. This tendency is not in itself evil. Most of us enjoy this concentrated and partly pre-digested food, and many of us thrive on it. It must, however, be admitted that the intestine of some may not have become adjusted to this ballast-poor diet, but the condition within the bowel of such persons may become pathologic, and that it is necessary for them to return more nearly to the diet of their ancestors by increasing the indigestible residue in their food.

The "back to nature" cry of the health faddist need not lead us to the habitual admixture of sawdust, bran or similar substances to our food. When, however, there is constipation, the question whether increase in cellulose is indicated is important. Unless the patient is of the type characterized by excessive digestion of cellulose and flatulence therefrom; and unless the patient suffers from gastric motor insufficiency or intestinal atony, we should favor cellulose in the diet. There are three forms in which cellulose may be added to the diet: in fruits, vegetables and bran. Of these, bran is the richest in cellulose and is one of the most effective purgatives of constipation.

If practicing physicians do not make more frequent use of bran, which its laxative properties have so long been recognized in the very general use of bran meals, to prevent a tendency to constipation in farm families, the evident reason for this is that bran is not a drug, and hence there is very little information regarding it to be found in the books ordinarily in the possession of medical practitioners.

Using, as we usually do, bran, the outer covering of wheat is exceedingly difficult to reduce to a fine powder. The trouble and expense of grinding it is so great that one of the first steps in the milling of flour is the removal of it. However, in rejecting the bran, the farmer discards some of the most useful constituents of wheat, and he loses from its composition:

Protein	1.6
Carbohydrate	1.6
Mineral matter	1.6

The most important constituent of bran is its cellulose, of which it contains almost 20 per cent. This cellulose is in a dense, woody form, almost indigestible in the human digestive tract. As the nutritive con-

stituents of bran are enclosed within walls of this indigestible cellulose, much of them passes through unchanged. Bran is therefore chiefly to be looked on as a form of almost indigestible carbohydrate, which is endowed with considerable laxative value, not only because it adds by its bulk to the distention of the intestine, but also because of the spiculate shape of its particles. Excessive irritation does not result from these; for, when properly moistened and heated, bran becomes as soft and pliable as wet paper, and hence produces merely a gentle titillation and is usable even in patients with a tendency to colic. Some of the cellulose undergoes fermentation, giving rise to gas and acid, both of which are laxative. It is furthermore possible that there is a chemical laxative factor present in bran itself, for W. H. Jordan, E. B. Hart and A. J. Patten of the New York State Experimental Station found that the laxative action of bran for cattle was lost when the soluble phosphorus compound named phytin had been extracted. These experiments will have to be confirmed for man.

The dose of bran is a considerable amount; tablespoonfuls rather than teaspoonfuls; two of them rather than one; and taken several times, at least twice daily, best with meals, and indefinitely. We do not have here a cure for constipation in the sense that its use can, after a while, be discontinued. It is generally necessary to employ bran as a regular ingredient of the diet; hence the importance of making the patient enjoy its use, and the desirability of making it an integral part of the meals by means of cooking. Of course, the patient may take it, as is often recommended, stirred into a glassful of water after meals. Sooner or later, however, he will get tired of this uninviting pottage, and "forget" to use it. Let the bran enter the kitchen and have the cook see to it that the patient takes enough by making it up into dishes so palatable and diversified that one will never tire of taking it. It is only when used in this way that bran really "cures" or takes care of constipation.

The subjoined cooking recipes<sup>1</sup> might furnish some suggestions for the palatable administration of bran. There are, of course, many other ways, among which may be mentioned: graham or whole meal bread and crackers; bran with cream and sugar; bran mixed, up to one third, with breakfast cereal; bran added to vegetable purées and to fruit sauces; bran incorporated in fish cakes, minced meat, etc. Perhaps the best way to serve it is in bakery products, in which bran may replace white flour up to the extent of 50 per cent. Even pie crust may thus be made with bran.

#### BRAN RECIPES

##### BRAN POTATO SOUP

Make potatoes, add water, milk or cream to make a thick cream, and add bran. To every cup of the thin cream add

- 1/2 cup bran
- 1/2 cup soft butter
- Salt, celery salt and paprika

Bring mixture to the boiling point and serve.

##### BRAN MUSH

- 2 cups bran
- 1 cup boiling water
- 1 tea spoonful salt
- 1 cu. cl. figs or dates

Add bran to boiling salted water and boil from three to five minutes. Cook one hour in a double boiler, adding the figs or dates ten minutes before the mush is done.

1 Adapted chiefly from Frances E. Stewart's "Cookery for Invalids" (Rand McNally & Co., to be published) and Abba Francis Patton's "Practical Dietetics" (McGraw-Hill, N. Y., published by the author, 1919).

\* This is the first of a series of articles in the pharmacology and practical application of the common laxatives and emetics. The first article appeared October 18.

BRAN MASHED POTATOES

2 cups hot mashed potatoes, 1 to 3 tablespoons butter  
freshly prepared  
¼ teaspoonful pepper ½ to ¾ cup hot milk or cream  
¼ teaspoonful salt ¼ cup bran

Add one-fourth seasonings to the potatoes and whip mixture until light. Stir in the bran and serve.

BRAN GRIDDLE CAKES

1 cup bran ½ teaspoonful salt  
1 cup flour 1 teaspoonful baking powder  
1 tablespoon sugar 1 cup milk  
½ teaspoonful butter or shortening 1 egg

Mix dry materials, add egg slightly beaten and milk and butter as substitute. Beat thoroughly and bake on a hot griddle. Serve with butter and syrup. This will make twenty cakes.

SWEET MILK BRAN BREAD OR MUFFINS

3 cups bran ¼ cup sugar  
3 cups white flour 2 cups milk or water  
2½ tablespoonfuls baking powder 2 eggs, beaten very light  
2 teaspoonfuls salt ¼ cup fat, melted and cooled

Mix the dry ingredients together thoroughly. Mix the liquid ingredients (including the fat, melted and cooled somewhat). Add the dry to the liquid ingredients, and mix only enough to blend them well. Bake in either of these forms:

As bread: Fill a greased bread tin two-thirds full of mixture and bake it forty-five minutes in a slow oven.  
As muffins: Fill greased muffin tins two-thirds full of mixture and bake from twenty to thirty-five minutes in a moderate oven, 342 F. or 190 C.

SOUR MILK BRAN BREAD OR MUFFINS

2 cups bran 2 cups thick sour milk or butter  
4 cups Graham flour milk  
1 teaspoonful soda 2 teaspoonfuls fat, melted and cooled  
2 teaspoonfuls salt  
1 cup molasses (not black)

Directions same as in preceding recipe excepting that the baking time for bread should be one and one-fourth hours.

This bread is almost as sweet as gingerbread. Children usually like it. When desired less sweet, reduce the molasses and increase the sour milk accordingly.

YEAST BRAN BREAD OR MUFFINS

1½ cups milk ½ cup lukewarm water  
3 teaspoonfuls molasses (avoid 2¼ cups white flour  
black) 1¼ cups Graham flour  
1 tablespoonful fat 1 tablespoonful salt  
2¼ cakes compressed yeast (size 2 cups bran  
1½ by 1½ by ¾ inch)

Salt the milk, then cool it to blood temperature. Blend the molasses, fat and yeast with the lukewarm water to make a smooth paste. Add the molasses mixture to the lukewarm milk. Add flour to make a sponge, or thick batter. Beat the sponge from three to five minutes, cover, and put in a warm place until it is double in bulk.

Add salt and bran, and beat dough to hard from three to five minutes in a bowl, using a wooden spoon. The dough should be of the consistency of soft baking-powder biscuit dough.

Half fill with dough a well-greased bread tin or muffin tin, then lightly rub the top of dough with fat.

Let dough stand in a warm place until it is double in size, then bake. Do not rub the dough while putting it into the oven, and it is only to fall. Bake in a cup.

Raisins, from one-half to 1 cup, soaked from one to two minutes in boiling water and then dried, or one-half cup of large raisins, cut in shreds, or both, may be added if desired.

BRAN BISCUIT

1 cup wheat bran 1 teaspoonful melted butter  
½ cup improved Graham flour 1 tablespoonful salt  
1 teaspoonful baking powder Milk

Sift dry ingredients, rub in the butter, and add milk to make a stiff dough. Roll it out and bake in hot oven.

BRAN COOKIES

1 cup bran 1 cup milk  
1 cup white flour ¼ cup molasses  
½ cup Graham flour ¼ cup milk  
2 tablespoonfuls butter or lard ½ teaspoonful salt  
2 teaspoonfuls baking powder 1 egg

Beat together butter and sugar, egg and milk. Add dry materials. Drop the mixed batter with spoon in well-greased tin. Bake about twenty-five minutes in hot oven. This makes three dozen cookies.

Raisins may be added as follows: Wash the raisins, let drain in warm water to cover and then boil them in the water until they are plump. Drain, dry and chop them.

Cinnamon, nutmeg and chopped nut may be added to the list of ingredients, if desired.

To vary the recipe the cookies may be covered with cooled and chopped figs or dates, and dusted with powdered sugar.

BRAN MACAROONS

1 egg 1 cup almonds (tooth-chippin)  
1 cup granulated sugar 2½ tablespoonfuls bran  
2½ tablespoonfuls flour

Beat egg and sugar until very light. Add nuts and then flour. Drop on buttered tin, and bake in a moderate hot oven ten minutes.

MAKING CASTOR OIL TASTEFUL OR TASTELESS

DR. GEORGE F. KEPPER LAJAYETE, Ind., writes: "There are the excellent articles appearing in THE JOURNAL on the Use and Abuse of Cathartics," especially the one in last week's issue on "Castor Oil," may I make a suggestion as to a way in which it may be made tasteless?

"Take a glass of ice water. Pour on the water the dose of the oil. The oil will congeal into a bolus, as it were, which will pass the lips, teeth and tongue as one mass, untrasted."

"This suggestion I obtained years ago from one of our elders in the profession."

COMMENT.—Numerous formulas have been suggested for making castor oil tasteful or tasteless. The "Pharmacology of Useful Drugs," by Hatcher and Wilbert, suggests that because of its disagreeable taste, castor oil is given preferably with pungent, freely frothing beverages, or enclosed in soft gelatin capsules, holding about 1 teaspoonful. It may also be administered in the form of a mixture or emulsion and the latter type of administration is becoming popular. The following may be used as a type formula.

	Gm. or Cc.
R Benzosulphimid (saccharin).....	0.65 1 grain
Oil of cloves.....	0.2 3 drops
Oil of cinnamon.....	0.3 5 drops
Alcohol.....	4.0 1 fl. dram
Castor oil, a sufficient quantity to make.....	100 3 fl. ounces

In making this mixture, the benzosulphimid, oil of cloves and oil of cinnamon should be dissolved in the alcohol and this in turn added to the castor oil.

BURNS OF THE EYE BY LIME

The increase in the use of chlorinated lime for household purposes has resulted in a somewhat greater prevalence of burns of the eye by this substance. During July and August some twenty cases were brought to the attention of the National Committee for the Prevention of Blindness. The circumstances in each case were that a sudden explosion of gas from the inside of the can followed the opening of the container, the shower of lime dust usually striking the eyes and face of the victim. In most cases, complete recovery followed, as medical care was usually provided immediately after the accident. The care of such a case usually includes anesthetization with a few drops of 1 per cent. solution of holocain or a 4 per cent. solution of cocain and then the removal of the remaining particles of the lime. The irrigating fluid should be a weak solution of vinegar to neutralize the caustic effect of the lime. Subsequently, cell applications may be applied to the closed lids, and a mild anesthetic used as a home and solution. Irrigate into the eye every two or three hours. If the burn is at all extensive, the conjunctival sac may be filled with an antiseptic ointment, which not only relieves the pain but also prevents the adhesion of opposing surfaces. The most important and important sequel is the adherence of the lid to the globe (symblepharon) when there are two opposing raw surfaces. In an endeavor to prevent these accidents, the national committee took up the matter with manufacturers and distributors. The latter report that chlorinated lime decomposes when exposed to high temperature or to dampness. To avoid smoking, it is recommended that a small hole be punched in the container to allow the gas pressure to be released before the top is taken off the can.

## DOES SILICON HAVE A PHYSIOLOGIC SIGNIFICANCE?

The occurrence of the element silicon as a constituent of animal tissues has often been reported. For the most part, however, it has been regarded as an adventitious component that has accidentally found its way into the organism and been deposited somewhere because of the insolubility of many of the compounds of silicon. Accumulations have been discovered in the lungs as the result of inhaled dust containing siliceous particles. Among gold miners, silicosis thus arises just as anthracosis results from the inhalation of coal dust, siderosis from iron-containing dusts, and aluminosis from clay dusts.

The late Professor Kobert of Rostock and his pupils have been inclined in recent years to ascribe great importance to silicon, which they regard as a normal rather than an accidental constituent of certain tissues. Ever since the discovery of the unique physiologic rôle of minute quantities of iodine in the body there has been a temptation to search for traces of many other elements not hitherto regarded as essential to the normal functions, and to discover a possible unexpected significance in their biologic occurrence. Manganese, arsenic and zinc have thus received consideration because they are quite commonly present at times in the living tissues. Silicon has likewise had its claims for recognition from the standpoint advanced. Thus Kunkel<sup>1</sup> of Würzburg, having discovered it in numerous analyses of the pancreas, actually arrived at the conclusion that silicon is stored in this organ much as iodine is deposited in the thyroid and iron in the liver. As the result of his numerous extensive investigations, Schulz<sup>2</sup> maintained that silicon is an accompaniment of all connective tissue, the content of the latter therein being greater in the less developed stages.

An occasional connection between silicosis and tuberculosis of the lung has been recorded in the past. In such cases, however, the tuberculosis has been regarded as a secondary factor to which all dust dis-

cases of the lung predispose. There is no doubt that silicosis may occur without any symptom of tubercles. Kobert and his pupils<sup>1</sup> have approached the relation of silicon to the lungs from a different point of view. Having observed that the connective tissue of the lungs contains silicon and that in the fibrous type of phthisis this tissue is further enriched in respect to the element, they assume that the latter plays a part in the successful development of that tissue which is responsible for the healing or circumscription of the tuberculous lesions. Consequently they have suggested the use of soluble silicates in the therapy of pulmonary tuberculosis.

Gonnermann<sup>1</sup> has revived the view that silicates may contribute to the induration of tissues which might, without silica, fail to heal satisfactorily in the neighborhood of lesions such as those described. He points out that many of the popular folk remedies for tuberculosis of the lung are comparatively rich in silica, thus suggesting an unsuspected possibility to explain their use. It would be unjustified to create any enthusiasm for a therapeutic suggestion that has comparatively so little to commend it. Even if the silicates are devoid of any real significance whatever in relation to the objects discussed, it is worthy of note not only that they are nontoxic in ordinary doses but also that silica is more widely distributed than is suspected in products that may serve as foods. Under these circumstances it need not be surprising if silica is distributed by chance rather than physiologic purposefulness in the body, just as its deposition in true silicosis is the result of accidental circumstances.

## THE CONSERVATION OF ANTISCORBUTIC FOODS

Reports which are accumulating from various regions of war-stricken central and eastern Europe indicate that dietary deficiency diseases, notably scurvy, are rife among the unfortunate populations, which are unable as yet to secure their usual quota of food in its normal variety. The possibility of relief is hampered by the difficulty in providing and transporting those foods which are recognized as having conspicuous protective value. Fresh vegetables and fruits, on which reliance is commonly placed to combat or avert scurvy, are scarce or unavailable. Fresh milk, which is usually depended on to safeguard the nutritive welfare of infants, is obtainable not at all or only with great difficulty in some of the afflicted regions. The dairy situation and the outlook for immediate relief are anything but promising.

In this predicament the agencies for relief have first of all considered the possibility of supplying vegetables,

fruits and milk—the foods seemingly most essential in the crisis—preserved in some way which would permit of sanitary and economic transport, as well as represent modest costs within the range of trade limitations. As has been indicated on previous occasions in THE JOURNAL, an unexpected obstacle was encountered in the more recent discoveries that various foods of this character lose their antiscorbutic potency in great measure or entirely as the result of the modes of preservation. This has been demonstrated for the current methods of desiccation with the aid of heat. The factors primarily responsible for the destruction of the antiscorbutic property are by no means understood as yet. Mere cooking in the usual culinary fashion does not necessarily destroy all the antiscorbutic potency of vegetables. Hess and Unger<sup>1</sup> have reached the conclusion that the method of preparing dehydrated vegetables may yet be perfected so that a product can be furnished that will be comparable in nutritional value to the fresh vegetable. They add that the problem seems to be one that is open to solution. The question of the degree of heating, which is generally regarded as of prime importance, appears to be merely one of several factors. Ideal conditions for furnishing dehydrated vegetables include the use of young vegetables, dehydrated shortly after they are plucked, and kept well sealed until they are to be eaten, and probably numerous other details which must be carefully observed if deterioration is to be prevented. Meanwhile no dependence can be placed on dehydrated vegetables as antiscorbutics.

The Committee on Accessory Food Factors, appointed jointly by the Medical Research Committee of England and the Lister Institute, has recently issued a statement that "canned vegetables are useless for prevention of scurvy." This dictum is probably the outcome of recent investigations conducted by Chick and her collaborators at the Lister Institute in London.<sup>2</sup> Experiments with cabbage and beans indicated that in the process of canning the greater part of the original antiscorbutic value of the raw vegetable is destroyed. In the case of runner bean pods, the loss is estimated at about 90 per cent. of the original value; in the case of cabbage, at about 70 per cent. of the original value. The process of canning cabbage included heating in water for about one hour at from 90 to 100 C., and for beans the process was repeated on the day following. This loss is primarily due to the destruction of antiscorbutic material occurring during the heating involved in the process of canning. A further loss may be expected to take place during the period of storage.

Before condemning canned foods in general as the result of such somewhat limited experience, we must recall the observations of American investigators on

the antiscorbutic value of canned tomatoes. Hess and Unger<sup>3</sup> have tested them with successful results both in the experimental scurvy of the guinea-pig and in infantile scorbutus. Tomatoes have also been desiccated without loss of all their antiscorbutic power.<sup>4</sup> Here, again, sweeping generalizations should be avoided.

We feel constrained to utter a similar warning in the case of dried milks. It is generally conceded that if milk is heated sufficiently, for example to 120 C. for an hour, its antiscorbutic power, at best not pronounced in the fresh fluid, is entirely lost. According to Barnes and Hume,<sup>5</sup> dried milk also is decidedly inferior. The specimen tested by these English investigators was desiccated by the Just Hatmaker process. Hess and Unger<sup>1</sup> have emphasized, however, that milk does not necessarily lose its antiscorbutic value in the course of drying. If it is dried rapidly, even at a temperature of about 240 F., it retains sufficient of the protective factor to have curative value, provided, naturally, that it was fresh at the time of drying. In considering the question of destruction of this vitamin by heat or by alkali, the duration of exposure to the detrimental influence is of the greatest importance. Let us hope that the manufacturers of dried milks, which seem destined to play an important part in the nutrition of the young in case fresh milk is not available, will devote their energies to the perfection of methods that shall in greater measure conserve the antiscorbutic potency of the mammary secretion. Barnes and Hume maintain as the result of their studies at the Lister Institute that "scalded" milk, that is, milk brought rapidly to a boil and then immediately cooled, is distinctly superior, as an antiscorbutic, to dried milk. They also venture to suggest, on the basis of what we regard as rather slender evidence, that winter milk is inferior to summer milk in antiscorbutic properties, corresponding to the differences in the cow's diet at these different seasons.

The recent investigations here and abroad have increased the list of products demonstrated to exert antiscorbutic potency, and have likewise helped to eradicate some erroneous beliefs. Orange juice no longer is the sole help in times of scorbutic distress. The latest addenda are the dry tamarind, cocum and mango, which possess, according to Chick, Hume, and Skelton<sup>6</sup> of London, a definite, if small, antiscorbutic value. The experimental demonstration of this fact accords with the esteem in which these fruits are held as antiscorbutics among some of the natives of India. Their value is now reported to be greatly inferior to

that of raw cabbages, swedes, germinated pulses, and orange or lemon juice, but equal or superior to that of carrots, beetroots, cooked potatoes or raw meat juice, compared weight for weight in the natural condition.

#### THE NEW BACCHUS

No longer should artists—at least American artists—represent Bacchus astride a wine barrel; the little god should be depicted astraddle a "patent medicine" bottle. While no statistics are at hand—largely because those who could collect such statistics are not going to publish them—on the increase in the consumption of the numerous highly alcoholized "patent medicines" since the advent of national prohibition, there is no question that the sales of these products have been mightily augmented. As every physician and pharmacist knows, there are on the American market a number of widely advertised and extensively sold "patent medicines" whose most potent ingredient is alcohol. All such preparations, of course, contain, in addition to the alcohol, certain drugs on which the manufacturers base their therapeutic claims. These drugs, in nearly every instance, are either harmless or, if potent, are present in such small quantities as to have a negligible physiologic effect.

The problem of controlling the sale of these alcoholic medicines can be satisfactorily solved in only one way and that way is to prohibit the use of alcohol in preparations of the "home remedy" type, that is, in those products which are sold indiscriminately to the public for the self-treatment of disease. Such action has already been taken with reference to a drug like cocaine, for instance, and in a modified form with reference to opium and its derivatives. Alcohol is a powerful drug. It is likely to be misused; so likely, in fact, that the United States has decided it is too dangerous to be used for beverage purposes. If alcohol is to be used for medicinal purposes it should be under medical supervision and the medical profession should be held as strictly accountable for any misuse of the drug as it is now held responsible for the misuse of the drugs covered by the Harrison Narcotic Law.

The manufacturers of "patent medicines" of the alcohol type all deny that the alcohol is present for its drug action; it is used as a "solvent" or as a "preservative" or "to prevent freezing" or for some other reason. They argue that certain drugs can be extracted only by means of alcohol. This is true. It is equally true that after these substances have been so extracted, the alcohol can be evaporated and the drug principles that are left can be put up in the form of tablets or capsules. In many instances glycerin can be used as a solvent where a liquid medicine is desired.

One of the chief arguments put forth by the manufacturers of alcoholic "patent medicines" is of the *ad hominem* type. They declare that physicians prescribe

tinctures, fluidextracts, etc., which contain alcohol in varying amounts. Very true. Physicians also prescribe such dangerous drugs as cocaine, morphin, strychnin and arsenic, when in their judgment such drugs are indicated. This is no reason, however, why dangerous drugs should be sold indiscriminately to every Tom, Dick or Harry who has a pain or who, by reading nostrum advertisements, has been made to think he has a pain.

The nub of the whole thing is that none of these alcoholized "patent medicines" would have any vogue were the alcohol removed; neither would such removal affect the therapeutic value—real or supposititious—claimed for such products.

#### THE MEDICAL CURRICULUM, THE LABORATORY AND MEDICAL PRACTICE

Tradition is potent in medical practice, as in other fields of human activity. We cling to the old so long as it is not positively harmful. Bloodletting as a routine procedure was as reluctantly abandoned as was the use of the magical rod. Likewise many remnants of the *materia medica* of bygone days are retained as a supposedly precious heritage, although the justification for their application in therapy would put a severe strain on the scientific logic of devotees. Rational therapy must be justified by demonstrable clinical results. This does not mean that drugs and pharmaceutical products are necessarily of limited value because the secret of their beneficial effects has not been unraveled by the scientific investigator. Science may be late in furnishing an explanation of unquestionable potency in long used agents.

Our criticism is leveled at those types of pseudo-therapy which retain procedures and products that may placate the patient while they leave the physician, like the medieval medicine man, a mere prescriber of a traditional something. Cushny,<sup>1</sup> in a lecture to the students of medicine at the University of Edinburgh, has well remarked that although we must not dispraise the ancient physicians, the fathers of medicine to whom we owe so much, too much veneration for our ancestors hardly makes for progress, and may be a burden to our young men. The division of medical teaching into a dozen or more departments, Cushny adds, had not for its object that the student should be taught twelve times as much, but that he should be taught more accurately. We must scrap our obsolete weapons, and send out young physicians adequately armed with the best, and not burdened with the superfluous. The teaching in *materia medica* should be limited to drugs of real importance in therapeutics or in the principles they illustrate.

Another criticism that is directed against the present day trend in scientific medicine intimates that it tends

1. Cushny, A. R.: *Progress in Materia Medica*. Edinburgh M. J. 2:1-317 (Dec.) 1918.

to develop an aloofness from the human being because of its devotion to the laboratory. It is assumed that the latter is essentially a factor either for devising methods of diagnosis or for exposing the worthlessness of many supposed remedies. Undoubtedly laboratory investigation has done much to relegate certain drugs and devices to the rubbish heap; but it has also furnished an intelligible explanation for the worth of many others. In this connection we cannot forbear quoting Cushny's reminder of the debt to the laboratory. It is a fact, he says, that is not always remembered, that in the last half century no drug of the first importance has entered by any other portal than that of the experimental laboratory. Without it, Cushny adds, we should have to depend on opium and morphin for soporifics; chloral and its allies would be unknown. Cocain and the local anesthetics and analgesics would not be available, nor the antitoxins and arsphenamin. If it were possible to estimate the value of the life saved and the suffering relieved by even two or three of the remedies introduced by the laboratory route, and put it against the expense of all the laboratory investigations throughout the world, the dividend would be found so enormous that the cry would be, not for economy, but for lavish expenditure in such a paying investment.

## Current Comment

### STANDARDIZATION OF LABORATORY TESTS

So long as laboratory tests employed by practitioners of medicine are simple, there is little opportunity for confusion in their interpretation. However, errors of interpretation are likely to occur in the use of complex reactions or when uniform standards are not adopted. Several years ago the writer of a paper on scabies asserted that all persons with scabies had albuminuria; subsequent investigation showed that the test for albumin which was used was so delicate that it showed the presence of albumin even in normal urines. Many of the modern laboratory tests, such as the Widal and Wassermann reactions, are extremely complicated. The technic of these tests has been gradually modified by different observers so that now many systems of performing the tests are in use. In a recent article by Kolmer and Flick,<sup>1</sup> eight different methods of performing the Wassermann test are compared, and it is demonstrated that each gives different results. The same thing is true of the Widal reaction, as has been pointed out by Dreyer. Obviously, it is desirable that every one who discusses the results of the Widal reaction or of the Wassermann reaction should refer to the same thing. When this is not the case, the figures regarding the validity of a given test presented by different observers are not comparable, and confusion rather than enlightenment results. The time has come when these tests should be standardized throughout the world. Such standardization need not exclude further

experimentation on any of the tests in question, and provision should be made for the reconsideration of the standards at stated intervals. As a step in this direction the U. S. Pharmacopoeia already has a section on Diagnostic Reagents and Clinical Tests which, thus far however, is chiefly concerned with the strength and purity of reagents. The United States government maintains a Bureau of Standards, and it is possible that through this organization or some similar one the important work of standardizing laboratory tests can be accomplished. In any event, the work needs to be done.

### THE ACTION OF THE PYLORIC SPHINCTER

The current teaching regarding the control of the pyloric sphincter and the emptying of the stomach is largely due to the writings of Cannon and his associates at the Harvard Medical School. They have suggested that it is under chemical rather than purely mechanical control. Acid on the stomach side is regarded as a cause of the relaxation of the pyloric sphincter, whereas on the duodenal side the same reaction tends to produce a closure of the sphincter and an inhibition of gastric evacuation. Among the evidences of the first proposition is the fact that carbohydrate meals with a low acid absorbing power leave the stomach rapidly; but if an alkali, like sodium bicarbonate, is added, the exit from the stomach is delayed. Proteins which combine with acids leave the stomach slowly as a rule, whereas acid proteins are discharged into the duodenum more promptly. This hypothesis fails to explain certain admitted facts, such as the emptying of the stomach in achylia gastrica and the rapid exit of water from the stomach. In extensive roentgen-ray studies on the movements of this organ in man, Cole<sup>2</sup> has pointed out that in health, as well as in disease, the first portions of the food ingested by the fasting stomach may leave it promptly. As acidity can scarcely be assumed to develop so early as a relaxing stimulus, Cole correlated the opening of the pylorus with the passage of peristaltic waves and an increased tonicity of the stomach. Investigations of the gastric functions, both in man and in animals, at the physiologic laboratories of the University of Chicago have brought Luckhardt, Phillips and Carlson<sup>3</sup> similarly to the conclusion that certain motor activities of the stomach are intimately associated with the relaxation of the pyloric sphincter, thus correlating this with mechanical as well as more purely chemical developments in the organ. Marked motor activities, either as tonus changes or peristalsis, as well as the presence of free acid may lead to inhibition in the tone of the sphincter at the pylorus and to its consequent opening. This explains why water alone may issue neutral from the stomach, as Ivy<sup>4</sup> has reported. According to the Chicago physiologists there is a more intimate relation between the muscular activity and the opening of the pylorus than between the latter and the reaction of the intra-

gastric contents. Thus they record that very quickly after ingestion of food, fluoroscopic examination of the stomach of man, while indicating the motor activity of the stomach, shows that the pylorus opens for the ejection of chyme with arrival at the sphincter of powerful advancing rings of constriction, perhaps aided, as has been suggested, by a general increase in the tone of the stomach musculature as a whole.

#### TEST FIGHT ON SOCIAL INSURANCE IN NEW YORK

The governor of New York has announced that, as a part of his administration program, an effort will be made at the coming session of the state legislature to pass a bill providing for compulsory state health insurance. In this policy, he has the support of the New York State Federation of Labor. The Medical Society of the State of New York, as previously reported,<sup>1</sup> at a special meeting of its house of delegates, unanimously adopted the report of its special committee on this subject, unqualifiedly opposing the passage of any law instituting a system of compulsory health insurance. This brings the question to a clear cut and definite issue in New York. As New York is one of the oldest and most highly developed states industrially, commercially and socially, it is an ideal state in which to discuss and test out this important subject. The limitation of the discussion to the legislature of one typical state will enable the opponents and advocates of health insurance to concentrate their energies to the best advantage.

#### ALLEGED PLACENTAL FUNCTIONS

The peculiar anatomic relations of the placenta have long lent an unusual interest to the study of its functions. There is no direct communication between the maternal and fetal circulations. The placenta represents the fetal organ for respiration, nutrition and excretion; but physiologists have not been content to limit the functions of the placenta to these more obvious necessities. Recognizing that simultaneously with the development of this structure there occur changes in the maternal organs that are not observed at other periods in the life of the female, efforts have been made to correlate or connect the concurrent phenomena. The placenta has been considered as having an internal secretion—as elaborating hormones that affect the maternal organism. For example, it has been suggested that the placenta is the specific source of a substance that causes the hyperplasia of the mammary gland during pregnancy. The evidence for this contention has been furnished primarily by experiments in which placental tissue was fed to virgin animals. A critical estimate of the results makes the hypothesis unlikely. Recently Hammett<sup>2</sup> has attempted a brief success at the Boston Lying-In Hospital to detect by bedside observation an increased growth of mammary tissue when desiccated placenta was fed

postpartum to lactating women, as compared with a series of patients not receiving the placental material. From the evidence at hand he concludes that it is reasonably certain that the placenta has little if any direct influence on the mammary development during pregnancy, the source of the stimulus being presumably elsewhere in the genital or fetal structures. Nor, according to the preponderance of evidence, is any influence exerted by the placenta on the flow of milk. Hammett and McNeill<sup>3</sup> fed 10 grains of desiccated placenta three times a day to more than 300 women without detecting any galactagogic activity in comparison with the secretion of mothers who did not receive the material. Hammett<sup>2</sup> has lately reached the conclusion, however, that there is produced in the placenta some substance capable of acting as a stimulus to growth, when ingested by the mother and passed on to the infant in the mammary secretion. Observations by Cornell<sup>4</sup> have been given a similar interpretation. Hammett makes the further deduction that it is not illogical to suppose that the placenta in utero also produces a substance that acts as a stimulus to fetal growth. However, the familiar shortcomings of arguments based on such indirect evidence must make us hesitate to give the placenta a place in endocrinology.

#### PIGMENTATION OF THE ORAL MUCOUS MEMBRANE

Although blackish pigmentation of the skin has been noted—aside from the coloration of the epidermal covering of the dark races—in freckles and in Addison's disease, it is not common as a purely pathologic manifestation. So far as the color in the various instances just referred to is due to that as yet poorly defined substance termed melanin, there is an impression among investigators that cells which do not normally form this pigment probably do not acquire the capacity to do so under pathologic conditions. Thus, the coloring matter of the so-called "melanosis" of the large intestine is said to be neither true melanin nor ordinary "waste" pigment.<sup>5</sup> The pigment deposited in the skin in Addison's disease is generally assumed to represent merely an exaggerated quantity of that normally produced there.<sup>6</sup> Parkes Weber<sup>7</sup> of London has recently referred anew to rare cases of black pigmentation of the mucous membranes of the cheeks, lips and mouth proper that are occasionally encountered and cannot be ascribed to disease of the suprarenal structures. It is associated with pigmentation of the skin of the face, especially about the mouth, and possibly of other parts of the body. Since the phenomenon has been observed by Rolleston<sup>8</sup> in persons

suffering from demonstrated pernicious anemia, it may be debated whether there is some intimate connection between the pathology of this disease and the pigmentation of the oral mucous membrane. It occurs in persons of dark complexion and notably in certain races. Hence Weber<sup>1</sup> is inclined to regard it as physiologic in character and perhaps atavistic in origin. Black patches are very common in the oral mucous membranes of dogs and other animals. Perhaps, now that attention is being directed more specifically to it, this form of pigmentation will be found more common in man, in whom it may represent a racial or ethnic feature rather than a purely pathologic manifestation.

## Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST; SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

### CALIFORNIA

**Anesthetists Organize.**—An organization to be known as the Southern California Anesthetists was formed at a meeting held in Los Angeles, last month.

**Personal.**—Drs. Anders Peterson and Charles E. Zerfing, formerly police surgeons of Los Angeles, have applied for passports to go abroad to make a study of leprosy and influenza. They expect to go first to China and to be gone for two years.—Drs. Laura T. Myers, Etta G. Gray and Lulu H. Peters, Los Angeles, are working together in Serbia.

**Arrested Fourth Time.**—Three times acquitted on a charge of practicing medicine without a license, Armonda Dominguez, the "Miracle Man," of San Bernardino, is reported to be again facing a jury on the same charge. Dominguez claims to have obtained his skill from his father who was a druggist and chemist and from studying botany and chemistry. He denies ever having attempted to commercialize his skill.

**Smallpox Prospects.**—At the eleventh annual conference of state, county and city health officials held in connection with the league of municipalities at Riverside, recently, a special mention was made of the rapid increase in smallpox throughout the state during the last year. It was stated by Dr. Allen F. Gilliland, Berkeley, state district health officer, that about 75 per cent. of the children in the state have not been vaccinated.

**Osteopathic College Seeks Mandamus.**—The College of Osteopathic Physicians and Surgeons of Los Angeles, according to report, has recently filed mandamus proceedings to compel the California State Board of Medical Examiners to approve the institution as a medical school. The institution had been so recognized a year or two ago but, it is alleged, recognition was withdrawn owing to the failure of the college to meet the requirements of the board.

**Lane Medical Lectures.**—The Lane medical lectures to be given by Dr. Alonzo E. Taylor, professor of physiologic chemistry at the University of Pennsylvania, are to be on the general topic of "The Feeding of the Nations at War." The following are to be the dates and titles of the lectures.

Dec. 8, 1919, The Problem of Feeding a Nation; December 9, The Feeding of the United Kingdom; December 10, The Feeding of France and Italy; December 11, The Feeding of the Enemy State; and December 12, The Food Problem of Europe After the War.

**New Memorial Laboratory to Open.**—The directors of the Santa Barbara Hospital have issued invitations to the formal opening of the new Memorial Laboratory and Clinic Building. This building was founded by the late Dr. Nathaniel Bowditch Potter, formerly of New York City, for a study and research of metabolic diseases and represents, in its building equipment and staff, the first completely organized metabolic unit in the country. It is receiving support from the Carnegie Foundation for the Advancement of Teaching. On the death of Dr. Potter, July 5, Dr. Nelson W. Janney, New York City, was appointed director.

**Changes in Emergency Hospital Department.**—The following changes were made in the Emergency Hospital Department of San Francisco by the city board of health: Dr. Edmund W. Butler, emergency surgeon, was raised to the post of chief surgeon, in charge of the Emergency Hospital Service, succeeding Dr. Alanson Weeks, resigned. Dr. Maurice Heppner, formerly resident surgeon of the San Francisco Hospital, was appointed emergency surgeon, relieving Dr. Albert H. Taylor from active duty. Dr. Henry J. Kreutzmann was appointed emergency surgeon and Dr. Gertrude A. Spriggs was also appointed emergency surgeon, relieving Dr. Charles J. Peterson from active duty.

### CONNECTICUT

**Medical Guilds in Italy.**—Dr. Edward C. Streeter, Boston, delivered an address, November 17, before the Yale Medical Society, New Haven, on "Early Medical Guilds in Italy."

**Personal.**—Dr. William M. Stockwell, New Britain, superintendent of the New Britain Sanitarium, has resigned, to take effect, Jan. 1, 1920. He has accepted a similar appointment at the State Sanatorium, Newington.

**Returned Service Men Welcomed.**—Middlesex County Medical Society celebrated the return of its military men at a banquet held in Middletown, October 9. Twelve of the seven-teen members of the society who were in military service were present and were the guests of honor, and Dr. Frank K. Hallock, Cromwell, acted as toastmaster.

**Mental Hygiene Conference.**—The annual meeting of the Connecticut Society for Mental Hygiene will be held Monday, December 15, at 3 p. m., in the building of the New Haven County Medical Society. Bishop Edward C. Achenan, Suffragan Bishop of Connecticut, will preside. The society will be addressed by the medical director, Dr. William B. Terhune, New Haven.

**Portrait Presented.**—At the meeting of the New Haven County Medical Association, November 5, a portrait of the late Dr. Henry Fleischer was presented to the association by his widow. Dr. Frank H. Wheeler, New Haven, made the presentation for Mrs. Fleischer, and the gift was accepted in behalf of the association by the president, Dr. Louis M. Gompertz, New Haven.

### ILLINOIS

**Building for Physicians.**—A building for the exclusive use of physicians is to be erected by Mr. J. Frank Donald at Rockford. The building will cost \$150,000 and will be equipped with a laboratory, drug and medical supply room, clinic suites, and garages.

**Smallpox in Monmouth.**—Dr. Charles E. Crawford of the state board of health went to Monmouth, November 20, for a conference with the mayor and other officials regarding the measures to be taken to prevent an epidemic of smallpox in the city. There are at present about twenty five cases reported, all of mild type.

**Personal.**—Dr. Alice Barlow Brown, Winnetka, who spent a year in Belgium, supervising relief work, left Chicago, November 29, on a relief mission to Serbia. She was accompanied by Miss Lucy M. Morehouse, acting superintendent of the Evanston Hospital.—Harold Swarberg, Captain M. C., U. S. Army, Quincy, who has been in charge for more than two years of the roentgen-ray laboratories of the U. S. Army general hospitals at Fort McDowell, Ga. and Fort Sheridan, Ill., has been discharged from the service.

**Tuberculosis Association Meeting.**—At the annual meeting of the Illinois Tuberculosis Association, Dr. George T. Palmer, Springfield, was elected president; Drs. Herbert C. Jones, Decatur, and Moss Maxey Albion, Vinton, vice presidents, and the following physicians members of the executive committee. Drs. J. W. Pettit, Ottawa; E. W. Figgelman, Edwardsville; W. M. Hartman, Mazoni; N. C. Iknyan, Charleston, and Samuel L. Gale, Elm. The association passed a resolution adopting the standard of sanatorium operation of the National Sanitarium Association and the National Tuberculosis Association, and recommending the rating and scoring of all public sanatoriums in Illinois on these standards by the state department of public health.

### Chicago

**Nurses to Graduate.**—The annual graduation exercises of the Chicago Training School for Home and Public Nurses were held at Meinhart Temple, December 2, when a class of 1,300 received diplomas.

**Illegal Practitioner Fined.**—According to report, George W. Butler of 2601 Calumet Avenue, was arrested by the Illinois Department of Registration and Education for violating the medical practice act and was fined \$25 and costs.

**Personal.**—Dr. Edward I. Moorhead, clinical professor of surgery in Northwestern University Medical School, has been appointed chief of the staff of Mercy Hospital.—Dr. Louis D. Moorhead has been appointed dean of the Medical School of Loyola University.

**Historical Society Meeting.**—There will be a meeting of the Society of Medical History of Chicago, at the City Club, December 9 at 6:30 p. m. at which a paper in memory of Dr. M. R. Frank will be read by Dr. Charles B. Reed. Dr. Harlow N. Meyer will speak on the "First Neurologist."

**Hospital Items.**—Jackson Park Hospital is to be erected at Seventy-Fifth Street and Stony Island Avenue, with a frontage of 143 feet. The building will be T-shaped and will contain sixty-eight rooms and will cost \$150,000.—An open meeting is to be held, December 10, at the home of Mrs. Julius Rosenwald, in connection with the urgent appeal received from the hospitals in Palestine where a serious shortage of supplies has occurred, particularly as regard towels, soap and washcloths.

**School Physicians and Nurses Needed.**—In consequence of the failure of the city council to supply funds to pay physicians and nurses to supervise the health and life of school-children, Drs. Frank Billings, James B. Herrick, Joseph L. Mayer, Joseph A. Capps and William Allen Pusey have addressed a letter to the newspapers of the city calling on the city council to make provision at once for this most important work, and in the event of their failure to do this, calling on the public to subscribe to a fund, which will enable the health department to carry on this most important work.—Of the 127 school nurses who were laid off owing to lack of funds 110 returned to work, November 25. The city council finance committee voted on that day, to transfer \$4,825 from health department salvage funds to the nurses' salary account. In addition, the committee agreed that the November and December salaries of 150 school physicians who give half their time to the schoolchildren, shall be paid when the 1920 appropriation bill is passed.

#### MARYLAND

**Personal.**—Dr. Ralph B. Seem, Baltimore, for several years assistant superintendent of the Johns Hopkins Hospital and for nearly two years, during the absence of Dr. Winford H. Smith, acting superintendent of the hospital, has accepted the position of superintendent of the Billings Memorial Hospital, Chicago. He will leave the Johns Hopkins Hospital about July 1, 1920, and, after spending several months in Europe, will assume his duties in Chicago.—Dr. Karl H. Van Niman, who, prior to service in the Canadian army, was assistant superintendent of the Johns Hopkins Hospital, has accepted the position of second superintendent of the Johns Hopkins and will assume his duties shortly after January 1. He will have charge of the administration of the laboratory and, according to present plans, will probably succeed Dr. Seem as assistant superintendent.—Dr. Carlisle S. Leitch, who is now in charge of the dispensary at the Johns Hopkins Hospital, will assume charge of the admission office after January 1.—Harry B. Gantt, Capt., M. C. U. S. Army, Marine Corps, was returned after an absence of more than two years, overseas, and is now stationed at Camp Dix, N. J., where he will be in charge. Dr. Gantt was for some time on the staff of the Tower Hospital in London, and then acted as medical officer of the Army of Occupation in an infirmary near the town of Tientsin.—Dr. George F. Sargent, for the last twelve years medical officer of the Staff of Dr. Shepard and Enoch Pratt Hospital, Towson, Maryland, has been appointed surgeon in the reserve corps of the United States Public Health Service. Dr. Sargent will be assigned to a post as superintendent of the local U. S. Public Health District, which includes Maryland and the District of Columbia.

#### MASSACHUSETTS

**Personal.**—Dr. Frederic K. T. Clark, Major, M. C. U. S. Army, Westfield, who, up to the time of his discharge from the service, was chief of the ophthalmologic and otolaryngologic reserve of U. S. Army General Hospital No. 1, New York City, has returned to his home.

**Tuberculosis Association Meeting.**—The Boston Association for the Relief and Control of Tuberculosis held its sixteenth annual meeting, November 20. It was voted to

change the name of the organization to the Boston Tuberculosis Association. Dr. George S. C. Badger was elected president, and an executive committee was elected consisting of the president, Dr. Vincent V. Bowditch, Mr. James N. Clark, Miss Isabel F. Hyams, Mr. P. J. McCormack, Dr. James J. Minto, Mr. George S. Mumford, Dr. Edward O. Otis, Miss Lillian V. Robinson, Dr. Arthur K. Stone, Mrs. Frederick M. Stone, Dr. William C. Woodward and Mr. Arthur V. Woodworth.

**Lowell and Cutter Lectures.**—Dr. Thomas M. Legge, chief medical inspector of factories in Great Britain, is giving the Lowell-Cutter lectures in preventive medicine this year. The lectures are given under the auspices of the School of Public Health of Harvard University, the Massachusetts Institute of Technology and the Division of Industrial Hygiene.

**Lowell Lectures** (Huntington Hall, 491 Boylston Street, 8 p. m.)—November 24, Industrial Diseases under the Medieval Trade Guilds; November 26, The Spirit of Work under the Medieval Trade Guild; December 1, Modern Industry and Art; December 4, The Edward Medal and Gassing Accidents; December 8, Industrial Poisons and their Prevention; Dec. 11, Ambras.

**Cutter Lectures on Preventive Medicine and Hygiene** (Harvard Medical School, Amphitheater Building E, 240 Longwood Avenue, 5 p. m.)—December 8, Twenty Years' Experience of the Notification of Industrial Diseases under the Workmen's Compensation Act; December 9, Industrial Diseases under the Workmen's Compensation Act; December 10, Medical Supervision in Factories.

#### MINNESOTA

**Veneral Disease Clinics in Minnesota.**—At the present time six distinct clinics are being carried on and financed in large part by the Minnesota State Board of Health. These clinics are: one for men and one for women in St. Paul, at the St. Paul Dispensary; this is backed jointly by the United Charities, the Wilder Charities and the state department. A clinic for men in cooperation with the University of Minnesota. A clinic for women operated by the state department and the city board of health at the City Hospital, Minneapolis. In Duluth, in rooms and with nurses furnished by the St. Mary's Hospital, a clinic for men and one for women is operated by the state department and the city board of health.

#### MISSOURI

**Reunion of Base Hospital Personnel.**—A reunion banquet of the officers and enlisted personnel of Base Hospital Unit No. 28 was held in Kansas City, November 6. Dr. John F. Binnie, Kansas City, presided as toastmaster.

**Maternity Home Closed.**—The maternity home conducted by Dr. A. L. Gray at St. Joseph has been closed. The St. Joseph Hospital will establish a maternity ward and Dr. Gray has been invited to take charge of that division of the hospital work.

**Municipal Venereal Disease Clinics.**—Dr. R. L. Russell, Hannansville, director of the venereal disease division of the state board of health, has established three municipal disease clinics in which 3,184 patients had been treated up to the middle of November.

**Personal.**—Dr. Harry M. Moore, St. Louis, has been appointed surgeon in charge of the Frisco Railway Hospital, Springfield.—Dr. Joseph McNearney, Florissant, physician to the state penitentiary, Jefferson City, has resigned and Dr. William A. Clark, Jefferson City, has been appointed to fill the position temporarily.

**Hospital Items.**—Edina has announced a campaign for funds to establish a hospital for that city and Knox County.

The Johnson Sanitarium, Springfield, which was recently purchased by the Springfield Hospital, has been renamed the Ozark Sanitarium and will be conducted as a mental and nervous disease department of the hospital. Dr. W. R. Summers, Springfield, will be in charge of the sanatorium.

A clinic was conducted by the welfare board staff at Noyes Hospital, St. Joseph, November 28.

#### NEW YORK

**Diphtheria Increased.**—During October, 575 more cases of diphtheria were reported in the state, exclusive of New York City, than were reported for September, and 945 more than for October, 1918. One third of the new cases were reported from Buffalo.

**Personal.**—Dr. Eugene N. Nesbitt, Brockport, has been appointed tuberculosis specialist for Grand Rapids, Mich.—Dr. Edward H. Coddling, health officer of New Rochelle, has been appointed chairman of the health center committee.—

Dr. Hermann M. Biggs, state commissioner of health, has been elected a life member of the New York State Organization of Public Health Nursing.

**Central District Physicians Meet.**—The annual meeting of the Medical Association of Central New York was held in Syracuse, October 30. Rochester was selected as the next place of meeting and the following officers were elected: president, Dr. Owen E. Jones, Rochester; vice presidents, Drs. Nelson G. Russell, Buffalo, and Howard L. Davenport, A. burn; secretary, Dr. Robert Burns, Syracuse, and treasurer, Dr. Thomas F. Laurie, Syracuse.

**Laboratory Directors Organize.**—At the meeting of directors of public health laboratories of New York state, held in Albany, November 12, it was voted to form a permanent organization to be known as the New York State Directors of Public Health Laboratories. Dr. Warren B. Stone, Schenectady, was elected president; Dr. Joseph S. Lawrence, Albany, vice president, and Miss M. B. Kirkbride, state laboratories, Albany, secretary-treasurer.

**New York City**

**Harvey Society Lecture.**—The fourth lecture of the Harvey Society by Dr. E. C. Kendall of the Mayo Clinic, Rochester, Minn., on "The Chemistry of the Thyroid Secretion," will be delivered at the New York Academy of Medicine at 8:30 p. m., December 13.

**"Live Longer Week."**—Health Commissioner Royal S. Copeland announces that the department of health has set apart the week beginning January 2 as "Live Longer Week." Elaborate plans are being made for a health campaign that will reach every inhabitant in the greater city.

**Personal.**—Dr. Harold W. Lyall, formerly with the New York City Research and Antitoxin Laboratory, Otisville, has been appointed bacteriologist in the division of laboratories and research, New York State Department of Health at Albany.—Dr. Jacob Sobel has been appointed professor of hygiene in the Fordham University Medical School.

**Medical Society of the County of New York Elects.**—At its annual meeting, held November 24, the Medical Society of the County of New York elected the following officers for the ensuing year: president, Dr. Charles H. Chetwood; vice presidents, Drs. George Gray Ward and Orrin S. Wightman; secretary, Dr. Daniel S. Dougherty; assistant secretary, Dr. J. Milton Mabbott; treasurer, Dr. James Pedersen.

**Two Anthrax Victims.**—During the second and third weeks of November, Bellevue Hospital has had two cases of anthrax. The first patient, a man from the Bronx, died, while the second, a girl employed in a shaving brush factory, who was taken to the hospital, November 1, was discharged cured, November 21. This makes twelve cases of anthrax treated at Bellevue Hospital during the past four years, six of whom have been treated by the use of the Eichhorn serum and have recovered.

**Birth Control Act Constitutional.**—The supreme court, November 17, dismissed without an opinion, for lack of jurisdiction, the appeal of Margaret Sanger, on the constitutionality of the New York State Birth Control Act. Mrs. Sanger was sentenced to thirty days' imprisonment for conducting a birth control clinic in Brooklyn. She appealed from this sentence to the appellate division of the supreme court, claiming that the law prohibiting the dissemination of birth control information was unconstitutional.

**Association of Cardiac Clinics.**—The first postwar meeting of the thirteen clinics which make up the Association of Cardiac Clinics was held at the New York Academy of Medicine, December 2. Dr. Joseph C. Roper gave his experiences with special charts for cardiac clinics; Dr. Heribert S. Carter presented his ideas on districting of the city for cardiac patients; Drs. Charles Hendee Smith and Frederic L. Brush, White Plains, spoke on the relations between cardiac clinics and convalescent homes, and Dr. William P. St. Lawrence discussed the relations between the cardiac clinics and the public schools.

**Lectures on Psychology.**—Several courses of lectures on psychology as applied to medicine have been instituted at Columbia University by the Students Pre-Medical Association. The course consists of six lectures dealing with the various phases of psychology which are of use to the physician, and the ways in which he can apply them. The abstract principles of psychology will also be presented. The opening address will be delivered by Prof. A. T. Poffenberger. There will be other speakers, and lectures will also be delivered by Professors Woodward and Hollingsworth of the

department of psychology. Each lecture will be followed by a general discussion.

**Hospital Drives.**—The campaign to raise \$1,000,000 for the United Hospital Fund, which began, November 23, and continued for ten days, at the end of the first six days had only three-fourths of the needed million in sight. Many of the forty-six hospitals belonging to the fund will be compelled to make individual campaigns to enable them to meet their annual deficits. One of the features of the campaign was a parade of the ambulances belonging to each of the forty-six hospitals from Harlem to the Battery.—The drive to raise \$100,000 for the Bronx Hospital, which was to have been held during the week of November 23 was postponed until the following week. The medical board of the Bronx Hospital at a recent meeting adopted resolutions which will make the institution an open hospital, so that physicians may enter private patients there and treat them without interference. According to statements made at the meeting, there are only three hospitals in this city where this can be done.

**PENNSYLVANIA**

**Hospital Memorial at Chester.**—Prominent citizens of Chester and vicinity were present at Chester Hospital, October 23, to witness the acceptance of a new building, which was constructed as a memorial to the late Mrs. Margaret A. Houston, the gift being made by her sons.

**Twenty-Fifth Anniversary Meeting.**—A buffet luncheon of the Harrisburg Academy of Medicine was held, November 20, to celebrate the twenty-fifth anniversary of the society. The principal address of the meeting was made by Dr. Lewellyn F. Barker, Baltimore, on "Group Study by Internists."

**Service Men Honored.**—Members of the Cambria County Medical Society who served in the world war were honored by their fellow members at a banquet, held November 13, at Johnstown. The society sent forty-six of its men to the various services and all returned safely. Dr. H. F. Tomb, Johnstown, acted as toastmaster.

**Priestley Home Bought.**—Graduate chemists of the Pennsylvania State College have purchased the original home and laboratory of Dr. Joseph Priestley, the discoverer of oxygen. The house is located on the banks of the Susquehanna River, at North Umberland, and it is planned to move it to the campus at State College and make it a memorial to the great scientist.

**Personal.**—Dr. D. F. Unger, Mercersburg, the oldest member of the Franklin County Medical Society, was the guest of honor at the November meeting of the organization.—Dr. George A. Deitrick, Sunbury, has been appointed local surgeon of the Philadelphia and Reading System, succeeding Dr. William L. Shindler, deceased.—Dr. Charles Roland resigned as health officer of Reading, October 29.—Dr. Harry E. Clark, Pittsburg, has been appointed superintendent and medical director of the City Poor Farm, Mayview.—Dr. J. Bruce McCreary, Shippensburg, has been appointed supervising medical director in charge of health supervisory work in a district composed of Perry, Franklin, Adams and Cumberland counties.—Col. T. Lyle Hazlett, Pittsburg, who was a surgeon of the Keystone Division in France, has been appointed medical director at the Mont Alto Sanatorium, succeeding Dr. F. C. Johnson, who has been granted a leave of absence.

**Philadelphia**

**Industrial Physicians and Nurses Organize.**—The Philadelphia Association of Medicine for physicians and nurses in industrial work was organized at the City Club, November 28. Dr. C. Taylor, physician for the Bell Telephone Company, was elected president; Dr. L. E. Hastings of the J. G. Brill Company, vice president; Dr. J. Gay of the New York Shipbuilding Company, secretary, and Dr. F. Cummings of the Curtis Publishing Company, treasurer. There are twenty-six charter members. The organization is to include the entire Philadelphia industrial district.

**Personal.**—Dr. Charles Lincoln Furlush, a former surgeon in the U. S. Army, and at one time director of the charities and hospitals in Havana, Cuba, has been named director of public health and charities by the mayor elect, J. Hampton Moore, as successor to Dr. Wilmer Krusen. Dr. Furlush was decorated as Companion of the Order of St. Michael and St. George by the Prince of Wales during his visit to Philadelphia, November 22.—Drs. J. M. Sterling, Norman S. Rothschild and John D. Donnelly have been appointed to positions in the Henry Phipps Institute by Dr. Edward Martin, state health commissioner.

## CANADA

**Epidemic Encephalitis.**—The death of a dentist from encephalitis le'argica has been reported from Calgary, Alta. Several deaths have been reported from Winnipeg, and one case has been diagnosed in Toronto.

**Hospital News.**—Orpington Military Hospital in England, an institution founded by the Ontario government, has recently been sold for \$400,000. It will be used as a central depot for crippled and permanently wounded men of the imperial army.—The Toronto General Hospital has been ordered closed to visitors on account of the smallpox epidemic in that city. The cases now number more than 700.

**Public Health News.**—The new farmer-labor government of Ontario has placed the health department under the minister of labor, who is now recognized as the minister of labor and public health. By this arrangement, Dr. J. W. S. McCullough, Toronto, chief officer of health for Ontario, will be required to serve under two ministers of the crown, as he occupies the office of deputy-registrar general under the department of the attorney-general of the province.

**Personal.**—Sir Thomas G. Roddick, Montreal, will spend the winter in Florida.—Dr. J. W. Brien, Essex, Ont., member of parliament, has been appointed medical officer to conduct a colony of Chinese to their own land, after overseas service.—Dr. James Third, Kingston, Ont., professor of practice of medicine in Queen's Medical College, has resigned.—Dr. C. W. Service, who has been in China for thirteen years, is spending a furlough in Toronto.—Dr. G. B. Archer, Toronto, who has been in France since 1916, is returning to his old work at Ranaghat, Bengal, sailing from Victoria, December 16.—Dr. Davidson D. Black, Toronto, has been appointed to the anatomical department of the Medical University, Peking, and has arrived in China.—Dr. H. P. Rogers, after four years' service in Mesopotamia and Syria, has returned to Toronto.

**Baby Saving Week for Halifax.** Halifax, N. S., had a "Baby Saving Week" from November 4 to 13, inclusive, under the auspices of all the welfare organizations of the city. There were three sessions daily, the first mainly for schoolchildren, at which they witnessed moving pictures and then had the exhibits explained to them. The afternoon and evening sessions were devoted to discussions on various health activities for babies. Among the principal topics discussed were "Nova Scotia's Baby Problems, Past and Present," "Better Babies for Nova Scotia," "Why Halifax Needs Plans for Babies," and "The Value of a Baby Life." At subsequent sessions the protection of babies from disease and the care of babies were discussed. The loaned exhibits occupied six booths, containing a mental and social hygiene exhibit lent by the public welfare bureau of Montreal, and there were also eight booths carrying graphic exhibits, and three booths used in measuring, weighing and judging the development of babies for six months, under the care of the Vancouver Order of Nurses.

## GENERAL

**Academy Election.**—At the annual meeting of the International Academy of Medicine, whose membership is composed of physicians of the twin ports of Superior, Wis., and Duluth, Minn., held in Superior, November 19, Dr. Richard C. Smith, Superior, Wis., was elected president; Dr. Carl A. Scherer, Superior, Minn., vice president; Dr. Herbert J. Orchard, Superior, Wis., secretary and Dr. Alex. J. Braden, Duluth, Minn., treasurer.

**Bequests and Donations.** The following bequests and donations have recently been announced:

Dr. J. G. G. Y. G. G. Hospital, \$1,000; Jewish Orphan School, \$1,000; St. Joseph's Hospital, \$1,000, by the will of Carrie D. Eiten.

Dr. H. A. D. D. L. L. Ky., \$2,000, by the will of his father, Dr. H. A. D. D. L. L. Ky., 1918.

Dr. H. A. D. D. L. L. Ky., \$2,000, by the will of his father, Dr. H. A. D. D. L. L. Ky., 1918.

Dr. H. A. D. D. L. L. Ky., \$2,000, by the will of his father, Dr. H. A. D. D. L. L. Ky., 1918.

**New Medical Society.**—A new medical society has been organized at Sharon, Conn., known as the Harlan-Dally Medical Association, whose membership includes physicians from East Dutchess County, N. Y., and West Litchfield County, Conn. The following officers were elected: president, Dr. L. E. Rockwell, Amenia, N. Y.; vice president, Dr. A. F. H. H. H. H. N. Y.; secretary, Dr. C. W. Bassett,

Sharon, Conn., and treasurer, Dr. A. I. Tuttle, Salisbury, Conn.

**National Committee for the Prevention of Blindness Meets.**

The National Committee for the Prevention of Blindness held a meeting in New York, November 21. Edward M. VanCleve, managing director, outlined the accomplishments of the society. Starting in 1915 with sixty-five charter members, it has now enrolled nearly 2,300 members in forty-seven states, in Cuba, the Philippines, Porto Rico, Mexico, China and Canada. It has pushed laws for the prevention of blindness and had them passed in eighteen states. Among those who addressed the meeting was Dr. Thomas D. Wood, New York, chairman on health problems in education of the National Council of Education. He stated that from 25 to 35 per cent. of the schoolchildren in this country have eye defects. At least 75 per cent. have something the matter with their health which lowers their efficiency. All but a small proportion of these eye defects can be remedied, but unfortunately so far only a few of the five or seven millions of children so handicapped have had the attention they need. The speaker advocated the periodical examination of the eyes of schoolchildren.

**Food and Nutrition.**—The National Research Council has formed a special committee on food and nutrition problems, composed of a group of physiologic chemists and nutrition experts. This committee will devote its attention and activities to the solution of important problems connected with the nutritional values and most effective grouping and preparation of foods, both for human and animal use. Special attention will be given to national food conditions and to comprehensive problems involving the coordinated services of numerous investigators and laboratories. The committee, with the support of the council, is arranging to obtain funds for the support of its researches, and will get under way, just as soon as possible, certain specific investigations already formulated by individual committee members and subcommittees. These include studies of the comparative food values of meat and milk and of the conditions of production of these foods in the United States, together with the whole problem of animal nutrition; the food conditions in hospitals, asylums and similar institutions; the nutritional standards of infancy and adolescence; the formation of a national institute of nutrition, and other problems of similarly large and nationally important character.

**Deaths Following Toxin-Antitoxin.**—On recommendation of the city board of health of Dallas that toxin-antitoxin be given as an immunizing agent against diphtheria, several hundred doses were administered by private and municipal physicians. Forty severe reactions followed the administration of a particular series issued by one manufacturer. The children who received this series manifested a severe reaction characterized by high fever, vomiting and pain at the site of injection, which occurred a few hours after administration. Within forty-eight hours the skin over the site of injection became intensely inflamed; the area extending over the forearm, shoulder and hand, and in some cases across the chest. Large vesicles filled with clear fluid appeared. General reaction subsided within four to six days and the local reaction within eight to ten days. Five deaths occurred in this series from twelve to sixteen days following the administration of the toxin-antitoxin, death being ascribed to acute myocarditis. The local reaction had disappeared a few days previous to death. No postmortem examinations were made, but the symptoms and physical signs which occurred were due to excessive amounts of toxin. All other series of toxin-antitoxin issued by this manufacturer and all ordinary antitoxin used were found to be harmless and not followed by reaction.

**Smallpox Quarantine Established at Canadian Border.**—More than 4,000 cases of smallpox have recently occurred in the province of Ontario, and four cases have been found in Buffalo, according to New York State Department of Health officials, who have investigated conditions at the border under instructions from Dr. Hermann M. Biggs, state commissioner of health. In response to a telegram from Surgeon-General Blue of the U. S. Public Health Service to Commissioner Biggs, requesting advice as to the necessity for establishing a quarantine at the border, the commissioner replied that conditions warrant such action. A quarantine is to be established immediately at all bridges and ferries leading into the United States from the infected territory and all persons who cannot give proof of recent vaccination or of having had the disease will be turned back. Health officials of border cities have been notified in regard to the conditions to be imposed, and railroad ticket offices in the Canadian

district where the disease exists have been requested not to issue tickets to points in the United States except on the presentation of a certificate of vaccination from U. S. Public Health Service representatives. About seven eighths of the 40,000 schoolchildren of Toronto have been vaccinated and the remainder will not be permitted to attend school until they have complied with this requirement. All travelers into New York and Michigan must show certificates that they have been vaccinated within one month. At Black Rock, November 26, forty-seven persons were held on one train until they could be vaccinated.

**Hookworm a Blight in the Draft Army.**—Part I of the annual report of the Rockefeller Foundation, made public, November 26, summarizes the results of investigations on hookworm in the Southern states. The report points out that the examinations for hookworm disease made among United States soldiers confirm in a striking way the board's experience of the last few years. "Judged by the Binet-Simon and other tests, many full-grown soldiers who harbored comparatively few hookworms had the mentality of persons only 12 years of age. The mentality of 10,000 men at Camp Travis who harbored these parasites was about 33 per cent. below normal." Mental tests of a similar nature among 340 schoolchildren in Queensland, Australia, showed that there was an average retardation of approximately two years among heavily infected children. The longer the infection persisted the greater was the retardation. Statistics are cited showing that the efficiency of laborers in various localities in Costa Rica, India and other localities has been increased 50 per cent. after hookworm treatment was put into operation. Encouraging reports of campaigns against hookworm are related, and the report reiterates the great service they have done to communities by demonstrating to the public its responsibility for general health, and stimulating it to a willingness to finance and carry on public health work of its own. A part of the report is devoted to the work that the Yellow Fever Commission of the Rockefeller Foundation has done during the past year and speaks encouragingly of the prospect of demonstrating that the true etiologic agent of yellow fever has been discovered by Dr. Hideyo Noguchi, which he has designated as *Leptospira icteroides*. The report tells of the demonstration, through the fight on yellow fever conducted by the board in Guatemala, that this scourge could be controlled with the personnel and facilities available in Central American countries and at a cost well within their financial ability. The report concludes with an account of the progress made in public health training through the establishment of a department of hygiene in the Faculdade de Medicina e Cirurgia at São Paulo, Brazil.

## FOREIGN

**Influenza in Spain.**—More than 2,000 cases of influenza have been reported at Lenares, about 50 miles northeast of Granada, Spain.

**Hospital Ship Disabled.**—A torpedo boat has towed the British hospital ship *King Edward* into Christiansand, Norway. The *King Edward*, which was sailing from Murmansk to London, was caught in a storm and disabled.

**Motor Cars Needed.**—The great scarcity of motor cars in England is reported to be a severe handicap to physicians. The British Medical Association has made an appeal to manufacturers to give priority to those who require automobiles for use in their practice.

**Physicians Elected to Italian Senate.**—Five professors in the Italian medical faculties were elected to the senate at the recent elections. The list includes Drs. Queirolo, Bianchi, Pascale, Rampoldi and Rattone, representing Pisa, Naples, Pavia and Parma. The president of the Italian Red Cross, a lawyer, was also elected to the senate.

**Cinema in Obstetric Teaching.**—November 6, Dr. G. Drummond Robinson, obstetric physician to the Westminster Hospital, demonstrated to the Royal Society of Medicine a cinematograph film illustrating the processes of normal labor, which is intended to improve the teaching of midwifery to medical students and midwives. The film comprised some 25,000 photographs from life and diagrams.

**Bubonic Plague in Constantinople.** Major Davis G. Arnold, director of the Near East Relief, addressed newspaper men of Constantinople—Greeks, Armenians, Jews, and French Levantines—at a meeting in Constantinople, asking them to aid the Near East Relief in its fight against the bubonic plague. More than \$40,000 worth of soap, linen and medicines are being distributed by the committee in Constantinople every month.

**Deaths in the Profession Abroad.**—Dr. E. Bonardi, chief of the large public hospital at Milan, professor of social medicine at the graduate school there, and author of works on various fields of medicine and geology.—Dr. H. Aronson, a Berlin bacteriologist who introduced certain serums and culture methods, aged 54.—Dr. L. Brieger, professor of internal medicine and hydrotherapy at the University of Berlin, aged 70.—Dr. J. A. Amann, a gynecologist of Munich, aged 53.

**Cambridge Institute of Parasitology.**—Mr. and Mrs. P. A. Molteno have announced their intention to provide funds for the erection and maintenance of an institute for parasitologic research in the University of Cambridge. They have offered a sum of £20,000 to provide a suitable building, with its fittings, for this work, and a further sum of £10,000 to form a fund to provide an income for the upkeep and maintenance of the institution, any surplus being used to further research carried on in the institute at the discretion of the director.

**The Plague of Venereal Diseases.**—The *Nederlandsch Tijdschrift* quotes the *Medicinsche Kliniek* of Berlin to the effect that the spread of venereal diseases there since the war has surpassed even the extreme prognostications. Enlightenment, warnings and penalties are proving futile to check the plague, although there have been provided ample opportunities for treatment under specialists (*Salvarsan-uitzate* they have been called). The only way to stem the flood is to keep the contagious in the hospitals. But the hospitals are crowded, and the medical journal suggests the advisability of putting up a large number of barracks at once for the purpose of housing the contagious cases of venereal disease. The great difficulty with this is said to be the lack of lumber for building the barracks.

**Typhus in Europe.**—A cable despatch states that typhus is sweeping Russia, an alarming increase of cases having set in during October. The *Public Health Reports* of Oct. 17, 1919, list 2,835 cases at Archangel and Riga during May and June. The same issue states that 3,125 cases of typhus were recorded at Cairo, January 1 to July 1. Typhus has been also present in fourteen provinces in Italy, and in the first week in June 3,470 cases were reported, but 3,321 of these were in Austrian prisoners. In the second week in July fourteen cases were recorded, and in the first week in August only six cases. The *Medicina Contemporanea* relates that a few small epidemic foci have developed at various points in Portugal and Spain, and as the first cases were mistaken for typhoid—even antityphoid vaccine being given at some points—the disease got good headway before it was recognized.

**Heat for Physicians in Berlin.**—The coal controller at Berlin is said to have relented from his former denial of special coal privileges to physicians, and the *Nederlandsch Tijdschrift* states that now elevators in doctors' residences can be run during office hours, and elevators can be run also for the sick who present a medical certificate to the effect that they are unable to climb stairs. The central water heating plant may also be operated when more than one physician is in the residence. Gas stoves can also be used by physicians who have a card from the medical chamber, and gas water heaters can be used by the sick who have a medical certificate to the effect that they need baths. It is further stated that efforts will be made to supply physicians with fuel alcohol (*Braundspiritus*) for sterilizing instruments and for illuminating purposes during the hours the gas is turned off. Fuel alcohol is said to give an illuminating flame when mixed with some substance with much carbon content, such as xylol.

**Spanish Physicians Win Strike.**—As already mentioned in THE JOURNAL, the municipal physicians of Jerez, Spain, decided some time ago to discontinue discharging their official duties, in view of the fact that the municipality owed them 135,000 *pesetas* (about \$27,000) and the refusal of the authorities to give satisfaction about the matter. The situation became so serious that the national government had to interfere finally, and dismiss the offending municipal council. A new council was appointed, one of the first steps of which was to pay on account 75,000 *pesetas* (about \$15,000) to the physicians, promising to pay the balance in a very short time. The attitude of the Jerez physicians had met with the general approval and support of the physicians from other parts of Spain. The Association of Physicians of Catalonia offered to the Jerez physicians the sum of 50,000 *pesetas* (about \$10,000), but this was declined with thank. This is probably the first time that physicians have in a body actually gone on a strike in defence of their rights.

**Polish Typhus Relief Expedition.**—The thirty-second train of supplies and equipment for the typhus campaign arrived in Warsaw October 23, and six additional medical officers and four commissioned officers of the line have arrived, but the need for medical officers is still urgent. Up to October 27, thirty-one commissioned officers and 420 enlisted men had arrived in Poland for duty with the expedition. The field columns are doing extensive work at Wlodawa, where much opposition was at first encountered, but conditions have now so changed that it requires military assistance to keep the people away from the bathing and delousing plants. Col. Harry H. Harvey, M. C., U. S. Army, Columbus, Ohio, director of field operations, reported that at Lemberg 50,000 people were waiting to be bathed and deloused. A detachment of the expedition has proceeded to Galizia to guard a trainload of gasoline to be shipped from that field. Col. Harry L. Gilchrist, M. C., U. S. Army, in command of the expedition, announces that field columns will be bathing and delousing in the cities of Pzedlborz, Slemniki, Wlodawa and Lawow, and that supplies will be distributed throughout the district of Lublin, Kielce and Leczyn as soon as transportation facilities are provided.

**Congress of Northland Internists.**—The Ninth Nordiske Congress for Internal Medicine was held at Copenhagen in August. Professor Faber presiding, the first meeting for several years. The main theme for discussion was the importance of dieting in the management of insufficiency of the heart and kidneys, introduced by Rubow and Motzfeldt. One session was devoted to diabetes. Faber showed that the blood sugar has three peaks during the day corresponding to the principal meals, and insisted that for each person there is a constant constitutional level for the sugar in the blood, above which limit sugar passes into the urine. Lundsjoern suggested that with grave diabetes it might be sufficient to keep the morning urine free from sugar. Lundsjoern's explanation that cyanosis is the result of increase in the amount of unoxidized hemoglobin in the blood has been mentioned on recently editorially (page 1216). He declared that it is impossible for cyanosis to occur with a hemoglobin percentage of less than 25. Dedichen spoke on the influence of athletics and games on the heart and Kuensel on the importance of cytologic examination of exudates. Josefson stressed the value of "diagnosis by minute particles," obtained by puncture from parenchymatous organs, etc. Kyll's device to measure the pressure in the capillaries attracted much attention. He drops oil on the skin and examines it under the microscope. The next meeting is to be held at Helsingfors in 1921, with Siever to preside. Venereal syphilis is the main subject appointed for discussion.

**Massacres of Armenian Physicians.**—As already mentioned (October 29, p. 1768), the Armenian Medical Association has issued a pamphlet (in French) describing the history—how it affects the medical profession—of the organized massacre in the part of the Turkish government in 1915 to exterminate the Christian inhabitants of Armenia. The pamphlet emphasizes the "large number of Turkish physicians who took an active part in organizing the massacres and deportations." At the head of the special commission—"Commissariat general de deportation et des massacres"—were Dr. Y. Y. Y. Y., the professor of legal medicine and Dr. Y. Y. Y. Y., the Constantinian medical faculty. Both of these physicians have felt since the pressure of the Allies that they should attempt to justice those responsible for the Armenian atrocities. Two of the twenty Turkish physicians who were engaged in this work are graduates of the Constantinian medical school. One of them was Dr. Rehid, who as a result of the massacre committed suicide as he was about to be deported. The other one of the others are in prison in Constantinople. The pamphlet gives the names of the next seven Armenian physicians who were killed. There are in India, besides a large number of Armenian physicians, a French school at Beirut and several hospitals of the American medical school there. Among these was Dr. Mikael Garabedian, who is mentioned as a graduate of the University of Chicago. Three graduated from each in Geneva and Lausanne. Dr. N. Dagbanyan is associate of the University of Paris, deputy in the Ottoman parliament vice president of the Armenian national assembly, a holder of a number of works in Armenian and French on bacteriology, medicine, and the history of Armenia, was massacred near Orria. Another list of fifty-two oth-

eraries represents the victims of typhus, the Turkish physicians sending the Armenians to the more dangerous posts. Among them are two said to have American diplomas and medical degrees, Drs. K. Donzakhian, aged 65, and S. Tchilingourian, aged 33. The pamphlet adds that the Turkish and German physicians said openly that the only reason why any Armenian physicians were left unmolested was because they were needed in the Turkish military hospitals.

#### LATIN AMERICA

**Physician Appointed to the Cabinet in the Republic of Colombia.**—Dr. Luis Cuervo Márquez has recently been appointed by the president of the republic of Colombia as minister of the interior (*cartera de gobierno*). Our exchange, the *Repertorio*, hails the appointment as a merited distinction and promise of brilliant work for the country. The Club Medico of Bogotá celebrated the event with much ceremony.

**Ground Broken for New Hospital.**—November 15, ground was broken by Dr. Bolisario Porras, president of the Republic of Panama, for the new Santo Tomas Hospital which is to be located in the suburbs of the city of Panama. The new institution, which will be in charge of Major Edgar A. Boveck, M. C., U. S. Army, is being constructed on the administrative plan by a commission of five members nominated by the president of the republic to accomplish the construction work. Separate buildings for the care of tuberculosis, venereal and contagious diseases are included in the plans for the new institution.

**Honors to Dr. Decoud.**—A special meeting in honor of Dr. D. Decoud was held recently at Buenos Aires on Dr. Decoud's retirement from the chair of clinical surgery. Dellor del Valle spoke of his eminent work as a teacher, surgeon and author, and Dr. G. Bosch Arana presented him with a gold medal as a tribute from his colleagues in the San Roque Hospital, and especially from the surgeons of the institution. Dr. Decoud recently received a diploma and medal from the officials of the International Exposition at San Francisco in honor of the opening of the Panama Canal. The medal was awarded for his collected medical works.

**Deaths in the Profession.**—Dr. B. Caldora, a young physician of Buenos Aires, prominent in political affairs.—Dr. J. H. de Andrade e Silva at S. Paulo, Brazil, recently returned from work in the Paris hospitals during the war.—Dr. L. Rufino, physician to the Rawson and San Roque hospitals at Buenos Aires, aged 62.—Dr. L. J. Velarde, surgeon inspector general of the Argentine navy until his retirement with the grade of surgeon major and pay of a vice admiral (*contralmirante*), aged about 65.—Dr. A. J. Drago, a leading medicolegal expert at Buenos Aires and writer on psychopathology and criminology, aged 58.—Dr. E. D. Zapata of Bogotá.

**Brazil Presents Hospital to Paris.**—The Paris medical faculty recently voted to express its gratitude for the gift from Brazil of the hospital at Paris equipped and maintained by Brazil during the latter part of the war. The installation is high grade in every respect, and is said to have cost Brazil 2,500,000 francs. The French army medical service was empowered to retain the hospital for two years, but has abandoned its rights in this respect and will give up the hospital next summer to the civil authorities, so that when the university year opens in November, 1920, a new clinic will be at the disposal of the sick and for teaching purposes to the medical students. The Assistance publique will supply the personnel and maintain the hospital after that date.

**Triennial Medical Congress of the Republic of Colombia.**—A large and representative gathering of the profession was held at Tunja in August with great festivities, as the date coincided with the centennial celebration of independence day. The congress is memorable further in the history of the organization of the profession, as the Colombian Medical Association was officially founded. The committee of organization includes Drs. J. D. Herrera, C. Esguerra, M. Jimenez López, R. Franco F., R. Amaya Ariza and R. Sannarín, with six alternates, Drs. L. López de Mesa, J. I. Uribe, J. Bajarano, E. Piedrahíta, J. del C. Acosta, and M. A. Rueda V. Eighteen resolutions were adopted by the congress, some asking for legislation on means to repress the spread of tuberculosis, hookworm, venereal disease and malaria; one specified eight concrete ways in which alcoholism could be combated. Others asked for legislation to regulate the practice of medicine, to found a national Pharmacoepia "to do away with the present anarchy in the official preparations as dispensed in the pharmacies." Legislation to restrict the sale of "patent medicine," was also demanded, and the

organization of a national public health and public charities department of the government, and the teaching of ethics in the medical schools. One resolution asked for the appointment of commissions to study the fauna and flora of the country, and the foundation of traveling scholarships to enable young physicians to study laboratory and public health and sanitation methods in other countries.

## Government Services

### Personnel of the Medical Department

For the week ending November 28, there were in the Medical Corps 2,318 medical officers from a total of 30,591 on duty, Nov. 15, 1918. The Medical Reserve Corps contained 3,917, an increase of fifty-eight over the previous week.

### MEDICAL OFFICERS, U. S. NAVY, RELIEVED FROM ACTIVE DUTY

<b>CALIFORNIA</b>	<b>NORTH CAROLINA</b>
Berkeley—Cohn, M. L.	Winston-Salem—Conrad, H. B.
<b>CONNECTICUT</b>	<b>WASHINGTON</b>
Bridgeport—Smith, E. S.	Seattle—Richardson, W.
<b>NEW YORK</b>

## Foreign Correspondence

PARIS

Nov. 6, 1919.

### Congress of Urologists

Among the subjects discussed at the nineteenth Congrès français d'urologie, held in Paris, October 8-11, was treatment of nontuberculous pyelonephritis.

#### NONTUBERCULOUS PYLEONEPHRITIS

Dr. Paul Fritschsch, formerly chief of the clinic for diseases of the urinary tract at the Faculty of Medicine of Paris, presented an interesting report on this subject. He pointed out the various causes of pyelonephritis and the different lesions that characterize it, and then drew the conclusion that a uniform method of treatment was impossible, but that the method used would necessarily vary with the case. Thus, while we are virtually powerless to prevent the development of ascending ureteropyelonephritis, therapeutic means are available, up to a certain point, to prevent ascending ureteropyelonephritis by a rational treatment of disorders of the ureter, the prostate and the bladder. All who are suffering from urinary or general contagious diseases should avoid chilling or any cause capable of producing a renal congestion. By an appropriate diet intestinal fermentation should be decreased and constipation should be guarded against. Also undue use of diuretics, balsamics and other irritants should be avoided.

Once the diagnosis of pyelonephritis has been made, the treatment will vary according as the condition presented is acute or chronic pyelonephritis. In the former case medical treatment should always be instituted unless there are urgent reasons for surgical intervention. Absolute rest should be prescribed. In the lumbar region a cupping glass or mustard rubefacient should be applied to effect revulsion. The pain should be relieved by hot compresses. To bring about the evacuation of pus and microbes, diuretics and urinary antiseptics will be prescribed. In certain cases more active intervention will be required, and it may be necessary to reestablish diuresis by means of subcutaneous or intravenous injections of artificial serum. The glucose serums are especially indicated, either in isotonic or in hypertonic solution.

In the majority of cases the acute symptoms subside under the influence of medical treatment. But things may turn out differently, and in that case we should have recourse to local treatment. Distention of the bladder, as recommended by Pasteau, should be done, and if that does not relieve the cystoscopic catheterization of the ureter and lavage of the pelvis of the kidney with a weak, tepid antiseptic solution is indicated (boric acid or borax solution, potassium permanganate and especially silver nitrate). Immediately after this lavage several cubic centimeters of a 3, 4 or 5 per cent silver nitrate solution, of a 1, 2 or 3 per cent protargol solution or a 5 per cent collargol solution should be instilled into the renal pelvis. Lavage of the renal pelvis is contraindicated in patients suffering from acute urethritis or an untreated form of cystitis; also if the general condition of the patient is bad.

If in course of treatment, the patient does not improve; if the urine contains a calculus is found, while the other is frankly sterile, or if the urine turns milky should be done at once, unless the general health of the patient is precarious, in which case the operation is indicated, this operation to be followed by cystostomy, nephrotomy.

In cases of pyelonephritis we should endeavor to treat and remove if possible the causal lesion (cystitis, urethral infection, renal tumor, etc.). Vasculotherapy and serotherapy may be employed concurrently with the customary measures, but have proved their worth, but they must under no circumstances be allowed to supplant the latter.

Dr. Fritschsch, professor in the clinic for diseases of the urinary tract at the Faculty of Medicine of Bordeaux, expressed his opinion to the effect that in acute nephritis he preferred to have recourse to nephostomy rather than to cystostomy. Nephrotomy, he contends, has the advantage of relieving the affected kidney during the period that the position of the renal pelvis is unknown, and fulfills perfectly the requirements for treatment of all infected organs—adequate bleeding, antiseptic drainage and lavage. As for the treatment of ureteropyelonephritis, Posson thinks that the choice of method of treatment is, after all, a question that is determined largely by the location of the lesions. If these

occupy only the inferior segment of the ureter, lavage and ureteral catheterization are sufficient. If, however, the lesions extend the whole length of the ureter and invade the renal pelvis and the calyces, antiseptic ureteral lavage may suffice, provided there are no diverticula or tortuosities, in which case nephrectomy must be resorted to. The same thing is true if there is renal suppuration or if the abscesses are disseminated through the parenchyma.

Dr. Kidd of London stated that since 1911 he has been treating nontuberculous pyelonephritis by lavage of the renal pelvis, ordinarily. He injects into the pelvis 4 c.c. of a 5 per cent colloidal silver solution and repeats this injection only twice (three injections in all). In forty-five cases of old pyelonephritis with retention of from 5 to 40 c.c. he has given lavage 121 times without anesthesia, a complete cure resulting in thirty-six cases.

### Antisyphilitic Treatment of Rebellious Incontinence of Urine

Dr. André Boeckel of Strasbourg related the case of a soldier who had suffered for a year and a half from incontinence of the urine that had proved rebellious to all forms of treatment instituted in various urologic centers. Boeckel decided to take the Wassermann reaction, which proved to be positive. He accordingly prescribed antisyphilitic treatment, and at the end of eighteen days the patient was completely cured of his weakness. It was apparently an early manifestation of tabes.

### Death of Dr. Robert Wurtz

The death of Dr. Robert Wurtz (physician of the Hôpitaux de Paris and agrégé professor on the Faculty of Medicine of Paris) has been reported. He was known mainly as a hygienist. He had published works on hygiene as pertaining to our colonies, on exotic diseases, on industrial poisoning, etc. He occupied the office of director general of the Institut supérieur de vaccine à l'Académie de médecine. Robert Wurtz was the son of the famous chemist, Adolphe Wurtz.

### Visit of Spanish Physicians

A mission composed of forty Spanish physicians, organized and conducted by Dr. José de Bleizegui, director of the *España médica*, has arrived in Paris. The reeducation center at Saint-Maurice, the Pasteur Institute, the War Museum and various hospital services will be visited.

### Personal

At one of its recent meetings the Academy of Medicine elected three correspondents (in national matters) for the fourth section (therapeutics and natural history as pertaining to medicine). Those chosen were: Dr. Sigalas, professor of pharmaceutical physics on the Faculty of Medicine of Lille; Dr. Guibert, professor of parasitology, and natural history as pertaining to medicine, on the Faculty of Medicine of Lyons.

Dr. Michèleau, agrégé on the Faculty of Medicine of Bordeaux, has been appointed professor of legal medicine on the Faculty of Medicine of Algiers.

### The Use of Saccharin

With the purpose in view of guarding against the threatened sugar famine during the war, the government in 1917 passed a law authorizing the use of saccharin in the preparation of certain products of consumption, especially certain beverages (*THE JOURNAL*, May 12, 1917, p. 1422). It was expressly stipulated that this special privilege should end with the issuing of the proclamation declaring the cessation of hostilities, but, since the reasons for the granting of the privilege still persist at the present time, the government has recently introduced a bill providing for an extension of time.

### Hygienic Exhibit Organized by the Rockefeller Mission

A hygienic exhibit organized by the Rockefeller mission has been installed in one of the town halls (*mairies*) of Paris. It aims to educate the people by means of pictures. Banners with colored figures and inscriptions develop a series of hygienic maxims, for example: "Your child has only two eyes, they must serve him his whole life through"; "the health of your wife and your children depends on you; help them to keep it"; "the intelligent employer provides ventilation and healthful surroundings in his workshops," etc. The pictures serve to show how these results can be attained. A collection of postal cards for the children affords them a great deal of amusement. On one card is represented a child

sneezing, while another nearby calls out to him "Keep your microbes for yourself, old boy." On another card is seen a group of children scarcely out of their swaddling clothes starting off to war, brandishing banners on which are printed their peremptory hygienic demands.

#### The Next Congress of French Orthopedists

The Société française d'orthopédie has fixed the date of its next congress, Oct. 8, 1920, and has put the following questions on the order of the day: (1) modern treatment of scoliosis. Essayist, Dr. Estor, professor of clinical pediatrics and orthopedic surgery on the Faculty of Medicine of Montpellier; (2) traumatic retraction of tendons (Volkmann's disease). Essayist, Dr. Denucé, surgeon of the Hôpitaux de Bordeaux and agrégé professor on the Faculty of Medicine; and (3) anastomosis of tendons in traumatic paralysis. Essayist, Dr. Mauclair, surgeon of the Hôpitaux de Paris and agrégé professor on the Faculty of Medicine.

#### RIO DE JANEIRO

Oct. 20, 1919.

##### Federal Ministry of Public Health

President Pessoa recently communicated to the house his desire to create a federal ministry of public health. The bill presented to congress advises the taking over by the new ministry of all departments dealing with health matters, public sanitation, water supply and sewerage. In this way the secretaries of the interior and of public works will be relieved of excessive work.

##### Hospital for Mental Diseases

The secretary of the interior visited the asylum for mental and nervous diseases and found it overcrowded, there being 1,460 patients, although only 800 can be housed comfortably; he therefore resolved to found a colony for these unfortunates in one of the suburbs of Rio, and also to have an asylum built for criminal lunatics, both to have all modern improvements.

##### Influenza Number of the Archivos Brasileiros de Medicina

A special number of the *Archivos Brasileiros de Medicina* has been devoted to influenza. The articles of Prof. Juliano Moreira on psychical disturbances determined by influenza and on influenza in the lunatic asylum during last November and its influence on mental diseases are worthy of special notice. Dr. Moreira's opinion is that the mental disturbances he noted, most or them benign were due to the influenza virus or its toxin. Among other manifestations, the grip provoked meningitis, pseudomeningitis and encephalitis. No case of paralytic dementia resulting from influenza was observed, although latent cases manifested themselves following influenza. Sixty per cent. of influenza psychoses resulted in recovery. Out of 1,470 patients of the asylum, 1,314 were stricken with the disease during the second half of October, and ninety-two, or 6.3 per cent., succumbed. During the same period, 160 new patients suffering with mental diseases due to the pandemic were interned, and in the first days of November, 114. Dr. Moreira did not observe any instance of remission in cases of paralytic dementia; on the contrary, he observed the exacerbation of the symptoms of patients suffering with diffuse latent meningo-encephalitis. Besides other interesting articles, Dr. Waldemar de Almeida publishes a complete bibliography of Brazilian publications on influenza. (See also page 1479.)

##### The New Director of Public Health

Dr. Carlos Chagas of the Instituto Oswaldo Cruz has superseded Dr. Theophilo Torres as director of public health. Dr. Torres did valiant service during the epidemic of influenza in 1918, and appointed commissions to visit the different states to extinguish foci of yellow fever. Dr. Chagas will continue as director of the Oswaldo Cruz Institute.

##### Memoirs of the Instituto de Butantan

The S. Paulo Instituto de Butantan for medical research has initiated the publication of a new scientific journal. The first number contains articles on atriolaria of Rio de Janeiro and its neighborhood, by F. C. Hoehne and J. G. Kuhlmann; a histologic study of the gland of Brazilian snake heads, by Dorival C. Pentado; antiscorpionic serum, by Dr. Vital Brasil, and a contribution to the knowledge of Brazilian snakes, by Dr. J. Florencio Gomes.

The second number treats of Bancroft filariasis; the classification of *Hemosporida*; a contribution to the parasitic mycology of Brazil, and a contribution to the treatment of the atonic and phagedenic ulcers. Dr. Afranio do Amaral, the author of the first paper, calls attention to the histologic characters of filariasis, which may serve as a basis for the diagnosis: inconsistency of globular alterations; reduction of the polymorphonuclear neutrophil leukocytes; with increase of the microlymphocytes during the night, and constant increases of the eosinophils, more accentuated during the apyretic periods; absence of globular alterations; absolute increase of the leukocytes; increase of the polymorphonuclear neutrophil leukocytes with reduction of the microlymphocytes, and diminution or absence of the eosinophils, which return before the paroxysm has passed. In the second paper, Henrique Aragão, using as a basis not only morphologic characters of the different hematozoa but particularly the knowledge which is possessed respecting their evolutionary cycle, proposes a new systematic grouping for the suborder of *Hemostozoa*, dividing it into the four superfamilies: *Haemogregarinoidea*, *Achromaticoidae*, new superfl., *Plasmodioidae*, new superfl., and *Toxoplasmoidea*, new superfl.

The first one is divided into families, *Hemogregarinidae*, with the genera *Haemogregarina*, *Lahl sterella*, *Karyolysas* and *Hepatozoon*. The second one includes two families, *Achromaticidae*, with the genera *Achromaticus*, *Smithia*, *Ellipsisoma*, *Rosicella* and *Rungiella*, and *Thileridae*, n. n., with the genus *Thileria*. The third one is subdivided into two families, *Haemoprotozoidae* with the genus *Haemoprotozoides*, and *Plasmodiidae*, with the genera *Plasmodium* and *Hemocystidium* and the subgenus *Laverania*. The fourth includes one family only, *Toxoplasmiidae*, and the only genus, *Toxoplasma*.

In the third article, Prof. Pirajá da Silva relates two interesting cases of Madura foot observed in Bahia. In the first case he isolated *Discomyces*, which he considers a new species and calls *bahiensis*; in the second one he isolated *Madurella romiroi*, n. sp.

In the fourth paper, Dr. Afranio do Amaral describes the treatment of atonic ulcers and phagedenic ulcers by means of local applications of normal dried serum, without the concomitant use of any antiseptic substance. On the first application of the serum, the ulcers begin to change in appearance, becoming clean and regular, and the tissues recover their activity. The sore heals rapidly and completely. In cases of phagedenic ulcers, a complete destruction of the fusospirochete association is observed.

##### Consanguineous Marriages

There is a bill pending in congress to repeal an article of the civil law code prohibiting consanguineous marriages which have not received the approval of the profession.

#### LONDON

Nov. 13, 1919.

##### Death of the Middle Classes

Under this title the *Times* emphasizes what is perhaps the most important result of the declining birth rate. The most recent report on this subject, that of the health officer for Chester, states that in 1918 there were 132 fewer births in Cheshire than in 1917. The rate for the county is now 15.9 per thousand of estimated population. That for England and Wales is 17.7, and for London, 16.1. Comparing these figures with the birth rate for the decennium 1901-1910 shows that the latter was 27.2. Going further back, the subjoined table may be constructed.

BIRTH RATE PER THOUSAND LIVING AT ALL AGES												
1851	1860	1861	1870	1871	1880	1881	1890	1891	1900	1901	1910	1918
34.1		35.2		35.4		32.4		29.9		27.2		17.7

In the same period (1851-1910) it is true that the death rate fell by 30 per cent. A large proportion of the fall is to be ascribed to the reduction of the infant death rate and to measures of public hygiene. The result has been that the falling birth rate has been to some extent compensated for by the falling death rate among the working and industrial classes, in which the annual gain and loss were very high thirty years ago. But that is not true of the middle classes. Their birth rate is falling rapidly; their death rate, never very high, is not falling. Thus the middle classes are suffering in the matter of population. We are witnessing what can be described without exaggeration as the death of the middle classes. Especially during the past three years, the middle class births have been rapidly diminishing. The

family of four or five has become the family of two or three and is in process of becoming the family of one. A great number of young couples now openly declare that they do not intend to have more than one child, and many decide to have no children at all. Every physician is able to corroborate these facts, and many physicians are consulted on the question of birth prevention. With the present cost of living, taxation, and the price of houses, a "family," as that term used to be understood, is impossible. It means no ascertainment but privation. It is therefore felt to be better to bring up one healthy child and afford it a reasonable education than to attempt to bring up three children on insufficient food and without being able to afford them a training for their life's work. But the mischief does not stop there. The marriage rate has also fallen. In 1917 it was 138 per cent. of the population at all ages. This rate was the lowest to that time recorded, being 11 below that of 1916 and 24 below the average rate of the quinquennium 1911-1915. Early in the war (which, as explained in previous letters, was at first an incentive to marriage), 1915, a maximum was reached at 194 per thousand. Marriages, and especially middle class marriages, are being postponed at present on account of housing and food difficulties, and there can be no doubt that many men are avoiding marriage altogether because of the severe financial strain which it imposes. The world is in a gay mood, and the attractions of domestic life are a salary barely enough for two are not conspicuous. As a bachelor a man may indulge in his tastes, preserve his freedom of action, and can afford to amuse himself with his friends. He shrinks from the alternative of stern, hard work, frugal living, a minimum of pleasure as that word is understood in our cities, and a maximum of anxiety. Moreover, the age question has to be considered. The proportion of bachelors marrying during 1911-1914 was about 39 per cent. In 1880-1890 it was 50 per cent. It was 37.6 in 1917. The proportion of bachelors marrying at ages over 35 has also increased markedly during 1916 and 1917. Of spinsters marrying during the later eighties, about 63 per cent. were under 25 years of age; of those marrying during the last five years, only 55 per cent. were under 25. The war, of course, has proved a disturbing factor in all statistics; but it is not to be doubted that among the middle classes, marriages are becoming not only fewer in number but also later in respect of the age of the contracting parties.

#### The Lancet on Its Defense

A correspondent has asked the *Lancet* whether all the present talk consists of bacteriologists. Our contemporary says that the answer is in the negative; but the implied criticism of the reports of recent issues is justifiable, and deserves a satisfactory rejoinder as it can supply. For many years there has been a progressive increase in the space allotted to bacteriology in its wider sense. The volumes from 1880 to 1900, for example, with the balance was then held, as well as the space between the various systems of the body, disease and its treatment, almost exclusively from the clinical standpoint. However, the balance has shifted, it is due to the alteration in the attitude of what has to be said in a medical journal. The clinical and therapeutic aspect must always remain the primary and important. Readers whose interests are primarily centered round the personal element in medicine, and who are busy with the minute enemies of human existence, are attracted to a new method—crisp and practical, and free from the voluminous and often unimportant, but apparently necessary, details which are a part of the daily medical practice. This is not done to endeavor to do justice to both sides, but to give emphasis to their interrelations.

For example, to take an example a circular on prophylactic measures against influenza recently addressed to the parents of the students in one of the leading women's colleges by a prominent physician, would be of little value unless it were rendered more forcibly by pneumonia. As a consequence of this limited amount of space will be asked to give a criticism of the subject which will be subject to intelligent criticism. Does it mean anything in the probability of Pfeiffer's bacillus being the cause of influenza as against a filtrable virus, and to estimate the utility of a vaccine for a disease the cause of which is unknown. The assertion that pneumonia is less liable to follow influenza in inoculated persons may have to be examined in the light of its bacterial causation

and the composition of the vaccine to be used. The problems arising out of this letter therefore suggest that in opening its columns generously to bacteriology, the *Lancet* is acting with appreciation of the needs of those not specially interested in the subject. It agrees, however, with its correspondent that communications have appeared in its columns that would have been, as it happens, more suitable for a purely technical publication. But it adds that it is not easy to foresee when any piece of work may not become of real clinical importance.

#### The Welfare of the Blind

A committee on the welfare of the blind, appointed by the government, has issued its report. The deficiency of the census of 1911 in the enumeration of the blind has been met by an inquiry through public bodies. A register formed on the replies shows a total of 25,840 blind persons in England and Wales. It is thought that, when omissions are made up, the total will be 30,000. Inquiry was made into the work of the blind, and it was found that the unemployable group (11,895) is the largest, being 46 per cent. of the total enumerated. This class represents the real crux of the problem of dealing with the blind. Of blind persons in occupations, the largest proportion are engaged in basket and cane work; there are relatively few in outdoor occupations. A large number of blind children are not attending school, and of these, 40.6 per cent. were returned as mentally defective. A table of the age of onset of blindness shows that 21.4 per cent. were blinded within the first year of life, the majority of them within the first few months. After the first year the incidence is, roughly, 10 per cent. for each decade up to 70 years. The inquiry did not elicit useful information as to the causes of blindness so far as disease was concerned, owing to the absence of medical opinion. But accidents were found to account for 12.3 per cent. of the total. It is believed that a considerable proportion of these cases of blindness would be prevented if better protection by goggles and the like were provided in certain industries. An analysis of 6,000 returns of eye accidents showed that 51 per cent. were due to chips of metal or grit striking the eye. Trade union wages do not allow the slow-working blind to gain a living; a scheme for the augmentation of wages has been framed which, it is believed, will provide an incentive to work and offer no inducement to malingering. During the war there has been ample work for the blind, and measures are to be taken to secure a sufficient diversion of work to keep them employed in normal times.

#### The Red Cross to Help Combat Tuberculosis

It has been decided that the British Red Cross, now relieved from its gigantic labors during the war, shall direct its activities against tuberculosis. At the conference of the national association for the prevention of tuberculosis, Sir Arthur Stanley, chairman of the British Red Cross, said that tuberculosis offered a field in which the society might be of the greatest assistance. It was hoped to form an organization by means of which every man, woman and child in the country might receive just that amount of skilled attention which is necessary in the early stages of any accident or disease, and so work on to the further stage when trained assistance could be given in the great hospitals of the country. The Red Cross had a very large army of motor ambulances in France and elsewhere which might be used for the benefit of civilians as they were for the benefit of soldiers. The whole country would be mapped out in such a way that no town or village should be more than 15 miles from an ambulance station. There was also scope for the cooperation of voluntary workers with the trained nurses in districts. More than half the time of district nurses in villages and other centers was taken up in work that might just as well be done by other people. It was therefore proposed to link up the ambulance system with another system under which, in every village and small town, the trained nurses would cooperate with the voluntary workers in such a way that the latter might be able to attend to the minor accidents and the initial stages of disease in their respective districts. The voluntary workers would be connected with a nursing center which should be in every considerable county town, together with a well equipped and well staffed hospital.

Broadly speaking, the whole matter resolved itself into three stages:—In the first stage, the early period of the disease, the voluntary workers could be of practical assistance. In the second stage, when the disease was well established and sanatorium treatment was probably required, the matter should be left to the state. No organization, however big, could meet the cost of the management of

sanatoriums. The third stage related to cases which had gone practically beyond help—the stage in which the sufferer naturally pined to get back to his own home at the time when it was the very thing that he should not do. In that stage such organizations could do good work by insuring for the sufferers the provision of homes so situated that they were easily available to the sufferer's family and friends, where he could be frequently visited and where he would be surrounded by homelike conditions, such as no state institution could insure.

**Flies as Carriers of Dysentery**

A report on bacillary dysentery in Macedonia, just presented to the Medical Research Committee, tends to show that flies carry the disease. The report is based on careful experiments, which were carried out by Capt. J. F. Taylor, under three heads: (1) a comparison of the number of flies present at different seasons in a certain area with the proportional incidence of bacillary dysentery arising in that area; (2) experiments to show that a fly, when deliberately infected with a bacillus of the dysentery group, is able to carry that bacillus and to infect suitable mediums with it, and (3) experiments to show that flies in their natural state were carrying dysentery bacilli. The first line of research resulted in a remarkable graph showing that in April, May and June, when the fly prevalence was at its height, the dysentery prevalence rose also to a height. This occurred again in September and October, both fly and dysentery prevalence rising steeply. The experiments proved that the insect can become the vehicle of both Flexner and Shiga bacilli. The flies were caught in sterile dishes and put into specially constructed cages. Food was passed in to them in a watch glass. It was found that they tended to die unless the atmosphere was kept moist. The food consisted of milk cultures of dysentery bacilli (Flexner and Shiga), or other material known to contain these organisms. The flies so fed were examined in various ways. Some were allowed to walk over the culture plate, others were killed and their legs alone used, and in some excreta were examined. A total of 382 flies were examined, and of these seventy-nine gave positive results. It is concluded that the fly is capable of carrying both types of dysentery bacilli and that the prospect of recovering the infecting organism from the fly diminishes very markedly after twenty-four hours from the time of infection. The latter point is new. Finally, it was found that flies living under natural conditions were carrying dysentery bacilli. These flies were caught in various parts of the hospitals, wards, kitchens and latrines. These experiments have great value at a moment when bacillary dysentery carriers are known to be present in this country. They suggest, too, that the assertion often made that infantile diarrhœa is a fly-borne disease may be well founded.

**Indians in the Indian Medical Service**

The Indian Medical Service has for many years contained a large number of Indians in its lower grades who have worked very well under British officers. The government is now bringing in a bill which will transfer a good deal of power to Indian representative bodies and possibly alter the predominant position of British officials in India. Important evidence has been given before a select committee on the government of India bill by Col. R. H. Elliot, who was a member of the Indian Medical Service for fifteen years and superintendent of the Madras Hospital. He said that Europeans do not like serving under Indians. They do not feel that they would receive the same support and make the same progress as under British superiors. Handing over the medical service to Indians would not have a good effect on the public health. It is not a racial question. There are many Indians under whom Europeans would be glad to serve, but they would not be willing to serve under the majority of Indians. Asked if in his opinion Indians should be excluded from the Indian Medical Service, he said he would rather not make any comment on that point, as it was too difficult. In his opinion the Indian people as a mass take no notice of or interest in sanitation. If the British interfered with water supplies such as wells and tried to bring sanitation about, they would provoke a great deal of ill feeling. At the present time to substitute Indian medical officers for British would be setting back the clock and stop the progress now being made. He agreed that a gradual substitution was quite a different matter, and this would no doubt come eventually. He himself had the greatest sympathy with the Indians. Their physicians had done really splendid work, and he looked forward with confidence to their doing still much better and more work in the future.

**Marriages**

- AARON LEIDY RUTH, Conshohocken, Pa., to Miss Jean Hodgott of Paisley, Scotland, in New York City, October 1.
- FRED ANDREW JOHNSON to Miss Reba Milburn Rouff, both of Greenville, Mich., at Grand Rapids, Mich., November 13.
- SAMUEL JONES BANFIELD, Omar, W. Va., to Miss Ethel Blanche Spriggs of Institute, W. Va., November 19.
- SAMUEL I. YARNELL, Chattanooga, Tenn., to Miss Nancy Myra Leeper of Lenoir City, Tenn., November 5.
- AMOS REGINALD SHIRLEY, New York City, to Miss Harriet Pauline Eastin of Chattanooga, Tenn., October 25.
- JOHN LESTER WEBB, Carbon Hill, Ohio, to Miss Dorothy Sweazy of Columbus, Ohio, October 29.
- CLARENCE BANCROFT INGRAHAM, JR., to Mrs. Agnes Reed, both of Denver, recently.
- AUSTIN MILLARD GROVE to Miss Maude M. PeTRY, both in New York, Pa., September 30.
- REA PARKEB, Smithfield, Va., to Miss Leslie Nalle of Culpeper, Va., November 19.

**Deaths**

- James Dudley Morgan \* Asst. Surg., Lieut. (j. g.), U. S. Navy, Washington, D. C.; Georgetown University, Washington, D. C., 1885; aged 57; demonstrator of anatomy from 1888 to 1899 and lecturer on differential diagnosis from 1897 to 1898 in his alma mater; associate and clinical professor of medicine in George Washington University, Washington, D. C., from 1910 to 1917; physician to Garfield Hospital since 1899 and chief of the medical service of Emergency Hospital since 1904; a member of the American Climatological Association; president of the Medical Society of the District of Columbia in 1906; president of the Columbia Historical Society from 1909 to 1916; died at his summer home, Chevy Chase, Md., November 21.
- Xavier Oswald Werder \* Pittsburgh; University of the City of New York, 1879; aged 61; professor of gynecology in the Western Pennsylvania Medical College and University of Pittsburgh; since 1889 a member of the American Association of Obstetricians and Gynecologists; treasurer of the association for eight years and its president in 1914; gynecologist to Mercy and Charity Hospital; consulting gynecologist to St. Francis, Allegheny General and Southside hospitals, Pittsburgh; an extensive contributor to the literature of gynecology; died, November 20.
- David Henry Dougan, Richmond, Ind.; Bellevue Hospital Medical College, 1874; aged 74; formerly president of the Denver Medical Society and a member of the Colorado State Board of Health, and surgeon-general of the National Guard of Colorado, with the rank of colonel; for one term mayor of Leadville, and president of the Carbonate National Bank, Leadville in 1891, and for twenty years president of the Commercial National Bank, Denver; died October 31 from carcinoma.
- Thomas F. Fonnannon, Emporia, Kan.; Louisville (Ky.) Medical College, 1879; aged (63); a local surgeon to the Missouri, Kansas and Texas Railroad; formerly president of the Emporia Board of Health, and member of the Kansas Medical Society; once first vice president of the Kansas Medical Society, and president of the Lynn County Medical Society; one of the founders of St. Mary's Hospital, Emporia; died November 20.
- Isaac Lafayette Watkins \* Montgomery, Ala.; Bellevue Hospital Medical College, 1878; aged (55); president of the Medical Association of the State of Alabama, and once president of the Montgomery County Medical Society; founder and physician to Highland Park Sanatorium, Montgomery; a member of the Southern Surgical and Gynecological Association; died, November 18.
- Douglas Luce, Tracy, Calif.; Starling Medical College, Columbus, Ohio, 1854; aged 89; a member of the Medical Society of the State of California, local surgeon to the Southern Pacific system until his retirement in 1905; assistant surgeon of the Forty-Fourth Ohio Volunteer Infantry during the Civil War; died in the Veterans' Home, Nassau County, November 4.

\* Indicates "Fallow" of the American Medical Association.

**Joseph Harry Collins** ★ Pittsburgh; Georgetown University, Washington, D. C., 1906; aged 36; assistant secretary of the Allegheny County Medical Society; a specialist in surgery, major, M. C. U. S. Army, and honorably discharged, June 24, 1919, died in the Union Protestant Infirmary, Baltimore, November 11, from strangulation of bowel after a gastro-enterostomy for duodenal ulcer after a surgical operation.

**John Myers Swan**, Canton, Ohio, University of the City of New York, 1885, aged 59, for twenty-nine years a medical missionary under the Presbyterian Board of Foreign Missions, for the last five years owner and operator of the Hillcrest Hospital, Canton, was struck by an automobile truck in Pittsburgh, November 11, fracturing his skull, and died two hours later in the West Penn Hospital.

**George Andrew Hettler**, Toledo, Ohio, University of Cincinnati, 1911, aged 34, formerly surgeon of the Third Infantry, Ohio National Guard; later major, M. C. U. S. Army, and on duty overseas with the 147th U. S. Infantry; awarded the Distinguished Service Medal, and honorably discharged, August 3; died, November 15, from scarlet fever.

**Edwin John Carpenter**, Corning, N. Y., University of Buffalo, 1891, aged 55, for many years a member of the board of education, and at one time president; once an alderman and for two terms coroner of Steuben County; a member of the medical staff of the Corning Hospital; died, November 14, from cerebral embolism.

**John Ross** ★ Pontiac, Ill.; Rush Medical College, 1894; aged 52; for twenty years and until the time of his death, secretary of the Livingston County Medical Society; died in St. James Hospital, Pontiac, November 18, from injuries sustained by being struck by a train, while driving in his automobile across the railway tracks.

**Arminius F. Bock**, St. Louis; University of Würzburg, Germany 1868, aged 73; a member of the Missouri State Medical Association, and a practitioner of St. Louis for half a century, one of the founders and first surgeon on the staff of the Deaconess Hospital; died, November 14, from heart disease.

**Henry Larned Sidebotham**, Philadelphia; Jefferson Medical College, 1880; aged 54, for two terms coroner's physician, and later resident physician at the Norristown State Hospital, medical inspector of the bureau of health; died in St. Mary's Hospital, November 16, from cerebral hemorrhage.

**William Hiller Richardson**, Vernon, Ind.; Medical College of Ohio, Cincinnati, 1875; Bellevue Hospital Medical College, 1878, aged 66, a member of the Indiana State Medical Association, president of the Jennings County (Ind.) Medical Society in 1917; died, November 3, from angina pectoris.

**Hamilton P. Franks**, Muncie, Ind.; Medical College of Indiana, Indianapolis, 1882; University of the City of New York, 1888, aged 70; a member of the Indiana State Medical Association, and formerly president of the Delaware County Medical Association; died, November 13.

**James K. Graham**, St. Joseph, Mo.; College of Physicians and Surgeons of St. Joseph, Mo., 1882; aged 60; a member of the Missouri State Medical Association, for two terms coroner of Buchanan County, and from 1898 to 1900 secretary of St. Joseph; died, November 10.

**Ernest J. C. Sward**, Lincoln, Neb.; University of Nebraska, Omaha, 1880, aged 46, elected secretary of the Nebraska State Board of Health in 1907; once president of the Burke County Medical Association, and coroner of Burke County; died in Ash Grove, Mo., November 19.

**James Marshall Jamison**, Bowling Green, Ky.; University of Kentucky, Lexington, 1870, aged 71, for several years president of the Kentucky State Penitentiary, Nashville but since 1862 in the insurance business; died in St. Joseph's Hospital, Lexington, November 18.

**Leon Thompson Burgess**, Chicago; Jenner Medical College, Chicago, 1897, aged 46; whose license was revoked, Feb. 7, 1918, by the Department of Registration for violation of the medical practice act; died, November 15, from pneumonia following an automobile accident.

**Herbert Leonard Strong**, Portland, Ore.; University of Oregon, Portland, 1918, aged 30, lieutenant (junior grade), U. S. N. R. F., on duty at the U. S. Naval Hospital, Mare Island, Calif., and relieved from active duty, August 27, died in the hospital, October 21.

**Albert Lee McGough**, Detroit, Detroit College of Medicine and Surgery, 1894, aged 49; a member of the Michigan

State Medical Society, and a member of the staff of the Harper Hospital; died in that institution, November 16, from heart disease.

**Sylvan Graham Bushey**, Camden, N. J.; Jefferson Medical College, 1891, aged 53; a member of the Medical Society of New Jersey; for twenty-four years a member of the board of health of Camden; died, November 16, from cerebral hemorrhage.

**Alfred Alexander Tyrrell**, Spokane, Wash.; Milwaukee Medical College, 1891, aged 53; first lieutenant, M. R. C. U. S. Army, and honorably discharged, Dec. 6, 1918; interu at St. Luke's Hospital, Spokane; died in that institution, August 15.

**Cyrus Clay Reichard**, Brownsville, Pa.; Northwestern University Medical School, Chicago, 1870; aged 75; a veteran of the Civil War; formerly president of the board of health of Brownsville; died in his office, November 17, from heart disease.

**Frank Richard Curney**, Dumas, Texas; University of Illinois, Chicago, 1904; aged 44; on duty in Panama and afterward in the Coast Survey at Manila; was killed, November 19, in a collision between automobiles, near Dumas.

**Elisha Green Hale**, Nashville, Ark. (license, Eclectic State Medical Board of Arkansas, 1903); aged 86; a veteran of the Civil War; for thirty years a practitioner, and since 1885 a druggist; died, November 16, from chronic cystitis.

**Walter Peyre Poreher**, Charleston, S. C.; Medical College of South Carolina, Charleston, 1891; aged 61; a member of the South Carolina Medical Association; professor of rhinology and laryngology in his alma mater; died, November 2.

**Richard Leiman**, Detroit; Detroit Homeopathic College, 1910; aged 36; a member of the Michigan State Medical Society; while on a hunting expedition, near Parry Sound, Ont., was accidentally shot and killed, November 8.

**Albert M. Eaton**, Philadelphia; Jefferson Medical College, 1872; aged 69; a member of the Medical Society of the State of Pennsylvania, and once vice president of the Philadelphia County Medical Society; died, November 19.

**Hiram Hunt** ★ Greenville, Me.; Bowdoin Medical School, Brunswick and Portland, Me., 1884; aged 58; a member of the consulting staff of the Eastern Maine General Hospital, Bangor; died, November 4.

**George Platt Waller**, Montgomery, Ala.; University of the City of New York, 1892; aged 64; a member of the Medical Association of the State of Alabama; died at a hospital in Montgomery, November 4.

**T. J. McCord**, Galena, Mo.; Kansas City, Mo.; Hospital College of Medicine, 1885; aged 77; for four years a surgeon of United States Volunteers during the Civil War; died, November 18.

**Alpheus B. Stroud**, Henderson, Texas; New Orleans School of Medicine, 1861; aged 80; a Confederate veteran; died at the home of his daughter in Mooringsport, La., November 5.

**William F. Maggard**, Corning, Calif.; College of Physicians and Surgeons, Keokuk, Iowa, 1879; aged 64; a member of the Medical Society of the State of California; died, October 21.

**Ebenezer Farrington Spaulding**, Boston; Harvard University Medical School, 1866; aged 84; from 1862 to 1865 surgeon of the Seventh Wisconsin Volunteer Infantry; died, recently.

**Charles Lethbridge Stowe**, Hilo, Hawaii; M.R.C.S. (Eng.), 1882; L.R.C.P. (Edin.), 1883; aged 62; a member of the Medical Society of Hawaii; died, July 6, from acute myocarditis.

**John Joseph Hayes**, Boston (once Massachusetts, years of practice, 1894); aged 68; at the time superintendent of the Delham County Jail and House of Correction; died, November 18.

**William Hamilton Crockett, Jr.**, Petersburg, Va.; University of Virginia, Charlottesville, 1902; aged 41; for several years coroner of Dinwiddie County; died, November 2.

**Junius Wooten**, Smith's Grove, Ky.; University of Louisville, Ky., 1868; aged 73; a member of the Kentucky State Medical Association; died, November 19, from nephritis.

**Thomas L. Eads**, Michigan City, Ind. (license, Indiana, 1897); aged 69; a practitioner since 1890; died, September 20, from septicemia following an infection of the hand.

**Gurley Curtis McCoy** \* St. Louis; Washington University, St. Louis, 1908; aged 35; who had devoted his attention especially to surgery; died, November 10, from nephritis.

**George S. Wilkins**, Brighton, Iowa; State University of Iowa, Iowa City, 1875; aged 66; died in the Jefferson County Hospital, Fairfield, Iowa, October 19, from nephritis.

**J. Alston Scott**, Monticello, S. C.; Medical College of the State of South Carolina, 1875; aged 66; died in the Columbia (S. C.) Hospital, November, 3, from heart disease.

**James L. Nelles**, Canton, Ill.; McGill University, Montreal, 1875; aged 68; a member of the Illinois State Medical Society; died, November 20, from heart disease.

**Richard W. Lease**, Redfield, Kan.; College of Physicians and Surgeons, Keokuk, Iowa, 1878; aged 68; a member of the Kansas Medical Society; died, November 9.

**Robert S. Hirsch**, Seward, Neb. (license, Nebraska, 1891); aged 71; an eclectic practitioner; also a pharmacist; for one term coroner of York County; died, October 29.

**John Lawrence Jordan**, Bennettsville, S. C.; University of the City of New York, 1868; aged 73; a Confederate veteran; died in a hospital in Richmond, November 15.

**J. C. Pickering**, San Francisco; Eclectic Medical College, San Francisco, 1893; aged 56; died in St. Joseph's Hospital, San Francisco, November 18, from dysentery.

**William W. Pearce**, Wankegan, Ill.; University of Illinois, Chicago, 1885; aged 61; for four terms mayor of Wankegan; died, October 16, from carcinoma of the jaw.

**Marcellus R. Jamison**, Greensburg, Pa.; Pulte Medical College, Cincinnati, 1881; aged 67; died in the Westmoreland Hospital, Greensburg, November 15.

**Albert Guy Howard**, Farmington, Me.; University of Vermont, Burlington, 1881; aged 72; a member of the Maine Medical Association; died, September 6.

**Wesley Kinney Bradner**, Bradley Beach, N. J.; Bellevue Hospital Medical College, 1876; aged 67; health officer of Bradley Beach; died, November 20.

**George Adams Barker**, Menomonie, Wis.; Bowdoin Medical School, Brunswick and Portland, Me., 1884; aged 64; died, November 16, from heart disease.

**William U. Martin**, Richmond, Ky.; University of Louisville, Ky., 1862; aged 86; a Confederate veteran; died, November 16, from carcinoma.

**Bernard Mellen**, Cleveland (license, Ohio, 1896); aged 69; a practitioner for thirty-five years; died, November 13, from cerebral hemorrhage.

**George C. Knight**, Barksdale, S. C.; Atlanta (Ga.) College of Physicians and Surgeons, 1900; aged 40; died, October 27, from nephrothiasis.

**Andrew Nickell Herring**, Deraff, Ohio; Eclectic Medical Institute, Cincinnati, 1895; aged 56; died, November 17, from heart disease.

**Irvin C. Conn**, Oakwood, Ga.; Maryland Medical College, Baltimore, 1904; aged 44; died, recently, from cerebral hemorrhage.

**David Crary, Jr.** \* Hartford, Conn.; Yale University, New Haven, 1869; aged 77; died, July 9, from chronic interstitial nephritis.

**John F. Kent**, Newburg, Ark. (license, Eclectic Board of Arkansas, 1903); aged 48; died, November 3, from gastro-enteritis.

**George W. Bradford**, Grandview, Mo.; Medico-Chirurgical College of Kansas City, Mo., 1900; aged 57; died, November 5.

**Herman Frumson**, St. Louis; Washington University, St. Louis, 1889; aged 66; died, October 31, from heart disease.

**Samuel N. Kelley**, Bellingham, Wash.; Hospital College of Medicine, Louisville, 1886; aged 55; died, November 15.

**William Parrish Camp**, Springfield, Mo.; Missouri Medical College, St. Louis, 1876; aged 78; died, November 9.

**Francis Charles Murphy** \* Boston; Harvard University Medical School, 1886; aged 53; died, November 16.

**William Huff**, Cove Creek, Ark.; University of Virginia, Charlottesville, 1868; aged 75; died, November 6.

**Hiram W. Nye**, Enon Valley, Pa.; University of Wooster, Cleveland, 1896; aged 76; died, November 19.

**John Michael Stephen**, Reading, Pa.; Jefferson Medical College, 1887; aged 64; died, November 10.

**Daniel Marion Moser**, Claremont, N. C. (license, North Carolina, 1896); died, November 9.

## The Propaganda for Reform

IN THIS DEPARTMENT APPEAR REPORTS OF THE JOURNAL'S BUREAU OF INVESTIGATION, OF THE CLINIC ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORY, TOGETHER WITH OTHER MATTER TENDING TO AID INTELLIGENT PRESERVING AND THE OFFER OF FREEDOM ON THE PUBLIC AND ON THE PROFESSION.

### ANTIMERISTEM-SCHMIDT

Some, possibly many of our readers, have received a letter from Cologne, Germany, from the "Bakteriologisch-Chemisches Laboratorium Wolfgang Schmidt." The letter contains a circular directing the attention of American physicians to "Antimeristem-Schmidt." It also contains some advertising leaflets. One physician in sending in this material to THE JOURNAL writes:

"A copy of the enclosed circulars has been sent to many of the physicians in this city, and probably elsewhere. Perhaps it has already been called to your attention. Let us be as liberal as possible with our recent enemies. The sooner the old channels of scientific communication are re-opened, the better. But let us not show such blatant commercialism from a foreign country to go unprotested, any more than we should if it were from our own."

It should be noted in passing that the envelop in which the Wolfgang Schmidt letter came has on its face a rubber-stamped impress to the effect: "Concerns Cancer Treatment." The circular letter declares that by means of Antimeristem Schmidt "either a cure or improvement has been effected in numerous inoperable cases" of malignant tumors. American physicians are asked "to employ the preparation when occasion arises" and are assured that "every medical man in city or country will be able to carry out treatment without preliminary knowledge." With the letter are two leaflets discussing the use and administration of the product; one contained what was called a "Synopsis of some of the more recent publications regarding the employment of Antimeristem-Schmidt in inoperable malignant tumors." The "recent" publications comprised three articles published in 1910 and one published in 1912!

Antimeristem-Schmidt was rather widely exploited some six or seven years ago. As was explained in THE JOURNAL of March 8, 1913, it is a preparation claimed to be useful in the treatment of inoperable cancer and as a supplementary treatment after operations for cancer. The treatment is founded on a theory advanced by one O. Schmidt that the cause of cancer is found in a fungus, *Mucor racemosus*, which, Schmidt at first asserted, carried a protozoon which he regarded as the real cause of the disease. The vaccine is said to be prepared from cultures from this fungus. While Schmidt claims that he has been able to produce cancer by means of the organism, scientific research has not verified his claims. Extensive clinical trials have shown the treatment to be without effect. THE JOURNAL also advised its readers on April 19, 1913, that no license for the sale of Antimeristem-Schmidt had been granted by the Treasury Department and, therefore, its importation into this country was prohibited. Neither the therapeutic nor the legal status of the product has been changed since then.

**Roentgen Examination of Abdomen.** The last work of the late Adolf Schmidt appeared in the *Deutsche medizinische Wochenschrift*, Feb. 20, 1919, p. 201, where he described the peculiarly instructive roentgen findings in the abdomen when from 1 to 3 liters of oxygen or air had been pumped into the abdominal cavity. He reproduced a number of roentgenograms showing the outlines of viscera thrown into sharp relief by this means. Rautenberg in the same issue reports excellent results from injection of air into the peritoneal cavity. He has been applying this method for five years, and describes twelve typical cases. The gallbladder is rendered visible by it. The findings with these methods are more instructive as the subject twists his trunk and bends over or reclines on different sides.

## Correspondence

## THE FALLING NECROPSY RATE

To the Editor.—The letter from Dr. Douglas Symmers in THE JOURNAL, Sept. 20, 1919, p. 929, is an interesting contribution to the subject of the falling necropsy rate and an excellent illustration of just the point which was made in my address on "The Relation of Pathology to Practice" (THE JOURNAL, Aug. 23, 1919, p. 569). I am glad to obtain the support in this matter of so well known a pathologist as Dr. Symmers, and regret that any phrase in my address seemed at all critical of the work of Bellevue Hospital, long known as one of the great institutions in this country. The use of the Bellevue statistics was merely in illustration of how low a good hospital could fall, and the facts were obtained from a letter from Dr. Symmers, in which the percentage of necropsies in 1917 is given as 11, in 1918 as "almost 7." In a more recent letter to me Dr. Symmers says that these figures for 1918 were based on the total number of deaths in the hospital, and that if the medical examiner's cases and the unclaimed dead, which pass out of the control of the hospital, are deducted, the actual percentage of necropsies by consent in 1918 is 10 instead of 7. With the additional figures for 1915 given in Dr. Symmers'

decision is rendered, not to carry them to a higher court, where undoubtedly a reversal would be obtained.

Still another factor is the indifference or even active opposition to necropsies on the part of those members of the hospital clerical staff who have to do with the relatives of the deceased. Still another, the opposition of many undertakers who find it less easy to embalm a body after a necropsy has been performed. The pathologist can do but little to improve any of these conditions except the last; if the large vessels are left long so that they can be more easily injected, embalming is facilitated. In most hospitals the pathologist never sees the patient or the family, and thus cannot appeal except through the lay management and the attending staff.

But the outstanding reason for the falling rate of necropsies is, I believe, the lack of interest of the attending physicians and of the interns; the intern is a mirror reflecting the attitude of the attending physician. If the percentage curve of necropsies in a hospital is examined, it will be found to vary with the members of the attending staff. On those services on which teaching is carried on, a higher rate of necropsies usually obtains; when the service changes to a man who is not interested in scientific medicine, the rate falls. The reason why a high percentage of necropsies is obtained at the Mayo Clinic and at the Memorial Hospital is that these institutions make it a business to secure consent.

These are some of the difficulties with which the teacher of pathologic anatomy has to contend, and they may explain why most of our pathologists have had to go to Germany to complete their educations. They will always prevent this country from equaling, much less surpassing, the opportunities in pathology which up to 1914 were available in both Berlin and Vienna. The only way in which we can equal our German colleagues is by a thorough revision of the laws permitting postmortem examinations, which implies the scientific education of our legislators—always a matter of great difficulty—and by a united effort on the part of the medical profession, to suggest which was the purpose of my address before the Section on Pathology and Physiology of the American Medical Association.

FRANCIS CARTER WOOD, M.D., New York.

## AN APPEAL FOR EMBRYOS AND FETUSES

To the Editor:—In 1906 I observed certain malformations of the human shoulder blade, and have given them the collective name "the scaphoid type of scapula," and suggested some of its possible bearings in general and special pathology. Personal observations and those of others have associated this form of scapula with problems intimately connected with those of heredity, longevity and racial morbidity. Notwithstanding the many studies which have been made on the scaphoid type of scapula, all of these must be considered preliminary to those which must follow before we shall be in a position to draw far-reaching conclusions, if any, in reference to the significance of this and associated anomalies.

Probably the most suggestive observation connected with the scaphoid type of scapula in man is its age incidence; that is to say, it occurs with great frequency among the young and with decreasing frequency in each succeeding decade of life when studied in comparatively large groups of individuals in the same period of time. There appear to be two possible explanations of this fact: Either (a) one form of shoulder blade changes into the other during periods of development and growth, or (b) many of the possessors of the scaphoid type of scapula are, in the broadest sense, the poorly adaptable, the unduly disease susceptible, the inherently weakened of the race. I have attempted to answer these questions by seeking evidence in various directions, and one of these has been a study of intra-uterine development of shoulder blades. My studies in this direction have been limited by the material at my disposal, which has been insufficient for a definite solution of all phases of this problem. I am, therefore, appealing to the medical profession for embryos and fetuses in any and all stages of human development,

Percentage of necropsies to deaths: A, at the Boston City Hospital from 1899 to 1918, inclusive; B, at St. Luke's Hospital, New York, from 1899 to 1918, inclusive.

leader to THE JOURNAL, there is shown a continuous fall in the percentage of necropsies in Bellevue Hospital. The absolute percentages are, of course, unimportant; the main fact is that even in a large city institution the percentage of necropsies has fallen in the last few years. This is equally true of many of the public and private institutions in the United States. I might perfectly well have cited St. Luke's Hospital with which I am connected, where the necropsy percentage has fallen, as is shown by the accompanying chart. The same is true of the Boston City Hospital, the figures for which are due to the kindness of Prof. F. B. Mallory.

The chief point it seems to me is to determine why this fall has occurred. In my address I pointed out some of the causes, but they are many and vary in their activity in different localities, but the most important one, to my mind, is that at which I spoke, the growing lack of interest in forensic and pathologic

Another factor is the widespread growth of Christian science and similar sects which teach nonmedical treatment. Where the relatives of a person dying in the hospital hold these beliefs are under the influence of sepiopathy, or "corpse-rot," a necropsy is, naturally, undreamable. Another factor worth mentioning in particular in New York is the peculiar wording of the state law permitting necropsies, which enables the relatives of the patient to bring suit for damages. The tendency has been to compromise such suits, rather than to fight them, and in cases in which an adverse

Regardless of the length of time the material may have been in a preservative, of whatever nature, it can still be utilized in these studies, although it is desired that *fresh material* be immersed in 10 per cent. dilution of liquor formaldehyd in a suitable container, and any material, *old or fresh*, be forwarded to my address, charges collect. Due acknowledgment will be made to those forwarding material.

727 Metropolitan Building.

"SPOILED CANNED FOODS AND BOTULISM"

To the Editor:—In THE JOURNAL, Oct. 4, 1919, there appeared under this caption a letter by Georgiana S. Burke discussing my paper on "The Bacteriology of Canned Foods" published in the *Journal of Medical Research* (39:349 [Jan.] 1919). The following are the most prominent points which call for explanation:

1. Mrs. Burke states that "Dr. Weinzirl restricts the term [commercial] to refer to those factory canned goods in which no spoilage has been detected and which are still being offered for sale." No such statement is made in the paper, nor was it contemplated. For the purpose of discussion merely, commercial packs were separated from experimental packs and from obviously spoiled samples.

2. "Three such spoiled cans [all sardines] are included among the 'commercial' or unspoiled cans which he examined. But for some unexplained reason he made bacteriologic examinations of only two of these cans, while the third can, which was the only one suggesting botulinus spoilage was not examined." No bacteriologically unexamined cans were included in the report. Mrs. Burke has not read correctly the table given on page 384 of my paper. The column designated "not examined" refers to cans not examined for leakage, after the can was emptied. The can in question did not contain *B. botulinus*.

3. "The point that I wish to make clear is that when Dr. Weinzirl says that '*B. botulinus* is not found in commercial canned foods,' he means that it is not found in unspoiled factory canned foods." On page 409 it is clearly stated that "members of the paratyphoid-entertidis group were not found, nor was *B. botulinus* ever isolated."

4. "A second criticism . . . concerns . . . the total number of 'commercial samples' examined . . . 782. . . . This is too small a percentage on which to base a conclusion in regard to so vital a subject as food poisoning." The conclusion is based on 1,018 samples and not on 782 as stated by Mrs. Burke; furthermore, this number of analyses is at least fourfold that of any previous investigation, and the work was done under the most elaborate technic ever attempted.

5. "The result would be more convincing if the author had made tests for the specific botulinus toxin to substantiate his bacteriologic findings." Such tests were made, but it was thought best to withhold them until more results are available. They will be presented in due time by one of my colleagues in the work.

6. "No data are given by Dr. Weinzirl as to the length of the periods that had elapsed between the processing of the cans and the making of the bacteriologic examinations." This criticism is quite unreasonable, for it is well known that grocers do not keep such records, nor is the date of processing stamped on the can.

7. I am pleased to admit that one just criticism is made by Mrs. Burke, and that is that the length of time the cultures were incubated is not clearly stated in the paper.

8. "From a consideration of the foregoing, I am of the opinion that Dr. Weinzirl furnishes very unsatisfactory evidence on which to base his conclusion that food poisoning organisms, such as *B. botulinus*, *B. enteritidis*, etc., are not found in commercial canned goods." Briefly stated, the evidence is as follows:

A. I did not find *B. botulinus* in 1,018 samples of commercial canned foods, although careful search was made for it. The samples included spoiled, experimental and marketable goods, and practically every variety was represented.

B. All the literature known to me did not reveal a single instance of *B. botulinus* having been found in factory canned food in the United States. Since our annual consumption must approximate five billion cans of such foods, it is truly remarkable that not a single instance should be reported in our scientific literature. It is all the more remarkable because botulism exhibits highly characteristic symptoms.

C. From the analyses made and from the evidence presented in the scientific literature, the natural conclusion to draw is that *B. botulinus* and its toxin are not found or are exceedingly rare in factory canned foods.

This brings me to the one case reported by Mrs. Burke as botulism due to factory canned food. I was not informed of it at the time of writing my paper, and I am not now aware that the evidence has been published before. It must be remarked, however, that the evidence presented by Mrs. Burke is not convincing, for if we grant that the case was botulism, we are still uncertain that it came from the corn.

Finally, permit me to state that I am professor of bacteriology in the University of Washington, and that during a year's leave of absence I held a research fellowship in the Department of Preventive Medicine and Hygiene in the Harvard Medical School, where I studied the bacteriology of canned foods. I have never had the honor of occupying the other position indicated.

JOHN WEINZIRL, Seattle.

University of Washington.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

THALION

To the Editor:—Kindly inform me regarding thalion, manufactured by the Vass Chemical Company, Danbury Conn. Please omit my name and address in answering in THE JOURNAL. H. C. W.

ANSWER.—Thalion is an heirloom of the days when lithium salts were supposed to be nature's antidote for a kind of ailments, supposedly due to excess of uric acid. It was advertised as a uric acid eliminant and therefore good for all kinds of diseases. The Council on Pharmacy and Chemistry published a report on thalion in THE JOURNAL, Nov. 3, 1906. At that time thalion was advertised by the Vass Chemical Company as a "laxative salt of lithia" with the chemical formula "3Li<sub>2</sub>O.Na<sub>2</sub>O.SO<sub>4</sub>.7H<sub>2</sub>O," and an elaborate structural formula was also furnished. The Council reported that the product was not a definite chemical compound, but a mixture consisting chiefly of sodium sulphate, sodium citrate and small amounts of lithia. In recent advertisements, thalion is referred to as "A Non-Effervescent Lithiated Laxative Salt," "a non-hygroscopic, non-deliquescent, granular salt of lithia," etc., but the chemical formula does not appear, nor is any definite statement of composition furnished. According to this advertising, the "indications" for thalion are: "gout, rheumatism, obesity, flatulency, constipation, acute and chronic, sluggish liver, Bright's disease, albuminuria of pregnancy, asthma, incontinence of urine, gravel, cystitis, chronic lead poisoning, headache, neuralgia, neurasthenia and lumbago. Hay fever, etc."

SYPHILIS IN TWINS

To the Editor.—I am treating twin children, one of whom had symptoms of hereditary syphilis which improved very much with mercurial inunctions. The other child is perfect the same with no syphilitic symptoms at all. How do you explain the fact that one has contracted the disease and the other has not? Should I treat the healthy child as a preventive measure? Dr. P. M. C.

ANSWER.—Several cases have been recorded of the infection of one twin with syphilis at birth while the other has been healthy. In a case recorded by Dr. George F. Still, one of the twins died with severe and fatal syphilis at the age of seven months, whereas the fellow twin was apparently perfectly healthy. In a case described by Sir Herman Weber

a syphilitic mother bore twin children, one of whom suffered with congenital syphilis and died at the age of seven weeks with diarrhœa, while the other remained perfectly healthy. Thus such cases are not inconsistent with fact, although a priori one would expect the event to be rare. The child who apparently escaped syphilis should be watched carefully for the appearance of the disease. It might be a wise policy to give this infant moderate courses of mercury by inunction. This would do no harm, and if the child is syphilitic, would be of benefit.

PIONEER MEDICAL MISSIONARIES

*To the Editor:*—Who was the first American medical foreign missionary? When did he begin his service?

D. I. HERRICK, M.D., Terhoo, Okla.

ANSWER—Dr. John Scudder entered medical missionary service in India under the Dutch Reformed Foreign Missionary Board, in 1819. His son, H. M. Scudder, appears to have founded the first hospital and dispensary in connection with American medical missions, at Arcot, India, in 1850. Peter Parker, who went to China as an American medical missionary in 1834, began to teach medicine to native students in Canton about 1839.

SODIUM CITRATE IN INFANT FEEDING

*Please inform me how sodium citrate is used in infant feeding, and why.* C. P. FERRIER, M.D., Fillmore, Calif.

ANSWER—Sodium citrate is added to the milk mixtures to prevent the formation of hard protein curds. Bosworth and Van Slyke have shown that increasing amounts of sodium citrate added to the milk increase coagulation time up to a limit of 17 grains to an ounce, after which the milk does not coagulate at all. If it is desired to use sodium citrate in this way, it may be prescribed safely in doses of 1 grain for each ounce of milk in the mixture.

## Medicolegal

### A Physician's Letter That Was Not Evidence

(*Richardson v. North American Life & Casualty Co. (Minn.)*,  
172 N. W. R. 131)

The Supreme Court of Minnesota holds that, in an action to recover on a life insurance policy, in which action misrepresentation of the physical condition of the insured was interposed in defense, a letter written by a physician who had treated the insured at about the date of the insurance contract, addressed to the insurance company, and therein stating the physical condition of the insured as he found from examination, as to the beneficiary was hearsay and inadmissible in evidence, the letter being no part of the proofs of death and not procured at the instance of the beneficiary, but having been procured solely by the defendant and in furtherance of its defense.

### Detention of Persons Infected with Venereal Virus

(*Ex parte Brown (Neb.)*, 172 N. W. R. 522)

The Supreme Court of Nebraska, in denying a writ of habeas corpus, and dismissing the cause, says that this was an original application in this court for the writ. The petitioner was quarantined in the detention home in the city of Omaha under an ordinance of that city, and the question presented was whether such detention, under the circumstances, was justifiable. The case was presented to this court on a stipulation of facts and without other evidence. The stipulation showed that the petitioner had been arrested on a charge of "being an inmate of an ill-governed house"; that she was tried on this charge and found guilty, and appealed the case to the district court; and thereupon the court trying her approved of her bond on appeal, and notified the keeper of the jail to release her from confinement "on the ground that she had furnished an appeal bond as provided by law." But these facts were immaterial in this case, because it was further shown by the stipulation that the health commissioner of the city of Omaha "caused said petitioner to be examined, and under his direction said examination was made and said petitioner found to be infected with communicable venereal virus; that thereupon said health commissioner ordered said petitioner to be isolated and quarantined by the proper authorities in the detention home of the city of Omaha for treatment for such reasonable time and in such reasonable manner as to prevent the danger of said petitioner from communicating such infection to others, and until the danger of the infection should be removed."

The petitioner cited and relied on *Wragg v. Griffin* (Iowa), 170 N. W. 400. In that case their statutes are cited, and the rules of the local board of health referred to, and the law is stated to be that they "do not authorize the board of health to deprive of his liberty one suspected of venereal disease for the purpose of forcing the exposure of his body to examination and compelling the extraction of blood from his veins in search of evidence of the disease." And, in the opinion, it is said:

It may be said at the outset that the objection raised by this petitioner does not necessarily challenge the validity of any statute or any rule of the board of health by which authority is given to quarantine persons who are afflicted with contagious disease, or to remove or segregate a person so diseased from his own home for detention in a separate house or detention hospital and there detain him until he has so far recovered his health as to be no longer a menace to the health of the community.

In this case the stipulation showed that the petitioner was "found to be infected with communicable venereal virus," and that she was only detained "for such reasonable time and in such reasonable manner as to prevent the danger of said petitioner from communicating such infection to others and until danger of the infection should be removed." There can be no doubt that under the Nebraska statute (Rev. St. 1913, Sections 4082, 4094), the city could by ordinance provide for such detention, and the ordinance as quoted in the petitioner's brief provided for such detention. In other words,

the court holds that, under the Nebraska statute, the city of Omaha is authorized to provide for the detention in the detention home in that city of persons "found to be infected with communicable venereal virus," for such reasonable time "as to prevent the danger of . . . communicating such infection to others." And, under such circumstances, such person will not be entitled to a writ of habeas corpus for release from such detention.

### Mistaking Pregnancy for Tumor—Expert Testimony

(*Bricker et al. v. Ring et al. (N. C.)*, 99 S. E. R. 58)

The Supreme Court of North Carolina affirms a judgment in favor of the defendants, who were charged with malpractice in diagnosing a case of pregnancy as one of tumor. The court says that, according to the defendants, it was very difficult to determine the woman's true condition, and that, in their opinion, the indications were that it was an ovarian tumor or cyst, but that the true condition could not be determined otherwise than by an exploratory operation, which was the nature of the one performed. The woman, aged 47, married, had given birth to three children at intervals of three and two years, the last one having been born twelve years prior to her visit, Jan. 8, 1917, to Dr. Ring. From the date of the birth of the last child until the latter part of August, 1916, she was regular in her periods, and only about Sept. 21, 1916, noticed the first irregularity, the period at that time being partially suppressed, and continuing with slight but constant flow, broken by periods of one or two days with an absence of flow. With the exception of one week, these conditions continued until Jan. 8, 1917, up to which time she had not observed any signs of pregnancy, but stated to Dr. Ring that she thought she had a tumor. There was an apparent enlargement of the abdomen. Without coming to a definite conclusion as to the true condition, but strongly suspecting a tumor, Dr. Ring advised going to see the other defendant, looking to an operation. That defendant made two examinations and diagnosed it as a submucous fibroid tumor or possibly a cyst, but said he was not sure about it, and advised an exploratory operation. An incision was made, which showed that the woman was only normally pregnant. There was no indication of tumor. The wound was closed, the patient recovered from it, and in due course she was delivered of her child without any untoward incident in the accouchment. There was much evidence taken at the trial on the questions of negligence and damages as to each of the two defendants, and the jury returned the following verdict: "Were the plaintiffs injured by the negligence or want of skill, of the defendants, or either of them? Answer: No."

Taking up the question of what are the duties and responsibilities of a physician and surgeon in the diagnosis of a case and the treatment of a patient under his care, the court says that a physician entitled to practice his profession, possessing the requisite qualifications, and applying his skill and judgment with due care, is not ordinarily liable for damages consequent on an honest mistake or an error of judgment in making a diagnosis, in prescribing treatment, or in determining on an operation, when there is reasonable doubt as to the nature of the physical conditions involved, or as to what should have been done in accordance with recognized authority and good current practice. Whether errors of judgment will or will not make a physician liable in a given case depends not merely on the fact that he may be ordinarily skillful as such, but whether he has treated the case carefully, and has employed in its treatment such reasonable skill and diligence as is ordinarily exercised in his profession. There is a fundamental difference in malpractice cases between mere errors of judgment and negligence in previously collecting data essential to a proper conclusion, or in subsequent conduct in the selection and use of instrumentalities with which the physician may execute his judgment. If he negligently omits to inform himself as to the facts and circumstances, and injury results therefrom, then he is liable. Whether the fetus was struck with life so that the beatings or sounds of the heart could be observed by examination, was a question of fact for the jury to decide on the evidence, as were the other questions involved.

It was competent to ask an expert witness whether, in his opinion, on the facts stated in the hypothetical questions, it found by the jury on the evidence, the diagnosis was made according to the approved practice and principles of the medical profession. It is not the province of an expert to draw inferences of fact from the evidence, but simply to declare his opinion on a known admitted or hypothetical state of facts. The rule is that the expert must base his opinion on the supposition that the jury will find the facts recited in the hypothetical question, and there must be evidence of those facts.

#### Inadmissible Bases for Expert Testimony

*Bill v. Milwaukee Electric Railway & Traction Co. (1919),  
12 N. W. R. 793*

The Supreme Court of Wisconsin, in affirming a judgment for \$25,000 damages in favor of the plaintiff for injury to his eyes by an electrical explosion or flash on one of the defendant's cars on which he was a passenger, says that a physician who was called as an expert witness by the defendant was asked on cross-examination by the plaintiff's counsel if he considered Oppenheim an authority on optic atrophy, the receiving a qualified negative answer, and the statement that the witness had read a part of Oppenheim's works, he was asked if he remembered at some time in his reading certain language. The witness stated that he could not recall having read it, and that he could not deny that it was a correct statement of what is generally taken to be the effect of dazzling on the human eyes by men skilled in the medical profession. Counsel stated that his purpose in asking the question was to ascertain whether or not the witness was familiar with this passage. Under repeated decisions of this court its admission was error. If, under the guise of finding out a witness' familiarity with the contents of medical works, counsel read extracts therefrom to him and inquire if he is familiar with them, then you can get the contents of every medical book before the jury. That, this court has, for good reasons, declared cannot be done.

Another physician called as an expert witness by the plaintiff, whom he had examined since this action was begun, but had never treated, was allowed to give an opinion that the plaintiff was totally blind in his left eye, basing such opinion in part on his examination and in part on subjective symptoms or on what the plaintiff had told him. This was error. A physician who treats a patient may give an expert opinion based on the result of his examination and statements made to him by the patient, but not one who does not treat the patient. The reason for the application of different rules in the two cases lies in this: When a patient submits himself to treatment, he does so for the purpose of curing himself of the malady afflicting him, and he is desirous to know and the presumption is that he will tell the truth to the physician. If he does not, he knows that not only may a cure not be effected, but he may seriously jeopardize his health by giving false information or withholding important information. But when he goes to a physician for examination for the purpose of having him testify, but not treat him, the physician is giving false information, and the inducement was to induce rather than to reveal the truth.

But the court does not think that the admission in evidence of the facts of the incompetent testimony was prejudicial. There was a basis of fact for the expert medical testimony, and the extent and permanence of the plaintiff's injury. The fact however, that there was a serious dazzling explosion or flash on the car, and that the plaintiff sustained a serious injury to his left eye, and probably to the right eye also, was clearly established. He was on the witness stand a great many times during the protracted trial, and he testified he saw the flash, the jury saw him and had an opportunity to note his conduct and appearance and to judge more correctly of his credibility than they could had. He said he was totally blind, and the jury no doubt believed him. The medical testimony was in direct conflict, even with the incompetent evidence. In such a situation this court cannot say that the result would probably have been different, if the error of the admission of evidence had not occurred, or that the result reached was clearly wrong.

## Social Medicine, Medical Economics and Miscellany

### THE CARDIAC CLINIC AT THE CENTRAL FREE DISPENSARY OF CHICAGO

LEO E. J. HARPEL, M.D., M.S.  
AND  
HELEN BECKLEY  
Director of Social Service  
Chicago

New York, previous to the war, found it necessary to establish a number of cardiac clinics in connection with its hospitals and dispensaries in order to meet the growing demands for proper medical treatment of its cardiac cases. Most of these clinics united to form what was known as the "Association for the Prevention and the Relief of Heart Disease," with Dr. Lewis A. Comor as its president. But owing to the fact that so many of the physicians were called into service, the clinics were to a large extent discontinued. A similar need was felt in Chicago, and an attempt was made to establish a cardiac clinic at the Central Free Dispensary in 1918; but as most of our men were called into service, it became necessary to discontinue it in order to meet the more urgent demands of the moment. In March, 1919, the work was again started and has progressed more rapidly even than was anticipated. Conferences are now being held every Wednesday and Saturday morning, and at each meeting there are from ten to twenty patients. Since the opening of the clinic in March, approximately 140 patients have been examined.

#### ROUTINE PROCEDURE

When the patients enter the clinic, a complete history, both social and medical, is taken. Special cardiac histories have been devised which simplify and at the same time give more complete information on which to base the diagnosis and subsequent treatment. The patients are then given a complete physical examination, including blood, roentgen-ray, electrocardiograph and urine examinations, whenever indicated. The medical advice given is largely dependent on the patient's home and working conditions. If his work is of such a nature as to interfere with his physical condition, he is advised to change his employment, and whenever possible, the social worker helps him find suitable work. Each patient is then advised as to the amount of physical exertion his heart will tolerate. When the heart is badly decompensated, he is sent to the Presbyterian Hospital where he can be placed in bed with absolute rest until his condition warrants his returning to work. After the first visit, an appointment is made, and the patient is urged to return at a later date for observation. In the interval, the social worker visits him at his home and place of employment to see that the physician's instructions are being carried out. A careful social record is kept on the medical chart so that one may see at a glance just what the patient's home and working conditions have been. For subsequent visits to the clinic, the social history is of utmost value as a guide in giving each patient the proper advice. Patients that have complications other than cardiac are referred to other departments in the dispensary. Many children are sent to the nutrition clinic, others to the nose and throat, and dental clinics, and still others to the syphilitic clinic.

#### TYPES OF CASES

Patients are referred to the clinic from a number of different organizations. Approximately nine different sources are now represented. The board of education has referred children between the ages of 14 and 16 who are anxious to go to work, but who because of their heart conditions are not given a working certificate until it is recommended by the cardiac clinic. If their conditions are very serious, they are advised against going to work and encouraged to continue their education as long as possible. Thirty-nine have been referred to the clinic, and of this number, twenty-four are now working. They are seen from time to time and

their employment is supervised. Dr. Brunner of the board of education is greatly interested, and it is hoped that as soon as the number of children warrants it, arrangements will be made in some of the schools to have classes on the first floor for cardiac cases. The social service department of the Cook County Hospital has referred twenty-four of its discharged patients to the clinic for further medical care and supervision. A few cases have been referred by private physicians. A large number have come directly to the clinic, because they were told by other physicians that they had heart trouble, whereupon they came to the clinic for corroboration and advice. A number have been referred from the various departments of the dispensary. The United Charities have referred thirteen; the Jewish Aid Society, four; the Central Charity Bureau, three; the Juvenile Court, three; the Visiting Nurses' Association, two, and the Immigrants Protective League, one.

In many instances, the patients are the heads of families, or are young adults who are helping to bear the responsibilities of the family income. They need social, as well as medical treatment, that will not only tide the family over present difficulties, but will also give a working plan for their future economic life. In such instances, it is not just temporary relief and supervision, but the making of a definite plan for the future that is required. In some cases the patients are children who should have vocational training in order that they may fit themselves to be independent in spite of their physical handicap. The social worker cooperates with employment managers of industrial plants in securing temporary relief for the various patients. In August, the clinic was without a worker, and because of lack of follow-up work, the attendance was very low.

Of the 140 patients seen in the clinic, twelve were sent to the hospital. Two died while at the hospital (one of hypertension with a systolic blood pressure of 300; the other of aortic regurgitation and stenosis); a third was sent home, but later died. All of the others have shown a decided improvement in their symptoms. During the summer months, twenty of the patients were sent on outings to camps, sanatoriums and convalescent homes. Sixteen of our patients are receiving special nutritional care. It is interesting to note that only forty-two have required cardiac stimulants, such as digitalis, strychnin and caffeine. Nine are under antisyphilitic treatment. The active therapeutic treatment, although essential, is by no means the main object of such a clinic. Prophylactic management of those cardiac cases in which slight injury to the heart has been noted should be the main aim, and only by repeated instructions to patients, particularly children, can we hope to prevent the numerous cardiac decompensations found in later life. This cannot be accomplished until a sufficient number of organized clinics are established in Chicago, and until such organizations can gain the cooperation of the various industrial plants and public schools. Many of our schoolchildren suffering from heart disease are undertaking strenuous courses in the gymnasium today. Ignorant of the seriousness of their condition, they are liable to undertake exercises which may lead to cardiac decompensation. As yet we have no careful supervision of such patients; not a few of them have come to the clinic with heart lesions, and complaining of dyspnea, dizziness and palpitation, while doing routine gymnastic work in school.

#### VOCATIONAL GUIDANCE

Some provision should be made for the employment of those patients unable to do regular work. This could best be accomplished by establishing a vocational department in connection with the clinic, where patients could learn a vocation that would be of value to them as a means of livelihood. Here, their work could be carefully supervised, and the amount of physical work could be graded in each individual case. Such patients in a well organized occupational department could soon be earning enough to maintain themselves as well as their families. Excellent cooperation has been established between the Central Free Dispensary and the Henry Favill School of Occupation. This institution is not large enough to meet the demands of a cardiac clinic

of this size, and a lack of funds prevents the institution's branching out along the practical vocational lines that these patients require. Six of the patients from the cardiac clinic have been referred to the Henry Favill School with special instructions as to the type and number of hours of work that they can tolerate. They are carefully supervised by a trained worker who reports to the clinic the general ability and progress of the patient. They do weaving, chair-caning, basket-making, sewing and special carpentry. Their hours of work are gradually increased as they become stronger. Unfortunately, the Favill School is unable to take children under 16 years of age or to take care of patients who are unable to leave their homes. The Service League for the Handicapped has provided material for knitting to be done by our patients at home. This does not solve the problem, as it gives no vocational training which would make the patients economically independent.

#### VALUE OF THE CLINIC

The educational and therapeutic value of such a clinic to the patient is self-evident. In a specialized department of this kind, a patient may receive more individual attention, and the follow-up work may be more unified and accurate. The physicians and students are also greatly benefited because of the almost absolute control an organization of this kind may have over the patients. The therapeutic effect on each individual case may be watched from time to time and any beneficial or deleterious results readily noted. In one single clinic, we were able to see cases of aneurysm, auricular fibrillation, heart block and several mitral lesions. The patients are always willing to cooperate with the physician, thus benefiting themselves personally, and they are also willing to aid by offering themselves for teaching purposes. Records are kept on file, so that on a moment's notice patients may be called on to appear in the clinic for further observation by the physicians and students. Should a series of cases of auricular fibrillation be desired, we need only notify these patients, and invariably enough will appear to make a very desirable clinic.

One can readily see how the establishment of these clinics with a unified organization in a city as large as Chicago can be of the utmost value to the community. In order to increase the efficiency of such a clinic, a full-time social service worker should be employed to devote her time to follow-up work and to the keeping of careful records for statistical purposes. The main object of this clinic should be to teach the patients a vocation that is best suited to their physical capacities. By so doing, many of our cardiac cases, now dependent on charitable organizations, may be made a benefit to the community and be economically independent. Every well established general hospital can and should have, as a part of its outpatient department, a well organized cardiac clinic.

122 South Michigan Avenue.

#### NUPTIAL PROTOGENESIC OR FIRST BIRTH DISTRIBUTION

In a series of 220,021 nuptial first births in Australia during the years 1907-1914, inclusive, the Australian statistician Knibbs has compiled the records according to "age last birthday" and "duration of marriage," by which he arrived at what may be termed "the nuptial or first birth distribution." In order to reduce the records so compiled to more of a percentage basis, Knibbs has multiplied the actual number of births in each instance by the factor that would make the total 1,000,000, and then has reported for each single month of duration of marriage from one to twelve and for each year from one to twenty-six the proportionate number of births that would occur on this basis. On examining this table one is struck by the large number of births that must be regarded as originating from prenuptial insemination. Age 16 of wife shows 382 births in a million during the first month after marriage, 423 during the second month 514 during the third, 532 during the fourth, 568 during the fifth, 541 during the sixth, 486 during the seventh, 295 dur-

ing the eighth, and only 91 during the ninth and 95 during the tenth month. Age 19 of wife shows 1,886 births during the first month after marriage, 2,227 during the second month, 3,513 during the third, 4,272 during the fourth, 5,127 during the fifth, 6,054 during the sixth, 6,760 during the seventh, 4,609 during the eighth, 2,850 during the ninth and only 3,909 during the tenth month. Age 21 of wife shows 1,877 births during the first month after marriage, 2,309 during the second, 3,454 during the third, 4,640 during the fourth, 5,704 during the fifth, 6,981 during the sixth, 8,331 during the seventh, 6,613 during the eighth, 4,613 during the ninth and 9,122 during the tenth month. Not until age 21 is reached is the number of births during the tenth month greater than the number during the seventh month. The relative proportion of births during the tenth month, as compared with those during the seventh month, increases from age 21 on. At age 23 of wife it is 11,981 as to 7,254, at age 24, 11,467 as to 4,959; at age 27, 7,649 as to 2,254; at age 30, 4,191 as to 877. After age 30 of wife there is not much difference in the relative proportion for the following ages. To be sure, a certain percentage of the births after six and seven months may be due to postnuptial insemination. What is the significance of the foregoing facts? Does a considerable portion of Australia's population believe that the marriage ceremony is superfluous unless children are to be born whose births must be made legitimate before the law? But before we apply this assumption to Australia, it might be interesting to know what results similar investigation would show in this and in other countries.

## Society Proceedings

### COMING MEETINGS

Society of American Bacteriologists, Boston, Mass., Dec. 30-31.  
Society of State of Association, New Orleans, Dec. 16-18.  
Western Kinetren Society, Chicago, Dec. 10-12.

### SOUTHERN MEDICAL ASSOCIATION

1919-20 Annual Meeting held at Asheville, N. C. Nov. 10-15, 1919

The President, DR. L. F. BARKER, Baltimore, in the Chair

#### Cautery in Acute Epididymitis

DR. J. C. VINSON, Tampa, Fla.: The procedure when properly carried out is painless. The treatment is essentially an in-office procedure. The effect on the infection is obvious. The immediate and remote effects are as good, if not better, than the cutting operation.

#### Value of Large Single Doses of Digitalis in Treatment of Heart Disease

DR. J. LANBY ROBINSON, St. Louis.: The administration of the tincture of digitalis in large single doses is advocated as a useful method of treatment in certain cases of heart disease provided the tincture is standardized, the dosage properly regulated, and the patient under close observation. This method of administration not only brings the heart rapidly under the influence of the drug, but also affords a much more means of studying its effect than the older method of small repeated doses. Problems of dosage, especially the relation to body weight, still need solution. The beneficial effect of digitalis in cases with cardiac irregularity caused by auricular fibrillation is especially emphasized by our experience.

#### Scientific Teamwork in Diagnosis and Treatment of Diseases of the Eye, Ear, Nose and Throat

DR. E. M. CARR, Dallas, Texas.: Group practice is desirable, whether it be from the point of view of a surgeon, a medical man, or an ophthalmologist dominating the situation.

#### Treatment of Visceroptosis

DR. F. W. WILKERSON, Montgomery, Ala.: For treatment, these patients may be classified as (1) those who can be

given ambulatory treatment and (2) those who require a preliminary period of rest in bed. The general principles of treatment are followed in both cases, the mild cases coming in the first class, the severe ones in the second class. Not all patients who have visceroptosis can be cured, but about two thirds can be given permanent relief and the other third temporary relief.

#### Intestinal Protozoa: Diagnosis and Treatment

DR. S. K. SIMON, New Orleans.: In only one instance do we possess a specific remedy against intestinal protozoa: infection by *Endameba dysenteriae*, which is promptly controlled by the use of ipecac or its alkaloid constituents. Emetin merits a high place in the treatment of the acute or active phases of all forms of endamebiasis, but cannot be depended on for the complete clearing of the intestinal tract in chronic cases. For this purpose I believe the entire powdered ipecac root is needed. This drug must be administered daily, in full concentrated doses, covering a period of from ten days to two weeks. If given by mouth in one dose in the form of enteric coated pills, the ipecac can be made to reach the large bowel, where absorption takes place directly within the confines of the disease area. The early optimism in regard to the Jutte method of transduodenal lavage has not proved justifiable, as I have convinced myself from numerous and repeated observations.

#### Effect and Maintenance of Intra-Abdominal Pressure

DR. J. B. FITTS, Atlanta, Ga.: Normal intra-abdominal pressure is a necessary physiologic entity. Low intra-abdominal pressure is a factor in general physical inefficiency. It is of particular importance in disease of the gastro-intestinal tract. It can be maintained by the application of physiologic principles.

#### Focal Infection

DR. THOMAS D. COLEMAN, Augusta, Ga.: In the treatment of cases of focal infection, it is essential that (1) the focus or foci should be removed when the end justifies the means, and one should keep in mind the possibility not only of not doing good, but also of doing harm: "Non nocere." (2) Every agency, both in building up the bodily defenses and ameliorating symptoms as they arise, should be employed. (3) To all those who lean to radicalism, I would suggest the motto: "Festinate lente."

#### Lesions of the Fifth Cranial Nerve in Connection with Auditory Vestibular Disturbance

DR. E. R. CARPENTER, Dallas, Texas.: The otologist should never be contented with making a diagnosis of nerve deafness, but he should determine whether or not the lesion is of intracranial origin. The prognosis and treatment depend on this point. The neurologist or brain surgeon may not be consulted until the disease has advanced too far to prevent deafness or loss of life. In Cushing's book on "Tumors of the Auditory Nerve," the sad fact appears that in his thirty-five cases the first symptom was disturbance of hearing, yet all the patients came to him in an almost hopeless condition, being either paralyzed, blind, or nearly blind, or they had some other equally serious complication that rendered the observation exceedingly dangerous and the prognosis serious even if they survived the operation.

#### Intranasal Surgery Without Packing

DR. WILLIAM T. PATTON, New Orleans.: The advantages of leaving out packing are greater comfort to the patient, who often is able to breathe through the nose continually, and much less reaction to disease in the nose. Usually twenty-four hours after operation, if clots are clearing out of the nose, it is surprising to see how little reaction remains. There really seems to be less bleeding without packing in most cases, that is, provided we use the epinephrin spray, cold compresses, and keep the patient in a reclining position. If a hematoma forms between the flaps, it is a simple matter to curet and again seal the flaps, applying compound tincture of benzoin. If there is much hemorrhage, it may become necessary to pack. Again no harm is done.

### Vincent's Disease

DR. JOHN J. SHEA, Memphis, Tenn.: Vincent's disease is a degenerative condition and not an inflammatory condition. A smear should be made and studied of every acute throat and gum disease, and not all the reliance be left to a culture. Medicinal treatment is only temporary, and surgical intervention is indicated for permanent relief. The infection should be made reportable, and in armies, schools and institutions, it should be considered contagious and should be quarantined. One should always work in conjunction with a competent dentist.

### Radical Mastoid Operation: Indications

DR. ELBURNE G. GILL, Roanoke, Va.: The radical mastoid operation is not indicated in all cases of chronic aural suppuration. It is possible to get dry cavities in most cases. The hearing in the average case should be improved. With proper technique, the operation is not dangerous. The condition calling for operation is usually a dangerous one, and is too frequently dealt with lightly.

### Comparative Study of Gastric Motility as Determined by the Ordinary Test Meal and Six Hour Barium Retention

DRS. HARVEY G. BECK and JOHN EVANS, Baltimore: Our observations indicate that frequently when adhesions involve the pylorus and duodenum, the power of the stomach to empty itself is at first increased and later diminished. The degree of gastric acidity seems to have little or no influence on the amount of gastric contents after a test breakfast or six hour retention. No interpretation should be made on this point without studying the acid curve by the Rehfluss method of fractional gastric analysis. The motor function of the stomach can be determined by the complete removal of a standard test meal with the partial vacuum method. There is no constant relation between the motor function as determined by the test meal method and six hour barium. Six hour barium retention occurs after a motor meal if the stomach contents exceed 200 c.c. in fifty minutes or 150 c.c. in sixty minutes. The comparative results of the two methods are most uniform and constant in duodenal ulcer. Six hour barium retention occurs more frequently in adhesions involving the pyloroduodenal region than in either duodenal or gastric ulcer. There is little evidence to show that the secretory function has any influence on the motor function in pathologic conditions affecting the stomach and duodenum.

### Interpretation of Muscular Imbalance

DR. HIRAM WOODS, Baltimore: The meaning of muscular imbalance cannot be determined by the balance test alone. Functional force of muscles should be determined by their power to overcome prisms. Owing to the close relation between accommodation and convergence and the ease with which they can be separated, convergence prism strength must be regarded as the extent to which this separation is possible, not as indicating the intrinsic power of the interni. In horizontal heterophoria the basis of calculation should be divergence power (abduction) because of the single nerve supply of the externus. The minimum of abduction should be 5 degrees, the minimum of positive relative convergence should be from three to four times as great. The vertical recti should practically balance each other at from 2½ to 3 degrees. In prescribing prisms for constant wear, the muscle to be helped should be weaker than normal and its antagonist stronger; otherwise, there is danger of converting one form of heterophoria into another.

### Signs and Symptoms of Hypopituitarism

DR. STEWART R. ROBERTS, Atlanta, Ga.: Undergrowth, dwarfism, dysgenitalism, feminine hirsuties, feminine type skeleton, lack of secondary sexual characteristics, genital atrophy and impotence, headaches, languor and weakness may appear in varying degrees in different cases at different periods. The classic signs and symptoms of hypopituitarism are subnormal temperature, dry skin, adiposity, low blood pressure, slow pulse, constipation, amenorrhea, drowsiness and inactivity. Lack of attention, impairment of memory, actual dulness, and mild psychoses to actual convulsive seiz-

ures with epileptic attacks may occur. The cause may be glandular deficiency of one or both lobes, a pituitary tumor with damage of the gland, or a neighborhood tumor or hydrocephalus with pituitary pressure. The symptoms of intracranial tumor may be more prominent than those of pituitary deficiency. Infantilism, dysgenitalism and obesity, symptoms of intracranial tumor, warrant pituitary study.

### Responsibility of Physicians Who Treat Malaria Cases

DR. C. C. BASS, New Orleans: The important duties or responsibilities of physicians who treat malaria cases are: To begin promptly proper treatment with the specific remedy for the disease, quinin, not neglecting it for spectacular methods of treatment; to advise the patient of the proper diagnosis and nature of the disease; to advise him of the mode of transmission of the infection and of the great danger of transmission to other members of his family and associates, endangering their health and perhaps life, and to advise and prescribe specific treatment which will disinfect the patient so as to avoid relapse and prevent transmission.

### Coccidioidal Granuloma

DR. KENNETH M. LYNCH, Charleston, S. C.: No successful treatment has been devised, and all patients but one died within from a few weeks to nine years. The patient who recovered was one in whom the infection was recognized in an extremity and the infected member amputated apparently before dissemination had occurred. I saw the first case of *Coccidioides immitis* infection in South Carolina and east of the Mississippi, it being the forty-fifth case, the second in a woman, and the fourth that had not been in California. It is highly probable that infection by *Coccidioides immitis* has occurred in cases in which we have not recognized it, and it is desirable that those cases of supposed tuberculosis in which the tubercle bacillus is not demonstrable should be investigated carefully for this or kindred infection.

### Status of Amebic Dysentery: Diagnosis and Treatment

DR. RANDOLPH LYONS, New Orleans: Macht and Fisher believe that benzyl benzoate has amebicidal qualities. Haughwout and Lantin treated eight patients (including Osuzano's two patients); all were benefited. The dose varied from 10 to 30 drops, three times daily. The cases have not been followed long enough to make any definite statement as to cure. Ipecac and its alkaloids are still the sheet anchor in the treatment of amebic disease. The tendency of the times is to administer a combination form of treatment, that is to say, emetin hydrochlorid is given hypodermically in conjunction with the oral administration of either emetin hydrochlorid, powdered ipecac or emetin bismuth iodid. Occasionally some other drug may be administered by mouth, as chapparro or bismuth.

### Subacute Combined Degeneration of Spinal Cord

DR. WILLIAM G. SOMERVILLE, Memphis, Tenn.: There is a similarity between the nervous symptoms of subacute combined degeneration of the spinal cord and pellagra. Both diseases have in common secondary anemia, gastro-intestinal disturbances, degeneration of the posterior and lateral columns of the cord, pigmentation of nerve cells, and frequent occurrence of mental symptoms. One of the chief points of difference is the presence in pellagra of the characteristic skin lesions. The secondary anemia is common to the two, but more intense in the subacute combined degeneration, and more likely to assume a pernicious type. *Ceromonia intestinalis-hominis* has been found in the intestinal discharges of both, in every case of pellagra, according to Jelks, and in my case of subacute combined degeneration.

### The Minnesota Rural Clinic

DR. E. J. HUCENIKENS, Minneapolis: The value of these rural clinics consists in: the teaching of the proper feeding of infants and children, and the especial value of maternal nursing; general hygiene instruction; the value of fresh air, sunshine and proper clothing; the early recognition of defects before they are obvious to the parents; the awakening of general interest in child health and child welfare and last, but not least, the education of physicians.

### Hookworm and Manifest Tuberculosis

DR. ROY D. ADAMS, Washington, D. C.: While hookworm disease and tuberculosis are often referred to in the literature as being related, and though the inference is frequently that the connection is one of cause and effect, no serious studies have been made which place the relationship on anything firmer than a speculative basis. A generally lowered resistance, incidental to hookworm disease, especially evident as anemia and malnutrition, is credited with being the essential factor producing lapse of immunity to tuberculosis. There is no evidence establishing any specific relationship between the two diseases. As it has been demonstrated that the mortality from tuberculosis may be reduced by a measure so simple as the elimination of hookworm when double infection exists, the obligation of the physician with regard to diagnosis and treatment is apparent.

### Empyema

DR. FRANK K. BOLAND, Atlanta, Ga.: Making the earliest possible diagnosis of acute empyema is a burden which falls in the general practitioner, the pediatrician and the internist, who must ever be ready with the exploring needle. How often has pus in the chest been called unresolved pneumonia for so many days or weeks that the condition was already chronic before its presence was known? Tube drainage and suction are needed. The use of surgical solution of chlorinated soda is not advised immediately following the opening of the chest in acute empyema. A few days later, when the abscess has had time to become well walled off, and there is no danger of a bronchus communicating with the cavity, it may be tried. The last word in the treatment of empyema has not been said.

### The Medical Profession in the War

DR. JERE L. CROOK, Jackson, Tenn.: Surgery's outstanding gains may be thus summed up: the Carrel-Dakin method of treating suppurating wounds; a revival of the use of débride-ment, first used extensively in the Napoleonic war; the treatment of shock caused by hemorrhage with blood transfusion and the citrate method, demonstrating the great superiority of blood over salt solution because the former has real sustaining power and the latter is temporary only because it merely carries it out of the vessels; the paraffin treatment of burns; improved methods in the treatment of fractures and the use of the Thomas and Blake splints and the alkan frame; early mobilization of injured joints; management of lung injuries; improvements in plastic surgery, and the education of the crippled.

### Toxic, Nonexophthalmic Goiter

DR. WILLIAM D. HAGGARD, Nashville, Tenn.: This type of goiter is quite as dangerous, if not more so, than exophthalmic goiter, because the toxin seems to have a selective action on the heart, causing the so-called "goiter heart," thyrotoxicosis instead of the mechanical "goiter heart" from pressure. It is more likely to be overlooked on account of the absence of exophthalmos. Many simple adenomas are prone to degenerate and produce toxic symptoms. An atoxic goiter may be of long duration before producing toxic symptoms. There is danger in administering iodine in a case of goiter of this nature. It may set up toxic and sometimes fatal symptoms. Toxic nonexophthalmic goiter occurs in one out of four cases that are not hyperplastic. Toxic goiter is an extremely insidious by-ligation. Operation for toxic nonexophthalmic goiter is dangerous, if not more so, than in the exophthalmic type, owing to the condition of the patient. In my last series of 100 toxic cases, exclusive of the so-called "goiter heart," death occurred in thirty-three operations, and only two deaths in sixty-seven exophthalmic cases.

### Nonhypertrophic Forms of Prostatic Obstructions

DR. HANFORD LEWIS and NEL S. MOORE, St. Louis: Hypertrophic obstruction at the bladder neck is a definite pathologic condition, appearing at any age, but most common in later life. Its diagnosis is practically easy, provided a systematic examination is made. Cystoscopy is most important. The treatment used is very simple and easy to do, if

done properly. The risk is comparatively small and the results in appropriate cases have been very satisfactory.

### Treatment of Acute Abdomen

DR. J. P. RUYAN, Little Rock, Ark.: It is a safe and sane procedure to operate early in acute suppurative peritonitis. After the stage of contamination comes, the stage of diffuse peritonitis, the Ochsner treatment offers the largest percentage of recoveries. The exceptions are perforation of duodenal ulcer and gunshot wounds of the hollow viscera. One should not be in too great a hurry to operate once the Ochsner treatment has been begun. Following the Ochsner treatment, operation should be done and Crile's principles applied in the after-treatment of all cases of septic peritonitis. When there are large areas of denuded peritoneum, from which may be expected a considerable flow of pus and serum, gauze drainage after the manner of Mikulicz or Price will give the most satisfactory results. In cases in which no peritoneal denudation has occurred, rubber tube drains will suffice.

### Malignant Moles

DR. H. H. HAZEN, Washington, D. C.: Every acquired mole and every congenital mole that is liable to irritation should be removed, preferably by canter. Whenever a mole begins to grow or to show signs of either irritation or ulceration it is an imperative sign for immediate extensive operative inference, preferably with the cauter, though this will often be too late. When numerous metastases have appeared, treatment is useless. In the cases in which involvement is only in the lymph nodes, extensive block dissection might occasionally effect a cure.

### Radium in Gynecology

DR. WILLIAM C. GEWIN, Birmingham, Ala.: Radium is the treatment of choice: in cases of menorrhagia of the menopause not associated with large fibroid tumors, and in which the possibility of carcinoma has been definitely eliminated; in cases of menorrhagia in patients between 35 and 40 years of age who have small sized mucous fibroid tumors with no demonstrable evidence of malignant conditions existing; in cases of myoma in which there is a contraindication to operation; in cases of menorrhagia in young persons who have resisted all medical treatment; in all cases with a malignant tendency, and in all operable cases after a complete surgical extirpation of all cancer possible as a prophylactic, and also to destroy such cancer cells as are not possible to be removed by the surgeon. In all inoperable cancers of the uterus, radium will relieve pain, eradicate the offensive odor from the discharge and stop the hemorrhage, and in many cases produce an anatomic and symptomatic cure when the patient seems to be moribund. Radium will render operable many cases that are inoperable. The use of radium is practically the only means of relief in cases of recurrent carcinoma of the uterus. In the use of radium it is very essential to have a thorough knowledge of the technic of its application and of its physical properties.

### Value of Radium in the Treatment of Bladder Tumors

DR. J. T. GERAGHTY, Baltimore: While benign and malignant papilloma and the early papillary carcinoma disappear under the influence of radium, the infiltrating types have proved very resistant to this agent. It is our procedure, therefore, when the infiltrating character of the growth has been determined and when the tumor is sufficiently localized to permit of complete removal, to carry out a radical resection. Following the removal of an infiltrating papillary carcinoma, cystoscopy should be done at an early date, as the not infrequent recurrences will yield promptly in many instances to radium, notwithstanding the resistance of the primary tumor. The use of radium has not diminished the tendency of bladder tumors to recur, recurrences being observed in about 30 per cent. of the cases treated. The recurrence, however, responds to radiation in most instances.

### Pulmonary Syphilis

DR. J. H. GIBBS, Columbia, S. C.: A chronic pulmonary disease, physically indistinguishable from the common types of

chronic pneumonitis, and producing a symptomatic picture similar to that of pulmonary tuberculosis, is not infrequently associated with a positive Wassermann reaction, and the favorable change in general and local conditions following antisyphilitic treatment is so striking as to lead one to the opinion that the syphilitic process is, at least, in part responsible for the pulmonary pathologic condition.

#### Ileocolitis

DR. N. C. WOMACK, Jackson, Miss.: Ileocolitis is mainly due to a gas-producing bacterium. In my opinion, this bacterium is an attenuated or malignant form of the colon bacillus. There is always an attending pyelitis in which the colon bacillus is found in great number. This pyelitis may antedate and certainly is the immediate complication of ileocolitis, and assumes the major rôle from the standpoint of the cause of death. In the treatment of ileocolitis, first attention should be paid to the kidney. Forced feeding of a selected carbohydrate diet with plenty of water should be given. All forms of rectal irrigation or alimentation should be interdicted on the ground that they not only do no good, but are distinctly harmful.

#### Maternal Feeding of Infants

DR. J. D. LOVE, Jacksonville, Fla.: The mother's dietary should consist of food generous in quantity, easily digested, and above all a food to which she is accustomed. A food that causes indigestion in the mother will cause trouble for her nursing baby. On the other hand, if a mother can handle well even the most indigestible food, her baby will rarely suffer in consequence. The gross appearance of breast milk furnishes an unreliable index as to its suitability for the baby. Before milk is pronounced as being too rich in quality, the presence or absence of colostrum bodies should have been determined. The mere fact that milk is scant in quantity furnishes no valid excuse for the withdrawal of the infant from the breast, but rather calls for supplemental feedings. In influencing the quality of breast milk, the maternal dietary, while of some importance, is a smaller factor than causes which operate through the medium of the mother's nervous system.

### CLINICAL CONGRESS OF AMERICAN COLLEGE OF SURGEONS

*Ninth Annual Meeting, held in New York, Oct. 20-24, 1919*

*(Concluded from page 1722)*

#### Brain Tumor

DR. HARVEY CUSHING, Boston: I have undertaken a statistical résumé of brain tumor cases (or suspected brain tumor cases) studied during a fifteen year period. Generally speaking, about 80 per cent. of these were tumors, of which half were verified by operation or necropsy. Another important question to settle is what are operative fatalities and what operative recoveries. Of twelve patients from whom tumors were removed, all died. Two patients entered the hospital within one week of each other. Both suffered from the rare kind of brain tumor, a cholesteatoma, or mother of pearl tumor. From a superficial study of statistics one might suppose this tumor is common, but only six have been recorded in the literature. It is of the highest importance in these cases to agree on certain standards of classification so that surgeons may know they are speaking the same language as regards results.

#### DISCUSSION

DR. CHARLES H. FRAZIER, Philadelphia: I would like to refer to the use of callosal puncture in this field. In all pretentorial tumors the symptoms are due to distention of the ventricles which often brings matters to a fatal issue. The increased tension appears before localization is possible. I hoped that an opening could be made and drainage instituted in the corpus callosum so that in an inoperable growth, the life of the patient could be prolonged by this means. It was, however, of but transitory benefit. Lately I have combined

callosal puncture with subtentorial decompression. My attention has also been attracted by the relation of chronic meningitis to brain tumors. An exploratory operation does not always exclude brain tumor, as the growth may be overlooked. In many cases, however, it seems that one is dealing with a preexisting meningitis. It is better not to wait to localize a tumor, but to operate early. There is clinical evidence that with the use of radium the tumor undergoes retrograde changes. In one such case, an enormous cerebellar tumor so adherent that its removal was impossible, the use of radium was combined with operative measures, and now five years later, there is no sign of recurrence. In another case, in which the patient was stuporous and bedridden from tumor at the cerebellopontile angle, a tube of radium was embedded and left in situ. The patient has recovered so far as to be able to return to work. As to operative mortality, I do not feel that when the patient dies of subsequent meningitis we should charge this up to operative mortality. The length of cure depends on the type of tumor. Endothelial growths are slow growing. Seven years would not be too long to wait for recurrence. All cases should be observed at least for five years.

DR. ALLEN B. KANAVEL, Chicago: Good results depend not only on the skill of the operator but also on the opportunity of early and correct diagnosis. The profession is too apt to believe that such symptoms as projectile vomiting, headache and choked disk are diagnostic. Progress will not begin until medical men learn that these are not the signs of brain tumor, but of its terminal stage. When this is learned we shall be able to cure, not merely relieve, the patients. Too often the case progresses far beyond the stage at which successful operation is possible. It is therefore necessary to arouse the interest of the profession to the diagnostic phase of the early stages. A nation-wide study must be inaugurated. Classified data should be collected and published. This would undoubtedly give rise to the performance of curative operations, instead of merely palliative ones.

DR. CHARLES A. ELSBERG, New York: Any one who has followed the history of brain surgery during the last fifteen years will feel that this field has not received the attention it deserves. The justification for specialization in neurologic surgery is now well recognized. The improvement in results in ten years is very striking. Mortality has dropped from 43 per cent. to 10 per cent. This is due to combined improvement in diagnosis and technic, and more skilful surgical judgment rather than to selection of cases. I saw one case of cholesteatoma in which three fourths of one hemisphere was involved. The growth was successfully removed and the patient recovered.

#### The Acute Abdomen

DR. JOHN B. DEAYR, Philadelphia: The acute abdomen occupies too prominent a place in mortality statistics. Among the reasons for this is the fact that too many untimely and unsuitable operations are performed in the treatment of this condition. This is in part due to the want of intimate knowledge of living surgical pathology, in part to too great a reliance on laboratory findings, and to the hesitancy to resort to radical measures in the hope that the symptoms may pass away under what is called conservative treatment. Occasionally, the acute abdomen is the result of conditions not recognized by even the most astute. The foolish belief that chronic ulcer, chronic gallbladder disease, chronic appendicitis, etc., can be cured by medicine, diet, rest, etc., is a perverted faith that courts disaster. A very abdominal wall which shows a penetrating wound, whatever its location and whatever the agent that inflicted the wound, should be opened. Similarly, severe blows on the abdomen, or a fall on the abdomen, or being crushed between wheels, should bring to mind the possibility of one of the various subacute injuries that not infrequently occur. In these cases it is better to open the abdomen on suspicion and do nothing than to wait for an untimely diagnosis and hemorrhage. The earlier the acute abdomen is seen and the earlier suitable surgical treatment is instituted the more favorable will be the prognosis. There are certain conditions of the abdomen in which surgery is not indicated.

Among these are acute dilatation of the stomach, acute post-operative gastric dilatation, acute gastro-enteritis simulating appendicitis, and conditions mistaken for the acute abdomen, such as pneumonia, diaphragmatic pleurisy, and the gastric crises of tabes. The physician and the laity should know the harmful possibilities of the purgative. The purge belongs to the same class, but is more deadly than morphin. In the acute abdomen amenable to surgery, early intervention is, of course, the best procedure. On general principles it may be said that in the acute abdomen with diffuse peritonitis, in the absence of a reliable history or a reasonably sure diagnosis and of a localised point it is good judgment to defer operation, treating the patient by strict anatomic and physiologic rest. In circumscribed or localized peritoneal inflammation, operation is comparatively, if not entirely safe, with proper support. The carefully elicited history is the point around which diagnosis should develop. I do not attach the same importance to the blood count that some surgeons do.

## DISCUSSION

DR. J. M. T. FINNAY, Baltimore: Two important things should be borne in mind:—One is the diagnosis and the other is treatment. The main question is how to make the diagnosis. When that is reached, the rest is easy. Several cases have come under my observation in which the symptoms pointed to an acute abdominal condition, and in one of these an operation for appendicitis was performed. In the course of twenty-four hours these patients were found to have peritonitis. Such occurrences serve to emphasize the difficulty of making a diagnosis of the acute abdomen, and the danger of mistaking something else for an abdominal crisis.

DR. GEORGE E. ARMSTRONG, Montreal, Que.: The difficulty of making a diagnosis in the presence of the acute traumatic abdomen may best be illustrated by citing several cases. Two cases have come under my observation in which after traumatic injury there was a quiescent period during which the patient manifested few symptoms, and yet at operation the small intestine was found to be completely severed and the ends of the intestine closed off by the local reflexes so that there was no leakage. It may be said that after certain traumatic injuries to the abdomen there is frequently a quiescent period of from twelve to twenty-four hours during which the patient and the patient may decide what is to be done. I would emphasize the evil of purgatives. The inadvisability of giving strong morphin is also to be emphasized. There are instances in which it is well, when the symptoms are few, to give food and water.

DR. STUART MCGUIRE, Richmond, Va.: It is necessary to emphasize that the acute abdomen is not always surgical and sometimes when it is surgical it has reached a stage at which operation would be unwise. In some cases by postponing operation and treatment by palliative measures a patient's case became a safe risk. When in doubt, I am inclined to wait. I agree thoroughly with the commendation of the surgeon here, but I do not think morphin has been given the credit it deserves. It should not be given while the diagnosis is being made, when the diagnosis is once made, the patient should have the relief from pain that morphin affords. I believe in the Fowler-October-Murphy treatment.

Berberi at Bahia. In a recent paper published by Dr. J. J. F. de Lima, de Bahia, he discusses the occurrence of berberi at Bahia during recent years, especially as shown in the mortality of the insane asylum and the state penitentiary. In the former there were in 1902, 34 deaths caused by berberi, 2 in 1903, 58 in 1904 while more recently there were 16 deaths in 1914, 4 in 1915 and 8 during the year 1917. At the penitentiary there were outbreaks of berberi in the years 1897, 1900, 1901, 1902, 1903 and 1908; in the latter year there were 112 cases with 62 deaths. In the marine hospital which is no longer in existence, there were in the years 1881-1892, 432 cases, practically all landed from warships. In the hospital of Santa Isabel for the last fifty years there has been an annual average of 18.48 cases making a total of 924 cases.

**Influenza Pneumonia and Dish Washing.**—Cummings believes that transmission of the potentially dangerous is group of pneumonia producing organisms, incident to promiscuous messing in the army, in public institutions, in public eating places and in the home, can be prevented largely by the disinfection of eating utensils with scalding water. The universal application of the principle of proper eating utensil disinfection will reduce enormously the prevalence of all sputum borne infections. As is shown in the institutional population, the influenza case rate was reduced by 66 per cent, and the mortality by 55 per cent, through the use of machine washed dishes. It is believed that a further reduction in these rates would have occurred had the full efficiency of all mechanical dish washers been utilized by the use of boiling water. This principle applies to public eating places, as well as to public institutions, and with equal force to the scalding of eating utensils in the private family.

**Wassermann Reaction: Preservation of Complement Serum.**—Of the sixteen methods studied by Kolmer and his associates, preservation with sodium chlorid at a low temperature yielded the best results. When complement is required in dilution of 1:10, the methods of Thompson and Neill are satisfactory for preserving guinea-pig complement for a period of two weeks, provided the serum is kept at a low temperature and preferably not above 4 C. When complement is required in dilution of 1:20 the addition of 0.17 gm. sodium chlorid to each cubic centimeter of serum and keeping at a low temperature preserves the complement for about three weeks.

**Wassermann Reaction: Human Versus Guinea-Pig Complement.**—These studies have shown that from 2 to 10 per cent. of human serums do not contain sufficient complement, natural hemolysin or both for the conduct of these special tests. Human complement is not as satisfactory as guinea-pig complement for the conduct of tests employing heated serum and spinal fluids. The advantages of tests employing human complement are (1) greater delicacy; (2) guinea-pigs are not required, and (3) sheep are not required if an anti-human system is employed. The disadvantages are (1) falsely positive reactions may occur; (2) falsely negative reactions may occur; (3) the serums must be fresh; (4) unsatisfactory with heated serums and spinal fluids; (5) complement, natural hemolysin or both may be absent from serums and (6) isoagglutinins may interfere in tests employing an antihuman hemolytic system. Of the special tests, those of Thompson and Bartlett and O'Shansky proved most reliable.

**Congenital Syphilis in Orthopedic Clinics.**—Roberts is convinced that many syphilitic infections which find their way into orthopedic clinics pass through unrecognized, first because the tradition that nearly all chronic destructive lesions of the spine and large joints are tuberculous has been accepted without question, and second, because the far reaching distribution of congenital syphilis and its potential dangers has been ignored.

**Chronic Diarrhea Probably Due to Syphilis.**—Liser reports a case of chronic diarrhea of one year's duration in which a cure was effected by arsphenamin and mercury. Syphilis as the cause seems reasonable, since malignancy, tuberculosis, hyperthyroidism, achylia and amebic dysentery can be excluded. No therapeutic measures of any kind were employed, except arsphenamin and mercury.

**Syphilitic and Arsenical Jaundice.**—Jaundice occurring in the course of an attack of syphilis is divided into two groups by Scott and Pearson: first, the jaundice that occurs in untreated cases of syphilis and which is due to an invasion of the liver by the *Spirochaeta pallida*, and second, that which occurs during or subsequent to the treatment of syphilis by arsphenamin, or its substitutes, and which may be due to the organism, the drug or a combination of both. Among 2,243 patients treated for syphilis Scott and Pearson found two cases which showed unmistakable evidence of belonging to the first group and thirty-nine to the second group.

**Four Fatalities Following Use of Arsphenamin.**—The four fatalities reported by Blanton followed an intensive course of arsphenamin treatment consisting of from four to six intravenous doses. There was an average interval of four days between injections; from 0.4 to 0.6 gm. arsphenamin were given at a time. Two days in three cases, and three days in the other case intervened between the time of the last treatment and the onset of the illness. The time elapsing between the admission to the hospital and death was two days in three cases and one day in the other. A striking similarity in symptoms, as well as in postmortem findings existed in all four cases. After a symptomless latent period of about two days, the development of sudden and profound coma was characteristic and dominated the clinical picture so that it was difficult to elicit any focalizing signs at all. There were no cranial nerve palsies. The pupils were dilated in two cases; in two they were unaffected. During the last twenty-four hours of life the reflexes disappeared in all four cases. Two patients had convulsions. Cheyne-Stokes breathing was present in all cases and death was apparently due to failure of the respiratory center. Pathologic study of the brains of these four cases showed similar lesions. These consisted in minute hemorrhages, scattered through and confined to the basal nuclei and that part of the cerebrum bounding the lateral ventricles. These were associated with a softening confined to this locality and seen easiest on gross examination. Cerebral congestion and edema were marked. Increase of cerebrospinal fluid was not a conspicuous finding. In only one case was there a slight fatty degeneration of the liver. In Blanton's opinion the cause of these mishaps is undoubtedly to be found in the toxic

by-products of arsphenamin synthesis, the exact nature of which is unknown.

**Treatment of Late Syphilis.**—Hazen says it is extremely improbable whether any case of late syphilis has ever been cured. Any patient with an active syphilitic process must have sufficient treatment to render the lesions inactive and the blood reaction negative. A small amount of treatment is dangerous, neurorecedives being especially liable to develop after one or two doses of arsphenamin. The condition of the heart and of the large vessels must be watched just as well as the nervous system.

\*Occurrence of Pfeiffer Bacillus in Measles. A. W. Sellards, and F. Sturm, U. S. Army.—p. 331.

Reaction of Leukocytes in Epidemic Influenza. B. Douglas, Baltimore.—p. 338.

**Fate of Bacteria Introduced into Upper Air Passages.**—The general result of Bloomfield's experiments indicates that even after a short period of time it is usually impossible to recover *Sarcina lutea* swabbed in large amounts on the tongue, nasal mucosa, or into the crypts of the tonsils, indicating the remarkable efficiency of the mechanism present in the upper air passages for disposing of this organism. The mouth bacteria play little, if any part, but the saliva and mouth secretions exert a prompt and marked bactericidal effect.

**Meningococcus Pneumonia.**—From the fact that meningococci rank third among the bacteria found most frequently in the lungs at necropsy in cases of pneumonia bemy exceeded only by pneumococci and *B. influenzae*, Holm and Davidson conclude that meningococci were an important factor in the causation of influenza pneumonia at Camp Coetquidon from Sept. 1, 1918, to Feb. 15, 1919. The meningococci present in the lungs in cases of meningococcus pneumonia were essentially the same type of organisms as those found in the spinal fluids in cases of epidemic cerebrospinal meningitis. Cases of meningococcus pneumonia may arise from contact with cases of meningococcus cerebrospinal meningitis and vice versa. The meningococci may produce either bronchopneumonia or lobar pneumonia.

**Occurrence of Pfeiffer Bacillus in Measles.**—The examination of a group of measles cases occurring a few weeks after an epidemic of influenza showed the presence of an organism indistinguishable from the Pfeiffer bacillus in twenty-five of thirty-one cases. This organism was obtained readily from the sputum and with little difficulty from the conjunctivae. The Pfeiffer organism was not obtained from the blood stream nor from the excised skin lesion. With the

presence of the above symptoms of measles these microorganisms disappeared rather rapidly in about three-fourths of the cases. The occurrence of the Pfeiffer bacillus both in measles and in infantile convulsions suggestive evidence against its etiologic relationship in either disease.

**Significance of Small Amount of Sugar in Urine.**—If with persistence and chronic nephritis there is but an occasional trace of sugar in the urine and the blood sugar is not abnormally high, then, Hamman says, the disordered carbohydrate metabolism must be subordinated to the renal or articular condition. If there is marked glycosuria and the blood sugar is unusually high, then the diabetes must be emphasized. The clinical history is of importance. Patients in middle life with mild diabetes often gradually develop arthritis and hypertension, so that finally the renal and articular conditions assume the prominent position in the clinical picture. On the other hand, Hamman has observed instances with hypertension over a number of years and has seen them gradually develop glycosuria and finally a definite clinical picture for carbohydrates.

**Tick Caused Paralysis.**—From the evidence accumulated, Todd says, it is probable that ticks may cause paralysis in human beings, especially in children. In rural districts, patients who develop cases of progressive and sudden paralysis should take it a practice to search for a tick. Care should be given to find all at the back of the head and neck. A tick found there should be removed carefully and sent, if possible, to a laboratory for examination and identification. If the tick's head be torn off and left on the patient's skin, the bite may become infected and an ulcer developed, and in the local infections which have been reported to follow tick bites were exceptionally severe. Practitioners who meet with cases where symptoms are associated with the presence of ticks should record their experience.

**Internal Hydrocephalus and Xanthochromia of Spinal Fluid.**—The syndrome of Froin consists of (a) a spinal fluid which is yellow color (xanthochromia); (b) which coagulates en masse and (c) shows an abundant lymphocytosis. The syndrome of Nonne consists of a spinal fluid showing (a) marked

increase of globulin, (b) without increase of cellular elements. The above features may be complete or partial, and variations may exist in the several factors. The syndrome of Froin, or xanthochromia alone, usually indicates an isolation of one portion of the subarachnoid space from the rest by tumor, adhesions, etc. This separation is usually found at the lower levels of the cord. Internal hydrocephalus may be associated with separation of the spinal from the cerebral subarachnoid space either by adhesions of the brain stem to the tentorium, or by hernia of the distended brain into the foramen magnum. In the case reported by Gordon the possible explanation is (1) basal meningitis (meningococcus or *B. influenzae*); (2) partial recovery; (3) obstruction of foramina in the roof of the fourth ventricle by meningitis; (4) development of a noncommunicating hydrocephalus; (5) hernia of the brain into the foramen magnum; (6) separation and sacculation of the spinal subarachnoid space; (7) development of partial Froin's syndrome lies in the separation of the sacculated portion of the subarachnoid space from the choroid plexus through which normally it is filtered and a reversion of its contents to a simple lymphoid material, yellowish, coagulating and cellular.

**Trypanosome and Spirochete Infections: N-Phenylglycineamide-p-Arsenic Acid.**—Jacobs and Heidelberger have been engaged in the synthesis of certain new types of organic arsenic compounds for the treatment of experimental trypanosome and spirochete infections. A number of substances have been prepared which have given interesting experimental results. However, those obtained with one in particular, the sodium salt of N-phenylglycineamide-p-arsenic acid were such as to demand special attention. The simplicity of this compound, the ease of preparing it, its relatively inexpensive character, stability and solubility, and its favorable biologic behavior, warrant further study. It readily yields a colorless, crystalline sodium salt which is extremely easily soluble in water, forming neutral solutions, which are perfectly stable. In fact, a 10 per cent. solution may be boiled a reasonable length of time without appreciable cleavage of ammonia or arsenic. The materials required and the method of preparation are described in detail.

**Therapeutic Action of N-Phenylglycineamide-p-Arsenic Acid in Experimental Trypanosomiasis.**—This acid is an agent of marked therapeutic action in the treatment of experimental trypanosomiasis of mice, rats and guinea-pigs. It possesses an average curative range of from 0.2 to 0.3 gm.

per kilogram of body weight of the sodium salt against a twenty-four hour infection in mice and rats produced by several species of pathogenic trypanosomes. Since the lethal dose for mice is from 2 to 2.25 gm. and for rats 0.75 gm. per kilogram of body weight, the curative ratios are 1:8 and 1:3, respectively. The curative dose for guinea-pigs is 0.15 gm. per kilogram of body weight, thus giving a curative ratio of 1:10. The trypanocidal activity of this compound is relatively rapid in all three animal species for the peripheral blood is cleared of organisms within twenty-four hours after its administration, and in addition, the lower limits of the curative range are comparatively sharply defined. Intra-peritoneal, intravenous and subcutaneous routes of administration for all practical purposes may be considered equally efficacious in *Tr. brucei* infections of mice both as regards the speed of action of the drug and the average curative range. The administration of the drug in therapeutic amounts in all three animal species is not followed by manifestations of organic or functional injury but, on the contrary, the general physical condition of the treated animal shows an immediate and continued marked improvement. The therapeutic activity in trypanosomiasis of mice, rats and guinea-pigs, as evidenced by the relative speed and sharpness of action, together with the curative ratio as expressed in fractions of the minimum lethal dose and the absence of organic injury or functional disturbance following therapeutic doses, are significant and characteristic features of the amide of N-phenylglycine- $\beta$ -arsonic acid.

Therapeutic results with the amide of N-phenylglycine- $\beta$ -arsonic acid were obtained in rabbits which showed well marked clinical signs of a definitely established disease, and in many instances the infection was extremely advanced and of prolonged duration.

**Action of N-Phenylglycineamide- $\beta$ -Arsonic Acid on Spirochetes Infections.**—This acid is capable of exercising a very definite effect on the course of infections produced by spirochetes of the recurrent group and by *Spirochaeta pallida*. It is difficult to say, however, just how these effects should be interpreted. In the case of the blood spirochetes, the infection is ameliorated, and even though the spirochetes are not immediately destroyed, the infection is frequently brought to a termination which leaves the animal in a condition not unlike that produced by more powerful spirocheticidal agents. That is, the infecting organisms are either affected in such a way that they eventually die off or are destroyed by the host in such a way that no lasting immunity is developed in consequence of their destruction. With either group of organisms, therefore, N-phenylglycineamide- $\beta$ -arsonic acid appears to act in a manner somewhat different from that of the usual spirocheticidal agents. While it does possess a considerable degree of spirocheticidal action, its chief effect is seen in the peculiar manner in which it modifies or controls the course of these infections.

**Changes in Testes in Pneumonia.**—Sixty cases were studied by Mills. Pneumonia was the cause of death in every instance, but in some cases it was the sole factor, while in others it was preceded by measles or epidemic influenza. The testicular changes in pneumonia are without clinical manifestations, are nonspecific, focal in character, independent of the infecting organisms or the antecedent disease, and vary in severity directly with the total length of the illness. The process is a continuous one, divisible into stages in which the following features are recognizable: (1) cessation of spermatogenesis; (2) degeneration of pre-formed spermatocytes, spermatids and spermatozoa; (3) desquamation of altered cells and fragments of the same; (4) formation of giant cells in the tubule walls with subsequent liberation into the lumen; (5) disappearance of all desquamated cells in all those derived from the spermatogonia by mitosis; (6) in some instances thickening of the hyaline layer of the basement membrane. The hemolytic streptococcus produced more extensive changes, both epithelial and interstitial, in primary pneumonia occurring during the measles epidemic than when pneumonia followed as a secondary infection; in the latter cases the pulmonary complica-

tions covered a relatively shorter period. Measles and epidemic influenza had little apparent effect on the testes, except that the former caused mild inhibition of spermatogenesis; evidence regarding the latter is inconclusive. The Pfeiffer bacillus was always associated with other organisms, in primary infections and in those following measles. It occurred alone in a few cases after epidemic influenza, but the testicular lesion was not distinctive. The pneumococcus when alone in primary infections or after an epidemic disease produced a uniformly mild picture which was not intensified when associated with the influenza bacillus. Giant cells were much more frequent after influenzal pneumonia, regardless of its cause and were associated with large numbers of other desquamated cells. They are formed in the walls of tubules by futile mitotic effort and incomplete protoplasmic separation, the abnormality of the process being further suggested by the early severing of cytoplasmic attachments and rapid desquamation.

**Empyema at Camp Dix.**—According to Leopold, the patients at Camp Dix who were suffering from empyema due to *Streptococcus hemolyticus* were operated on immediately on finding the organism in the pleural fluid. The operations were performed under local anesthesia. The mortality in this group of cases was 54 per cent. The average mortality among these cases in the national army cantonments was 30.2 per cent. The highest mortality reported was 84 per cent, in a series of eighty-five cases.

**Multiple Neuritis of Toxic Infectious Origin.**—Gordon analyzes seventeen cases. They followed infectious diseases: pneumonia, three cases; typhoid, five cases; measles, two cases; influenza, two cases, puerperal states, three cases. The author suggests that hepatic insufficiency might be responsible for the trouble. Gordon says that however plausible the infectious theory of multiple neuritis may be, hepatic insufficiency seems to form a strong basis even if the disease develops in the course of infectious processes. Moreover the clinical picture in such cases presents certain special features and with such a uniformity that polyneuritis with a hepatic etiology may be considered as a special entity.

**Lung Abscess Following Tonsillectomy.**—About a week after removal of the tonsils Lilienthal's patient began to cough and expectorate foul sputum and occasionally blood. For days and even weeks at a time the patient felt fairly well and coughed but little. Then there would be an attack of fever, hemorrhage, emptying of the abscess, and much coughing with the discharge of large quantities of fetid pus. In the beginning of the illness, the pneumococcus was found in the sputum and autogenous vaccines were given with no apparent improvement; indeed, there was some hemoptysis after each injection. The roentgenogram showed that in the right chest, there was a cavity in the midclavicular line; an area of infiltration from the seventh to the ninth ribs (middle lobe) with a cavity about the size of a walnut; infiltration about 4 inches vertical by 3 inches horizontal. There was much infiltration into the lung tissue outside the zone of inflammatory reaction. The patient's condition went from bad to worse and finally Lilienthal removed the lower, middle and part of the upper lobe of the right lung. The man returned to his work, that of hospital secretary, July 16, 1917, exactly four months after his operation. When clothed, his figure looks symmetrical but there is considerable contraction of the right chest. The wound remained open for nearly a year longer, then gradually closed, but reopened once or twice and finally healed soundly.

**Fats, Cholesterol, Sugar in Blood of Pregnant Women.**—Schiller claims that there is no hyperglycemia in the later months of pregnancy or in the first two weeks after pregnancy. Glycosuria and alimentary glycosuria during this period can be explained by the activity of the glands of internal secretion or as a renal hyperfunction. Hyperlipemia in pregnancy is in reality for the most part a hyperglycemia. There is no parallelism between cholesteremia and hyperglycemia in pregnancy. The etiology of this condition is as yet not established. It seems that the endocrine glands are to be looked on as an important factor.

**Gangrenous Appendicitis and Labor.** Grattan cites the case of a young, vigorous woman, primipara, with a negative Wassermann, normal obstetric outlook and no complaints, in whom there was the simultaneous occurrence of early labor pains with abdominal symptoms, ending in the diagnosis and operation for appendicitis. A totally gangrenous appendix, with abscess and about to perforate was removed. This was followed by protractus of a seropurulent character. A normally formed and developed full term baby and placenta were delivered. A state of apnea in the baby, lasting forty-one minutes, with good pulse was followed by a normal course of three hours. Apnea recurred with normal periods of breathing, finally ending in failure of the baby's heart action and death one and one-half hours after delivery. The cause was probably toxic from the pus in the mother's appendix. There ensued postoperative complications in the mother, i. e., cardiac and renal failure, almost of fatal termination and undoubtedly of toxic origin from the appendix. A subsequent autopsy was an evidence of the effect of the toxemia on the liver function. Complete recovery followed without residual pulmonary and with cardiac, renal or other residue of the complications and without invalidism of any kind.

**Prognosis in Hyperthyroidism.**—Hertzler points out that in hyperthyroidism the general tendency is toward recovery

and that many patients do recover spontaneously. Recovery may be expedited by judicious operations. The time for operation must be selected carefully and the operation chosen must be commensurate with the resistance of the patient. Above all, the operator must ever hold the fact before himself that his operations must be without mortality lest his therapeutic endeavors prove a greater menace than the disease. The young man is too apt to assume that whatever good follows his efforts must have come because of such efforts, and if disaster is averted, it must be because of his efforts.

**Exophthalmic and Thyrotoxic Goiter.**—MacLean has done bilateral resection in thirty-one cases of true exophthalmic goiter or in cases with positive symptoms of hyperthyroidism where both lobes of the thyroid were enlarged. There was no operative mortality in this series.

**Large Vesical Calculi.**—The calculus in Smith's case weighed 38.5 ounces (1,155 gm.) in the moist state. This did not include any of the flakes and fragments which were lost during the removal and which would have at least brought the total weight up to 40 ounces. It was ovoid, light brown in color, smooth and flaked easily. It measured 9.6 by 14.2 centimeters with a circumference of 36 centimeters. Its cut surface resembled the cross section of a tree, being built up of numerous, concentric, yellowish white lamellae about twenty in number. It was apparently of the same composition throughout, no distinct nucleus or foreign body being present. Chemical analysis showed urates, calcium oxalate and earthy phosphates. The urates were the predominating salts. Mucin was also present.

**Operation for Inguinal and Femoral Hernia.**—The method described by LaRoque is offered as a modification of the standard operative procedures employed for the cure of inguinal and femoral hernia. The entire operation is "open." The general peritoneal cavity is opened well above the hernia and exploration is made carefully. Enucleation and removal of the entire sac, including the redundant peritoneum in the region to a point well above the neck of the sac is surely and safely accomplished with the minimum amount of trauma to the cord and other structures in the region. The internal ring and beginning of the spermatic cord can be easily and adequately lifted upward and outward, thus certainly obliterating the internal ring and actually transplanting the proximal portion of the cord at its origin (both of which procedures are useful) rather than merely shifting only the middle or distal portion of the cord to an apparently changed location (the needfulness and permanency of which is questionable). Hernias which have been previously incompletely removed and in which the canal has been properly sutured (so-called recurrences) with a portion of the original sac and its neck remaining, may be cured completely with the least trauma to the cicatricial tissue following the previous operation and without the necessity of reopening a partially or completely obliterated canal.

**Suspension with Fascia Lata in Prolapse of Uterus.**—Freeman secures access to the uterus in the usual way. If the patient is still within the childbearing period, she must be sterilized, best by ligation of the severed ends on themselves. A strip of fascia lata, about 6 inches in length and three-fourths inch in width, is then obtained from the outer side of one of the thighs. The uterus is held firmly while a closed pair of small, sharp pointed, curved hemostatic forceps is plunged from one side to the other directly through the substance of the uterus close beneath the peritoneum covering the fundus, but not penetrating into the cavity. The forceps should be entered just internal to the attachment of one of the tubes and brought out at a corresponding point on the opposite side, although if the organ is large it may be well to tunnel it somewhat more anteriorly in order to prevent undue pressure on the bladder when the uterus is suspended from the tendons of the recti muscles. The strip of fascia is then dragged through so that its center rests in the middle of the tunnel and its loose ends project from either side. Catgut stitches are inserted to close the openings of the tunnel, thus preventing oozing and holding the

fascia in place. The ends of the fascia are secured around the tendinous insertions of the recti muscles in order to bind the fundus of the uterus securely and closely to the anterior abdominal wall. This is accomplished first by stripping back the anterior sheaths of the muscles for a short distance above the pubes, so as to uncover the tendons, and plunging through these and the underlying peritoneum from without inward, a pair of pointed hemostatic forceps with which the ends of the fascial strip are seized and dragged into place, one on either side of the abdominal incision. After the peritoneum is closed, the ends of the fascial strip, which have been retained in forceps to prevent retraction, are pulled tight enough to hold the uterus firmly against the abdominal wall and are then crossed over the median line, best by tying them in a half knot, and stitched securely to each other in several places by means of chromic gut so that they cannot slip. The wound is then closed in layers. Additional security against slipping may be obtained by catching the ends of the suspending fascia in the bight of a figure of eight silkworm-gut suture used in closing the abdominal incision.

**Fenestrated Band in Fractures of Bone.**—Collins describes a new metal band consisting of an alloy of nickel and silver which he has used in operations on lone fractures.

**Patella Splint.**—The appliance used by Rectenwald consists of thin leather straps and felt pads held in place by a mixture of tallow (1 dram) and burgundy pitch (3 ounces).

- With the 1/1st Lowland Field Ambulance in Gallipoli. G. H. Edington.—p. 238.

**Syphilis of Circulatory System.**—MacKenzie says that cerebral arteritis (or meningitis) of the late secondary stage should be treated with arsphenamin, beginning with 0.1 gm. and gradually increased to 0.4 gm. until a total of 3 or 4 gm. has been given. Mercury should also be given, and the result controlled by examination of the blood and cerebrospinal fluid. Late cerebral arteritis (chronic meningitis) should be treated by the initial administration of mercury and iodids for a fortnight, to be followed by gradually increasing doses of arsphenamin, the mercury and iodids to be continued meanwhile, and the results controlled by examination of the blood and cerebrospinal fluid. The greatest precaution must be observed in the treatment of arteritis and its coronary and myocardial complications. Preliminary measures of a hygienic and dietetic character must be taken before having recourse to the administration of arsphenamin. The general condition of the patient must be such as to preclude the possibility of circulatory failure incidental to the vasomotor disturbances which occasionally follow arsphenamin injection. The efficiency of the circulation must be restored to as great an extent as is compatible with the nature of the lesions. Iodid and mercury should be administered orally for a period of a fortnight, and, following this, an injection of 0.1 gm. of arsphenamin may be given

This should be repeated every three days for a fortnight, when the dose may be increased to 0.2 gm. In no case should more than 0.2 gm. be given at a time. Careful observation should be made to note the possible advent of a vasomotor reaction during the injection. This is heralded by a change in the quality of the pulse, which takes on a bounding character and increases in rapidity, and also by a flushing of the face. If any of these phenomena appear, injections should be stopped immediately. The accessory treatment employed in cardiac syphilis with coronary disease, aortic regurgitation, or angina should be continued. Varicose ulcers or chronic phlebitis of the later stages should be treated with arsphenamin and mercury in the ordinary way. In a case of chronic varicose ulcer, excellent results are obtained from the local application of gauze soaked in a 1 in 30 solution of alkalinized arsphenamin. This may be alternated with the local application of fresh human serum applied in the same way.

**Etiology of Infantile Marasmus.**—In Hutchison's opinion there is no evidence to show that in infantile marasmus a defective absorption of fat is a factor in its causation either through imperfect digestion, passage of unduly large motions, or through a defect in the absorptive capacity of the bowel wall. Saponification of fats does not lead to loss of fat through defective absorption. A high percentage of insoluble soaps in the feces fat simply upsets the soap-fatty acid balance, and since the insoluble soaps possess feeble hydrophilic properties, constipation results. The iodine value of the feces fat is lower than in health, and this suggests that in marasmus there may be a qualitative error in absorption rather than a quantitative one. The alkaline reserve of the blood in marasmus is lower than in health, but the diminution is small, and does not suggest an acidosis of any consequence. There is no evidence that there is a lower alkaline reserve on a whole milk diet than on a weak fat milk, so that apparently in marasmus there is not an incomplete metabolism of fat.

**Use of Platinum Chlorid in Pneumonia.** Anklesaria has made use of a 0.1 per cent solution of platinum chlorid in 5 minims doses, in combination with Burney Yeo's effervescent quinin mixture, every four to six hours, in the treatment of pneumonia. He claims to have had very good results. The effect in some instances was really very striking. Within twelve hours of the treatment a noticeable change for the better was observed. He has also used quinin in a somewhat different form and manner. An ounce of good quinin is well rubbed with an equal quantity of powdered carbonate of ammonia. The powder is then made into a paste with an ounce of liquor ammonia and set aside for an hour. Absolute alcohol, 4 ounces, is now added to the paste and the solution is filtered. The filtrate thus obtained is added to a pound of aromatic spirits of ammonia (B. P.). The clear mixture is labeled mixture of quinin carbonate, I 20. It is prescribed as follows:

	Gm or Cc	
℞ Solut bicarbonatis	4	5 j
Mist quinniae carbonatis	8	5 ij
Vinopiperisanales	2	5 iij
Syrup aurantii	4	5 iij
Aquar. aromat.	100	5 ℥ss
M. Ft. misturam		
Sig. One ounce every four to six hours.		

To the mixture for an adult, 10 minims of a 1:1000 platinum chlorid solution are added on the first day, 7.5 minims on the second day, 5 minims on the third day also on the fourth day if necessary, and then it is continued in 3 or 5 minim doses until recovery.

Ulcerona Spreading Mastoid Disease. E. C. Lewis—p. 830.

**Microscopic Diagnosis of Amebic Dysentery.** For the fixation and staining of amebae, motile and encysted, Haig makes thin smears from the fresh stool, selecting, where present, a portion containing mucus and blood, on cover slips, and floated, without drying, smear downward, on the following fixing solution, corrosive sublimate (saturated aqueous solution) 2 parts; absolute alcohol, 1 part. Fixation is complete in about thirty minutes. The smears are then placed thin upward in iodized alcohol in order to remove the last traces of sublimate, washed in distilled water, and then stained as follows: (1) Soak for several hours in a 4 per cent. solution of iron alum (made with violet crystals); (2) wash in distilled water; (3) stain in Heidenhain's hematoxylin for several hours (or over night); (4) wash in distilled water; (5) place in 1 per cent iron-alum solution until decolorization has reached a satisfactory stage; (6) wash in distilled water and counter stain with 5 per cent. aqueous eosin solution; dehydrate through the alcohols, clear in xylol, and mount on a slide in Canada balsam.

**Mechanism of Immunization.**—Mackenzie claims that the addition of pancreatic coenzyme and of vaccine to serum or blood *in vitro* exerts a lyolytic action. The serum so treated has bactericidal properties. The resulting tissue lipolysis in the case of vaccine appears in certain details to be different from pancreatic lipolysis. Preliminary experiments indicate that serum (autoserum) diluted and heated in which the coenzyme or coenzymes of the serum are present activates in a similar way the inactive prolipase of fresh serum. It induced tissue lipolysis an explanation in part is afforded of natural and therapeutic immunization.

**Picro-Brass in Treatment of Lupus.**—Ellis now uses a saturated solution of picro in sulphuric acid. This is made by adding picro acid to sulphuric acid and raising to a temperature of 100 C., a subsequent addition of 1 per cent. picro being made. The combination has been named sulphuric picro. The amount of picro acid taken up is about 2 per cent., and the liquid does not show the presence of free picro acid. Ellis claims that its power of selection of tissue for tissue is immediately apparent on application, and that the more force is deeper and more extended than is the case in the picro brass preparations. (See also THE JOURNAL, April 16, 1919, p. 1191.)

## Bulletin de l'Académie de Médecine, Paris

Oct. 15, 1919, No. 1

- \*Hypertension Arteriale. L. Martin—p. 17.  
\*L'Action de l'Acide Sulfurique. L. Legros—p. 181.  
\*Sérum Remède de Wessely. J. Bourgaud—p. 183.  
\*L'Étiologie Gécrite. Cause de Sterilité. R. Blondel—p. 185.  
\*L'Étiologie de l'Aviateur. Georges Ferry—p. 188.  
\*Émission des Doses de Radiant Energy. H. Guilleminot—p. 191.

**Twenty-Five Years of Diphtheria Antitoxin.**—Martin analyzes the records in regard to the prevalence and mortality of diphtheria since the introduction of antitoxin in 1894. The highest known death rate per hundred thousand inhabitants, before that, he says, was 200 at Berlin in 1893; next at Paris, 100 in 1882. Since then Paris has never gone as high as 27.7 except in the year 1901, and the average every-

where has been below 20, and often below 10. The improvement has been progressive and continuous. "Would that other diseases might soon profit in the same way," he exclaims, "by this fruitful union of the bacteriologist and the practitioner."

**Improved Technic for Cultivation of Anaerobes.**—Lignières calls attention to the advantages of a semiliquid culture medium for cultivating anaerobes, a soft, tremulous jelly made by adding only 0.25 per cent. gelose to the bouillon. He calls it "quarter gelose," and inoculates it with the germs from a pipet as usual. In addition to the ordinary solid and fluid culture mediums we now have the semiliquid, which affords the complete response to our queries.

**Operative Correction of Wrinkles.**—A method of taking up a fold in the skin in the shadow of the hair, etc., to smooth out wrinkles was described in these columns, July 5, 1919, p. 70. Bourquet gives the details of the principles here, but no illustrations.

**Hyperthyroidism as Responsible for Sterility.**—Blondel comments on the prevalence during the war of the emotional factors known to cooperate in the production of exophthalmic goiter, and remarks that he has not been surprised to find hyperthyroidism much more prevalent now than in former years, especially in women. Any one of the main symptoms, the exophthalmos, the tachycardia, tremor or goiter, may alone reveal the excessive functioning of the thyroid, and explain any one of numerous trophic and other changes. Chief among these he has noticed a decrease in the size of the uterus. This atrophy of the uterus is possibly the explanation of sterility in certain cases, and as such the causal hyperthyroidism should be combated. There are several ways of doing this, raying the thyroid, injecting serum from thyroidectomized animals, thymus treatment, and other means.

He prefers thymus treatment, and has been using it for years as the routine treatment in exophthalmic goiter. He gives half of a raw thymus from a lamb, chopped and mixed with a little flour, salt and butter to make small balls that are mixed with soup as it is eaten. Subcutaneous injection of the extract is more active, but less convenient for the patient. Thymus treatment is logical, he reiterates, on account of the antagonism between the thymus and thyroid, and years of experience have proved the soundness of these premises. He warns in conclusion that we must be wary in giving iodine in cases of amenorrhoea or we may whip up an incipient exophthalmic goiter. The thymus treatment in these cases of sterility might be supplemented by massage of the uterus and dilatation with laminaria for three or four days, each month or two months. The pathologic condition does not seem to be able to right itself spontaneously but with this treatment perseveringly carried out good results were obtained in the majority of his cases.

**Influence of Repose on the Blood Pressure of Army Aviators.**—Ferry explains the two main phases of aviators' asthenia, and comments on the depressing and sclerosis-inducing action on the human organism of aviation, and on means to stave this off as long as possible by rest, diuretics, epinephrin, and heart tonics.

**Calculation for Doses of Radiant Energy.**—Guilleminot gives the mathematical expressions for the penetrating power of the roentgen rays.

## Bulletin Médical, Paris

Oct. 4 and 11, 1919, 33, Nos. 42-43

- \*Curability of Renal Tuberculosis. F. Cathelin—p. 555.  
\*Traumatism of the Wrist. Jeanne and A. Mouchet—p. 567.

**Curability of Renal Tuberculosis.**—Cathelin discusses whether there is a possibility that the tuberculous processes in the kidneys which surgeons remove might have healed under medical measures alone. The intense cystitis is the sign of surgical renal tuberculosis, and it is no more possible to cure this by medical measures alone than the lesions in the kidney above. He defies any one to find a single specimen of kidneys preserved in the museum of the Hôpital d'urologie in which any medical treatment could have offered

any chance of a cure. The medical cases, he reaffirms, are those with lesions in both kidneys, with pyuria and bad general condition. "Medical," here, means only "Bilateral: Hands off," whatever the anatomic form may be. Study of the physiology and the chemistry of the kidney will bring further progress; the pathologic anatomy is of little moment as the tuberculous process is single, although we encounter it in different phases.

**Mechanism of Traumatism of the Wrist.**—Jeanne and Mouchet illustrate the exact mechanism of the different ways in which the wrist may become dislocated or fractured. This gives the clue to treatment in each case. See review in Paris Letter, p. 1625.

- \*Differential Auscultation. L. Azoulay.—p. 797
- Sensory Disturbances in Case of Cerebellopontine Angle Tumor. P. Marie, C. Chatelin and H. Bouttier.—p. 800
- \*Alcohol in Cerebrospinal Fluid. E. Lenoble and F. Daniel.—p. 804 and p. 809.

**Differential Auscultation.**—Azoulay remarks that bifocal auscultation seems to be almost unknown in France although it has long been practiced in the United States but has never been utilized to the full, he thinks. The lumen of the stethoscope is too narrow, as a rule, and he has found that it works best in connection with a telephonist's headpiece. Changes of attitude may facilitate the examination.

**Alcohol in the Cerebrospinal Fluid.**—In this fifth communication on this subject, Lenoble and Daniel report that tests on eight persons demonstrated that exactly 325 gm. of absolute alcohol must be ingested before any appears in the cerebrospinal fluid. It appears first in the urine, and disappears early here. The subjects were in the hospital for white swelling, pulmonary emphysema or other chronic pathologic condition, and the alcohol was given in wine or rum. They describe further five cases in which the alcohol found in the cerebrospinal fluid gave the clue to the diagnosis. In three cases this demonstrated that the alcohol had been responsible for the fatal cerebral hemorrhage, and testified further that at least 325 c.c. of alcohol had been ingested. In another case it proved that irregular epileptiform seizures and acts of impulsive violence which had been ascribed to the underlying epilepsy were in reality the consequences of alcohol intoxication. This case suggests the necessity for revision of certain phenomena which we now attribute to petit mal. In the fifth case, mental impairment and tendency to ataxia in the man of 54 were explained by the alcohol found in the lumbar puncture fluid during eighteen days. When it finally disappeared from the fluid, all the symptoms subsided also, and the diagnosis was clear for the first time.

- Electric Alarm Bell System for Control of Actual Death in Cemetery Watch Station. J. Peyrol.—p. 434

**Deformity from Fractured Pelvis.**—Andréolias relates that cesarean section was done just as labor began, with complete success, although the left side of the pelvis was reduced in size by at least a half from the old fracture.

**Intermittent Claudication.**—Cornet's patient was a woman of 75 with renal sclerosis and intensely painful arteritis of the tibiais posticus. An elastic band was thrown around the thigh at the upper third to relieve the pain, which it accomplished at once. The constriction was not tight enough to arrest the pulse in the dorsal artery in the foot; it was kept up for two hours and repeated twice the next day. The intermittent claudication had been rapidly progressive, and the edema, hypo-esthesia, hypothermia and some purpuric patches indicated obliteration of the vessel. But the imme-

diately subsidence of the pain and edema and the retrogression of the entire syndrome seemed to indicate merely spasm of the artery, on a basis of arteriosclerosis.

**Torsion of Spermatic Cord.**—Papin reports two cases. In one the torsion was of the recurring form with occasional attacks of pain and abdominal reflex phenomena. In Lapointe's compilation of thirty-seven cases, seven were of this recurring form. In two thirds of the cases in which the pedicle was untwisted and the testicle left unmolested, suppuration compelled its removal later. The infection responsible for this may have been blood borne, or from the usually coexistent hernia, or the operation may not have been aseptic, the damaged testicle being defenseless against germs that a sound organ would speedily master.

**Modification of the Pupil Reflexes.**—Cabannes discusses reflex pupil anomalies in one or both eyes, especially non-talentic anomalies.

**Journal de Radiologie et d'Electrologie, Paris**

October, 1919, 3, No. 9

- \*Increase in Outline of Heart on Reclining. H. Dausset.—p. 385.

- \*Roentgenotherapy in Paget's Disease. G. Haret.—p. 416.
- \*Movements of Luminous Particles in Gas. H. Guilleminot.—p. 419.

**Change in Outline of Heart in Different Positions.**—Dausset calls attention in particular to the increase in the area of dullness over the heart when the subject reclines. He found that the heart spread out in this way in twenty-two of fifty men examined while twenty-five showed no change. These were the strong and robust; men with flabby muscles and not breathing with normal force were more apt than others to show this spreading out of the heart area. In some, only a certain part of the heart spread out in this way, which may prove useful in differential diagnosis. The outline of the area may increase by as much as 30 sq. cm.

**Tubes for Roentgen Work.**—Arcein analyzes some of the phenomena presented by the tubes in instantaneous radiography with his timing record. They may throw new light on the composition of the rays. He remarks in conclusion that the size of the zone of impact is an important factor in the results. For radiotherapy, the zone of impact should be large, to generate and diffuse heat, but in seeking for a minute foreign body, in the eye for instance, the smaller the zone of impact the better. It might be well to ask dealers to specify the size of the zone of impact when buying a tube.

**Roentgenologic Signs of Abscess in the Liver.**—Colanéri shows by six illustrations the presumptive signs of an abscess in the liver. He classifies them as static or radiographic, and functional or radioscopic signs.

**The Electric Reactions in Tetanus.**—Gauducheau records the findings with electric tests applied to muscles and nerve in a man who had quite recovered from tetanus, and in a second man just entered on convalescence. The response were still far from normal.

**Table for Radium Exposures.**—Laborle publishes a long table for ready reference and comparison for doses and duration of exposures to radium emanations in closed tubes.

**Radiologic Findings After Operative Treatment of Gastric and Duodenal Ulcer.**—The numerous roentgenograms reproduced confirm the satisfactory outcome when the pylorus has been excluded by throwing a ligature around the stomach above the lesion, after the gastro-enterostomy has been concluded. Although the peristaltic waves are arrested by the ligature, yet they have not shown any lack of vigor during the nearly two years since.

**Roentgenotherapy in Paget's Disease.**—Haret relates the clinical cure by raying of Paget's disease of the nipple in a woman of 70. He has now two cases in which the clinical cure dates from nine to ten years, and one from six years, while two cases are still improving under treatment. These facts justify a more optimistic view of this disease.

**The Movements of the Luminous Particles in Gases.**—Gaullemont describes experimental confirmation of the kinetic theory of heat, commenting on the special interest this has for radiologists.

### Journal d'Urologie, Paris

Oct. 1-7, 1919, 8, N. 4

- \*Ascendens Urethritis.—Rochet—p. 187.
- \*Hydronephrosis Revealed by Trauma.—Ames and Delord—p. 285.
- \*Incontinence with Renal Tuberculosis.—G. Constantinesco—p. 291.
- \*Microscopic Examination in Urologic Cases.—M. Vivier—p. 295.

**Ascending Urethritis.**—Rochet has been studying on dogs, rabbits and guinea-pigs infectious processes in the lower urinary passages with intact or only slightly involved kidneys. The findings confirm his clinical experience that infection may spread upward, favored by some retention or chronic congestion of the ureter from some focus nearby, or by direct trauma of the ureter from a calculus or catheter. The ascending infection is less grave than the descending, if it can be arrested in time by curing the cystitis, correcting retention and disinfecting the whole tract and rendering it freely permeable throughout. Some minor operation may be necessary for this, to remove constricting bands, etc., as in a case described in a young woman. She had been having for two years attacks of pain in the right ureter region, and the catheter showed pyuria in the lower segment while urine from the pelvis was normal. There was a history of occasional brief mild cystitis; only the colon bacillus and diplococcus could be cultivated from the urine. The exposed ureter was found dilated in the lower half, and embedded in a thick fibrous sheath although the ureter walls were supple. The ureter was merely freed from this adherent sheath, and the clinical cure has been complete during the nine months to date. Rochet has found that an oily or fat vehicle for disinfection of the urinary passages clings longer to the walls and is more effectual than an aqueous solution of the disinfectant. He is now testing the application to the flumes of the bladder of substances that may generate gas or fumes that can find their way spontaneously into the ureters, iodin, hydrogen dioxide or formaldehyd, for example.

**Hydronephrosis Revealed by Trauma.**—The hydronephrosis in the boy of 12 developed in about five days after the fall on the abdomen, and 3 liters of blood-stained urine were found in the kidney. In the eighteen similar cases on record the average interval was three or four weeks, but in some cases it was several years. The operation in this case the fifth day demonstrated beyond question that the hydronephrosis was of long standing, and that the trauma had merely exacerbated and revealed it. The boy's girth had always been rather large.

**Incontinence of Urine in Renal Tuberculosis.**—This is Constantinesco's second communication on this subject, and he now relates that nocturnal incontinence of urine was the first symptom to bring the patient to the physician in two of a recent series of twenty-eight cases of renal tuberculosis. These two patients were 15 and 17 years old, and the incontinence had followed a period of increased frequency of micturition.

**Microscopic Examination in Urologic Cases.**—Two colored slides are used in this concluding instalment of Vivier's work. He warns that microscopic examination is instructive only when the urine is fresh and clean, and that there is no possibility of error otherwise. The best plan is to send the patient home to the laboratory.

- \*Wound in Breast and Abdomen.—Schwartz and Quénu—p. 301.
- \*Treatment of Tuberculosis of the Uterus.—P. Nolle—p. 305.
- \*Obstetric Therapeutics for Tuberculosis.—J. Jaubert—p. 311.

**Wounds Involving Both Chest and Abdomen.**—Schwartz published in 1912 a study of injury of the diaphragm from gunshot or stab wounds, and he here brings the subject down to date with the ample experience of the war. The incision he advocates and illustrates was described recently, page 1315, as used for diaphragmatic hernia.

**Chronic Tuberculous Endocarditis.**—The boy of 13 whose case is described by Nohécourt has chronic endocarditis although he has never had acute rheumatism, chorea or scarlet fever, but he shows numerous local tuberculous lesions, caries of the spine, spina ventosa, tuberculous abscess, tracheobronchial glandular lesions and mediastinitis. The boy is thus *un tuberculeux et un cardiaque*, and treatment and prognosis have to be heard this in mind.

**To Combine Orthopedic Treatment and Heliotherapy.**—Jaubert refers to tuberculous joint disease, and shows the different casts, splints, beds, etc., which ensure immobilization while permitting ample exposure to the sun. Hinged plaster casts can be removed during the exposures, and he describes the technic for making very thin light casts with celluloid or plaster and glue.

### Presse Médicale, Paris

Oct. 18, 1919, 27, N. 60

- \*Treatment of Intolerance for Milk.—E. Weill—p. 601.

**To Cure Infants of Intolerance for Milk.**—Weill relates that in the last six months he has had thirty breast-fed infants and eleven partly breast fed who all presented digestive disturbances for which no infection nor intoxication could be incriminated, and no lesion of any kind could be found. He reasoned that these digestive disturbances must be a manifestation of anaphylaxis, and he sought to combat them by antianaphylaxis, that is, by subcutaneous injection of milk. The favorable results surpassed all his anticipations. This vaccination is specific; human milk vaccinates against breast milk alone, and cow's milk against cow's milk. The infants given the injection six months ago have had no relapses and have developed normally since. He describes eight cases to show the different types of disturbances from intolerance of milk in infants without organic lesions. Some vomit soon or late after most of the feedings, and the milk may be quite fluid; some have a higher number of stools. They are greenish and accompanied with chafing. Or there may be tenacious constipation. These digestive disturbances are usually associated with nervousness. The babe often screams after feeding as if suffering, until it vomits. It is restless, starts at the slightest sound, stiffens in its mother's arms, and is hard to get to sleep, but there is no fever and the general condition keeps good. Eczema or impetigo may be observed, but no eruptions suggesting anaphylaxis. Change to another milk or food or certain drugs may correct the disturbances, but only transiently; the latter return sooner or later. The best results have been obtained when milk was dropped entirely, but infants are unable to thrive in the long run without milk.

In some of his cases the intolerance for breast milk was apparent from birth; in others, not until a month or two later. One previously healthy infant developed them at the age of 1 month when the mother had a plegmon. Inter-current disease in either the babe or the mother may modify the milk or the digestion so that this intolerance may become manifest at any time. The identity of symptoms and of the therapeutic influence of the subcutaneous injection of the specific milk shows the common basis for the primary and secondary intolerance. He injects the milk in the flank as a rule. With cow's milk, there is a rise in temperature for a few hours but not with the milk from the nursing woman. In two cases a reinjection induced slight shock for ten or fifteen minutes, the extremities growing cold. The breast milk can be injected raw, boiled, or heated to 110 C.; cow's milk should be boiled or heated to 110 C. for twenty minutes. The dose of 5 or 10 c.c. seems to be best. If the improvement is not pronounced, he makes a second or third injection, proceeding always by the Besredka progressive method, first 0.5 c.c., then 2 c.c. an hour later and not until after three hours the full dose of 5 or 10 c.c. In one case severe laryngospasm in an infant of 12 months seemed to be arrested by less than 1 c.c. of the milk injected twice. Weill is now trying this antianaphylaxis in cases of congenital vomiting, injecting both the mother and the infant with the mother's milk.

Oct. 25, 1919, 27, No. 62

\*Syphilis of the Stomach. R. Bensaude and L. Rivet.—p. 621.

**Syphilis of the Stomach.**—Bensaude and Rivet review the manifold forms in which syphilis may manifest itself in the stomach, describing with the roentgenologic findings a number of typical cases. There are no pathognomonic symptoms, but when everything else can be excluded, syphilis can generally be accepted, as also when there is multiple localization, as in esophagus and stomach, or the skiagram is unusual. A vigorous course of arsenical treatment improves the general condition whatever the cause, as a rule, but in syphilis the local lesion shows marked improvement besides. By this twofold effect they were able to differentiate and cure the syphilis in ten recent cases. This drug test is most instructive when it has been preceded by failure of dieting and the other ordinary measures for treating stomach derangement. Iodin and mercury by the mouth are usually well borne in case of gastric syphilis, while lesions of other kinds are aggravated by them. Stenosis once installed is scarcely amenable to any medical treatment, but before this stage is reached there is no pathologic condition which yields such brilliant therapeutic successes as gastric syphilis.

\*Primary Suture for Skull Wounds. E. Chauvin.—p. 371.  
\*Roentgenology of Tuberculosis. L. Ribadeu Dumas.—p. 373.  
\*Ether in Treatment of Tetanus. Audrain.—p. 376.  
\*Vaccine Therapy of Typhoid. P. LaFosse.—p. 377.  
\*Breech Presentation. H. Vignes.—p. 378.

**Primary Suture After Wounds of the Brain.**—Chauvin reports eighteen cases with thirteen healing by primary intention after primary suture. The outcome is not known in the other cases or they are still under treatment; only one was still wearing the drain when discharged. He sutured without draining only in four cases, but he never left the drain in place for over three days.

**Early Diagnosis of Tuberculosis.**—Ribadeu-Dumas expatiates on the valuable aid from roentgenology in detecting incipient tuberculosis. It not only locates the focus in the lung but shows up the diseased mediastinal glands which are the most evident tuberculous lesions in children.

**Ether in Treatment of Tetanus.**—Audrain states that the benefit from intramuscular injection of ether in whooping cough inspired him to treat tetanus by inhalation of ether. The amount was not enough to put the patient to sleep. The patient held the mask himself and the ether was given, 60 c.c. morning and night, by the drop or teaspoonful. Seven patients thus treated recovered, but the eighth died the tenth day with asystole for which chlorin impurities in the ether were probably responsible.

**Vaccine Therapy in Typhoid.**—LaFosse gave Besredka's sensitized vaccine in 62 cases of typhoid; all recovered except 12. The prompt cure under the vaccine was striking in 24, the course was protracted in 12, and 10 developed complications and 4 had a relapse.

**Breech Presentation.**—Vignes discusses some recent publications on this subject.

**Revue Franc. de Gynécologie et d'Obstét., Paris**

August, 1919, 44, No. 8

\*The Justomnor Pelvis. L. Demelin.—p. 270.  
\*Erosions of Uterine Cervix. D. Christides.—p. 287.  
\*Premonitory Signs of Eclampsia. A. Van Cauwenbergh.—p. 294.  
\*Hydrasarcoma from Fibroma in Uterus. J. Doyerey.—p. 302.  
\*Inversion of Puerperal Uterus. A. Grosse and Collet.—p. 305

**The Justomnor Pelvis.**—Demelin applies this term to the pelvis that is too narrow in an otherwise well formed woman. It may be of the adult type but unduly small or it may be

of the infantile, funnel shape. The hips are narrow, the diameter from crest to crest is only 24 or 25 cm. instead of the normal 27 or 28, and the diameter from spine to spine only 18 to 21 cm. Menstruation is usually late, and some endocrine disturbance is responsible for this and for the premature junction of the epiphyses or primary points of ossification which arrests the growth of the pelvis, just as premature occlusion of the fontanelles arrests the growth of the skull. The accoucheur should be warned by the external measurements of the pelvis, roentgenography, etc. Premature delivery at the eighth month is advocated by some, but this has more drawbacks than advantages. If the conjugate diameter is 9 cm. or less, cesarean section at term is far preferable. Forceps is better than version if delivery by the natural route is attempted; the head should be in the oblique diameter and convergent forceps chosen. The difficulty increases with the progress of labor with this type of pelvis.

**Erosions of the Uterine Cervix.**—Christides extols the advantages of Filhos' paste as a caustic but nontoxic treatment for erosions of the cervix. Its former vogue died out on account of the difficulty of applying it, but he has conquered these difficulties and describes seven cases in detail to show its superiority to other methods of treatment in old rebellious cases when operative measures are refused. The caustic of Filhos is a mixture of caustic potash and quicklime in alcohol, in pencil form. Aubert has also reported excellent results in fifty cases. The caustic is applied with special forceps to the erosion and is held there until this mucosa turns black and oozes. This takes only two or three minutes at most. The surface is then wiped off and tamponed with medicated gauze. Two vaginal douches are given daily and the application is repeated when the eschar has dropped. From two to four applications are the maximum.

**Premonitory Signs of Eclampsia.**—Van Cauwenbergh writes from Ghent to comment on the frequency of eclampsia recently and the scarcity of warning symptoms from it. The urine was often apparently normal, but eclampsia was most common when there had been digestive disturbances, uncontrollable vomiting in particular. In suspicious cases, venesection may be useful, or at least the natural losses of blood should not be combated before an amount of blood equivalent to a venesection has been lost. Hence pituitary treatment is contraindicated. In one of the five cases of eclampsia reported in detail, a primipara of 18 had had actually no symptoms, except a little pain in the stomach, when the eclampsia developed. In another case, except for two periods of vomiting, early and late in the pregnancy, conditions were normal, but the young woman died in a convulsion. Another woman had a rapid delivery after pituitary extract had been given on account of the complete inertia of the uterus after labor had commenced, accompanied by frequent vomiting. Delivery was rapid but the uterus kept contracted for forty-eight hours, and there was scarcely any blood lost. Thirteen hours later cramps in the stomach developed, followed in four hours by convulsions and coma, but the woman recovered. In two previous pregnancies there had been vomiting but no eclampsia. In this latest delivery, the pituitary extract had locked up the uterus so there was not the usual loss of blood, thus depriving the woman of this safety vent, and tipping the scale in favor of eclampsia. The intense contractions which it induces may also tend to bring on convulsions. In the fifth case described there was no albuminuria but during labor there were headaches and disturbance in vision and a little edema in the feet. Expulsion was rapid and there was considerable loss of blood. The bleeding kept up for some time, but he refrained from injecting ergot or pituitary to arrest it. This escape of blood was followed by immediate subsidence of the headache, etc. He is confident that eclampsia had been impending in this case but was warded off by the profuse losses of blood.

**Revue Neurologique, Paris**

August 1919, 20, No. 8

\*Intracranial Treatment of Syphilitic Diseases of the Nervous System. G. R. Lafora.—p. 625.  
\*Neurotic Manifestations of Typhoid. D. J. Patton.—p. 630

**Intraspinal Treatment of Syphilitic Diseases of the Central Nervous System.** Lafora now has a record of fifteen cases of general paralysis in which the manifestations of the disease have retrogressed under his treatment, not only the symptoms but the laboratory findings in the lumbar puncture fluid as well. This latter does not occur with the spontaneous remissions in general paralysis. The secret of success, he says, is to diagnose the disease in its earliest phases, before it has been under way for more than six or eight months. This is possible, he explains, by the laboratory findings in the cerebrospinal fluid and blood. Two of these laboratory reactions are characteristic of general paralysis alone, namely, the Wassermann test applied with only 0.2 c.c. of the cerebrospinal fluid, and the special curve of the colloidal gold test the figure being very different from the figure with other forms of cerebrospinal syphilis. With these two reactions, general paralysis can be detected even before any clinical symptoms become manifest. Then intraspinal treatment may arrest it for years, and perhaps permanently. It must be kept up possibly for a year and a half, that is, until the few laboratory reactions are permanently negative. Nine or ten months sufficed in some of his cases.

The same treatment proved almost always effectual in eight cases of tabes, the subjective symptoms rapidly subsiding, with some of the objective symptoms. It also proved the most effectual means to arrest progressive amaurosis, and in syphilitic radiculitis it suppressed the pains much better than intravenous treatment. He gives intravenous treatment in the intervals, testing the susceptibility by gradual therapeutic preparation, both intraspinally and by the vein, as he describes in minute detail. His list includes also four cases of syphilitic spinal and two of cerebral paraplegia. He uses the autoserum prepared in vitro by the Byrnes and Ogilvie methods. Four or five injections are made by the vein at intervals of from four to six days, 0.01 gm. of mercury and arsphenamin. The first intraspinal injection was made with arsphenaminized serum, never more than 2 or 3 mg., and the maximal dose ever reached was 4 mg. of mercuric chlorid or 7 mg. of (French) neo-arsphenamin. The intervals were from twenty to forty days while the collections by the vein were made about twice a week, alternating the mercury and the neo-arsphenamin and suspending for two or three weeks at the end of six months. The efficacy of this treatment is extremely manifest in syphilitic processes which have not yet invaded the deep parenchyma of the nervous system, and meningeal lesions are only just beginning around the nerve lesions. (His previous report on the subject was mentioned in these columns, Dec. 14, 1918, p. 2031.)

**Nervous Manifestations of Typhus.**—Paulin refers to the tardy meningeal reaction in typhus, and the unequal pupils. He noted the latter in 60 per cent. of his cases, and it was evident months later, suggesting syphilis. Neuritis is also common, he saw fifty-five cases with this complication. In another case of neuritis, facial diplegia developed nine months after the typhus, in two others during convalescence.

1919, 49, 1, 1. Maffei, C. Centralis Constipating Effect of Opium Prepara-  
tion, p. 185

**Partial Antigens in Diagnosis and Treatment of Tuberculosis.** Walther refers to the Deycke-Much partial antigens, which, with so much conflicting testimony is accumulating. He applied them in the diagnosis of tuberculosis of 157 subjects, including 24 clinically healthy, 54 with bone and joint tuberculosis and 43 with urogenital tuberculosis. Only 15 of the total 157 failed to respond and 8 of these were in advanced tuberculosis, the others were normal children and young people. The titer of the response varied widely within brief periods, the conditions being apparently the same at each test. It seems as if the theory of the partial antigens is not based on solid premises, but it is important for research on immunity, and deserves further study as it throws light on many obscure points. Striking

benefit was not obtained with the partial antigens in any instance, but some improvement was evident in some of the 29 cases of bone or joint tuberculosis and 5 of urogenital lesions.

**The Influence of the Morphin Content on the Constipating Action of Opium Preparations.**—The research was done on cats, and ten roentgenograms show the progress of the contrast meal. Uhlmann states that his findings confirm the different action of morphin and opium. The former whips up peristalsis, while the latter induces relaxation, actual atony. With colic pains, morphin arrests the pains but the peristaltic movements persist or may be exaggerated. Opium arrests the pains likewise, but in a different way, by relaxing and quieting the bowel.

\*Typhus. Camillo Artom.—p. 985.

\*Acute Lymphatic Leukemia. A. Gasbarrini.—p. 996.

**Typhus in Prisoners' Camp in Italy.**—Artom found at the necropsies during an epidemic of 500 cases of typhus at the prisoners' camp at Itri that edema of the brain, bronchopneumonia, and nephritis were constant. The mortality among the prisoners was 20 or 30 per cent. as they were debilitated from inadequate food before they had been taken prisoner. Among the Italian troops in the region the mortality was only 4 or 5 per cent. In one case there was no spotting at any time and none could be induced although the typhus was otherwise typical. Among unusual complications were laryngeal paralysis, panophthalmitis, intensely painful peripheral neuritis, and inflammatory processes in ear and parotid (fifty) and gangrene from arterial thrombosis, bilateral in most of the cases.

**Acute Lymphatic Leukemia.**—The boy of 15 died two months after the first symptoms had been noted, but a period of marked improvement had followed an intravenous injection of antistreptococcus serovaccine. There was a violent reaction with intense chill for an hour then fever of 40.2 C. Then great improvement followed; by the third day the leukocytes had dropped from 220,000 to 55,200 and by the twelfth day to 6,400 and the proportion of immature cells was much reduced. The uric acid content of the urine increased materially at the same time, confirming the actual leukolysis. An intercurrent febrile gastro-intestinal derangement from an error in diet aggravated the anemia, and the boy died within two days.

\*Cerebrospinal Fluid in Typhus. R. Monteleone.—p. 1009.

\*Modification of Bassini Method. M. Battaglia.—p. 1012.

River Fever in Japan. C. Basile.—p. 1016.

**The Cerebrospinal Fluid in Typhus.**—Monteleone was impressed with the high tension and high albumin content of the lumbar fluid in typhus, while the Nonne reaction was constantly negative. Agglutination with the proteus X occurred parallel with the blood and spinal fluid.

**Improved Herniotomy.**—Battaglia extols the advantages of the modification of the Bassini technic which he describes. He prepares the threefold layer as for a Bassini, and sutures with cross or D'Antona sutures if the muscles are stout. If not, he takes U sutures, the loop passing through the muscle fibers above and from within. The suture at the pubis includes the rectus muscle. When the sutures are drawn up the planes lap, and recurrence of the hernia is practically impossible. With this technic he has never felt the need for plastic reinforcement, not even in men of 60 to 75 with hernias of ten or twenty years' standing, actual ventrations.

Sept. 6, 1919, 33, No. 36

Large Doses of Quinin in Malaria. Alvaro da Franca Rocha.—p. 281.

**Vesicovaginal Fistulas.**—Adeodato relates that the gap in the vesicovaginal septum in the case he describes was 3 cm. in diameter. The perineum had been lacerated, besides, at the delivery about two years before. The fistula was readily corrected by a modification of the Ferguson-Braquehay method, but he ascribes this success to his systematic preparation of the woman for the operation. With a retention catheter the urine was diverted, and hexamethylenamin and sodium benzoate were given, along with hot vaginal douches and tonics. Under this treatment the urine returned to normal, and the fistula became much smaller so that the operation was much facilitated. He dissected the tissues to separate the vesical and vaginal walls for 1 cm. back from the fistula all around, leaving a layer of vaginal tissue adherent to the bladder tissue in a ring around the fistula. The bladder defect was then drawn up and sutured, turning in the mucosa with the crown of vaginal tissue, leaving this to project into the bladder lumen. The vaginal opening was then closed with a suture thread passed through the farthest points of the separation of the vesical and vaginal tissues. By this means the former seat of the fistula was strengthened with quadruple layers of tissue. The knob projecting into the bladder will probably become flattened out in time as the bladder stretches and relaxes.

- \*Vaccination Against Tuberculosis. J. Ferrán. p. 181

**Ptosis of Liver with Cholecystitis.**—The woman had had various attacks of vomiting and fever with pain in the iliac fossa but the region was too tender for palpation and the walls were rigid. The laparotomy on the assumption of chronic appendicitis, disclosed instead a much sagging liver, with emphyema and stones in the gallbladder. One pole of the liver had sagged until it reached nearly to the groin. The tip of the gallbladder was at McBurney's point and explained the tenderness here, pressure on the gallbladder merged with stones and pus giving a typical reaction. The first cholecystectomy was done at Caracas in 1918, but a number have been done since.

**Care of the Insane.**—Ayala comments on the revolution in insane asylums since the colony system came into vogue, and describes the fine institution of the kind in charge of Calred in Argentina and the Magdalena colony in Peru. Calred described his methods and success at a medical congress at Lima in 1913, and, without waiting for the congress to close, the authorities of the antiquated local asylum burned the old strait-jackets and other appliances for forcible constraint. "It was like an *autó da fe* of former days," Ayala remarks, "and from the ashes of these outworn appliances has developed the new modern open-door colony." He urges Venezuela to follow in the footsteps of Peru.

**Vaccination Against Tuberculosis.**—This is Ferrán's own announcement of the principles of his method of vaccination

against tuberculosis, as he presented it at the recent Spanish medical congress. See Madrid Letter, page 1074.

**Necessity for Sanatoriums for the Tuberculous.**—Timón says in the course of his remarks on tuberculosis, that great progress would be realized if the public dreaded tuberculosis as they dread leprosy, and made provision in the same way for segregation. Leprosy is very far from being as contagious as tuberculosis, the germs of which are spread at every breath, every greeting and every contact. He appeals to the authorities for the foundation of a sanatorium for the tuberculous in the Cartagena district. There is already a sanatorium for lepers.

**Code of Ethics.**—This proposed code was described in these columns recently, page 1170.

\*Vaccine Therapy in Influenza. A. Salvat. p. 108.

**Insanity in the United States.**—Santos Ruluabco reviews with much detail the census compiled by the Committee for Repression of Mental Diseases, showing the numbers and distribution of the insane in this country in 1915. He remarks that "the large percentage of insane inhabitants is not to be wondered at in a country where the business failures mount up to 1,500 a month, and suicides average 16,000 per year, and the natality is the lowest of all civilized peoples."

**Pure Insufficiency of Pulmonary Valves.**—Del Campo ascribes to pure insufficiency of the pulmonary valves the hypertrophy and dilation of the right ventricle, with a diastolic murmur heard loudest in the left second intercostal space, and the dyspnea accentuated by effort. The patient was a woman of 24 with positive Wassermann reaction. Under specific treatment these symptoms subsided to a certain extent, and the patient had no return of the former attacks of hypostholy during the nine months to date. He calls attention to the anemic oscillation evident in the pulse tracings given from this case, saying that this has differential importance as the greater circulation cannot be absolutely normal in this case. The tracing was most instructive when taken with the drum revolving at high speed.

**Recurring Dislocation of the Shoulder.**—Bastos Ansart describes the recurring dislocation to relaxation of the subscapular muscle. He corrects this by suturing the free margin of the subscapular to the periosteum of the anatomic neck and to the lips of the biceps. This simple operation answered the purpose admirably in the single case in which he has applied it to date. The man, an aviator, has had no return of the dislocation during the seven months since.

**Vaccine Therapy of Influenza.** J. J. M. p. 61.

**Syphilitic Perienteritis.**—This is the concluding installment of this long and profusely illustrated article on the chronic symptoms of the abdomen which may be a tardy manifestation of inherited syphilis. Castex and Delfor regard the latter as a very frequent—perhaps the most frequent—cause of membranous bands and kinks. The inherited syphilis may likewise induce a set of chronic symptoms without appreciable anatomic lesions. The disturbances are due to deficient functioning of the endocrine glands which are the physiologic stimulators and regulators, the suprarenals and thyroid in particular. This type of chronic disturbance implies a prognosis and treatment quite different from those with membranous peri-enteritis, but the two types were combined in some of his cases. In six typical cases described, the patients were men of 20 and 28 and two women of 25 and 31. Some required surgical measures besides specific treatment, but great improvement or a complete cure was realized in all.

**Therapy of the Hematuria in Treatment of Tuberculosis of Urinary Apparatus.** J. F. M. p. 66.  
**The Urinary and the Duty to Society.** G. Araz Alfaro.—p. 68.

**Ascites from Inherited Syphilis.**—The child of 4 had had severe intestinal disturbance soon after birth, and the liver and spleen became enlarged and ascites had developed. Examination of animals was negative, but treatment for several months marked improvement. An intercurrent pneumonia was followed by return of the ascites, evidently due to the work of the pneumococcus, and thus developed. The child had a laparotomy to break up adhesions and drainage of a hemorrhagic effusion, and a second intervention to clear out a pus pocket. Then milder mercurial treatment of the child was required promptly to clinical health.

**Heliotherapy plus Tuberculin in Treatment of Tuberculosis of the Urinary Apparatus.**—Mieres describes three cases of tuberculosis of the kidney or bladder or both, in two men of 25 and 28 and a woman of 32, in which all the symptoms were completely relieved under combined heliotherapy and tuberculin treatment. He began with only five minutes' exposure and increased to full sun baths. The doses of tuberculin were extremely minute, seeking to imitate Nature's method of mineralization by the minimal amounts generated in a small innocuous focus. In three other similar cases the same treatment was realized, and in a seventh case the same treatment is in progress.

**Diagnosis of Tuberculosis of the Urinary Apparatus.**—A. B. Vasconcelos. p. 14.  
**Diagnosis of Tuberculosis of the Urinary Apparatus.**—A. B. Vasconcelos. p. 14.

**Professional Secrecy.**—Vallejo discusses whether the authorities have any right to compel a physician to violate professional secrecy. In connection with the organized campaign against venereal diseases, a bill was presented in the legislature to compel physicians to report to the Consejo Superior de Salubridad all the syphilitics among their clients, specifying names, etc. Vallejo quotes Hippocrates' oath on the inviolability of the professional secret, and states that a similar oath is exacted of the medical graduates of the University of Montpellier. He would like to have a similar oath made part of the graduation procedures everywhere. The Mexican laws on privileged communications are based in the main on the United States laws. He reproduces the principal paragraphs, and points out certain contradictions, and emphasizes that society has other and more important interests than mere conviction of criminals.

**Intravenous Injections in the Neck.**—Vasconcelos' two photographs show the technic for injection into the jugular vein. He cites Najera, who witnessed in 1912 injections by the jugular vein, and Lerelde who in his (1917) work mentions the advantages of the jugular vein for injection in children. Vasconcelos congratulates Kaliski for his recent work on the subject in *The Journal*, May 31, 1919, p. 1613, seeking to render more popular this method which with a certain skill is simple, harmless and useful. He has applied this technic himself in giving arsphenamin to five men and neoarsphenamin to five women, and the patients found it more agreeable than by a vein in the elbow. But he prefers the latter for the routine route, next the jugular, or a vein in head or foot, or by the rectum, never utilizing a varicose vein, as Rosenheck proposes, as this might set up phlebitis.

**Simultaneous Extra Uterine and Normal Pregnancy.**—M. Fenger.—p. 1113.  
**Abnormally Small Hearts.**—K. Secher.—p. 1119.

**Normal plus Extra-Uterine Pregnancy.**—Fenger comments on the rarity of the coincidence of intra-uterine and extra-uterine pregnancy. In Neugebauer's compilation of 169 cases, the diagnosis had been incarcerated retroflexion in 6 cases, and the attempt in 3 of the cases to correct the displacement proved fatal. In 127 of the cases rupture led to intervention, but in the majority the intra-uterine pregnancy was not discovered at the time, the changes in the uterus being attributed to the influence of the tubal pregnancy. The gravid uterus usually expelled its contents soon afterward, as in the personal case he describes. Eleven days after the laparotomy for the ruptured tubal pregnancy, phlebitis developed and a 6 cm. fetus was found in the vagina. The pregnancy continued uninterrupted only in 8 of the 70 in this group. In 40 of the 169 cases the uterus abortion occurred first, and the extra-uterine was not suspected; 27.5 per cent. died from lack of proper operative measures when the tube ruptured. Death usually occurred in an hour and was ascribed to shock from the abortion. Even in the cases in which a prompt laparotomy saved the woman, the ectopic pregnancy was a surprise. In 42 of the 169 cases both pregnancies continued to the twenty-eighth week or to term. In 4 cases both children were viable, the acconcheur delivering one from within and one from outside the uterus. In 10 cases the extra-uterine fetus was expelled through a fistula. Some of the women succumbed to fulminating intraperitoneal hemorrhage in these late cases. The main thing is to bear in mind the possibility of a normal plus an ectopic pregnancy. It is so rare that we are apt to forget the possibility. According to Neugebauer, the true condition was recognized at the operation only in 7 cases.

**Small Hearts.**—Secher reviews recent literature on the constitutionally small or drop heart, pendulum heart and thorax paralyticus, and emphasizes the lesser resisting power in these conditions. Geigel multiplies by  $\frac{3}{2}$  the figure representing the area of the heart and divides by the figure representing the length. The quotient in normal subjects ranges from 15 to 23. He found it under 14 in 10 per cent. of 2939 persons examined.

## RECONSTRUCTIVE SURGERY OF THE HAND\*

JOHN C. WILSON, M.D.  
LOS ANGELES

AND

CLARENCE H. HYMAN, M.D.  
CLEVELAND

One of the most perplexing problems that were presented to the orthopedic surgeon during the war was the restoration of function in injuries of the hand. Each case presented many difficulties rather than a single problem. Complete restoration of function, or as nearly complete restoration as possible, is essential before the full duty of the surgeon to the soldier is fulfilled. An all too frequent mistake has been to send the man with imperfect function of the hand to his home to work out motion in the wrist or some of the small joints of the hand by himself. Many of these men live in remote districts and will never come under medical supervision again.

It has not seemed practicable to divide this subject in any way; therefore an attempt will be made to paint the picture as it actually presents itself. Injuries of the wrist joint will be considered in a general way because of the necessity of securing the proper relation of the hand to the forearm.

### INJURIES TO SOFT PARTS

*Dorsal Surface of the Hand.*—These wounds were found to be due for the most part to machine gun bullets or fragments of shell casing, and as a general rule they were of the oblique type. The dorsal surface of the hand is exposed to projectiles to a greater extent than the palm because of the position assumed when it is hanging by the side or when it is active. Cicatricial tissue follows these wounds because of the presence of infection in all instances. The scars are unsightly, often tender and easily abraded, but they interfere to a lesser degree than does the presence of scar tissue in the palm of the hand.

Frequently, cicatrices of the dorsum of the hand may be excised and the skin freed sufficiently to allow closure of the defect due to the removal of the scar tissue. In case this procedure is followed, care must be taken to preserve the circulation in all parts of the skin flaps, for, although an occasional small skin

slough has occurred, this method of skin repair has proved satisfactory.

*Palmar Surface of the Hand.*—Extensive scarring of the palm of the hand may lead to contractures of the thumb, as in Case 10 (Figs. 1, 2 and 3). The skin of the palm cannot readily be mobilized; hence excision of an appreciable amount of scar tissue leaves defects that must be repaired by skin and fat from other parts of the body. This is best accomplished by transplantation of a section of skin, fat and superficial fascia from the abdominal wall by means of the method described by Babcock as illustrated in Figures 4 and 5. The area of scar tissue is completely excised in order that the blood supply between the flap and bed may be readily established. A flap of skin, superficial fascia, and fat is dissected free from the abdominal wall, except for the pedicular attachment, which should if possible be the superior portion of the flap. Great care should be taken to make the flap fit the bed accurately. It is then sutured along the free border to the skin margins of the bed, care being exercised not to constrict the pedicle of the transplant. The hand is then put up in a comfortable dressing for a period of about nine days. During this time the abdominal flap will acquire sufficient blood supply to allow the pedicle to be severed. In all probability the union between the sutured flap and the skin margin will be complete; but it may be possible that one of the corners of the transplant will show signs of necrosis, and a definite line of demarcation may be present. In case this has occurred, the necrotic area may be trimmed away and the vascular edge of the transplant approximated to the skin margin, usually resulting in prompt union. By this means a serviceable skin surface is provided in place of a tender cicatrix, and a suitable bed is secured for the tendons.

### TENDON INJURIES

Few of the projectiles passed completely through the hand, and as a result the greater number of these cases were injuries only of the extensor tendons. In twenty-five cases the extensor tendons were involved, and in three cases only the flexor tendons; in four cases both flexor and extensor tendons had been subjected to injury. In the last group, the damage was done by a projectile entering on the dorsal surface of the hand and passing out through the palm.

Three distinct types of cases with tendon involvement may be described, namely, complete division, partial division and adherent tendons.

*Complete Division.*—When complete division had taken place, it was not uncommon to find the severed ends embedded deeply in callous or scar tissue in the

\*From U. S. Army General Hospital, No. 6, Fort McPherson, Ga., at which Dr. Wilson was chief of the orthopedic service and Dr. Hyman orthopedic surgeon.

\*Because of lack of space, this article is abbreviated by the omission of many case reports. The complete article will appear in the reprints, a copy of which may be obtained on application to the authors.

hand in a plane corresponding to the course of the projectile. By careful dissection the tendon could be freed and often exhibited very little destruction, a fact that proved of great value in considering the repair.

*Partial Division.*—In the small number of cases in which the tendons were partially divided, an over-

Fig. 1 (Case 10).—Perforating gunshot wound of the hand with large cicatrix in the palm. The flexor tendons of the thumb and the first two fingers have been divided. Note the adduction deformity of the thumb.

production of fibrous tissue along the remnants of the tendon sheath and beneath the skin prevented return of function. Prior to operation it was impossible to differentiate this group.

*Adherent Tendons.*—Tendon adhesions were due to lacerated wounds in the long axis of the hand, followed by infection. The differentiation between this type of case and complete division presented no great difficulty for the reason that attempted active extension of the digits showed distinct evidence of force being transmitted along the tendon course.

For the sake of classification, these three groups have been described in detail; but one must bear in mind the fact that rarely was a single one of these conditions present at one time.

*Treatment of Tendon Injuries.*—That a moderate range of joint motion must precede tendon function is an axiom well worth remembering. It is useless to expect a repaired or liberated tendon to combat an

Fig. 2 (Case 11).—Cicatrix has been excised, tendons repaired, and transplant placed. Skin edges are not entirely healed.

ankylosed joint; therefore in describing the treatment of tendon injuries we shall assume the range of motion of the joints of the hand to be moderately free.

*Complete Division.*—When tendon division had taken place, tendon repair or tendon transplantation was, of course, considered. By careful dissection it

was possible at times to separate enough of the tendon from the cicatricial tissue to allow end to end repair. When such gaps were present that end to end repair was impossible, the extensor indicis and extensor minimi digiti were available for transplantation as extensors to any of the digits except the first. The tendon of the extensor carpi radialis brevis may be transplanted into the distal tendinous portion of the extensor ossis metacarpi pollicis or extensors longus or brevis pollicis, as in Case 38. In case of ankylosis of the wrist, the extensors carpi radialis longior and brevis, the extensor carpi ulnaris, and the flexors carpi radialis and ulnaris may be utilized.

*Partial Division.*—When partial division had taken place, the rational procedure was followed. The tendons were liberated from the bed of scar tissue and the divided portion sutured. In many cases of complete or partial division, adjacent tendons were found to be bound down to the metacarpals or the interossei by dense scar tissue.

*Adherent Tendons.*—The problem of tendon adhesions was met by tendon liberation and early active motion, which should be understood to be due to active contraction of muscles which will produce motion of the affected tendons, or by tendon liberation and an

Fig. 3 (Case 10).—Five weeks after operation. Transplant of skin fat and fascia healed. Note the abduction of the thumb.

autogenous fat and fascia transplant. Fat and fascia were transplanted in eight cases, infection following in one case within forty-eight hours. In four cases, the skin remained healed for fourteen days, when the skin margins separated slightly, liberating a considerable amount of oily fluid, the result of fat decomposition. In two cases, the wounds healed promptly after the discharge, and in the two remaining, infection followed and the transplants were extruded, leading of course to absolute failure. In three cases, satisfactory return of tendon function followed. If a fat and fascia transplant is used, the difficulties of skin closure are multiplied several fold. In view of the skin defects that were dealt with, it is possible that conclusions should not be drawn from these cases. However, the fact remains that the best results were obtained without fat and fascia transplants, in cases in which early active motion was instituted, often within a few hours after operation.

#### FRACTURES OF THE CARPUS

Fractures of the carpus are considered only so far as they are factors in determining the relationship of the hand to the forearm. In several instances, fractures of the scaphoid and semilunar bones with dis-

placement of the proximal fragment were found to limit dorsal flexion by mechanical blocking, and as a result the muscle balance of the hand was destroyed (Cases 7 and 12). This lesion was only a component part of the picture, but necessitated consideration before perfect functional restoration could be gained. Even though a considerable range of motion was present in an arc of palmar flexion, measures to bring the hand into a position of dorsal flexion with somewhat of a sacrifice, if necessary, of the arc of motion seemed advisable for the sake of restoration of the normal muscle balance.

When the carpal bones had been extensively destroyed, radial deflection of the hand was found to occur in conjunction with palmar flexion. The articular surfaces of the radius and ulna were often destroyed by the injury or the associated infection. Motion in the position of deformity was painful, and the deformities showed great tendency to recur after correction by mechanical measures.

The best results were obtained by carporadio-ulnar resection of bone, sufficient to allow correction of the deviation of the hand and to allow the hand to be set at an angle of 40 degrees of dorsal flexion, with fixation in this position until firm bony ankylosis had occurred, care being taken to preserve tendon and joint function during this period.

Fig. 4 (schematic). — Single pedicle abdominal flap in position, vascularized and ready to be cut free.

Fig. 5 (schematic). — Flap liberated with method of abdominal skin closure. Incisions along dotted lines allow skin margins to be approximated.

#### FRACTURES OF THE METACARPAL BONES

Fractures of the metacarpal bones calling for special consideration by the orthopedic surgeon are of two varieties; those with nonunion, and those with union in such a position as to disturb the alinement of their respective joint surfaces.

Nonunion is rarely seen when approximation of the fragments has occurred. The lack of union is generally found to be due to defects in the shafts, and may be associated with destruction of either of the articulating extremities.

The loss of proximal metacarpal fixation is a troublesome factor, especially if associated with ankylosis of the metacarpophalangeal joints, because of the false point of motion. An attempt to secure proximal metacarpal fixation is advisable, either by implantation of the metacarpal shafts into the carpus, or, if the defect is too great, by means of an autogenous bone transplant that will bridge the gap between the metacarpal and the carpus in juxtaposition. This having been accomplished, the proximal arm of the lever becomes fixed, and the problem of restoration of motion in the metacarpophalangeal joint may be attacked.

Ununited fractures of the metacarpal bones disturb the function of the metacarpophalangeal joints because

the proximal end of the distal fragment becomes tilted forward, throwing the articulating surface backward, changing the arc of flexion, and destroying the muscle balance of the finger in question. At operation the fragments may be properly approximated and the defect in the shaft repaired by a carefully cut tibial

Fig. 6 (Case 16). — Amputation of four fingers through distal part of metacarpal shafts, unhealed; greatest tenderness over the only available point of apposition for the thumb.

transplant or by exogenous bone. In two cases of repair by autogenous bone, the results were most gratifying, while exogenous bone (beef) was used in one case with an unsatisfactory result.

Destruction of the distal metacarpal articulating surfaces presents greater difficulties. The management of this condition depends on the number of

Fig. 7 (Case 16). — Appearance of hand two months after operation. Unhealed cicatrix has been excised, and skin fat and tissue transplant from the abdominal wall has healed, resulting in a good functional result. A prosthesis was readily fitted to the stump to be worn for esthetic effect when desired.

fingers involved; and if only one, the extent of the process will determine the treatment. A point of

approximation for the thumb should be preserved, and if need be, an ankylosed metacarpophalangeal joint may be considered to obtain this end. Should the

Fig. 8 (Case 24).—Amputation of index finger; flail third finger due to resection of metacarpal with extensive scar tissue formation following gunshot wound.

function of the remaining digits be undisturbed and one metacarpal be extensively involved, amputation of the digit with resection of the fragments of the metacarpal shaft will give the best result, as in Case 24.

Fractures of the metacarpal bones with union in malposition do not require special remark except that the normal relationship of the joint surfaces must be secured to insure the return of greatest function. This realignment is easily accomplished after an osteotomy at the point of election.

#### JOINT INVOLVEMENT

Of primary importance in reconstructive surgery of the hand is the condition of the joints; for regardless of how ingenious or how skilfully executed, an operation on tendons, failure to secure a good functional result will be certain if there is marked limitation of motion or ankylosis of the joints to be functionated. Muscular contraction is a means of

Fig. 9 (Case 4).—Appearance of hand two months after operation. Scar was removed, and the third metacarpal repaired by transposing the remains of the shaft of the second metacarpal and finger used in position of slight palmar flexion to allow approximation of the thumb. This procedure was imperative to secure a point of approximation for the thumb because of ankylosis of the fourth and fifth metacarpophalangeal joints.

producing joint motion; and if there is not already passive motion in a joint, it is a waste of time and energy, both to the patient and the surgeon, to per-

form a tendon operation and then expect a result. In those cases in which ankylosis or limitation of motion is expected, there are positions of election to secure the maximum degree of usefulness.

Limitation of motion in a joint may be due to extra-articular causes, usually when associated with gunshot wounds with infection, to a thickened contracted capsule, or to intra-articular causes, usually a fracture extending into the joint, or to destruction of the articular cartilage.

All injuries of the wrist joint should be treated with the wrist in a position of dorsal flexion, particularly when there is any likelihood of a resulting limitation of motion or complete ankylosis. If the wrist is in a position of palmar flexion or in a neutral position, the force of the grip is diminished because of the loss of muscle balance. The position of dorsal flexion is the position of strength. To secure this position, it is necessary to devote special attention to the splinting. Any of the ordinary cock-up splints will usually suffice if properly applied and observed. If the tendon injury is uncomplicated by joint involvement, the mere passive attitude of the hand in palmar flexion will result in a deformity that may require months of treatment to restore function.

In practically all cases of injury to the tendons of the fingers there has been a marked limitation of motion of the metacarpophalangeal joints, and the

Fig. 10 (Case 23).—Persistent hyperextension of metacarpophalangeal joint as a result of excision of scar and a posterior capsulorrhaphy.

fingers were as a rule found in a position of hyperextension. This deformity was associated with thickening and contraction of the joint capsule. Baking, massage, contrast baths and other physiotherapeutic measures commonly used seemed of very little benefit without elastic traction. A very satisfactory apparatus may be improvised such as is shown in Figures 15 and 16. The rubber tubing is attached to the fingers by adhesive plaster and then attached to heavy iron wire embedded in a molded plaster-of-Paris palmar splint that will extend to the elbow. The traction must first be made in the line of deformity. By bending the wire, the deformity can gradually be overcome and flexion of the fingers produced. In conjunction with this traction and flexion, it is important that daily massage and manipulation be given with the splint removed, with the exception of the adhesive bands attached to the fingers. Good results have been obtained more rapidly by a transverse posterior capsulorrhaphy at the time of the tendon repair. The fibrous capsule of the metacarpophalangeal joint is incised transversely, allowing the maximum of palmar flexion at this joint immediately. Massage and exercise must be used faithfully after this operation to obtain the best results.

One case of recurrent dislocation of the first carpo-metacarpal joint was observed in this series of cases. This was due to impacted fractures of both the trapezium and trapezoid bones of the wrist which altered

the plane of the articulating surface of the trapezium. The joint was partially stabilized by passing a heavy silk ligature through the base of the first metacarpal, and thence through the body of the trapezium. This ligature was tied with the thumb in a position of extreme extension. The result seemed most satisfactory, for at the end of four weeks the patient had recovered complete function of the first digit and had suffered no relapse at the time of departure from the hospital, several weeks later.

The limitation of motion in the interphalangeal joints caused comparatively little difficulty, as these conditions were readily amenable to physiotherapeutic measures.

#### AMPUTATIONS

Evidences of conservation of the structures of the hand are seen constantly. Thanks to the able surgery performed at the front, metacarpal stumps that might be of value as apposing digits have been preserved. It must be borne in mind that a functioning thumb with a point of apposition will make a useful hand, and that the artificial hand with all of the delicate mechanism has never been perfected to the degree of

Fig. 11 (Case 23)—Limit of voluntary flexion of the finger ten days after dorsal transverse incision of the capsule of the metacarpophalangeal joint.

usefulness equal to that of apposing digits or parts of digits.

In case all fingers are amputated, the point of apposition, which will necessarily be metacarpal stumps, must be covered with integument that is not sensitive. Unfortunately, laceration of soft parts is more extensive than the resection of bone, resulting in the formation of cicatricial tissue over the osseous structures. Scar tissue is prone to crack and become abraded with the slightest trauma. This cicatricial tissue may be replaced with skin and fat by resection of the entire scar and transplantation of a pedicle of fat and fascia, after the technic illustrated in Figures 4 and 5 with the result shown in Figure 7. In this particular instance the result was most pleasing, because a tender unhealed stump of a hand was transformed into a functioning member.

The question of finger amputation is open to considerable controversy; but it seems to be agreed that in case both flexor and extensor tendons of one digit, excepting the first, are involved, amputation should be considered. Metacarpal and metacarpophalangeal joint injury with tendon involvement of only one

digit, except the first, should always be treated by amputation of the digit. Metacarpal shaft destruction which may occur without tendon injury does not

Fig. 12 (Case 21).—Ankylosis of the wrist joint in a position of palmar flexion with marked disturbance of muscle balance of the flexors and extensors of the fingers and partial ankylosis of all of the small joints of the hand. This condition was not amenable to mechanical treatment.

require amputation of the digit if the distal articular surface of the metacarpal is uninvolved.

#### TIME OF OPERATION

The time of operation in the cases reported was earlier than has been customary. Rarely was any plastic work attempted before the wounds had been healed two months. After this period had elapsed, the area of injury was subjected to intensive mechanical irritation; and if no reaction appeared in the skin or subcutaneous tissues, pain and tenderness being absent, it was felt that the problem might be attacked surgically with impunity.

A few infections occurred, but the percentage was so low that early operation is to be encouraged in order that the soldier may be restored to usefulness as soon as possible.

Case 10.—A soldier, admitted, Dec. 26, 1918, had received a perforating gunshot wound of the palm of the hand, Oct. 27, 1918. Infection followed immediately. On admission a large irregular scar was present in the palm with a contracture

Fig. 13 (Case 21)—Eight weeks after fixation of hand in a position of dorsal flexion, with rapid return of function of the digits under therapeutic measures that were unavailing before the correction of the palmar flexion deformity.

causing an adduction deformity of the thumb and flexion of the index and middle fingers. The flexor longus pollicis tendon and the tendons of the flexors profundus and sublimis digitorum to the index and middle fingers were divided. There was a distal articular fracture of the third metacarpal. Operation, March 22, 1919, after wounds had been healed

eight weeks. The flexor tendons to the thumb, index and middle fingers were repaired and the entire mass of scar tissue excised. A transplant of skin, fascia and fat was transplanted into the palm by the two stage method. The flap was cut loose ten days later. At present, five weeks

Fig. 14 (Case 28).—Roentgenogram taken five weeks after repair of metacarpal defects by autogenous bone transplants.

following operation, the skin transplant is healed and there is distinct flexion power in the thumb, index and middle fingers. Repair of the extensor tendons is to be done later.

CASE 16.—A soldier received a machine gun bullet wound of the right hand, July 28, 1918, resulting in amputation of the four fingers at the metacarpophalangeal joints. There was normal motion in the thumb but there was difficulty in apposing it to the stump, which was covered by a tender granulating surface with surrounding skin poorly nourished. Operation, Dec. 5, 1918, when the entire scar over the end of the stump was excised and a thick double pedicle skin flap from the abdomen was sutured in place. The flap was cut loose nine days later and the skin of the flap was sutured to the hand. The skin flap was entirely healed three weeks after operation; on the patient's discharge, two months later, there was a narrow linear scar encircling the transplant with a good tough pad, to which he could appose the thumb.

CASE 21.—March 15, 1918, a soldier accidentally cut himself with a knife on the left palm. Infection followed which was treated by multiple dorsal incisions. When admitted, July 23, 1918, there was a bony ankylosis of the wrist in extreme palmar flexion, with ulnar deflection, and no motion in the metacarpophalangeal joints. Massage, manipulations under ether, and plaster-of-Paris wedging were tried with no improvement. Operation, Feb. 6, 1919, when wounds had been healed six months. A wedge of bone was removed from the lower end of the radius, scaphoid, and semilunar to allow the hand to be brought up into dorsal flexion. The wound healed by first intention and at present, ten weeks after operation the wrist is in a position of 30 degrees dorsal flexion, and there is no ulnar deflection. There is also marked improvement in the range of motion of the fingers, each of which can be apposed by the thumb.

CASE 23.—A soldier, admitted, Oct. 25, 1918, had been wounded July 18, 1918, by a fragment of a shell. The thumb and first finger were amputated leaving the proximal half of the second metacarpal bone. On admission the wound was not healed. Nov. 27, 1918, the remaining part of the second metacarpal bone was removed. The wound healed, Feb. 1, 1919. Motion was limited in all of the joints of the remaining fingers. March 19, 1919, the scar was excised and manipulation allowed free motion in all of the joints except that of the third metacarpophalangeal joint. A posterior capsulorrhaphy was done at this joint allowing free motion. Five days following operation, active motion was possible at these joints. The wound healed by first intention and at present, seven weeks after operation, the patient can flex the metacarpophalangeal joint 60 degrees and he has good motion in the interphalangeal joints.

CASE 24.—A soldier received a perforating gunshot wound of the right hand, July 15, 1918. On admission the wound was healed. The index finger with the distal end of the second metacarpal was amputated, and there was an ununited fracture of the shaft of the third metacarpal with a flail middle finger. Operation, Jan. 15, 1918, when the wound had been healed four months. The scar was excised and the shaft of the second metacarpal was transplanted between the remaining ends of the third metacarpal. The divided extensor tendon to the middle finger was sutured. One week after operation there was a separation of the skin edges of the wound. The wound healed in two months with ankylosis of the metacarpophalangeal joint, but the whole middle finger, which was abducted, was a decidedly useful member. There was good union in the fractured third metacarpal.

CASE 28.—A soldier, admitted, Feb. 19, 1919, had received a perforating gunshot wound of the left hand, Oct. 1, 1918. The wound became septic and drained about one month. On admission he showed a small healed scar on the palm and a large stellate scar on the dorsum of the hand. There was laceration of the extensor tendon to the ring finger. The extensor tendons to the middle and little fingers were bound down in scar tissue resulting in complete loss of function of the middle and ring fingers. There was only slight power of extension in the little finger. There was also a comminuted fracture, ununited, of the shaft of the third and fourth metacarpals, with marked overriding. Operation, March 22, 1919, when the wound had been healed ten weeks. The tendons of the middle and little finger were liberated from the scar and the extensor indicis tendon was transplanted into the distal end of the extensor tendon of the ring finger. Bone grafts, 4 cm. long, from the left tibia were transplanted between the fractured ends of the third and

Fig. 15.—Front view of efficient elastic traction splint used to obtain flexion of the small joints of the hand, first suggested to us by Major M. S. Danforth, M. C., Providence, R. I.

fourth metacarpals. The wound healed by first intention, and at present, five weeks after operation, there is good union in the fractured metacarpals and almost complete power of flexion in the middle and ring fingers.

CASE 38.—A soldier received a gunshot wound of the right forearm, Nov. 1, 1918, which divided the belly of the extensor

communis digitorum muscle and destroyed the nerve supply of the extensor longus and brevis pollicis, resulting in loss of power of extension of the thumb and third and fourth fingers. The wound healed four weeks after injury. Operation, April 9, 1919, four months after wound had healed,

Fig. 16.—Side view of elastic traction splint.

when the muscle belly of the extensor communis digitorum was repaired and the extensor carpi radialis brevis was freed at its insertion and transplanted into the distal tendinous portion of the extensor longus pollicis. Eight weeks after operation, the soldier had almost complete return of extension in the thumb, third and fourth fingers.

## THE GASTRIC HYPERMOTILITY ASSOCIATED WITH DISEASES OF THE GALLBLADDER, DUODENUM, AND APPENDIX

A CLINICAL AND EXPERIMENTAL STUDY\*

GEORGE DAVID STEWART, M.D.

AND

WILLIAM HOWARD BARBER, M.D.

NEW YORK

The stomach in a general way is recognized by the diagnostician as the spokesman for disease anywhere within the abdominal cavity, but particularly for organic disturbances of the gallbladder, duodenum and appendix. It is not only very difficult to ascertain which of these three organs is afflicted, but it is often impossible to free the stomach entirely from suspicion of disease. It becomes, therefore, of the utmost importance to the abdominal surgeon to have some system of classifying gastric motor pictures by which a pathologic condition of the stomach is established or eliminated, so that he may determine what organ is pathologic if the stomach is normal, and to what extent the diseased organ is involved.

There are obviously two means of studying the reflex activity of the stomach: the review of recent hospital records, and the duplication, as far as possible, of the human disease equations in the experimental laboratory. The reports of gallbladder, duodenum, and

appendix cases in the Third Division, Bellevue Hospital, from 1911 to the present time, have been reviewed, and from these have been selected only those cases with full roentgenographic reports based on complete gastro-intestinal examination confirmed or modified by direct inspection of the open abdomen. In those few instances in which the roentgenographic diagnosis did not correspond to the actual findings at operation, the error, which was one of inference and not of observation, was corrected. For example, a persistent irregularity in the outline of the stomach has been called organic and, at operation, the stomach appears absolutely normal; this same stomach is known to functionate normally in terms of emptying and of secreting; it is obvious that the "irregularity" described as organic may be either organic or inorganic; and, on the foregoing basis, the roentgenographic description is changed from "probable adhesion" or "scirrhus involvement" to gastrospasm. The pathologic findings have been purposely omitted; their significance, as far as the stomach function is concerned, may be the measure of the stimulation or depression of the stomach.

From these surveys, it appears that the percentages of hypermotility, hypomotility and normal gastric function in gallbladder disease (meaning cholecystitis with or without cholelithiasis) are: hypermotility, 68.4; hypomotility, 0; normal, 31.6; in diseased duodenums (duodenal ulcers): hypermotility, 75; hypomotility,

Fig. 1.—Diffuse pylorospasm secondary to postappendical obstruction. There was no bismuth to be seen beyond the obstruction in the pylorus. The bowel was wholly free from bismuth.

12.5; normal, 12.5; and in "chronic appendicitis": hypermotility, 55; hypomotility, 0; normal, 45.

There are in this, as in any similar review of case statistics, many sources of error. A few of these are: the general condition of the patient; the emotional state of the patient at the time of the roentgen-ray examina-

tion; the irritability of the stomach at the time of the examination, and the presence or absence of other diseased foci in the body. These factors should enter into the accompanying tables as variables; and the extent to which they affect the motor pictures of gallbladder,

were either normal or functionally inactive. This attitude is well depicted in Moschowitz' report<sup>1</sup> on chronic appendicitis (1,500 cases) in which the reality of chronic inflammation of the appendix existing at all is questioned. On this basis, the 55 per cent. of appendixes giving hypermotile stomachs in Table 3 represent acute exacerbations of appendicitis. "Chronic appendicitis" in a fair percentage of instances is accompanied by adhesions or scar tissue from previous attacks of acute appendicitis which, in themselves, have been shown to influence the tone and motility of the duodenum and stomach. A very recent example

Fig. 2.—Duodenospasm secondary to postappendical obstruction, with retention in stomach and duodenum, as shown by the retained lumina.

duodenal and appendix-stomach cases should appear in the variations in each set of cases. Hypermotility is evidently the rule in each group; hypomotility and normal stomach, being variables, indicate, for example, malnutrition, depression, a phase of gastric inactivity,

(Fig. 1) of postappendical adhesions involving the terminal ileum, cecum, uterus and right ovary, associated with spasm of the second portion of the duodenum and with diffuse pylorospasm giving a twenty-seven-hour end-ileal retention and a six-hour gastric residue, illustrates this relationship. It is, no doubt, fair to conclude that the probabilities of gastric hypermotility as described above in the presence of diseased gallbladders, duodenal ulcers, and chronic appendicitis of the mean case, as seen at Bellevue Hospital, are, respectively, 68, 4, 75 and 55.

or the presence of two or more associated lesions. Some of these appear on the hospital charts; many, obviously, do not and cannot. A possible effect of two simultaneous lesions may be seen in Table 4.

The appendix group represents the greatest degree of variation. Hirsch, whose opinion is based on an enormous experience in such cases, holds that the rule is hypermotility for the stomach after chronic appendicitis. The "normal" percentage of 45 is probably due to the fact that a large proportion of the appendixes

the course of the experiment; and his abdomen was opened in the upper half so as to expose the stomach and duodenum with the least possible trauma of handling and of instruments. Under these conditions, the stomach was watched for the appearance of the normal two-cycle contractile phase. When these contractions appeared, which might be at once or after the lapse of half an hour, or if the organ was not properly irritable or not irritable at all (these animals had to be excluded), the stomach was considered to be approximately normally contracting, and any changes in these contractions produced by parietal and visceral traumas were carefully noted. In one instance, a non-irritable stomach was made to contract by gently blowing air into it through an esophageal catheter. This relation of the stomach contractions to rise in intragastric pressure is especially represented in the paper mentioned.<sup>2</sup> In these experiments, the latency of gastric response to extrinsic stimulation corresponded roughly to the latent period of contraction for involuntary muscle. This interval was often three minutes, but varied from less than one minute to ten minutes. In a fair proportion of the animals, it was impossible to describe normal contractions for the stomach at all

TABLE 4.—SURGICAL GALLBLADDER AND APPENDIX

Case No.	Operation	Roentgen Ray Finding for Stomach

2. C.19	Appendectomy; cholecystectomy	(S) Normal

or to arouse in them any reaction to extragastric stimuli. These animals are not included in Table 5.

It should be added that all these experiments were carried out before a review of the hospital records was undertaken—which should add weight to the striking correspondence in the two data. On the basis of these experiments, the motor functions of the stomach after gallbladder stimulation, in percentages (eleven cases) are: hypermotility, 61.5; hypomotility, 0; normal, 15.4; retrostalsis, 23.1. After traumatization of the duodenum (six cases), the gastric motility is: hypermotility, 66.7; hypomotility, 0; normal, 22.2; retrostalsis, 11.1; and after clamping of the appendix (cecum) (four cases): hypermotility, 100; hypomotility, 0; normal, 0; retrostalsis, 0.

In comparing the two series, it will be noted that the variables: general condition of the patient, the emotional state, the gastric irritability, and the possibility of other diseased foci occurring at the same time, enter into both the human and the canine groups, although it is no doubt true that in the latter these elements are better controlled. This is particularly applicable to the appendix cases in which the potential appendix even after pathologic examination, in many instances, in the hospital series remains problematic, while there is no doubt of essential injury to the dog's cecum which is held in a tightly locked crushing clamp. Retrostalsis appears in the experimental but not in the clinical series. This is probably accounted for by the fact that

patients who are vomiting are not submitted to roentgen-ray examination, although Hirsch reminds us that occasionally he has seen this phenomenon take place during fluoroscopic examination of the stomach. On the other hand, if vomiting did occur at the moment the roentgenogram was taken, it is probable that the direction of the wave from the pylorus toward the cardia could not be ascertained. Antistalsis is seen in the canine group because the animals are studied under conditions of acute traumas which provoke vomiting in the anesthetized creature. The human cases were chronic; the mammals correspond to acute types; but when it is remembered that the patients present themselves during their periods of acute suffering, this apparent dissimilarity loses weight.

It is apparently impossible, in the light of our present knowledge, to exclude absolutely, without direct examination, a pathologic condition of the stomach in the reflex type of individual under discussion. The roentgenologists are working on this problem, and it is hoped

that something will come of it. From experience with the surgical stomach, as presently outlined, one is led to conclude that the incisure or localized gastrosplasm, which may be a response to direct or to extragastric traumas, should practically always be associated with the gastric lesion and should relatively infrequently accompany the diseased gallbladder, duodenum and appendix. Given the pathologic grouping of individuals that the roentgenologist sees, it is probably true that the incisure is not infrequent after lesions of the gallbladder and duodenum, and not uncommon after appendicitis. What has been said of the incisure probably largely applies to spasm of the pyloric sphincter. On the other hand, diffuse pylorospasm very infrequently follows clinical and experimental disease of the gallbladder, duodenum and appendix.

To estimate in advance from a study of gastric motor physiology to what degree the suspected organ is diseased may not be out of the range of human possibility. A closer cooperation between the roentgen-ray and experimental laboratories, operating room, and pathologic laboratory may work to this end. There are two investigations that throw some light on a means of indicating the diseased organ and the extent of disease: one is that of antistalsis in the stomach, and the other is the selective response of the fundus and pylorus to extrinsic stimulation. Both of these problems are undergoing further study.

#### SUMMARY

1. For the past eight years, the records of chronic cholecystitis, with or without cholelithiasis, duodenal ulcer, and chronic appendicitis bearing roentgen-ray notes on the gastric motor function and verified by open operation, disclose gastric hypermotility for gallbladder disease in 68.4 per cent., for duodenal ulcer in 75 per cent., and for chronic appendicitis in 55 per cent. of cases.

2. Experiments purposely carried out in the open surgical abdomen antedating this clinical review give hypermotility for gallbladder disease in 61.5 per cent., for duodenal trauma in 66.7 per cent., and for appendix disease in 100 per cent. of experiments.

3. The motor characteristics of surgical lesions of the stomach are the incisure, and pylorospasm (pyloric-sphincter-spasm) in that they probably more frequently occur in the presence of essential disease. Diffuse pylorospasm appears very often "reflexly."

#### ABSTRACT OF DISCUSSION

DR. ANTHONY BARBER, New York: Gastro-enterologists seem to have a very hazy idea as to what tonus really is. Some work in this has been done recently by Dr. Byrne of Louisiana University, presenting tonus in a way which is both practical and understandable. Tonus may be defined as the part of a postural status, which may be maintained by the act of the muscle. As I stand here you are making an effort my muscles are in a state of jel. There is an afferent element, the element that is actually the nervous system, mainly the cerebrospinal system, that represents the active part of tonus. I am going to speak particularly in the subject of hypermotility. I notice that in the statistics here, there are in the first instance, gallbladder 68 and appendix 55 per cent., whereas in the second instance, the gallbladder is reduced to 61 per cent. and the appendix elevated to 100 per cent. In my opinion, hypermotility is of no diagnostic significance in gallbladder pathologies. It is of significance in disease of the stomach, duodenum and appendix. The reason it should

not be considered in gallbladder cases is anatomic as well as clinical. The nerves of the stomach come from both pneumogastrics and sympathetics, containing medullated and nonmedullated fibers. Here the sympathetic system is a complex of both kinds of fibers. The nerves that supply the stomach come from the gastric plexus and these also supply the upper level of the duodenum—thus hypermotility in duodenal ulcer. The right vagus is the more important in this connection, in that it supplies fibers to the posterior wall of the stomach, the solar plexus, spleen, pancreas, intestine, midcolon and suprarenal. Thus the stomach has direct connection with the appendix as is the fact with the duodenum. The nerves of the gallbladder come from the solar plexus through the hepatic plexus, which is in the lesser omentum in company with the bile ducts, hepatic artery and portal vein. It innosculates with the left vagus but this only supplies branches to the anterior surface of the stomach over a very limited area of the stomach—thus the gallbladder is very indirectly connected with the stomach and then only in small part. I feel definitely that the roentgen-ray teaching of hypermotility of the stomach as a symptom of gallbladder pathology should be eliminated.

DR. R. WALTER MILLS, St. Louis: I do not understand what Drs. Stewart and Barber mean by hypermotility, whether they speak of total gastric motility, initial motility, or fractional motility, which, by the way, may be the method of the future. In a series of 2,500 cases in which I determined the exact time of total gastric motility after a standard roentgen-ray test meal to within seven minutes, no such findings as have been given by the present investigators were obtained. For instance, in that series there were fifty-three cases of gallbladder disease and 25 per cent. of them showed hypomotility instead of hypermotility, as indicated by a six-hour residue after the barium meal. In a series of 203 cases of duodenal ulcer, 49 per cent. showed hypomotility in the sense of total motility. In appendicitis, motility was practically that of a series of one thousand cases without any organic or marked functional disturbance. A great factor in estimating gastric motility is the type of individual. For instance, in the two extremes of bodily habits, the stomach of the asthenic often will not clear of an average contrast meal in six hours. I have seen the same meal emptied from the stomach of the other extreme of type, the hypersthenic, in one and one-quarter hours. These are extremes. All motilities between these two form a gradient. If all persons are grouped in four types, hypersthenic, sthenic, hyposthenic and asthenic, their stomachs will be found to empty about as follows: The hypersthenics in four hours, the sthenics in four and one-half hours, the hyposthenics in five hours and the asthenics in five and one-half hours. The work of Dr. Alvarez on visceral neuromuscular activity as related to peristalsis and motility indicates that many gastric hypomotilities where the lesion is within the stomach, are the result of inhibition rather than of crippling of the gastric expulsive mechanism.

DR. J. O. PALEFSKI, New York: The conclusion reached by the authors is generally recognized among roentgenologists—that hypomotility is usually found in intestinal cases. However, I do not believe we can take that as a clinical application, because usually gallbladder cases that come under observation show that the predominating feature is that of gastro-intestinal stasis. At Bellevue Hospital, it has been my invariable experience from the clinical point of view that the reports showed hypomotility; while after a really mixed meal there is, perhaps, in about 80 per cent. of cases a residue after six or seven hours. I do not believe we can test the gastric motility through barium. In order to test the motility we must take into consideration the factors which enter into motility or the evacuation—the normal acidity, the normal stimulation. I feel that this is a very important point in gastro-enterology and it requires team work on the part of the gastro-enterologists as well as the roentgenologists to come to a conclusion.

DR. VAN VALZAH HAYES, New York: It seems to me that we do need a more thorough method, a more satis-

factory method of testing the motility of the stomach. Just one example:

Recently a patient came to my office. I took an ordinary test breakfast and to my surprise found present pieces of vegetable eaten at dinner the night before. The patient was then sent for roentgen-ray study and the barium was given. The roentgenologist reported that "the stomach evacuates itself rapidly and is almost completely empty at two hours."

DR. G. A. FRIEDMAN, New York: I would like to ask Dr. Stewart whether he has had occasion to examine his patients roentgenographically after their appendixes or gall-bladders were removed, and whether the roentgen findings in regard to motility of the gastro-intestinal tract were different from those found before operation. If the disturbance in motility was due to the diseased appendix or to the diseased gallbladder, normal motility should have established itself after the surgical procedures. If, however, the postoperative roentgen findings were identical with the preoperative findings, it may then be questionable whether the altered motility discovered previous to operation was really due to the pathology in the appendix or gallbladder. May it not be possible, then, that the disturbance in nerves regulating the musculature was the primary factor for the disturbance in motility?

DR. WILLIAM HOWARD BARBER, New York: In regard to the connections of the extrinsic gastric nerves with "reflex" gastric motility: keeping in mind the anatomy, as Dr. Bassler has described it, it is very difficult to interpret the effects on stomach tonus produced by traumatizing, clinically or experimentally, extragastric tissues; it is difficult to affirm positively that such effects are vagus or splanchnic. These nerves have been divided in the chest and in and about the stomach. From these experiments, it appears that the vagus nerve carries motor fibers to the fundus and inhibitory branches to the pyloric part. Appendical, duodenal and gallbladder irritation in the present series is most often associated with gastric hypermotility. One occasionally sees in the course of an operation, gastric motor waves followed (as the traumatism of handling continues) by fundic relaxation and, later, by pyloric relaxation or total dilatation. These changes may be due to the loss of vagus control or to the stimulation of the sympathetic.

Under the head of hypermotility are included the gastric spasms. Pylorospasm may be confined to the anatomic sphincter or to the pyloric end of the stomach. It is believed that the spasms are qualitatively identical with hypermotility. Increase in force characterizes the spasmodic contractions, but increase in rate characterizes the cycles in hyperperistalsis. Hypermotility must be differentiated from "emptying time" for it is evident that a forcibly contracting stomach may be associated with early emptying or retention accordingly whether there is pyloric relaxation or obstructive pyloric spasm. For this reason, the gastric "motor" meal is not a motor meal at all but significant of the time of gastric emptying. Of course, the anatomic types, spoken of by Dr. Mills, are to be considered among the variables influencing the tone and motility of the mean stomach. The choice of the opaque meal and the interpretation of the roentgenograms have been left with the roentgen-ray department. The gastric motor function following operation was largely a personal equation. It is to be expected that this improves as the general condition of the patient improves.

**Report on After-Care of Poliomyelitis.**—The annual report of the New York committee on the after-care of infantile paralysis patients has just been made public, and shows that during the past year 8,253 patients have been cared for. The report shows that regular after-care has resulted in great improvement in most cases and in many instances in permanent cure. It finds, however, that there is still a great deal to be done, and a survey now under way indicates the necessity of complete records of cripples, additional clinics, and increased means of transportation, and the development of field agencies to help those in need of orthopedic assistance.

## BLOOD TYPE CLASSIFICATIONS, WITH A SLIGHT MODIFICATION OF TECHNIC

REPORT OF THE RESULTS OF MORE THAN A THOUSAND CLASSIFICATIONS

GEORGE R. MOFFITT, M.D.  
Major, M. C. U. S. Army; Officer in Charge

GEORGE F. KLUGH, M.D.  
Captain, M. C. U. S. Army

AND

CHESTER E. SHEPARD  
Second Lieutenant, Sanitary Corps, U. S. Army  
FORT McPHERSON, GA.

During the year ending Feb. 1, 1919, 1,122 blood type classifications were completed in the laboratory of the U. S. Army General Hospital No. 6 and the Department Laboratory, Southeastern Department, U. S. Army, Fort McPherson, Ga.

The whole blood, slide method was employed, the technic of which, having been slightly modified by this laboratory, is herewith reported.

The blood of the individual to be typed is collected from the finger tip in a leukocyte counting pipet. The pipet is not washed out with sodium citrate solution before taking the blood, as is usually advised; but the citrate solution (2.5 per cent.) is drawn to the 0.5 mark

### RESULTS OF CLASSIFICATIONS

Types	Number	Per Cent.
1. ....	54	4.8
2. ....	601	53.6
3. ....	70	6.2
4. ....	397	35.4

of the pipet tube and the blood then drawn up until the bulb is half filled, when the blood remaining in the tube is drawn up about 1 mm. from the tip or point of the pipet and the citrate solution again drawn to the 0.5 mark. As a result of drawing the blood up to about 1 mm. from the tip of the pipet, a small space of air is placed between the blood and the solution, preventing admixture of the two fluids in the tube so that the solution may be drawn to the 0.5 mark without difficulty. Without this little bubble of air, it is impossible to observe the surface of the citrate solution in the tube since it mixes with the blood.

It has been observed that by drawing the citrate solution twice to the 0.5 mark instead of once to the 1.0 mark, a clot never forms in the bulb, since the solution and blood are more thoroughly mixed.

Several bulbs of blood are collected and blown into a small tube, such as a Wassermann tube. Blood from a known Type II individual (several of whom are on duty in this laboratory) is similarly collected.

The admixture of the unknown and known bloods is made by using the white blood counting pipet instead of a capillary tube. The Type II blood is drawn to the 0.1 mark and then the unknown is drawn up until the 1.0 mark is reached. This admixture is blown on a slide and thoroughly mixed by being drawn up and down in the pipet several times; any bubbles are broken by being blown on through the pipet. The entire amount of mixed blood is then drawn into the leukocyte pipet tube and blown on a drop of physiologic sodium chlorid solution on another slide (near one

end), and any bubbles are broken as before and a cover slip dropped on it.

The same process is repeated, one part of the unknown being used and nine of the Type II, which after being mixed is placed in a drop of saline on the opposite end of the same slide. The agglutination is observed with the low power of the microscope and is complete in ten minutes, sometimes in a much shorter time.

An agglutination at only one end means a Type I or Type IV, the latter if nine of the unknown agglutinates the known II, Type I if nine of the known II agglutinates the unknown.

No agglutination on either end of the slide commonly means a Type II, but there is an exception to this, as will be shown below, and agglutinations at both ends indicate a Type III with the following exception: Some Type IV bloods possess such high agglutinating power that the one tenth amount causes agglutination in the nine tenths of the Type II, giving agglutinations at both ends of the slide. It so happens that the agglutination occurring in this manner is generally somewhat weaker or less pronounced at one end than at the other, but this is not always the case. It is therefore customary in this laboratory to verify all Type III agglutinations with a known Type III, and also to corroborate the result further by agglutinating with known Types I and IV.

The exception to the statement that no agglutination on either end of the slide indicates a Type II is due to the fact that some bloods are apparently lacking in some substance or agent which, in a manner similar to the action of complement in fixation reactions, causes or permits the agglutination to proceed. When two bloods in both of which this ingredient is wanting are brought together, no agglutination results regardless of the type they may be. The accidental occurrence of such phenomena on several occasions in this laboratory has led us to confirm all results which indicate Type II by agglutination with a known Type IV.

## NOTES ON DIGITALIS MEDICATION

HAROLD F. B. PARDEE, M.D.

Assistant Attending Physician, New York Hospital  
NEW YORK

### I. THE RATE OF DISAPPEARANCE OF DIGITALIS FROM THE BODY

When we try to maintain a patient under the full therapeutic effect of digitalis, we have always been bothered by the fact that we do not know the rate at which the body can dispose of this substance by excretion or destruction. It seems likely from recent research by Hatcher and Eggleston that both of these processes occur.

The patient is either unable to pass gradually out from under the influence when too small a dose is given, or with over-administration of the drug to have a series of symptoms which give the impression that the patient is essentially susceptible to the vomiting.

It is evident that a final experiment would not give a definite answer to the question of the rate of disappearance of the drug, because of the marked variations that were found between different species.

The question was therefore applied directly to the patients by the following method: The drug was given so as to produce one of the mild toxic symptoms and then stopped entirely for a number of days. It was then given again until the same toxic sign reappeared. The amount of the drug used in the second course, divided by the number of days between the two toxic points, would give the daily average of the drug that had disappeared from the body in the interval, assuming that there is no change in the patient's tolerance for the drug, a fair assumption, as will be pointed out later.

The initial course was given so that the toxic symptoms appeared in from two to six or eight days, usually starting with doses of 30 minims of the tincture every four hours, or even 1 dram for the first three doses, and continuing with 15 or 20 minims every four hours. The second course was usually given in a similar way, starting with large doses and continuing with 20, 15 or even 10 minims every four hours, or three times daily. The second course was completed in an average of six days, though in a few cases it was prolonged, by using smaller doses, to ten, fourteen or seventeen days.

### SIGN FOR DISCONTINUING DRUG

Vomiting was the symptom that was most frequently used as a sign for stopping the drug, as it was felt that this was a quite definite end-point. In one case the appearance of dropped beats due to heart block was used, electrocardiographic records confirming the clinical diagnosis, and in two cases severe nausea without vomiting caused the stopping of the drug at the end of each course.

The patients included ten cases of chronic cardiac valvular disease, three cases of chronic myocarditis, and one case each of chronic adhesive pericarditis, chronic parenchymatous nephritis and chronic interstitial nephritis. At the time of the first course they all showed signs of a rather marked degree of heart failure, but by the time of the second course, most of them were in better condition. The same lot of tincture of digitalis was used throughout this series. It was standardized by the cat unit method through the kindness of Prof. R. A. Hatcher and was found to be about an average strength tincture, having 1.25 c.c. per cat unit.

The details and results of the administration of the test on twenty-two occasions are shown in Table I. The figure that represents the average rate of disappearance of the drug from the body is 22 minims of the tincture per day. In half of the cases the figure was below this and in half above it, the maximum variations being from 55 per cent. below to 82 per cent. above the average. The rate of disappearance seems to be independent of the amount of digitalis present in the body at the time, for it does not vary with the number of days elapsing between the first and the second points of toxicity. Nor was any relation noted between variations in the rate of disappearance and either the weight of the patient, the size of the doses of the tincture at the time vomiting occurred, the rapidity of administration of the total dosage, or the degree of heart failure shown by the patient at the time of the test. Susceptibility of the patient to the drug did not appear to influence the result either, for the rate of disappearance of the drug bore no relation to the quantity of digitalis per pound which was required to produce toxic symptoms in the patient's first course.

In five cases (2, 4, 6, 8 and 9 in Table 1), the test was repeated after an interval and in one case twice repeated, so that we have a total of six repetitions. In three of these the difference between the first and the later figures is not great, but in one case it is 9 minims, in another 10 minims and in another 17 minims. This variation does not seem to depend on the dosage used or on the length of time elapsed between the days on which digitalis was stopped in the successive courses. It does, however, vary with the days of administration

return of the vomiting. Ten minims of the tincture<sup>2</sup> three times daily will lead to vomiting in the majority of cases, since fifteen of our twenty-two tests showed a slower rate of disappearance than this. Our results also demonstrate a new phase of the variability, from one individual to another, in the action of digitalis, a variability in the rate of disappearance from the body.

II. THE THERAPEUTIC DOSE OF TINCTURE OF DIGITALIS

In the course of the previous work it was possible to determine the amount of digitalis that was necessary to produce those early toxic manifestations (nausea, vomiting or dropped beats due to heart block) which are commonly encountered when the drug is given in sufficient dosage to obtain a prompt therapeutic effect. Sixteen suitable cases were found, nine of which were included in the previous series also. There were seven cases of chronic cardiac valvular disease, two of chronic myocarditis, two of chronic adhesive pericarditis, two of chronic parenchymatous nephritis, and one each of chronic interstitial nephritis, acute fibrinous pleurisy and carcinoma of the mediastinal glands. The noncardiac cases were included for the purpose of comparison; and since they did not give figures at either extreme of our results, it was felt that this was evidence that the handling of digitalis is not essentially different in cardiac and noncardiac cases.

TABLE 1.—THE RATE OF DISAPPEARANCE OF DIGITALIS FROM THE BODY

Patient	Condi- tion	Days Elapsed between Two Points of Stopping Digitalis	Minims. (Total) in Course	Days of Administration of Course	Dosage During Last Day	Minims per Day Disappearance
1	A	9	90	1	30 m q4h	10

22	B	11	440	6	20 m q4h	40
Average.....		13		6		22

A indicates that the patient shows only slight signs of heart failure, B indicates that the patient shows moderate signs of heart failure, C indicates that the patient shows marked signs of heart failure.  
\* These two patients had not yet reached the toxic stage with the dose recorded.

of the last course, being higher in a given patient when the course covers a greater number of days. This variation is not proportional to the number of days, nor can any explanation for it be offered.

The results of this investigation resemble those of other work on digitalis in the variability of the figures, but nevertheless in eighteen of the twenty-two tests the result lay between 12.3 and 30.6 minims per day, while in eleven tests, half of the total, it was between 13.3 and 27 minims, the latter a total variation of only 62 per cent. of the average. It is evident from this that the average figure of 22 minims per day would afford a fairly satisfactory basis for long continued digitalis medication, since in only half of the cases would it be much more or much less than the patient's ability to dispose of the drug.

BEARING OF RESULTS OF INVESTIGATION ON ADMINISTRATION OF DIGITALIS

These results seem to have two important bearings on the administration of digitalis over long periods of time. They demonstrate the approximate efficacy of the dosage of 10 minims of tincture of digitalis twice daily, which has commonly been considered sufficient to maintain the digitalis effect which has been already produced by larger doses. Only after a considerable number of days will a patient on this dosage come to be much below the grade of digitalization at which he started, and only occasionally will this dosage lead to a

TABLE 2.—THERAPEUTIC DOSE OF TINCTURE OF DIGITALIS

\* Did not vomit after this dose.

THE AVERAGE PERIOD OF ADMINISTRATION

None of these patients had received digitalis previous to this experiment for a period of at least three weeks. The drug was given as previously described for the first course, the average period of administration being six days, never over eight days except on one occasion, which was a repetition of the test after a thirty day interval (Patient 11, Table 2).

In this repetition of the test we see the influence of a lengthened period of administration. The first test

2 It must be remembered that 10 minims is equal to ten 1/2 drops of tincture of digitalis, according to the dropper used.

was complete in four days and the second in nine days. Allowing for a daily disappearance from the body of 22 minims of the tincture for each of the five extra days, the figure for minims per pound of body weight is reduced to 2.8 minims, which is not very different from the 2.14 minims of the first test in this case. The time factor has a much more evident effect in the last two cases in Table 2, neither of which are included in the average for the series. The figures of 6.1 minims and 6.64 minims per pound of body weight represent the amount of the drug given over periods of twenty-two and twenty-one days respectively. When these are corrected to allow for a daily disappearance of 22 minims per day for each day over the average time of administration for the series, namely, six days, they are reduced to 2.23 and 4 minims per pound, respectively, which makes them quite comparable with the rest of the series.

Table 2 gives the data for these experiments, the average for the seventeen courses being 3.3 minims per pound of body weight. The variation is from 36 per cent. below this to 50 per cent. above it.

The only work with which this may be compared is that done by Eggleston,<sup>1</sup> who also found marked variations from the average dose of the tincture, variations from 38 per cent. below to 71 per cent. above the average. Since he used larger doses of the tincture, toxic effects appeared in his series after an average of only three days. His results, moreover, were reduced to a standard strength of tincture such that one cat unit equals 1.00 c.c., a stronger tincture than ours. If Eggleston's figure of 2.2 minims per pound of body weight is corrected for the difference in strength of the tinctures it is raised to 2.75 minims; and if further corrected for the three days longer that were required to produce toxic effects in our experiments, considering that 22 minims per day were disposed of and taking into account that the average weight of his patients was 140 pounds, the figure becomes 3.23 minims per pound, which is quite in agreement with our figure of 3.3 minims.

#### THREE IMPORTANT POINTS

Three things among these results seem to demand special mention. The importance of the period of administration is very great, for each day some of the drug is destroyed or excreted from the body. The average amount of tincture required to produce a full therapeutic or early toxic effect is found to be in agreement with Eggleston's figure, and the variations from one individual to another are of the same considerable magnitude that he found.

#### IMPORTANCE OF A KNOWLEDGE OF THE VARIABILITY OF THE INDICATED DOSE

The variability of the dose of digitalis for different individuals is of great importance in therapeutics. Realizing that a variability has also been found in the rate of disappearance of the drug from the body, it will be plain how complicated the problem of digitalis medication must be. Two things, however, are quite plain: when the patient has received enough digitalis for his own special organism he will show one of the early toxic effects, usually nausea or vomiting. If after this he continues nauseated while the drug is being given, it means that he is receiving too much, that is, an excess over his average daily rate of disap-

pearance. We must carry these facts of variable susceptibility and variable disappearance clearly in mind, and combine with them the fact that digitalis is continually being disposed of by the body even during the period of administration, in order to avoid two common errors of clinical observation which may arise when digitalis is given. When a patient does not react to a usual dose of tincture of digitalis, it does not necessarily mean that the tincture is weak. It is possible that the patient may have a high susceptibility, and may require perhaps 4 or 5 minims per pound of body weight instead of the usual 2 or 3 minims, or the drug may have been given at such a slow daily rate as to little more than keep pace with the disappearance. On the other hand, the reappearance of vomiting a short time after resuming digitalis does not mean that the patient is one whose stomach cannot tolerate the drug. The time that has elapsed since the last vomiting must be considered, as well as the daily dosage.

#### FACTORS MAKING FOR A LOW VENEREAL RECORD IN THE AMERICAN EXPEDITIONARY FORCES

P. M. ASHBURN, M.D.

Colonel, M. C., U. S. Army  
WASHINGTON, D. C.

The venereal disease incidence in the American Expeditionary Forces is considered as probably much lower than that ever obtained in our own army or in any other army operating in Europe. This opinion is not susceptible of proof as regards the armies in Europe, as the methods of reporting cases and estimating rates are not comparable. In the American army, cases were found largely as the result of physical inspections held at least twice a month, while in most other forces only those cases in which excuse from duty was granted or hospitalization occurred became known.

#### THE VENEREAL DISEASE RATE

The American incidence rate, based on inspection and stated in annual rates per thousand, varied for the greater part of the time during which American troops were present in large numbers in France between 62 and 31, averaging in the neighborhood of forty-five cases per thousand men per annum. This rate was never before closely approached in the U. S. army. It rose rapidly as troops were being sent home, but this rise was partly fictitious, and the true rate at that time was undeterminable. The corresponding incidence rate in the United States was always reported as higher than in France, averaging above 60 even after the armistice. It is thought that this was an error, as there is no sufficient reason known to account for a higher rate in the United States. Ignoring that rate, however, and considering only the low rate in the American Expeditionary Forces, this appeared the more remarkable for the following reasons:

(a) Many men in the United States were sufficiently near their usual safe sources of sexual gratification, whether wives or mistresses, to enable them to indulge occasionally and so avoid the call set up by prolonged abstinence.

(b) One of the most potent influences affecting conduct is the public opinion of a home community. While

<sup>1</sup> Eggleston, C. C. *Digitalis Dosage*. Arch. Int. Med. 16:1 (July) 1917.

in America most men were within reach of that opinion, in France they were away from it. Furthermore, public opinion in France differs radically from that in America in regard to male chastity. Notorious lack of such chastity certainly carries reproach in the United States. It does so to a much less degree, if at all, in France.

(c) Discomfort, overcrowding, mud, wetness, lack of fuel and lack of amusement were more marked in France than in the United States, and the comparative luxury and comfort of the prostitute's room was greater in France.

(d) Solicitation by prostitutes is nowhere in America anything like so common, so open, so attractive, as it was almost everywhere in France. In cities like Paris, Tours, Nice and Marseilles, real virtue was necessary to resist it at all times.

(e) Alcohol was much more easily, cheaply, abundantly and openly obtainable throughout France than in the neighborhood of any camp or post in the United States. Alcohol has always been considered an aid to prostitution and an important factor in the spread of venereal disease.

#### CAUSES FOR THE LOW INCIDENCE RATE

An effort was therefore made to obtain information which would account for the low incidence rate and which would furnish data for formulating answers to certain important, but at that time, wholly unanswerable, questions, namely, What proportion of Americans remained chaste in France? What proportion of exposures were followed by the use of prophylaxis? What is the average number of unprotected exposures per case of infection? What is the average number of exposures with prophylaxis per case of infection?

With this object in view a questionnaire was sent out in order to secure information on the following subjects:

1. What is the percentage of chaste men among soldiers?
2. What is the average number of nonprotected venereal contacts to each case of venereal disease?
3. What proportion of men have been exposed to venereal disease (that is, what proportion have had sexual contacts in France) without using prophylaxis?

The suggestion was given that information on these subjects might be obtained by having organizations of white soldiers addressed by urologists, who would set forth the need of this information and state to the men that their aid was desired in obtaining it. The urologists could then ask the men to fill out and turn in without signature a mimeographed questionnaire card giving the following information:

1. Have you had sexual intercourse in France? If so, approximately how often?
2. Have you always used prophylaxis after intercourse? If not, how many times have you failed to use it? (If the exact number of times is not known, make an estimate or state average frequency.)
3. Have you had venereal disease? If so, did it follow intercourse with prophylaxis? Did it follow intercourse without prophylaxis?

It was requested that an inquiry of this nature on a scale as large as was readily practicable be made and that the results be promptly reported.

The questions were answered more or less completely by 13,648 men located in four base sections, principally at Bordeaux, St. Nazaire, Brest and Tours.

The men's own papers from Bordeaux and St. Nazaire were unfortunately not sent to me; only compilations of the replies were sent. But the papers from Tours and Brest, more than 3,000 in number, I received myself and have analyzed carefully, and certain deductions are based on that analysis only, for the reason that that was the only material available for an analysis of the sort. The total replies covered more than 104,000 illicit exposures and 215 acknowledged cases of venereal disease. Among the Tours and Brest papers there were 7 per cent. in which the men failed to answer the question as to whether they had had venereal disease; and the compilations sent from Bordeaux and St. Nazaire did not give information on that point. It is probable that the majority of men refusing to answer this question had had venereal disease in some form.

In addition to the foregoing material, the deductions set forth are based on a questionnaire put out by Col. George Walker, which was answered by 614 men who had contracted venereal disease, on reports of prophylaxis and on all reports concerning venereal disease incidence in the American Expeditionary Forces. From these sources I have drawn information that seems to me to justify the conclusion that antiveneal measures are effective in the following order:

1. Those that keep men chaste.
2. Those that diminish the opportunities for sexual contact, especially efforts at the suppression of prostitution.
3. Those that diminish the dangers of contact, especially venereal prophylaxis.
4. Those that exact punishment.

#### INFLUENCES THAT MAKE FOR CHASTITY

Thirty-four per cent. of 13,648 white men taken at random in the service of supply, abstained from sexual intercourse while in France, a period varying from eight months to two years and probably averaging about ten months. One third of all men were thus practically excluded from the possibility of obtaining venereal disease, and one third of the possible venereal rate was thus eliminated. As to what induced this proportion of men to remain chaste, I can advance only opinions, not proof.

My opinion, based on conversations with men, gratuitous information inserted in replies to questionnaires, and my observations of the men, is that by far the most important factor were those inherent in the men rather than in the antiveneal campaign, factors such as character, religion, love, loyalty and self-respect.

The most common reasons advanced by men to account for their own chastity were loyalty to a wife<sup>1</sup> or a sweetheart at home, or a resolution of abstinence before sailing and pride in keeping it.

Another third of all men indulged in intercourse so infrequently as to make their chances of acquiring disease quite small; and relative continence was probably next in importance after real chastity in keeping down venereal disease.

As to how powerful the vigorous and extensive antiveneal campaign waged in all camps and cities of the United States from the time we entered the war was in leading men to avoid prostitutes there is no means of knowing; but there is ample reason for supposing that it was a very potent factor. Well reared boys

<sup>1</sup> The Second Report of the Provost Marshal General, page 11, indicates that 11 per cent. of the first year's recruits were married.

and men in general desire to do what they know to be right; and when it is difficult to do so, a little encouragement from the outside is of the greatest value. Such encouragement was certainly afforded by the campaign of propaganda.

Another, and in France even more powerful, encouragement and aid was General Pershing's well known stand in regard to venereal diseases and prostitution. The effect of that stand and of the vigorous action based on it was to make every line officer in the American Expeditionary Forces, from generals down to second lieutenants, realize as never before that he had a great responsibility for the occurrence of venereal disease among his men; and there grew up a disapprobation of venereal contacts and of prostitution that eventually became so general as almost to deserve the name of public opinion.

After self-respect and duty, public opinion, especially that of his own locality, is one of the most powerful factors in influencing the conduct of a man. The two things just discussed, the campaign of propaganda in the United States and the official attitude of the high authority in the American Expeditionary Forces in regard to immorality and prostitution, together influenced army public opinion most favorably and usefully, especially in bringing home to inexperienced line officers their responsibilities for the instruction and control and the standards and public opinion in their organizations, and for the resulting bearing and behavior of their men. The obvious facts that the acquisition of venereal disease was purely an affair of individual conduct, and that the company officer was in a better position than chaplain, physician or any other staff officer to influence the conduct of his men, had not been seen or appreciated by many of them.

The influence of work, play and amusements in keeping men away from prostitutes cannot be expressed in figures; but it was great, and the Red Cross, the Y. M. C. A., the Knights of Columbus, the Y. M. H. A., and similar organizations that so liberally provided amusements, did a very valuable work in keeping down venereal disease, as in many other respects.

#### FREQUENCY OF EXPOSURE IN RELATION TO PREVALENCE OF VENEREAL DISEASES

It is self-evident that not nearly all exposures to venereal disease are followed by disease. The same thing is true of all diseases. Furthermore, some, if not all, of these diseases can be introduced only through a lesion of the skin or the mucous membrane, thus greatly lessening the danger. The fact that I was unable to obtain from other sources any information as to what proportion of exposures are followed by infection was one of the principal reasons for sending out my questionnaire. However, the information furnished by the stragglers is somewhat difficult to classify. If the answers of only those men who had conducted themselves properly enough to indicate pretty strongly that they avoided prostitutes rather than mistresses, and who achieved acquiring venereal disease by contact, the number of unprotected exposures per case of infection varied from eleven at Brest to thirty at Tours, while the number of exposures followed by prophylaxis per case of infection ranged from twenty-five at Brest to seventy at Tours.

If the replies of all men whose intercourse was so infrequent as to suggest employment of prostitutes, and who answered the questions as to whether or not

they had acquired venereal disease be included, the Brest rates rose to 115 and 118, while if total admitted venereal disease be divided among total reported contacts, making no allowance for the 7 per cent. of men who do not state whether or not they had venereal disease, the St. Nazaire rates rose (or fell) to 312 unprotected or 1,180 protected exposures per case of infection, while in the whole series the rate was 204 unprotected or 615 protected exposures per case.

From an analytic study of replies in my possession and from collateral evidence, I think that in France there were about thirty unprotected contacts with women of promiscuous sexual habits for each case of resulting venereal disease, while prophylaxis as used in France reduced the incidence to about one third of what it was without prophylaxis or, roughly, to ninety exposures with prophylaxis for one infection.

This proves up, in a way, since from one fourth to one third of contacts are not followed by prophylaxis, while half of all venereal disease followed the neglect of prophylaxis.

The one third as many exposures is balanced by the three times greater liability to infection.

#### EFFECT OF OPPORTUNITIES FOR CONTACT

A fact that stands out clearly, from whatever angle of approach the inquiry be made, is that venereal disease incidence rises and falls with the rate of contacts or the intercourse rate. This is one of the strongly condemning facts about licensed prostitution or permitted houses of prostitution. Orders issued from general headquarters placed all prostitution under a ban and all known houses of prostitution "out of bounds;" but various influences, among them an honest belief on the part of some officers that regulation of prostitution was the best means of controlling venereal disease, led to occasional and sometimes frequent neglect or violation of this order, so that there were many opportunities for observing the effect of open or tolerated houses. Always, so far as I could learn (and I made diligent inquiry), the result was an increase in the contact rate, manifested by a rise in the prophylaxis rate and followed by a rise in the venereal rate. So, in addition to being condemned as a sin against marriage and against a society grounded on monogamous marriage, and as a corrupter of police and public morals, the house of prostitution is condemned by its fruits and as a producer of venereal disease.

One third (approximately) of all men in France indulged in sexual intercourse less than ten times each, many of them only once or twice. If, as I believe, there were thirty unprotected contacts or ninety protected ones for each case of venereal disease resulting in the respective classes, it may be seen at once that the chances of any one man in this third of the total acquiring venereal disease were very small and that, after chastity, relative continence was probably the next most important factor in keeping down the incidence rate.

An interesting sidelight is thrown on this question by a consideration of the incidence rates of the armies as compared with those in the service of supply. The rates of the former group were for several months only one third to one half as high as those of the latter group, owing principally to the fact that the opportunities for exposure were relatively exceedingly limited in the territory occupied by the armies. Later, as the armies moved into Luxembourg and Germany

and the men became acquainted with the people, but particularly as large and larger numbers of men were sent back to leave areas, the contacts increased and the venereal disease incidence rose until it almost equaled that of the service of supply.

#### BAD INFLUENCE OF LEAVES ON VENEREAL RATES

The experiment of sending men to leave areas, an experiment based on most praiseworthy desires to interest and educate the men, had a deplorable influence on the venereal rates. The release from strict discipline and in many respects from military control, the transition from a busy life to a wholly idle one, from one wherein women scarcely entered to one in which their seductions were very appealing, and the pocketful of money that the leave men carried, were sufficient to account for much disturbance of conduct; but, in addition to that, some men actually expressed the opinion that the purpose of the leaves was to allow them to have a good time with the girls after a prolonged forced abstinence. The unfortunate result was that the contact rate among men on leave was high, and in a short time the army rates began to rise. Investigation of each individual case then showed that from 50 to 70 per cent. of the venereal disease in the armies was coming from leave areas and towns en route thereto.

As indicating the high contact rates in the areas, it may be stated that, although the men stayed for only one week, the official reports of prophylaxis showed 128,637 treatments given to 430,646 leave men, a prophylactic rate of 29.8 per cent. *per week*. The rates in different areas varied from 5.6 per cent. in the Pyrenees area of Eaux Bonnes, where the population and prostitutes were scarce, to 104.7 for Nimes, a relatively large city with only a small number of leave men.

Financial condition naturally has a great influence on the contact rate, which rises at and immediately after pay days, yet 27 per cent. of 614 men who acquired venereal disease in France asserted that they had done so without money and without price; and from places so widely separated as Antwerp and Biarritz, it was officially reported that most sexual contacts with American soldiers did not involve a money consideration.

Season has an influence, and both contact and incidence rates rose markedly in the late spring and early summer. How much of these increases was due solely to seasonal influences and how much to psychologic states related to the approach of peace and the prospect of return home is undeterminable.

That entertainments or other occupation had a great influence in keeping men out of mischief is not to be doubted. Many facts indicate that a majority of venereal contacts were most casual happenings, due often to temporary lack of other occupation or interest. That they were easily and surely prevented by a tactful word in time is clearly shown by the results of the work of a very remarkable woman in the service of the Y. M. C. A. in Paris, who, at the time when I last had reports of her work, had successfully separated 1,100 American soldiers from French street walkers between the hours of 8 p. m. and 2 a. m., without one failure and with but one insult from a soldier.

According to statements made by 614 soldiers with venereal disease, alcohol seems to have played a smaller part as a factor predisposing to venereal disease in the

American Expeditionary Forces than would be supposed. Of the 614 men, only 215 admitted the use of alcohol before exposure, and only eighty-five admitted intoxication. Considering the ready accessibility of alcohol in France and its well known reputation as an attendant and promoter of venery, these figures are surprising; but as the percentage of abstainers from alcohol in the American Expeditionary Forces is not known, their significance cannot be fully appreciated.

#### INFLUENCES THAT DIMINISH THE DANGERS FROM ILLICIT CONNECTIONS

The most important of the influences tending to diminish the dangers from illicit intercourse are (1) inspection and detection of diseased persons and their segregation in such a manner as to prevent their transmitting their diseases, and (2) venereal prophylaxis, which, as prescribed in the American Expeditionary Forces, was simply an intelligent and controlled effort to disinfect a person and part already exposed to infection.

Inspection, if followed by segregation of infected persons, should do great good; and as applied to soldiers it is thought to accomplish much. In our army the practice is of several years' standing, and inspections must be made at least as often as twice monthly. Men found to have venereal disease are placed under treatment, and supposedly under restriction of movements until freed from infectious lesions. There is some evasion of the orders, but the enforcement and results are generally good. The men are kept from spreading their diseases and are given early and good treatment. Inspection of prostitutes should theoretically likewise be of great value. That it is so is extremely doubtful. There is no doubt as to the wisdom of segregating a prostitute found suffering with transmissible venereal disease; but that routine inspection, especially inspection followed by certification as to freedom from disease, does good is very doubtful; that it does harm is certain. The doubt about the good resulting is based on these facts:

(a) The inspections furnished are usually so imperfect as to be mere formalities in many instances, and without value. I know of no more striking evidence of this than that furnished by Col. George Walker, namely, that in *five years* only five cases of syphilis were detected in inmates of houses of prostitution in all the city of Paris.

(b) The inspections for many reasons, mainly economic, cannot be made nearly so frequently as exposures, and a woman found free from disease on one day may develop it the next and have intercourse with a hundred or more men before the next inspection.

(c) The prostitute has many reasons for wishing to escape segregation and withdrawal from her business and pleasure, and she also acquires skill in passing inspections.

(d) A thorough and efficient inspection is a time-consuming and skilled procedure, and it must be paid for accordingly. If the state or municipality pays, the cost is considered prohibitive. If the woman pays, there is at once established a fair presumption of partiality.

Harm is done by examination and certification of good health because such certificates, when shown, create a feeling of safety that is unjustified.

For these reasons, examination of prostitutes should not be relied on as a sound measure of venereal dis-

ease control, and it should not be followed by certification of good health; but, if used, it should be followed by prompt segregation and treatment of women found diseased. It was a measure almost entirely ignored in the American Expeditionary Forces, and was without influence on the low disease rate.

#### VENEREAL PROPHYLAXIS

Veneral prophylaxis stands on a somewhat similar but different basis. There is some reason to fear that too great confidence in the value of prophylaxis, and especially of a prophylactic measure taken in advance of connection, may relieve inhibiting fears and so tend to promote illicit connections. On the other hand, the duty of trying to protect a soldier from his own folly and to save his services to the government, and to disinfect him and prevent his acquiring venereal disease to which he has been exposed, is analogous to the duty of vaccinating him after his willful exposure of himself to smallpox, or that of treating him to prevent the possible loss of an eye injured in a drunken fight of his own seeking. The use of prophylaxis, *after the exposure*, is justified and a duty in that sense. As stated above, prophylaxis as it was used in France, that is, without making allowance for errors in technic or delay in seeking it, reduced the liability to venereal disease to about one third of what it would have been otherwise. It is probable that improvement in administration and elimination of delays would further improve results.

The much greater relative frequency of chancroid in France, approximately two fifths of all venereal disease as compared with less than 4 per cent. of the total venereal disease brought in with the draft, and the lesser relative frequency of gonorrhea, two fifths as compared with four fifths, taken in connection with the fact that the relative proportions were not greatly different in France among men who had contracted venereal disease after use or after neglect of prophylaxis, makes it very difficult to state in what degree prophylaxis is effective against the individual diseases. However, our impression in France was that, as used, it was less effective against chancroid than against gonorrhea or syphilis.

#### PUNISHMENT AS A FACTOR IN PREVENTING VENEREAL DISEASE

In America the man excused from duty because of venereal disease not acquired in line of duty receives no pay for the time he is so excused. Furthermore, if he has acquired venereal disease from an exposure not allowed by prophylaxis, he is tried by court-martial for neglect of prophylaxis. In the American Expeditionary Forces the acquiring a venereal disease was in itself a military offense to be tried by court-martial, and neglect of prophylaxis as a separate count. Furthermore, for a part of the time, all infected men were sent to venereal camps and there segregated, a measure amounting to punishment in some respects, and during another part of the time collective punishments, for example, restrictions as to passes, were inflicted on organizations having high venereal rates.

These collective punishments were effective in bringing down venereal rates and influencing public opinion against sexual offenders within the organization, but they were regarded as unjust because they punished the innocent with the guilty, and they were therefore ordered stopped.

It is wholly just and fair to stop pay for time lost from duty because of the man's own misconduct; otherwise a premium is placed on misconduct and a man could escape much disagreeable and hard work and still draw his full pay by the expedient of acquiring venereal disease. Furthermore, the result of this policy in reducing venereal disease justifies it.

Good arguments can be advanced for making the acquisition of venereal disease and the neglect of prophylaxis military offenses and demanding trial for the offenders.

It is probable that the knowledge that punishment will follow the acquisition of venereal disease cause some men to abstain from intercourse; but it is probable that this influence is less potent than those previously discussed, for the reason that most men do not themselves expect to "get caught" at any specific time, and the additional reason that, as stated above, a large proportion of illicit contacts are very casual affairs and are brought about by circumstances that lead to the forgetting or neglect of prudent counsel of "safety first." What can most be depended on to stand against the alluring circumstances of a temptress occasion are fixed principles, and fixed habits of thought and character. These are the effects of reading and of lifelong education rather than of sporadic efforts spent on adults.

#### STUDIES ON HYPERTHYROIDISM\*

FRED M. SMITH, M.D.

CHICAGO

This report is based on the study of thirty men in whom the physical findings were suggestive of hyperthyroidism. They had rapid pulse, enlargement of the thyroid gland, fine tremor of the hands, moist, clammy palms, and some of the eye signs usually associated with exophthalmic goiter. The object of the observations was to determine if possible whether the thyroid gland was the basis of these physical findings.

#### METHOD OF STUDY

In addition to the usual routine physical examination and laboratory work, blood sugar determinations were made following the administration of glucose by mouth. The response to epinephrin and the effect of thyroid feeding were also noted.

*Technic of the Sugar Tolerance Test.*—The test was made in the same manner as that recently described by Janney and Isaacson<sup>1</sup> except that the blood sugar determinations were made by the Lewis-Benedict method.<sup>2</sup> The patient was not allowed breakfast. About 8 a. m., a sample of blood was taken for the initial blood sugar determination. The patient was then weighed, after which he was given a glucose drink containing 1.75 gm. of glucose per kilogram of body weight, dissolved in from 250 to 300 c.c. of water. Early in the work, blood was withdrawn for sugar determinations at one-half, one, one and one-half, two and three hour periods following the administration. Later, however, as we were interested only in whether the blood sugar returned to the fasting value within two hour period, blood sugar readings were made in

2. Lewis, R. C., and Benedict, S. R.: *J. Biol. Chem.* **20**: 61, 1917.

of 5 c.c. of 1:1,000 epinephrin (adrenalin) solution was made into the deltoid muscle. Records were made of the pulse, respiration, and blood pressure every two minutes for ten minutes, and then every five minutes for one hour. Following this, observations were made at ten minute intervals for one half hour. In the meantime, any subjective symptoms that might arise were carefully noted. We considered a reaction positive when there was an increase of from fifteen to twenty points in the pulse rate and blood pressure, accompanied by an exaggeration of the tremor of the hands, nervousness, palpitation of the heart and arterial pulsations.

**Method of Thyroid Administration.**—The men were put to bed and isolated in one end of the ward. Other convalescent patients were instructed not to disturb them. The desiccated thyroid gland of sheep was used (Lilly's preparation). The initial dose was one-fourth grain morning and evening. This dose was increased one-fourth grain each day and was continued until there was a response or the patient was getting 5 grains a day. The pulse was taken four times a day. The nurse was instructed to take the pulse, whenever possible when the men were asleep. A definite increase in pulse rate while asleep, associated with increased nervousness and irritability, was regarded as a positive reaction and the thyroid discontinued.

In Table 1 are given the physical findings, differential blood count, blood sugar determinations, response to epinephrin and thyroid, final diagnosis, and the disposition of the thirty cases studied.

#### GENERAL HISTORIES AND SYMPTOMS

Most of the men gave Texas as their native state. Illinois was represented by four; Pennsylvania and Arkansas by two each; Mississippi, New York, Oklahoma, Colorado, Wisconsin and Missouri by one each.

Fifteen men had been in service from two to six months, and nine from six to twelve months. Four had given one and one-half years of service; one, practically three years, and one, four years. The majority of these men had responded well to military service. Only four gave a history of being unable to do their work.

Practically all of them were convalescing from influenza. They had been retained in the hospital because of their rapid pulse. In eight instances the influenza was complicated by pneumonia; in two, the pneumonia developed during the course of measles.

The predominating symptom was nervousness. Twenty-four made this complaint. Ten men had, in addition, palpitation of the heart, shortness of breath, dizziness, and a feeling of exhaustion on exertion. The remaining six men had no complaint other than slight weakness, which is to be expected during the convalescent period of any serious illness.

In eight men, these symptoms were not noted prior to their recent illness. In fifteen instances, the onset dated back to two, three, four, six years or even childhood. As far as could be determined, the army service had not aggravated these symptoms except in three instances. These three men had become more nervous and had lost from 10 to 15 pounds in weight in the last two months. They still, however, were able to do their work fairly well.

#### PHYSICAL FINDINGS

All of the men except two had a lagging of the upper lids (von Graefes sign). This sign was variable: one

day it might be marked, and the next day not demonstrable. In ten cases there was an apparent widening of the palpebral fissure (Stellwag's sign). None had a distinct exophthalmos.

**Thyroid Gland.**—In every case the thyroid gland was distinctly enlarged. In most instances this enlargement was recorded as being slight. The right lobe was the portion that was involved in the majority of cases. On palpation the gland was found to be of soft consistency, with the exception of an occasional firmer area in either the upper or the lower pole.

**Pulse Rate.**—The pulse reading was made in each instance after the patient had been quiet in bed for several minutes. In practically all of the cases it ranged from 90 to 100 under these conditions. One of the noticeable features was the marked increase in the rate of the pulse under the least excitement. The true rate could not be obtained until the men became acquainted with their physician and became accustomed to having a stethoscope placed on the precordia, or the radial artery palpated.

**Blood Pressure.**—The blood pressure was based on several determinations made under uniform conditions. In twenty cases, it was about normal for men between 20 and 30 years of age. In ten, the systolic pressure ranged from 130 to 155, and in one case it was as high as 170 mm. of mercury. In none were there any evidences of kidney lesions.

TABLE 2.—BLOOD SUGAR VALUES IN CONTROL CASES

Case Number	Before Glucose, per Cent.	Two Hours After, per Cent.	Three Hours After, per Cent.
1.....	0.086	0.084	0.084
2.....	0.090	0.090	0.084
3.....	0.084	0.092	0.086
4.....	0.087	0.090	0.084
5.....	0.091	0.087	0.090
6.....	0.080	0.080	0.087
7.....	0.093	0.090	0.084
8.....	0.088	0.083	0.081
9.....	0.092	0.096	0.094
10.....	0.084	0.082	0.092

**White and Differential Blood Count.**—The blood counts were always made in the morning, from two and a half to three hours after breakfast. In a few cases, there was a slight polymorphonuclear leukocytosis. In four men, this was accounted for by a slight tonsillitis which disappeared in a few days. In the other cases, we were unable to give a satisfactory explanation. In nine cases, there was a relative increase in the small mononuclear cells above 30 per cent.

**Blood Sugar.**—We were particularly interested in whether the blood sugar returned to the fasting level within a two hour period following the administration of 1.75 gm. of glucose per kilogram body weight. Consequently, only the values prior to and at two and three hour periods after the administration of glucose have been tabulated (Table 1). In Cases 1, 3, 7, 16, 22 and 30, the blood sugar value ranged from 0.102 to 0.117 per cent. at the two hour period. In Case 1, this was 0.012 per cent.; 3, 0.024 per cent.; 7, 0.03 per cent.; 16, 0.036 per cent.; 22, 0.006 per cent., and 30, 0.027 per cent. above the fasting level.

Table 2 shows the blood sugar values in ten convalescing men from a general medicine ward taken as controls. They had no symptoms or findings suggestive of hyperthyroidism or other endocrine disturbance. It is noted that the blood sugar two hours

after the administration of glucose varied very little from that of the fasting level.

**Response to Thyroid Feeding.**—Six men were definitely sensitive to small doses of desiccated thyroid gland. This was manifested by an increase in pulse rate, flushing, nervousness, and palpitation of the heart. In other words, there was a definite aggravation of the symptoms that these men presented. In two cases, the reaction was noted when they were getting

influenza was most probably a big factor in the production of their condition.

Five of the men diagnosed as having irritable heart were returned to duty. These men had a tolerance for exercise equal to that prior to their illness. The two remaining patients were discharged on a surgeon's certificate of disability. Their disability was not incurred in line of duty, and graded exercise and general treatment did not appreciably improve their tolerance for work.

Those men that were diagnosed as having simple tachycardia were all returned to duty. They were able to do strenuous exercise. The symptoms that some of them presented disappeared. None of the men considered in this report returned to the hospital within the two months' period during which they were followed. As far as we were able to ascertain, they were giving good service.

COMMENT

**Value of the Sugar Tolerance Test.**—It is well known through the work of Geyelin,<sup>4</sup> Janney and Isaacson,<sup>5</sup> Hamman and Hirschmann,<sup>6</sup> Wilder and Sansum,<sup>6</sup> and others, that there is a disturbed carbohydrate metabolism in a large percentage of cases of hyperthyroidism. This is manifested by a delayed blood sugar curve, as illustrated in Chart 1. This represents the blood sugar values at stated periods in a hyperthyroid case following the administration of glucose. The urine contained sugar at the one, one and one-half and two-hour periods

The value of the test for sugar tolerance in the diagnosis of early hyperthyroidism has not been definitely determined. Janney and Isaacson seem to think that

Chart 1.—Blood sugar values at stated periods in a hyperthyroid case following the administration of glucose. The urine contained sugar at the one, one and one-half and two-hour periods

1 1/2 grains a day; in one, 2 grains, and in three, 2 1/2 grains. In the remaining cases, doses of 5 grains a day had no appreciable effect.

**Epinephrin Test.**—Eleven men responded positively to the epinephrin test. In two other cases, there was a reaction which we did not think was sufficiently definite to record as positive. The six cases that were hypersensitive to desiccated thyroid gave a positive response to epinephrin.

DIAGNOSIS

The diagnosis of hyperthyroidism was made in six cases. The most convincing evidence in favor of this diagnosis was the response to thyroid feeding. There was also in these cases a suggestion of disturbed carbohydrate metabolism and a hypersensitivity to epinephrin. The latter two facts might be considered as supporting evidence.

Seven cases were diagnosed as irritable heart. All of these patients had the symptoms of shortness of breath, feeling of weakness, and palpitation of the heart on exertion. In five instances, this condition had existed prior to their entrance into military service. In the remaining two cases, the trouble resulted from influenza. Three patients gave a positive response to epinephrin. None reacted to thyroid.

The remaining seventeen cases were diagnosed as simple tachycardia. One of these men had a subacute bronchitis following influenza. In the remaining sixteen patients no etiologic basis was established for the tachycardia. Four gave a positive epinephrin response.

DISPOSITION OF PATIENTS

Two of the men diagnosed as having hyperthyroidism were recommended for "a surgeon's certificate of disability." The condition of these men had definitely existed prior to their entrance into the army, and it did not seem likely that they would be able safely to do full duty again. The remaining four were returned to duty. They had given good service prior to their recent illness. At the time of their discharge from the hospital their general condition seemed very good. The

it is of considerable value even at the stage when the fasting blood sugar concentration is normal. These investigators state that the difference between the fasting blood sugar level and that two hours following the administration seldom exceeds 0.01 per cent. Five of

4. Geyelin, H. R.: The Carbohydrate Metabolism in Hyperthyroidism as Determined by Examination of Blood and Urine, *Arch. for Med.* 14: 975 (Dec.) 1915.  
5. Hamman, Lou, et al: *Harvard Medical Studies on Blood Sugar*, *Arch. Int. Med.* 20: 161 (Nov.) 1917.  
6. Wilder, R. M., and Sansum, W. D.: *Blood Sugar and Glucose Tolerance*, *Harvard Medical Studies*, *Arch. Int. Med.* 10: 111 (Feb.) 1917.

the cases considered in this report ranged from 0.012 to 0.036 per cent. above the fasting level at the two hour period. When compared with the results of the remaining thirty cases and with those of the controls, they are at least suggestive of a disturbed carbohydrate metabolism. These results might, therefore, be considered confirmatory evidence in favor of the diagnosis of hyperthyroidism if associated with other reliable positive findings.

**The Epinephrin Test.**—It seems to have been fairly conclusively proved by Cannon<sup>7</sup> and his associates that there is a hypersensitive sympathetic in the cases of hyperthyroidism. Goetsch,<sup>8</sup> working on this basis, devised the epinephrin test employed in this work. His conclusions, that this test is of considerable value in the diagnosis of borderline cases of this condition, seem convincing in view of the operative results in his series of cases.

May we not have a hypersensitive sympathetic which is not associated with hyperthyroidism? Frazier and Wilson,<sup>9</sup> Peabody,<sup>10</sup> and I<sup>11</sup> have obtained a positive test in men with irritable heart in whom the thyroid has not been established as the etiologic factor. The men considered in this report who had a possible disturbed carbohydrate metabolism and who reacted to small doses of thyroid gland all responded to threshold doses of epinephrin. Seven other men, however, who had a normal blood sugar curve following the administration of glucose and did not respond to thyroid feeding also reacted positively to the epinephrin test. Further investigation is necessary to clear matters.

**Thyroid Feeding.**—Even though the theory that hypersecretion of the thyroid is the cause of hyperthyroidism is questioned, it is admitted that a large percentage of these patients are very sensitive to small doses of thyroid gland, so sensitive, in fact, that the use of thyroid in doubtful cases of hyperthyroidism is considered a dangerous procedure. Musser<sup>12</sup> and Forchheimer<sup>13</sup> cite cases of hyperthyroidism in which a small dose of thyroid caused death. In the experiments here reported, possible harmful results were borne in mind and the desiccated thyroid stopped as soon as a definite reaction was noted. No ill effects resulted.

#### HYPERTHYROIDISM AND IRRITABLE HEART

The part that the thyroid plays in the etiology of irritable heart has been a much debated question. This was especially true in England during the early years of the war, and to a less extent later in this country. Goodall,<sup>14</sup> in the Chadwick lecture, based on the study of 2,250 cases of irritable heart, thought the thyroid was responsible in a large percentage of the cases. Sir James Barr,<sup>15</sup> White and Herman-Johnson,<sup>16</sup> and others held similar views. Lewis<sup>17</sup> and his co-workers, on the other hand, reported a thyroid enlargement in only 4 per cent. of 504 cases studied. They seemed to be convinced that hyperthyroidism was an unimportant

factor. A number of their men were tested with thyroid extract.

In this country, Harlow Brooks<sup>17</sup> believes that the thyroid plays an important rôle in the cause of irritable heart. Friedlander and Freyhof<sup>18</sup> take an opposite stand. Other very reliable medical men who have expressed themselves in my presence are divided on the question.

These studies I have made go to show that in some cases that might ordinarily pass for irritable heart, the thyroid plays an important rôle, though its hyperactivity may be unmasked only after most searching inquiry into the history, careful physical examination, and special investigation by such means as the sugar tolerance, epinephrin and thyroid feeding tests.

#### CONCLUSION

1. Thirty men were studied in whom the physical findings were suggestive of hyperthyroidism. In six instances, this was the final diagnosis. This diagnosis was based on the response to thyroid feeding, the reaction to epinephrin, and the blood sugar curve following the administration of glucose. The results of the thyroid feeding were considered the most reliable evidence in favor of the diagnosis made. This was further substantiated by positive response to epinephrin and a suggestive disturbed carbohydrate metabolism.

2. Seven cases were diagnosed irritable heart. In five instances this trouble had existed prior to the entrance of the patients into military service. In two cases, it seemed to be the result of influenza.

3. Seventeen cases were diagnosed simple tachycardia. In sixteen instances, no cause for the tachycardia was found. None of the cases diagnosed irritable heart or simple tachycardia responded to doses of 5 grains of desiccated thyroid, nor was there any suggestion of disturbed carbohydrate metabolism.

122 South Michigan Avenue.

#### PROGNOSIS OF SPECIFIC AORTITIS

WILLIAM D. REID, M.D.

BOSTON

In January, 1909, the first case of syphilitic disease of the aorta appeared in the necropsy records of the Massachusetts General Hospital. In this case the spirochetes were first successfully demonstrated by Professor Wright, and thus the clinical entity of specific aortitis was given pathologic confirmation in this country. A recent informal discussion disclosed the fact that no one really knows much about its prognosis, and it was suggested that the medical records should be analyzed to see what light could be thrown on the subject. The importance of specific aortitis is the more apparent when we note that, since the above-mentioned case of January, 1909, the disease has been found in 5.5 per cent. of the hospital necropsies, and in 4.5 per cent. it was in an advanced stage or was the primary cause of death.

In pursuance of the foregoing suggestion, I have carefully examined the 105 records from the outpatient department in which the diagnosis of specific aortitis has appeared. For the purposes of this study the

investigation has been limited to cases in which the diagnosis was made before a definite aneurysm was present, as it was in these presumably earlier cases that the information as to prognosis was desired. It was felt that aneurysm may better be studied by itself. Believing that some readers might hesitate to accept the diagnosis in some of the cases, I have further excluded all records in which the diagnosis was not confirmed by a positive Wassermann reaction, roentgenographic findings, or both, or at least supported by repeated examinations made by more than one member of the visiting staff.

It is evident that a study with a view to obtaining data as to prognosis is attended with serious handicaps. Three of the more evident difficulties are:

1. Ignorance of the gravity of the disease and sheer inability to leave their work prevented some patients from attending the clinic frequently enough to be given treatment in its best form.

2. The patients were not all given identical treatment, owing, no doubt, to the fact that the exhibition of arsphenamin and allied arsenicals has been in process of evolution. During its first years, I recall, it was not considered proper to administer arsphenamin in cardiac cases, and since it has been extended to such, the administration has varied in size and number of doses.

3. A trouble that directly affects my own attempt to find out results is the failure to trace patients who are no longer attending the clinic. Thus, I obtained only twenty-two answers to follow-up letters.

THE MATERIAL STUDIED

As the primary purpose of this paper is information as to prognosis, I shall not go deeply into the signs and symptoms; but some statement is necessary in order to give a picture of the material on which I am basing my findings. Resort to the medical literature has purposely been avoided, so that, if possible, I might bring a fresh point of view to the subject.

I selected sixty-one cases, of which fifty-six were men, and five women, with the average age of 43.7 and 44.4 years, respectively. The female group is too small to make it appear practical to separate further the statistics by sex.

*History of Syphilis.*—In thirty-five cases, previous syphilis was admitted, in eighteen it was denied, and in eight there was no statement on the record. The average number of years, in the thirty-five cases in which the disease was admitted, was 16.

*Wassermann Reaction.*—The reaction was recorded as strongly positive in twenty-five, and varied from positive to suspicious in twenty-three other cases. In two of the patients the reaction was negative at first and later became positive.

*Symptoms.*—Shortness of breath, pain in the chest, or both, were present in all of the cases. Cough was present in fifteen cases, and cardiac palpitation in nine. The duration of the symptoms before reporting to the hospital was recorded in twenty-five cases, the shortest being two weeks and the longest five years, with an average of one and a quarter years.

*Physical Findings.*—Supracardiac dulness was increased in twenty-seven cases. In twenty-three patients there was a diastolic murmur best heard in the typical aortic areas, and in nineteen there was a systolic murmur in the same location, while in twenty cases both murmurs were present. The heart was

enlarged laterally in twenty-nine cases and downward in nineteen, respectively. In one of the patients an aneurysm of the right subclavian artery developed while under treatment.

*Röntgenographic Findings.*—The average width of the aorta, in the twenty-two cases in which orthodiagraphy was employed, was 7.5 cm. The greatest width recorded was 10.3 cm., and the least 6 cm.

RESULTS

Twelve patients are known to be dead, ten living, and thirty-nine untraced.

*Dead.*—Twelve patients died, of whom five were given arsphenamin, and seven received merely mercury and potassium iodid. Table 1 gives the age, dosage of arsphenamin, number of doses, the year in which the treatment was given, date of death, and the duration of life, in years, after the diagnosis of aortitis was established, respectively.

TABLE 1.—DURATION OF LIFE IN PATIENTS TREATED WITH ARSPHENAMIN

Age	Dose, Gm.	Number	Date	Death	Duration Years
37	.3	2	1913	1917	4.5*
47	.45	5	1914	1919	5.
38	—	3	1915	1915	—
34	.3	5	1918	1918	4.5†
35	.15	5	1918	1919	1.1
Average age, 38		Average duration, 3.07 years.			

\* Committed suicide because of pain in the chest and general poor condition.

† Aortic arch broadened to 10.5 cm. (by percussio) at time treatment was started.

‡ Case already under treatment four years.

The seven patients treated with mercury and potassium iodid alone may be represented in Table 2, in which are given the age of the patient, and the duration of life after the onset of symptoms and after the commencement of treatment, respectively.

TABLE 2.—DURATION OF LIFE IN PATIENTS TREATED WITH MERCURY AND POTASSIUM IODID

Age	After Symptoms	After Treatment
47	3.5	.2
50	3.5	.45
51	4.	2.5
52	3.	.5
59	—	4.
21*	5.5	.5
39	2.5	1.
—	—	—
45 Average	3.6	1.3

\* Note age.

It is suggestive that the length of life among these twelve fatal cases, after establishment of the diagnosis of aortitis is about 3 to 1 in favor of those receiving arsphenamin.

*Living.*—Of the ten patients whose present condition is known, nine have received intensive treatment, that is, arsenical and mercurial injections. The number of doses varies from three to fifteen, with an average of seven and a half per patient, and the dosage employed ranges from 0.1 to 0.4 gm. with an average of from 0.15 to 0.2 gm. Alternating with these are courses of mercurial injections, such as mercurial (gray) oil, 1 grain for from eight to ten weeks. In addition, potassium iodid is given by mouth.

The tenth patient, whose trouble was diagnosed in January, 1919, is not at present attending the clinic, but her condition is known to be worse.

The improvement noted in symptoms and not in physical signs. It should be observed that a dilatation of the aortic arch to more than 9 cm. is not, in two cases, incompatible with relative freedom from symptoms and ability to work.

TABLE 3—PRESENT CONDITION OF NINE PATIENTS

Age	Duration, Years	Condition	Physical Status	Width of Arch (by Roentgen Ray), Cm.
41	6	Good*	Able to work	9.1
44	5.5	Good	Able	7.5
4	5	Good	Able	...
...	4	Good	Able	...
...	4	Good	Able	6.0
...	7.5	Dyspnoic	Unable	...
4	1.75	Dyspnoic	Unable	...
...	7	Good	Able	9.5
...	1	Dyspnoic	Unable	7.5

Average age at which treatment was started, 47.8 years.

Average duration, 3.2 years.

\* The term "good" is used in the sense of relatively free of symptoms.

† Condition good, but patient is in an institution under treatment for general paresis.

*Untraced.*—An examination of the cases in which persons were under treatment for a time but with whom I was unable to establish contact shows twenty-four cases treated five months or less and therefore not deemed worthy of further analysis, and fifteen cases which I shall list (Table 4) according to the physical findings present at the initial examination. The inference, if any, which may be drawn from the findings is the tendency toward better results among the cases in which treatment was started before the more serious physical changes were present.

TABLE 4—PHYSICAL FINDINGS IN FIFTEEN CASES AT INITIAL EXAMINATION

(a) Double murmurs: 8 cases.			Time	Results
Diastolic murmur	Potassium Iodid			
2	+	+	2 months	Slight improvement
1	+	+	10 months	Worse
2	+	+	7 months	Unchanged
—	+	+	6 months	Unchanged
3	+	+	2 years	Improved
—	+	+	13 months	Unchanged
—	+	+	5 months	Worse

(c) Systolic murmur at aortic area and cardiac apex.			Time	Results
—	+	+	4 years	Unchanged
—	+	+	3 years	Much improved
—	+	+	5 months	Improved
(d) Cardiac enlargement only: 2 cases.			Time	Results
—	+	+	3 years	No signs of disease
—	+	+	7	Improved
—	+	+	1 year	Improved
(e) Double murmur and cardiac enlargement			Time	Results
—	+	+	1 case.	Improved
(f) Heart negative			Time	Results
—	—	—	2 years	About the same

## COMMENT

In the study of these records, certain impressions have come to me. For instance, of the sixty-one patients, thirty-one are not now under treatment at the hospital, and of those, twenty-two were in attendance for less than five months or made only two or three visits. Some, of course, may have continued treatment elsewhere, but I fear far too few. This suggests that most attention has been paid to emphasizing to the patient the importance of adequate therapy. The value of our increased power to diagnose syphilis of the aorta is certainly slight if it does not lead to treatment. Perhaps the following up of these patients, afflicted with a disease of progressive nature but who are not appearing for treatment, can be undertaken by the social service department.

These patients were first under treatment in various departments of the clinic: mostly the skin and syphilis, the neurologic, the medical, and occasionally elsewhere. It is evident, therefore, that those treating patients for the nonvascular manifestations of syphilis should bear in mind the possibility of this complication and, if necessary, refer them for medical examination.

A very satisfactory improvement in the character of the records has been noted since about 1915, making it apparent that the problem is becoming better understood. Thus, data are given as to the Wassermann reaction, supra-cardiac dullness, and roentgenographic mensuration of the great vessels. Of the latter we are hopeful that in the future there will be more cases roentgenographed a second time or more, as from these, more accurate conclusions may be drawn as to the effect of any particular therapeutic measures and as to prognosis.

The disease is progressive, as evidenced by the fact that in many of the cases one may read of the development of the physical signs from practically normal to a slight diastolic or systolic murmur in the aortic area, later both murmurs, and gradually cardiac enlargement outward and downward.

A slight analogy may be drawn between the diagnosis of appendicitis and of pulmonary tuberculosis, which, formerly tardily made and followed by bad outcomes, now are made in an earlier stage of the affections and with a much brighter prognosis. For example, we have been trained to make the diagnosis of pulmonary tuberculosis before the appearance of the tubercle bacilli in the sputum. Undoubtedly some mistakes are made as a result of this dictum, but who can doubt that the institution of treatment early has been a vast gain? If we can have the courage to diagnose specific disease of the aorta before it and the heart are irretrievably damaged, a long stride will have been taken toward improving its prognosis.

## CONCLUSIONS

Specific aortitis is a disease of progressive character and of serious prognosis.

The weight of evidence is against the power of mercury and potassium iodid alone to produce an arrest of the disease. Intensive antisyphilitic therapy is now being administered with promising results.

Every case presenting the symptoms of substernal pain and shortness of breath, not definitely explained by other cause, should be promptly studied as to the presence of specific aortitis. Early diagnosis is imperative.

The cases in this study which have received adequate treatment and in which the present condition is known are as yet too few to justify positive conclusions as to prognosis. After a few more years, another study of the records should obtain material of more value as to the end-results.

**The Right to Marry.**—A careful student of the literature and of the facts of eugenics realizes the complexity of the problem and the reason why we should be cautious about pushing everything to the point of legislative regulation. It is in the interest of civilization to provide principles and customs rather than laws, and to give the plain sense of the individual a chance to develop and to become effective. Give the people the facts and some help to think and the right sources of advice, and there will surely be results.—A. Meyer, *Canadian J. Mental Hygiene* 1:148 (July) 1919.

A CASE OF RAYNAUD'S DISEASE  
ASSOCIATED WITH  
SCLERODERMA

FREDERICK P. MOERSCH, M.D.  
ANN ARBOR, MICH.

Up to the present time we are still without definite knowledge regarding the etiology and pathology of Raynaud's disease and allied conditions. The present case offers some interesting features, for which reason it is

Fig. 1.—Nodules occurring over middle joints of fingers

thought advisable to add it to the literature. It has been frequently noted in Raynaud's disease that there is a hereditary tendency. This, however, has not been determined in the present instance, and from our observations no definite etiologic factor could be established. Occupations and various trades have been mentioned as possible causes; but in the light of more recent investigation it does not seem that they have any definite relation to the disease. In the case here presented the factor of exposure enters; but it is questionable what part it played in the etiology. We have had this patient under observation from February, 1919, until a very recent date.

REPORT OF CASE

*History.*—The history as given by the patient is practically negative. There is no indication of any similar trouble in the family. Alcoholism is denied; there have been no cases of epilepsy, migraine or other nervous disorders either in antecedents or collaterals.

The patient was born in 1889 in New Mexico. As a child he was healthy and strong. He attended school up to the age of 18, after which he was employed in several positions, always making good money and never being discharged. He has been a moderate drinker, but never indulged to excess; a moderate smoker, and absolutely denies any venereal infection. He is married and has one living, healthy child. His wife is in good health and has had no miscarriages. Prior to entering the service, he was employed as a special officer for a trust company. In November, 1916, he was accidentally shot in the left thigh, making a speedy recovery. There is no history of tropical disease or other serious ailment. He has had no operations. In September, 1917, he entered the service, at which time he was in very good health, going to France in the spring of 1918.

*Present Trouble.*—The first indication of any trouble appears to have been evidenced by the man early in August, 1918. At that time his organization was in "support," having been in the trenches a few days before. It was during one of these days as he was writing a letter that he noticed a queer feeling in his fingers, and it appeared rather difficult

to hold a pencil. On close inspection, he found that the knuckles of both ring fingers appeared somewhat swollen and blue. He gave this condition no special attention, considering it some passing and harmless ailment. August 5, a few days after he had noticed the first trouble, he was gassed and sent to the hospital because of some lung disturbance. He apparently recovered within a few days and was returned to duty, feeling about as well as usual. He believes, however, that following this experience his hands and fingers caused him more trouble. It seems that his hands would become cold and blue, and if he got chilled, the fingers would turn white and become numb. This condition continued for some months. At times it would bother him considerably, and again he would go days without any apparent difficulty. Oct. 7, 1918, he sustained a so-called shell shock, when he was confined to the hospital for one month. He returned to this country early in 1919 and has been under observation since that date.

Following his shell shock in October and while in the hospital, he believes that his symptoms gradually became more marked, that the other joints of his fingers became involved, and would become stiff, cold, swollen, and at times white. During his stay in the hospital, he developed a small mass on the sole of the left foot which was opened and a serum expressed. At the same time the heel of the left foot became black and numb, two small bluish white spots appearing in the center of this black mass. An incision was made, and apparently the discoloration vanished without any sloughing of the skin. He denies that he sustained any injuries to his extremities while in France, and does not believe that he was ever exposed to extreme cold, at least no more so than any of his comrades.

*Examination.*—The man was well built, and there was no general deformity. The skin and mucous membranes were normal with the exception of the condition here noted. Physical and neurologic examinations were negative except for the findings here recorded. There were to be noted over the joints of the fingers on both hands, as shown in the accompanying illustrations, symmetrically placed indurated nodules which were adherent to the skin, but independent of the bone. These nodules occurred at the junction of the second and third phalanges. These were not painful, but

Fig. 2.—Induration along tendon sheath of middle finger.

appeared to cause a certain stiffness in the joints. Immediately over the masses, there was a slight impairment of sensation to touch and pin prick. There was to be noted in the palms of the hands an apparent thickening along the tendon sheaths of the third fingers which felt firm and indurated. There was also a mass on the sole of the left foot, while on the right foot there seemed to be the beginning of a similar condition. On several occasions, it had been noted that the fingers had become cyanotic, while at others, especially following a cold bath, the distal portions of the fingers had become white, during which time they would feel numb. Objectively, however, no definite change could be determined. The urine examination revealed a faint trace of albumin on a few occasions. The blood was

sermann reaction was negative on repeated examinations. The blood count was practically normal. Nasal smears on several occasions were reported negative. A section removed from one of the masses over the fingers showed a marked increase of fibrous and connective tissue, very much in the nature of a fibroma. Along the margins, which were rather vascular in character, many small bundles of connective tissue were noted. There was very little cell infiltration, and no acid-fast bacilli were found.

At the last examination, July 15, it appeared that the patient's physical condition remained about the same. There were occasional headaches, and at times he seemed somewhat restless and irritable. The condition of his hands had gradually grown worse. The nodules had increased somewhat in size, and they were painful and caused considerable stiffening of the joints. As a result of this the thumb of the right hand could hardly be moved. The thickening, which confined itself to the palmar side of the hands and plantar side of the feet, gradually increased, and the mass that had made its appearance on the right foot was now fairly prominent. There were no added sensory changes. A roentgen-ray examination was probably negative.

#### COMMENT

The diagnosis of this case seems fairly certain. As to etiology, no positive factor can be ascribed. The history of exposure enters very strongly, but with so many individuals experiencing the same hardships, it does not seem fair to assume exposure as a causative factor. Thus, in spite of a negative history one may have to assume a neuropathic groundwork and an unknown exciting cause.

### AUTOTRANSPLANTATION OF THE KIDNEY\*

CARLETON DEDERER, A.B., M.D., M.S.  
BAY CITY, MICH.

In 1917, after devoting several months to an experimental study of the elements of vascular suture, I attempted the autotransplantation of a kidney into the

Fig. 1 (Dog B 976).—Autotransplanted kidney, removed from its site of implantation in the neck in the one hundred and twenty-fifth day.

neck in the dog. After five partially successful operations, complete success was attained.

\* Extract from thesis accepted by the Graduate Faculty of the University of Minnesota in partial fulfillment of the requirements for the degree of Master of Science in Surgery, June 19, 1919.

May 2, 1917, the left kidney of Dog B 976 was transplanted into the neck by uniting the renal artery at its bifurcation with the common carotid artery, and the renal vein to the external jugular vein. Some of the details of this experiment have been published.<sup>1</sup>

Fig. 2 (Dog B 976).—Cross section of the normal ureter on the one hundred and twenty-fifth day after operation; paraffin, hematoxylin and eosin;  $\times 15$ .

Two weeks after transplantation, right nephrectomy was performed. The dog lived more than four months; it died as a result of hydronephrosis.

#### EXTRACT FROM PROTOCOL

Dog B 976.—Aug. 18, 1917, three months and sixteen days after the transplantation, and three months and two days after the second nephrectomy, analyses were made for comparison of the stream urine and of that which ran down

Fig. 3 (Dog B 976).—Cross section of the transplanted ureter on the one hundred and twenty-fifth day after operation, showing enormous hypertrophy in the transplanted ureter due to the obstruction at the meatus in the skin; magnified the same as Figure 2.

the animal's neck. The results of these analyses are given in the accompanying tabulation.

1. Dederer, Carleton: Studies in the Transplantation of Whole Organs, I. Autotransplantation of the Left Kidney to the Neck with Right Nephrectomy in the Dog, J. A. M. A. 70:6-9 (Jan. 5) 1918.

August 27, the ureter protruded about 6 mm. Every ureteral contraction shot a stream of urine. Four c.c. of urine could readily be obtained by pressure on the kidney.

August 30, a detailed examination was made of the state of the hydronephrosis:

8:15 p. m., the animal was quiet, not alert. The outside diameter of the kidney in the neck was 7.7 cm.

8:16 p. m., the ureter was opened by a slit about 1 cm. long. This resulted in the escape of more than 25 c.c. of urine, which was tinged with blood from the incision.

8:25 p. m., the size of the kidney (external measurement) was 4.7 cm. including skin and fascia; the kidney was in its proper place in the neck.

8:34 p. m., 5 c.c. of urine were excreted in one minute (57 drops), and a stream about 1 mm. in diameter could be pressed out.

8:58 p. m., the dog was standing quietly, not alert.

9:01 p. m., a specimen of urine (3 c.c.) showed it to be clear and alkaline with a faint trace of albumin, and to contain a few erythrocytes. There were no casts and no epithelial cells; there were triple phosphates.

rhage); nitrogen of urea and ammonia, 5.69 mg. per cubic centimeter. A specimen taken forty-five minutes later (3 c.c. in one minute) showed a few erythrocytes and triple phos-

Fig. 5 (Dog B 976).—Silk suture material at the site of anastomosis on the one hundred and twenty-fifth day after renal autotransplant. Paraffin, hematoxylin and eosin;  $\times 900$ .

phates, a trace of albumin, nitrogen of urea, and ammonia, 12.18 mg. per cubic centimeter.

After this the dog wasted away, and after an unsuccessful attempt to homotransplant a kidney the animal was killed,

9:09 p. m., its weight was 7.8 kg.

9:36 p. m., the weight was 7.7 kg. The dog had lost 0.1 kg. in twenty-seven minutes after the obstruction in the ureter had been slit open.

COMPARISON OF URINE

Surface Urine	Stream Urine
Amber	Amber
Cloudy	Clear
Slightly alkaline	Very slightly alkaline (less change in the litmus paper)
No albumin	No albumin
Few leukocytes	No cells or detritus
Epithelial cells	
Triple phosphates	
Amorphous detritus	

10:26 p. m., the dog came out of the dog house and stood around for a time and then returned. The urine was flowing freely and was clear.

Examination of a specimen of urine (25 c.c.) taken from the hydronephrotic autotransplanted kidney, after the removal of the obstruction to the urinary flow, revealed many erythrocytes (from the incision); albumin (due to hemor-

Sept. 3, 1917. The transplant was made in the femoral region, and no function resulted, probably owing to venous stasis from unavoidable vein kinking, and venous constriction. Necropsy revealed that the autotransplanted kidney in the neck had a dilated pelvis and a markedly hypertrophied and dilated ureter (Figs 1-6)

## CONCLUSIONS

In experimenting with the transplantation of a dog's kidney to the neck, the question of hydronephrosis may become of importance. The signs of a developing hydronephrosis are quite characteristic. They consist of an apparent enlargement of the kidney which has been secreting satisfactorily, as can be easily observed in the neck, and hypertrophy of the ureter, which is evidenced by a strong squirting of a stream of urine away from the dog.

DERMATITIS FACTITIA COMPLICATING  
HYSTERICAL PARALYSIS\*

SAMUEL AYRES, JR., M.D.

BOSTON

## REPORT OF CASE

*History.*—Miss M. G., aged 28, unmarried, white, was referred by her physician to the Massachusetts General Hospital with a diagnosis of osteomyelitis because of pain and paralysis of the leg with a cutaneous lesion involving the foot and leg.

The present illness, as told by the patient, began eight years before when she and her cousin were "fooling" around with a male boarder at the cousin's home. As the patient was walking down the front steps, the man stretched out his foot, tripping her and causing her to fall three or four steps. She remained unconscious all night, and the next morning found that there was soreness in the left hip and sharp localized pain on attempted motion. She felt "sick all over" and was kept in bed for two weeks. Then on attempting to walk she experienced severe pain in the left leg. She felt determined to be up and around, however, and in order to lessen pain, held the left leg stiff and dragged it. The pain persisted and after a time she found that the leg was becoming rigid and could not be bent easily. About a year after the fall her physician applied a wire splint, which extended from the waist to the ankle and immobilized the entire left leg. This was worn continuously for two years, the pain being present only at times. Since wearing the splint she had never been able to walk without crutches, and the leg had been stiff at the knee and ankle and to some extent at the hip. During the previous year the pain had extended from the hip and now involved the entire leg. The pain was described as deep, sharp, and interfering with sleep. Cutaneous sensibility in the entire leg had been impaired almost from the beginning of the present illness.

About three years ago, the patient experienced a nervous breakdown, which her physician said was probably due to the monotony of sitting still and sewing. This began with increasing irritability and crying spells, which later developed into what was called "meningitis." This so-called meningitis came on gradually at first, with pain in the lower spine which worked up to the head. The entire duration of the nervousness was about two years, the patient being confined to bed continuously for fifteen months. She had many convulsions, at all, accompanied by unconsciousness and vomiting. She had epileptiform, and she was catheterized frequently. She did not recall whether she had any fever, or any manifestations of urine or feces during convulsions. She never felt her tongue. Toward the latter part of her illness she had frequent severe abdominal pains directly after eating, followed by vomiting. She said that she had many "aches" in and down her spine. During those two years of "nervousness" almost daily hypodermic injections of morphine were given by her physicians, and for the latter five or six months sometimes twenty or thirty injections a day. They had for the relief of pain and for spasms.

During the past ten months the patient had lived at a sanatorium in Maine where she went for the relief of morphin-

ism, and it was from there that she was sent to this hospital for the skin condition, pain in the leg, and vomiting. During the past three weeks she had vomited after nearly every meal.

According to the patient the skin eruption on the left foot, leg and thigh had been present for the past two or three months. Her description of its development is enlightening in view of our own findings:

"It began first on the big toe and looked like purple blotches. These spread over the foot and up the leg, usually purplish at first, sometimes red. Sometimes the blotches would persist for several days, and then little drops of blood would ooze out." The patient stated that on several occasions she had witnessed the drops of blood "ooze out." There was some soreness in the skin lesions, but no pain or itching.

The family history revealed that the mother had a nervous temperament, one paternal aunt had nervous attacks of choking and spasms, and the father had congenital nystagmus; otherwise it was negative.

The patient had had an appendectomy ten years previously; had always had occasional headaches; had had nystagmus since birth; had worn glasses for near-sightedness since the age of 9; had had transitory blurring of vision for ten years; had had double otitis media following measles five years previously; had worn upper and lower false teeth since the age of 18 because her teeth decayed; had had pleurisy during childhood; had always been constipated; had had attacks of vomiting ever since she could remember; had had irregular, painful and scanty menstruations, the last period occurring six months previously; had had nocturia for four or five years, and two years before had passed stones by the urethra accompanied by pain and hematuria; had had occasional fainting spells since childhood, and had never weighed over 100 pounds.

*Examination.*—The left leg was the interesting feature of the physical examination. The extremity was almost rigid in extension, only slight flexion was permitted at the hip because of pain; the knee allowed only the slightest possible movement, and the ankle was slightly movable. There was complete anesthesia to touch from the hip down; a pin prick, however, was perceived as a tactile sensation. The sensory disturbance was less marked on the posterior aspect of the leg.

Sense of position in the toes was completely lost. The knee jerk was not obtained, and the plantar reflex was sluggish. Reflexes elsewhere were normal. Over the dorsum of the foot, extending just beyond the base of the toes and upward over the medial, anterior and lateral aspects of the lower leg, also on the inner aspect of the heel, there were areas of vertical, parallel, short scratch marks, some with adherent crusts of dried blood. Over the foot, especially, there was a diffuse background of dull red or purplish discoloration, which, however, was absent higher on the leg. On the lateral aspect of the thigh there was a discrete area, the size of a half dollar, consisting of vertical parallel scratches without any discoloration.

The skin elsewhere was normal; there were no scars or other evidence of abscesses over the spine such as the patient described. There were no other neuromuscular disturbances except for the nystagmus, which was congenital, and paralysis of the external rectus muscle of the left eye, of uncertain duration. The remainder of the physical examination was essentially negative.

Röntgen-ray examination of the involved leg disclosed some atrophy of all the bones but no involvement of any of the joint surfaces. The systolic blood pressure was 155, diastolic 100. Temperature and respiration did not vary from normal. The pulse averaged 90. The urine showed a very slight trace of albumin, many white blood cells and epithelial cells, but no casts. The Wassermann reaction and the white count were not taken, but there is no reason to believe that they would have added any information of importance.

A steel phonograph needle was found in the patient's hand bag. On the point of the needle there was a small red

\*From the Department of Neurology, Massachusetts General Hospital.

stain, which was demonstrated both chemically and morphologically to be blood. When the stain was dissolved in physiologic sodium chlorid solution, hemin crystals were obtained, and red blood corpuscles could be seen under the microscope.

When confronted with our evidence the patient denied that the dermatitis had been self-inflicted. The facts, nevertheless, are interesting, especially the objective appearance of the skin with the obvious scratch marks, as contrasted with the patient's description of the development of the lesions.

*Treatment and Result.*—Our treatment consisted largely of psychotherapy, together with active exercise and passive movements. Dr. Robert F. Loeb, who had the immediate care of the patient during most of her nine days' residence in the hospital, explained in detail the nature of her disorder, and endeavored to rationalize it for her. We were unsuccessful in discovering any repressed emotion as a cause for the hysterical manifestations during the past eight years, but from the circumstances attending the onset, it is not improbable that the patient told us only part of the story. However, we did not insist on learning the details, but advised her to confide in some one who was sympathetic and who could be trusted whenever situations arose with which she was unable to cope. In spite of her "severe pain" we found it necessary to give chloral hydrate only once, and acetylsalicylic acid only on a few occasions. No treatment

undoubtedly has a neurotic predisposition as shown both by her family history and her past history. It is quite understandable how a mental conflict lodging in such a soil can produce the hysterical picture described.

The lesson to be drawn from the cutaneous lesions is that, first, the appearance of the lesion is more to be trusted than the history, and second, a lesion that is obviously artificial in appearance is probably artificial in etiology. Such self-inflicted injuries may be done to excite sympathy, to escape duty, to assist in winning damage suits, or occasionally, as is probable in this case, they may be done in a state of amnesia or semi-consciousness.

As illustrating that the neurologic condition described above is not rare, a companion case was recently discharged from this hospital relieved of a spastic paraplegia with anesthesia of over two years' duration. The history, examination, and treatment were essentially similar to the foregoing case, except that there were no cutaneous lesions. On entrance the patient was entirely unable even to stand; she did not feel the floor under her feet. After remaining in the hospital two months, she was able to walk unassisted,

Dermatitis factitia produced by a steel phonograph needle

aside from cleanliness was needed for the skin lesions. The patient, herself, requested not to be given morphin. She seemed intelligent and desirous of getting well.

It is always gratifying to know that our measures have been successful. The patient was sent back to the sanatorium in Maine, and both she and her physician were told that there was no organic trouble and that she would recover complete use of her leg by following rational treatment—active exercise, passive movements, massage, and above all a proper mental attitude, realizing that her paralysis was due to functional inhibitions and that the skin lesion was self-inflicted, even though she herself may not have been actively conscious of the act. Two weeks later one of the nurses of this hospital received a letter from her, which reads in part: "I'm getting on fine—can get about my room without crutches, although I often lose my balance and my strength leaves me, but I shall persevere until I can do better."

#### COMMENT

This case illustrates a condition that is well recognized, but not as generally, apparently, as it should be. It brings out the contrast between treatment and mistreatment. In other words, a patient who has been an invalid, unable to walk without crutches for eight years, finds herself in the course of three weeks under rational treatment perfectly able to use her "paralyzed" leg and to walk without crutches. This patient

and sensation had returned. A few weeks after discharge a letter was received in which she stated that her improvement had continued, and that she could go up and down stairs and could walk almost as well as ever—and this after two years of invalidism, treated by her local physician for "incurable spinal trouble."

**Striking the Source of Infection.**—A knowledge of the physical conditions and the regulation of the personal hygiene of the individuals making up a unit or closely associated group is fundamental in all community health activities. It is the custom nowadays for a municipality or state to pass drastic laws regulating garbage disposal, the location of corrals and pig styes, the cleanliness of slaughterhouses, and the distribution of milk and foodstuffs. . . . While such laws may be rigidly enforced, a typhoid carrier, a victim of tuberculosis, or one who has a mild case of any one of the serious communicable diseases, may sow these diseases broadcast. One tuberculous person or typhoid carrier in a community may do as much harm to the individuals therein as lax enforcement or even non-enforcement of the laws pertaining to sanitation. It is not difficult to see the incongruousness of a regulation which requires the screening of foodstuffs and at the same time makes no provisions whatsoever for determining whether the person who prepares the food or distributes it is a typhoid carrier—John Sundwall, *Pub. Health Rep.*, Nov. 7, 1919.

## Clinical Notes, Suggestions, and New Instruments

### EMPHYSEMA OF THE CECUM

REPORT OF A CASE

ELMER D. TWYMAN, M.D., KANSAS CITY, MO.

**History.**—Mr H. C., aged 22, white, American, a coast guard, chart No. 1,574, was admitted to the U. S. Marine Hospital, Port of New York, Nev. 9, 1918, complaining of a dull pain in the right iliac fossa. The complaint had lasted for four days; he was nauseated but he had not vomited. The dull ache, which had no connection with eating, was continuous. The patient complained of diarrhea.

There was nothing significant in his past illnesses or family history. He denied venereal disease. His parents and three sisters were living and well.

**Physical Examination.**—The only abnormalities noted were diffuse tenderness in the right hypogastric region and a slight rigidity of the rectus muscle. No signs of tenderness were elicited by pushing gas around in the colon; moderate tenderness was noted in both lumbar regions posteriorly. There was gross abdominal distention; but deep palpation revealed a mobile mass, the size of a small kidney in the right iliac fossa. It was of a doughy consistency suggesting a fecal impaction. Movement was elicited by manipulation and by the patient's breathing.

**Operation.**—Under ether, a high rectus incision revealed a mass, injected with blood, bound with adhesions, and distended in the subperitoneal layers by bubbles of gas. It was crepitant to the touch, like lung tissue. At one point on the outer side of the cecum, among a mass of subperitoneal gas bubbles, was something that gave an appearance of milklines, such as a thymus or a leukocytic infiltration. The small tatty tags were highly distended with small gas bubbles. After the separation of a few adhesions of the omentum to the colon and of the colon to itself, the mass was thus analyzed:

The transverse colon was normal. At the hepatic flexure was a sharp angulation marking the limit of the gaseous distention. Proximally the ascending colon was markedly thickened in size and apparent thickness of its walls (three times normal). The ascending colon was followed caudad to the ileo-cecal junction and to the caecum. At this point, reversing its direction, but not so sharply angulated, it was followed into the cecum. It was seen that the cecum and lower portion of the ascending colon lay side by side with the proximal portion first described, but in the antiparallel direction. The appendix was given off at the extreme distal end of the cecum, lying in immediate contact with the gallbladder. It was inflamed, but not adherent to the cecum. It was not crepitant. It was knotted into a double U by fibrous bands in its mesentery arising profusely from the tissues of the renal sulcus. Cutting the appendiceal mesentery and a number of bands in the peritoneum to the outer side of the cecum permitted the restoration of the cecum and ascending colon to their ordinary

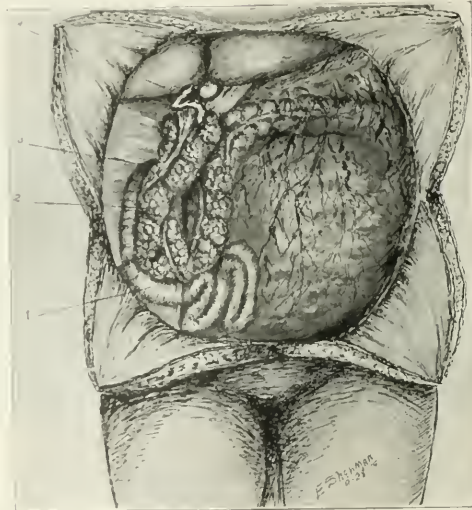

position. The fixed portion of the iliac mesentery was then sought, and the terminal 8 inches of the ileum isolated and followed caudad to the ileocecal valve. It was found that 4 inches cephalad to the valve, the ileum was bound down broadly and tightly over the psoas muscle for an inch and a half. The appearance was of a congenital arrangement plus additional bands of inflammatory origin or due to traction. The ileocecal valve lay on the outer and distal side of the loop described by the cecum and ascending colon. The arrangement was such that the terminal portion of the ileum from the ileocecal valve to the ileopsoas attachment was under tension, which tended to increase with functional movements of the colon. This tension was completely relieved by the division of the bands and the replacement of the colon in its normal position. The two angulations of the colon appeared also to be sufficiently relieved. The degree of distention of the ileum cephalad to the psoas adhesion was judged to be so small and the symptoms, that is, the obstructive symptoms, so mild as not to justify a separation of this broad and well functioning adhesion, especially considering the dangerous proximity of the iliac vessels. No attempt was made to cover the raw surface on the outer side of the colon or to dictate the final position of the cecum

(other than its replacement by hand. The appendix was removed and the stump buried. The wound was closed without drainage. Three small bits of gaseous injected tissue were removed and sent to the laboratory, and direct smears and aerobic and anaerobic cultures ordered.

**Laboratory Reports.**—The first smear, stained with methylene blue, contained many polymorphonuclear leukocytes with intracellular diplococci. In the second smear, fewer numbers were observed and the diplococci were stained positive by the Gram method. All cultures were reported negative after one week's growth. As the laboratory was rushed with work incident to the epidemic, I have not regarded this result as legitimate but simply as an unavoidable misfortune.

**Progress of the Case.**—The patient left the house in two weeks. On full diet, he experienced no trouble. He stated that he was then conscious that there had always been something wrong with his abdomen. The mass had disappeared, and there was little postoperative abdominal reaction.

416 Argyle Building.

Emphysema of the cecum: 1, ileum under a hand; 2, emphysema of the cecum; 3, ileocecal junction; 4, appendix and bands of adhesions.

**Experimental By-Products.**—The first voyage of Columbus was an experiment. It is not always that experiments may be performed in the laboratory, for many of them must be on a national or world-wide scale, as is true today of many social experiments. Sometimes the by-products of an experiment are themselves of great value, an illustration of this is Columbus' discovery of the variation of the magnetic declination. Not always, of course, are the by-products of the main experiment so evident as they were in this case of Columbus' first voyage; nor are they so overshadowed by the importance of the main result. In such by-products may be the greatest value of the experiment. While the result of the main experiment is usually the reward of clear thinking and precise manipulations of the experimental apparatus, the by-products are usually the reward of a comprehending observation.—Mills, "The Realities of Modern Science."

A HOME-MADE ORTHOPEDIC TABLE

LOYD M. BERGEN, M.D., HIGHLAND PARK, ILL.

There is often need of an orthopedic table where the small volume of work does not justify the purchase of elaborate

Fig. 1.—Sacral and shoulder supports removed with table set for roentgenography or operation.

and expensive apparatus; the home-made table here illustrated will supply this need.

I made a small model in a few hours, and the table itself was constructed by the janitor of the Highland Park Hospital, chiefly from pieces of scrap piping. The illustrations demonstrate clearly the construction and application.

The patient being placed in position, the small steel cables are attached to the ankles, and traction is applied. The four padded leg supports are then dropped out of the way by simply pulling out the four pins with which they are transfixed.

The post supporting the sacral rest is made of slightly smaller piping, slides easily through the "four-way" fitting, and rests in the T socket below. In this way the post and saddle are

Fig. 2.—Shoulder, sacral and leg supports in place to receive patient.

simply lifted out when the apparatus is to be used as an ordinary table. The chest and shoulder support is made of wrought iron strips with ordinary ball bearing roller skate wheels, obtainable in any good hardware store. The ratchet

wheels are part of a Ford motor car, and cost one dollar apiece at the dealer's. They require some turning down in a lathe, as in the original they are too thick to go through the slots in the piping.

The cross bar for arm extension rests on the table frame, and bolts are dropped through perforations in the two pipes. It is lifted off when not in use.

SEROUS MENINGITIS FOLLOWING INJECTION OF ANTITETANIC SERUM

OSCAR BERGHAUSEN, M.D., CINCINNATI

A boy, aged 3½ years, who had been in the best of health, stepped on a nail two weeks before I saw him, Sept. 26, 1919. The wound was indifferently treated by one physician so that Dr. George Sikes of Pleasant Ridge was consulted two days later. The wound was then opened, cleansed and properly cauterized. The little boy was given 2,000 units of antitetic serum; the wound healed perfectly. A week after the serum was given, a typical serum rash developed but soon subsided. Four days later the child was playing in the yard as usual, when he began to drag the injured leg. That afternoon he was taken sick rather suddenly, and fever developed, but there was no nausea or vomiting. The mother noticed that the child could not move the injured (right) leg or the left arm. He seemed to hold his head toward the right side. Dr.

Fig. 3.—Patient suspended, with leg supports dropped out of the way.

George Sikes was called and decided not to use antitetic serum, giving the child a dose of castor oil instead. The next morning the child was no better so it was brought to a hospital in this city where I saw him just two weeks after the original injury.

The child was crying. The skin was covered with a profuse reddish macular eruption, confined mostly to the lower extremities. He apparently did not move the left arm. The pupils were equal; there was no involvement of the cranial nerves. The heart and lungs were apparently normal; the examination of the abdomen was negative. The child held himself rigid. There was Kernig's sign, but no opisthotonus. The temperature was about 102; the pulse was rapid. I told the family that in my opinion the symptoms could not be due to tetanus, and expressed the opinion that it possibly was due to the injection of horse serum, although the typical serum rash had disappeared four days previously. In the afternoon the temperature rose to 104; the pulse was 128, and the respiration 36. While sleeping, the child would twitch its face. I had Dr. Robert Ingram see the child with me.

In addition to the symptoms and signs that I have mentioned, he found an ankle clonus of both legs, mostly right, and an edema of the right upper lid. He diagnosed the condition as cerebrospinal meningitis according to the syndrome,

the cause of which was unknown. He advised a spinal puncture. The fluid came out under great pressure, was clear, contained no cells, no increase in globulin, and gave a negative Wassermann reaction. Within two hours' time the child was quiet, fast asleep, and the temperature was nearly normal. All symptoms apparently had disappeared, the child could move both legs and arms, and the edema was decreasing. Within two days' time the child apparently was well, and went home. Since then it has been free from a recurrence of the symptoms. To my mind the foreign protein (horse serum) had produced an anaphylactic reaction which was later complicated by the development of an acute serous (edematous) meningitis.

19 West Seventh Street.

#### FOREIGN BODY IN RECTUM

EDWARD A. DOWNS, M.D., SAN FRANCISCO  
SURGEON, U. S. Army Transport "Logan"

The note on a glass tumbler in the rectum<sup>1</sup> brings to mind a somewhat similar case that I observed in 1907:

A marine engineer, after an exploit on the "Barbary Coast" in San Francisco, was the victim of rowdy companions. Next day, while searching within the rectum to determine the cause of certain unusual symptoms, he located something that felt like the edge of a glass. Manual manipulations failed to dislodge the intruder, so he tried thumb forceps. The result was that a particle of the edge of the glass was snipped off with each grasp of the instrument, leaving a serrated edge, as shown in the accompanying illustration, around the top of the glass.

Examination in the knee-chest position, with the vaginal speculum and long dressing forceps, revealed the base of the glass 9 inches within the rectum.

Pieces of gauze bandage were dipped in plaster-of-Paris paste and inserted with long dressing forceps repeatedly,

When applied to the rectum, and glass packed with plaster-of-Paris paste, the gauze bandage, containing pieces of the jagged edge of the glass, formed as shown.

until the glass was packed overfull. The last strip was sufficiently long to leave more than 12 inches free for traction. Within half an hour the plaster was solid. As traction was made, small particles of loose, hardened plaster preceded the glass, and fragments and splinters were incorporated with them. No difficulty was experienced in bringing the glass to the sphincter. This was dilated with the vaginal

speculum, and the foreign body was withdrawn with little resistance and no bleeding.

The object proved to be a common 5-ounce "high ball" glass. The victim returned to duty next day. There was no after-pain or complications.

#### A CASE OF BILATERAL CONGENITAL FUSION OF THE RADIUS AND ULNA

JULIUS KAUFMAN, M.D., BROOKLYN

This case is, I believe, of sufficient interest from a developmental standpoint to warrant its being recorded. Whether

Fig. 1.—Lateral view of left forearm. Fig. 2.—Lateral view of right forearm.

it is just one of the freaks of development that we encounter so often, or whether it has some atavistic significance, I am not prepared to state.

Private A. J. L., white, aged about 24<sup>1</sup>, was admitted to our hospital area at Mars-sur-Allier, France, complaining of "joint trouble." As long as he could remember, he had had only limited motions in both his forearms. The condition had been becoming progressively worse. Flexion and extension were somewhat limited and painful. There was only a minimum of pronation and supination.

Clinically, both the arms were held in the position of mid-pronation. Extension and flexion of the forearm on the arm was but little limited, the patient complaining of slight pain during these motions. That there was true ankylosis could easily be inferred by the complete loss of active and passive pronation and supination. Actions that involved these motions were compensated for by using the shoulder joint.

Roentgenograms of both forearms revealed an exactly symmetrical fusion of the upper extremities of the radius and ulna, with rather incomplete development of the radial head. Following the course of the radius from below upward, with the forearm fully extended on the arm (by means of stereoscopic plates), one saw that the radius crossed the ulna from within out, anterior to it, fusing with it in its upper extremity, the radial head lying at about the level of the capitellum, but slightly posterior to it.

There can be little doubt that the condition was a congenital one. Its long-standing history, the absence of trauma or any other etiologic factor, and the symmetrical involvement all point to this.

<sup>1</sup> See also, Orval, A Glass Tumbler in the Rectum, J. A. M. A. 72: 1-5 (May 1) 1919.

<sup>1</sup> It was impossible to obtain complete data, owing to the patient's immediate evacuation from this area.

### USE AND ABUSE OF CATHARTICS \*

(Continued from page 1769)

#### AGAR

Having shown that there existed a variety of constipation, characterized by the passage of a scanty amount of fecal matter in the form of dry, hard lumps, and that this was due to excessive bacterial digestion of cellulose, Adolf Schmidt<sup>1</sup> suggested the use of agar, well known as a bacterial culture medium employed because it is not liquefied or digested by micro-organisms. This substance, a dried mucilaginous material (hemicellulose) extracted by hot water from certain Japanese algae, is almost indigestible in our alimentary tract. Hence it passes through the intestine, adding bulk to the feces and softening them by virtue of its property of retaining moisture.

Agar generally occurs in bundles of translucent pieces, but is best obtained for medicinal use in the form of shreds or coarse powder. When finely pulverized, it may produce colic. It has a slight odor and an insipid mucilaginous taste; it is insoluble in cold water, but slowly soluble in hot water, a 1.5 per cent. solution producing quite a stiff jelly on cooling.

Agar is indicated in those cases of chronic constipation in which it is considered desirable to increase the bulk of the feces, and in which bran is not well borne or does not act well. Persons in whose intestine cellulose is digested to an excessive degree are likely to find bran not only deficient in activity, but, like other fermentable cellulose, troublesome by the production of flatulence. For such, agar may be just the right dietetic corrective. As it is deficient in influence on peristalsis, it is likely to be useless in atonic constipation, such as in that of the aged; on the other hand, it may be used in spastic constipation and in mucous colitis.

As in the case of other evacuants acting chiefly in a physical manner, agar must be taken in large and liberal doses, and regularly for a long time. A dose of from 30 to 40 gm. may be required. Usually the patient is directed to take one or two heaping teaspoonfuls once a day, preferably with his breakfast. From two to four days may elapse before an effect manifests itself. If none appears, the patient should increase the amount ingested by taking additional doses with other meals. As much as four tablespoonfuls and even more may be needed. In such a case, it is best to employ some other evacuant instead, or in addition. Children of 4 or 5 may require two teaspoonfuls (4 gm.) daily. Once regularity has been established for a week or two, the patient should tentatively reduce the dose, to discover the smallest amount required by him; and this may have to be continued many months, perhaps indefinitely. As it, therefore, is really an article of diet, we must invoke the art of cookery to make the patient relish taking the remedy, or it will be discarded sooner or later, even though it produces a satisfactory result.

Adults usually prefer to take it in shredded form (cut agar). This may be eaten with cream and sugar.

\* This is the ninth of a series of articles on the pharmacology, physiology and practical application of the common laxatives and cathartics. The first article appeared October 18.

<sup>1</sup> Schmidt, Adolf: Neue Beobachtungen zur Erklaerung und rationellen Behandlung der chronischen bakteriellen Obstipation, Munchen, med. Wehnschr. 52: 1970 (Oct. 10) 1905.

Many prefer to eat it mixed with gruels or any of the ordinary cereal breakfast foods. It may also be added to cooked fruits, vegetables or thick sauces. For the adult, however, it should not be cooked with the food. Agar may be used, instead of bran, in the various cooking recipes given in connection with bran. When used in the making of cakes, biscuits or cookies, it should always be added just previous to baking.

Children require agar in finely granular or liquefied form. When shredded agar is given in their food, many of them will carefully separate each piece in their mouth and spit it out. To liquefy agar, it must be boiled with water until it has become thoroughly homogeneous. Several hours' hard boiling may be required. Thus it may be cooked up with cereal or in soup; but such dish must not be allowed to cool before it is eaten, otherwise it will gelatinize. Of course, agar may be eaten in the form of jelly. Strauss<sup>2</sup> gives this recipe for an agar jelly:

Wash 5 gm. of agar in cold water, then soak in hot water, and boil with from 300 to 400 c.c. of water until clear. Strain through gauze, and add any one of the following flavorings: wine, sugar and lemon peel, coffee, cacao, cream, yolk of egg, etc., and set aside to cool.

The limitations of agar as a laxative are perhaps best shown by the fact that Adolf Schmidt, who first proposed its use for this purpose, found it necessary to make it more reliable in its activity by adding 25 per cent. of aqueous extract of cascara sagrada. This combination of Schmidt's is being promoted as a proprietary medicine. One of the objections to such a combination is the impossibility of varying the relative dosage of its ingredients. If it is found necessary to supplement agar with an active cathartic, let the cathartic be given separately. Then it will be possible to adjust the dosage to the needs of the individual patient; and it will also be possible gradually to reduce the dosage of the active cathartic until the patient is finally weaned from it. While it may be admitted that little, if any, harm could come from using agar indefinitely, it is certainly true that the indefinite consumption of cascara sagrada, or of any other active cathartic, leads to habituation of this drug.

(To be continued)

## New and Nonofficial Remedies

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

W. A. PECKNER, SECRETARY.

**HOYT'S GLUTEN SPECIAL FLOUR**—A gluten flour containing protein, 80 per cent. fat, 1 per cent. and starch less than 10 per cent.

*Actions and Uses.*—Hoyt's gluten special flour may be given when a diet relatively free from carbohydrates is desired, especially in diabetes. It does not make a satisfactory bread but may be used to prepare muffins, flat cakes or gruel.

The nutritive value of 500 gm. of Hoyt's gluten special flour corresponds approximately to 1810 calories, of which 1640 are due to protein, 45 to fat, and 125 to carbohydrate.

Manufactured by the Pure Gluten Food Company, Columbus, Ohio. No U. S. patent or trademark.

Hoyt's gluten special flour is prepared by washing a wheat flour dough with cold water until the entire content of the wheat flour has been completely freed from starch as is possible by mechanical means. The residual mass is then dried and ground.

SATURDAY, DECEMBER 13, 1919

The Current Medical Literature and other departments in this issue are curtailed, owing to the shortening of the hours of labor to comply with the ruling of the fuel commission. The shortening occurs almost wholly in the middle section of THE JOURNAL—the last form to go to press. The precipitate nature of the ruling is responsible for this unevenness. Sympathetic readers will pardon the curtailment as well as any delay in the receipt of THE JOURNAL.

## DIET AND INTESTINAL BACTERIA

There are many indications in the recent literature of alimentary bacteriology leading to the conclusion that diet can play a significant rôle in determining the bacterial flora of the intestine. The attempts to establish specific types of micro-organisms in the enteric tract by feeding bacterial cultures have not proved successful in the way that the enthusiasts of the Metchnikoff school were led to expect. Despite the positive claims of the manufacturers of such products, the preponderant view at present is against the probability of success in the efforts to implant strains of bacteria in the intestine by feeding cultures of them. On the other hand, there is growing evidence that the flora in the bowel can be profoundly altered by changes in diet.

Torrey has demonstrated the striking effect of various high-calory diets on the fecal flora of typhoid patients. In some cases the addition of from 250 to 500 gm. (8 to 10 ounces) of lactose a day to the other ingredients of the ration brought about a transformation of the fecal flora from the ordinary type to one strongly dominated by *Bacillus acidophilus*. In more recent investigations on dogs, he has further established the promptness and uniformity with which they respond to diet by changes in their predominant alimentary bacteria. As Mendel has recently pointed

out, the determination of the conditions under which desired intestinal floras can be established opens up a fruitful field for the clinical investigator. This is further emphasized by the new observations of Porter, Morris and Meyer<sup>3</sup> of the University of California Medical School. They show that children whose diet is well balanced and whose nutrition is normal have an intestinal flora consisting of fermentative and putrefactive types of micro-organisms without preponderance of either; but when large quantities of cow's milk are fed, the flora becomes more complex and tends to include a predominance of facultative putrefactors. Putrefactive bacterial types are, furthermore, characteristic for children who suffer from certain forms of alimentary intoxication with malnutrition.

According to the San Francisco pediatricians, the return of such children to normal health is coincident with a regression of the intestinal flora toward predominantly fermentative types. Such a change, they further aver, can be brought about in the infant by withdrawing animal protein and persistently feeding large amounts of lactose and other carbohydrates—not, however, by mere administration of cultures of *B. acidophilus*. Since the progressive cessation of the symptoms of intoxication and a return of toxemic patients to nutritional health coincides, to cite Porter, Morris and Meyer, with the recognizable dominance of a fermentative flora, the therapeutic value of suitable dietary regulations is obvious. For years it has been customary, in the management of infants suffering from putrid diarrhea, to furnish cereal decoctions or carbohydrates like lactose and maltose to them. The wisdom of such dietotherapy in suitable cases is being established on a scientific basis by some of the studies like those to which we have just referred.

## BOTULISM: I

The striking symptoms and high fatality of botulism have given to this disease, as to rabies, an interest and a conspicuousness far beyond its relative importance as a cause of death. Two recent fatal outbreaks of "food poisoning," one in Ohio, the other in Michigan, have been attributed, it seems with justice, to botulism intoxication from ripe olives packed in California, and these tragedies have increased the uneasiness felt by some persons about the dangers from this cause. American investigators in the past few years<sup>4</sup> have added much to our knowledge of

botulism, and several recent articles, especially, have helped to define the conditions under which this serious form of food poisoning may take place.

It has been shown that the name of botulism, or sausage poisoning, is quite inappropriate to this form of bacterial intoxication as it occurs in the United States. Canned string beans, asparagus, corn, apricots, ripe olives and cheese have been implicated at various times and places, while meat products have seldom been causally connected with such cases. Apparently the majority of outbreaks on record in this country have been due to household canned foods, and one of the points in dispute has been whether a similar danger is to be feared from factory canned foods. The difference of opinion among workers in this field is exemplified by correspondence recently appearing in THE JOURNAL from two correspondents.<sup>5</sup> Some of the points raised in the correspondence are of general interest.

There is no doubt that the early statements of van Ermengem, the discoverer of *B. botulinus*, about the low heat resistance of this organism are incorrect if applied to all conditions or all strains. Most of the American strains, so far from being killed by heating to 80 C. for one hour, will withstand much higher temperatures, some even resisting the temperature of boiling water for a considerable period. The history of the canned foods implicated in botulism poisoning shows that the spores of *B. botulinus* pass through the ordinary processes of household canning without destruction. It seems to be a fact that, as far as recorded cases go, only two or three instances of botulism poisoning have been traced to factory canned goods, as against a much larger number attributed to foods prepared in the household. Whether this difference is due to the superior germicidal efficiency of factory methods of heating or to the circumstance that spoiled or swelled canned goods are more likely to be eliminated in the course of ordinary trade procedures or to a combination of these factors cannot be definitely established at this time. It does not seem, however, that we are justified in asserting that a danger is entirely absent because it is exceedingly slight.

The main point of difference between the correspondents mentioned seems to hinge on the interpretation given by Weinzirl to the results of an extended bacterial examination of canned foods undertaken in the Department of Preventive Medicine at Harvard University.<sup>6</sup> The investigation forms part of a comprehensive study of canned foods, which is being carried out under the direction of Dr. M. J. Rosenau with the aid of a grant supplied by the National Canners Association. The conclusion drawn by Weinzirl to which particular exception has been taken is that

"food poisoning organisms, such as *B. botulinus*, *B. enteritidis*, etc., are not found in commercial canned foods."<sup>7</sup> It is unfortunate that this matter was not allowed to rest in the form in which it appears in the summary of results: "Members of the paratyphoid-enteritidis group were not found, nor was *B. botulinus* ever isolated." This plain description of findings becomes transmogrified by Weinzirl in his "conclusions" into a general statement which would hardly be justified even by a more extensive investigation than that here under discussion, and which in its present form might lead to serious misinterpretation.

On the other hand, it must be admitted that a rather too positive tone pervades portions of Mrs. Burke's letter. It is hardly justifiable to insinuate, however vaguely, that a group of workers is influenced by any consideration other than the desire to seek the truth and find it.

It seems hardly fair or wise to cast discredit on the work of a group of scientific investigators, comprising some of the best known names of the country, apparently on the ground that the money for the work has been provided by a commercial association. The word "commercial" is frequently used as a general term of opprobrium, but, as Roosevelt would have said, there is a "good" as well as a "bad" commercialism. It is not our understanding that money was given to Harvard University for the purpose of "exonerating" factory canned goods from any charge whatsoever, but simply for the purpose of discovering actual conditions and, so far as those conditions might be undesirable, of discovering and applying appropriate methods of improvement. It can hardly be assumed that the officials or any of the members of the National Canners Association would favor for an instant a plan to ignore or overlook any danger of botulism poisoning that might exist. Their interests, "commercial" as well as simply human, lie wholly in the direction of discovering what the danger is, how it arises, and how it can best be avoided or overcome. Denial or concealment is the last policy sound business judgment would dictate.

#### SECURING OFFICERS FOR THE ARMY MEDICAL CORPS

The Military Committee of the House of Representatives, it is reported, has agreed on a peacetime regular army of 300,000 men and 18,000 officers. The number of officers, in excess of the actual need in the army, was decided on in order to provide in training for the national guard and reserve officer training corps units. Probably, therefore, from 1,800 to 2,000 regular medical officers will be needed. The problem of securing young men for the Regular Medical Corps has long been a difficult one to solve; the need for

<sup>5</sup> Burke, Georgia S. Spoiled Canned Foods and Botulism, J. A. M. A. 73: 1978 (Oct. 4) 1919. Weinzirl, John. *Ibid.* 73: 1289 (Dec. 6) 1919.

<sup>6</sup> Weinzirl, John. The Bacteriology of Canned Foods, J. M. Techn. 33: 349 (Jan.) 1919.

<sup>7</sup> Weinzirl, John. *Quoted* 6, p. 111.

<sup>8</sup> Weinzirl, John. *Footnote* 6, p. 111.

a larger corps merely emphasizes the problem. At the present time the difficulty is increased because of the low pay, although undoubtedly this will be removed by a bill now before Congress which provides for a 30 per cent. increase in pay and emoluments. This means compensation which will compare favorably with the income of the majority of civilian practitioners. But the increase in pay alone will not be enough to attract a sufficient number of volunteers to the service under present educational conditions.

Many state licensing boards are requiring a year's hospital internship in addition to the four years' professional training, and an increasing number of medical colleges are requiring a fifth year of hospital work before granting the degree. This hospital year is a good thing; so far as the public is concerned, one of the most important advances in medical education. However, young physicians with such training are likely to see more allurements in private practice than in the army. In addition, there is the worry and work of passing the army examinations. Hence, if the army is to depend on this class of well-trained men to fill its medical corps—and it is this class that is wanted—it will take a long time before the Medical Corps will secure its full quota under present methods of taking in these men.

But why should the army wait for this complete training? Why should it not take the man when he has completed his fourth year and give him his hospital year as a noncommissioned officer in the Medical Department? The Walter Reed Hospital offers a splendid opportunity for such work as the hospital year is supposed to require; in addition, there are the available division hospitals. If such a method of recruiting were adopted, it would be a double advantage to the student: (1) He would be taken from an A-grade medical school on his record in that school, without having to go through the ordeal of an examination—this to some students would be an attractive feature, and (2) he would receive pay and subsistence during the hospital year, at the end of which he would receive his diploma, just as he would if the year had been spent in a civilian hospital. These factors, taken together, should appeal to the average fourth-year student.

There are two obstacles to this proposition, neither of which, however, is serious. First, the law requires that an applicant for the Medical Corps of the Army must have an M.D. degree from a reputable and well-recognized medical school, second, the medical school which requires the hospital year—and soon all medical schools of any standing will do so—would have to agree to recognize the army hospital as satisfying their requirements for the hospital year. The first obstacle could very easily be overcome by a slight modification of the present requirements, or by having the student go through his hospital year as a noncommissioned

officer. The second also can surely be overcome, for certainly medical colleges will willingly grant recognition to the divisional hospitals of the army—at least to the great Walter Reed Hospital.

## Current Comment

### THE FATE OF PROTEINS INJECTED INTO THE CIRCULATION

The fact that considerable quantities of blood, a fluid exceptionally rich in protein, can be introduced into the circulation without untoward effects and frequently with benefit has occasionally fostered the belief that other more easily obtainable protein solutions also could be infused occasionally with advantage. Before the rôle of digestion as a preliminary to assimilation was understood as well as it is at present, the possibility of direct nutrient benefit from proteins and other foodstuffs introduced directly by injection into the circulating medium of the body or less directly by the subcutaneous path seemed more plausible. Today it is the amino-acid digestion end-product, in the case of proteins, that counts as the real nutrient unit. The nitrogenous pabulum of the tissues is believed by the great majority of physiologists to circulate as amino-acids, which are the prime sources of constructive transformations in the tissues. If this hypothesis is correct, unaltered, that is, undigested foreign protein which finds its way into the blood stream may be expected to behave essentially like foreign material in the body. There are many experiments on record to indicate that this is true so far as the appearance of protein in the urine is evidence that protein introduced parenterally fails of utilization. Casein is, in a sense, not an entirely foreign protein, since it is actually manufactured in body cells by the mammary gland. Nevertheless, even this substance is not retained in the body when it is introduced through channels whereby digestion is avoided. Aaron,<sup>1</sup> who has repeated some of the earlier attempts at intravenous nutrition with proteins, has succeeded in recovering in the urine as much as 58 per cent. of the casein injected in animals. The futility of further procedures in this direction should henceforth be clearly understood.

### THE PREVALENCE OF SYPHILIS

It is difficult to obtain accurate figures showing the prevalence of venereal disease. Many observers have attempted to collate statistics, but certain inherent difficulties have always prevented satisfactory results. The disinclination of patients to give out information regarding these so-called "secret" maladies has always been a troublesome factor. The development of the complement fixation test has enabled us to reach conclusions regarding syphilis that are more definite than any obtained before the introduction of this method. Day and McNitt<sup>2</sup> have recently studied nearly 3,000

<sup>1</sup> V. Aaron, B.: Das Schicksal des intravenös verabreichten Caseins, *Ztschr. f. physiol. Chem.*, 98: 49, 1916-1917.  
<sup>2</sup> Day and McNitt: *Am. J. Syphilis*, 3: 595, 1919.

patients in the hospital and outpatient services of the Barnes Hospital of St. Louis. Among their well-to-do patients, a little over 6 per cent. gave a positive Wassermann reaction. Among the middle class, represented by patients in the pay wards, something over 13 per cent. gave evidence of syphilis, and in the lower class of white patients, nearly 20 per cent. gave evidence of the disease. Among the colored patients, 30 per cent. in the wards gave a positive Wassermann reaction. In the dispensary nearly 16 per cent. of the white and over 40 per cent. of the colored patients gave a serologic evidence of syphilis. These figures, covering a comparatively large series of patients, indicate the prevalence of the disease among the average sick and not among the average well. As the existence of a previous syphilitic infection predisposes to other diseases as well as sending many patients to the hospital with the late manifestations of syphilis in the internal organs, the figures cannot be considered applicable to the general population.

## Medical News

(PUBLISHERS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST; SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

### CALIFORNIA

**Joint Meeting.**—The Los Angeles County Medical Association held a joint meeting with the Southern California Medical Society, December 4 and 5, in Los Angeles. The address of the president, Dr. Edward W. Burke, Redland, was on "Medical Readjustments Following the War."

**Soldiers Honored.**—A banquet was given at Hotel Alexandria, Los Angeles, December 11, in honor of the members of the Los Angeles County Medical Association who have been in the military service during the world war. About 265 members gave up practice to enter the medical corps and of this number all but twenty-four have returned.

### DISTRICT OF COLUMBIA

**Changes in Faculty.**—General William H. Arthur, M. C., U. S. Army, has been appointed professor of military hygiene in the Georgetown University, Col. William O. Owen, M. C., U. S. Army, head of the department of anatomy, and Dr. William G. Irving, professor of orthopedics in the institution.

**Personal.**—A reception was tendered by Major-Gen. Merritt W. Ireland, Surgeon-General, U. S. Army, and Mrs. Ireland, at their apartment in the Wyoming, recently, to the faculty and student officers of the Army Medical School. —Matthew A. Delaney and William J. L. Lyster, colonels M. C., U. S. Army, were decorated by the Prince of Wales with the order of St. Michael and St. George, at the investiture, November 13.

**Testimonial to Dr. Kober.**—To express the admiration and gratitude in which Dr. George M. Kober is held by his pupils, friends and co-workers, it has been decided to issue as a testimonial to these sentiments an anniversary publication dedicated to him, on the occasion of his seventieth birthday, March 28, 1920. Dr. George Tully Vaughan has been selected as chairman of the organization; Mr. Felix Neumann of the Army Medical Museum, as secretary; Mr. John Joy Edson, as treasurer, and as members of the committee at large, Gen. Robert E. Noble, Drs. Charles D. Walcott, Wilfred M. Barton, J. W. Fewkes, Walter D. Hough, L. O. Howard, Ales Hrdlicka, Washington, and T. Michleson, Prof. W. H. Holmes, and Mr. N. M. Judd. The anniversary publication will be the issue of the *American Journal of Physical Anthropology*, which will be published in the latter part of March, and will be known as the George M. Kober Anniversary number.

### ILLINOIS

**Personal.**—Dr. Josephus J. Brown, for nearly forty-one years a practitioner of Troy, has disposed of his entire business and property interests and expects to locate in California. —Dr. Lee C. Harlan, Madison, is convalescent after a severe infection of the hand.

**Chiropractor Convicted.**—According to a news item, Dr. H. N. Mettler, a chiropractor of Rock Island, recently convicted in the circuit court for treating human limbs without a license, was fined \$200 and costs, amounting to \$220. This case has attracted much interest among chiropractors all over the state of Illinois and Iowa and is expected to set a precedent. It is understood that Dr. Mettler will qualify for a license and continue his practice in Rock Island.

### Chicago

**Election of Officers.**—Medical Department Post No. 31 of the American Legion announces the election of the following permanent officers: commander, Dr. John F. Van Pelt; vice commander, Dr. Henry C. Lampe and adjutant and treasurer, Dr. Thomas P. Foley.

**Personal.**—By the will of Robert L. Reid, who killed himself, December 1, his body is bequeathed to his friend and employer, Dr. Augustus G. Haefliger "for scientific purposes." —Dr. J. W. Hilbert has been appointed physician to the Studebaker Corporation, South Bend, Ind.

### LOUISIANA

**War Service Physicians Organize.**—The military service in the military service during the war toward

the American Legion, November 28, electing the following officers: commander, Dr. John B. Elliott, Jr.; vice commander, Dr. Joseph A. Danna, and adjutant and finance officer, Dr. John F. Dicks.

**Personal.**—Dr. Walter J. Otis, formerly of Waverly, Mass., and more recently in the division of neuropsychiatry of the army, has located in New Orleans.—Dr. James T. Newman, New Orleans, has been appointed superintendent and surgeon in charge of Providence Hospital, New Orleans, an institution for colored patients.

**Case of Yellow Fever in New Orleans.**—The president of the state board of health reports that William H. Stevens of New York City, a passenger from Merida, via Progresso, returned on a steamer which arrived in New Orleans, December 2, and at 10 p. m., December 4, from yellow fever. The disease was promptly recognized and all precautions were taken.

**Bubonic Plague.**—The president of the dock board announces that all port facilities of New Orleans, save five wharves, are to be ratproofed at an expenditure of about \$100,000. The other facilities of the board will gradually be made rat-proof, the necessary funds being borrowed.—The seventh case of bubonic plague reported this year in New Orleans is that of John Unger, a rat catcher in the Public Health Service, who was seized with the disease, November 25.—One death from bubonic plague occurred, November 25. The case was detected, November 22, and was sent to the isolation hospital, where serum was administered, but it was too late to save the life of the child.

#### MARYLAND

**Personal.**—Dr. Raymond Pearl, professor of biometry and vital statistics in the school of hygiene and public health at Johns Hopkins University, has been appointed statistician to the Johns Hopkins Hospital.

**Fire at Johns Hopkins.**—McCoy Hall and others of the old buildings of Johns Hopkins University were destroyed by fire, November 27. The loss is covered by insurance, but valuable libraries and records of the school of hygiene and public health which occupied the second floor of McCoy Hall were destroyed with irreparable loss. On the day before the fire Dr. Raymond Pearl, in charge of the department of biometry and vital statistics in the school of hygiene at Johns Hopkins, moved to McCoy Hall, his entire private scientific library, including about 15,000 reprints and pamphlets, and the accumulated unpublished records of his work for the last twenty years. These were entirely destroyed. Sir Arthur Newsholme lost many of his private papers in the fire.

#### NEW YORK

**Addition to Hospital.**—A twenty-five bed addition to the University Municipal Hospital for Infectious Diseases has just been completed. This addition consists of isolation rooms and two small wards, and gives the hospital a total bed capacity of more than 100 beds.

**Personal.**—Dr. Albert H. Garvin has resigned his position of superintendent for the State Hospital for Incipient Tuberculosis at Bay Brook to accept a similar position at a sanatorium for incipient tuberculosis, located near Detroit, at a salary of \$10,000 a year.—Dr. John J. Lloyd, Jr., superintendent of the Tuberculosis Sanatorium, Westchester has been elected superintendent of the Blue Ridge sanatorium, now under construction, near Charlottesville, Va.

#### New York City

**Academy Election.**—At a stated meeting of the New York Academy of Medicine, December 4, the following officers were elected for one year, president for three years, Dr. Rufus A. Cook, treasurer for five years, Dr. W. Gilman Thompson, secretary and committee of education for five years, Dr. Sidney Powers, librarian, member of committee of library, Dr. Cary York. The term of the president, Dr. George David Stewart, expires next year for another year.

#### OHIO

**Library Given Medical Society.**—Mr and Mrs. J. H. Himes, Canton, have given the Canton Medical Society a medical library in liquidation of a fund of \$1000 to be used in the purchasing of medical journals.

**Personal.**—Dr. Irwin A. Petersen, Cleveland, has been appointed director of department of health service of the American Red Cross.—Dr. Paul G. Woolley, Cincinnati,

professor of pathology of the University of Cincinnati, has resigned.—Dr. Robert B. Woodward, Somerset, has been elected mayor of the village. This is the fifteenth term he has served as executive officer of the village.—Dr. Van S. Deaton has been elected mayor of Troy.—Dr. Clarence W. Russell, Springfield, who has been ill with heart disease at the home of his sister in Burton, is convalescent and has resumed practice.—Mrs. Rena D. Reed, wife of Dr. Charles A. I. Reed, Cincinnati, died recently from cerebral hemorrhage.

#### PENNSYLVANIA

**Personal.**—Dr. E. Olivia White, Philadelphia, has been appointed assistant chief of the division of child hygiene of the state health department.—Dr. Frederick W. Coover, Harrisburg, has been elected surgeon emeritus on the staff of the Harrisburg Hospital.—Dr. J. Allen Jackson, Philadelphia, chief resident physician of the department for the insane of the Philadelphia General Hospital, has resigned to accept a similar position at the State Hospital for the Insane, Danville.

**Tuberculosis Night.**—A special meeting was held at the College of Physicians, December 10, and designated "Tuberculosis Night." Similar meetings were held at the branches of the Philadelphia County Medical Society, all open to the public. This meeting was for the discussion of a campaign against tuberculosis. Dr. Edward E. Martin, commissioner of health of Pennsylvania, spoke on the work of the state in its fight against this disease and Clifford B. Comelley, commissioner of labor of Pennsylvania, spoke of tuberculosis in its relation to the wage earners. Edward Keenan, president of the central labor union of Philadelphia, discussed union labor's interest and place in the tuberculosis crusade.

**Jefferson Establishes a Dietetic Center.**—The Tuberculosis Society of Philadelphia has established a dietetic center at the Jefferson Department of Diseases of the Chest at 238 Pine Street. The first class attended by state nurses took up the preparation of economical and nutritious foods and the ultimate plan is to establish dietetic clinics throughout the state. The nurses will be taught to instruct mothers of families and urge pupils to attend the classes. Ultimately it is hoped to establish regular dietetic clinics at all hospitals. Classes are under the supervision of Miss Idella G. Miller, a dietitian furnished by the Tuberculosis Society. These are held each afternoon and evening and consist of one and a half hour periods. Instruction will cover preparation of simple foods and the making of ideal menus designed to supply the greatest amount of strength. The Social Service Department, headed by Miss Eleanor Finken, is actively cooperating in this movement.

#### Philadelphia

**Society Honors Service Men.**—The L. Webster Fox Ophthalmological Society of the Medico-Chirurgical College of Philadelphia held its annual banquet at the University Club, November 22, in honor of its members who were in the military service during the war. Dr. John A. Brophy presided as toastmaster.

**Hatfield Lectures.**—Lecture No. 2 of the Nathan Hatfield Lecture series will be delivered at the College of Physicians of Philadelphia, December 16, at 8:30 p. m. by Dr. Harvey Cushing, Boston, professor of surgery in Harvard University, on "The Major Trigeminal Neuralgias and Their Surgical Treatment."

**Tuberculosis Days.**—Tuberculosis day was observed in the schools of the city, December 5, was observed in the synagogues, December 6, and in the Sunday schools and churches, December 7. Special attention was called to the sale of Red Cross Christmas seals, now being conducted under the auspices of the Philadelphia Tuberculosis Committee.

#### CANADA

**Personal.**—Dr. John A. Anyot, Toronto, deputy of minister of health for Canada, has left Ottawa to confer with Dr. Gordon Bell, provincial bacteriologist in Winnipeg, to discover the sources of the so-called sleeping sickness reported from western Canada.

**Public Health News.**—It is now definitely stated that the smallpox outbreak in Ontario has been traced to Toronto. Up to the end of November there was a total of 1,673 cases in that province with no deaths. Most of these occurred in Toronto, the figures being 1,356. The disease has occurred in thirty counties of Ontario. During November, the Ontario Board of Health supplied 240,000 individual doses of small-

pox vaccine. There has also been a considerable increase in Ontario of other communicable diseases. There were in November 438 cases of scarlet fever with seven deaths; diphtheria, 621 cases with 48 deaths; typhoid fever, 53 cases, 24 deaths; tuberculosis, 157 cases, 124 deaths. During the month there were 275 cases of venereal diseases as against 96 for the same month in 1918.—A deputation of Montreal physicians in the interests of public health is visiting Toronto and interviewing the medical officer of health with regard to the outbreak of smallpox.

#### GENERAL

**Personal.**—Frederick F. Russell, Col., M. C., U. S. Army, has been appointed official representative of the Medical Corps on the government division of the National Research Council.

**Biologists to Meet.**—The executive committee of the Federation of Biological Societies has called the annual meeting at Toronto, Ont., December 29 to 31. This federation includes the American Physiological Society, which at this time will hold its thirty-second annual meeting.

**New York Medical Weeklies Resume Publication.**—We congratulate our contemporaries, the *New York Medical Journal* and the *Medical Record*, on having resumed publication after a six weeks' vacation, the result of a strike. Both journals are issuing the belated issues as rapidly as possible, and, unless further troubles ensue, within a week will appear normally.

**Meeting of the Child Hygiene Association.**—At the annual meeting of the American Child Hygiene Association, held in conjunction with the convention of the Southern Medical Association at Asheville, N. C., last month, St. Louis was selected as the next place of meeting, and the following officers were elected: president, Dr. Philip Vanfingen; president-elect, Prof. Charles A. E. Winslow, New Haven; vice presidents, Drs. W. M. Chapman, Montreal, and Howard C. Carpenter, Philadelphia; secretary, Henry F. Helmholz, Evanston, Ill. (re-elected); treasurer, Austin McClanahan, Baltimore, and executive Miss Gertrude B. Knipp, Baltimore (re-elected).

**American Red Cross Wishes Fifty Physicians.**—The American Red Cross wishes to obtain fifty medical officers for service in Europe and elsewhere. Qualified practitioners who have had military experience are preferred. Captains and lieutenants will be given preference, but those who held the grade of major will be considered, provided they are young, active and efficient. The pay will be that which they received in the service, plus 10 per cent. for overseas, with a liberal allowance for commutation. The Red Cross does not desire to sign a contract for a period of less than one year, although when necessary in a few cases the contract will be for a period of six months. The qualifications must be similar to those required by the Army and Navy for entrance into these services. Young men, preferably not over 35 years of age, are preferred. They must be physically sound and of good moral character, as they will be representatives of the medical profession of the United States in a foreign country. The work will be interesting. For further information address Brig.-Gen. Robert E. Noble, Army Medical Museum, Washington, D. C.

#### FOREIGN

**Centennial of the French Académie de Médecine.**—As Dec. 20, 1920, is the centennial of the Académie de médecine at Paris, a committee of six members was recently appointed to have charge of the celebration of the anniversary.

**Harveian Festival.**—The Harveian festival was celebrated with full honors by the Royal College of Physicians of London, for the first time since 1913. The oration was delivered by Dr. Raymond H. P. Crawford, and dealt with the fore-runners of Harvey in antiquity. The speaker supported the thesis that in the matter of circulation of the blood Harvey's indebtedness to any but Aristotle was negligible. After the oration the president presented the Baly Medal to Dr. Leonard E. Hill.

#### LATIN AMERICA

**Red Cross Commissioner to West Indies.**—The American Red Cross has selected John A. Swan, Lieut.-Col., M. R. C., U. S. Army, as a commissioner to visit the Virgin Islands, Haiti, and Santo Domingo, and make a survey of the work to be done. There is now one Red Cross hospital in Santo Domingo, at Seibo, which is officered and manned by the Medical Corps of the Navy.

## Foreign Correspondence

LONDON

Nov. 19, 1919.

### The Medical Research Committee

The fifth annual report of the Medical Research Committee (a body appointed under the national health insurance act to undertake research) has issued its fifth annual report. This surveys the advances in medical science during the war, and indicates how they may be utilized in peace. Some very interesting researches are described. One is that of Dr. Benjamin Moore on "photosynthesis." He finds that in the presence of sunlight, but without the aid of bacteria, both fresh water and marine algae are able to take nitrogen out of the air and to "fix" it. The nitrogen is taken up probably as nitrites and nitrates formed by the action of light on nitrogen and oxygen in the air or dissolved in water. Evidence has been found that the so-called "active oxygen" of fresh country air is not ozone, but nitrogen peroxid, probably formed by ultraviolet light causing direct union of nitrogen and oxygen. The ultraviolet rays are largely filtered out of the light in city atmospheres. Further, there seems to be a relation between what is called the "ozonometric" chart and the energy of the sun.

An important investigation on the prevention of influenza by the use of gases has been undertaken by Dr. Alexander Gregor, health officer for Falmouth. He noticed that the employees in gas works did not suffer from influenza. This suggested that gases might be used as a prophylactic. Dr. Benjamin Moore collaborated with him in devising methods for the slow and safe discharge of nitrogen peroxid at a concentration fit for breathing and with other gases (sulphur dioxide, nitric acid and acetone). It was found that exposure to these gases caused a great diminution in the growth of bacteria obtained from swabs of the throat and nose. The application of these results is described in the *British Medical Journal* by Dr. Gregor. An outbreak of influenza took place in a camp, and it was resolved to try to disinfect the men *en masse* with nitrogen peroxid, which was generated by placing strips of copper in nitric acid. The concentration of the gas was so arranged that the odor was not irritating or disagreeable. The men were kept in the gas for ten minutes. No complaint was made as to any untoward effect or after-effect. About 400 were passed through the chamber in five days. Unhappily the battalion was in process of being broken up, for which reason accurate results could not be obtained. However, the fact was established that it was quite practicable to expose bodies of men to the fumes without either personal discomfort or ill effect. A gang of navvies living in a large shed in dock was then experimented on. Two men who contracted influenza were removed to the hospital. They were exposed to sulphur dioxide; half an ounce of sulphur per thousand cubic feet was burned slowly in their sleeping quarters while they were going to bed and rising in the morning. This caused no discomfort and little irritation, and was continued for fourteen days. No other case of influenza occurred.

### Anthrax in Shaving Brushes

The contraction of anthrax from infected shaving brushes imported from Japan has already been reported. Cases have again occurred, due to a consignment from that country. Two cases are reported in Norfolk and two in London. Dr. Andrews, bacteriologist to St. Bartholomew's Hospital, has found anthrax bacilli in six out of nine brushes examined.

### Memorials to Lord Lister

Two memorial tablets to Lord Lister have been unveiled, one at University College and the other at University College Hospital, where he was student and house surgeon from 1843 to 1852. A distinguished audience was present. Sir George Makins, president of the Royal College of Surgeons, delivered an address. He said that no memorial stone was needed to perpetuate Lister's fame. There was a splendid monument already in the collected edition of his scientific papers. Sir J. J. Thomson, president of the Royal Society, gave an address on Lister's connection with the society which claimed to have recognized his merits at a very early stage in his career. He was elected a fellow in 1860, when 33 years of age. His father and a brother were also fellows, as was a nephew now. In 1880 he was awarded a royal medal, and in 1902 the Copley medal, which the Royal Society considered the highest honor it had to bestow. (Cont.)

connection with the administration of the society began with his appointment as foreign secretary in 1893, a position he held until elected president in 1895. He held that office for five years, during which time many important branches of work were undertaken, including the setting up of a committee for the investigation of tropical diseases, and the establishment of the National Physical Laboratory. From his experience when serving on the council with Lister he had been impressed by his courtesy. Discourtesy in him was unimaginable. His personality seemed to banish the microbes of discourtesy from the committee room as effectually as his discovery had banished the germs of foul disease from the surgical ward. His kindness was conspicuous. In deciding on the bestowal of medals and prizes, he sympathized with the unsuccessful more than he rejoiced with the victors.

## PARIS

Nov. 6, 1919.

## Congress of Orthopedists

At the first congress of French orthopedists, a partial report of which was given in THE JOURNAL, November 29, two of the subjects discussed were: war spondylitis, and treatment of pseudoarthrosis.

## WAR SPONDYLITIS

In his communication, Dr. Froelich, professor of clinical pediatrics and orthopedic surgery on the Faculty of Medicine of Nancy, passed in review all the chronic lesions of the vertebrae that he has seen in soldiers. Among the non-traumatic affections, aside from Pott's disease, he mentioned particularly syphilitic lesions, the true character of many of which fails to be recognized; rheumatismal spondylitis occurring in young subjects and marked by rapid development; typhoid spondylitis, and acute osteomyelitis; furthermore, in young soldiers, acute kyphoscoliosis, result of over-exertion, attended with fever and a general debilitated condition, and the staphylococcal infection described by Kirmison under the name of "kyphoscoliosis of apprentices."

Among the traumatismas may be mentioned spinal lesions with loss of a portion of bone, and fractures caused by projectiles, often the origin of osteitis and of fistulas far removed from the original lesion. The internal traumatismas under various forms of spondylitis: "vertebral insufficiency" so called, described by Denecé, in which a simple wrench or sprain, without lesions discoverable roentgenographically, causes a great deal of trouble and often presents serious aspects difficult to control; hystero-traumatic kyphosis, or camptocormia as it has been called, occurring in men who have been engulfed by the bursting of a shell, which often produces a vertebral sprain and consequent traumatic lesions. Examination of the roentgenogram for fractures is negative, but they are often present nevertheless, and the patients do not recover until they have worn a corset-shaped cast for a year. All too often such men have been regarded as malingerers; whereas, the fact is, some of them have not recovered yet, although there has been a cessation of hostilities.

Then there is the Verneuil-Kummel type of fracture of the spinal column, the evolution of which in three periods is well known: a brief period of pain after the injury, followed by a period with no symptoms, and then a progressive rigidity and renewed pain. These patients are often required to wear a plaster cast, which gives support to the spine, and effect a cure in many cases. Froelich thinks that it is possible to diagnose the case in the start by means of a lateral roentgenogram revealing a compression in the contact base of the vertebral body, the Hilts or the Albee fracture would be indicated.

## TREATMENT OF PSEUDO-ARTHRITIS

All the speakers who took part in the discussion were agreed that the treatment of war pseudo-arthritis is much different from the treatment of pseudo-arthritis resulting from simple fractures (*fracture simples*). The reasons advanced for this difference were: the extent of the loss of bone, the nature, the long supuration of the wounds, the extent and the depth of the resulting scar tissue, latent abscesses which cause the wounds to become reinfected, and the state of extreme calcification found in the ends of the bones. Dr. Maffraire, surgeon of the Hôpitaux de Paris and agrégé professor on the Faculty of Medicine, remarked that there was, however, an enormous difference between the wound in the beginning of the war and the wounds in the last years of the war, after the practice of conserving adherent bone fragments and the primary and delayed

closure of wounds were introduced. In spite of this improvement the treatment was still much more difficult than in pseudo-arthritis in peace times, which explains the variety in the methods of intervention used during the war.

Dr. Judet of Paris stated that he was somewhat skeptical in regard to bone grafts (whether of dead bone or of live bone); likewise with respect to osteoperiosteal grafts. He cited two cases in which he had followed for a long time, by means of roentgenography, a dead osteal graft and osteoperiosteal grafts and had watched their resorption without reproduction of bone. He had seen roentgenograms of other grafts and the reproduction of thin transverse strips of bone, but he had never seen a large, solid bone.

Dr. Roche of Bordeaux took exception to Judet's statements. He thinks that the results shown in the roentgenogram are not always an accurate measure of the actual clinical results. Some cases of pseudo-arthritis present firm consolidation to the palpating hand, whereas the roentgenogram shows little or nothing of these changes. In fact, there are cases presenting absolute solidity of certain parts although no corresponding roentgenographic shadow is obtained. Personally, Roche has used the Albee graft or the total fibular graft without the periosteum. If a focus of osteomyelitis is found, osteosynthesis should be done. It is useless to try to apply a graft if the loss of substance is great; cicatrization should take place before a graft is applied. General treatment by means of organotherapy and heliotherapy; also treatment of a coexisting diabetes or syphilis, offer great aid. Methodical exercise helps to adapt and strengthen the graft. If the first graft is not a success, others may be tried and often prove successful. Before attempting operations of this kind the surgeon should be well equipped with instruments and should be well supplied with "bony armament." The graft should not be placed in a position "approximately correct," but should be wedged in and fitted tight, for osteogenic growth will thus be much facilitated.

Dr. Albee of New York City, in a long communication, told of the results that he had secured by the use of bone grafts in fractures and in pseudo-arthritis. The results have been published in his work on the surgery of bone grafts (1-15). In the last ten years he has performed 1,950 bone grafting operations. He emphasizes the disadvantages of dead bone as a graft. Since 1911 he has used only live bone. The graft should include the whole thickness of the bone: periosteum, outer compact layer, cancellated tissue, endosteum and marrow. He emphasizes also the superiority of the electric twin saw over the hand chisel in preparing the graft. The advantages of this saw are: great rapidity (ten minutes being sufficient for most graft operations in fractures) and greater exactitude in the coaptation of the bone fragments. In pseudo-arthritis there are two essential features to be observed: (1) the use of grafts that are long enough to reach the healthy bone. It does not suffice that the graft is left in contact with the fibrous, decalcified ends of the sound bone. All the bad results that are not due to infection come from too short grafts. If the fractures are of old origin and if fruitless attempts at suture have been made, the grafts should be of greater relative length than otherwise; (2) the absolute adaptation of the graft to its site. Herein lies the advantages of the "inlay graft," a technic described by Albee. Such an inlay graft is resistant to infection and may be applied even to a suppurating bone. Immobilization of the member is indispensable, the apparatus varying with the conditions. Massage and mobilization are begun very soon, but restriction of movement should be continued for three or four months.

## Marriages

CHARLES MILLER HATCHER, Ass. Surg., Lieut. (j. g.), U. S. Navy, U. S. Naval Hospital, Las Animas, Colo., to Miss Janice M. Miller of Massies' Mills, Va., at Richmond, Va., October 21.

HALLIBURTON McCoy, Lieut., M. C., U. S. N. R. F., Asheville, N. C., to Miss Emma Louise Garnett of Charlottesville, Va., October 25.

HARLEY THOMAS CANNON to Mrs. Lillie Wright Lowere, both of New York City, at Greenwich, Conn., November 15.

THOMAS HARRISON FLESHER, Edmond, Okla., to Miss Margaret Elizabeth Cherry of Ardmore, Okla., October 18.

EMIL ARNOLD SCHLAGETER, Chicago, to Miss Agnes Clare McLHenry of New Richmond, Wis., September 18.

## Deaths

**Edgar Reid Russell** \* Asheville, N. C.; University of Maryland, Baltimore, 1895; aged 49; a member of the American Academy of Ophthalmology and Oto-Laryngology; one of the founders and formerly professor of diseases of the eye, ear, nose and throat in the North Carolina Medical College, Charlotte; a member of the surgical staff of the Meriwether and Presbyterian hospitals, Charlotte, and of the Charlotte Sanatorium, and president of the Charlotte Medical Society; died, November 27, from septicemia following a scratch of the hand.

**John Robert Tackett**, Meridian, Miss.; Tulane University, New Orleans, 1889; aged 50; captain, M. R. C., U. S. Army, and honorably discharged, Jan. 10, 1919; a veteran of the Spanish-American War; professor of theory and practice of medicine and internal medicine in Meridian (Miss.) Medical College; a member and once vice president of the Mississippi State Medical Association, and a member of the Mississippi State Board of Health; surgeon in the National Guard of Mississippi; died, November 25.

**James Milton Flint**, Medical Director, Rear Admiral, U. S. Navy (retired), Washington, D. C.; Harvard University Medical School, 1860; aged 81; who entered the Navy, April 14, 1862; was made medical inspector in 1893, and medical director in 1897; and was retired in 1900; he served as fleet surgeon of the Asiatic Fleet in 1894 and 1895; was honorary curator of the division of medicine of U. S. National Museum from 1881-1882, 1888-1891 and since 1895; died, November 21.

**Walter Seymour Reynolds**, New York City; University of the City of New York, 1892; aged 55; a member of the Medical Society of the State of New York; clinical assistant in genito-urinary diseases in the College of Physicians and Surgeons in the City of New York since 1898, and attending surgeon in the genito-urinary department of University and Bellevue Medical College since 1900; died, November 24.

**Willis Clark Noble** \* Montclair, N. J.; University of the City of New York, 1891; aged 65; for eighteen years a medical missionary in charge of the Mission Hospital of the American Board Commissioners of Foreign Missions at Paotingfu, China; physician, assistant attending surgeon and radiographer of the Mountsinide Hospital, Montclair, since 1902; died, November 21, from cerebral hemorrhage.

**Simone C. Adams**, Mexico, Mo.; Louisville (Ky.) Medical College, 1880; aged 67; for twenty years proprietor of the Mexico Hospital and Adams Institute for Treatment of Drug Addicts; formerly secretary of the Audran County Medical Society; died, November 23, at the Amanda Hospital, Mexico, a short time after a surgical operation.

**Leonard Basil Gapinski**, Chicago; Chicago College of Medicine and Surgery, 1916; aged 26; first lieutenant, Medical Reserve Corps, U. S. Army, and honorably discharged, June 28, 1919; died, November 1, in St. Mary of Nazareth's Hospital, Chicago, from streptococcus infection following an accidental cut of the lip.

**Abraham Joseph Arbeely**, Washington, D. C.; Syrian Protestant College, Beirut, 1872, Imperial University, Constantinople, Turkey, 1878; aged 67; also a dentist; founder and president of the Syrian-Greek Orthodox Church and Benevolent Society; founder and publisher of the *Star of America*; died, October 30.

**William Gilbert Povey**, Detroit; University of Michigan, Ann Arbor, 1899; aged 46; formerly demonstrator of gynecology in the Western Reserve University, Cleveland, and a member of the staff of the Lakeside Hospital Dispensary; died, November 24, after a surgical operation.

**Maurice J. Vigneux**, Nelson, B. C.; McGill University, Montreal, 1911; aged 41; who had just returned after eighteen months' service in France, was accidentally drowned, August 22, while endeavoring to rescue a little girl who had fallen into the lake at Connaught Park, Nelson.

**William H. Perry**, Cartersville, Ill.; College of Physicians and Surgeons, Keokuk, Iowa, 1878; aged 68; a member of the Illinois State Medical Society and president of the Williamson County (Ill.) Medical Society in 1913; died, November 15, from cerebral hemorrhage.

**Frank Dwight Crim** \* Utica, N. Y.; College of Physicians and Surgeons in the City of New York, 1871; aged 63; a member of the staff of Faxon Hospital, Utica; from 1888 to

1895 a resident of Lincoln, Neb., and for a time coroner of Lancaster County; died, November 27.

**Jesse Yeager Scott**, Washington, Pa.; University of Pennsylvania, Philadelphia, 1875; aged 71; a member of the Medical Society of the State of Pennsylvania; surgeon to the Washington Hospital; a director of the Washington Trust Company; died, about November 28.

**Clayton Welch Seaman**, Buffalo; New York Homeopathic Medical College, New York City, 1896; aged 50; a member of the Medical Society of the State of New York; visiting physician to the Buffalo Homeopathic Hospital, and Ingleside Home; died, November 13, from tuberculosis.

**Oliver J. Gronendyke**, Newcastle, Ind.; Medical College of Ohio, Cincinnati, 1885; aged 55; a member of the Indiana State Medical Association; for eighteen years a member of the local school board; died at Martinsville, Ind., November 23, from pneumonia.

**Walter B. Helm** \* Rockford, Ill.; Northwestern University Medical School, Chicago, 1884; aged 60; president of the Tri-State Medical Association; consulting surgeon to Rockford Hospital; died in Wesley Hospital, Chicago, November 28, from pneumonia.

**Edward McLaren Darrow** \* Fargo, N. D.; Rush Medical College, 1878; aged 64; the oldest practitioner in point of service in North Dakota; died in St. John's Hospital, November 25, from carcinoma of the liver, after an exploratory operation.

**Robert Hanley**, Kingston, Ont.; Queen's University, Kingston, Ont., 1888; for eight years a member of the city council; surgeon at the Portsmouth Penitentiary; died in the Hotel Dieu, Kingston, September 18, after an operation for appendicitis.

**George Washington Coker**, Bartow, Fla.; College of Physicians and Surgeons, Baltimore, 1885; aged 58; a member of the Medical Society of Virginia; died in a hospital in Charlotte, N. C., November 12, after a surgical operation.

**Harmon Baker Gibbon** \* Tiffin, Ohio; Cincinnati College of Medicine and Surgery, 1877; aged 67; president of the Ohio State Medical Association in 1916 and 1917; died, November 23, from angina pectoris.

**David Hopper Warner**, Newmarket, Pa.; University of the City of New York, 1880; aged 57; a member of the Medical Society of the State of Pennsylvania; died, November 24, from cerebral hemorrhage.

**Alonzo H. Lothrop**, Lexington, Ind.; Kentucky School of Medicine, Louisville, 1876; Louisville (Ky.) Medical College, 1894; aged 77; a veteran of the Civil War; died, November 21, from tuberculosis.

**Louis F. Klemm** \* Milwaukee; Milwaukee Medical College, 1909; aged 49; physician of Milwaukee County from 1906 to 1915; died, recently, from chronic interstitial nephritis.

**Louisa Schlegel**, Brooklyn; New York Medical College and Hospital for Women, Homeopathic, New York City, 1889; aged 72, died, November 23, from arteriosclerosis.

**Alexander C. Smith**, Indianapolis, Indiana Eclectic Medical College, Indianapolis, 1881; aged 70; for forty-six years a practitioner; died, November 22, from heart disease.

**Byran A. Rabe**, San Francisco, Western Reserve University, Cleveland, 1871; aged 70; a veteran of the Civil War; died, November 23, from carcinoma of the liver.

**James Wesley Alexander**, Woodland Mills, Tenn.; University of Louisville, Ky., 1876; aged 64, also a banker; died, October 27, from carcinoma of the stomach.

**John M. Turk**, Canton, Ga.; Reform Medical College, Macon, Ga., 1858; aged 85; a Confederate veteran; died November 11, from cerebral hemorrhage.

**Jacob Heater**, Philadelphia; Penn Medical University, Philadelphia, 1840; aged 87; for many years a practitioner of Trenton, N. J.; died, November 24.

**Mason J. Skiff**, North East, Pa.; College of Physicians and Surgeons, Keokuk, Iowa, 1884; aged 70; died, October 21, from chronic interstitial nephritis.

**Samuel L. Adair**, New Washington, Ind.; Kentucky School of Medicine, Louisville, 1868; aged 70; died, November 16, from cerebral hemorrhage.

**William Thompson Houser**, Portland, Ore.; Physio-Medical Institute, Cincinnati, 1874; aged 70; died, November 6, from cerebral hemorrhage.

**Robert Leonidas Knox**, Memphis, Tenn.; University of Nashville, Tenn., 1859; aged 83; died, October 7.

\* Indicates "Fellow" of the American Medical Association.

### "DEFECTS IN THE TEACHING OF PATHOLOGY, AND THE LAY PROFESSOR"

To the Editor.—Will you allow me to reply to the article by Dr. Symmers on "Defects in the Teaching of Pathology, and the Lay Professor" (*THE JOURNAL*, Nov. 29, 1919, p. 1651), as his stigmatization of the so-called lay professor is entirely and shows a lack of appreciation of the contributions of these men to medical progress. The naive admission that it may not be logical, but is essentially human, gives conclusive evidence that there has been engendered a strong defense reaction against the acknowledgment that any person, whatever his training, may have any conception of the labyrinth of medical subjects unless he has successfully completed a prescribed course in a medical school leading to the degree of M.D. As I look at it, the first task of any individual entering on the study of medicine is that he acquire a knowledge of the normal human body in its structure and mechanisms. For if he knows not the normal, how can he detect deviations therefrom? And what does anatomy, gross and microscopic, embryology, physiology, and biochemistry purport to teach if not these fundamental conceptions of the make-up and workings of the normal organism? If such foundation is established, the lack of information as regards deviation or pathologic conditions lies not in lack of perspective, sense of proportion, or appreciation of relative values on the part of the "lay professor," but rather in the teaching inability of the later instructors.

As we must expect a teacher of mathematics to be the possessor of an engineering degree, a teacher of literature to be a successful author, so to demand a teacher of the fundamental medical subjects to have run the gamut of medical school curriculum from obstetrics to psychiatry. Not that I would for one moment deny that that man who does not take an intelligent interest in medicine as a whole, and the possibilities of the application of a knowledge of his subject to practice, is unfit for teaching medical students; but I assert that the man need not necessarily have tacked after his name the magic symbols M.D. any more than an instructor of French need be of Gallic extraction.

Does any informed and intelligent individual for one moment believe that medicine, medical schools and medical students are the losers by having as teachers such men as Fahn, Mathews, MacCollum, and many others possessing the *Respect* (?) Ph.D. degree? Or that these men are lacking in perspective, appreciation of relative values and sense of proportion? Let those that doubt show equal contributions to medical progress, and I will gracefully retire.

FREDERICK S. HAMMETT, Ph.D., West Philadelphia, Pa.

### "INTENSIVE" ANTISYPHILITIC TREATMENT

To the Editor.—The casual reader is likely to get his impressions from headlines rather than from tables of figures buried in the body of an article. The title of the interesting paper on toxic jaundice (Lynch, T. J. and Hoge, S. F.: *Toxic Jaundice*, I. "Intensive" Antisymphilitic Treatment, *THE JOURNAL*, Nov. 29, 1919, p. 1687) conveys the unmistakable impression that the untoward effects reported were the results of "intensive" treatment with arsphenamin. Perusal of the paper, however, shows that the authors entertain views regarding the meaning of the term "intensive" wholly at variance with current conceptions. They state: "In the so-called intensive treatment from 0.4 to 0.6 gm. are given at weekly intervals over a period of from six to eight weeks." This is a complete falsification of the common use of the term "intensive"; most sphyliographers understand by this term the employment of arsphenamin in full doses at short intervals over short periods, as, for instance, in the method which I have been using for the past five years—parenterically, without any untoward result whatever—three full doses in three days. As a matter of fact, it appears that in the

authors' cases the toxic symptoms developed in sphyliotics who had received four doses of arsphenamin with intervals of a week between treatments. This is not intensive treatment.

It is interesting to note, furthermore, that the authors seem aware of the fact that toxic jaundice is unrelated to large dosage or frequent administration because they (correctly) state that "this accident [toxic jaundice] is liable to occur after a single dose."

We do not know the factors on which the occurrence of toxic jaundice depends. Millions of injections of arsphenamin have been given by the once-a-week method; the deaths from acute degeneration of the liver number probably less than a hundred. Why intimate that "intensive" treatment is responsible for them?

A year or more ago, the editor of a widely read medical journal, commenting on deaths from hemorrhagic encephalitis after arsphenamin, issued a warning against "intensive" methods and large dosage, ignoring the fact that the deaths in question had occurred after the ordinary once-a-week treatment with moderate doses. One fact is that deaths from hemorrhagic encephalitis have occurred after a single dose as small as 0.2 gm. and also after treatments administered at intervals of three weeks.

We know as little of the causes of hemorrhagic encephalitis after arsphenamin as of acute yellow atrophy. We do know that large dosage or frequency of administration are not necessary or even usual factors. The ipse dixit of prejudice and unfounded assumptions will not help us in the solution of these questions.

SIGMUND POLLITZER, M.D., New York.

## Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

### POLYMORPHONUCLEARS IN MALARIA

To the Editor.—Please describe the changes, if any, in the polymorphonuclear neutrophils in estivo-autumnal fever.

M. S. D., Dothan, Ala.

ANSWER.—While in the acute malarial attacks of average severity the absence of leukocytosis is of considerable corroborative value, a slight leukocytosis amounting to about 10,000, with an increase in the percentage of polymorphonuclear cells, has been observed by Billings and others. In the more severe estivo-autumnal attacks a definite leukocytosis has been observed, especially in the hemoglobinuric or blackwater type of malarial infection. The extent of the leukocytosis varies between 10,000 and 35,000, although many attacks fail to cause any distinct increase. During the afebrile periods the eosinophils are usually increased; neutrophil myelocytes are occasionally present, rarely eosinophil myelocytes. Pigmented leukocytes are seen in the majority of cases, especially in the severe and fatal cases. They include mononuclear and polymorphonuclear leukocytes.

### LUBRICATING JELLY

To the Editor.—Please publish a formula for a good lubricating jelly. The cost of jelly, when one uses considerable in an office practice, is quite high if one has to depend on the tubes as sold in the drug stores.

S. E. HOWARD, M.D., Rochester, Minn.

ANSWER.—The subjoined formula for an inexpensive lubricating jelly which has been used in the German Hospital (now the Laikenan Hospital), Philadelphia, for a number of years was published in *THE JOURNAL*, May 12, 1917, which see:

Tragaeanth, whole	3 gm.
Glycerin	25 c.c.
Phenol	1.5 gm.

Distilled water, a sufficient quantity to make 300 c.c.  
The tragaeanth is broken in small pieces, and put into a wide-mouthed bottle; the other ingredients are added, and the bottle is frequently shaken.

### Illinois March Examination

Mr. F. C. Dodds, superintendent of registration, Illinois Department of Registration and Education, reports the written and practical examination held at Chicago, March 3-6, 1919. The examination covered 10 subjects and included 100 questions. An average of 75 per cent was required to pass. Of the 168 candidates examined, 150 passed and 18 failed. Fifteen candidates were licensed by reciprocity. The following colleges were represented:

College	PASSED	Year	No. Grad.	Licensed

\*Seventy-one of these candidates received limited licenses, pending completion of their hospital internship.

ELECTRICITY IN MEDICINE: A PRACTICAL EXPOSITION OF THE METHODS AND USE OF ELECTRICITY IN THE TREATMENT OF DISEASES. COMPRISING ELECTROPHYSICS, APPARATUS, ELECTROPHYSIOLOGY AND ELECTROPATHOLOGY, ELECTRODIAGNOSIS AND ELECTROPROGNOSIS, GENERAL ELECTROTHERAPEUTICS AND SPECIAL ELECTROTHERAPEUTICS. By George W. Jacoby, M.D., Consulting Neurologist to the Lenox Hill Hospital and Dr. Ralph Jacoby, A.B., M.D., Chief of Clinic, Neurological Department, Lenox Hill Hospital. Cloth, Price, \$5. Pp. 612, with 200 Illustrations. Philadelphia: P. Blaisdell's Son & Co., 1919.

In presenting the subject of electricity in medicine, the authors have restricted themselves almost entirely to the use of electric currents in all fields of medical practice, exclusive of surgery. Therefore, phototherapy and the roentgen ray are discussed merely in a fundamental way. The subject matter is presented so as to impart knowledge of the fundamental laws, the ability to use instruments in their application and such other prerequisites as the physician may need when using electricity as a remedial agent. The book is divided into six parts: on electrophysics; apparatus required for the therapeutic and diagnostic use of electricity; electrophysiology and electropathology; electrodiagnosis and electroprognosis; general electrotherapeutics, and special electrotherapeutics. In view of the extensive use made of electricity in the diagnosis of disturbed function of the muscles and motor nerves, the section on electrodiagnosis and electroprognosis is of particular interest. The numerous charts and tables add greatly to the value of this section. The authors have not presented anything new; but they have collected information from many sources, and they present it in a concise manner which will appeal to those who are interested in the use of electricity in medicine.

DISEASE OF THE EAR IN SCHOOL CHILDREN. An Essay on the Prevention of Deafness. By James Kerr Love, M.D., F.R.F.P.S.G., Lecturer on Diseases of the Ear, University of Glasgow. Cloth, Price, \$1.75. Pp. 94. New York: William Wood & Co., 1919.

Love discusses the school clinic as carried out in Glasgow, where children with ear trouble are treated. Such clinics save the child and the parent the loss of time necessitated by going to a hospital dispensary for treatment. This is an important economic consideration, as it usually means the loss of half a day to both the children and the parent to receive treatment at the hospital dispensary. Separate chapters are devoted to a discussion of the relation of the most exanthems and hereditary syphilis to ear trouble. The most interesting chapter is the one devoted to hereditary deafness. In this the author applies the principle of the mendelian theory of heredity to hereditary deafness and makes a strong plea for the education of the public on the inevitable result of the propagation of deafness by marriages of people suffering from a hereditary form of deafness. He is dealing only with school children, but his arguments for the elimination of hereditary deafness by marriage control applies as well to the much more common form of hereditary deafness, that which develops, as a rule, in early middle life. We refer to otosclerosis. Love looks forward hopefully to "the passing of deafness," first, by increasing our control of the infectious fevers and of syphilis and, secondly, by the elimination of hereditary deafness by the education of the public concerning hereditary deafness and by rational control of marriage among those inheriting deafness.

LENZMANN'S MANUAL OF EMERGENCY MEDICAL, SURGICAL AND OBSTETRIC THERAPEUTICS, INCLUDING A TREATISE ON THE DISEASES OF THE LARYNX AND THE PHARYNX. By J. LENZMANN, M.D. M.R.C.P. (Ed.). Cloth, Price, 41s. Pp. 345. New York: William Wood & Co., 1919.

It is stated that this book is based on the English edition of Lenzmann's "Mergencies," which appeared in 1914, but that the text has been entirely rewritten and the subject matter revised so extensively that it is practically a new work representative of the teaching of standard British authorities on medical, surgical and obstetric emergencies. Each topic is discussed in its entirety as to the etiology, symptoms, pathology, diagnosis and treatment. The advantages in accordance with accepted practice and only well

known and accepted remedial agents are recommended. Its value would be greater if the subject-matter were more condensed, less discursive and, therefore, more quickly available when an emergency arises.

#### Inability to Take Treatments Contracted for

(*J. W. Samsel, Inc., v. Hans (N. Y., 17 N. Y. Supp. 378)*)

The Supreme Court of New York, Appellate Division, First Department, in reversing a judgment for \$300 and costs rendered in favor of the plaintiff and affirmed by the appellate term, holds that a person who contracts to pay a certain sum for treatments for a specified time, but is physically unable to take the treatments and promptly notifies the other party to that effect, need not pay for the treatments, on the ground of want of consideration for the contract. The court says that the plaintiff was a business corporation organized and created "to establish, maintain and operate an institution in which persons may obtain accommodation for rest, personal exercise, bathing, massage and hygienic treatment." The defendant, being in ill health, was induced to look over the plaintiff's quarters, and finally to remove his clothing. After his heart and lungs had been examined by listening to them, he was arrayed in a rubber coat and given certain athletic exercises, which he was informed were characteristic of the treatment which he would receive if he entered into a contract with the plaintiff. Among other things, he was put through a course of setting-up exercises, as they were called. The medicine ball was tossed, and, lying prone on the floor on his back, he was required to work his neck off the floor. After this treatment was completed, and he was kept up on down with alcohol, he signed what was called an application which stated that he applied for membership in the institution to include three half hours per week for two (two) consecutive weeks, and agreed to pay \$300 on acceptance of this offer. But the day following he was sore and lame, and a serious trouble developed with his neck, which he attributed to the trial treatment; and he at once notified the plaintiff that he would be unable to continue, or to accept the course of treatment mentioned in the application which he had signed. Moreover, he testified that his condition became so serious that it became necessary to call a physician, who, for several days, treated him for his condition and the serious trouble with his neck; that at the close of the trial he had not recovered, and was then under treatment for the difficulty. The proofs showed that he was physically unable to receive the treatment for which he had agreed, and for which he had agreed to pay \$300. In short, he agreed to pay \$300 on consideration that he receive the treatment and instruction contemplated in the written application which he made. The furnishing of such treatment and instruction was the only consideration for his promise to pay. At the time he made the application he was in no position to know that he would be physically unable to take the treatment. When he found out that he was too weak to receive such treatment, he promptly notified the plaintiff that he would be unable to fulfil his contract. Under such circumstances, the plaintiff was relieved from liability to pay the amount of the contract price, and the judgment in favor of the plaintiff should be reversed, and the complaint dismissed, with costs to the defendant in all courts. All of the members of the court concurred in this.

Furthermore, two members of the court think that a contract entered into by the plaintiff claimed right of recovery against the defendant lay in the fact that, under the statute and under the decisions of the New York courts, the plaintiff was, at the time, engaged in the practice of medicine without a license, in violation of Subdivision 7 of Section 160 of the Public Health Law; but the majority, or three members of the court, hold otherwise, being of the opinion that the plaintiff was not engaged in the practice of medicine within the definition and purport of the statute.

\*Specific Treatment of Typhoid. W. R. Stokes and H. W. Maldeis, Baltimore.—p. 625.  
\*What Is Influenza? G. A. Soper, Washington, D. C.—p. 635.  
\*Transposition of Viscera, Tertiary Syphilis. C. G. Lane, Boston.—p. 641.

**Specific Treatment of Typhoid.**—In thirty-one cases of typhoid treated by Stokes and Maldeis with vaccines the dosage used was 10,000,000 bacteria, usually given subcutaneously, at intervals of several days. The number of doses varied between one and six. No practical results were obtained by this small dosage since the average duration of the disease was thirty days, and patients who even received the first dose on the second, third and fourth days showed no tendency toward a decrease in the duration of the disease. The mortality in these cases was five, or 16.1 per cent. The next set of cases treated numbered about sixty. Doses beginning with 50,000,000 bacteria with an increase to 100,000,000 and 250,000,000 at intervals of several days were used. The duration of the disease was shortened in a fair number of cases and not a few showed actual rapid decline of the temperature to normal after several of the doses had been given. The records in this series were lost, hence exact data cannot be given. In the third series, ten patients were treated by intravenous injections of a sensitized typhoid vaccine made from the Rawling's strain. Immune serum was added to the vaccine until the agglutinins had all been saturated by the immune serum. Of these ten patients, six were treated before the tenth day of the disease. The diagnosis was verified by blood cultures and the Widal reaction. Four patients were treated after the tenth day and showed only a positive Widal test, the blood cultures being negative. In five of the six early cases, two injections were given at intervals of about four days and in three of these cases the disease seemed to be aborted. In two other cases the temperature gradually dropped to normal in about eighteen days and remained so. In the other early case only one injection was given, and the case followed the regular typhoid course. Doses of 300,000,000 bacteria were given and the injection was followed by a slight chill and a rise in temperature of from 1 to 1.5 F., and no dangerous symptoms were noted. In the four late cases the Widal was positive but the blood culture was negative and the vaccine did no harm but no apparent-benefit was derived from the treatment.

**What Is Influenza?**—Soper states the weight of evidence of all kinds indicates that the influenza which was pandemic is a highly virulent form of a disease which is commonly with us.

**Transposition of Viscera, Tertiary Syphilis.**—Lane reports a case of complete congenital transposition of viscera, functioning perfectly, associated with tertiary syphilis but no history of previous symptoms.

\*Immunity of Coloradoans to Pulmonary Tuberculosis. H. B. Whitney, Denver.—p. 268.

**Immunity of Coloradoans to Pulmonary Tuberculosis.**—A conviction held by Whitney for many years and expressed emphatically in this paper, that most Coloradoans are practically immune to pulmonary tuberculosis, has been greatly strengthened by his investigation of some statistics. Only a very small percentage of deaths from tuberculosis are said to occur among the native Coloradoans.

- Bacillus Botulinus. G. S. Burke, Palo Alto, Calif.—p. 555.

**Infection by a Fusospirillary Organism.**—Mellon isolated a fusospirillary organism from a case in which it caused generalized infection, involving also the kidney and lung, the point of origin being presumably in the appendix. Its branching filamentous forms relate it closely to the streptothrices, while its bacillary and cocal phases relate it to the lower bacteria. The branching filaments were not cultivated from the renal abscess or the lung puncture, although many of them could be demonstrated from the material in both locations—in fact they constituted the bulk of the flora present in the lung puncture material. They were cultivated from broth blood cultures, however, partly as the result of an irregularity in the preparation of the medium and partly from a radical change in the environmental conditions at a certain stage in the culture's development.

**Occurrence of Bacillus Botulinus in Nature.**—Two hundred and thirty-five cultures were made by Burke from samples collected in five localities in central California, 50 or more miles distant from each other. The cultures covered a wide range of material, including tap water, hay, leaves, vegetables and fruits in various conditions, insects, spiders, sowbugs, snails and caterpillars, garden soil, manure from hogs, hogs, and chickens, and also samples from the claws, beaks, crop, gizzard and intestinal contents of birds. Seven cultures containing *B. botulinus* were found. Burke concludes that *B. botulinus* is widely distributed in nature.

- Tetany in Eunuchoid; Report of Case. H. W. Walman, Rochester, Minn.—p. 433.

**Pathology of Human and Experimental Poliomyelitis.**—Three pathologic types of anterior poliomyelitis are recognized by Howe. (1) cases in which the lesions are limited to infiltration of the pia and blood vessels, the mesodermic tissue type; (2) cases in which the main feature is degeneration of the motor cells in the anterior horn, accompanied by the proliferation of neuroglia, the ectodermic type, and (3)

the mixed type. In the second group the changes in the central nervous system of man are polymorphous. The reaction in the ganglion cells and nuclei makes it possible to recognize not less than eight different forms in the degenerative process consequent to the poliomyelitic infection. The first group presents the more general reaction of the organism to the infection, manifested by changes in the central nervous system and the lymph tissues of the body. In human poliomyelitis the pathologic reaction to the virus is a mixed one.

**Differential Diagnosis of Hyperthyroidism.**—Basal metabolism and alimentary hyperglycemia, with special reference to the differential diagnosis of hyperthyroidism from clinical conditions bearing some resemblance to it, is the subject of McCaskey's paper. Another purpose is to point out the limitations of these laboratory methods, which, however valuable they may be, should always be regarded as subsidiary to the general clinical picture. McCaskey is convinced that the symptoms of hyperthyroidism and hypothyroidism are due to quantitative variations of thyrotoxin in the body cells; that the fundamental phenomenon which dominates the entire clinical picture from cretinism to "Basedowism" is perversion of the metabolic rate; that this metabolic rate has its absolute equivalent, in accordance with fully established physical laws, in the heat production of the entire mass of body cells; that this heat production is essentially a process of oxidation and is equivalent to the quantity of oxygen consumed, the latter being regulated by, and dependent on, the metabolic rate; that it is now possible with the comparatively simple Benedict portable respiration apparatus to determine clinically the oxygen consumption over a sufficient period of time, say ten to fifteen minutes, with sufficient accuracy for all clinical purposes; that if food metabolism is eliminated by twelve to fifteen hours' starvation (the usual normal condition in the morning), and the metabolism of voluntary muscular effort is eliminated by absolute rest in the recumbent position (one half to one hour is sufficient time), there remains only the energy output—the heat production—the metabolism of the circulatory and respiratory mechanism, with small and probably negligible additions for the phenomena of secretion and the intracellular chemical changes of the cells of the body while at rest, which is called basal metabolism. This so-called basal metabolism is very constant, not only in the same individual but in all individuals when calculated in proportion to the area of body surface, varying in health, in a large majority of people, probably less than 10 per cent from the average normal rate. Alimentary hyperglycemia following the ingestion of 100 gm. of glucose is present in probably every case of thyrotoxicosis. It is rarely, if ever present at the end of the first hour in normal persons, although it may have occurred at the end of about thirty minutes. Its presence, therefore in one hour and especially in two hours always indicates abnormal carbohydrate metabolism unless gastro-intestinal function is delayed. It is often latent and, of course, in manifest diabetes, in alcoholism, malignant disease, arthritis and very probably in a considerable number of infectious, acute, subacute or chronic, in the same category with arthritis. While it is true that one can only by a careful carbohydrate test, one which is excluding hyperthyroidism, is very great and probably exceeds 90 per cent. In hyperthyroidism there is no such

stant direct ratio between its intensity and the height of the alimentary hyperglycemia, although, in general, the blood sugar values in severe cases are high. Too much importance should not be attached to alimentary blood sugar values below 140 mg. of sugar in 1,000 c. c. of blood, although sharp lines of demarcation cannot yet be drawn

Cardinal Principles in Cardiology Practice.—Among the cardinal principles in the early examination of chronic affections of the heart Lewis places: 1. The symptoms and signs of cardiac failure. These are subdivided into (a) general; (b) the early evidence of an impaired circulation; (c) the signs of cardiac enlargement and its degree without attempt to differentiate dilatation and hypertrophy. 2. The signs of valvular disease. 3. The presence or absence of fibrillation of the auricles. 4. The presence or absence of evidence of disease if found its etiology is to be taken into considera-

tion. The first three cardinal points are those which command consideration first; the last three assume cardinal importance in cases in which, on the basis of one or more of the first three points disaliding heart disease is already diagnosed.

Causation and Treatment of Rickets. Pritchard maintains that practically all varieties of malnutrition occurring during infancy and early childhood tend to terminate in rickets, provided they are sufficiently severe or long enough continued. They should not, however, be regarded as evidence of rickets unless they are actually accompanied by the typical changes in bone which are characteristic of the disease. The essential and central feature of rickets, Pritchard says, is the want of calcification or mineralization of developing bone, and this, in its turn, is due to the existence of requirements for calcium, which for the time being are more urgent than those of developing bone. These urgent requirements are the necessity for neutralizing acid bodies in the blood; in other words, to neutralize or compensate an existing acidosis. Pritchard argues that all chronic conditions of malnutrition, of whatever kind or from whatsoever cause arising, finally terminate in an acidosis, and all claims on alkaline bases arising in connection with the neutralization of this acidosis must be satisfied before those of developing bone are attended to.

Herpes Zoster of Glossopharyngeal Nerve.—The symptoms presented in Neve's case were: (1) fever and vomiting; (2) facial palsy of peripheral type; (3) an auditory nerve affection; (4) on the mucous surface supplied by the glossopharyngeal nerve an eruption resembling that of herpes zoster; (5) pain felt behind the ear and down the left side of the neck posteriorly.

Gynecomastia in Young Boys.—Ingleby's patients were 7 and 9 years of age, respectively. Only one breast was hypertrophied in each case.

Pathologic Changes in Kidneys due to Intravenous Injection of Alcohol.—Honda found that by infusing alcohol into the vein of the rabbit, an acute inflammation of the malpighian bodies develops. By infusing alcohol continuously from time to time, for a considerably long time, the inflammation gradually assumes a chronic nature and at last turns into atrophy. During such process, a passive increase of the connective tissue is observed to take place. No megalocytes have been demonstrated in the malpighian bodies. By the intravenous injection of alcohol, a large quantity of fatty granules was seen deposited in the epithelial cell layer of the malpighian bodies during the early period, but later they were seen to disappear most probably by transportation. By the intravenous injection of alcohol, the deposition of lipoidal substance in the main duct has not been seen to occur during the earlier stage, but later the fatty degeneration has been observed to take place somewhat remarkably.

**Weil-Felix Reaction in Mild Epidemic of Typhus.**—Napier is of the opinion that the Weil-Felix reaction will still have to be classed as an aid to diagnosis only. From the fact that a positive result in a dilution of 1:50 is given by 8 per cent. of normal refugees, 25 per cent. of patients with fever other than typhus and typhoid and in nearly every case of typhoid fever, it is obviously unsafe to make a positive diagnosis unless a higher titer than this is obtained. It is very exceptional to get any agglutination in a dilution of 1:100, except in cases of typhus and typhoid; so that, if one can exclude the latter, one can with comparative safety regard a case that gives agglutination in this dilution within the first six days of the disease as one of typhus. However, as in the Widal reaction, the most reliable points in diagnosis are the increasing titer in the early and the decreasing titer in the later stages of the disease. Comparing this reaction in the diagnosis of typhus with the Widal in the diagnosis of typhoid, Napier points out that the former has two distinct advantages: (1) a positive reaction can be obtained at an earlier date; and (2) agglutination occurs in much higher dilutions. Of fifty-nine cases, including eight cases which were classified as doubtful, only twelve failed to cause agglutination in a dilution of 1:1,600, and of these only two were adults who were tested at a period of the disease when one would expect to find a high agglutinating power in the blood—that is to say, between the tenth and twentieth days of the disease. None of the fifty-nine probable typhus cases failed to give agglutination in a dilution of 1:640, and of the seventy-seven control and two probable nontyphus cases, classified as doubtful, not one gave agglutination in a dilution of higher than 1:400, and only one in a dilution as high as this. Thus there is a very sharp line of distinction between the positive and negative results. A disadvantage of the reaction is that in an ordinary severe case by the seventh day, the earliest day on which one can guarantee a definite result, the diagnosis, clinically, is usually beyond doubt. This, however, does not apply in the milder form of the disease, where the diagnosis is often in doubt until about the fifteenth day, when the temperature drops suddenly.

**Weil-Felix Typhus Test.**—Of fourteen cases of typhus fever tested by Compton, thirteen showed a well marked Weil-Felix reaction; one case gave such a feeble reaction that it might well have passed unperceived and been returned as negative.

**Specific Reactions of Pfeiffer's Bacillus.**—The results recorded by Fleming and Clemenger show clearly that the various strains of Pfeiffer's bacillus are very different in their agglutination reactions. In most of the cases the agglutinins formed are either quite specific to the particular strain injected, or they are very nearly so, and in every case but one agglutination was observed in a much higher dilution with the homologous strain than with any of the others. The one exception agglutinated one of the heterologous strains to the same titer as the homologous strain, and it agglutinated all the other strains tested to a lesser extent. These results indicate that the *B. influenzae* of Pfeiffer is really an associated group of bacteria without the marked unity in immunity reactions seen in other epidemic causing bacteria such as typhoid and cholera. These facts agree with Park's results and are a strong indication that Pfeiffer's bacillus is not the primary cause of influenza, but that the primary infective agent awakens the activity of organisms which have been leading a more or less saprophytic existence in the respiratory tract.

- \*Special Degenerations Produced in Rabbits Immunized with Pancreatic Ferments. H. Wago, Tokio.—p. 31.

**Special Degenerations Produced in Rabbits Immunized with Pancreatic Ferments.**—A hyaline or an amyloid-like degeneration was produced experimentally by Wago in animals immunized with pancreatin, trypsin and amyllopsin. Therefore, he concludes that the occurrence of these degenerations seems to show a relation between the quantity of the antigen given and the duration of the experiments.

Archives des Maladies de l'App. Digestif, Paris

October, 1919, 10, No. 5

- \*Giant Gastric Ulcer. A. Mathieu and F. Montier. p. 257.  
 Ulcerative Stenoiditis with Death from Ulceration of the External Iliac Artery. A. Chahier and C. Dunet.—p. 280.  
 \*Alimentary Anaphylaxis with Asthma. V. Cordier.—p. 287.

**Giant Gastric Ulcers.**—Montier reports three cases of gastric ulcer and cites a fourth case in all of which ulceration of the lesser curvature covered an area of 6 by 12 cm.; 8 by 14 or 4 by 15 cm. The patients were men of 48 to 56 and they had had stomach disturbances for from five to ten years, with periods of remission of from six months to two years' duration. These periods of silent latency, the absence of vomiting, and the distaste for meat seem to be characteristic of this type. Hemorrhage was responsible for the fatal outcome in two of the cases, the vicious circle after gastroenterostomy in the third.

**Alimentary Anaphylaxis and Asthma.**—In Cordier's case the man developed asthma for the first time at 42, following errors in diet. New attacks were brought on experimentally by ingestion of peptone, and he was cured by antianaphylaxis. The asthma returned later after a series of banquets, the attacks menacingly severe, the dyspnea and distress keeping up all day, but there was no nausea or other digestive disturbance. The following day he refused all food and there was no asthma that night. The next day he ate his usual meals and had frightfully severe asthma that night, with a syncopal condition. The connection between the abundant meals and the asthma was determined by various tests, as also the fact that the albumin was the responsible element. The man was then given two rectal injections daily of 10 gm of peptone, dissolved in milk, with a few drops of laudanum, just before the principal meals. Under these injections he could eat albumin, etc., at will, and for nearly two weeks that this was kept up he was free from asthma. Then, without his knowledge, the peptone was omitted from this injection one day, and that night the asthma returned as severe as ever. The man had thus two ways to ward off asthma, namely, by refraining from animal albumin or by taking the antianaphylactic peptone enemata. The patient finally wearied of these measures, and after repeated errors in diet the antianaphylaxis lost its efficacy. Then autoserotherapy proved successful for a time, 5 c.c. of blood from a vein in the arm being injected subcutaneously. But after a time this also lost its power, and the asthma is now regular, but moderate, every night, even on a meatless diet. Sweats like those of food poisoning are common, as also anguish beyond that from the asthma, and a mild but fetid diarrhoea. The asthma in these cases in time passes into ordinary asthma. It is possible that many cases of ordinary asthma began with the alimentary form.

- \*Biologic Diagnosis of Pregnancy. Paul Bar and G. Lalle. p. 391.  
 \*Welfare Work for Prospective and Nursing Wage-Earning Mothers. H. Krüger. p. 401.

**Biologic Diagnosis of Pregnancy.**—Bar and Écalle review the bases, the workings and the diagnostic significance of the deviation of complement test, the Abdrhalden method, the intradermal reactions, the characteristic changes in the oxytryptic power of the serum, and the activating power of indox venom. Their conclusions are that the clinical benefit from these numerous and difficult researches is very meagre and out of all proportion to the efforts made. None of the tests

give distinct findings until so late in the pregnancy that no test is required. The reaction to intradermal inoculation of placental peptone was vague and uncertain in the 25 pregnant and 14 nonpregnant women tested, but this method of testing with placental extract—analogs to the skin and intradermal tuberculin tests—they think deserves further study. "The results achieved show how rich will be the harvest for those who continue the work only outlined at present. Then we will understand better the mechanism of the rapid adaptation of the maternal organism to the development of the fetus, the symbiosis of mother and fetus, and the anomalies in this symbiosis, and this example of a physiologic nature will throw light on the mechanism of immunity." The report is based on applications of the tests to nearly 400 pregnant women and over 100 nonpregnant. The findings in the 310 women tested by the Alderhalden method confirm the general assumption that a negative response may be regarded as eliminating a developing pregnancy, but a positive response does not certify to a pregnancy, as this may be obtained under certain other conditions. The response was positive in 33 per cent. of over 100 certainly nongravid women.

**Welfare Work for Mothers.**—The aim of Keiffer's address, which was delivered at the recent Congress of Gynecologists at Brussels, is to suggest ways and means to lighten the burden of childbearing for working women.

Mortality and Mortality of Children in French Regions Occupied by the Germans. A. Calmette. p. 198.  
 Association with Acute Appendicitis. Bars. p. 207.  
 Tetanus in France. C. Nour and R. Mercier. p. 216.  
 Heredity of Tuberculosis in Cattle. Moussu. p. 217.

**Tetanus During 1918.**—The statistics cited show that even during the worst offensives, the number of cases of tetanus among the troops never surpassed 0.3 per thousand anywhere, in 1918.

**Bovine Tuberculosis.**—Moussu deplors the practical failure of the means officially adopted to repress the spread of tuberculosis in cattle. In principle they are logical, but in practice they do not answer the purpose, as private interests do not comprehend their import. Better results might be realized if the local breeders would organize and cooperate with the official cattle inspectors to educate and protect the cattle men against loss, and advise them how to improve their stock.

 Total Heterostoma Through the Diaphragm. Kolland. p. 243.  
 Nephritis. Vascular. P. Le Noir. p. 245.

**Acute Appendicitis.**—This is a continuation of the discussion as to whether to operate at once or defer to a quiet interval. All the speakers agreed that acute appendicitis belongs to the surgeon and that he should be summoned at once; not necessarily to operate, but to decide whether and when to operate.

**Syphilitic Vesicorectal Fistula.**—Penneuz calls attention to the absorption of infection of the kidney in his case, although treatment has been passing into the bladder for months. The patient was a man of 69, and the surgeons had advised amputation. Endoscopy showed the ulceration in the bladder and its perforation into the rectum, but the tissues around were normal. There was no history of a chancre, but a tumor increasing the stomach had subsided under specific treatment, and years before and under mercury and iodine the fistula between the bladder and rectum healed up completely and promptly.

**Neuropathic Vomiting.**—Le Noir has found that isolation and psychotherapy are best promoted by keeping the patient constantly in bed and removing everything that could possibly suggest vomiting even handkerchiefs and newspapers, so that if any vomiting is done, it will have to be on the bed-sheet or floor. Restriction to nothing but water the first day also helps. Moist heat is kept permanently on the stomach and fluid food, and very little of that, is given at first.

In case of vomiting of pregnancy, he sometimes succeeded by allowing nothing by the mouth during the day, and giving water by the rectum in the morning, and toward evening an injection of 4.15 gm. each of chloral and potassium bromid. Then a full meal is given, lingering over it until the effect of the sedatives becomes apparent. Then the patient is left quiet in the dark as she drops to sleep. Even if she vomits in the morning, the food by that time has been passed along. With the above measures, isolation need not be so strict, but it must be rigorously enforced with true hysteria.

Case of Multiple Manifestations of Tertiary Syphilis. R. Le Clerc. p. 813.  
 Quinin Prophylaxis of Malaria in Troops. E. Job and L. Hirtzmann. p. 817.  
 Jaundice during Arspenamin Treatment. G. Milian. p. 821.  
 Control of Arspenamin Treatment. Sicard, Haguenau and Kudelski. p. 833.  
 Nephritis of Intestinal Origin. Heitz-Boyer. p. 813.

**Jaundice During Arspenamin Treatment.**—Milian insists that arspenamin has no affinity for the liver, and that the jaundice which may develop under it is referable to the action of the syphilis on the liver. He describes three convincing cases which demonstrate, he says, the nontoxic character of the jaundice, and that pushing the arspenamin is the only means to conquer the jaundice. It is often rebellious to treatment by the usual technic, but may yield promptly to mercury given by the mouth. He declares that all drugs to act on the liver are more effectual when given by the mouth, as the drug goes straight to the liver by this route. In the cases reported, the jaundice disappeared when more and larger doses of the arspenamin were given. He advocates selecting the route as called for by the individual case to reach the points involved; that is, by the vagina, glands, rectum, skin and digestive apparatus, besides the intramuscular, intravenous and arterial routes.

**Control of Arspenamin Treatment.**—Sicard and his co-workers give daily intravenous injections of 0.15 gm. of neo-arsphenamin to a total dose of 6 or 7 gm. in women and of 7 or 9 gm. in men, about forty or sixty injections in all. They keep watch for signs of intoxication by the terminal (not the initial) erythema, the absence of the Achilles tendon reflex, the tardy jaundice, the variations in weight and temperature, and chief of all, by the urea content of the blood. They disagree with Milian in regard to the nonaffinity of the drug for the liver, saying that it damages the liver and the amount of this injury is reflected in the urea content of the blood. Another sign that might be instructive is the presence of blood in the stools, as neo-arsphenamin has an erosive tendency on the duodenal mucosa.

**Nephritis of Intestinal Origin.**—Heitz-Boyer remarks that colon bacillus nephritis has been well studied in children and in the pregnant, but he knows of no comprehensive work on the enterocolic syndrome in adults and the elderly. The suppurating type is the best known. He has had fifty cases of this form; in some the septicaemia, in others the cystitis or pyelonephritis dominated the clinical picture. The clinical aspect may be widely variable, but the lack of any precise etiology, and the rebellious and recurring character of the symptoms are characteristic. But the most important criterion is the recovery when treatment is addressed to the intestines and the urinary apparatus is left unmolested. This was particularly striking in elderly women with pendulous abdomen. Local treatment of the bladder and pelvis gave only transient relief, but treatment of the enteritis cured the whole clinical picture. The cases described confirm the blood-borne origin of the nephritis and that the bladder is infected only secondarily. The intestinal pathologic conditions in these cases

vary within a wide range, from chronic constipation of long standing to quite mild enteritis. The bowel symptoms may be slight and fleeting, as in one case in which pyuria with rebellious cystitis for five years healed soon after the intestinal pathologic condition had been cured. Hydronephrosis, lithiasis and ptosis were excluded and an intestinal origin seemed probable to explain the colon bacilli in the urine. Several consultants were unable to detect any bowel disease, but, from lack of other factors, Heitz-Boyer persuaded the woman to follow a strict intestinal regimen. On this the urinary disturbances promptly retrogressed, and there has been no return during the five years to date. It would be interesting to examine the urine for colon bacilli as a routine measure with enteritis. Latent bacilluria might explain a number of puzzling conditions in the urinary apparatus.

**Atony of the Esophagus.**—The necropsy findings showed nothing to explain the dysphagia. It had become installed after a bicycle accident, and the difficulty in swallowing was so great that during the eight months the man of 60 had lost nearly 60 pounds in weight. There was no pain, but he found it almost impossible to swallow, fluids often escaping through the mouth and nose. Nothing to suggest stenosis, spasm or compression could be discovered during life or after death. The whole trouble seemed to be merely atony of the esophagus, no peristaltic movements of any kind being detected. This pseudo-esophagism or dysphagic atony usually allows fluid to run down into the stomach, the reverse of what is observed with spasm. Solid substances are also liable to pass along, but soft, pasty substances are unable to progress. In the case reported, all the types of food seemed to find equal difficulty in reaching the stomach; there was probably some paralysis of the pharynx which aggravated the disturbances. Roentgenoscopy and exploratory catheterization readily differentiate this type of dysphagia, the contrast suspension forming a narrow, continuous band the length of the esophagus.

**Heliotherapy of Cutaneous Tuberculosis.**—Dufourt has given systematic sun baths in fifty cases of cheesy tuberculids and has been much gratified with the benefit therefrom. He first opens and removes the cheesy matter before applying the heliotherapy, saying that surgical aid is indispensable to render the heliotherapy effectual. The sun will heal the living tissues, but dead tissues have to be got out of the way before it can accomplish its task. With lupus the rays have to be concentrated with a lens adapted to keep out the ultra-violet rays, and the lupus tissues have to be compressed to force out the blood which would otherwise absorb too much of the healing rays. Eight or twelve months or longer have to be devoted to the treatment of lupus, as a rule, but there are exceptions to this. In one case lupus which had destroyed the nostrils and part of the upper lip and extended out on the cheeks, healed completely under five months of fifteen minutes insulation daily. He tries to avoid strong reactions, as they seem to do more harm than good, and he reiterates that heliotherapy can be applied anywhere, even in the big cities. He adds that if a suspicious lesion improves under heliotherapy, this is good testimony to its tuberculous nature. "If it proves refractory, hunt for some other cause." Syphilitic lesions do not heal under heliotherapy; at least that has been his experience.

"La Médecine."—As will be seen by the numbering of the pages, this new magazine aims to give a number of short articles on vital questions of the day, written by men who are contributing most to settling these questions. There are no illustrations, and each of the monthly numbers is to be devoted to some one branch of medicine—surgery this time. A brief summary in English and in Spanish follows each article.

**Pseudarthrosis.**—Dujarier remarks that the pseudarthrosis of peace is usually simple, and the cause is the interposition of some fibrous or muscular tissue. After removal of this, the fragments should be freshened economically, generally by scraping, and then after reduction and coaptation the parts should be held in place with a wire tied around at different points. Where this *cerclage* is not practicable, a plate should be screwed on or the parts held with clips. If the pseudarthrosis is accompanied by loss of substance requiring a graft, it is better to wait until the fistula has healed. But this is not indispensable. He has operated in a suppurating focus with complete success in a number of cases, paying great attention to ample draining. He now has a total record of 140 cases of pseudarthrosis.

**Acute Rebellious Dysentery.**—Cotte advocates appendicostomy early, not merely as a last resort, and expatiates on its advantages for flushing out and disinfecting the lower bowel, preferably with a 1 per thousand solution of silver nitrate, once or twice a day. This brought rapid improvement in his cases, refractory to the ordinary measures.

**Cancer of the Colon.**—The main point in treatment is an early diagnosis, and Okinczye pleads for an exploratory operation when a man or woman over 45 has constipation or it becomes aggravated, with frequent digestive disturbances, and blood in the stools, and these minor symptoms persist. To wait for occlusion is a fatal error. He discusses the technique, advocating colectomy at one sitting with end-to-end suture, reinforced with omentum.

**Cancer of the Rectum.**—Mondor regards irregularity in the stools in a person over 45 as a revealing sign of cancer of the rectum. If the physician heeds it and makes a digital examination of the rectum, it may save him the humiliation of treating the patient for months on the mistaken assumption of dyspepsia, sciatica, hemorrhoids or chronic appendicitis, when an early operation might have cured him of his malignant disease. Digital examination will confirm the diagnosis almost certainly, and reveal the involvement of the retroperitoneal glands. To ensure removal of all diseased tissues, the operation has to be by both the abdominal and the perineal routes.

**Ether in Infections.** Soulioux pours 200 or 250 gm. of ether into the abdominal cavity in case of infection of the peritoneum, after the pus has been evacuated. The ether is then wiped out again aided by its evaporation, until more is left, and the cavity is drained. He uses ether to sponge out other cavities, after appendectomy, gynecologic operations, etc., and ascribes to the ether a number of recoveries in otherwise hopeless cases.

- Radical Treatment of Frontal Sinusitis. P. TERRIER, p. 442.
- Tetanus. G. A. LIEBHARD, p. 453.

**Physiology of the Greater Omentum.**—Ames reviews in turn the four main properties of the greater omentum, its sweating out properties, thanks to its movability; the phagocytic defense it can call into play, and its antitoxic and its plastic roles. He says, "The omentum changes its position with a sort of intelligence, like the chemotaxis of the leukocytes. It is important therefore to refrain as much as possible from resecting the omentum, also in case of peritonitis to promote the bactericidal action and the agglutinating secretion by local heat and sodium nucleinate, or by subcutaneous injection of 2 per cent. nucleic acid (Mikulicz) or by injection into the abdominal cavity of saline. . . ."

Another point to be borne in mind is to refrain from hindering its active movements, and hence one should be chary of morphin. . . . The abundant vascularization makes particularly important all measure to ward off hemorrhage." He advises firm ligatures in series when the omentum has to be incised, and urges utilizing to the full the protecting and plastic properties of the omentum to reconstruct and reinforce passages and cavities. Lanz has even used the omentum to patch the mesentery.

**Trauma of the Chest and Pulmonary Tuberculosis.**—Tecon reports that contusion of the chest was followed by the development of pulmonary tuberculosis in 60 per cent. of his 15 cases. He also found 3 cases with a history of contusion of the chest among 1,033 tuberculous inmates of the Leysin sanatorium. Sörgel and Mantoux found only 9 and 5 per cent. with pulmonary tuberculosis after contusion of the chest, while Tecon's proportion is 42 per cent.; this latter figure shows the decreasing influence of the imprisonment and confinement. He was able to find only 0.38 per cent. with a history of exposure to war gases among the 1,033 tuberculous inmates. He urges that men wounded in the thorax should be kept under surveillance as this may clear up a number of obscure cases. In the 42 cases of trauma of the chest which he has been studying, only 14 developed pulmonary tuberculosis later, and only in 8 is the direct connection with the trauma beyond question. Shell and gas wounds are far less liable to this evolution than penetrating wounds as was mentioned in the summary on page 1398 of the last installment of this article.

**Negative Scrapings with Uterine Cancer.** Gouin reiterates that negative scrapings in uterine cancer should be the guide in the treatment regardless of possibly negative findings with the curet. It rarely happens that the clinical and microscopic findings are in conflict. This is liable, however, when the cancerous growth does not show on the surface. The microscopic examination, however, could strongly suggest malignancy. In one woman 42-43 the scrapings were negative but the curet scrapings had shown a normal stem of placental growth, and a mass when there were generally absent blood clots. A nodule protruded from the cervix, and a small, firm, translucent fluid mass from it. The polypoid mass was removed but the placental mass was retained, although the slight bleeding kept it with fairly good pains in the uterus. Vaginal curetting was finally performed. This disclosed an adenocarcinoma in the wall of the uterus although the

mucosa seemed normal throughout, except for one small patch not quite so smooth as the rest. In a second case a woman of 35 noted that the menstrual discharge was growing progressively more profuse and that there was a pinkish discharge during the intervals. She had borne six children. Not a trace of malignant disease could be detected with the curet, and the presumptive diagnosis was fibrous degeneration of the mucosa. The patient made several trips to health resorts but there was no improvement during the year. Then she expelled two small tumors, one a polyp with a large clot of black blood, including formations resembling chorionic villi. This was accepted as indicating that there had been a pregnancy. But the persistence of pain was too suspicious of malignant disease, and subtotal hysterectomy disclosed a spindle-cell sarcoma. The scrapings in both these cases had never shown anything suggesting malignant disease, the mucosa being practically normal throughout, but the papillomatous polyp in one case and the pseudochorionic tissue expelled in the other warned of possible malignant disease. Both of the women are in good health to date, two years since the operation.

**Dangers of Radical Treatment of Frontal Sinusitis.** Terrier regards frontal sinusitis as a more serious condition than disease in the antrum of Highmore. Fatal complications occur so often that the surgeons' zeal to operate has moderated. But a radical operation is the only means of salvation in many cases. Opening up the sinus may precipitate the evolution of postoperative complications, some latent focus being roused thereby to activity. Phlegmon of the upper lid or brow is the consequence of defective drainage or sepsis. It may reinfect the sinus, and entail meningitis or cerebral abscess. The variability in the size and shape of the sinus is an important factor in the outcome, the large cavities having usually thin walls, and dehiscence is frequent. Recesses and crevices may escape complete disinfection, and pus may collect in them, and sequester form—this is always menacing for the intracranial organs. The ethmoidal cells should also be scrupulously investigated. The symptoms of a new infection may take some time to develop, so the surveillance after an operation should not be abandoned too early. He quotes Boeninghaus' statement that he knows of 26 cases of death after the Killian operation alone; meningitis was responsible for the fatality in 20 of them. Whether the technic or the gravity of the condition is responsible, this high mortality is impressive; the temperature suggests involvement of the meninges even before the operation. An incomplete operation has been the cause of many disasters; the operation itself seems to enhance the virulence of germs that escape disinfection. An abscess in the frontal lobe can generally be regarded as an extension of the sinusitis. If the olfactory zone is involved, the infection spreads by the lymphatics. He describes a personal case in which old pansinusitis in a man of 48 with pyocete in the left frontal sinus had entailed considerable destruction of bone. Death occurred from purulent meningitis the third day after an operation on the pyocete. No opening into the brain from any sinus was discovered.

**Tardy Tetanus.**—The man of 34 had a small erosion on the left wrist from an automobile accident, with contusion of the shoulder and slight contusion of the brain. Antitetanus serum was injected (10 c.c.) and the man returned to work the fourth day. Thirteen days later tetanus developed but the man recovered under serotherapy, a total of 293.5 c.c. of the antiserum in seventeen days. Phenomena of anaphylaxis hampered the treatment materially, but were finally overcome by diluting the antiserum. The 293.5 c.c. of the antiserum thus represented 490 c.c. of fluid. The injections were made subcutaneously except one of 10 c.c. by the vein which was followed by rigors, and the man felt that he was dying.

**Differentiation of Fats by Histochemistry.**—Escher gives a colored plate which shows the color reaction of a large number of different fats to the same stains. Research in this line affords a basis for greater precision in estimating and classifying fats and lipoids. The color reactions are characteristic and specific for different groups of fats. He declares that the varying affinity for stains has not been utilized to the full to date in studying animal and plant tissues. We may yet be able to distinguish different but seemingly identical substances by the optic changes, just as the mineralogist distinguishes them with his optic methods in the mosaic of stone dust.

**The Hard Boiled Egg Test Breakfast.**—In this fourth account of research on lactic acid in the stomach, Rodella emphasizes the instructive findings when the test breakfast consists of a hard boiled egg (without the yolk) and 400 gm. tea. This ensures that the test breakfast is free from bacteria, while it contains a fermentable substance to which the stomach is accustomed, and the amount of penetration of bacteria into this substance allows an estimate of the bacterial action going on in the stomach not only by fermentation but by microscopic examination. He gives the details of ten cases of various gastric pathologic conditions to illustrate the information derived with this test breakfast, not attainable in any other way. The rolls, etc., of the ordinary test meals are liable to contain many bacteria. The Sahli meal does not inform in regard to fermentation processes or allow differentiation of the fermentation bacteria—all of which is possible with the hard boiled egg meal, he says. With this he has ascertained that with nervous dyspepsia free from catarrhal complications the recovered egg white never contains any micro-organisms. The larger numbers and the most species are found with chronic gastric catarrh with much retention, and with incipient cancer. He adds that just as the presence of lactic acid in the stomach has proved sometimes an unreliable guide in respect to gastric cancer, the white-of-egg test breakfast may prove unreliable in certain cases. But on the whole, he reiterates, it seems destined to prove a valuable addition to our diagnostic measures, especially in combination with Uffelmann's ferric chloride reaction.

### Policlinico, Rome

\*Contusion of Pancreatic Cyst. G. Roggi, p. 1033.

\*Meat From Animals with Fontanel Mouth Disease. I. di Pace, p. 1039.

**Hematoma in Pancreas Cyst.**—Ruggi's patient was a girl of 9 who had bumped into the corner of the table; pains in the left gastrocolic region kept recurring, with vomiting. The operation confirmed the assumption of a hematoma in an old retroperitoneal cyst in the pancreas. He fastened the walls of the cyst to the lips of the transverse incision, 15 cm. long, in the abdominal wall, after suturing a tear in the peritoneum. Healing was complete in a little over two months.

**Is Foot-and-Mouth Disease Transmissible to Man?** Di Pace cites evidence from various countries to show that the aphthous fever of cattle can be transmitted to man, but that contagion occurs comparatively rarely. Milk from infected animals is the source of the greatest danger. A trace of fluid from one of the vesicles is enough to contaminate a large amount of milk; one cow with the disease can infect the milk from the whole dairy. But there is no evidence, he says, that the virus invades the muscle tissue, and there need be no fear of harm, he reiterates, in eating the meat provided the animal is slaughtered and eviscerated at once and the meat is well cooked. Unless these two conditions can be fulfilled, the meat should not be used, as toxins resistant to heat may spread to the muscle tissue under other conditions. He quotes Prof. Mazzini to the effect that the soldiers in the Turin district have been fed on meat from cattle with epizootic aphthae, and that he used it in his own family without the slightest disturbance therefrom.

\*Surgery of the Lungs. E. Azevoli, p. 879.

**Influenza.**—Bertolini discusses the literature on the effects of influenza on the circulatory, digestive and urogenital organs.

**Superposed-Hands Palpation of the Abdomen.**—Boeri extols the advantages for palpation of the abdomen when the left hand is used for the palpation, as if it were the palpating instrument, while the right hand, superposed on the other, applies the force. The fingers of the left hand applied flat only have to register the sensations experienced from the palpation, the fingers of the other hand, applied slanting on the lower hand, doing the pushing into the depths for the palpation. The mental work of appreciation of the findings and the muscular work are thus thrown on separate hemispheres of the brain, and greater precision is attained. He compares this with the common observation that persons seated at a lecture or play listen and understand better than those who stand throughout. This *palpazione mediata* is indicated when the abdomen is extra large, or distended, or the walls contracted, or when it is desired to palpate deep-lying organs.

**Cervical Ribs.** Meucci adds another to the thirty-five operative cases of cervical ribs he has found on record. The young woman had noticed for four winters various nervous disturbances in one arm, formication, prickling, weakness, etc., but these disturbances subsided during the warm weather. They returned in a graver form each winter, until the entire arm and shoulder were weak, and any pressure caused pain. No benefit was obtained from tonics, massage and electricity, and palpation finally revealed a cervical rib. It was resected through an incision along the trapezius.

Sept. 3, 1919, 33, No. 30

\*Enterocolitis in the Newly Born. C. de Rezende, p. 297.

**Diagnosis of Leukemia.** Fróes stains the blood specimen with a stain composed of 1 gm. methylene blue in 90 gm. distilled water and 10 gm. alcohol, with 0.5 cc. of hydrochloric acid. The acid destroys the hemoglobin of the erythrocytes while the blue stains the nuclei of the leukocytes. As the leukocytes are in such abnormal numbers, there are so many nuclei to take the stain, that the blood specimen is decidedly blue instead of the greenish brown with normal blood.

**Enterocolitis from Inherited Syphilis.** De Rezende refers to the colitis produced by newly born infants, describing a typical case in which the child screamed with pain after nursing, until it was about 2 months old, when it gradually seemed to throw off this tendency. None of the ordinary measures had been of the slightest avail and the retrospective diagnosis was inherited syphilis. Similar experience, since its fourteen years of practice, have confirmed the fact that whenever a newly born infant, called by its own mother, presents intestinal derangements characterized by frequent stools with greenish mucus with or without blood admixture and tenesmus, unrelieved steadily should be suspected. Usually the diagnosis appears immediately after birth. It is not abundant, not every diaper is soiled. The

## TYPHOID FEVER IN THE AMERICAN ARMY DURING THE WORLD WAR

FREDERICK F. RUSSELL, M.D.

Colonel, M. C., U. S. Army  
WASHINGTON, D. C.

It has now become possible to compile the statistics for typhoid and the paratyphoid fevers for the period of the great war. The figures for the year 1917 were published in the last annual report of the Surgeon-General; and the figures for 1918 will soon be ready for publication. I am permitted to select the compilations presented here from the forthcoming report because of their immediate interest.

In Hawaii, during September, 1917, there was a water-borne epidemic of typhoid of the classic type, giving the first opportunity since the introduction of vaccination into the Army for a comparison of the rates among the vaccinated and unvaccinated. The

TABLE 1.—TYPHOID EPIDEMIC IN HAWAII, H. T., IN THE  
FALL OF 1917

	Population No. of Water of System	No. of Cases per Thousand	Deaths		Mortality Rate per Thousand	
			Num- ber	Per Cent.		
Vaccinated.....	4,087	55	13.45	4	7.4	0.97
Unvaccinated.....	812	45	55.41	7	15.5	8.62

infectious material was traced to a Japanese laborer who had been employed, until he was taken sick, in the construction work on the water supply system.

The salient facts in this water-borne epidemic of the classic type are set forth in Table 1.

The morbidity was four and one-eighth times as high, and the mortality eight and seven-eighths times as high among the unvaccinated as it was among the vaccinated. In addition, there were eleven other cases among unprotected persons who used a different water supply, and from the date of onset of the disease there is reason for believing them to be contact cases. There were no corresponding contact cases among the vaccinated. Between September 23 and January 17, there was a total of 111 cases, fifty-five among the troops and fifty-six among the civilians.

In 1917, there were in the entire army 297 cases of typhoid, thirteen cases of paratyphoid A, and seven cases of paratyphoid B. A large proportion of these cases were in the incubation state of the disease on the patients' entrance into the military service, and the reports received from France show that many of the cases occurring there were among men who had, for

one reason or another, failed to receive the typhoid vaccine.

The ratios in 1917 for the Regular Army, National Guard and National Army were: Regular Army, 0.25 per thousand of strength; National Guard, 0.70, and National Army, 0.27.

The high rate, relatively, among the troops in the National Guard was due to the fact that they were mobilized in their own states and did not come immediately under federal control, and in many cases vaccination and sanitary protection were delayed.

The total rates for the entire army, officers and men, white, colored and native troops, for the past years are shown in Table 2.

TABLE 2.—RATE OF TYPHOID FEVER IN THE ARMY AND IN  
THE CORRESPONDING AGE GROUP IN CIVIL LIFE FOR  
THE PAST EIGHTEEN YEARS

Year	Army		Civil Deaths from Typhoid Fever: Age Group, 20 to 29 Years. Rate per Thousand of Population	
	No. of Cases	Ratio per Thousand Deaths	Ratio per Thousand	Total Males
1890	531	5.75	69	0.46
1900	594	6.43	78	0.42
1902	555	8.58	69	0.40
1903	348	5.82	39	0.33
1904	247	5.62	12	0.33
1905	193	3.57	17	0.30
1906	347	5.66	15	0.32
1907	208	3.53	16	0.19
1908	215	2.94	21	0.28
1909	173	3.03	16	0.23
1910	142	2.32	10	0.27
1911	44	0.83	0	0.23
1912	18	0.31	3	0.18
1913	4	0.04	0	0.18
1914	7	0.07	3	0.15
1915	8	0.08	0	0.18
1916	25	0.23	3	0.12
1917	297	0.41	23	0.11
1918	768	0.30	133	0.09

\* Voluntary vaccination against typhoid.  
\* Compulsory vaccination against typhoid.

The rate for the age group 20 to 29 and the rate for males only, which is calculated for six different years, was obtained through the kindness of Dr. William H. Davis of the Bureau of the Census. It was not possible to obtain such a rate for the entire registration area of the United States, and the table has been prepared, therefore, from data from the original registration states: Connecticut, Indiana, Maine, Massachusetts, Michigan, New Hampshire, New Jersey, New York, Rhode Island, Vermont, and the District of Columbia.

Current statistical reports warrant the belief that in these older, more highly urbanized states, the typhoid rates are notably lower than in the remaining part of the registration area. Any comparison, therefore, with these civil statistics errs on the side of conservatism.

From Table 3 of the paratyphoid fevers in the Army, it is apparent that they have not, in our experience, been of very much importance, and until the outbreak of the world war, it was never considered necessary to impose the discomfort of vaccination on the entire army to protect against so slight a danger.

From a consideration of Table 2, it is evident that during the first year of the war, 1917, the rate in the

TABLE 3. RATES FOR PARATYPHOID

Year	Cases	Ratio	Deaths	Ratio
1911	2	0.03	0	0.00
1912	4	0.05	0	0.00
1913	8	0.07	0	0.00
1914	9	0.10	0	0.00
1915	9	0.09	0	0.00
1916	410	2.38*	4	0.02†
1917	13	0.09	0	0.00
	7	0.01	0	0.00
1918	7	0.03	0	0.00
	11	0.01	0	0.00

Army, including all cases, both among the vaccinated and the unvaccinated, was 0.03 per thousand of strength, as compared with a rate of 0.14 per thousand of population among young men of corresponding age at home under peace conditions. In 1918, the Army rate was higher, 0.05 (0.03 in 1917), owing to the number of cases which developed in France. Yet, including all these cases, the rate was less than half the civil rate for males in the eleven original registration states (0.11 per thousand).

The Army rate for 1918 is made up from data for the troops in the United States, where the rate was 0.03, and for the American Expeditionary Forces, in which the rate was 0.08 per thousand; so it is seen that the rate for our expeditionary forces was considerably less than the civil rate at home. By those who were in France and who know the conditions under which our troops were compelled to live at times, and in view of the almost continuous exposure to large doses of infectious material, coming both from enemy sources and from the native French population of the country side, this low rate of 0.08 per thousand is accepted as evidence of the great protective power of the T. A. B. vaccine.

One more point, however, should be brought out before making final deductions from this table: it is based on an average annual strength of 2,518,499.

TABLE 4.—NUMBER OF PEOPLE FURNISHING A CASE OF TYPHOID FEVER, OR A DEATH FOR EACH PERIOD

Period	Population Furnishing One Case	Population Furnishing One Death
1917	7	71
1918	3,756	25,641
Record for the entire war (1917, civil life)	No record	7,142
Record for the entire war (1918, civil life)	No record	9,990

The length of service of many men, for one reason or another, was short, a few months, or even a few weeks; and the actual number of men in the service during the year was almost twice as large as the average annual strength. On the first day of November, 1918, there were 1,971,000 men in France and 1,663,000 in the United States, a total of 3,634,000 on that day alone. If typhoid were one of the diseases which recurred in the life of man, the annual rate, based on the average strength, would nevertheless be a fair statement; but, of course, typhoid fever rarely, if ever,

occurs twice in the same person; the number of cases depends directly on the number of men in the service, regardless of how long they remained. We know that during the period of the war (April 6, 1917, to Nov. 11, 1918) approximately 4,000,000 men served in the Army; and during the full two years we had a total of 1,065 cases of typhoid fever, or one among every 3,756 men. In the Spanish war there was one case for every seven men (141 per thousand). In 1917 and 1918, the total number of deaths was 156, or one death among 25,641 men. In the Spanish war there was one death among every seventy-one men (14 per thousand).

In the restricted registration area given in Table 2, there was one death for every 7,143 males (20 to 29 years of age) in 1917, and one for every 9,090 of the same age group in 1918. These figures are recorded in Table 4.

The relation of the mortality in the present war to that of previous wars can be shown in another way; that is, by estimating the number of deaths in our army in the world war, according to the rates which prevailed during the Spanish and the Civil wars. The period covered by Table 5 is from Sept. 1, 1917, to May 2, 1919. The two diseases, malaria and dysentery, which have been most often confused with typhoid, are also included for completeness.

TABLE 5.—RELATION OF MORTALITY IN THE WORLD WAR TO THAT OF PREVIOUS WARS

	Number of Deaths That Occurred in Present War, Sept. 1, 1917—May 2, 1919: Average Strength Approximately 2,521,396	Number of Deaths That Would Have Occurred if the Civil War Death Rate had Obtained	Number of Deaths That Would Have Occurred if the Spanish American War Death Rate had Obtained
Typhoid fever...	213	51,133	68,164
Malaria.....	13	13,951*	11,317
Dysentery.....	42	63,898†	6,382†

\* Includes malaria, remittent and congestive fevers.

† Includes dysentery and diarrhea.

## COMMENT

It is evident from these tables, therefore, that anti-typhoid vaccination, carried out as it was by a personnel which had not been carefully trained in its administration, gave a high degree of protection to our forces under the conditions of hurried mobilization and of warfare, and reduced the rate, not only below the rates for previous wars, but also below the rate found in civil life in some of the older states where the entire population is protected by all the sanitary measures of modern life.

**Yellow Fever in New Orleans.**—The first appearance of yellow fever in New Orleans was in 1769. The next appearance of yellow fever in New Orleans was in 1791, and from then on until 1883, scarcely a year passed by that there was not an outbreak of more or less severity, with the exception of the period during the Civil War, at which time the city was practically free from this disease, there being no cases in 1861 and for the next four years, 2, 2, 6 and 1 deaths are recorded, respectively. This freedom of New Orleans from yellow fever was due to the blockade, and proved that yellow fever was not endemic there. But in 1867 there was a severe outbreak with 3,093 deaths; at this time the population was 184,503. There were epidemics again in 1889, 1897, 1898 and 1899. From that date on there has been but one epidemic of yellow fever, the memorable one of 1905.—Augustin, "History of Yellow Fever."

### THREE CASES OF AORTIC ANEURYSM TREATED BY WIRING AND ELECTROLYSIS

HOBART AMORY HARE, M.D.

Professor of Therapeutics and Diagnosis, Jefferson Medical College  
PHILADELPHIA

On a number of occasions in the past I have reported in the pages of THE JOURNAL and in the *Therapeutic Gazette* cases of aortic aneurysm treated by the introduction of gold-platinum wire and electrolysis. The previously reported cases combined with the three herewith presented, make a total of thirty.

#### THE ESSENTIAL POINTS FOR SUCCESS

There are several points essential to the success of this method, and a number of others which, when understood clearly, show why it cannot always succeed:

1. The aneurysm must be sacculated, not fusiform, and if it be of the dissecting sacculated type it is the most favorable for good results. It is not only useless but dangerous for obvious reasons to operate on a fusiform aneurysm.

2. Although it is not at all necessary for the aneurysm to have eroded the chest wall so as to protrude, it must be close enough to the chest wall anteriorly or posteriorly to permit the insulated needle to enter the sac.

3. The wire must be of gold and platinum so that it will coil properly in the sac. A gold-copper wire is useless because the copper is eaten out so rapidly by electrolytic action that the procedure cannot be completed.

Fig. 1 (Case 1).—Aneurysmal growth, 10 inches in width and 8 inches from below upward.

4. Great care must be taken that the skin over the sac is protected from electrolytic action by having the external part of the needle well insulated as well as the shank.

5. Depending on the size of the sac, the amount of wire varies, but it is usually from 15 to 20 feet.

6. The time during which the current is allowed to pass is usually about forty-five minutes, and the current strength must be turned on and off very gradually.

7. If the street current is used, great care must be taken that the proper reducing apparatus is employed, and also that the table on which the patient lies is insulated with rubber pads and that the operator and his assistant wear rubber-soled shoes.

The facts that stand in the way of complete success are that in a large proportion of cases the entire aortic wall is diseased, the area operated on being chiefly in

Fig. 2 (Case 1).—The crosses show the points at which the wiring was introduced into the aneurysm.

trouble. Solidifying the contents of the sac is well so far as it goes, but other parts of the aortic wall give way later. In many cases the entire arterial system is diseased, and the only patient I have seen who did not get relief from pain before the operation was finished died suddenly sometime later and the necropsy revealed a second sacculated aneurysm just above the diaphragm which had ruptured.

#### THE PROGNOSIS

The prognosis, therefore, depends largely on the general state of the vessels. If this is good and the aneurysm seems to have resulted chiefly from injury, the prognosis is better than if the general vascular state is bad. Syphilis is manifestly an active factor.

When the growth is very large, and particularly if its pressure has already begun to cause pulmonary edema or pleural effusion, the procedure is, of course, a forlorn hope.

The value of the procedure lies in the following facts:

1. The extraordinary decrease in pain, which, as already stated, usually takes place soon after the current begins to pass. Whether this easement of pain is due to decrease in the tension in the sac with its associated diminution of pressure on adjacent tissues or whether it is due in whole or in part to a sedative effect of the current, I am unable to state; but I am inclined to the former view. This relief from pain, which has previously required large amounts of morphin, justifies the operation even if life is not greatly prolonged.

2. Arrest of the progress of the growth, at least in the direction in which it threatens to rupture. I have reported a number of cases in patients in whom blood

was actually oozing through the discolored skin when treated, but who lived for months.

#### REPORT OF CASES

CASE 1.—J. K., aged 40, was first seen because of pain in the chest, April 12, 1915, when a diagnosis of aortic

Fig. 1 (Case 1).—A mass of fine coiled wire found at necropsy in the remaining portion of an enormously dilated aortic arch.

aneurysm was made by his physician, Dr. Koder, who reported that by Aug. 24, 1915, it bulged distinctly, and pain and dyspnea were fairly constant. When examined roentgenologically, Dec. 29, 1915, a very large aneurysm

having occurred to the left, a second operation was performed, 16 feet of wire being used to avoid the tendency to rupture and in order to relieve pain caused by the new source of pressure. Two days after this second operation, the patient volunteered to tell the students in the amphitheater that he had slept seven hours the night before and suffered no discomfort except a "coughing spell."

This man died, Feb. 16, 1916, from pulmonary edema, and necropsy revealed an enormously dilated aortic arch in the ascending portion in which a mass of fine coiled wire was found surrounded by blood clot. Evidently the wire used at one of the operations coiled not in the sac as intended; but it did no harm. This dilated part of the aorta communicated directly with a large tumor-like sac in which another mass of blood clot was found about the second coil of wire. This is shown in Figure 3.

Life was prolonged in Case 1, but the chief gain was in the relief of pain.

CASE 2.—In S. K., aged 42, a bottle blower, a very large aneurysm of the descending arch pointing anterolaterally (Fig. 4) measured 14 inches from below upward and 12 inches transversely. The illustration does not show quite

Fig. 5 (Case 3).—An aneurysm of the ascending arch about 2 1/4 inches in diameter, sharply defined and sacculated.

Fig. 6 (Case 2).—A large aneurysm of the descending arch pointing anterolaterally and measured 14 inches from below upward and 12 inches transversely.

involving the entire arch, but pointing anteriorly, as shown in Figures 1 and 2, was found. Jan. 17, 1916, I introduced 8 feet of wire the largest amount I had on hand, and passed the current for thirty minutes, the maximum being 35 milliamperes. Great pain was completely relieved in one hour. The tortuosity of the abdominal veins due to pressure is well seen. Twelve days later, an extension of the bulging

the true elevation. The subcutaneous tissues of the entire side from the axilla to the pelvis were purple from extravasated fluid.

The operation was performed, July 25, 1918; 18 feet of wire were introduced, and the current was passed for one hour and eleven minutes, the strongest being 40 milliamperes continued for eleven minutes. This patient had some evidence of pulmonary edema before the operation, but it cleared up afterward. The purple color of the side already described changed in a few days to a light yellow, showing that the extravasation had ceased. Twenty-four hours after the operation, the pulse returned to the left wrist. The patient was, however, very difficult to control; he continually got out of bed and walked into the corridor. He died, Aug. 26, 1918, from internal rupture of the aneurysm, one month and one day after operation.

CASE 3.—F. W., aged 50, an iron worker, referred to me by my colleague, Dr. McCrae, eight months previously began to have pain in the right side of the chest, just outside the sternum. A month later he noticed a slight lump. He complained on admission of moderate thoracic pain increased by effort. His general condition was good, and he had no

cough nor tracheal tug. A roentgenographic examination of his chest disclosed an aneurysm of the ascending arch about 2½ to 3 inches in diameter, rather sharply defined and sacculated. The descending arch was slightly dilated.

June 4, 1919, I introduced 20 feet of wire and passed the current for forty minutes, the greatest strength being 46

Fig. 6 (Case 3).—Appearance of the mass fifty-four days after operation.

milliamperes. This patient was also relieved of pain very promptly. Figure 5 shows the site and size of the growth one week after operation, the broken area being clotted blood and collodion. It was difficult to keep him in bed. He persisted in getting up and going to the toilet. Nevertheless, pulsation steadily diminished and the growth decreased in size, so that by the expiration of fifty-four days, July 28, the mass was as small as seen in Figure 6. Two days before this last photograph was taken a man in the same ward became maniacal, and, leaping out of bed at 10:30 p. m., ran to the end of the ward, where he seized the nurse by the throat. My patient leaped out of bed shouting for assistance, ran to the man and threw him to the floor, and all this without any apparent detriment to his aneurysm. At the time of writing this report, ten weeks after operation, the man is urging that he be allowed to go back to work, and only a very faint impulse can be felt in the spot involved.

COMMENT

The best result so far achieved in my series of cases has been in the case of a man who lived in comfort for three years, although threatened with pulmonary edema when operated on. He did not die from his aneurysm but was killed by a freight train that backed down on him as he was walking along the tracks.

1801 Spruce Street.

**Is Your Community Fit?**—Have you a safe water supply? How do you know that it is safe? You cannot know unless you have bacteriologic tests made frequently and regularly. Typhoid fever, diarrhea, dysentery, and other water-borne diseases may be expected unless your water supply is kept safe. Do you permit a large proportion of your citizens to use water from wells which may be polluted? If your town is small and not provided with waterworks it is possible that insanitary privies and unsafe methods of disposal of human excreta are polluting your wells.—*Pub. Health Rep.*, April 25, 1919.

TRUE PROSTATIC CALCULI

REPORT OF TWO CASES

E. P. MERRITT, M.D.

Associate in Genito-Urinary Surgery, Emory University (Atlanta Medical College); Cystoscopist, Grady (City) Hospital; Urologist, Georgia Baptist Hospital

ATLANTA, GA.

The two cases given herewith present true prostatic stones. The etiology of this type of stone, according to Young and Thompson<sup>1</sup> corpora amylacea, is as follows: The stones, having attained the size of their enclosing follicles, act as foreign bodies, and in consequence of the general law that all mucoid membranes, when sufficiently irritated, throw out a deposit of calcium phosphate and carbonate, ultimately form calculi. The amount of earthy matter varies from 45 per cent. in the concretion to 85 per cent. in the calculus. The number of stones is large as a rule, although one of my patients had only one, buried deep in the gland.

REPORT OF CASES

**Case 1.**—*History.*—A white man, unmarried, aged 25, whom I saw, April 21, 1919, reported a family history of no importance, and a good past history except that he had had a severe case of typhoid fever in 1910 which had necessitated his being in bed for two months, after which he was weak for some time. He denied venereal disease. His present trouble, burning sensation while voiding which increased at termination, had begun four months before. Blood was present in the urine at intervals. Strenuous exercise caused much discomfort and increased uneasiness in the perineal and pelvic regions. Nocturnal emissions occurred every few weeks, followed by severe pains and frequent urination. The patient had taken all forms of modern treatment for verumontanitis and prostatitis with no relief. He feared sexual intercourse on account of distressing pains afterward.

*Examination.*—The patient was in fairly good physical condition, but had a "hang-over" look on his face. The physical examination was negative. The urine contained a few pus cells, the specific gravity was 1.010, it was amber, and the reaction was alkaline. There were no casts, no sugar and no albumin. The genitals were normal. The prostate by

Fig. 1 (Case 1).—A very definite stone formation. The stone was not quite so large as the shadow, but was surrounded by hard fibrous tissue which cast some of the shadow. This illustration shows how plainly a prostatic stone may be demonstrated in some cases.

the rectum was very tender and slightly enlarged and so sensitive that it was impossible to express fluid.

Cysto-urethroscopic and cystoscopic examination revealed a normal anterior urethra, a very red and tight posterior

<sup>1</sup> Cabot, *Hughes Modern Urology*. Philadelphia, Lea & Febiger, 1914: 773, 1918.

urethra and a somewhat enlarged and inflamed verumontanum. The trigon showed marked redness; the bladder was normal otherwise.

*Diagnosis.*—Stone in the prostate was thought of, as the treatment for the troubles mentioned was of no avail. A roentgenogram revealed a small shadow in the median line of the prostatic region.

*Operation and Result.*—I advised an operation, which was performed immediately. A small stone was removed from the median lobe which was found to be encapsulated with fibrous tissue.

I received a letter from the patient, August 15, in which he said, "Entirely relieved, feel better than I have for years; am not nervous and do not get up to urinate at night as before."

*Case 2 (first).*—A white man, aged 44, married, with five children, whom I saw, March 1, 1919, reported a family history of no importance. He had always been healthy, although he had had gonorrhoea twenty years before which had lasted for several months, giving him considerable

albumin in abundance, and much pus. The specific gravity was 1.015. The urine was alkaline.

Cysto-urethroscopic and cystoscopic examination revealed the anterior urethra and the prostatic urethra tight, and the latter highly inflamed. The structures seemed normal in size; the trigon was exceedingly red and the prostate was enlarged. Roentgenoscopy of the urinary tract proved negative except for a shadow in the median line of the prostatic region.

*Diagnosis.*—The condition was diagnosed prostatic calculi, and operation was advised. The patient gave immediate consent. Eighteen small stones were removed. There has been complete recovery to date as far as I know.

#### CONCLUSIONS

We overlook prostatic stones when we should not.

Like cancer, they appear in a majority of cases after thirty years, although this should not be misleading.

The symptoms vary and are misleading, especially if the patient has had gonorrhoea previously.

A more thorough examination of this class of patients is indicated, and they should have more thought than they usually obtain, especially when the ordinary methods of therapeutics do not relieve.

I cannot agree with Hubeny<sup>2</sup> when he says that every case may be definitely established by means of the roentgen ray.

The percentage of failures has not been recorded, so far as I have noticed. There must be some, but a high percentage is no doubt demonstrated by the roentgen ray.

The method of removal after diagnosis depends on several pathologic presentations. No fixed or set rule for every case is advisable.

It is fairly well established that venereal diseases are not absolute predisposing factors.

The symptoms are well worth studying.

Fig. 1. Case 1. A case in which eighteen stones were removed from the prostate. A cystoscope with large depressor was inserted into the urethra, and the stones were found in the median lobe. By this procedure a large amount of pus was removed. The stones may be found, as well as the fibrous tissue, in the vesiculae.

troubles. There were no visible complications. He had thought he was well until ten years before. His present troubles had begun with frequent urination, burning, etc. These symptoms became gradually worse and increased in severity until he had was the only place of comfort at times. For the last year, he suffered so much that work was almost impossible. At no time did he see blood in the urine. The pain became almost constant in the perineal and pelvic regions. At times there was great distress in the rectum, especially when the patient was constipated and at defecation. Sexual intercourse was almost impossible on account of the pain that followed. The patient was very nervous.

*Examination.*—The patient looked emaciated and distressed. The physical examination was of no importance otherwise. The genitals were normal; the prostate was very tender to the least pressure and was somewhat enlarged and baggy. Secretion showed much pus and low grade infection. No stone could be felt. In the urine there were phosphates,

## CHORIO-EPITHELIOMA OF THE TESTIS

WITH REPORT OF A CASE

HARRY JACKSON, S.B., M.D.

Attending Surgeon, Cook County Hospital; Associate in Surgery,  
Northwestern University Medical School

CHICAGO

Much of the mystery and confusion that surrounds the subject of mixed tumors of the testis has been cleared up in recent years by the work of Schlegelhauser and Pick abroad, and of Ewing in this country. These men have shown that practically all of the so-called mixed tumors of the testis are teratomas having tissues composed of the three primary germinal layers, the ectoderm being represented by cysts lined with flat epithelium, the endoderm by cysts lined with columnar or ciliated epithelium, and the mesoderm by connective tissue, cartilage, bone, and muscle. These primary tissues may form organs and blood vessels in a more or less orderly imitation of a fetus. Very often one type of tissue grows more rapidly than the others, and overshadows or even suppresses them, so that the presence of only one tissue is not absolute proof against its teratomatous origin. Should the tumor undergo a malignant change, as sometimes happens, more than one type of germ layer may be represented, giving the picture of a carcinoma in one part of the tumor, a sarcoma in another part, and an endothelioma in still

2. Hubeny, M. J.: Prostatic Calculi from the Roentgen Ray Diagnostic Standpoint, *Am. J. Roentgenol.* 6: 286 (June) 1919.

a third portion, whence the term "mixed tumor." Usually one type of the tissue predominates, however, and first produces metastases. In some tumors, the imitation of a fetus is further exemplified by the finding of chorionic villi either in the form of benign hydatid mole or the malignant chorio-epithelioma. The tumor herewith reported is that of a simple teratoma occurring after an operation for hernia, and showing a gradual growth for two or three years. It then grew much more rapidly, and in two months had attained three times its previous size. At its upper pole a separate mass had formed, which, on microscopic examination, proved to be a pure chorio-epithelioma. The metastases in the lungs and liver were those of chorio-epithelioma.

HISTORICAL DATA

Marchand's dictum that chorio-epithelioma is a tumor occurring only in the female no longer holds. Schlagenhauser<sup>1</sup> was the first to point this out in 1902, when he noted in one of his cases of mixed tumor of the testis that the malignant portion was the exact counterpart of chorio-epithelioma in the female. He then examined the material in the Vienna collection and found five cases, each of undoubted hydatid mole and chorio-epithelioma, among the mixed tumors of the testis. Since his unique report, Warthin, Emanuel, von Hanseemann, Debenardi, Albrecht, Ewing and others have reported similar cases. Cooke<sup>2</sup> collected forty-six instances from the literature in 1915, and added a forty-seventh. Woglom,<sup>3</sup> in 1917, collected reports of sixty-five cases, and added two of his own, showing that the condition is not so uncommon and is being diagnosed with greater frequency.

Before 1902, these tumors were reported under a variety of names. Malassez, as early as 1878, accurately described one, and reported it as a "sarcome angioplastique." Others reported it as lymph endothelioma, embryoma, alveolar carcinoma, teratoma, sarcomatous carcinoma, cystoma, adenoma, etc. Recently, Hartman and Peyron<sup>4</sup> reported thirteen placentomas and fourteen choriomas from their material. Hartman differentiates these by the fact that choriomas are composed of primitive cells of the chorio-ectoderm which in proliferating retain their embryonic character. The placentomas, which he believes have received too little attention, show cell types of adult placenta.

ETIOLOGY

There has been much speculation as to the etiology of teratoma, both in the female and in the male. One of the earliest theories is that of Virchow, who believed that cells could undergo metaplasia. As our knowledge increases, there is less and less belief in the idea that cells may change their morphology in the sense that Virchow taught. St. Hilaire believed that these tumors grew from fetal inclusions. Waldeyer taught that certain cells of the testis could develop parthenogenically.

Marchand and Bonnet considered the possibility of development of a polar body. The same authors also taught that in the early cleavage of the ovum a blastomere became isolated and later developed into a more or less imperfect embryo. These early blastomeres, arising as they do from the first few divisions of the fertilized ovum, are totipotent and are thus capable of producing all of the tissues of the body. Later divisions are only multipotent; they can reproduce many tissues, but not all. Cohnheim's theory of their development from remnants of the wolffian body or Müller's duct has been put forward by Carazoni, recently. Perhaps the most popular theory today is that these teratomas develop from sex cells whose normal development in the male into spermatogonia has been suppressed but whose potencies remain intact, ready to express themselves in the various forms of simple or complex teratomas.<sup>5</sup>

Fig. 1.—Chorio-epithelioma of testis: syncytial cells encroaching on the blood sinuses in the center and to the right; Langhans cells toward the periphery at the left;  $\times 225$

PATHOLOGY

The teratoma of the testis presents a variable gross appearance:

In the simplest forms there may be seen two or more types of tissue, usually masses of cartilage, and glandular tissue, held together by a stroma of embryonic connective tissue that is lymphoid in character. The more complex contain a number of different kinds of tissues and approach the structure of an embryo more closely. They are very often cystic, the cysts being lined by flat, cylindrical or ciliated epithelium. Others more solid may contain portions of organs, such as heart, lung, kidney or thyroid, but show no orderly arrangement of parts. The latter are more commonly intratesticular.

5. Ewing: Teratoma Testis and Its Derivatives, Surg., Gynec. & Obst., 12: 235, 1911.

1. Schlagenhauser: Wien. klin. Wchnschr., 1902, Nos. 22 and 23.  
2. Cook: Bull. Johns Hopkins Hospital 10: 215, 1915.  
3. Woglom: St. Lukes Hospital M. & S. Rep., New York 4: 148, 1917.  
4. Hartman and Peyron: Bull. de l'Acad. de med., June, 1919.

Teratomas are usually well circumscribed and have their origin either within the testis or from one pole. They may grow slowly for several years and then suddenly assume a much more rapid growth, become malignant, and produce metastases. This change to malignancy affects more than one type of cell coincidentally, and the metastases may have the build of a teratoma or of only one type of cell. Chorio-epitheli-

Fig. 2.—Teratoma of testis: dark portion above chorio-epithelioma; about two-fifths actual size.

oma has not been reported as occurring in boys below the age of puberty or in the aged. In two cases the breasts hypertrophied and secreted colostrum. Metastases from the carcinomas occur in the regional glands of the groin and in the retroperitoneal lymph glands along the femorals and aorta. Metastases from sarcomas and chorio-epitheliomas occur early in the lungs by way of the venous channels. They can be readily demonstrated by the roentgen ray.

#### DIAGNOSIS

It has been recently shown that more than 80 per cent of the solid benign tumors of the testis are teratomas. The cystic forms must be differentiated from hydrocele with thickened walls. With symptoms referable to the lungs and loss of weight and anemia, and possibly hemoptysis, the diagnosis of tuberculosis will be made quite commonly. The stereoscopic roentgen ray of the lungs will show, in the case of metastases from the testis, that the lungs are riddled with multiple, rounded, well defined shadows of varying diameters.

#### PROGNOSIS AND TREATMENT

Teratomas are usually well encapsulated, and early removal of all tumors of the testis will usually be complete and show no recurrence. With early regional metastases and their removal, especial care being taken in the case of carcinoma to look for metastases retroperitoneally, the prognosis as to recurrence is fair. With metastases in the case of chorio-epithelioma or sarcoma, when they occur in the lungs or liver, the prognosis is hopeless.

#### REPORT OF CASE

*Onset and Course.*—C. B., a livestock dealer, single, aged 23, of American birth, noticed, about three years before I

saw him, a small, hard nodule near the upper pole of the right testis. The nodule gradually grew larger till it attained the size of a hen's egg. It was painless, and never was reducible. About three months before, the mass suddenly began to grow much more rapidly and reached the size of a grapefruit. It was tender to the touch and there was some dragging pain. There had been a loss of weight of 5 pounds within the past month, and the patient had noticed shortness of breath and slight hemoptysis within the past week. An operation for inguinal hernia had been performed on the right side about four years previously. His habits were negative. His father died of abscess of the ears; a brother died of a malignant tumor of the rectum; the mother and a sister were living and well.

*Physical Examination.*—The patient was pale and undernourished. The mouth showed carious teeth and the tonsils were large and scarred. Respiration was rapid and shallow, but there were no large areas of dullness in the chest. There were many moist râles over both lungs. The heart was negative; the liver and spleen were not palpable, and there was no tenderness or swelling or fluid in the abdomen.

There was a solid mass in the right side of the scrotum the size of a grapefruit which was separable into two parts. The lower part, which was well within the scrotum, was hard and painless, and was much the larger; the upper portion was softer and was tender, and was a little larger than a hen's egg. It was connected to the lower portion by a thickened band, and lay in the lower portion of the inguinal canal. The inguinal glands on the right were palpable. The examination of the rectum, extremities and nervous system was negative.

Fluoroscopic examination revealed multiple bilateral, rounded shadow densities that were not indicative of pulmonary tuberculosis. The findings were typical of sarcoma of the lung.

The blood Wassermann test was negative.

*Operation and Result.*—The tumor was removed under general anesthesia, as it was well encapsulated within the tunica albuginea. The complete removal was easy, and the wound healed by primary union. The neoplasm had completely obliterated the testis and epididymis. The respirations became more rapid and labored in the course of the next

Fig. 3.—Chorio-epithelioma of testis—metastases in lung.

three weeks, and death occurred with symptoms of edema of the lungs.

*Postmortem Examination.*—Request for partial necropsy was granted. The lungs were in a state of marked edema, and about forty hemorrhagic, friable nodules varying in size from a hazelnut to an English walnut were found scattered throughout both lungs. One similar nodule was found on the anterior surface of the liver. The rest of the abdominal organs showed no changes. The retroperitoneal glands were not palpable.

Examination of the primary tumor revealed a firm, globular mass with an enlargement at its upper pole, the diameters of the entire tumor being 11 by 6 by 10 cm. The larger portion that lay in the scrotum was about the size of an orange, being smooth and well encapsulated by the tunica albuginea, which was somewhat thickened. The consistency was firm, and on section it cut with considerable resistance in some portions, which on close inspection proved to be due to the presence of cartilage. The tumor on cross section was grayish in some portions, and light yellowish in others. The central portion appeared softened and necrotic. Scattered over the surface were numerous small cysts about the size of a pea. Near the periphery of the section at the lower and external parts were two separate areas of cartilage each measuring 2 by 3 cm. in diameter. The upper portion of the neoplasm, which seemed to arise from the upper border of the main tumor, presented an entirely different appearance. This mass was much softer in consistency, the color on cross section showing areas that were light and dark red, resembling recent and old blood clots. It was quite friable and showed a network of grayish trabeculae. The metastases from the lung were soft nodules that were quite friable, and red. On cut section these nodules resembled quite closely the appearance of the upper portion of the original tumor. Microscopically, sections taken from various areas of the main tumor mass disclosed areas of cartilage intermixed with areas of connective tissue and cysts lined by flat and cylindrical cells. The cysts were numerous and many of them microscopic in size. The connective tissue was lymphoid in character. In one area there were large spindle-shaped cells, with little or no stroma, which was quite suggestive of the structure of a large spindle-cell sarcoma. In other areas the tissue was myxomatous, and in the central portions it was undergoing necrosis. There were numerous blood vessels throughout the section. Sections taken from the smaller, hemorrhagic mass revealed blood cells, some fairly well preserved, others in various stages of degeneration. There were many bands of fibrin of varying thickness interlacing the areas of blood cells. Toward the periphery there were bands of fibrous tissue, infiltrated with round cells, on which lay a tissue that was quite characteristic of the chorio-epithelioma as seen in the female. Surrounding the numerous wide blood spaces of this region were cells composed of nuclei that varied in shape and size, some of them clustered together simulating giant cells. These nuclei stained darkly and were surrounded by a vacuolated cytoplasm but no definite cell wall. They encroached on the walls of the blood spaces, and in some instances were found within blood spaces. Beneath this syncytial tissue were cells that had smaller nuclei, surrounded by a vacuolated cytoplasm and a definite cell wall, in papillary arrangement, which resembled the layer of Langhans. Sections taken from the metastases in the lungs betrayed a similar picture to the foregoing, except that the hemorrhagic areas were smaller and the syncytial areas proportionately larger.

SUMMARY AND CONCLUSIONS

1. More than 80 per cent. of the solid benign tumors of the testis in the light of recent investigation have been shown to be teratomas. The finding of two or more types of tissue in a tumor of the testis, whether benign or malignant, speaks for a teratoma.
2. In the malignant forms, distant as well as local metastases should be looked for, and to this end a roentgenogram of the lungs is essential.
3. The finding of a tumor mass in a teratoma, which on cut section resembles old or fresh blood clot, is pathognomonic of chorio-epithelioma.
4. One should be on one's guard in cases of tumor in the scrotum, with hemoptysis and loss of weight, against making a diagnosis of tuberculosis without taking into consideration the possibility of metastases from a chorio-epithelioma.

DRAINAGE OF THE ABDOMINAL WALL  
IN ACUTE APPENDICITIS

DANIEL N. EISENDRATH, A.B., M.D.  
CHICAGO

Every surgeon is familiar with the fact that a more or less extensive infection between the layers of the

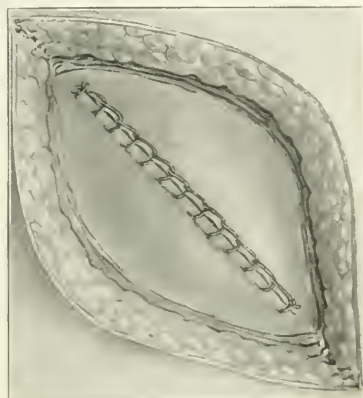

Fig. 1.—Peritoneal incision closed with chromic catgut.

abdominal wall frequently complicates an operation for the removal of the acutely inflamed appendix. One

Fig. 2.—Soft rubber drain (A) inserted between edges of separated internal oblique fibers, to drain subserous layer.

would, of course, expect suppuration in cases of appendical abscess or of spreading peritonitis; but

1. I have employed the term "spreading" peritonitis because so far as the operator can determine there is no walling off of the pus. My object in the term "general" because one cannot be sure that the pus is in all parts of the peritoneal cavity.

that it may occur even when there is no visible sign of a spread of the infection beyond the walls of the appendix is not generally appreciated. Not infrequently one sees extensive infection of the abdominal

Fig. 3.—A, as described in Figure 2. B, soft rubber drain inserted into subcutaneous layer. C, silkworm-gut drain inserted in peritoneum.

wall in cases in which a gangrenous or very acutely inflamed appendix had been removed without drainage of either the peritoneal cavity or of the abdominal wall. The former will take care of the infection, as a rule, in such cases; but the muscular, aponeurotic and fatty tissues of the abdominal wall possess a far lower degree of resistance, and within the first week, or at times a little later, one is often surprised to find evidences of more or less extensive infection of the tissues in the vicinity of the incision. This late suppuration is always a source of disappointment to the patient, and often greatly prolongs the period of convalescence. In order to anticipate such an infection, I have adopted drainage of each layer of the abdominal wall as a routine procedure in the following classes of cases: (a) acute gangrenous and acute catarrhal cases without visible perforation or pus formation; (b) acute cases with abscess formation, and (c) acute cases with a more or less generalized (spreading) peritonitis.

The McBurney muscle splitting incision is amply large enough to enable one to remove the appendix in the majority of cases. In exceptional instances, the anterior rectus sheath is incised transversely and the rectus muscle pulled inward as suggested by Weir, in order to have a larger exposure. The chief advantages of the muscle splitting incision are (a) that it is less likely to be followed by hernia than is the case with a right rectus or pararectal incision, and (b) that it enables one to drain every layer of the abdominal wall far better than any other incision.

In the first class of cases, namely, acute gangrenous and acute catarrhal cases without visible perforation, the peritoneum is closed without drainage (Fig. 1). A

piece of Penrose soft rubber wicking is then placed down to the peritoneum between the edges of the internal oblique (Fig. 2). Sutures are now inserted on each side of this drain to approximate the fibers of the internal oblique. A similar piece of soft rubber drain or Penrose wicking is inserted (parallel to the long axis of the incision) between the internal oblique muscle and the external oblique aponeurosis (Figs. 3 and 5). The cut edges of the latter structure are approximated up to the points of emergence of the drain. Finally, a drain (made by twisting some strands of silkworm) is also inserted parallel to the long axis of the wound in the subcutaneous fatty layer (Figs. 3, 4 and 5). The appearance of the skin incision is shown in Figure 4, with the three drains emerging, respectively, at the center and at the extremities of the incision.

In cases in which an abscess has been found, the peritoneum is not closed, but a cigaret drain is inserted to the bottom of the abscess cavity. If the abscess is in the true pelvis, I prefer to close the peritoneum of the original incision and only drain the abdominal wall as in Class A. Before closing the peritoneum, however, a suprapubic stab wound is made and a cigaret drain inserted into the true pelvis according to the method of Van Buren Knott. In this connection, emphasis cannot be too strongly laid on the value of the Fowler position in the drainage of foci of suppuration on each side of the colon so as to prevent the extension of infection to the subphrenic space.

In the fourth class of cases, that is, when there is a spreading, more or less diffuse peritoneal infection, the procedure is quite similar to that just described. The peritoneum at the site of the original incision is closed without drainage, but each layer of the abdominal wall

Fig. 4.—Skin incision closed, showing drains for various layers emerging, respectively, through center and ends of original incision (compare with Figs. 1, 2, 3 and 5).

is drained by the method outlined (Figs. 1 to 5 inclusive). Only the true pelvis is drained by a cigaret drain made by inserting some strips of pulled gauze into one of the larger sizes of soft rubber (Penrose wicking) drains. This cigaret drain is removed after

forty-eight hours, and an empty soft drain reinserted and gradually shortened.<sup>2</sup>

Drainage of the abdominal wall by my method of individual layer drains does not interfere with the healing of the wound, and it shortens the period of convalescence. The drains are not pulled out until the skin sutures are removed—about the eighth to the tenth

Fig. 5.—Sectional view with drains placed in various layers of abdominal wall. A, B and C as in preceding illustrations.

day. If infection has taken place through the unavoidable contact of the acutely inflamed appendix or some pus with the abdominal wall, there is no opportunity for burrowing to take place in the subserous, intermuscular or subcutaneous spaces. The pus finds a pathway toward the surface, and secondary drainage

of the abdominal wall becomes unnecessary. I can warmly recommend the adoption of this method as a routine procedure.

30 North Michigan Avenue.

<sup>2</sup> The technic employed by the author in cases of spreading (generalized) peritonitis will be fully described in a paper to be published shortly.

**Infant Mortality.**—Indisputable statistics demonstrate an infant mortality rate of at least thirteen deaths under 1 year of age for every hundred living births, the world round, and the existence of appalling causative conditions of such a nature as urgently to call for . . . remedial work on the part of all thinking men and women in this country. The same conditions which cause the death of thirteen out of every hundred babies born throughout the civilized world leave more or less permanent stamps on perhaps two or three times as many more babies who somehow manage to crawl over the infant dead line, many of whom will be the fathers and mothers of the next generation. The problem of infant mortality is far more than one of decreasing the number of infant deaths. Its scope is world-wide, and on its partial solution at least depends the welfare of posterity.—E. B. Phelps.

## THE PREVENTION OF SIMPLE GOITER IN MAN\*

### THIRD PAPER

O. P. KIMBALL, M.D., J. M. ROGOFF, M.D.

AND  
DAVID MARINE, M.D.  
CLEVELAND

This report is based on the reexamination of the girls in the public schools of Akron, Ohio, in grades from the fifth to the twelfth, inclusive, made from Nov. 26 to Dec. 3, 1918—nineteen months after beginning the prophylactic use of iodine. The first report<sup>1</sup>—a survey

TABLE 1.—ANALYSIS OF THE RECORDS OF NEW PUPILS

of the incidence of thyroid enlargements (goiter)—was based on the examination made in April, 1917. The second report<sup>2</sup> gave the results of the examination in November, 1917—seven months after beginning the prophylactic use of iodine.

The same classification of the condition of the thyroid has been used as in previous examinations, namely: normal, slight, moderate and marked enlargements, adenomas and persistent thyroglossal tracts.<sup>3</sup> The pupils were further examined for gross manifestations of exophthalmic goiter and myxedema. No obvious case of either of these diseases was detected.

### ANALYSIS OF THE RECORDS OF NEW PUPILS

The results of these examinations are given in Table 1.

For comparison and reference, the figures of the original survey in April, 1917, and of the second exam-

\* From the H. K. Cushing Laboratory of Experimental Medicine, Western Reserve University.

<sup>1</sup> Allied by a Grant from the Committee on Therapeutic Research of the Council on Pharmacy and Chemistry of the American Medical Association.

<sup>2</sup> Kimball, O. P., and Marine, David: Prevention of Goiter in Man, *Second Paper*, *Arch. Int. Med.* **22**: 41-44 (July) 1917.

<sup>3</sup> Persistence of the thyroglossal tract is the best evidence of enlargement of the thyroid during fetal life.

ination in November, 1917, are added. The subjects included in this table are all new admissions to the public schools and presumably had not previously received iodine. Owing, however, to the very extensive use of iodine in some form, both by the public and the profession, it is probable that some of these pupils had had iodine for one reason or another, but no attempt was made to detect such cases. Iodine administered in any form markedly affects the thyroid.

The figures in the first line represent the results of the original survey of all girls in grades from the fifth to the twelfth, inclusive. The figures in the second line represent: (1) incoming fifth grade girls; (2) girls entering other grades of the public schools between April and November, 1917, and (3) girls of two schools that accidentally lost the records of those not taking the prophylactic treatment. The figures in the third line represent only girls in the incoming fifth grade and girls entering other grades.

The progressive increase in the percentage of normal thyroids (43.6, 47 and 55.4 per cent.) for the three periods is due to the preponderance of fifth grade girls in the second and third groups. Fifth grade girls average 10 years of age and are for the most part below the age of the greatly increased incidence of thyroid enlargement.

#### EFFECT OF PROPHYLACTIC TREATMENT

The same method as outlined in the first paper and modified in the second paper was used, i. e., 2 gm. of sodium iodide were given in 0.2 gm. doses for ten consecutive school days, repeated each autumn and spring. The results are given in Tables 2 and 3. For reference and comparison, the figures for the November, 1917, examination are added.

The most striking fact brought out is that not a pupil in whom the thyroid was normal at the November, 1917, examination, and who took iodine, showed any thyroid enlargement; while of those not taking iodine, 15.9 per cent. showed definite enlargement. This effect is similar to that noted in last year's examination. As was noted last year, a distinct therapeutic effect is again observed in that the glands of 38.1 per cent. of the pupils with slightly enlarged glands decreased following the use of iodine, while of the glands of those listed as not taking iodine 27.8 per cent. showed a decrease in size. This difference is much less than that found last year and suggests that many pupils with slight goiter were taking iodine privately. The same therapeutic effect is also noted in those with moderate and marked enlargements, and again the percentage differences between those taking and those listed as not taking iodine is less than last year's figures.

The main effects of the administration of iodine observed during the second year are similar to those noted during the first year. The danger of iodism or of exophthalmic goiter from the use of such amounts of iodine as were given is shown to be negligible.

#### SUMMARY

1. Simple goiter in man may be prevented on a large scale.
2. The method used is practical and economical, and can be recommended as a public health measure in goiter districts.
3. Two gm. of sodium iodide given twice yearly, as we have indicated, seems adequate.

## TREATMENT OF EMPYEMA\*

RALPH F. HARLOE, M.D.  
BROOKLYN

During the past two years many new methods of surgical procedure for the relief of the ever increasing number of cases of empyema following influenza and

Fig. 1.—Trocar and cannula for insertion of rubber tubing between ribs.

pneumonia have been brought before the medical profession, and each paper written has been read with keen interest looking toward the ideal operation to limit the duration and the morbidity of this disease.

The surgical staff of the Long Island College Hospital determined that the empyema problem should be carefully studied in as broad a manner as possible. All patients with empyema entering the hospital were assigned to the service in the Carrel-Dakin wards.

#### THREE METHODS OF TREATMENT

*The Rockefeller Base Hospital Method.*—Our procedure from October, 1917, to January, 1919, was the

Owing to lack of space, this article is abbreviated in THE JOURNAL by the omission of the report of cases. The complete article appears in the reprints, a copy of which may be obtained on application to the author.

wired tubes after the manner of the treatment used at the Rockefeller Base Hospital in New York. These irrigations were continued until smears taken every second day showed only one bacterium in five fields, after which the tubes were removed and the wounds closed. We had varying success with this method with

Fig. 3.—Tube and chest pad in place.

adults. Of sixteen patients, two died; the wounds in the other cases, with the exception of one, were completely closed at the time of the patients' discharge. The time required for closure varied from twenty-eight days to eighteen weeks. With small children, intercostal drainage and irrigation were resorted to. Of five cases between the age of 1 and 5 years, there were three deaths and two recoveries. In these three babies, a complicating pneumonia on the opposite side occurred. There is no doubt in my mind that continued contact of the body with the wet dressing, especially in the winter months, was a contributory factor in these secondary pneumonias.

**The Mazingo Method.**—A No. 1 Dakin tube was inserted into the seventh or eighth intercostal space by means of a trocar and cannula, a safety pin was passed through the edge of the tube, and small squares of gauze were placed on each side of the pin. The gauze was strapped to the skin with adhesive plaster. The pus was then aspirated with a urethral syringe followed by irrigation with Dakin's solution every two hours, after which a clamp was placed over the end of the tube. This method of aspiration and irrigation was shortly abandoned because of constant leakage of pus around the tube, four or five days after operation, due to the contraction of skin away from the tube. The three patients on whom we used this method were later resected and treated by open drainage and irrigation.

**The Phillips Method.**—In January, 1919, Lieutenant Phillips applied his negative pressure apparatus on a patient with empyema in one of our clinics. When observed four days later with the roentgen ray, the thorax still appeared to be half filled with pus, and although the negative pressure was constantly maintained and the cannula kept clean by means of the

attached curet the pus ceased to flow into the bottle. After another four day interval, a roentgenogram again was taken which disclosed the same condition as before.<sup>1</sup> It was at this time that the apparatus began to leak slightly from beneath the rubber cap; so it was removed, and the patient was treated by the method that I shall describe later. I did not use the Phillips method on any other patient as I had thus summed up its disadvantages: First, the pressure of the metal cannula between the ribs was extremely painful when the patient moved about so as to bring the outer portion of the apparatus in contact with the bed. Secondly, the cannula did not permit the passage of large masses of fibrin even after several days. Thirdly, there could be no assurance that the pleural cavity was free from infectious organisms at the time the apparatus was removed. The cost, which was high, would have been of secondary importance if the method had been ideal.

THE AUTHOR'S METHOD

After having observed the advantage of lung expansion as brought out by Phillips' negative pressure apparatus, I felt that a combination of both the Mazingo and the Phillips method would produce a technic which, while maintaining a negative pressure, would permit irrigation with Dakin's solution.

First, after a roentgenogram of the patient has been taken to determine the location of the pus in the thoracic cavity, the skin over the affected side of the thorax is prepared with 3.5 per cent. tincture of iodine. After two or three minutes, the iodine is washed off with 95 per cent. alcohol and the area for the insertion of the trocar is anesthetized with 0.5 per cent. solution of procaine. The area usually selected is the seventh or eighth interspace in the midaxillary line. The pres-

Fig. 4.—General view of one corner of ward showing boxes at heads of beds and special carriage with pump connected to the bottle.

ence of pus and the thickness of the thoracic wall is now determined by means of a 30 c.c. Luer syringe and aspirating needle, after which a small incision is made through the skin at this point to permit ready

1. The supposed area of pus which persisted in this case was found to be a large mass of fibrin which was shown by frequent roentgen ray examinations to be gradually dissolving under the influence of Dakin's solution used in connection with our own method.

passage of the trocar and cannula. The trocar and cannula are inserted slowly to the previously measured distance; then the trocar is withdrawn and the thumb of the left hand is placed quickly over the cannula to prevent the outflow of pus or rush of air. We are now ready for the passage of the rubber tube through

A small box hanging from the middle cross-bar at the head of the bed contains a 5-liter bottle fitted with a two-hole rubber stopper through which pass two snugly fitting glass tubes bent at right angles. The tubes pass into the bottle just as far as the shoulder, one being an inch shorter than the other. The short tube is connected with a 3-inch piece of thick walled rubber tubing containing a hard rubber stopcock, which in turn is connected with the tube from an electric vacuum pump. The longer glass tube is connected with about 3 feet of the same rubber tubing, which runs alongside the pillow and is joined through a hard rubber stopcock to a hard rubber Y tube, the stem of which connects with the tube leading from the patient's chest. The third arm of the Y tube connects with a third similar stopcock and a piece of rubber tubing running to a bottle of Dakin's solution on a board above the patient's head.

Fig. 5. Apparatus applied to patient in children's surgical ward, showing entire process.

the cannula into the pleural cavity. A stiff-walled rubber tube about 14 inches in length and conforming in outside diameter to a No. 18 French catheter is selected. Three small side openings are cut about three-sixteenths inch from the end. This is called the inner end of the tube, and it is the one which is placed inside the thorax. To insert the tube, the outer end is closed with an artery clamp, and the inner end placed in position so that, as the thumb over the cannula is removed, the tube may be passed quickly into the thorax. A distance of 5 inches is sufficient. The cannula is slowly removed, and when just free of the skin, a clamp is applied behind it, the outer clamp removed, and the cannula slid off. A 30 c.c. Luer syringe is then attached to the tube, and a small quantity of pus (about 10 c.c.) is aspirated to insure absence of kinks.

After the tube has been properly placed, it is necessary to maintain it in this position and also to prevent the passage of air into the thorax between the tube and tissue. To accomplish this, a specially designed rubber cap is fastened to the skin by means of Zamboni's glue. After the cement has been applied to the skin and inner surface of the rubber cap, the thorax tube is pulled through the cylinder of the support by means of a clamp and the whole pressed tightly on the body.

When the cap is stuck firmly, it is further supported in place by three 2-inch strips of adhesive plaster pressed tightly against it and passed around the chest. A bandage covering the adhesive plaster will prevent its edges and corners from rolling up. The patient is then ready for aspiration of the pus.

A gage, graduated in millimeters of mercury, is attached to the pump. If the pump is started at about 40 mm. negative pressure and the stopcocks are turned in the proper direction, the pus will begin to flow freely into the bottle. When the pus ceases flowing, the stopcock in the tube leading to the bottle containing the pus is closed, while the stopcock in the tube from the Dakin bottle is opened and about 50 c.c. of Dakin's solution are permitted to run into the pleural cavity. This stopcock is then closed, the one leading to the bottle is opened, and the Dakin's solution passes from the pleural cavity into the bottle. This aspiration and irrigation is continued until the returning fluid from the pleural cavity is clear. The procedure is repeated every two hours during the day, and every four hours during the night. After a few days,

Fig. 6 (Case 8).—Pleural cavity before, and four days following, insertion of tube.

when the flow of pus has nearly ceased, the Dakin's irrigations are given only at 8 a. m., 2 p. m. and 8 p. m. At each of these periods, 15 c.c. of glycerin, containing 2 per cent. formaldehyd (children, 10 c.c.), are injected and all stopcocks closed and kept closed until the time arrives for the next irrigation.

When patients are able to be up and about, the chest tube may be clamped and disconnected, and the clamp

2. The clamps on the tube must be properly alternated so that no air is permitted to pass into the thorax while the cap is being adjusted.

pinned to the dressing so that it will not drag on the tube.

Dressings should be reapplied at least once in two weeks or oftener if they show any signs of leaking. Care should be taken that the chest tube is not removed and that it is safely clamped.

Since January, fourteen cases have been treated by this method. Two children are still under treatment.

COMMENT

It would have been gratifying had I been able to carry out this method of treatment on a larger number of patients before reporting the results obtained, but the ease with which the operation is borne and the absence of all discomfort following the application of this method prompts me to report it at this time. Among other advantages of this method, I might add: There is no collapse of the lungs, and therefore no loss of function. This is of great importance, especially in an associated pneumonia of the opposite side. There is no deformity of the chest or spinal curvature as generally follows a radical rib resection. There are no wet dressings to be changed, as all pus and washings are out of sight in the bottle behind the head of the bed. Most of all, there can be no pocketing with the lungs drawn down, filling the chest cavity; if we have no pocketing, it is safe to assume that we shall have less, if not entire absence of, chronic empyema. Besides this, we obtain chemical sterilization of the pleural cavity under a constantly maintained negative pressure.

EFFECTS OF HOOKWORM DISEASE ON MENTAL DEVELOPMENT OF NORTH QUEENSLAND SCHOOLCHILDREN \*

J. H. WAITE, M.D.

State Director, International Health Board

AND

I. L. NEILSON

School Nurse, Queensland State Department of Public Instruction

CAIRNS, QUEENSLAND, AUSTRALIA

During 1918, the state of Queensland, Australia, the Australian Institute of Tropical Medicine, and the International Health Board conducted jointly a hookworm survey in the northern portion of the state of Queensland, and through stool microscopy found 21 per cent. of the total population to be infected. The parasite was harbored by two fifths of the schoolchildren, a great many of whom showed physical dwarfing and sexual retardation.

In order to learn whether mental impairment might be due to hookworm disease, this investigation aimed to measure the mentality of a large number of children, and then to compare the results of the infected group with those of the noninfected group. The measures of intelligence employed were Goddard's 1911 Revision of the Binet-Simon scale,<sup>1</sup> and the Porteus mazes,<sup>2</sup> both of which were applied and scored according to

the standard methods prescribed, excepting only the use of Australian copper and silver currency, and the substitution of Goddard's alternative problem sentences for the 10, 11 and 12 year groups.

The selection of 340 children for mental testing was made by one of us (Waite) purely on the basis of

composite list, which was placed in the hands of the test-worker (Miss Neilson), who applied and scored all tests without any knowledge of the results of stool examinations. In the Porteus mazes and the several Binet tests, time records were taken with a stop watch.

Figure showing Binet test results for three groups: Hookworm free, in lightly infected, and heavily infected cases, according to the Porteus and Binet test scales.

Before the final scoring was made, the chronological age of each child obtained from the school records was checked for accuracy wherever possible with the child's birth certificate. After scoring was completed, the names were separated into three groups, as shown in Appendixes A, B and C.

A comparison of the group data so obtained clearly demonstrates that hookworm disease slows down the mental processes, and that it impairs the mentality.

1. *Mental Sluggishness.*—In Tables 3 and 4, the total success times are registered for Binet test VIII, 2, and for the Porteus mazes. To count backward success-

Fig. 4.—Mental retardation in years by age groups in hookworm-free, in lightly infected and in heavily infected cases, according to the Binet-Simon scale.

fully from 20 to 1 required two seconds longer, on the average, for the "heavily infected" group than for the hookworm-free group. Likewise in the successful solution of the Porteus mazes, the "heavily infected"

TABLE 5.—GROUP RESULTS

group uniformly required more time than the hookworm-free children.

2. *Impaired Mentality.*—The summary of the non-infected, the "lightly infected," and the "heavily infected" group results given in Table 5 reflects the data shown in detail in Appendixes A, B and C.

The Australian hookworm-free children give Binet results comparable with American findings; 78 per cent. of Goddard's series<sup>4</sup> tested "at age" or within one year thereof, while 76 per cent. of our noninfected series fall within these limits. The significant fact demonstrated by the present study is that considerable mental disability can be directly ascribed to hookworm infection. By the Binet scale, all combined causes of mental impairment other than hookworm infection produce an average case retardation of 3.9 months, while light hookworm infection gives an average case retardation of 9.3 months, and heavy infection of 23.4

<sup>4</sup> Goddard, H. H.: Two Thousand Children Measured by the Binet Simon Scale of Intelligence, *Ped. Sem.* 18: 232-259 (June) 1911.

months. The Porteus mazes give similar results at a somewhat higher scoring level, which is probably due to the method of scoring.<sup>5</sup>

Further light on the impairment from hookworm disease is gained by the comparison of the yearly age groups in the three classes of children, as shown in Table 6.

Assuming that hookworm infection and reinfection is of long-standing duration, the results here shown indicate that the disease produces cumulative mental retardation to the extent of 6.6 months at 8 years of age, 19 months at 11 years, and 25.0 months at 14 years of age, over and above ordinary retardation found in noninfected cases. A similar observation has been reported by Strong<sup>6</sup> in his North Carolina study.

In this connection, Stiles has shown in hookworm-infected children a cumulative impairment of memory,<sup>7</sup> and a failure to advance at normal rates through the grades.<sup>8</sup>

COMPLEMENT FIXATION TEST FOR  
TUBERCULOSIS

J. STUART PRITCHARD, M.D.  
AND  
C. E. RODERICK, M.D.  
BATTLE CREEK, MICH.

In this series, 466 cases were studied. The final diagnosis was: pulmonary tuberculosis, including suspects, 220; extrapulmonary tuberculosis, 13; nontuberculous, 233.

METHODS EMPLOYED

All patients were first given a general examination by the internist who referred them to us for intensive study of the lungs on account of pulmonary physical findings, the past history, or present suggestive symptoms.

SUMMARY

1. Hookworm disease in North Queensland children produces measurable mental sluggishness.
2. Hookworm disease in North Queensland children retards their mental development in proportion to the massiveness of the infestation.
3. Prolonged hookworm infection appears to produce cumulative mental retardation.

**Treatment of Large Furuncles and Carbuncles.** Kurtzahn advises to loosen up back into sound tissue each of the four flaps of the crucial incision and pack loosely with medicated gauze. This insures much better drainage, while the hollow basin left heals over faster than the deep crater of the usual crucial incision. His communication on the subject, with illustrations, appeared in the *Deutscher medizinische Wochenschrift*, April 10, 1919, p. 409.

The clinical chest study by Pritchard consisted of a careful history, a physical and fluoroscopic examination with an interpretation of stereoscopic plates of the chest, and three sputum tests as well as a three days' pulse and temperature observation.

The serologic study by Roderick consisted of a Wassermann study with both cholesterolin and acetone antigens, and a complement fixation test with two anti-gens for tuberculosis.

The work was finished separately and charted. The physical findings were recorded before the roentgenographic interpretations were made. In no case did the laboratory have any information regarding the patient. We estimated the complement fixation in terms of +, ++, +++ and ++++, but considered all cases below +++ as negative; therefore, in our report, all positives represent +++ or ++++.

FINDINGS

The majority of patients examined consulted the internist on account of other affections, and, with few exceptions, pulmonary tuberculosis was not suspected.

Most of the patients complained of digestive disturbances or disorders of the nervous systems. This accounts for the large percentage of nontuberculous cases found in the series.

*Complement Fixation with Tubercle Bacilli Antigen.*—Of 220 tuberculous patients (pulmonary), 123, or 55.9 per cent., gave a reaction. Of thirteen tuberculous patients (extrapulmonary), seven, or 53.9 per cent., gave a reaction. Of 233 cases not recognized as tuberculous, thirty-eight, or 16.3 per cent., gave a reaction. It appears from these figures that the pulmonary and extrapulmonary cases gave about the same percentage. The nontuberculous patients were not robust; all complained of ill health, so that the 16.3 per cent. positive reactions were not found in healthy individuals.

*Stage of Disease (Pulmonary), 220 Cases.*—The classification of the National Tuberculosis Association was used in all the cases studied. Sixty incipient cases gave a reaction in twenty-six, or 43.3 per cent. Sixty-five moderately advanced cases gave a reaction in forty-four, or 67.6 per cent. Thirty-six advanced cases gave a reaction in twenty-seven, or 75 per cent. Fifty-four suspected cases gave a reaction in twenty-six, or 44 per cent. In the fifty-nine suspected cases we did not find enough evidence to justify a positive diagnosis, but we believe that a pulmonary tuberculous lesion was present in each case. We found it difficult to distinguish many of these from incipient cases. The classification of such cases always differs considerably, depending not only on the knowledge and skill of the examiners, but also on their standards. We strove to be conservative.

*Relation of Reaction to Activity (220 Cases).*—One hundred and sixteen cases, or 52.8 per cent., were diagnosed as active. Forty-five cases, or 20.4 per cent., were regarded as inactive. Fifty-nine cases, or 26.9 per cent., were considered suspicious.

*Relation of Reaction to Activity in Different Stages of Disease.*—Forty-two active incipient cases reacted in twenty-one instances, or 50 per cent. Forty-five active, moderately advanced cases reacted in thirty-four instances, or 75 per cent. Twenty-nine active, advanced cases reacted in twenty-four instances, or 83 per cent. We recognize the chance of error in attempting to distinguish between activity and inactivity. Our object was to find out whether we could demonstrate that specific toxins were being absorbed from the pulmonary lesion. In many instances it was found difficult to do this. Such cases we called suspicious. Certain cases in which there were nervous irritability, digestive disturbances, with malnutrition, physical signs, and crossing temperature curves, were classed as active, even if the temperature and pulse were normal. We were doubtful in such cases that sufficient absorption was taking place to account for the patient's indisposition.

*Reaction in Relation to a Previous History of Hemoptysis (Extrapulmonary Cases).*—Among 220 patients, thirty-two gave a history of hemoptysis, and representative of 27 per cent. of the reacted. We considered members of hemoptysis in all cases in which we were sure that the blood reported came from the lower respiratory tract. A few cases of streaked sputum were included.

*Reaction in Relation to a Previous History of Pleurisy (Pleurothoracic Cases).*—Of 220 patients, seventy-two gave a history of pleurisy and forty-two, or 58.3 per cent., of these reacted.

*Reaction in Relation to Previous History of Rectal Abscess.*—There were eight patients with a history of fistula in ano dating from the time of the examination to a period as far back as fourteen years previous; five of these gave a reaction.

*Reaction in Relation to History of Exposure.*—Of 220 patients, sixty gave a history of exposure, and thirty-five, or 58 per cent., reacted. In this test we considered only such patients as gave a history of a father, mother, sister, brother, wife or husband who had had tuberculosis and with whom the patient had lived for some time.

*Comparison of the Complement Reaction with Tuberculin Tests.*—1. The intracutaneous test consisted of 0.05 mg. in 0.05 c.c. dilution. Of forty tests, twenty-two were positive to tuberculin, while five gave positive complement fixation reactions. Of the eighteen that were negative to tuberculin, two gave a positive complement fixation reaction.

2. Calmette, 0.5 per cent. O. T., Vaughan's<sup>1</sup> method: Of twenty-three routine tests, twelve were positive to tuberculin, and three gave a positive complement fixation. Of the eleven that were negative to tuberculin, two were positive to a complement fixation.

Total . . . . .	39	194	233

*Nontuberculous Cases.*—Of 233 cases, thirty-eight, or 16.3 per cent., gave a reaction. In the fifteen cases of asthma, five reacted. It is possible that a tubercu-

1. Vaughan V. C., Jr.: Importance of the Tuberculin Reaction in the Diagnosis of Early Pulmonary Tuberculosis, J. A. M. A. 61:1591 Nov. 10, 1913.

lous process was veiled by the signs of chronic bronchitis, but we could not demonstrate its existence. Out of the twenty-four cases of chronic bronchitis, five reacted, and as in the cases of asthma, a tuberculous process might have existed without being detected. In the cardiac cases, distant roentgenograms and electrocardiographic tracings were made. The cases of cholecystitis were proved by operation. All three cases of malaria gave a strong positive reaction, and in each case the plasmodia were isolated. Tuberculosis may also have existed without our detecting it. In the four cases of malignancy, two were positive to the complement fixation test. We can offer no explanation of this, although all cases were proved to be malignant by operation and by study of removed tissue. In ninety-five cases we could detect no evidence of organic disease of any kind, and eleven of these reacted. Small tuberculous foci may have been present and not observed regardless of our investigation.

**Wassermann Reaction.**—A routine Wassermann test was made on all patients. In 233 tuberculous cases, four, or 1.7 per cent., were positive. In 233 nontuberculous cases, seven, or 3 per cent., reacted. In 456 cases studied, eleven, or 2.3 per cent., were positive.

LABORATORY TECHNIC

The serums in this series of cases were examined by the following technic:

With few exceptions, the blood was collected before breakfast, which is an important factor in securing satisfactory serum. The collecting of a specimen after a meal will often give "fatty serum." This, in turn, may bring about unreliable results, especially when a bacterial emulsion antigen is used.

Fresh serum was used in nearly all the tests on which our findings were based. In a few instances, the specimens were placed in the ice box over night. A certain number of samples were preserved for a period of from one to seven days, and the test was repeated every twenty-four hours. This was done in the hope of causing more accurate and clean-cut reactions. We found, however, some serums negative on the first day which later became positive; but most of them were anticomplementary after the third day, and consequently gave unreliable results.

**Antigen.** The antigen used in this series was the bacterial emulsion of Miller, some of it obtained from a manufacturer of biologic products and some made in our own laboratory. The two antigens gave practically the same results.

Since the conclusion of this series, we have been using, in addition to our own, three antigens furnished us by Petroff. It is our intention to report on these in the near future. These antigens are all extracts rather than emulsions of the tubercle bacilli. The extract antigens show a higher titer and less tendency to be anticomplementary.

**Complement.** Anesthetized guinea-pigs were bled from the heart. The same pigs could be used again in the course of three weeks for complement purposes. The serums of three guinea-pigs were pooled and used in all cases within the first sixteen hours.

An interesting observation was recently made when all tubes in the Complement Titration 2 showed inhibition. The various reagents were investigated and the complement found to be at fault, although there was complete hemolysis in Titration 1, in which no antigen was used. Another group of pigs was bled and the

serums were used for a complement fixation on the first three pigs, none of which gave a strong positive reaction. This experience led us to make a routine complement fixation test on our pigs, classifying them, according to their reactions, into positive and negative groups. At present we are attempting to ascertain whether a guinea-pig giving a positive reaction, when used for complement, will have any effect on the reaction of a patient's serum.

**Amboceptor.**—Rabbit antisheep amboceptor, made and titrated in the usual way, was used throughout.

**Sheep Cells.**—The sheep's blood was obtained from the jugular vein and collected into 1 per cent. sodium citrate solution made up in physiologic sodium chlorid

TABLE 3.—PRELIMINARY AMBOCEPTOR TITRATION

Complement	0.05	0.1	0.15	0.2	0.25	0.3
Amboceptor	0.2	0.2	0.2	0.2	0.2	0.2
Complement	0.05	0.1	0.15	0.2	0.25	0.3
Amboceptor	0.15	0.15	0.15	0.15	0.15	0.15
Complement	0.05	0.1	0.15	0.2	0.25	0.3
Amboceptor	0.1	0.1	0.1	0.1	0.1	0.1

solution. The cells were then washed in salt solution from five to seven times at 3,000 revolutions per minute, or until the supernatant solution was free from albumin by the heat and acetic acid test. A 2.5 per cent. suspension of washed sheep cells was made and used.

**Salt Solution.**—We use a 0.85 per cent. salt solution and agree with Petroff that the reaction of this reagent is of vital importance and should be that of the blood.

**Glassware.**—All glassware used must be dry, and free from chemicals. Although it need not necessarily be sterile, it is preferable to have it so.

**Technic.**—On each day of the test the reagents are titrated for their respective values. A convenient and satisfactory manner of determining the strength of the amboceptor and the complement at the same time is to use guinea-pig serum in a 10 per cent. solution and dilute the amboceptor so that one unit is contained in 0.1 c.c. (Table 3).

TABLE 4.—TITRATION OF COMPLEMENT

Complement	0.05	0.1	0.15	0.2	0.25	0.3
Salt solution	0.1	0.1	0.1	0.1	0.1	0.1
Complement	0.05	0.1	0.15	0.2	0.25	0.3
Antigen	0.1	0.1	0.1	0.1	0.1	0.1
Complement	0.05	0.1	0.15	0.2	0.25	0.3
Antigen 1	0.1	0.1	0.1	0.1	0.1	0.1

Sheep cells, 0.5 c.c. of a 2.5 per cent. suspension, were added to each tube and incubated in the water bath at 37° C. The smallest amount which produced complete hemolysis was read and noted.

Bacterial antigens, such as we have used in this series, have a marked tendency to retard hemolysis. In view of this fact, we have found it well to titrate our complement as in Table 4, which leads to a more accurate determination of the unit. The antigens were diluted so that 0.1 c.c. equaled one unit.

The tubes were placed in the water bath for one-half hour at 37° C., at the end of which time one unit of amboceptor and one unit of sheep cells are added. The rack is again incubated in the water bath for one-half hour and a reading made at the lowest point at which hemolysis is complete. This amount of complement is then taken for the unit and used in the test.

Six tubes containing, respectively, from one to six units of amboceptor, minus complement, were used as a control for that reagent, and the complement control arranged in the same way, omitting the amboceptor. All serums were inactivated at 56 C. for one-half hour; 0.1 cc. of serum was used throughout.

Paul Lewis<sup>3</sup> has called attention to the length of incubation and Petroff<sup>4</sup> to the temperature. We have employed a two-hour incubation at from 36 to 37 C., after which the cells were added and the rack placed in the bath for twenty minutes to estimate the amount of active amboceptor present. Later the proper amount is added and incubated for thirty minutes. A preliminary reading is made and the racks placed in the ice chest over night, and a final reading is made in the morning. We have found no noticeable difference between the evening and the morning readings.

#### OBSERVATIONS

1. In this series the complement fixation reaction was used as an aid in diagnosis, and not as a control in treatment. In attempting this study, we did not seek a test for tuberculosis which could be considered definite, we were only hoping to find a new link in the chain of evidence leading to a diagnosis of clinical tuberculosis.

2. This reaction does not give as valuable or consistent information in relation to tuberculosis as does the Wassermann reaction in regard to syphilis.

3. Sufficient information may be gained by the application of this test to warrant its routine application.

4. If our observations have been reasonably accurate, and 69 per cent. of active moderately advanced cases give a reaction compared with 16 per cent. reacting in cases not proved tuberculous, we feel that the test is of value and should be included in the routine examination, but should not be relied on without additional and confirmatory evidence. Rales in the chest alone cannot be considered as a sign of clinical tuberculosis, nor can we rely on any one sign except tubercle bacilli in the sputum, and even this observation should be checked by more than one sputum examination. Therefore, any test which adds to our information, although not conclusive in itself, should be used as a link in the chain of evidence.

5. A false reaction calls for a careful study of the case to ascertain the presence or absence of an active tuberculous lesion.

6. We found no tendency to cross fixation with the *M. tuberculosis* reaction.

7. We fully realize the great prevalence of nontuberculous pulmonary pathology conditions, and we have as a result tried to ascertain the cause of the patient's obstruction rather than to try to prove the existence of a case of tuberculosis.

8. There are many advanced cases of pulmonary tuberculosis in which no reaction occurred. An explanation of this point is that the cells have lost their power of reaction owing to their prolonged saturation with specific toxins.

9. A Wassermann test should be made in all cases of suspected intestinal obstruction, as the two diseases may be present at the same time.

10. The test is of great help to us in differential diagnosis. It also acts as a stimulus to more careful clinical observation.

11. We should like to call attention to Caulfield's<sup>5</sup> able work on this reaction in 1911.

12. Brown and Petroff<sup>6</sup> have pointed out a very practical application of the test in which they were able to regulate the exercise of the tuberculous patient.

### INTRA-UTERINE INTESTINAL OBSTRUCTION FROM INSPISSATED AND IMPACTED MECONIUM

JESSE G. M. BULLOWA, M.D.

AND

ROBERT EMERY BRENNAN, M.D.

NEW YORK

#### REPORT OF CASE

Baby W. was born in the Nursery and Child's Hospital after normal labor. She was normal except for her abdomen which, instead of being scapoid, was slightly distended. At the time no significance was attached to this. Twenty-four hours later it was reported that the baby had not passed meconium. Her temperature was 97 F.

Examination revealed a slightly rounded abdomen, discolored in the upper portion. No masses could be felt, though there was an indefinite resistance in the right upper quadrant. The rectum was empty. Through a small Kelly cystoscope in the rectum, a small dimple was seen about 1 inch above the anus. A small amount of sebaceous material exuded from time to time through this opening. There was considerable straining against the cystoscope.

The following morning the temperature had risen to 102 F. The abdomen was tense and much more swollen, and the baby's knees were drawn up. That afternoon under chloroform anesthesia, Dr. Brennan made a median incision. Considerable free fluid was evacuated. The coils of the intestine were injected, covered with fibrin, and much distended. Meconium was visible through the thin walls. A thin, tape-like band passed from the right lower quadrant across the abdomen and ended in the blind anal pouch. This proved to be the totally collapsed large intestine which was 1 cm. broad, and had a perfect lumen. The contents were whitish, sebaceous material similar to that which had exuded into the proctoscope. The distention of the small intestine terminated in a funnel which ended in relatively normal sized intestine about 1½ inches from the ileocecal junction. The appendix was apparently normal. An ileostomy was hurriedly performed, and five hours later the child died.

Subsequently, it was found that the intestinal blockage was due to impaction of the white inspissated and stratified contents. Apparently there was no gross abnormality of the intestine. Permission to remove a portion of the intestine was not obtained.

#### COMMENT

We have found no report of the occurrence of a similar case. The situation of the obstruction 1½ inches from the appendix suggested the influence of a Meckel's diverticulum. Of this there was no macroscopic evidence. No muscular abnormality was visible. The cause of a local inspissation of the intestinal contents is unknown. The tentative preoperative diagnoses were: intestinal obstruction: (1) from volvulus; (2) maldevelopment of the intestine, especially lack of fusion of the sigmoid and rectum.

The presence of rhythmic movements which caused a dimple to appear in the proctoscope, and the evacuation of even small amounts of sebaceous material served to indicate that there was a muscular continuity

of the intestine. This should prove of great value in the future.

This case is interesting, also, as giving the absolute size of the colon in the new-born, as well as the origin of at least part of the meconium.

### Clinical Notes, Suggestions, and New Instruments

#### ARSPHENAMIN VERSUS NEO ARSPHENAMIN

JAY FRANK SCHAMBERG, M.D., PHILADELPHIA

Professor of Dermatology and Syphilology, Jefferson Medical College,  
Professor of Dermatology and Syphilology, Graduate School of  
Medicine of the University of Pennsylvania

There is on foot a world-wide campaign for the control and suppression of syphilis. The medical profession is in accord in its belief that the best remedies for this disease are the new organic arsenicals and mercury. No one has yet evolved a crystallized formula for the treatment of syphilis which has been generally accepted. There are many standards of treatment, but no standard. Different authorities have their individual preferences as to the strength of the dose of the arsenicals, the frequency of administration, the duration of the course, and the choice of the compound to be employed. In other words, the medical profession is groping to find a therapeutic procedure which will combine safety and maximum efficiency. The trend of the best opinion is to make the treatment, particularly in the early stages, as intensive as is consistent with safety. The curability of syphilis is, in general terms, directly proportionate to the age of the disease. Patients treated intensively in the early stages have the best chance of recovery.

A problem of importance which requires early solution is that of the comparative merits and demerits of arspfenamin and neo-arsphenamin. Heretofore, the best qualified physicians in the country have dominantly employed arspfenamin. But quite recently new light has been shed on the properties of these two compounds which prompts a reexamination of the subject.

During the war, nearly all of the treatment of syphilis carried out along the fighting front by French, English, American and German physicians was with concentrated injections of neo-arsphenamin. Dr. Hugh Young of Johns Hopkins University and Dr. Edward L. Keyes of New York have had an enthusiastically favorable impression of this method of treatment. Let us examine briefly the relative advantages and disadvantages of the two compounds in the light of our present knowledge.

The preparation of arspfenamin solutions is more complicated than that of solutions of neo-arsphenamin, requiring a) they do neutralization with sodium hydroxide. The drug must be given in a gravity buret with at least 120 cc. of water for each 0.6 gm. (To be sure, many thousands of injections of arspfenamin have been given in a piston syringe in 30 cc. of water. Most of these have been matted with accident, but a number of untoward results and some deaths have followed this practice which is now discontinued.)

Neo-arsphenamin may be prepared much more rapidly and may be injected in 5, 10 or 20 cc. of water in a piston syringe. A very small needle, which is easier to insert into small veins, may be employed, thus causing the patient less pain. These are advantages which save time and increase the simplicity of the technique. There are, however, more important questions which relate to the comparative curative properties and to the toxicity of the two compounds.

I think that most syphilographers believe that arspfenamin is more curative than neo-arsphenamin, and in this they

are correct. The circular accompanying the original German neo-salvarsan marketed in this country stated, "The activity of neo-salvarsan is at least as great as that of salvarsan." This I believe is erroneous.

According to the arsenic content of the two compounds (about 20 and 30 per cent., respectively) 0.9 grain of neo-arsphenamin should be equivalent to 0.6 grain of arspfenamin, but as a matter of fact it is not. In a paper recently read before the Philadelphia Pathological Society, Schamberg, Kolmer and Raiziss showed that instead of requiring 33 1/3 per cent. more neo-arsphenamin than arspfenamin to sterilize rats experimentally infected with *Trypanosoma equiperdum* (horse syphilis or "la dourine"), it required approximately twice as much of the former. This trypanosome reacts chemotherapeutically much in the same manner as *Spirochaeta pallida*.

It might be admitted that twice as much neo-arsphenamin as arspfenamin must be given to achieve the same results. In terms of arsenical content, one third more arsenic would be introduced into the body. This would appear to be most undesirable were it not for other factors.

Schamberg, Kolmer, Raiziss and Weiss, in a communication read before the American Dermatological Association in Atlantic City in June, 1919, demonstrated that arspfenamin, in practically all concentrations in which it is used, hemolyzes red blood cells in vitro. Neo-arsphenamin on the other hand, does not hemolyze the cells in any of the concentrations ordinarily employed. Furthermore, the hydrogen-ion concentration of neo-arsphenamin is practically that of the blood, whereas both alkaline and acid solutions of arspfenamin are very different in hydrogen-ion concentration. There is, therefore, less biochemical disturbance of the blood and tissues after the administration of neo-arsphenamin.

Studies of the comparative toxicity of arspfenamin and neo-arsphenamin are most interesting. In general terms, neo-arsphenamin is over two and one-half times less toxic for white rats, by intravenous injection, than the arspfenamin from which it is made. A lot of arspfenamin which is tolerated by rats in the dose of 100 mg. per kilogram of body weight, when converted into the "neo" compound, will be tolerated in from 250 to 300 mg.

The addition of the "formaldehyd sulphosylate group" apparently lessens the affinity of the compound for the protoplasm of the parasite, but seems to lessen the affinity for the body proteins still more. The lessened affinity is due to the closing of one of the "amino" groups.

We should expect from the foregoing observations that neo-arsphenamin would be subjectively better tolerated than arspfenamin, and this, as a matter of fact, is the general experience. It must be realized that neo-arsphenamin is much more unstable and therefore undergoes change in the powder form much more readily than arspfenamin.

It should never be administered if the solution is not brilliantly clear, for a cloudy solution will produce immediate reactions with syncope (in rare cases fatal) as the dominant symptom. If filtering doses not completely clarify the solution, it should be discarded.

Despite such reactions, the cloudy solution does not show increased toxicity in animals. The action appears to be mechanical.

#### SUMMARY

Neo-arsphenamin is less active therapeutically than arspfenamin, but the difference in this respect appears to be largely made up by the discrepancy in the tolerated dose. We have found it possible to give neo-arsphenamin in full doses at frequent intervals without reaction. We commonly administer in appropriate cases 0.9 gm. three times a week in early cases of syphilis. Neo-arsphenamin appears to create less commotion in the blood and tissues than arspfenamin.

Which compound will ultimately be accorded preference cannot be foretold. I do not know of any rigid and extended comparative test of the two compounds, in a large series of patients with careful data on the serologic end results. Such an investigation is now being carried out.

AND CHARLES R. BRIDGES, INC. THE TREATMENT OF DRUGS

### USE AND ABUSE OF CATHARTICS\*

(Continued from page 1877)

#### CASCARA SAGRADA

The former official name of this drug, *rhamnus purshiana*, so called after F. F. Pursh, who described the plant in 1814, has been changed by our present pharmacopœia in favor of the older, shorter, and more authoritative name *cascara sagrada* (sacred bark), given to it by the early Spanish settlers of California, who found this bark used by the native Indians as a cathartic.

Though it was not until 1878 that the drug was introduced, it gained in favor so rapidly that it is now official in all the pharmacopœias excepting the Finnish and the Portuguese, and it is one of the most generally used drugs. Granting that, like all other cathartics, it is employed much oftener than it should be, and admitting that there is such a thing as fashion in the use of drugs, yet we must recognize that a substance with such a history must have some merit.

Experience shows that it is a mild yet reliable cathartic, quite free from tendency to griping and almost devoid of contraindications, a remedy which does not readily lose its effect on prolonged use. As it acts by stimulating peristalsis, it is especially indicated in atonic constipation, such as that of the bed patient. It is mild enough to be used in pregnancy. It would, of course, be contraindicated in spasmodic constipation. Occasionally one finds a patient in whom it fails to act. For such, *sema* forms a good succedaneum.

*Cascara sagrada* is rather slowly acting, requiring from six to ten hours for effect. Hence, when a single dose is to be given, it is best administered at bedtime. More commonly, and perhaps more efficiently, it is employed for the purpose of increasing the irritability of the intestinal musculature by being administered in divided doses, either before or after meals, and at bedtime.

*Cascara sagrada* lacks its intensely bitter taste. This is so marked that *cascara* should not be prescribed in the bitter form without asking the patient whether he is willing to take either mealtime. However, the bitter taste can be practically abolished by treating the bark with a dilute solution of magnesia, during its extraction. This is done in the preparation of the aromatic fluidextract of *cascara sagrada*, U. S. P., which, sweetened with glycerol, sucrose and saccharin, and flavored with a mixture of anise, nutmeg, coriander and cardamom, constitutes a veritable masterpiece of pharmaceutical engineering. It is pleasant enough for children to take without protest. However, the bitterness is removed at the expense of some activity, so that the relative efficiency of the aromatic fluidextract to the fluidextract is 1 to 3 or 4. This can, of course, be remedied by suitably large dosage. For the children, to whom the administration of the bitter fluid

extract is little less than inhuman, the following dosage of the aromatic fluidextract may be required:

	Cc.
Child, 6 months old	From 1 to 2
Child, 18 months old	From 2 to 3
Child, 3 years old	From 3 to 4
Child, 5 years old	From 4 to 8
Inf. adults	From 4 to 15

The expense is probably the only objection of using this preparation in the adult, for the plain or bitter fluidextract of *cascara sagrada* is effective in much smaller dosage (from 1 to 4 c.c.). The bitterness of this preparation is best overcome by having the patient put the dose into gelatin capsules just before taking. One or two of the larger sized gelatin capsules (00) filled with the fluidextract generally suffices to secure daily evacuation, especially when taken after each meal and at bedtime. Owing to the presence of 75 per cent. water in the fluidextract, such capsules cannot be kept on hand or prepared by the druggist. Patients readily fill these capsules for themselves, when provided with a medicine dropper.

The bitter fluidextract taken without encapsulation might be valuable in a case in which, in addition to constipation, anorexia is to be combated. For such a patient, this prescription might be of advantage:

	Cc.
℞ Fluidextract of <i>cascara sagrada</i> .....	30
Compound tincture of gentian.....	30
Mix. Label: One-half to one teaspoonful, in a little water, half hour before meals.	

In this prescription the compound tincture of gentian is merely used as a vehicle to avoid prescribing of dropdosage, which, being less convenient, should be employed only when distinct advantage is gained thereby, as in case of ascending or descending dosage. To this prescription, tincture of *nux vomica* might be added with possible advantage in doses of 1 c.c., unless the patient is suffering from excessive reflex excitability.

It is often successfully employed as an adjunct to the dietetic and exercise treatment (discussed under "Bran and Agar") of chronic constipation, in the following manner: The patient, provided with a prescription for the fluidextract (bitter preferred, but the aromatic if the patient objects to bitterness), should first of all determine the smallest dose required by him to obtain an action of the bowels at least once and not more than twice a day. He should be told that the medicine is merely given him to provoke a call to stool; and that, if this is neglected, the previous day's dosage has been wasted. As initial dose a half teaspoonful might be suggested, to be taken before meals and at bedtime. This dose is used regularly for a week; then half the dose is continued for a week; and this again cut in half and taken for a week; and so on, until it has been reduced to but a drop or two, when it might be discontinued. A patient who fails to respond to a faithful application of this combination therapy is in need of some form of physical treatment (enemas, massage, electrotherapy or surgery), after a careful and thorough study of his case (including roentgenologic examination); and, if physical therapy is inapplicable or fails, may have to be fitted with a habitual cathartic, for which purpose administration in pill form is best.

The extract of *cascara sagrada* is the least reliable *cascara* preparation. While the average dose of this preparation is given by the pharmacopœia at 0.25 gm., which makes a good sized pill, even two or three times this dose may fail. Extract of aloes is so much sup-

## New and Nonofficial Remedies

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

W. A. PUCKNER, SECRETARY.

### LACTIC ACID-PRODUCING ORGANISMS AND PREPARATIONS\*

Milk soured by the accidental presence of acid producing bacteria (buttermilk, etc.) or by the intentional addition of certain strains of bacteria with or without the association of alcohol-producing yeasts (kefir, kumyss) has been used as a food for centuries. This is due to the fact that the products were palatable to many or to a very general opinion among the laity as well as among physicians that they were advantageous for certain disorders of the gastrointestinal tract. A great stimulus to the employment of fermented milks was given by the theories of Metchnikoff regarding intestinal putrefaction. These theories, entirely unsupported by scientific evidence, were in part that the products of intestinal putrefaction, elaborated chiefly in the large intestine, were absorbed and largely by their action on the walls of the blood vessels produced arteriosclerosis and premature senility. He also advanced the theory that the growth of the proteolytic bacteria, many of them anaerobes, which elaborated these poisons could be modified or prevented by the presence in the intestines of lactic acid-producing bacteria, especially *Bacillus bulgaricus*. No one seriously subscribes to these opinions at the present time; but, on the other hand, there is evidence that the administration of sour milk products is at times beneficial. This is particularly true in pediatrics. In this field fermented milks have found a wide application. They are used in vomiting and in acute diarrhea as well as in chronic disturbances of the gastrointestinal tract. Under certain conditions it may be advisable to give very little fat; under others a diminution of this may not be necessary. By the use of cultures of acid-producing bacteria milk of any fat content may be fermented and the fermentation may be inhibited at any time. On what the particular value of these milks depends is not known at the present time. There can be no doubt but that a wide clinical observation gives a basis for the opinion that for certain types of gastric and intestinal disturbance fermented milk accomplishes more than sweet milk with a similar fat, sugar and protein content. Some acid producing organisms give rise to much more uniform, smoother products than do others. Bacteria of the Bulgarian bacillus group, usually in association with *Streptococcus lacticus* have been found particularly satisfactory.

There is little evidence showing that organisms of the Bulgarian group can be implanted in the intestinal tract. They may be found in the stools so long as they are ingested in considerable numbers. As soon as the ingestion of them ceases they disappear from the stools.

There is little satisfactory proof to indicate that liquid cultures or aqueous suspensions of lactic acid-producing organisms are of value as local applications to mucous membranes or in arresting putrefaction or suppuration in wounds, abscesses and sinuses. In such conditions their use seems to be still in the experimental stage.

Sour or fermented milk may be administered in the form of buttermilk or soured skimmed milk, the lactic acid being

produced by action of the paralaetic acid organism *Streptococcus lacticus* which grows readily at room temperature, or in the form of sour milk produced by *Bacillus bulgaricus*, alone or in the presence of *Streptococcus lacticus*. Kefir and kumyss are produced by the action of lactic acid-producing organisms associated with an alcohol-producing yeast, which also acts on the proteins of milk and renders them somewhat more digestible.

When the ferments are administered in the attempt to cause their implantation in the intestinal tract, the Bulgarian bacillus is commonly, though without good reason, given preference, either in the form of tablets or of liquid cultures. Liquid cultures, and still more the tablets, containing the Bulgarian bacillus deteriorate with age, the deterioration being retarded by low temperatures. All lactic acid ferment preparations must be stored in an ice-chest and should be marked with an expiration date, after which they are not to be used. Bacteriologic examination of various commercial cultures and tablets has often shown them to contain few, if any, living Bulgarian organisms.

*Bacillus bulgaricus* belongs to a group of bacteria which has not received much scientific attention. This group is widely distributed through nature. *Bacillus bulgaricus* is a long bacillus, sometimes fairly slender and sometimes fairly thick. It has a tendency to filament formation in old cultures. It grows preferably under anaerobic conditions, but grows well also under aerobic conditions. Different strains vary in this respect. Young cultures are gram-positive, but in old cultures gram-negative forms may appear. If the gram stain is applied and a red counter-stain used, one filament may appear blue in some parts and red in others. Sometimes there is a tendency to granular staining if methylene blue is used. Branching is occasionally observed, the bacillus taking on the shape of the letter "X" or "Y", and also resembling another organism of this group, *Calvillus bifidus*. Carbohydrates are of material aid in successful cultivation of this bacillus. Broth with 2 per cent. dextrose is quite suitable for most strains, especially if calcium carbonate in the form of pieces of marble is added, so that the acid formed during growth is promptly neutralized. The medium par excellence is milk or some medium prepared from milk. Milk agar prepared by precipitating the casein and dissolving agar in the whey, is an excellent medium, especially if dextrose is added. Milk is acidified rapidly and a coagulum is formed with little separation of whey. The amount of acid formed varies with different strains. 1 to 3 per cent. or even more being attained.

Slightly different varieties of *B. bulgaricus* are used for the preparation of a milk which is usually called Bulgarian milk. In some instances the milk becomes more or less slimy; in others, the coagulum is smooth and of a creamy consistency. There should be little or no separation of whey. The delicate character and palatability of the product depends largely on the early interruption of the incubation period, and on keeping the milk at a low temperature.

The acid produced is 94 per cent. lactic acid. It has been stated that the butter fat and the casein are decomposed. If this is true the reaction is slow and the result not noticeable for several days.

The group of bacilli to which *B. bulgaricus* belongs is sometimes called "lactobacilli." They are able to multiply in the presence of considerable amount of acid and therefore belong to the group often misnamed acidophil. They are not acidophil in the true sense of the word, but are acid-resistant. Whether we are justified in distinguishing species in this group, or only varieties, remains a subject for research. Probably the lactobacilli form a large group consisting of many varieties, as does the *B. coli* group or the group of streptococci. Research will probably show that some varieties retain their properties with tenacity while other varieties are readily transformed. Market milk usually contains bacilli of this group. The optimum temperature for cultivation is about 45°C. Milk inoculated at this temperature will, as a rule, turn very sour in the course of twenty-four to forty-eight hours and show an acidity of from 2 to 4 per cent. The lactobacilli have been considered active in the ripening of certain cheeses. They are found in the feces of man and animals. It is stated that the feces of infants can be used for the preparation of buttermilk after several transfers through milk. The Bulgarians, if they look their "mava," which is the name of the starter for their sour milk can replace it by using part of the stomach or intestines of a calf.

Cultures may be prepared in broth containing dextrose, or better in whey broth, whey agar, or in sterilized milk. Viable cultures decrease rapidly. Frequent transfers are therefore necessary. To preserve a culture in best condition it should be transferred at least once every two days. A milk culture will contain living bacilli for many days, but their activity becomes impaired.

**Infant Mortality.**—The infant mortality rate throughout the birth registration area as a whole that is the number of deaths under 1 year of age per thousand born alive was 93.8 in 1917 as against 101 in 1916 and 100 in 1915. Among the twenty states these rates ranged from 67.4 for Minnesota to 119.9 for Maryland. *Bulletin*, State Board of Health of Rhode Island, August, 1919.

# THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

535 NORTH DEARBORN STREET - - - CHICAGO, ILL.

Cable Address - - - "Medic, Chicago"

Subscription price - - - - - Five dollars per annum in advance

Contributors, subscribers and readers will find important information in the second advertising page following the reading matter.

SATURDAY, DECEMBER 20, 1919

This issue of THE JOURNAL was made up during the time the strict orders of the Fuel Commission were in force. These prevented our printing department from working more than three days a week. When the order was rescinded it was too late to rearrange the issue, as the front and last forms had already been printed. This explains the small size of this issue. It will be noticed that the advertising as well as the reading pages have been reduced; this was made possible through the courtesy of some of our advertisers who complied with our request to omit the usual insertion of their announcements. We hope to catch up next week, although handicapped with a holiday and the index number.

## HYPERTENSION AS AN EXPRESSION OF THE LACK OF THE WELL-BALANCED LIFE

Within comparatively few years the sphygmomanometer has won a permanent place in the armamentarium of the physician. Like other instruments of precision, it has enriched the technic of diagnosis and made therapy more easily evaluated. Systolic and diastolic pressures and the difference between them known as pulse pressure have become something definite. Hypotension and hypertension have attained a familiar soundness among laymen; so that a well known physician, referring to the case with which high blood pressure can now be diagnosed, said of the use of the instrument: "I think any social worker would be better for knowing it and could learn it in fifteen minutes, and almost out of the simplest, it is the most important of all medical tests."<sup>1</sup>

The "popularizing" of an instrument of precision or of a diagnostic technic is likely to lead to misinterpretation, particularly of the sort that represent the relation of cause and effect. The occurrence of sugar in the urine is often thought of as a disease, whereas glycosuria is, of course, merely a symptom. The

interrelations between hypertension and conditions that often occur along with it have also been much misunderstood. The familiar statement that "there are two main causes of high blood pressure—arteriosclerosis and kidney trouble"<sup>2</sup> has lately been called into question by those who have carefully analyzed the problem. Whatever the ultimate origin may be, the immediate cause of arterial hypertension must be either an increased output from the heart or an increased resistance to the escape of blood from the larger arteries. The latter alternative seems to be the only tenable one on the basis of the evidence now available. The resistance that occasions the hypertension is by no means always due to sclerosis of the larger vessels; for there are records of not a few carefully studied cases occurring without evidence of either kidney or arterial disease. There is undoubtedly often an association of sclerotic changes and high pressure; but it does not follow that this is invariable or that the hypertension is the sequence.<sup>3</sup> A recent writer<sup>3</sup> has thus presented the logic of the situation: The finding of a certain pathologic lesion at postmortem is no proof whatever that this lesion was the cause of the signs or symptoms during life. A lesion may very well be the end of a physicochemical or metabolic process which is not demonstrable at necropsy. It would be equally logical, for instance, to conclude that the left ventricular hypertrophy or an apoplexy is the cause of hypertension, although we know that these lesions are results and not causes.

Hypertension may be regarded as a sort of compensatory process in an attempt to bring greater efficiency to an impaired circulation. If we may think of arteriosclerosis as at least occasionally secondary to this deviation from the normal—as a sequence to circulatory decompensation or even as independent of it—to what shall the ultimate etiology of hypertension be ascribed? If arteriosclerosis and Bright's disease have the same pathogenesis, the lesion being determined by the nature of the organ or tissue involved, what induces the primary vascular or circulatory defect? These questions cannot yet be answered definitely. To attribute them to excesses in eating or drinking, to tobacco or alcohol, to undue discharge of epinephrin from overstimulated suprarenal structures, to the damage of "wear and tear," is to veil our ignorance in well sounding words. Without attempting to determine the "why" of hypertension, Moschowitz<sup>3</sup> has ventured to describe a type of person, conforming to certain physical and psychic complexes, in whom hypertension is very likely to occur. Here is his picture:

The patients are overweight and sometimes even obese. The neck is short, the muscles are soft, their bodily movements are sluggish, their carriage and walk are ungraceful and they lack the spring and élan of the former athlete.

2. Campbell Hewlett, A. W.: *Monographic Medicine*, New York, 1: 107, 1916.

3. Moschowitz, E.: *Hypertension: Its Significance, Relation to Arteriosclerosis and Nephritis and Etiology*, *Am. J. M. Sc.* 158: 698 (Nov.) 1919.

1. Clegg, R. C.: *A Layman's Handbook of Medicine*, Boston, 1916, 274.

Physically, these people are tense; they pursue their vocation with tremendous seriousness and worry over trivialities. Phlegm and hypertension are, in my experience, antagonistic. Furthermore, these individuals have narrow intellectual horizons. Their interest in anything outside of their business is desultory. They have no hobbies.

The prototype of the candidate for hypertension whom Moschowitz has thus cleverly portrayed shows his most conspicuous mental incapacity in an inability to play. If it shall prove of value in prophylaxis to know the type, we must regard him, according to Moschowitz, as the antithesis of the child, both in mind and in spirit. If the psychic, as well as the physical, takes a part in the development of hypertension, we may well advocate, vigorously and often, a larger element of play in the routine of those who conform to the type. If age is not merely a matter of years, we must keep alive that spirit of childhood which is not "blighted by the premature struggle for existence or the gloom of a depressing environment." In anticipation of the danger of hypertension we must put back play into the lives of those who know only adult work; for in a well balanced life the spirit of the child, with its humor, imagination, its enthusiasm for sport and love of vacations furnishes that which "neutralizes the corroding acid of the 'fret and fever' in our lives."

#### GOVERNMENT TRUSTEESHIP OF MEDICAL PATENTS

In the various scientific departments of the national government, workers have discovered new methods of procedure, or new products, which gave promise of benefit to mankind. Many of these discoveries have been patented and dedicated to public use, though relatively few have yielded practical results, the ideas having been a contribution to academic discussion rather than a stimulus to industry. The reason is apparent: Capital will not venture in a new industrial enterprise unless it has some degree of protection during the developing period—that is, a limited monopoly. A concomitant drawback under our present system of public owned patents has been the lack of reward or adequate recognition of the government inventor; this dulls the incentive to create new improvements or useful additions.

As an attempt to remedy these evils, there has been introduced recently in both houses of Congress a bill "authorizing the Federal Trade Commission to accept and administer for the benefit of the public and the encouragement of industry, inventions, patents and patent rights . . . as these may from time to time be tendered it by employees of the various departments or other establishments of the government or by other individuals or agencies" (studies ours). It is proposed that the commission shall grant licenses for the use of the inventions, thereby collecting fees,

a certain percentage of which would be disbursed for remuneration to the inventors of such patents as have proved meritorious. Thus the advantages would be the commission of a definite official agency to be responsible for the patents, to be alert to see that the patents are respected, and to insure adequate recompense to both the licensee and the patentee, without undue commercial exploitation. But of greater interest, especially to the medical profession, is the possibility of a satisfactory patenting of medicinal and surgical articles; the bill provides specifically that, in the interest of the public, "other individuals" may tender their rights to the Federal Trade Commission.

It has been regarded as against the principles of medical ethics to patent instruments or medicaments for personal gain. However, as was pointed out recently in THE JOURNAL,<sup>2</sup> this does not mean that patenting *per se* is wrong; in fact, it is at times desirable to patent new discoveries, especially drugs, in order to insure reliability. The problem has been how to make available the patented product in the interest both of the public and of medical science. It would seem that the proposed bill suggests a means, acceptable to the medical profession, for the control of patents in the fields of medicine and surgery; the success will depend on the wisdom exercised by the Federal Trade Commission in the method of granting licenses. Judging from the recent activities of this body in the licensing of former enemy owned patents (such as barbital, procain and arspenamin), a wise policy will probably be followed. The bill as proposed gives opportunity for the medical research worker to obtain recognition, and possible emoluments, for distinctive contributions, without making him subject to criticism. It contains many constructive possibilities, and should receive the endorsement of those interested in the altruistic success of science.

#### BOTULISM: II

In one respect the work of the Harvard investigators referred to last week<sup>3</sup> has thrown some light on the possibility of botulism poisoning from factory canned goods. Both Weinzirl<sup>4</sup> and Cheyney<sup>5</sup> have shown that commercial canned goods, as found in the markets, are not always sterile. The proportion of cans containing viable spores of aerobic organisms varies according to the foodstuff, but may reach as high as 25 per cent. (canned meat). As long as access of air is shut off, these aerobic spores do not develop; and the canned food, though not sterile, remains unpoisoned. If spores of anaerobic bacilli are present originally in the food

material, they too may resist heating; but they may subsequently grow in the absence of oxygen, leading to swelling of the can, which is then discarded as not being merchantable. The odors of spoiling or souring that appear usually to be caused by *B. botulinus* constitute an additional safeguard, and these signs of warning may conceivably be a more efficacious protection in the case of canned foods purchased in the market than in those prepared in the household. There seems no reason for supposing that food material contaminated with the spores of *B. botulinus* may not be subjected to ordinary factory processing without destruction of the spores; later these spores may germinate and produce a potent toxin. The extraordinarily small number of botulism outbreaks traced to factory canned goods indicates that practically the danger is very slight. This, however, does not mean that every reasonable precaution against its occurrence should not be taken.

Little has been known until recently about the distribution and habitat of *B. botulinus*. Outbreaks of botulism have been reported in Belgium, France and Germany; but it is a singular fact, often commented on, that Great Britain appears to have been entirely exempt. In the United States the majority of the reported outbreaks have occurred in California, or have been due, as in the case of the ripe olives referred to before, to foods packed in that state. Cases have occurred, however, in Idaho, Colorado (attributed to food canned in Kansas), Indiana (source of food unknown), Massachusetts and other localities. Particularly interesting observations have been made on the relation of *B. botulinus* to forage poisoning, and the specific organism has been isolated from material implicated in forage poisoning both in Kentucky<sup>6</sup> and in Illinois.<sup>7</sup> There is thus evidence that *B. botulinus*, although perhaps relatively common on the Pacific Coast, occurs in widely separated parts of the country.

Apart from actual outbreaks of botulism, the bacillus itself of late has been rarely found in nature. Kemper and Holark,<sup>8</sup> in 1897, reported finding the organism in the intestinal contents of a normal hog; but until the recent work of Burke,<sup>9</sup> this instance has remained practically alone. Mrs. Burke has succeeded in isolating *B. botulinus* in seven out of 235 cultures made from material collected in five localities in central California. Four of the five localities visited yielded the organism, the exception being a deserted ranch. The cultures covered a wide range of material, *B. botulinus* being found in such diverse objects as the leaves of the bean plant, moldy hay, bush beans, cherries and spiders. Mrs. Burke believes that the evidence

strongly suggests that *B. botulinus* may be closely associated with or disseminated by spiders or insects common in gardens in California. It is clear from these observations that the organism may be present on fruits or vegetables when they are picked. Further observations of this character are needed to determine whether *B. botulinus* occurs as commonly in other parts of the United States as in California, and whether in that state certain localities are more seriously infested than others.

Our present knowledge of this important pathogen indicates that it is of more common occurrence in some areas than in others; that it may find its way into canning factories as well as into the family kitchen; that its spores may survive relatively high temperatures to germinate subsequently and produce a potent toxin, and that in spite of the usual warning given by signs of decomposition, contaminated food may be eaten and cause death. Methods of canning on a large and on a small scale should be devised which will kill the spores of *B. botulinus*. Meanwhile we may urge again, as we have heretofore, that canned food showing signs of spoiling should not be eaten. It should also be remembered that the toxin of *B. botulinus* is destroyed by boiling, so that canned foods boiled before they are eaten are rendered materially safer.

## Current Comment

### WILL YOU HELP?

With the expiration of the calendar year, subscriptions to THE JOURNAL and Fellowship dues for 1920 will become payable. To send a bill under first-class postage to each subscriber and Fellow entails a total expense of several thousand dollars, and is more or less a dispensable formality. Therefore, instead of a personal statement being mailed, a slip for 1920 subscription and dues will be inserted in THE JOURNAL next week. This slip, though less formal than the personal statement, will perform its essential functions. It will remind you that dues are payable, and it will be a convenience in remitting. We are counting on your cooperation.

### THE PASSING OF THE AMERICAN JOURNAL OF OBSTETRICS

The publishers announce the discontinuance of the *American Journal of Obstetrics and Diseases of Women and Children* with the issue of December, 1919, after fifty-one years of continuous publication. It was founded by Dr. Benjamin F. Dawson in May, 1868, and continued as a quarterly until 1872, when it was taken over by William Wood & Company and changed to a monthly. Dr. Dawson was succeeded as editor by Dr. Paul F. Munde and he, in turn, by Dr. Brooks H. Wells, later with Dr. George W. Kosmak. Since the death of Dr. Wells

<sup>6</sup> Graham, Brewster and Post, *Bull. U. S. Geol. Surv.*, 7 and 105, Kentucky Agr. Exp. Sta. 1907.

<sup>7</sup> Graham, Brewster, Brewster and J. S. Smith, *Forage Poisoning, The Relation of B. botulinus to Forage Poisoning in Cattle and Horses*, Michigan Agr. Expt. Sta. 1911, Illinois Agr. Expt. Sta. 1911.

<sup>8</sup> Kemper and Holark, *Ann. Entomol. Soc. Amer.*, 1907, p. 85.

<sup>9</sup> Burke, George S., *The Occurrence of Botulism in California*, *Nature J. Bacteriol.*, 4: 1-11 (Sept. 1919).

in 1917, Dr. Kosmak has acted as editor. As its name indicates, when this journal was started it was intended to fill a need, for then it was popular for a physician to claim as a specialty obstetrics and the diseases of women and children, these comprising the bulk of practice. Today, however, they are practically three distinct specialties linked only by a weak relationship. The *American Journal of Obstetrics* has had an honorable and useful career, and has been a credit to both its publishers and its editors.

**CHANGING THE FLORA OF THE  
INTESTINAL TRACT**

In spite of scientific evidence demonstrating the difficulties of changing the intestinal flora,<sup>1</sup> some physicians continue to recommend the use of organisms of the *Bacillus bulgaricus* group to displace other supposedly harmful intestinal bacteria. Without denying the possibility that certain forms of bacterial infection of the digestive tract are harmful, it is not untimely to point out again that the mere administration of *Bacillus bulgaricus* or similar organisms will not result in changing the preexisting intestinal flora. Recently Distaso and Sugden<sup>2</sup> have demonstrated that those organisms which produce indoxyl and allied substances in the test tube are the same organisms that produce them in the human body with the resulting appearance of indicanuria. As an incident in this investigation, the authors found that it was impossible in the lower animals to displace the existing intestinal flora by feeding antagonistic bacteria. On the contrary, they showed that all that was necessary to produce this desirable effect was a change in the diet of the animal. It cannot, of course, be definitely concluded from these experiments that a similar course of events takes place in human beings; but the work strongly emphasizes that the best means to reduce one variety and to increase another variety of bacteria in the intestinal tract is to change the character of the diet. In lower animals, when the appropriate diet is introduced, the bacterial substitution takes place automatically.

**ARROGANCE NOT DEFEATED**

The *New Freie Presse* of Munich recently discussed, in a most optimistic manner, the situation of the German chemical industry:

German brains, it is now planned, are to be fired by esterite gold and pressed into the service of our former enemies, principally in America, where drug, chemical products and dyes are so awfully scarce. American indigo, it is said, has been rejected by the dyeing industry, the same as American salvarsan by physicians. No wily Americans have offered a Munich chemist an annual salary of 2,000,000 marks.

To those who are familiar with what American chemical industry has accomplished during the war, this item would be amusing if it did not reveal the fact that the old arrogance and conceit, which it was hoped the war would somewhat modify, still dominate to a considerable degree the German mind.

**THE NEW ORLEANS SESSION**

**Address of the Local Committee on Arrangements**

The Local Committee on Arrangements for the New Orleans session, April 26-30, 1920, the personnel of which was announced last week (page 147), requests that all communications for the attention of the Local Committee on Arrangements, or the chairman of any of its subcommittees, shall be mailed to Room 1216, Maison Blanche Building, New Orleans.

**Medical News**

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST, SUCH AS RELATIVE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

**CALIFORNIA**

**Tax on Physicians.** By a law of California, an annual tax of \$2 due, Jan. 1, 1920, is payable by every individual who holds any form of certificate which entitles him to practice any system of healing art in the state. If the payment is not made within a period of sixty days, delinquency becomes operative and a fee of \$10 is required to reinstate the certificate of such delinquent.

**Injunction Granted Health Institution.**—The San Diego Society for the Cure and Prevention of Tuberculosis won a victory on November 29, when Judge Lewis granted a temporary injunction to prevent the city recorder of East San Diego from further interfering with the operation of the hospital. The charge against the society was that it had violated an ordinance prohibiting the maintenance of a hospital within the corporation of East San Diego. The hospital maintained, first, that it was established previous to the incorporation of East San Diego, and, second, that it is conducted under the laws governing the state board of health, and that a municipality cannot pass ordinances conflicting with a state law.

**ILLINOIS**

**Hospital Staff Changed.** Dr. Charles B. Caldwell of the Florida State Hospital has been appointed assistant superintendent of the Lincoln State Colony to succeed Dr. Thomas H. Leonard, resigned.

**INDIANA**

**County Honors Service Men.**—The meeting of the Grant County Medical Society held in Marion, November 27, was especially designed to honor its members who were in the army service during the world war. Drs. Erle O. Daniels, Joseph P. Pearle and others of the service men responded to toasts.

**Personal.** It is reported that Dr. Edwin Walker, Evansville, who has been seriously ill for several months, is slowly gaining in health. Dr. R. H. H. Bandy, mayor of Muncie, is said to have been found guilty November 11 of a conspiracy to use the mail to defraud, to have been fined \$1000 and sentenced to two years imprisonment in the federal penitentiary, Atlanta, Ga. Dr. Horatio H. Kappert, secretary of the Colonial Board of Health, has resigned and has been succeeded by Dr. James W. Leonard. Dr. Homer N. Oliphant, National Military Home, has been appointed associate surgeon for the Clover Leaf System at Frankfort. Dr. George S. Miles, superintendent of the Indiana School for Feeble-minded, Fort Wayne, has resigned.

**MARYLAND**

**Annual Meeting of Baltimore City Medical Society.** At the annual meeting of the Baltimore City Medical Society held December 5 at Osher Hall the following officers were elected: Dr. Harvey B. Stone, president; Dr. Edward A. Leeper, vice president; Dr. Frank S. Lynn, secretary, and Dr. Charles E. Brack, treasurer. Dr. Guy L. Hanson, the retiring president, was appointed a member of the board of censors.

**Building for Hygiene School.**—On account of the destruction by fire of the School of Hygiene located on the Hill

buildings of the Johns Hopkins University, a resolution granting the Johns Hopkins University permission to erect a temporary frame building for the use of the school was introduced into the Baltimore City Council recently and, under suspension of rules, referred to Building Inspector Osborne for report and recommendation. The building is to be 120 by 50 feet and two stories in height.

**Plans for New Hospital.**—Plans for a hospital at Curtis Bay have been drawn and the members of the Curtis Bay Board of Trade, which include the heads of virtually all the manufacturing enterprises in the district have decided to petition the next legislature which convenes in January, for funds to establish the institution. A hospital is needed in that locality in the case of accident at the plants, the patient must be sent to the South Baltimore General, Mercy or University Hospitals, all of which are a considerable distance from Curtis Bay.

**Personal.** Dr. James J. Mills has fully recovered from an attack of pneumonia and has returned to his home in Baltimore. Dr. Charles B. Thompson, secretary of the Mental Hygiene Society, whose office was in Levering Hall, which was gutted by fire on November 27, when McJoy Hall and other buildings of the old Johns Hopkins University unit were destroyed, has announced that all records of the society have been found intact and that the manuscript of the book on mental disorders in which he has been working for several years was not destroyed.

### MINNESOTA

**Personal.**—Dr. George W. Beach, superintendent of the Minnesota State Sanatorium, Walker, has been appointed chief of medical activities under the Serbian Relief Committee of America, and will leave this month for his new headquarters at Cacak, Serbia.

**Pioneer Honored.** Dr. Eysander P. Foster, Minneapolis, believed to be the oldest pioneer in Hennepin County, who came to St. Anthony in the summer of 1848, and later served in the Civil War, was the guest of honor at the meeting of the Territorial Pioneer Women's Club, and the Territorial Teachers' November 24, on the occasion of Dr. Foster's eighty-fourth birthday.

**Southern Minnesota Officers.** At the annual meeting of the Southern Minnesota Medical Association held in Mankato, December 1 to 4, Fairmount was selected as the next place of meeting and the following officers were elected: president, Dr. Herbert Z. Giffin, Rochester; vice presidents, Dr. Arthur F. Wilson, Minneapolis, and Walter J. Richardson, Fairmount; secretary, Dr. Henry T. McGuigan, Red Wing (retired); and treasurer, Dr. George F. Merritt, St. Peter (retired).

**Conservation of Vision.** At the last session of the legislature a bill was passed providing for the establishment of classes for the conservation of vision, by appropriating a total of \$20 per annum for each child requiring the special benefit of such classes. Mr. Meyer of Ohio has been appointed secretary of the department, and Dr. Douglas F. Wood, Minneapolis, an ophthalmologist, has donated his services for the examination of candidates and treatment of children admitted for conservation of vision classes.

### MISSOURI

**Semcentenary of Dr. Griffith.** At the meeting of the Jackson County Medical Society, December 2, it was decided that a memorial be given at 10 o'clock, March 4, 1920, in honor of the eminent authority of the entrance into practice of Dr. Jackson G. Griffith, Kansas City.

**New Officers.** At the annual meeting of the Jackson County Medical Society held in Kansas City, December 2, following officers were elected: president, Dr. John F. Buehler, president; Dr. George E. Bellows, secretary; Dr. Paul H. Winkler, and treasurer, Dr. William F. Kuhn. —**International Association of Ex-Medical Officers of the United States.** A meeting of Ex-Medical Officers of the United States was held at the meeting held in Springfield, Dr. William A. Delzell, Springfield, was chosen president, Dr. Louis M. Edens, Cadoux, vice-president, Dr. Horace A. Lewis, Springfield, secretary, Dr. Robert M. Linn, Springfield, corresponding secretary, and Dr. James H. Fairright, Springfield, treasurer.

### NEW YORK

**Personal.** Dr. David H. Atwater, Rochester, has succeeded Dr. Milton Chapman as one of the two coroners of Monroe County.

**Society of Medical Jurisprudence Elects.**—At the three hundred and fifth regular meeting of the New York Society of Medical Jurisprudence, December 8, the following officers were elected for the ensuing year: president, Dr. Nathan B. Van Fossen, New York; vice president, Charles Oakes, Esq.; treasurer, Charles P. Blaney, Esq.; corresponding secretary, Dr. Edward E. Hicks, Brooklyn; and recording secretary, Dr. L. Howard Moss, Richmond Hill.

### New York City

**Personal.** Dr. Mark J. Schoenberg has been appointed adjunct consulting ophthalmologist at the Presbyterian Hospital.—Dr. Royal S. Copeland, commissioner of health, is reported to have resigned, December 5, on account of the refusal of the comptroller to permit the Board of Estimates to pass on an appropriation of \$30,000 for the treatment of drug addicts. The mayor refused to accept the resignation and intimated that the board would eventually make the appropriation.

**Reconstruction Commission Urges Increased Health Activities.**—A report recently submitted to Governor Smith by the New York State Reconstruction Commission contains recommendations urging the establishment of community health centers throughout the state. Since the appointment of the commission last January, its committee on public health has been studying the problem of community health measures. In twenty-nine communities that reported to the committee there were only five clinics for children of the preschool age, compared with forty-eight infant welfare stations. The ideal plan for welfare work would be to house all activities in one building: child welfare work, prenatal, dental, tuberculosis and general medical clinics. This work, in the opinion of the committee, should be taken out of the field of private philanthropy and should be fully supported by the state and the local municipal governments. The report also recommends an extension of maternity center work, the adoption of ordinances requiring the pasteurization of milk, and the establishment of new courses to fit women to do health work below the technical standard required of the registered nurse. The report says that a year of training in a hospital, with a large experience in bedside care of the sick, would fit a large number of women so that they would be able to care for most cases of illness.

### OHIO

**Health Commissioner for Toledo.**—An examination board composed of Drs. Walter W. Brand, Chester W. Waggoner and William H. Fisher, has been appointed by the civil service commission to conduct the examination for full time health officer of Toledo. The position will pay a salary of \$6,000 a year.

**Personal.**—Dr. Paul G. Woolley, Cincinnati, is reported to have accepted the direction of a laboratory for medical diagnosis at Detroit.—Dr. Nolan E. Leake, Van Wert, who has been two years in the United States service, has returned and resumed his position as pathologist at the Van Wert County Hospital.

**Tablet Unveiled.**—A memorial tablet to the late Dr. Phineas Sanborn Conner, Cincinnati, was unveiled at Good Samaritan Hospital, November 12. Dr. Conner was a member of the staff of the hospital for forty years. Exercises were held in the chapel and addresses were delivered by former students of Dr. Conner, including Dr. Louis Schwab, Robert Carothers and Clement C. Fife. The tablet was unveiled by a grandson of Dr. Conner.

**Hospital Standardization.**—Hospital executives from various parts of the state met in conference called by the state department of health, December 3, at which questions arising as a result of recent legislation regarding the registration, definition and classification of hospitals were discussed by Dr. Andrew R. Warner, secretary of the American Hospital Association, State Senator Howell Wright, secretary of the Cleveland Hospital Conference, and others.

### OKLAHOMA

**Personal.**—Dr. George W. Goss, Pawhuska, has been appointed health commissioner for Osage County.—Dr. Wilber E. Rammel, Bartlesville, who was operated on recently for the removal of gallstones, is reported to be convalescent.

**University Hospital Dedicated.**—The State University Hospital, Oklahoma City, established primarily to serve those citizens of the state who would otherwise be unable to secure satisfactory hospital service, was formally dedicated Novem-

ber 13. Dr. Jabez N. Jackson, Kansas City, Mo., delivered the dedicatory address. The hospital contains 175 beds of which twenty-five are in private rooms, eight wards, containing separate wards for men and women, and for white people and negroes. There are five operating rooms and ample diagnostic laboratories.

**PENNSYLVANIA**

**Personal.**—Dr. Theodore H. Jones, West Hickory, was operated on at St. Mary's Hospital, Rochester, Minn., November 22, and is reported to be doing well.

**Mellon Lecture.**—The annual Mellon lecture of the Society for Biological Research of the University of Pittsburgh will be delivered by General William C. Gorgas at Pittsburgh on Jan. 8, 1920. The subject of the address will be "Yellow Fever." General Gorgas has just returned to the United States from an extensive trip through Central and South America. In his address he will describe the present plans and progress of the work on yellow fever.

**Millions to Hospitals.**—By the will of Henry C. Frick, the residuary estate is to be divided into 100 shares valued at about half a million dollars each. Of these, Mercy Hospital receives ten shares, or about \$5,000,000, and each of the following institutions receives one share valued at about \$500,000: Pittsburgh Free Dispensary; Western Pennsylvania Hospital, Pittsburgh; Uniontown Hospital; Cottage State Hospital, Connellsville; Westmoreland Hospital, Greensburg; Mount Pleasant Memorial Hospital; Braddock General Hospital; Homestead Hospital; Children's Hospital, Pittsburgh; and Allegheny General Hospital, Pittsburgh.

**Philadelphia**

**Personal.**—Dr. Richard M. Pearce has been appointed chief director of the Division of General Medical Education of the Rockefeller Foundation. Dr. Joseph M. Sterling has been selected as assistant in the state tuberculosis dispensary. Dr. Norman S. Rothschild has been made an assistant in the prenatal clinic and Dr. John D. Donnelly has been appointed head of the baby dispensary of the Phipps Institute. Dr. Dorothy Child, who spent a year in France in charge of the Children's Hospital, Avion, has been appointed head of the division of child health, a recently created branch of the state department of health. Dr. Elizabeth O. White has been appointed assistant to Dr. Child. Capt. Orlando H. Petty, attached to the Fifth Regiment, U. S. Marine Corps, has been awarded the Congressional Medal of Honor by President Wilson for courageous care of wounded during the battle of Belleau Wood, June 11.

**Pathologic Laboratory Dedicated.**—December 11, a new pathologic laboratory was dedicated at the Philadelphia General Hospital. The building, which is three stories high, cost with equipment about \$300,000. It was built with an appropriation from the city councils, which have also provided an annual budget for a corps of men in all departments of laboratory work. The exercises were opened with a brief address by Dr. Riesman, chairman of the committee on dedication. Dr. Wilmer Krusen, director of public health and charities, received the keys from the architect, Mr. Philip Johnson, and accepted them on behalf of the mayor of the city. The principal address was delivered by Dr. William H. Welch of Johns Hopkins University, who spoke of the important part played by morbid anatomy in the advancement of medicine. Drs. Arthur Dean Ewan, Chicago, and Louis B. Wilson, Rochester, Minn., also spoke. Inspection of the building followed the exercises.

**CANADA**

**University Will Rebuild.** Laval University, Montreal, will raise \$3,000,000 for the purposes of a new university, to replace the old buildings recently destroyed by fire. The building of students' quarters was also mooted at the organization meeting, as well as pensions for all the members of the staffs of the various faculties.

**Personal.**—Sir Andrew McPhail, Montreal has resigned as chief editor of the *Canadian Medical Association Journal*, on account of impairment of vision. Prof. John G. (Alan) has resigned from the chair of pathology of McGill University, Montreal, to accept the chancellorship of the University of Liverpool, England. Major Fred J. Colling, C. A. M. C., Toronto, who had charge of the medical services for the British military mission, Siberia, has returned to Toronto. Previous to going to Siberia he served three years with the Royal Army Medical Corps in France. Dr. J. Harold

White, Moose Jaw, Sask., who saw service with the Royal Army Medical Corps in Gallipoli, Egypt, and other places, and who was also on the western front, passed through Toronto recently on his way to the Pacific coast. He will return east shortly and spend the winter in Peterboro, Ont.

Dr. John B. Playter McMurrich, professor of anatomy in the University of Toronto, and director of the anatomic department, has been elected dean of the faculty of arts. Dr. George F. Stephens has been appointed superintendent of the Winnipeg General Hospital. Dr. Henry R. Storrs has been appointed superintendent of St. Paul's Hospital, Vancouver, B. C. Dr. William C. Arnold, Dubuc, Sask., head of the medical branch of the Soldiers' Civil Reestablishment for Saskatchewan, has been appointed deputy director of medical service for Canada with the department.

**GENERAL**

**Change of Meeting Place.**—Unavoidable circumstances have necessitated the change of the meeting place of the Federation of American Societies of Experimental Biology. This meeting, which was to have been held at Toronto, December 29 to 31, will be held on the same dates at Cincinnati.

**Tri-State Physicians Elect Officers.**—At the thirty-fifth annual meeting of the Tri-State Medical Association of Mississippi, Arkansas and Tennessee, held in Memphis, November 18 to 20, under the presidency of Dr. James W. Gray, Clarksdale, Miss., the following officers were elected: president, Dr. John F. Sanders, Blytheville, Ark.; vice president, Drs. Thomas F. Hudson, Luxora, Ark.; secretary, Dr. Arthur F. Cooper, Memphis, and treasurer, Dr. James A. Vaughan, Memphis (re-elected).

**The Work of Nurses in the War.**—A report of the work of army nurses on the western front, from May 8, 1917, to May 31, 1919, has been rendered to the Surgeon-General, by Miss Julia C. Stimson, acting director of the Army Nurse Corps. Of the 21,430 nurses of the Army Nurse Corps, 10,245 saw overseas service, 266 died, and three were wounded in action. All of the nurses of the American Expeditionary Forces were graduates and were recruited largely through the nursing service of the American Red Cross.

**Deficiency Appropriation Asked for Regulating Sale of Biologic Products.**—A deficiency appropriation of \$25,000 is asked by the United States Public Health Service to carry out the provisions of the act to regulate the propagation and sale of viruses, serums, toxins and analogous products, the expenditures being held necessary between February and June, 1920. The sum of \$30,000 additional is asked for the purchase and installation of furniture and equipment for additions to the Hygienic Laboratory at Washington, D. C.

**Bequests and Donations.** The following bequests and donations have recently been announced:

The city of Monticello, Ill., for the maintenance of a public hospital, \$100,000 and his residence property by the will of John Kirby, Monticello, Ill., and an additional \$5,000 in case this bequest proves insufficient.

Hospital for Sick Children, Toronto, \$5,000 by the will of W. D. Methew, Toronto.

Hospital for sick children, as a wing to the General Civic Hospital, Ottawa, Ont. \$100,000 by the will of Hiram Rowley, Ottawa.

St. Vincent's Hospital, New York City, \$3,000 on the birth of the first child, by the will of Mr. Eamne Rockwell Dennis.

Artery, N. Y., Hospital for the voluntary estate value of \$10,000 by the will of Ethan M. Robinson.

**Expenditures for Public Health.**—A number of reports on general medical and public health subjects have been made by the executive departments to the Congress. The Surgeon-General of the Public Health Service has reported the expenditure of \$197,708.74 of an appropriation of \$400,000 for the prevention of the spread of epidemic diseases. The expenditures are listed as follows: plague eradication measures—Louisiana, \$21,150, California \$25,518, Washington \$4,280, trachoma—Virginia \$519, Kentucky \$27,728, Tennessee \$3,477, North Dakota \$3,521; typhus fever prevention, Texas border \$40,296. Preventive measures, Cuba \$3,500, Baltimore quarantine \$12,140, Mexico \$2,531, South America \$2,516, China \$3,148, Italy \$2,750, miscellaneous \$17,471.

**Bill to Administer Patents.**—A bill to enable the Federal Trade Commission to act as trustee for patent holders introduced in both Houses of Congress. It reads:

Be it enacted by the Senate and House of Representatives in Congress assembled, That in any case in which the Federal Trade Commission is authorized to investigate and report on the validity of a patent, or in which the Commission is authorized to issue an order of compulsory license, or in which the Commission is authorized to issue an order of revocation of a patent, or in which the Commission is authorized to issue an order of cancellation of a patent, the Commission shall have the right to administer the patent in question, and to collect and distribute the royalties thereon, and to take such other action as may be necessary to carry out the purposes of this act.

ed, and otherwise to administer, on behalf of the United States, under such regulations and in such manner as the President shall prescribe, inventions, patents, and patent rights which said commission deems it to be in the advantage of the public to be so accepted, as these may from time to time be tendered it by the employees of the various departments or other establishments of the government, or by other individuals or agencies, and to cooperate, as necessity may arise, with scientific or other agencies of the government in the discharge of the duties herein set out.

Sec. 2 That the Federal Trade Commission be, and is hereby authorized, and empowered to collect fees and royalties for licensing said inventions, patents, and patent rights in such amounts and in such manner as the President shall direct, and shall deposit the same with the Treasurer of the United States, and of the total amount of such fees and royalties so deposited a certain percentage, to be determined by the President, shall be reserved, set aside, and appropriated as a special fund to be disbursed as directed by the President to remunerate inventors for some of their inventions, patents, and patent rights contemplated by the act as may prove meritorious and of public benefit.

Sec. 3 That the appropriations of any governmental department, bureau, office, or establishment, are hereby made available for the payment of the cost of the Patent Office for and in connection with the granting of patents contemplated by this act.

FOREIGN

**Personal.** Dr. John Graham has been appointed professor of anatomy in Anderson College of Medicine, Glasgow, succeeding Dr. Alexander M. Buchanan, deceased.—The Royal Society of London has awarded the Copley Medal to Prof. W. M. Bayliss for his contributions to general physiology and biophysics.

**Professorial Appointments.** At the University of Lyons, Dr. Mouriquand has been appointed professor of general pathology and therapeutics in place of Professor Lesieur, deceased, and Dr. Pelicard has been appointed professor of general anatomy and histology, succeeding Professor Renault, who has retired from active service.

**Secure Passage Early.**—The International Congress of Surgery will convene in Paris, July 19, 1920. On account of the expected rush of tourists next season, it is suggested that those who wish to attend the congress, engage their steamship passage as soon as possible. It is estimated that at least two million tourists will leave the United States next season.

**Personal.** Sir William Osler, Regius professor of medicine at Oxford University, who is reported to have been seriously ill with bronchial pneumonia, is now said to be improving.—Dr. William W. Peter and family sail from San Francisco for China, December 13, on the Pacific Mail Steamship Company, and are due to arrive in Shanghai, Jan. 10, 1920. Dr. Peter has been for ten years a missionary in China.

**Biologic Products Legislation in Spain.** The government of Spain has recently adopted regulations governing the manufacture, sale and importation of biologic products. Hereafter, before any product can be sold in Spain it will be necessary to obtain a license from the Inspección General de Sanidad. In the case of foreign products, their importation will be permitted only in case they have been licensed by the government of the country of origin, in addition to complying with all requirements for Spanish products.

**Franco-Swiss Interuniversity Conference.**—Delegates from German, French and Swiss universities met recently at Garmisch and made arrangements for interchange of students and professors with seats for corresponding work. Professors from Lyon and Vanvers of Lille were the French delegates for the medical schools, and they established the standards and requirements being practically identical in France and Switzerland, in the medical courses which correspond in corresponding semesters in either country. The same procedure in the other, Switzerland was arranged for the professors from Latin Switzerland and those from German Switzerland. The arrangements have to be ratified by the proper authorities before they can go into effect and they are expected to be certain.

LATIN AMERICA

**Paraguay Organizes for the Fight Against Tuberculosis.**—The *Revista Médica* states that the Liga paraguaya anti-tuberculosa has recently been organized at Asunción. The committee is headed by Dr. A. Barbero, president, J. B. Benza, vice president, J. M. Mernes, secretary, and J. P. Vera, treasurer. One of the first steps taken by the new league was to send a note of thanks to the association of women which has been collecting funds for construction of a pavillion for the tuberculosis.

Government Services

Personnel of the Medical Department

For the week ending December 12, there were on duty in the Medical Corps 2,244 officers; the Medical Reserve Corps contained 4,114, an increase of 116 over the previous week.

Foreign Correspondence

MEXICO CITY

Nov. 30, 1919.

The Academy of Medicine

This association has moved its offices to the medical school building which it occupied once and was compelled to give up about four years ago. In the meetings held last month, several important subjects were discussed. Dr. Demetrio López reported that he has begun to use the method recommended by Danielopulo for the treatment of typhus fever. This treatment consists, as can be seen from an abstract in THE JOURNAL (March 23, 1918, p. 891) in administering intravenous injections of chlorinated artificial serum. López, although not committing himself definitely, because of the small number of patients he has treated, says that the treatment has impressed him very favorably. The vacuum extraction of cataract according to Barraquer's method (summarized in THE JOURNAL, Oct. 25, 1919, p. 1318, and Dec. 8, 1917, p. 2006) was the subject of another communication by Dr. Velez. After studying carefully the technic of the Spanish oculist, he has practiced the operation both on cadavers and on patients, and declares himself pleased with the results. Dr. Velez showed Barraquer's original apparatus, and explained the advantages of substituting the aspirating pump of the original apparatus, which is operated by hand (somewhat like a bicycle pump but in the reverse direction), for one operated by electricity. Dr. Perrin presented a paper illustrated with films on the development of the embryo, and explained the different stages of the sea urchin after fecundation. Drs. Villarreal and Arroyo discussed the treatment of malignant cancer of the uterus through electro-coagulation and radium and the different methods of staining *Sprochaeta pallida*, and the respective diagnostic value of these methods.—As a guest of honor, the session of the 19th instant was attended by Dr. Roberto Maurer, the medical officer of the Uruguayan cruiser *Uruguay*, who is also connected with an official mission from his country to Mexico. Dr. Antonio F. Alonso, former corresponding member of the academy in the city of San Luis Potosí, after fulfilling the association requirements, has been appointed to a vacancy in the section on ophthalmology.

Sanitary Conditions in Mexico

There were only thirteen cases of typhus fever in this city during October. According to the sanitary authorities, this is due to compulsory bathing and delousing among the lower classes. There have been observed many foci of malaria of the acute, hemorrhagic type in different parts of the country. Such foci have been found in different states of the Pacific Coast from Sonora to Chiapas, on the Mexican Gulf, Tamaulipas, Veracruz, etc., and even in the center of the country as, for instance, at Guanajuato.

None of the gulf ports have been invaded by the plague, in spite of the active commercial relations with New Orleans, because even before official notice was received of the occurrence of plague in the United States, the department of public health of Mexico quarantined the ships proceeding from New Orleans.

Nothing new has been heard about yellow fever in Yucatan. It is understood that the disease is still present, since the quarantine against the port of Progreso is still in force.

**The Blind**

According to statistics that have been compiled recently, there are about 120,000 blind in this country, among a population of about 16,000,000. About 80 per cent of these cases seem to be due to ophthalmia neonatorum.

**Monument to a Physician**

There has been built in the cemetery of Tepeyac a monument to Dr. Antonio Márquez, who belonged to the Cruz Blanca (White Cross) Association. Dr. Márquez lost his life in this city when he was attending professionally the numerous persons wounded during one of the riots engineered by the reactionaries to depose President Madero in February, 1913. The monument was built on the initiative of the above mentioned society and the inauguration was attended by many prominent persons.

**Donation**

Mr. Edward L. Doheny, president of an American oil company, has given the sum of 4,000 pesos (about \$2,000) to the Sociedad Protectora del Niño (Infant Welfare Society). Other persons have also made generous gifts, among them being Mrs. Esther C. de Nieto.

**Personal**

Dr. Agustin García Figueroa, director of the National Library and well known as an author and politician, has died. Dr. E. Caturegli has been appointed on an official mission to London. Drs. Ocaranza and Izquierdo, professor and assistant professor of physiology in the school of medicine, have been designated members of the American Association for the Study of Internal Secretion. Dr. F. Castillo has begun to discharge his duties as chief of the medical-legal corps of the federal district. Dr. Pedro Fuentes has been appointed member of the superior board of public health to fill the vacancy left by the death of Dr. Fructuoso Valdés. Dr. Theodore C. Lyster, former colonel of the U. S. Army, is now in Mexico representing the yellow fever commission of the Rockefeller Foundation, headed by General Gorgas. Dr. Lyster has conferred with Dr. Jose Maria Rodriguez, director of the superior board of public health, who offered to help him in every possible way. Dr. Lyster expects to visit Merida, Yucatan, to continue his experiments on yellow fever; and after completing his work there, plans to go to Brazil.

**LONDON**

Nov. 19, 1919

**The Declining Birth Rate**

The great loss of life in the war has drawn increased attention to our declining birth rate. At the last sitting of the National Birth Rate Commission, Sir Rider Haggard (the author) said that within the last half century it had become known that the birth rate could be kept down by artificial means. Woman had once more eaten of the fruit of a forbidden tree of knowledge. At first, the practice was confined to the upper classes, but now it seemed that it was gradually spreading through the whole community of every western nation and in one, France, was in full operation, so that the death rate exceeded the birth rate, which continued to fall. In our educated and professional classes many causes combined to prevent increase, as was evidenced by the number of "only sons" killed in the war. The maternal instinct was not highly developed in a considerable proportion of modern women, nor was the paternal instinct always strong in men. It was not right that civilized woman should become a breeding machine, but if able to do so without injury to health, a married woman should enrich the population by four or five children. Yet the average number of children in the classes mentioned was 2.3. The teeming millions of the East were ancestor worshippers and polygamists. Unless some startling change occurred, it appeared as though within the next two centuries the dominion of the western races would cease, as that of Rome ceased, perhaps before a new influx from the East beneath which their remaining population would be submerged. He saw only one hope. Perhaps the vast female electorate, which was coming into being, would as a mass bring pressure to bear on individual selfishness, and change the attitude of the nation toward this vital problem.

At the church congress, Dr. Amand Routh (the gynecologist) read a paper on the birth rate. He said that the

natural increase of population for the first time in our statistical history had ceased, for during the six months ending March 31, last, the deaths in England and Wales, exceeded the births by 126,445. Smaller families in the upper and middle classes were mainly the result of widespread knowledge of how to prevent conception. It was often arranged before marriage or early in the honeymoon that for a certain number of years conception was to be avoided. Was it ever right to avoid conception permanently in the marriage state? He believed not except for medical reasons. The ideal would be that no methods of conception control, except abstinence, should be used without previously obtaining the advice of a physician. There were medical reasons why a given couple should not have further children; but the physician should decide. There were four groups of alternatives which under varying circumstances might be adopted to discourage artificial control of conception: continence; occasional abstinence "with consent for a time," as advocated by St. Paul; midintermenstrual abstinence, as sanctioned by most of the churches, and natural alternatives to conception control. The question to decide was whether the relatively poor who had large families should be so educated in all the methods of conception control that they should have the same knowledge and be supplied with the same appliances as the rest of the community; or whether we should not concentrate rather on educating the middle and upper classes and warn them through the agencies of the church and the medical profession of the dangers, national disloyalty and moral wrong of contraceptives. Our nation owed its position in the world to its former large families and could not have too many children today for it to protect and populate its colonies.

**PARIS**

Nov. 13, 1919.

**Loss of Life in the War**

M. Louis Marin has just published statistical information covering the loss of life caused directly by the war of 1914-1918, as shown by official reports from all branches of the service.

The losses of the French army (officers and privates) up to the time of the armistice, Nov. 11, 1918, according to the figures established up to June 1, 1919, were 1,354,400. Since the armistice, 600 officers and 28,000 privates, under treatment in the hospitals, have died as the result of wounds or disease. The losses in the French land forces, as reported June 1, 1919, have risen to 1,383,000; but the death of only 1,322,400 is definitely known, the balance, 20,600, being unaccounted for. This final report of losses (dead and unaccounted for) represents 16.44 per cent of the mobilized war effective of 8,410,000 men (195,000 French officers, 7,740,000 French privates, 200,000 territorials from northern Africa, and 215,000 colonial troops).

Since the beginning of the war, 4,193,981 wounded and 4,988,213 sick have been admitted to hospitals. Many men were admitted several times. M. Marin estimates the number of wounded officers and privates at 2,800,000.

The total losses of the French land forces are, therefore, 1,383,000 killed (dead or unaccounted for) and 2,800,000 wounded, half of whom were wounded more than once. Of the 1,383,000 killed, 36,800 were officers. The number of French prisoners captured during the war was 495,400.

The final report of losses in the French navy cover 10,515, of whom 5,521 are known to have died, while 4,994 were unaccounted for.

The losses in the allied armies up to Nov. 11, 1918, in dead and unaccounted for were: Belgium, 440,000; Great Britain, 809,000 (682,000 from the United Kingdom and 127,000 from British dominions and colonies); Greece, 12,000; Italy, 494,000; Roumania, approximately 500,000, which includes, however, living prisoners; Russia, 1,200,000 (based on doubtful information dating from October, 1917); Serbia, 297,000; and the United States, 114,000.

The number of living prisoners up to Nov. 11, 1918, for the various allied armies was: Belgium, 70,000; British Empire, 171,000; Greece, 7,400; Italy, 485,000; Russia, 2,000,000; Serbia, 82,400; and the United States, 4,800.

The losses in the enemy armies are thus estimated by M. Marin: Austro-Hungarians, 1,522,817 killed or unaccounted for (presumably dead); Bulgarians, 101,224 killed or unaccounted for; Germans, 2,041,000 killed and unaccounted for (presumably dead); and Turks, 325,000 killed.

**Birth Rate Propaganda and the Election Campaign**

The Comité permanent de la natalité (created by the Congrès national de la natalité et de la population held in Nancy,

Sept. 25 to 28, 1919 (THE JOURNAL, Nov. 1, 1919, p. 1377), has decided to initiate very active propaganda in favor of such legislative measures as appear indispensable to effect an increase in the French birth rate and to establish anew vigorous and prolific French families. The Comité permanent de la natalité was presided over by M. Paul Deschanel, president of the chamber of deputies. In a public declaration the committee demands that the candidates at the parliamentary elections shall insert in their platform the following legislative measures: (1) the household franchise, a bill that proposes to amplify the elective franchise of the heads of families; (2) relief of heads of large families from the unusual financial burdens now resting on them; (3) special concessions, premiums and gifts in favor of large families; (4) the campaign against wretched tenement houses, with a view to procuring hygienic apartments and good moral surroundings for large families; (5) repression of abortion and the so-called neomalthusian propaganda; the accord of the right of direct summons to the Public Morality League (in consideration of the furnishing of suitable bonis), in order that the league may be given the opportunity of "cleaning up" a street and of watching over and endeavoring to make more effective the laws for the protection of the family and of childhood; (6) relief, in time of peace, of large families from a portion of their military burdens, and (7) the establishment of a national office in charge of all matters pertaining to the raising of the birth rate.

#### Personal

At a recent meeting the Academy of Medicine elected Dr. Vaquez to active membership in the section on therapeutics and natural history as applied to medicine, to succeed Fr. L. Ranhaud Blanchard. Dr. Vaquez is professor of internal pathology on the Paris Faculty of Medicine.

#### Death of Dr. J.-L. de Lanessan

Dr. J.-L. de Lanessan, former minister of marine, died recently in his estate at Ecouen, at the age of 76. De Lanessan was born at Saint-André-de-Tulzac, July 13, 1843. He studied medicine for a time, and later was admitted to the naval sanitary corps, from which he resigned in 1870 and returned to Paris, where as a collaborator of Baillon he became agrégé professor of natural history on the Faculty of Medicine. During this period he published the "Manuel d'histoire naturelle médicale." Later de Lanessan was tempted to enter politics. He became municipal counselor at Paris in 1879, and two years afterward he was elected to the chamber of deputies. His knowledge of colonial affairs caused him to be appointed in 1891 governor general in Madagascar. In 1899, he accepted, in the Waldeck-Rousseau cabinet, the office of minister of marine, in which position he displayed great activity and put through a number of important reforms. De Lanessan published a large number of works on political subjects: "De la colonisation," "Nos forces navales," "Nos forces militaires," "Le Bilan de notre marine," "Les Empires germaniques," "Histoire de l'Entente cordiale franco-anglaise," etc.

### Marriages

REMY DE NOHIEL, Nelson, Horton, Wis., to Miss Pauline M. Donald of Prescott, Ariz., September 17.

EDITH HARRIS ANDERSON, Omaha, to Miss Helen M. Mangel, at Chicago, September 3.

JOSE A. WELLS, Hales Corners, Wis., to Miss Lillian Graham of Burlington, Wis., October 22.

JOHN H. WATSON, to Miss Zoe Burnsted, both of Chetek, Wis., October 22.

THEODORE LINDENSON, GURBERT, Dallas, Texas, to Miss Dorothy Balthus at Gard, Ct., E. I., N. Y., October 4.

ANDREW P. KENNEDY, Cthersville, Ind., to Miss Mentoria M. Deane, October 5.

FRANK LAURE WYSON, to Miss Jennie Goodwin Snead, both of Linton Park Va., October 25.

EMMETT FRANCIS REESE, to Miss Lynie Ridley, both of Courtland Va., November 5.

WILLIAM RUSSELL ELLISON, Baton Rouge, La., to Miss Mary Wynona Simmons of Enterprise, Ala., November 4.

STANLEY J. BOWN to Miss Anna Mae Martin, both of Richwood, Ohio, November 15.

### Deaths

Louis Augustus Speth, Philadelphia; Bellevue Hospital Medical College, 1894; aged 56; a graduate of the New York College of Pharmacy, in 1891; a veteran of the war with Spain; acting assistant surgeon, U. S. Army, from 1900 to 1902, with service in the Philippine Islands; from 1907 to 1909 on duty with the Panama Canal Commission; major, M. R. C., U. S. Army, and honorably discharged Dec. 12, 1918; died in the Abington (Pa.) Memorial Hospital, December 3.

Edward O. Powers, Baton Rouge, La.; Tulane University, New Orleans, 1896; aged 54; a member of the Louisiana State Medical Association; a member of the general assembly from 1904 to 1908, and of the state senate since 1916; died in the Baton Rouge Sanitarium, December 1, as the result of injuries received in an automobile accident, November 29.

Paul Barnett Coble \* Capt., M. R. C., U. S. Army, Indianapolis; Central College of Physicians and Surgeons, Indianapolis, 1905; aged 35; died, May 11, at Camp Hospital No. 1, Gondrecourt, France, from the effects of phosgene self-administered, it is believed, with suicidal intent.

Samuel Houston Landrum \* Altus, Okla.; University of Nashville, Tenn., 1899; aged 52; honorably discharged as lieutenant, M. R. C., U. S. Army, Dec. 21, 1918; while making a night call near Altus, during a blizzard, November 27, was killed by the overturning of his automobile.

Henry Clinton Hood, Palm Beach, Fla.; Long Island College Hospital, Brooklyn, 1883; a pioneer practitioner of Palm Beach; a member of the Inlet commission and during 1917 a member of the legislature; died at the Emergency Hospital, West Palm Beach, November 18.

Otto Nicholas Bergmeyer, Dayton, Ky.; Eclectic Medical Institute, Cincinnati, 1916; aged 31; who was honorably discharged as first lieutenant, M. R. C., U. S. Army, Jan. 9, 1919; died, in Seton Hospital, Cincinnati, November 24, after an operation for appendicitis.

Washington Kilmer, Orlando, Fla.; Albany (N. Y.) Medical College, 1860; aged 81; a member of the Florida Medical Association; a veteran of the Civil War; one of those who combated yellow fever during the epidemic in Florida in 1887; died, November 24.

George Hamilton Stubbs \* Birmingham, Ala.; Southern Medical College, Atlanta, Ga., 1895; aged 50; oculist and oculist to St. Vincent's and Hillman hospitals, and to the Southern and Alabama Great Southern Railroads; died, November 28.

James M. Walker, Denver; Homeopathic Medical College of Missouri, St. Louis, 1871; aged 72; for six years a member, and for three years president of the State Board of Medical Examiners; a veteran of the Civil War; died, December 3.

Vaulx Gibbs, Chattanooga, Tenn.; University of Nashville, Tenn., 1878; aged 63; a member of the Tennessee State Medical Association; formerly physician in charge of the East Tennessee Home for Disabled Soldiers; died, November 30.

Henry Gansevoort Cooke, New Brunswick, N. J.; College of Physicians and Surgeons in the City of New York, 1857; aged 86; formerly a member of the attending staff of Wells Memorial Hospital, New Brunswick, died, December 4.

James Haggerty Struble, Kearny, N. J.; Albany (N. Y.) Medical College, 1869; aged 77; a veteran of the Civil War; formerly practitioner and druggist in Passaic, N. J.; died in the Home for Disabled Soldiers, Kearny, December 3.

David Albert Gleason, North Bennington, Vt.; Baltimore Medical College, 1896; aged 49; a member of the Vermont State Medical Society, district surgeon to the Rutland Railroad; died, December 4, from cerebral hemorrhage.

Charles Pickhardt Haller, Bridgeport, Conn.; Hahnemann Medical College, Philadelphia, 1902; aged 49; honorably discharged as captain, M. C., U. S. Army, May 11, 1918, on account of physical disability; died, November 9.

Lionel Rideout Lumby, Pontiac, Mich.; University of Michigan, Homeopathic Medical School, Ann Arbor, 1893; aged 54; a member of the Michigan State Medical Society; died, November 21, from angina pectoris.

T. Eugene Stokes, Greenville, S. C.; Atlanta (Ga.) Medical College, 1889; was killed near Duncan Mills, November 24, by the overturning of the automobile in which he was riding.

\* Indicates "Fellow" of the American Medical Association.

**Terrence Gustavus Riley** † Harrington, Del.; University of Pennsylvania, Philadelphia, 1888; aged 54; while performing a surgical operation at the home of a patient in Harrington, November 26, died suddenly.

**William P. Gamber**, Ann Arbor, Mich.; Western Reserve University, Cleveland, 1881; aged 64; formerly secretary of the board of education of Stanton, Mich.; died, November 17, from chronic nephritis.

**Edward Blanchard Patterson**, Sandpoint, Ida.; University of Michigan, Ann Arbor, 1886; aged 61; a Fellow of the American Academy of Medicine; died, November 5, after an emergency operation.

**Hazenwood A. C. Bradfute**, Loyston, Tenn. (license, Tennessee, 1889); aged 74; a practitioner for more than fifty years; a veteran of the Civil War; died, November 15, from bronchopneumonia.

**Charles Winthrop Fish** † Los Angeles; Western Reserve University, Cleveland, 1884; aged 59; one of the founders of the Pacific Hospital; died, November 25, from septic pneumonia.

**John McFaydan**, Yuba City, Calif.; University of Pennsylvania, Philadelphia, 1876; aged 69; died in the Rideout Hospital, Marysville, Calif., November 24, from heart disease.

**Thomas Greenwood Howard**, Selma, Ala.; Washington University, Baltimore, 1868; aged 71; a member of the Medical Association of the State of Alabama; died, November 23.

**Oliver M. Beck**, Feesburg, Ohio (license, Ohio, years of practice, 1896); aged 86; a practitioner of Brown County for sixty-three years; died, October 23.

**Virgil E. Andrew**, Indianapolis; Central College of Physicians and Surgeons, Indianapolis, 1890; aged 58; died, September 26, from cerebellar cyst.

**Henry L. Hutson**, Garwood, Texas (license, Texas, Fifth Judicial Board, 1901); aged 46; was found dead from heart disease, in his office, November 29.

**Eleanor E. Fish**, Chicago; Loyola University, Chicago, 1910; aged 50; died in a drugstore in Chicago, December 6, from organic heart disease.

**W. G. Drummond**, Bryan, Texas (license, Texas Twentieth Judicial District Board, 1899); aged 51; died, November 24, from cerebral hemorrhage.

**Oscar L. Peak** † Topeka, Kan.; Cincinnati College of Medicine and Surgery, 1878; aged 70; died, November 29, from cerebral hemorrhage.

**George W. Newcomer**, Connellsville, Pa.; Physio-Medical Institute, Cincinnati, 1867; aged 74; a veteran of the Civil War; died, November 21.

**William Benjamin Kayler**, Toronto; Queen's University, Kingston, Ont., 1896; aged 58; died, September 7, from carcinoma of the stomach.

**Clark Everon Brothers**, East Akron, Ohio; Eclectic Medical Institute, Cincinnati, 1881; aged 66; died, December 2, from heart disease.

**George W. Vickers** † Phoenix, Ariz.; Starling Medical College, Columbus, Ohio, 1882; aged 66; died, August 27, from heart disease.

**Elizabeth Cubbage Geis** † Casper, Wyo.; Chicago College of Medicine and Surgery, 1914; aged 34; died, November 19, from pneumonia.

**Gaston Boyd**, Newton, Kan.; Medical College of Ohio, Cincinnati, 1874; aged 75; for several terms mayor of Newton; died, recently.

**Francis M. Sexton**, Las Cruces, N. M.; Tulane University, New Orleans, 1876; aged 69; died, November 3, from cerebral hemorrhage.

**John Leffler**, San Francisco, Cooper Medical College, San Francisco, 1874; aged 77; died, November 26, from chronic nephritis.

**Harry Spenser Brown**, Chicago; McGill University, Montreal, 1873; aged 73; died, November 26, from cerebral hemorrhage.

**Homér W. Osborn**, Cleveland; Homeopathic Hospital College, Cleveland, 1871; aged 76; died, November 20, from heart disease.

**Laurence Frank Keith**, Wareham, Mass.; Boston University, 1907; aged 36; died, September 19, from valvular heart disease.

**Jonathan L. Wilkinson**, Dundas, Ont.; Victoria University, Coburg, Ont., 1870; aged 80; died, October 4, from pneumonia.

## The Propaganda for Reform

IN THIS DEPARTMENT APPEAR REPORTS OF THE JOHNSON'S BUREAU OF INVENTION, OF THE COUNCIL ON PHARMACY AND CHEMISTRY, AND OF THE ASSOCIATION LABORATORY, TOGETHER WITH OTHER MATTER TENDING TO AID ILLICITLY PRESCRIBING AND TO OPPOSE FRAUD ON THE PUBLIC AND ON THE PROFESSION

### LACTIC ACID FERMENTS

#### Report of the Council on Pharmacy and Chemistry

The following report has been authorized for publication by the Council. The revised general article on Lactic Acid-Producing Organisms and Preparations, which will appear in New and Nonofficial Remedies, 1920, is published in the New and Nonofficial Remedies department of this issue of THE JOURNAL.

W. A. PUCKNER, Secretary.

In preparing the 1920 edition of New and Nonofficial Remedies it seemed desirable to give careful reconsideration to the use, in medicine, of lactic acid bacteria—and products prepared by means of these bacteria—in relation to practical therapy. A special committee consisting of a physiologic chemist (Lafayette B. Mendel, chairman), a pediatricist (John Howland), an internist (W. P. Longcope), a rhinologist (H. I. Lillie) and a bacteriologist (L. F. Rettger) took up the problem. The following circular letter was sent to a large number of well-known bacteriologists, clinicians and manufacturers who might be assumed to have experience or information which would enable them to express a helpful opinion on certain debated questions relating to the practical use of lactic acid bacilli in clinical medicine:

"Dear Doctor: The Council has been discussing the question as to whether or not the lactic acid-producing organisms, and preparations produced by their action, shall be retained in New and Nonofficial Remedies; and if so, what, if any, revision should be made of the general discussion now appearing in the book.

"Although there is still wide diversity of opinion as regards the possible value of these products, either as administered by mouth or for application to arrest putrefaction in wounds, the enthusiastic support of their use on the part of their former advocates seems to have abated in recent years. As the time for more exact judgment concerning their therapeutic value appears opportune, the Council would value your opinion on any or all of the following questions:

"1. Do you regard the administration of milk soured by means of the Bulgarian bacillus, alone or in combination with other organisms, to have advantages over the administration of sweet milk, buttermilk or milk soured in the ordinary way? If so, what advantages may properly be ascribed to milk preparations obtained by action of the Bulgarian bacillus?

"2. Do you consider it rational to administer preparations containing viable cultures of the Bulgarian bacillus with the expectation of securing their implantation in the intestinal canal? On what facts or evidence do you base your opinion?

"3. Do you consider the application of cultures of the Bulgarian bacillus to infected suppurating sinuses, cavities, etc., rational? On what facts or evidence do you base your opinion?

"4. If in your opinion there is therapeutic value in products of Bulgarian bacilli, what revision of the article 'Lactic Acid Producing Organisms and Preparations' which now appears in New and Nonofficial Remedies (see enclosure) would you advise?

"5. Have you had occasion to employ preparations of viable cultures of *Bacillus acidophilus* for any of the purposes indicated in 2 and 3? Do you favor the inclusion of *Bacillus acidophilus* preparations in New and Nonofficial Remedies?

"In answering these questions it should be borne in mind that, though products shown to be worthless are not accepted for New and Nonofficial Remedies, preparations which give promise of therapeutic usefulness are accepted; in fact, New and Nonofficial Remedies is naturally a book devoted to medicaments in the experimental stage.

"Your reply to all or any of the above questions will be appreciated."

The replies to this letter, while they have been decidedly valuable to the committee, show considerable divergence of

opinion. In general it seems that the bacteriologists and scientific laboratory workers show far less enthusiasm for the claims of lactic acid bacteria to a place in practical therapy than do the clinicians. The information on many points is, however, still so vague and empirical that it is almost impossible to formulate a rational plan based on acceptable scientific evidence. In view of the enthusiasm with which the use of the products is heralded by a considerable number of clinicians, whose opinions are evidently based on empirical data, it seems advisable to the committee, pending the acquisition of further knowledge, to retain those preparations in N. X. R. in the present with a revised statement regarding their possible usefulness.

The committee's opinions have elicited the general opinion that the lactic acid bacilli must be effectively implanted in the alimentary tract by the cultures thereof and that it is not rational to attempt such an implantation. The overwhelming preponderance of opinion is against the usefulness of cultures of the bacilli in infected sinuses, cavities, etc.

In view of the uncertainty regarding the rôle of the bacilli in epilepsy the committee recommends that cultures in this connection be not included in N. X. R. at present.

Information from various sources indicates the importance of controlling the ability and purity of the cultures offered for sale. This the Council has done in the past and must do in the future. The committee submits a revised statement in N. X. R. 1-20 with the recommendation that all preparations of lactic acid products listed therein be made in conformity therewith.

## Correspondence

### "INFLUENZA AND EPILEPTIFORM ATTACKS"

*The Editor:*—Dr. L. Pierce Clark (*THE JOURNAL*, Dec. 5, 1919, p. 1772) introduces his report of a case of influenza and epileptiform attacks with the words: "Since no case has as yet been reported in which epilepsy or epileptiform attacks were apparently first initiated by influenza. . . ." Of course, Dr. Clark must mean that no such case has been reported from the 1918-1919 epidemic of influenza, since there are numerous cases in the literature from previous epidemics, at least one. But the present epidemic of influenza seemed to have a much more potent effect on patients already afflicted with epilepsy than of the direction of producing epilepsy or epileptiform syndromes. Maillard G. and Brunc, in the *Annales de l'Épilepsie*, 27:70 [Feb. 10] 1919, consider the topic "Epilepsie et épilepsie" under the heads of (1) "The Influence of Influenza on Epilepsy," and (2) "The Influence of Epilepsy on Influenza" and the latter was certainly much more pronounced in France than the former.

I have personally communicated with practically all the foreign authorities in the United States in regard to the onset of influenza in epilepsy, and in answer to the query as to whether any cases had been admitted for whose epileptic attacks followed had been given or considered a corroborating answer there was a unanimous reply of "None." (See *Journal of Nervous and Mental Disease*, 1919, 49:103.) However, we had no such case, although we had a number of convulsed epileptics whose disease was undoubtedly aggravated by the influenza.

Consequently, Dr. Clark's claim for priority in the report of an epidemic of epilepsy precipitated by influenza is, like many similar claims, probably ill justified. In regard to the importance to be attached to previous epidemics, one may well recall the occurrence of a series of "Influenza Leçons" in the *Revue de Médecine et de Chirurgie* for 1890 which is mentioned in the matter is well summarized in his article on "Influenza, Épilepsie, Choléra," volume on Malaria, Influenza, Diphthérie, etc., page 63 of the English translation, "Influenza, épilepsie, le choléra" in children with an epidemic of cholera, and very rarely in adults with typical influenza, often attended with total unconsciousness and convulsions, etc." Leichtenstern then goes on to con-

sider "those cases in which directly following the influenza attack a typical but chronic epilepsy develops." He thinks that all of these cases end in recovery and believes that there is no case on record of permanent epilepsy following influenza. He then cites one case in detail, and proceeds to the discussion of "many other forms of convulsions and disturbances in movement" observed subsequent to influenza.

Leichtenstern also points out that the early German name for influenza, *Blut-katarrh*, had reference to the sudden onset of the disease, and cites various forms of convulsive onsets, as on pages 513 and 519 of the reference cited above, in these cases chiefly in children.

Other references are:

Rulemann, J. Die Influenza im den Winter 1889-1890, Leipzig, 1891 (a monograph of 188 pages).  
Lindgraf, Gesellschaft der Charité Aerzte in Berlin; *Berlin, Klin. Wochenschrift*, 1890, Nos. 9 and 12.  
Van Deventer, *Centrabl. f. Nervenh. u. Psychiat.*, 12:49.  
Jaccoud, *Pathologie interne*, Paris, 1870, p. 780; *Nouveau Dictionnaire*, Paris, 1873, Part 16, p. 740.

These references and a brief discussion of the subject were presented in the course of a more general article in the *Archives of Neurology and Psychiatry* (September, 1919, pp. 291-337).

Finally, one is moved to inquire if the child reported by Dr. Clark were not possibly hypophrenic or at least retarded to start with. A child capable, at 2 years of age, of only "some words" and the ability "to walk with slight support," would hardly be considered up to normal standards, unless the brief reference to these faculties has permitted too wide an inference.

KARL A. MENNINGER, M.D., Topeka, Kan.

### "THE OMISSION OF DRAINAGE IN COMMON DUCT SURGERY"

*To the Editor:*—I have welcomed the important communication of Drs. Richter and Buchbinder on this subject in *THE JOURNAL*, December 6. Although undoubtedly not giving the last word, the authors serve the good purpose of stimulating controversy on the vital subject of drainage of the common bile duct—a subject which in greater part surgeons the world over seem to regard as settled.

The authors emphasize the desirability of closing the abdominal wound without drainage in order to avoid adhesions, taking it for granted, I presume, that it would be superfluous to call attention to the much more serious and occasionally disastrous results which follow the prolonged loss of bile by way of the incision into the common duct. To surgeons who are not prepared to follow the example of Drs. Richter and Buchbinder I would recommend drainage of the common duct by a small tube passed well into it through the cystic duct. This is the method practiced by me at present. The incision into the common duct is closed with great care and the line of suture tested by injections through the tube in the two ducts. On the third or fourth day the tube is clamped and, if the bile is found to pass freely into the ductus choledochus, is removed. Usually the leakage thereafter of bile is insignificant in amount; there may even be merely a slight stain on the first dressing after removal of the tube.

All that we gain as a rule by drainage of the bile duct is relief of tension. This relief is afforded by drainage by way of the cystic duct and tends to insure prompt healing of the line of suture of the common duct. Aside from the deplorable condition of the patient brought about by the great loss of bile, it seems irrational to me to place a drain in the infected common duct through the line of the incision into it with the expectation that primary healing of the wound in the duct will usually take place. Unquestionably the entire line of suture, contaminated inside and out with pus-producing organisms and further imperiled by the presence of the tube, has in many instances broken down.

Very slim cigaret drains (three or four or more) should surround the tube in the cystic duct and be removed with it on the third or fourth day. The gauze tips which serve to hold the drains in place should project hardly if at all

## Book Notices

WAR NEUROSES AND STRESS SYNDROMA. By Fred W. Mott, F.R.S., F.R.C.P. Second Edition, in two Volumes. Neurological, Changing Edition. With a Preface by the Rt. Hon. Viscountess Addison, M.P. London, 1919. \$6.00. 348, with illustrations. New York: Oxford University Press, 1919.

In this book are collected the results of an exceptionally wide experience of neuroses developing in the British Army. Throughout it presents the appearance of a collection of cases, mostly brought together owing no doubt, to the need for such a source of information on the part of medical officers engaged in the work of reconstruction. The material shows a lack of grouping, and there is a somewhat confusing transition from one topic to another. Part of this is due to the fact that Dr. Mott, before the war, interested himself almost wholly in pathologic histology and anatomy, and he evidently finds it difficult to feel quite at home in discussing disorders which he recognizes as psychogenic in nature. Unfortunately, the author also has repeated the views which he published in 1916 on the nature and causation of shell shock, although he admits that he has been obliged since then to change them. He makes it quite clear that he recognizes two types of cases, the one due to real structural damage to the nervous system, for which he uses the term "compensational shock," and the other, by far the more frequent, which is functional in character and which he calls "emotional shock." Obviously the two are quite distinct, although they may occasionally be present in the same case. To call them both shock, therefore, is simply to perpetuate the grave error, which belongs to the title shell shock, long since discarded by the British Army. In the text these two types of disorder are perplexingly mixed at times.

The areas of structural lesion due to the effects of high explosives are admirably described and discussed. Excellent illustrations of the histologic changes are given and comparisons made with the effects of carbon monoxid poisoning, so which Mott had previously done much work. The descriptions of the various forms of functional disorder are excellent and well illustrated by cases. No essential difference between the war neuroses and psychoses and those of peace times were discovered, although the symptomatology was found to be colored by the military nature of the conflicts and experiences that called them forth. The views expressed with regard to prognosis are entirely sound, though not given with the same detail as is done in the case of histologic lesions. The differentiation from malingering is discussed clearly and interestingly. In an appendix is a valuable and well illustrated summary of the methods of study and examination of patients.

In spite of a few minor drawbacks, the book is a decided contribution, generally well founded, helpful to the general practitioner, and one which the busy practitioner cannot afford to be without.

Medical Director, Department of Psychiatry, D. C. L. Officer, Army Medical Service, Washington, D. C., and Lecturer, 1920.

THE UNIVERSITY OF CHICAGO. 1919-20. Second Year of Its Program. Chicago, 1919. 47 pages. Price of amount per week (approximately) \$1.00. Chicago: University of Chicago, 1919.

These tables have been given before the profession for many years and appear in the same form as previously, containing data on first aid, dosage, weights and measures, statistical tables, etc. For the physician they constitute an acceptable and useful little Christmas gift.

### Emergency Treatment Obtained Without Notice to Employer

Board of Control of Pontiac State Hospital (Mich.),  
172 N. W. R. 530a

The Supreme Court of Michigan, in affirming an award of \$189 made against the defendant by the state industrial accident board, in favor of the plaintiff for medical, surgical and hospital expenses incurred by him as the result of an accidental injury which he sustained while in the defendant's employ, holds that cases may arise in which the employer will be liable for such expenses although not given an opportunity to furnish needed medical and hospital services as required by the workmen's compensation act. The court says that in this case the plaintiff, in attempting to lift or carry some material, experienced an injury, the nature of which he did not then apparently understand or localize, but which caused him to suspend work, telling his "boss," who was the superintendent, that he was sick and had to go home, which he did, arriving there between 9 and 10 o'clock, as his wife testified, not yet knowing what ailed him. Shortly before noon he discovered that he was suffering from a hernia. During the day he experienced increasing pain and grew weaker. His wife summoned their family physician, who called shortly after supper, and found the plaintiff suffering with a strangulated femoral hernia, which in the physician's opinion, demanded prompt surgical action, and he at once called in for consultation a surgeon in whom he had confidence, and an immediate operation was deemed by them necessary to save the patient's life. He was thereupon taken in an ambulance to the city hospital before dark that evening, and operated on almost immediately, remaining in the hospital nineteen days. Was the defendant employer liable for the expenses thus incurred? It appeared undisputed that within twenty-four hours after the accident the defendant was fully notified of it, and told where the plaintiff then was, by his wife, who requested aid in his behalf. After such notice, request, and reasonable opportunity to furnish or offer the required treatment, and failure to act, the defendant was clearly liable for the plaintiff's reasonable expenses in securing them during the remainder of the three weeks after the injury. The more serious question was that of the expenses incurred in the claimed emergency prior to notice.

In this case there was, as the result of prompt and efficient action after the plaintiff's critical condition was discovered, an early and full recovery, at small expense to the defendant compared with a death loss, which was threatened and would have been the result of delay until the following morning, as the undisputed medical testimony showed. It was indicated that the plaintiff, after his return home and his distress increased, was not in a physical or mental condition to judge or act in the matter. His wife was not shown to have then known he had sustained an accidental injury. She knew he was sick, and, when his condition indicated the need, called in their family physician, who recognized the emergency. Broadly considered the statute as to medical service to be paid for by the employer involves the combined interests of both parties. What services were actually and reasonably necessary to that end, and what is a fair compensation therefor, are the vital inquiries.

Unquestionably that construction of the statute is logical, and the adopted rule sound, which requires notice and opportunity to the employer to select the physician and furnish the needed service during the prescribed three weeks before the injured party can secure it at the employer's expense; but in the many complications which arise in industrial activities it is not an unreasonable or strained construction of the statute, in view of its purpose, to recognize as inferable exceptions in extraordinary cases when the surrounding circumstances and critical condition of the injured party present emergencies, or exigencies demanding prompt action, which reasonably warrant the injured party in securing the then needed service at the employer's expense without first

giving notice and opportunity to furnish or offer it. Such cases are, of course, distinctively exceptional and consequently rare. When such exception is claimed, the question of a pressing necessity demanding and excusing prompt action before reasonable time for notice and opportunity thereafter for the employer to act becomes primarily an issue of fact.

#### What Constitutes an Insane Delusion

(*In re Sturtevant's Estate (Ore.)*, 180 Pac. R. 595)

The Supreme Court of Oregon, in holding that, as there was some evidence on which the testator in this will case could found a perfectly natural belief that his son had not dealt fairly with him, it was not an insane delusion although the belief was probably a mistaken one, says that a "delusion" is a fixed belief in a proposition which has no foundation in evidence, and which is so extravagant that a reasonable man would not adhere to it. It is a fixed and extravagant belief that a fact exists when there is no evidence to furnish a basis to such belief. The rule in regard to this matter is very similar to the rule adopted in Oregon in regard to the verdict of a jury. If there is any evidence to sustain the verdict, it must stand. So here, if there is any evidence to support the belief, it is not a delusion. Furthermore, it is not sufficient to show that a testator had delusions on some subject, if these delusions did not affect his mind in making his bequests.

### SOUTHERN MEDICAL ASSOCIATION

Thirteenth Annual Meeting, held at Asheville, N. C., Nov. 10-13, 1919

(Concluded from page 1797)

#### Serotherapy of Whooping Cough

DR. R. M. POLLITZER, Charleston, S. C.: We must differentiate sharply between the use of a vaccine as a means of prevention or of cure. It is true that at times, when it is begun as a prophylactic, we realize after the first or second doses that the disease is present already. Nevertheless it may be used in well children as an immunizing agent before exposure or before the onset. The reports as to its efficacy are quite varying. In a few cases I have employed the vaccine in well children who have never had the disease. Subsequently they were unintentionally exposed and did not contract it.

#### Otitis Media

DR. LAWRENCE T. ROYSTER, Norfolk, Va.: Otitis media may occur with fever and without pain, or with pain and without fever. The former is more frequent in infancy and early childhood, while the latter is more likely to occur in later childhood. It is an error to suppose that because a child does not have an earache, there is no middle ear inflammation. In Norfolk the first outbreak of influenza affected comparatively few children, while, during the second, a comparatively larger number of children were affected. In both outbreaks, the incidence of otitis was large. The treatment of otitis media, uncomplicated by mastoid involvement, is comparatively simple, though the results are by no means always gratifying. I can see no rational reason for treating an otitis media by applications to the drum through the external auditory canal. I have seen more cases that were treated in this way eventually require an incision than I have seen cases subside under this treatment. Uniformly red drums, even without bulging, should be incised. In cases of slightly red membranes it has been my custom to use menthol, camphor and liquid petrolatum in the nose, with the idea that such a mixture contracts the swollen mucous membrane at the inner opening of the eustachian tube, and thereby

promotes drainage of the middle ear. When cases of middle ear inflammation are accompanied by tenderness over the mastoid cells it is generally agreed that the drum should be cut under the supposition that drainage of the mastoid cells through the middle ear is promoted. Conversely, then, why should not early incision be made, thereby promoting drainage and relieving pressure, thus preventing extension to these cells?

#### Cases of Spinal Muscular Atrophy Probably of Werdnig-Hoffmann Type

DRS. J. H. MASON KNOX, JR., and GROVER F. POWERS, Baltimore: We are inclined to believe that the symptoms in our three cases, namely, general symmetrical muscular weakness noted at birth with loss of reflexes, and diminution in response to electrical stimulation, can be explained most satisfactorily on the assumption of a primary spinal atrophy and secondary muscular involvement, although the possibility of a reverse process cannot be excluded. The third patient, who is still living, has apparently improved somewhat, which may be accounted for by the development of certain intact and innervated muscle fibers remaining. It would seem from a consideration of the growing literature that many transitional cases do occur between the group of cases described as myotonia congenita (Oppenheim) and those of infantile spinal muscular atrophy (Werdnig-Hoffmann), and that both these conditions may be due to a congenital defect in development of the lower motor neuron tract, affecting certain ganglion cells of the cord and the muscles they supply.

#### Treatment of Enterocolitis in Infancy

DR. W. W. HARPER, Selma, Ala.: The indications for treatment are: prompt cleaning of the intestinal canal by catharsis and enema; withdrawal of all food for from twenty-four to forty-eight hours; sowing of the intestinal canal with virile strains of lactic acid bacilli; an abundance of water by (a) mouth, (b) rectum and (c) hypodermoclysis; free administration of alkalis, and, if acidosis threatens, the use of carbohydrates; adoption of measures to prevent urinary suppression, and early return to the breast or bottle. As an initial purge, I prefer castor oil. If the first dose is vomited, a second dose is given at once; and if this is vomited, a third dose is given. From the three doses, sufficient oil will be retained to act. A soda enema (two teaspoonfuls of sodium bicarbonate to a quart of warm water) is given every six hours for the first twenty-four or forty-eight hours. These enemas clear the intestine of feces, and furnish water and alkalis to the tissues. All food is withdrawn at once and water is forced—the minimum amount of water to equal the amount of milk taken in health. When the infection is mainly confined to the colon, after the initial purge, paregoric is given to relieve pain and to diminish the frequency of stools. The enema is given only once a day, as frequent enemas irritate the bowel and disturb the patient. For tenesmus, and to hasten the cure, nothing has served me so well as an enema of silver nitrate solution, from 0.5 to 1 per cent. in distilled water. The intestine having been flushed with sterile tap water, 8 ounces of silver solution are allowed to run into the colon through a large catheter. While the patient is waiting to pass this, the mucosa of the rectum is painted with 12 per cent. silver nitrate. The whole painted area is neutralized by allowing a strong solution of sodium chloride to flow through the rectal catheter. This gives marked relief.

#### Report of Hepatic Aneurysm

DR. EDWARD B. ANDERSON, Chattanooga, Tenn.: The patient's history, his radial aneurysm, the hemorrhage in the liver, the gangrene in his toes and later his leg, caused by general arterial disease, makes it almost certain that the hemorrhage in the liver must have been the result of a rupture of a small aneurysm of one of the branches of the hepatic artery. The fact that it occurred in the substance of the liver, and that it was controlled by parenchymatous sutures (two mattress sutures) and a gauze pack, would indicate that only a peripheral branch was involved. **Cervix of Uterus After Radiation.**—Alter's study of about 275 specimens showed that the primary effect of the rays of radium in the case of the basal cell carcinoma of the cervix is the destruction of the cells of the malignant parenchyma. The increase of stroma is secondary, due to the disappearance of the parenchyma, having been formed mostly from wandering cells. The chromatin substance of the parenchyma cells displayed the greatest sensitiveness toward the rays of radium, showing conspicuous features of destruction. The protoplasm of the parenchyma cells shows marked but not such obvious changes.

**Essential Atrophy of Pancreas.**—Five cases have been studied by Oertel. There exists a well expressed essential atrophy of the pancreas due to loss and collapse of its parenchyma associated with irregular, diffuse, aborted regeneration. It leads anatomically to a definitely recognizable entity. It appears that this lesion represents a pathologic exaggeration of normal, physiologic processes of regression and progression which are constantly going on in the pancreas.

**Wound Healing.**—The points established by Akaiwa as the result of his study are: larger wounds close relatively more rapidly than smaller wounds. Shallow wounds close more quickly than the deeper ones. The contraction of the tissue does not participate in the processes leading to the closure of the wound.

**Primary Lymphoblastoma of Intestine.**—About 246 cases of lymphoblastoma of the intestine were collected by Graves from the literature and three new cases are added, in one of which the patient is in good health approximately three years after operation. One patient died with metastases in the lungs and elsewhere seven months after operation. In one case there is apparently recurrence within the abdominal cavity thirty-eight months after operation.

**Combined Tumors of Kidney in Adults.**—Of the three tumor specimens described by Barry the first contains the elements of a fibrosarcoma and of a suprarenal cell carcinoma; the second is a combination of a fibrosarcoma and of a papillary adenocarcinoma; and the third consists of a suprarenal cell carcinoma and leiomyosarcoma.

**Acinar Cells of Pancreas.**—The diseases in which toxic necrosis of these cells were found most frequently by Parker were pneumonia, diphtheria, acute peritonitis and other processes due to the streptococcus and pneumococcus, rarely to *Staphylococcus aureus*. Toxins which cause lesions in the heart, liver, kidney and suprarenals cause similar lesions in the acinar cells of the pancreas, which Parker says heretofore have been overlooked.

- A Returned Soldier Carrier of Meningococcus. C. H. Nammack, New York.—p. 590.
- Commotional Shock Caused by Shell Explosions. A. Leri, Paris, France.—p. 591.

**Angina Pectoris.**—Gordinier maintains that patients who have angina pectoris associated with or followed by myocardial insufficiency, and particularly auricular fibrillation, flutter, or alternation, should receive digitalis until relieved and then be treated for a long period of time with small tonic doses of the drug. After the paroxysm passes the patient should be advised to rest absolutely for a period of several days, and should be coached carefully in regard to diet, elimination, exercise and work. Iodids lessen the severity of the pain and widen the interval between the attacks, and may cause their cessation.

**Auscultatory Percussion in Diagnosis of Cardiac Lesions.**—Milroy again calls attention to the greater diagnostic value and accuracy of auscultatory percussion of the heart over other methods. He says that in ignoring this method of examination the profession has been depriving itself of an aid of the utmost value.

**Cardiovascular Apparatus in Pulmonary Tuberculosis.**—Zueblin points out that in the study of pulmonary tuberculosis certain disturbances bearing on the cardiovascular apparatus deserves attention. The heart and vessels show abnormal function and pathologic changes to a greater or lesser extent in tuberculosis. Deviations from normal function and size are of interest not alone from the diagnostic standpoint, but prognostically and therapeutically as well. Zueblin presents his findings in both male and female patients in various stages of tuberculosis as to the size and position of the heart and the character of heart sounds; also the pulse, blood pressure, cardiac activity and vasomotor changes.

**Blood Transfusion in Subacute Sepsis.**—Zingher advises that blood transfusions be used more extensively. The special indications considered are subacute sepsis, associated with extensive suppuration or with infected compound fractures, with anemia and emaciation of varying grades; also as a prophylactic measure in enfeebled individuals before severe operations and in cases of postoperative surgical shock resulting from extensive loss of blood during an operation. The transfusion should be of moderate amounts of blood from 250 to 300 c.c., and repeated, if necessary, every seven to fourteen days.

son's patient, a male, 26 years of age. He also had some pain in the abdomen after almost every meal but less severe than the pain in the attacks. Then he had an attack more severe than any he had experienced before. The pain was different (not cramplike in character) and not localized to the lower right quadrant entirely, but extended across the abdomen to some extent. He was sick in bed a week. A diagnosis of chronic appendicitis was made. At operation the appendix was free but thickened and indurated, and because of a tumor mass, which led Henson to suspect carcinoma, the last 3 or 4 inches of the ileum, the cecum, ascending colon and 2 or 3 inches of the transverse colon were removed. Incision into the wall at almost any point revealed pus. The epithelial surface of the mucous membrane seemed intact. Typical tubercles were found on microscopic examination thus clearing up the etiology.

**Cancer of Stomach with Associated Pellagra.**—Bryan's patient was 49 years of age. He gave a distinct history of ulcer of the stomach twenty years ago. Two years ago he commenced to lose weight and noticed a small knot in the stomach. His tongue was thickened, red and had deep furrows, and there appeared on the back of both hands a symmetrical eruption. He consulted a physician who pronounced it pellagra. The diagnosis of cancer of the stomach was confirmed at operation and microscopically.

**Case of Hodgkin's Disease in Girl Two Years Old.**—The unusual features in Porter's case were: (1) the early age of onset; (2) the female sex of the child (males are affected at a ratio of 6:1); (3) rapid onset which followed what was undoubtedly an infection involving the gastro-intestinal tract; (4) early and extreme involvement of the mesenteric and retroperitoneal glands; (5) late and slight involvement of the cervical glands which are usually affected early and profoundly; (6) remarkable, extensive and early involvement of the skin in morbid process; (7) extreme edema of the legs while the anemia was still far from profound; (8) intermittence of the fever and the toxic symptoms which on several occasions gave an unwarranted hope for improvement; (9) repeated but temporary improvement of the child after blood transfusions; (10) absence of any demonstrable infective agent, *Coccobacterium Hodgkini* or other organisms in the glands for diagnostic purposes; (11) extensive invasion of the lung septums by the endothelial cells characteristic of this disease; (ordinarily such invasion is limited to the peribronchial and superficial pleural areas of the lung); (12) unusual size of the spleen, which in this disease is most often is but moderately enlarged. It extended as far forward as the umbilicus and down to within an inch or less of the iliac crest.

- Giant Muscicle of Appendix. W. G. Nash—p. 567.
- \*Polycythemia Vera (Rubra) Complicated with Hypertension. F. J. Tyrrell—p. 569.

**Giant Mucocele of Appendix.**—The tumor in Nash's case was 7 inches long, 7½ inches in circumference, and weighed 8½ ounces.

**Polycythemia Vera (Rubra) Complicated with Hypertension.** In Tyrrell's case the thyroid gland was enlarged and symptoms of hyperactivity were present. The patient gave a history of gradually increasing cyanosis during the last eight years, some shortness of breath and increasing muscular weakness. The superficial femoral arteries were tortuous and thickened. The radial pulse felt hard and gave the impression of high tension. The artery was thickened. The systolic blood pressure, taken in three separate positions, was always about 120. The heart was not enlarged. A complete blood examination was made, with the following result: Red blood corpuscles, 9,000,000 per cubic millimeter;

white blood corpuscles, 25,000 per cubic millimeter; hemoglobin, 125 per cent; color index, 0.8 per cent. A differential blood count revealed: polymorphonuclear neutrophils, 80.8 per cent; small lymphocytes, 10.4 per cent; large lymphocytes, 5.6 per cent; eosinophils, 0.4 per cent; mast cells, 2.8 per cent; myelocytes, none. There was, therefore, both polycythemia and leukocytosis.

**Compound Fracture of Femur in Upper Third.**—Lee discusses the essentials of correct treatment of fractures of the femur and describes his pelvic femur splint which consists of an adjustable grip with two pads which fit the pelvis, and modified Thomas' frames for both lower extremities are hinged on to the pelvic grip. These frames can be adjusted to any desired position. There are no bands encircling the limb, hence no interference with the circulation occurs. The author also describes an adjustable splint for the arm. The splint consists of two parts. One fits firmly onto the trunk and hip; the other carries the limb. The patient carries his upper extremity with the whole weight supported by his body, hence the limb is kept quite steady and at rest.

- Secondary Infections in Influenza. P. S. Munnell—p. 351.
- \*Case of Supercute Pulmonary Edema. A. R. S. O'Connell—p. 353.

**Pulmonary Condition Found in Warfare.**—The symptoms in the condition reported on by Stewart and Robertson are cough, sticky sputum, hemoptysis or even slight hemorrhage and great breathlessness, amounting in some cases to paroxysmal dyspnea. There is dulness in the right inter-axillary region, bronchial breathing, inspiration being accompanied by numerous rales of varying coarseness, associated usually with less weight, lassitude and loss of appetite. In most of the patients present all the classical signs and symptoms of pulmonary embolism, with this exception, that there is always a certain amount of cyanosis, even with normal traces of oxygen in the spittle. The patients are particularly prone to anxiety, which is due to a well defined delirium of the second variety. These patients are generally fatal unless they are treated. They have lain for a long time, comatose in the bed. The best treatment of the pulmonary embolism is to give 50 per cent solution of sodium chloride intravenously. However, the important part of the treatment is the deep search massage of the feet in which carotid pulsation can only be felt by compressing the artery with the thumb 2 to 2½ inches from the distal end of the artery, and from 2 to 2½ inches from the distal end of the artery, and from 2 to 2½ inches from the distal end of the artery, and from 2 to 2½ inches from the distal end of the artery, and from 2 to 2½ inches from the distal end of the artery.

**Case of Supercute Pulmonary Edema.** A case of superacute pulmonary edema is reported by O'Connell. The condition arose from acute pulmonary embolism. The patient died in a case of extreme cyanosis and was impacted by cyanosis, red cells and phosphaemoglobin. The patient was 41 years

of age. She died two and one half hours after the chest was aspirated. The necropsy showed that the right pleural cavity had been almost drained of fluid. Southwood is convinced that Riesman's "congestion by recoil" explanation applied here; compression of the lung gave rise to changes in its blood vessels, congestion after reexpansion led to transudation of serum. The death was asphyxial in type.

### Archives des Maladies du Cœur, etc., Paris

August, 1919, 12, No. 8

\*Variations in the Blood Pressure. 1. LERICQ.—p. 137

**Variations in the Blood Pressure During Prolonged Examination.**—Tixeront examines the pressure in the humeral artery by auscultation for five minutes at a time. This protracted examination with Korotkoff's technic has revealed, he says, different types of conditions in the circulation: the normal, with a slight lowering during systole and steady diastole; and the abnormal, of which there may be two forms, those with no fluctuation in the tension, and those with extremely wide fluctuations. This latter group may have an emotional, irritable or diseased heart, or an overexcitable sympathetic vasomotor system, or a tendency to paralysis of the vessels. The absence of any fluctuation may be explained by predominance of the moderating element (vagus), or by hidden lesions of the arteries or by inexcitability of the sympathetic system. A record of the blood pressure should include, besides the Mx and the Mn in mm. mercury, mention of the method employed (oscillometer, palpation, auscultation, etc.), the artery examined, the corresponding pulse figures, and whether the blood pressure was initial or terminal (at the end of five minutes). A detailed record of the findings is better yet. With these data from a five minute examination, we have complete oversight of the conditions in the blood pressure.

### Bulletin de l'Académie de Médecine, Paris

Nov. 4, 1919, 82, No. 34

\*Welfare Work for Infants. G. Bosc.—p. 253.

\*Surgical Treatment of Fractures. Dauriac.—p. 276.

\*Fractures of the Lower Joints and Pseudarthroses. Dauriac.—p. 278.

**Prophylaxis of Child Abandonment.** Bosc relates that the mortality among the infants in the public hospital at Tours was always very high, reaching 50 per cent. in 1916 notwithstanding that the healthier children were boarded out in their country to be brought up on the bottle. In 1916 new regulations were put into effect so that every woman desiring in the Maternity was compelled to remain and nurse her child for three months. No applicant was received at the Maternity unless she consented to stay afterward for three months. During this period her board and lodging were free and she is paid besides 125 francs a day, about 25 francs. She is then to be paid returnfare for her own child, and may be kept as long as she will stay and nurse the child. Since this regulation went into effect, thirty-two abandoned women out of 244 abandoned have been detained in this way and the mortality among the infants has dropped from 50 to 27 per cent. Another advantage of this plan is that when the mother has nursed her child for a month and seen that she will be able to nurse her child about abandoning her child, she can then be attended, and makes the necessary arrangements to take her child with her when she leaves. Not only this, but has been abandoned by its mother during these months, she is given money to keep the children with them, and is allowed to receive for nursing the premium of 30 francs a month, to be given to the child as well as friends, but they usually use the money of their little one with maternal zeal.

**Esthetic Incision for Ovariectomy.** Jayle had occasion recently to operate on a patient's model with disease in the right adnexa. The incision he used left absolutely no trace, and he mentioned the esthetic as well as other features. The transverse incision in the hairy region was about 6 or 7 cm. long. The rectus muscle was drawn with a retractor toward the median line, also the hypo-gastric muscles and the peritoneum was opened and the lips separated with a small retractor with narrow blade. The pelvis was in a

sloping position (45 degrees) and this exposed the right adnexa and they were removed. The patient was then turned on the right side; the cecum then presented and the appendix was removed. He calls this the transverse and lateral esthetic suprapubic incision, and commends it in high terms especially as it overcomes the difficulty of differentiating between appendix and adnexa lesions, as it allows access to both, while reducing the trauma of the intervention to the minimum. Even with a pregnancy of from one to three months, the uterus is left practically unmolested. He has applied this incision in about twenty cases, with increasing satisfaction.

**Treatment of Fractures with Bone Grafts.** Dauriac is enthusiastic over the fine results of immobilizing fractures with bone grafts cut to fit by Albee's technic with electricity. He has been treating fractures in this way since 1910, with constantly perfect outcome. The only metal for holding fractures in place that answers its purpose is Treves's aluminum alloy. The tissues seem to stand this metal without reaction, and he has found it useful in various ways. He is now having screws and a cable made of this alloy which he thinks promise well.

**Pathogenesis of Loose Joints.**—Dauriac states that there are 15,000 wounded soldiers on record who have been left with flail joints, *membres ballants*. He ascribes this mainly to the "condition of chronic and profound intoxication which was the result of the too exclusive use of meat in the army ration. This with abuse of alcohol and of vinegar prevented normal repair." It cannot be charged to suppuration because he had fourteen cases of simple fracture which never has consolidated, although the men are not syphilitic. An additional factor is the lack of reaction on the part of the nervous system from the strain of service on the firing line. He explains further how the bone softens and loses its minerals when the fracture breaks up the natural static conditions of pressure on the bone from both ends. This pressure must be restored, to keep the bone normal, and for this reason he always uses when possible a long implant of bone, reaching at each end into normal tissue where it can obtain a good blood supply, to restore the primitive dynamic conditions of axial pressure. From the fact of this pressure, the implant will become organized, become stronger, and adapt itself to acquire the shape, the size and the resistance of the bone in which it has been incorporated.

### Bulletin Médical, Paris

Oct. 25, 1919, 33, No. 47

\*Surgical Treatment of Cancer of the Tongue. P. Sebileau.—p. 617.

Idem. M. Vallas.—p. 627.

\*Early Diagnosis of Cancer of the Tongue. M. Ferrand.—p. 629.

\*Buccal Leukoplakia. P. Fernet.—p. 632.

**Cancer of the Tongue.** Sebileau emphasizes the necessity for prompt and complete removal of all the tissues possibly involved, and discusses the preferable technic. The statistics on record all show the favorable outlook when the cancer can be removed by the natural route, and the gravity of operations by surgical access otherwise, although some even of these patients have survived for ten to twenty years. But not over 15 per cent. are living by the close of the fifth year.

Vallas' own experience has been 44 per cent., surviving for three years at least when the cancer was on the movable part of the tongue; none surviving with cancer at the base of the tongue, and 55 per cent. surviving with cancer of the floor of the mouth, but in three cases the interval since has been over three years. Reviewed further in the Paris Letter, page 1712.

**Early Diagnosis of Cancer of the Tongue.** Ferrand says that in a recent series of 17 cases of cancer of the tongue 10 were operable and 6 were nearly so. Only one was in an early stage. These cancers may develop as a papillomatous growth or as a small tumor, with early erosion and ulceration, or as a minute fissure or ulcer with hard base. Microscopic examination of a scrap would reveal the malignant growth early, even before the growth has assumed the appearance of a neoplasm. With a suspicious lesion, no time should be wasted in watching its further progress, especially when

the malignant disease is installed in a syphilitic inflammatory lesion or leukoplakia.

**Leukoplakia.**—Fernet remarks that the transformation of a patch of leukoplakia into an epithelioma is of such frequent occurrence (from 15 to 50 per cent.) of some think that leukoplakia is a potential cancer. He warns against irritating the growth with caustics, and against wasting time on treatment of syphilis or waiting for glands to enlarge. He warns further against trying roentgen and radium treatment, as these do no good and may do actual harm. If the microscope does not reveal malignant disease, every effort must be made to prevent local irritation. When the leukokeratosis is thick and fissured, to ward off cancer it may be well to strip off all or part of the mucosa, cauterizing then to arrest hemorrhage.

- \*Recent Progress in Therapeutics. P. Carnot and F. RATHERY.—p. 333.
- Treatment of Gangrenous Infections. G. LARDENIS.—p. 347.
- \*Pituitary Treatment of Diabetes Insipidus. P. LEROUBOULET.—p. 353.
- Hematopoietic Serotherapy of Malarial Anemia. SARAILHE.—p. 358.
- Mesothorium in Therapeutics. P. CARNOT and A. GUILLAUME.—p. 364.

**Recent Progress in Therapeutics.**—Carnot and RATHERY review what has been accomplished with proteosotherapy, vaccines, chemotherapy, etc., in the last twelve months. They conclude by calling attention to the researches on the physiology of nutrition, the indispensable amino-acids, the minimum of nitrogen and of vitamins. "The American and English schools have contributed the most to the study of these questions. They are destined to revolutionize the old principles of alimentary hygiene and dietetics, and have considerable interest for therapeutics."

**Pituitary Treatment of Diabetes Insipidus.**—Lerouboulet concludes his discussion with the assertion that subcutaneous injections of the posterior lobe of the pituitary in diabetes insipidus have proved their certain symptomatic action. Both from the standpoint of diagnosis, therapeutics and pathogenesis, the results achieved form one of the most interesting chapters of modern organotherapy.

**Presse Médicale, Paris**

- \*Primary Grave Jaundice. M. GARNIER and J. REILLY.—p. 641.
- \*Projectiles in Cerebral Ventricles. G. L. REGARD.—p. 645.

**Primary Grave Jaundice.**—Garnier and Reilly expatiate on the discovery of the icterohemorrhagic spirochete which has shown that what used to be all grouped as icterus gravis consists really of two widely separate diseases. The characteristic feature of the spirochete form is not insufficiency of the liver but just the reverse. The liver is whipped up to extra functioning, but the bile is poured into the blood instead of into the biliary passages although the latter are permeable. The kidney functioning is almost entirely suppressed. The uremia increases from day to day. The spirochete seems to act primarily on the proteic substances, especially the hemoglobin-producing elements; it whips up the liver and blocks the kidneys. This is the form of icterus gravis that has been described under the names of the renal form of grave jaundice, grave jaundice with intact liver grave jaundice with anuria, hepatonephritis, hepatorenal insufficiency and acute nephritis with jaundice.

The other form of icterus gravis is acute yellow atrophy of the liver. Fatty degeneration of the tissues is the anatomical characteristic of this type, the metabolism of fats bearing the brunt of the attack, just as the protein element bear it in the spirochete jaundice. Their experience with a whole army during three years has confirmed that practically every case of primary grave jaundice fell into one or the other of these groups.

**Projectiles in the Cerebral Ventricles.**— REGARD comments on the ease, simplicity and harmlessness, comparatively speaking, of the removal of a projectile from the lateral ventricle under roentgen control. When the projectile reaches the fourth ventricle, death follows before any diagnosis is possible. The operation can be done at two sittings, first cutting the large flap, and later extracting the projectile

without general anesthesia. The danger from the operation is hemianopsia, but this disappears rapidly even when it was total at first. The patient also seems a little dazed for a few days but then throws this off and if no other lesions interfere, recovery is complete.

- \*Food for Growing Children. P. N. DECAUPE.—p. 673.
- \*Suture of Spurring Wounds. BERGERET and GALVEZ.—p. 675.
- \*Massive Saline Infusion at Amputations. N. C. LAPAGE.—p. 676.

**The Diet for Children.**—Nobécourt discusses the proper diet for children from 2 or 3 to 14 years old and over. He deplores the way in which the needs for growth are often overlooked, and says that the results of war restrictions have thrown much light on dietetic questions, especially so far as children are concerned. He gives tables showing the proper proportions at different ages.

**Secondary Suture of Suppurating Wounds.**—Bergeret and Galvez describe eight typical cases to demonstrate that thorough sterilization with neutral solution of chlorinated soda, by Carrel's technic, allows the wound to be sutured early, and this avoids long hospital care and unsightly, painful wounds and the complications liable with protracted suppuration.

**Injection of Saline During Amputation.**—Lapeyre's experience indicates that injection of a large amount of saline into the principal vein of a crushed limb that is being amputated attenuates materially the gravity of the operation, as these patients are always suffering from more or less shock.

- Action of Thorium Lanthane, etc., on Bacteria. A. SARTORY.—p. 406.
- Case of Thompson's Disease. A. BARBIER.—p. 408.
- \*Adhesive Pericarditis and Surgical Correction. BARBIER.—p. 409.

**Operative Treatment of Adhesive Pericarditis.**—Delorme's suggestion to correct conditions in adhesive pericarditis by breaking the adhesions is discussed by Barbier from various standpoints. Hallopeau and Delbet have tentatively and partially applied this cardiolysis, and noted improvement in the play of the heart after adhesions had been detached. The method is as yet wholly in the realm of theory and hypothesis, but this cardiolysis seems logical although it has not been demonstrated to date that isolated fusion of the parietal pericardium with the heart is enough in itself to induce the symptoms of adhesive pericarditis. These symptoms can be explained more plausibly by the fusion of the outer layer of the pericardium with the pleura and to the chest walls, compelling the pericardium and consequently the whole myocardium to yield to the tug of the chest walls in their excursions. The main objection against Delorme's cardiolysis is that recurrence of the adhesions is almost inevitable unless part of the pericardial wall is resected.

- \*General Physiology of the Temperature Sense. J. BACHMANN.—p. 31.
- \*War Mental Disturbances. CHARRON and BROWN.—p. 39.
- \*Mental Pericarditis. H. PÉRIER.—p. 54.
- Slow Motion Electrocardiogram. R. DUBOIS.—p. 55.

**The Temperature Sense.**—Bachmann and his colleagues pathologically change in the *Reptura* but have been well studied, and he contributes here a comprehensive study of it under physiological conditions.

**War Mental Disturbances.**—Charron and Brown emphasize the importance of laboratory research on the blood and urine as a means of monitoring mental derangement. They say that the diagnosis of mental derangement is generally accepted as a signal to retreat from the combat, interference but their experience teaches into the contrary. Treatment may be actually curative, mental treatment being under the control of the laws of general pathology. In two cases of acute mental derangement, the area of contact in blood and urine proved to be abnormally high, and as this returned to normal under proper treatment the mind cleared up likewise.

the tube. At the line of junction a brown ring forms, and this tint spreads upward, and sometimes a gray cloud forms on the surface of the urine above. In twenty-four hours all the fluid is an even brown. Albumin does not interfere with the reaction.

**Angiokeratoma.**—Canelli describes the clinical findings and the pathologic anatomy in five cases of angiokeratoma in young adults. One patient he had known from childhood. The fingers and toes were the seat of the lesions in all but one.

**Purulent Arthritis After Smallpox and Influenza.**—One babe of 4 months developed purulent polyarthritis after smallpox, and the 10 month babe purulent monoarthritis after influenza. Both children recovered promptly and completely under treatment with an autogenous vaccine.

**The Alleged Rachitism in the Young of Thyroidectomized Rabbits.**—Rusca reproduced the experiments in this line of Claude and Rouillard (1913) but with absolutely negative results.

- \*Typhus. Vittorio Giacanelli—p. 1067.

**Ulceration of Nasal Septum from Chromium Fumes.**—Ranelletti remarks that ulceration and perforation of the nasal septum are the characteristic occupational injury from the production of sodium chlorate by electrolysis from potassium bichromate. In the last three years he found this ulceration in the nasal septum in twenty-five of thirty-eight workers examined, including four with perforation. The thirty-one other workers also presented similar lesions, so that 56.5 per cent. of the sixty-nine workers in the factory had the ulceration, and in 15.7 per cent. of those affected there was perforation. This proportion is less than was reported by Hermann in Germany in 1900, where 79 per cent. of 257 workers were affected. A loose plug of salicylated gauze introduced into each nostril seems the best individual preventive known to date; cotton interferes with breathing.

**Typhus.**—In 10 per cent. of Giacanelli's 220 typhus patients at a camp of war prisoners, defervescence occurred by lysis, and suppurative parotitis developed in 20 per cent.

**Riforma Medica, Naples**

- \*Roentgen Treatment of Surgical Tuberculosis in Children. R. Espinola—p. 313.

**The Child Welfare Congress.**—The *Archivos* is the official organ of both the Argentine and the Uruguay Sociedad de Pediatria, and this issue is devoted to the recent second Congreso Americano del Niño. The conclusions are given of all the principal addresses, with the discussions and the resolutions adopted by the meeting. Most of the leading addresses have been recently reviewed in these columns when published elsewhere, especially those on poliomyelitis, hysteria in children, early diagnosis of brain tumors in children, motor plastic amputations in children, etc.

**Tuberculous Glands in the Neck.**—Various speakers reiterated that the tonsils are usually the primary source of tuberculous glands in the neck, and that treatment should include the mouth and nose in general. Robertson asserted, "La radiotherapia es el tratamiento de eleccion en las adenitis tuberculosas" of the neck. Surgical measures are preferable when several glands are involved, as modifying injections have little prospect of success except when there are only a few and well isolated glands affected. He insists that particles of food, even with the healthiest teeth and in well kept mouths, putrefy and induce a septic condition which entails a defensive reaction in the tonsils and mucosa of the nasopharynx. This in time renders the mucosa more permeable for micro-organisms, and the glands in the neck may soon feel the effects.

**Classification of Gastro-Intestinal Disturbances in Infants.**—Gaugé is chief of the Institut de Puericulture No. 1 at Buenos Aires, and he declares that there is no need for revision of the present classification, especially that based on Finkelstein's premises.

Velasco Blanco prefers to classify them according to the food, infection or a constitutional predisposition is primarily responsible, emphasizing that the toxicosis is distinguished by the paradoxical reaction to the food.

**Roentgen Treatment of Bone and Joint Tuberculosis in Children.**—Espinola asserts that roentgen therapy, as distinct to a leading place among the methods of treating surgical tuberculosis. The technique has to be correct and the dose individualized; some processes heal under small doses, others require intense exposures. His experience as chief of the roentgen service in a large hospital is summarized more and more, he says, the value of this treatment in surgical conditions of bacterial origin. In a patient operated for surgical tuberculosis in the children, the procedure is as follows: The glandular masses break down into fragments, in proportion to the amount of the type involved. Cold abscesses and hepatic pus in suppuration should be evacuated by puncture from the side, and the cavity exposed to intense x-rays. The dose should be kept in proportion to the virulence of the infection. He has found it possible to ray large tuberculous abscesses daily, reaching a total fifteen times greater than the cytobion dose, without inducing radiodermatitis, nothing more than a superficial exfoliation that drops off in ten or fifteen days, leaving normal skin below the mortified shell, on condition that three or four week intervals are used, and making allowance for the increased susceptibility of young children and of surgical accessibility. The reaction should be controlled for some time, and the rays have healed to a great extent.

\***The Prognosis with Valvular Heart Disease.** G. Hergueta. p. 22.

\***Clinical Course of Endocrine Orbits.** F. Hernando. p. 23. (Cont.)

**Hemorrhages of the Retina in Influenza.** González has considered five cases of hemorrhages in the retina during convalescence from influenza. He gives illustrations of the different types of hemorrhages observed. He obtained marked improvement or even clinical cures with sweats and local application of heat. Instillation of a drug to dilate the vessels has little prospect of success in the posterior segment of the eye. He never witnessed any benefit from such with hemorrhage of the retina. The outlook seems to be more favorable than with hemorrhage of the retina from other cause, but all hemorrhages in the retina are grave.

**The Prognosis with Valvular Disease.** Hergueta remarks that the prognosis depends as much if not more on the liver and kidneys as on the heart itself. Mitral valvular disease is more apt to damage the liver than a pulmonary valvular defect and this is particularly liable to occur with lithiasis, malaria, and syphilis. Hence the extreme importance of the liver antecedents with any form of heart disease, although complete tests of liver and kidney functioning are seldom included, as they should be, in the routine examination of a patient with heart disease.

**Gastric Disease of Endocrine Origin.** Hernando here continues his study of this subject, read at the inaugural meeting of the Spanish Association for the Advancement of Science. He remarks that the glands with an internal secretion influence the digestive apparatus not only by their secretions but through the interrelation of the vegetative nervous system. Universal ashenia or splanchnoptosis is probably a consequence of congenital changes of this origin. This secretion may be modified by the functioning of the endocrine glands, but this is usually in the line of hyposecretion although occasionally cases of hyperchlorhydria are encountered in persons with excessive thyroid functioning. The extract of the normal thyroid has a stimulating action on gastric secretion and in persons with suprarenal insufficiency a suprarenal extract has an inhibiting action on gastric secretion. His own and others' research has demonstrated that increased motility seems to provide conditions favorable for the development of gastric ulcer, pointing to the vagus sympathics, the modified functioning of the vegetative nervous system, the persistence of or reflux to the body-blown acid in the stomach, and the hyperactive power to micturition in general. He has observed gastric ulcer only in cases with symptoms of excessive suprarenal insufficiency, but probably comparatively more cases could be recognized if other factors in the pathogenesis of gastric ulcer in certain cases. The injurious effect of caffeine and nicotine on persons with hyperchlorhydria and gastric ulcer may be explained by the exhaustion of the suprarenals which they induce. This explains the beneficial effect of the suprarenals replete with epinephrine and suprarenal extract in general. He gives in Spanish an 184 additional references, all given with the full titles, and a bibliography of the literature. (Friedmann and Kendall).

### Progresos de la Clínica, Madrid

\***Operative Treatment of Pulmonary Tuberculosis.** Morales. p. 49.

\***Chemical Analysis of the Blood.** Poyales. p. 56.

\***Roentgenography in Renal Tuberculosis.** Serés. p. 59.

**Operative Treatment of Pulmonary Tuberculosis.** Morales declares that when an artificial pneumothorax cannot be realized a thoracoplasty operation may answer the same

purpose, and that the induced pneumothorax is indicated whenever one lung is gravely diseased while the other lung is sound or nearly sound. It is indicated also when there is profuse or frequently recurring hemoptysis, all from the one lung. Even if the other lung is "touched," it is still relatively indicated, weighing well all the circumstances. A thoracoplasty operation must not be regarded as particularly grave; it is generally applied only in cases in which all other means have failed and the disease is progressing. The mortality is below 5 per cent, he says, while its results are good enough on the whole to repay. He noted femoral thrombophlebitis in one case as a disagreeable complication of thoracoplastics, and knows of another case of the kind. The tendency to hemoptysis was promptly and permanently arrested by the collapse of the lung. He resects the ribs close to the spine, the incision starting at the second rib and curving away from the spine in the lower third, ending at the eleventh rib, resecting 8 or 10 cm. of each rib. The patient's tolerance is tested first by making only the lower half of the incision and resecting only the seventh to the eleventh ribs. If this is borne well, the operation is concluded at the one sitting. Operations directly on the lungs are very rarely indicated. The mortality is enormous and the benefit transient, as a rule. In three cases in which a cavity was opened and drained, all the patients died. But it might be considered as supplementary to thoracoplastics, always bearing in mind the chronic fistula which it usually entails. Surgical measures in pulmonary tuberculosis should aim merely to favor the natural healing processes.

**Chemical Analysis of the Blood.** Poyales expatiates on the importance for the general practitioner of determining the content of the blood in sugar, creatinin, urea, uric acid and cholesterol, and he describes the simplest tests for the purpose with the colorimeter and centrifuge. He also gives a colored plate showing the color findings with these five substances in the blood.

**Roentgenography in Renal Tuberculosis.** Serés reproduces some instructive roentgenograms, and remarks that the shadows of calculi are generally within the outline of the calices or pelvis, while tubercles are in the kidney substance itself. Even when calcified, the tubercles do not cast such a solid and uniform shadow as a stone, while the outline is not regular like that of a stone.

**The Bassi Metabolism:** Modification in Fever. E. Gómez A. p. 4  
**Centers for Optic and Auditory Perception.** V. Ribón. p. 10.  
**Criminal Responsibility of the Insane.** A. Gaitán U. p. 17. (Cont.)  
**Importance of Some Knowledge of Legal Medicine by Legal and Penal Authorities.** R. Fajardo Vega. p. 34.

**The Cortical Center for Vision and Hearing.** Ribón discusses the topography and the physiology of the brain center or centers which allow perception of the impressions transmitted by the optic and auditory nerves. He expatiates on the close connection between these nerves in this respect, and on the way in which music often takes advantage of this fact to give an impression of actual color. The range of the wood wind instruments represents one color, other instruments, other scenes and colors. The flutes and horns in the introduction to Haydn's "Creation," for example, reproduce the fresh coloring of the morning.

**Treatment of Hydatid Cyst in Lung.** Domingo Prat. p. 433.

**Hot Wet Pack to Entire Body in Operative Syncope.** G. Zorraquín. p. 447.

**Exophthalmos from Fracture of Base of Skull.** The lateral pulsating exophthalmos was evidently caused by an arteriovenous aneurysm in the young man. The aneurysm was the result of a railroad accident fracturing the base of the skull and the temple region, nine months before. He

complained of an intense intracranial murmur which sounded to him like the scraping of a saw. Compression of the carotid arrested this murmur. The communication between the two lateral sinuses explains how the arteriovenous aneurysm from a rupture on one side may induce exophthalmos of both eyes. In all such cases rupture of the carotid on only one side was found, with a single exception. In a second case, a compressing bandage and injections of gelatin were followed by retrogression of the exophthalmos and murmur which had developed after an automobile accident. There is evidently a tendency to a spontaneous cure in a large proportion of such cases when the concomitant lesions are not irreparable. In the first case described, the internal carotid was ligated and the murmur and pulsation disappeared at once on one side and nearly so on the other, and the exophthalmos retrogressed somewhat. The symptoms returned later on the other side, and the carotid on this side was ligated also. After months of visual sensory blindness, vocal motor aphasia, and agraphia with some paralysis, as is described in detail, he gradually learned to speak anew and is able to go about alone.

**Ileus in Tuberculous Peritonitis.**—Bolo reports six cases in children and adults, and emphasizes that operative treatment is directly contraindicated under these conditions.

- \*Normal Copper in Toxicology. L. P. J. Palet. p. 151.
- \*Proposals for Organized Welfare Work for Infants. G. Sisto, D. Aguilar and J. C. Navarro. p. 154.

**Pulmonary Amebic Lesions.**—Destéfano and Sammartino report a case of what they call right corticoepileptitis. The insidious onset, the acute exacerbations and the protracted course and symptoms gave no clue as to whether the tubercle bacillus or the pneumococcus was responsible for the clinical picture. There was a focal reaction, with fever, to the tuberculin test, and by the third month the aspect was that of tuberculosis in the "hectic" stage, with intense anemia and profuse night sweats. For three weeks the man had been having a constant cough, with profuse blood-stained expectoration but no signs of suppuration. After ergot, calcium chlorid, horse serum, epinephrin, etc., had failed to arrest the hemorrhagic tendency, and the condition was daily growing worse, emetin was given, 0.04 gm being injected subcutaneously every day. The result from the very first injections was most surprising. The cough, hemoptysis, fever, and sweats had permanently disappeared by the fifth or sixth injection, and by the tenth, the final injection, nothing was left of the whole process, but a slight restriction of the excursions and vocal vibrations in the right base, with slight dullness and slight reduction of the vesicular murmur. In less than six weeks the man of 34 had regained over 46 pounds.

They know of only three similar cases on record of a nonsuppurative amebic focus in the lung. In one case the

patient had chronic amebic dysentery but no amebas were found in the sputum. In the others the findings were positive. Rousseau was impelled to examine the sputum for amebas in his case solely by the resemblance he noted between the sputum and amebic dysentery stools. This total group of four cases shows that *Entamoeba dysenteriae* is capable of inducing congestion in the lungs and hemorrhage, without suppuration, and even without clinically appreciable lesions in bowel or liver. Even when no amebas can be found in the sputum, in puzzling cases of pleuro-pulmonary processes, a rapid and energetic course of emetin treatment might not only clear up the diagnosis but promptly cure the patient.

**Surgical Orthopedic Correction of Congenital Stenosis of Uterine Cervix and of Congenital Antelexion.**—Boero has modified Iribane's appliance for this purpose and gives an illustrated description of his own device. It is made of stout wire, shaped something like a palm-leaf fan. The handle is introduced through the internal os and the broad blades are sutured to the lips of the cervix (the cervix first slit on both sides). The blades are then spread, and the whole is left in place for twenty, thirty or more days. He calls this device the histeroeticon, and says that it enables the general practitioner to correct these congenital anomalies responsible for dysmenorrhea or sterility or both.

**Examination in Urogenital Cases.**—This is one of Castaño's regular lectures in the course on genito urinary disease.

**Normal Copper in the Liver.**—Palet's research on fifty-four cadavers failed to confirm the presence of copper in the normal human liver. Incineration with magnesium oxid he found a simple and reliable means of investigating the copper content of tissues.

**Welfare Work for Infants.** The Sociedad de Pediatría of Buenos Aires appointed a committee to propose ways and means for child welfare work for protection of the infants of wetnurses and of unmarried mothers, federation of all agencies working in this line, and means for publicity and propaganda. This is the report of the committee.

- \*Conservative Turbinectomy. Ernesto Bada. p. 866.
- \*Excessive Worship of Facts. A. Sánchez Herrojo. p. 867.

**Bacteriologic Prognosis in Typhoid.** Páez relates that among his more than 1,000 cases of typhoid in the last eight years were eleven in which both agglutination tests and hemocultures were negative although the clinical manifestations of the disease were beyond question by the second week. All in this group died. He urges others to note whether such negative findings imply always a fatal outcome.

**Conservative Turbinectomy.** Botella presents a wedge the entire length of the bony portion of the inferior turbinate. The outer flap left is drawn forward and adapted with the other raw surface. Then through a nose speculum, gauze is packed around to hold the flaps in position, without the necessity for suture. In three days the raw surface have become united, leaving merely a linear scar. This method he declares has all the advantages of the Freer, Watson and Yankauer technic without their doubtful results.

**The Idolatry of the Fact.** Sánchez Herrojo declares that too many are inclined to regard facts as the whole of science, when in reality it is only half.

**The Superficial Leishmaniasis of Surinam.** Bonne relates that warts of tropical leishmaniasis is common in Surinam, and a disease of the skin acquired in the interior is called "bush warts." But his research has demonstrated that the latter is a leishmaniasis. He gives an illustrated description of it, saying that it seems to be the only form of leishmaniasis known in the Netherlands West Indies. The fact that it is contracted only in forest regions suggests some reservoir for the virus in some forest insect or plant.

**Can Mutation of Bacteria Be Induced?** Schade was able to cultivate to a high point already existing properties in the color bacilli in his extensive research, but there was nothing to suggest mutation.

**Movements of Fetal Thorax Like those of Respiration.** Kowner comments on Mink's article (of which a summary was given in THE JOURNAL, Nov. 8, 1919, p. 1482). He insists that long before birth the fetal thorax is making movements like those of respiration. Abfeld called attention to them years ago, and Kowner has repeatedly demonstrated them to students. The movements jolt the whole trunk, and these regular movements can occasionally be felt with the hand laid on the abdomen. They differ completely from all other movements of the fetus and when they occur it is usually in a rapid tempo, about 60 to the minute. The advantages from this preliminary exercising of the respiratory muscle are obvious. He ascribes them to irritation of the respiratory center by accumulation of carbon dioxide. This may become exaggerated during the birth process. If there is too much carbon dioxide the respiratory center becomes paralyzed. In such a case the measures to resuscitate the child born in asphyxia are successful only in so far as they mechanically induce an artificial respiration. He describes how this is accomplished by swamping, by placing the child in a hot bath, and by pulling the tongue forward in clearing the throat of secretions. Under these circumstances, respiration cannot be induced by reflex action. It cannot be induced by any means if the air passages are filled too deep with amniotic fluid, mucus and mucus drawn in during intra-uterine life by some pathologic exaggeration of the regular physiologic movements of the fetal thorax resembling those of respiration. Swamping the child is first and foremost a means for artificial respiration; any reflex action with it is only secondary. But when artificial respiration has improved conditions, freeing the respiratory center from the excess of carbon dioxide, then the means to induce reflex action are used to complete the work as the reflex excitability is regained. Irritating the nose with a feather and blowing air into one nostril, to clear the other, as Mink advocates, have the drawback that the nose is liable to be filled with fluid and mucus, and these procedures might do harm.

**Herpes Zoster and Chickenpox.** Bruining cites von Geisay's thirteen cases in which herpes zoster had been followed within two weeks by chickenpox. Gara has reported a case in which two children in one family had chickenpox and the third developed herpes zoster, all within two days. Hvidtvede recently had a case of herpes zoster in a woman whose nursing child developed chickenpox ten days after her first symptoms. Two weeks later an older child, and again another two weeks, the third child, all developed chickenpox. Bruining reports the case of a man who had herpes zoster on the face, but this diagnosis was apparently corrected to herpes zoster. The next day typical chickenpox appeared, and the two ran their usual course together.

#### Acta Medica Scandinavica, Stockholm

NOVEMBER 52, N. 4

\*The Scandinavian Societies. G. Bruns, 167. E. Germain.

The "Acta Medica." The *Nordiskt Medicinskt Arkiv*, medical journal, appears under its new name in a brilliant new volume. The editorial staff includes two leading internists from Sweden and Norway and one from Denmark and from Finland, with a long list of collaborators in each country. The Latin title page aids in the international character which the editors are seeking to impart on it.

**Residual Nitrogen.** Brun's article fills this entire issue of 280 pages, relating his findings in research on the nonprotein nitrogen in the blood serum and cerebrospinal fluid in persons with chronic kidney disease. He compares with these findings those from ten other persons with healthy kidneys. The kidney cases are classified according to the pathologic conditions, and the findings are tabulated for comparison and especially the relative proportion in the serum and spinal and also the relative proportions of the various elements of the residual nitrogen.

Influenza in the Tuberculous; Typical and Atypical Fever. N. Lund, p. 1153.

Forceps with Transverse Presentation. C. Kielland, p. 1197.

**Thoracoplastic Operative Treatment of Pulmonary Tuberculosis.** Bull has done a thoracoplastic operation in 37 cases of pulmonary tuberculosis and he tabulates the details and outcome in all. The mortality was 30 per cent. in his earliest 11 cases but since then only 4 per cent. and he ascribes this improvement to his practice of doing the operation at two sittings, with an interval of three or four weeks between them. Of the 33 who survived the operation, 7 died later from the progress of the tuberculosis, one surviving for four years; one succumbed to influenza, but 25 are still living, and 11 of these can be regarded as cured, with full earning capacity; 7 still show symptoms, and in 7 the interval since the operation is too short for determination of the outcome, but most of them regard themselves as cured. A very favorable outcome was thus realized in over 33 per cent. of 30 patients, including a number with an interval since of almost five years. When there is a cavity, he aids in the "collapse therapy" by implanting a piece of adipose tissue, cut to fit, from the abdominal wall. In the cases which showed little if any improvement, the operation was incomplete or the general health so poor that the thoracoplasties should not have been attempted. One died from intercurrent disease and in 7 the other lung became affected. Influenza also cooperated in rendering the outlook less favorable than might otherwise have been the case. The danger of the other lung's becoming diseased is the Damocles sword to fear. It is possible that adhesions in the lungs may be responsible for the failures in certain cases; this is a question requiring further study. The thoracoplasties does not interfere with the use of the arm, nor disfigure, especially when fat implants were used.

**The Nose as a Factor in Disease of Lacrimal Passages.** Malling reviews literature on this subject from 1880 to date, and describes his own examination of 192 patients with abnormal overflow of tears without macroscopic evidence of disease in the lacrimal passages. In 155 of them the nose or its annexes showed more or less pathologic changes, and this had evidently been a factor in 96 per cent. of the total epiphora cases without macroscopic lesions in the lacrimal passages. Pathologic conditions in the nose or sinuses were found in 58 per cent. of the dacryocystitis cases. The nose and its sinuses should be thoroughly overhauled in all cases of disease of the lacrimal passages. If this is detected in its incipency, it may be possible to cure it in time to ward off stricture. He tested the permeability of the passages by instilling into the conjunctiva a drop of a solution of 0.2 gm. fluorescein and 0.35 gm. potassium carbonate in 10 c.c. water. After waiting two minutes, through a nose speculum he wipes with cotton the mucosa just below the inferior turbinate. The interval before the cotton shows traces of the stain is an index of the permeability of the lacrimal passages, etc. If no stain appears in fifteen minutes, he rinses out the passages in the usual way and treats any catarrhal conditions found.

**Forceps with Transverse Presentation.** Kielland gives three illustrations of his special forceps and mode of applying them.

## DO CALORIES MEASURE THE VALUE OF FOOD?\*

HENRY DWIGHT CHAPIN, M.D.  
NEW YORK

As the attention of physicians is being called more and more to problems of nutrition and their solution, it may not be out of place to reexamine some of the foundations of our teachings and see if they are altogether sound.

### CALORIES AND FOOD VALUES

Much is written and said about calories, as, the food value of a certain substance is so many calories; and there is a suggestion that a calory is a sort of food ingredient, the real value of food depending on the number of calories present.

A calory is a measure of heat, just as grams, ounces or pounds are measures of weight. If a table of food values was prepared which stated that a definite quantity of milk yielded 6 pounds, meat 8 pounds, bread 4 pounds, and soup 1 pound, the natural question would be, "Pounds of what?" Scant attention would be paid to any one dwelling on the value of particular foods, because the pounds were there. Is it any more rational always to dwell on the value of a definite quantity of food simply because it contains so many calories? The most diverse kinds of food may have the same caloric value but a very different nutritive value.

The calory method of feeding is based on the assumption that nutrition processes depend solely on the oxidation of food, and that the heat given off as the result of the oxidation is the sole measure of the value of the food. In practice, the tendency is to keep a table of calory values from which a diet is made out by an arithmetical process, and the physician is likely to feel that if the calory count is correct, the food problem is properly solved.

In experimental nutrition, however, it is soon found that nutrition is not a simple oxidation process. Many feeding experiments have been conducted with animals to see if food materials from different sources, having supposedly the same chemical composition and yielding the same number of calories as the result of oxidation, have the same practical food value. One of the most notable of these experiments was made by Hart, McCollum, Steenbock and Humphrey<sup>1</sup> at the Wisconsin Agricultural Experiment Station with a large number of animals over a period of four years, and some of

their remarks and conclusions make interesting reading. They say, in part:

There is evidence from the data that there is a distinct and important physiologic value to a ration not measurable by present chemical methods or dependent on the mere supply of available energy. While the latter are important and give valuable data for a starting point, they are, nevertheless, inadequate as final criteria of the nutritive value of a feed. . . . Probably none have felt the limitation of mathematically constructed feeding standards more than those who have taken a prominent part in their development, and even the practical and successful feeder uses these standards only as a help, varying the kind, as well as the proportion of total nutrients in the ration to meet the requirements of the individual. The kind of nutrients, however, receives his attention only when their effects are extremely pronounced and immediately apparent. . . . But in addition to the limitation of mathematical standards, which consider only digestible nutrients, or the total net available energy of a ration, there are still other important factors that must be considered. We refer to what may be called the *physiologic value* of the ration. . . . There are many different proteins, in addition to nitrogen-bearing bodies of nonprotein character; fats of different compositions and degree of saturation; carbohydrates of many types; and almost a host of undetermined and undefined bodies in the daily ration of a domestic animal. . . . Unquestionably the *physiologic value* of a ration is largely dependent on its chemical constituents, but the usual determinations made on feeding materials do not reveal the character or manner of combination of many of the constituents. Consequently, the *physiologic value* can be determined in the present state of our knowledge only by long continued observations of the reaction of the feed on the animal.

Since the foregoing experiments were conducted, animal feeding experiments have been widely carried on, and it seems to be the universal finding that the number of calories a food yields on oxidation is not at all an indication of its feeding value. Bayliss<sup>2</sup> says:

Heats of combustion do not necessarily give the actual energy value of foodstuffs as available in the organism. . . . In the animal body, energy is derived from chemical combination. This form of energy is readily converted into various other forms without the necessity of passing through the form of heat.

### ANAEROBIC AND AEROBIC REACTIONS

At this point it may be well to call attention to a fact not generally known, namely, that large quantities of the common foods are used by animals by anaerobic metabolism, since air is not essential to animal life in all cases. Mammals and birds quickly die from lack of oxygen. Frogs may remain alive for days in an atmosphere containing no oxygen. Fish and reptiles

\* Read before the American Pediatric Society, Atlantic City, N. J., June, 1919.  
1. Research Bull. 17, University of Wisconsin Agricultural Experiment Station.

2. Bayliss, W. M.: Principles of General Physiology. New York, Longmans, Green & Co., 1915.

may live without air for some time, while insects will live and be active in a vacuum for several days. Leeches can live ten days without oxygen. Bunge<sup>3</sup> says:

I have made many experiments with the roundworm of the gut, and have satisfied myself that these animals can live in media entirely free from oxygen for from four to five days and be extremely active during the whole time. Whoever has seen these movements must be convinced that oxidation is not the source of muscular energy in these animals.

It is evident that animals which eat the common food-stuffs and obtain energy from them for days at a time in the absence of oxygen do not carry on their vital processes and obtain energy as the result of oxidation, and that for them the amount of heat that can be produced by oxidation of the food they utilize is of no interest.

In the bodies of higher animals it appears that the processes of nutrition are a combination of anaerobic and aerobic reactions. From reading Bayliss it would seem to be fairly well settled that the primary processes in the bodies of higher animals are anaerobic, and that the aerobic processes are secondary. The contraction of the muscles is an anaerobic process:

There is neither consumption of oxygen nor evolution of carbon dioxide. It is not an oxidation process. . . . To restore the potential energy which the system has lost in contracting, energy is supplied by another reaction of a chemical nature, which succeeds the contractile stage. . . . The energy required for the second process is afforded by a reaction in which some substance, carbohydrate or fat, is oxidized. Much oxygen is used and carbon dioxide given off. . . . Consideration of life without oxygen leads to the view that the actual source of the free energy required by a living organism is a secondary matter. If it cannot be obtained by oxidation, other chemical reactions, although of a less efficient kind, are made use of.

If this is the case, it is easy to understand how the large number of animals that can live without oxygen obtain their energy—they simply use more food and discard it at the point at which oxidation begins in the aerobic animals.

#### VALUE OF THESE FACTS TO THE PHYSICIAN

These facts are of much importance to the practicing physician. He is required to solve numerous problems which call for the selection of food of the right *physiologic value* for a given individual. What may be the right physiologic value for one may not be suitable for another. It is possible that the difficulty lies in a percentage of anaerobic metabolism in one case and aerobic metabolism in another. It has been conclusively shown that in practice the caloric value of a food is no strict indication of its nutritive value, but it has not been shown why this is so. With the recognition of the fact that an animal body is not merely a furnace in which food is burned, but that a long series of chemical changes in the food takes place, it is not difficult to see why practical results often cannot be obtained with foods valued only by their oxidation properties. To quote Bayliss again:

The general conclusion seems to be justified that the cell mechanisms are such as to be able to use chemical energy whether it comes from oxidation or otherwise, and that they are independent of the particular chemical reaction which furnishes it.

The animal body is highly complex, with a metabolism that is in part anaerobic and in part aerobic, as some tissues live by the former process and others by the latter.

#### SUMMARY

Heat or energy may be produced by chemical cleavage as well as by oxidation. Heat may be a degradation of energy, and in the human organism it is an excretion. Heat measurement alone is not a safe guide for the calculation of food values. This is especially true at the beginning of life when growth is the all-important factor. The foods that *build* rather than those that readily undergo oxidation must be properly gaged if we are to have healthy development.

A false theory does harm in that it points in the wrong direction, and it is a question whether it is not time to weigh carefully the caloric theory of feeding and restrict or partially abandon its use. To take its place, a system of teaching must be constructed based on a knowledge of the physiologic properties of the various food elements and the fact that there are mixed types of metabolism. Some form of biologic testing of foods must be elaborated if an always reliable gage of nutrition is to be established.

## ANAPHYLACTIC DEATH IN ASTHMATICS\*

T. HARRIS BOUGHTON, M.D.

CHICAGO

The increasing frequency with which antitoxic serums are being administered, both for curative and for prophylactic purposes, and the increasing number of diseases for which antitoxins can be prepared, make the subject of anaphylactic death of particular interest to the clinician. That many cases of bronchial asthma are the result of sensitization to the emanations from horses presents an added complication, for the existence of this sensitization makes these persons unusually susceptible to horse serum, and thus it is occasionally dangerous to administer prophylactic or curative serum in amounts sufficient to be effective. There are many cases recorded in the literature in which serious collapse has followed the administration of antitoxic serum, and a few instances in which death has occurred.

It is, of course, needless to remark that the total number of such cases is an almost negligible percentage of the total number of cases in which injection was made. At first, these cases were frankly not understood, or they were ascribed by some to status lymphaticus.<sup>1</sup> Now, however, we recognize that most of these cases of sudden death are due to anaphylaxis—a condition brought on by the sensitization of the patient to horse serum. This sensitization may have been induced during the treatment by the necessity of giving two or more doses of antitoxin over a period of six or more days; or it may have been caused by an injection of antitoxin given for some previous illness (this factor seems to have caused few, if any, deaths); or it may have been due to some unknown cause, and have existed for a long time. A large pro-

\* From the Department of Pathology of the University of Illinois College of Medicine.

<sup>1</sup> Park Harvey Lecture, Jan. 20, 1906.

portion of these sudden deaths are found to occur in asthmatics. Thus Gillette<sup>2</sup> reports a case of his own, and has collected from the literature and by personal correspondence twenty-nine more instances in which collapse or death followed soon after the administration of antitoxic serum. Of these thirty patients, sixteen died and fourteen recovered. Of the sixteen patients that died, ten were in good health at the time of the injection, three were suffering from mild attacks of diphtheria, and in two the degree of illness is not stated. In all the onset and course of the attack were so typical that there can be no doubt that these were genuine anaphylactic deaths. In one (Case 8) there is room for some doubt, as the child was quite sick and lived for ten hours after the injection. In nine of the sixteen fatal cases there was a definite history of asthma. In two of the nine instances, it is stated that proximity to horses brought on the attacks; in the other seven, the exciting cause is not stated. Of the fourteen patients that lived, nine were asthmatic; in two cases, the attacks were brought on by proximity to horses; in the other seven, the exciting factor is not mentioned. In two of the nine instances, the asthma is reported to have been cured (one was a typical horse asthma; in the other the excitant is not stated); in one case, the asthma was definitely not cured; and in the rest, the later course of the asthma is not recorded. Walker<sup>3</sup> has recorded a case of asthma in which the disease was brought on by an injection of horse serum (antitoxin), though it had never been present before the injection. There is at least one other such case in the literature. Sewall<sup>4</sup> records the case of a man who developed rabbit asthma after an injection of rabbit serum.

In all the recorded cases of serum anaphylaxis, the history of the attack is strikingly constant. Almost invariably it begins within two or three minutes after the injection, but in one recorded nonfatal case (Gillette's Case 6) the attack did not begin for twenty-four hours, but then it was perfectly typical. In fatal cases, death usually occurs within five minutes after the injection, though occasionally it is postponed for from thirty to forty-five minutes. The most prominent symptom is dyspnea. This may be accompanied by pain, either at the site of injection, or in the chest or head. Headache is very common. A marked cyanosis usually comes on at once, and frequently urticaria or edema is present. A sense of impending death occasionally occurs. The heart usually remains strong, and continues beating long after respiration has ceased.

In three of the cases reported by Gillette, postmortems are recorded. In the Langerhans case no anatomic lesions were found beyond an enlarged thymus. In Gillette's own case the postmortem report states that the lungs were larger than normal and passively congested. There was an adhesion of the pericardium to the heart (there was a history of rheumatism for several years). The kidneys were softer than normal, and more moist. The spleen was engorged with venous blood, dark and granular. Otherwise all organs were negative. In one other case, the postmortem report states that "the lungs and cavities of the heart were

in such condition as could only be brought about by sudden and extreme spasm, such as might be accounted for by an acute attack of asthma." I have collected records of several other cases of anaphylactic death which will be reported elsewhere in detail, but in none of these cases is a history of asthma recorded.

There are in the literature the reports of nine cases of bronchial asthma with postmortem records: Ellis<sup>5</sup> has collected records of seven and has reported one, and Brown<sup>6</sup> has added another. In Brown's case, the patient died from pneumonia. He had been suffering from myocardial insufficiency and cirrhosis of the liver; he had had no asthma for the last two or three months of his life. In the other cases, death occurred during an asthmatic attack, but the postmortem report covers only the condition of the lungs. In none of these cases is the exciting cause of the asthmatic attacks mentioned. It is impossible to show any direct relationship between these cases and anaphylaxis.

#### REPORT OF CASE

*History.*—A man, aged 29, who, for the last ten or twelve years, had been subject to attacks of bronchial asthma when in proximity to horses, and who had read a good deal, and was informed on the relationship of anaphylaxis to asthma, was anxious to have a desensitizing dose of horse serum, although he was familiar with the danger. He was taken to a hospital, and 1 minim of normal horse serum was administered intravenously.

Within two minutes a typical attack of asthma supervened. He was given 10 minims of epinephrin (adrenalin) intravenously, with definite relief for about ten minutes. In all, 50 minims of epinephrin were given in five doses, intravenously. Each gave relief for several minutes; but eventually the patient died, forty-five minutes after the injection of serum. The postmortem was performed within an hour and a half after death.

*Postmortem Findings.*—The body was very slender; the waist was narrow; the ribs were "dished in" at the level of the lower end of the sternum. The face was cyanotic; the lips were swollen, but herpes was not present. The body was still warm; postmortem rigidity was not present. There was very little subcutaneous fat.

The abdominal cavity showed intense injection of the vessels everywhere, being especially marked in the veins of the stomach, mesentery, gallbladder and appendix. The entire small intestine was bright red, and the dilated submucous vessels showed distinctly through the intestinal wall. The parietal peritoneum was markedly injected. No exudate was visible in the peritoneal cavity.

Both lungs were enormously distended and emphysematous. The left lung showed a small area of hemorrhage on the lateral portion of the lower lobe, about 4 cm. in diameter, with a gelatinous organizing exudate at this point. On section, the lungs were found to be dry. The right pleural cavity was largely obliterated by firm, fibrous adhesions. No fluid was present in either cavity. The thymus was not enlarged.

The pericardial cavity was negative. The heart was firm and of normal size and appearance, except for a few minute subpericardial petechial hemorrhages on the posterior surface.

The liver, which was paler than normal, extended to a point one inch below the umbilicus. No gross structural change was noted. The gall bladder was markedly injected.

The stomach showed the "hour-glass" conformation (post-mortem?). The veins on the greater curvature were enormously distended. There were no subserous hemorrhages. The mucosa was negative.

The spleen was negative except for the presence of a number of small, reddish brown foci, about 1 mm. or less in diameter, located in a group of from twenty to thirty along the anterior border.

<sup>3</sup> Walker, I. C.: The Treatment of Patients with Bronchial Asthma by Subcutaneous Injections of the Proteins to Which They are Sensitive, J. M. Research, 20: 423 (July) 1917.

<sup>4</sup> Sewall, Henry: Some Relations of the Brain and of the Olfactory Apparatus to the Processes of Immunity, Arch. Int. Med., 13: 856 (June) 1914.

<sup>5</sup> Ellis, A. G.: The Pathology of Asthma, J. P. M., 1: 11, 1911.

<sup>6</sup> Brown, O. H.: Asthma, S. Trans., C. V. M. F., 1: 1, 1911.

The kidney were about normal in size; the capsule was smooth; there were no dilated veins on the surface. On sectioning, there was a marked hyperemia, but no other change. The suprarenal was negative.

There was a Meckel diverticulum about 12 cm. long with a slight constriction at the tip.

*Microscopic Examination.*—Lungs. There was moderate passive hyperemia, but no edema. There were a few small interstitial hemorrhages. A little mucus, and a few desquamated epithelial cells were seen in some of the bronchioles. The peribroncholar muscle was well developed. A few arteries showed greatly thickened walls, and many showed moderate thickening of the walls.

Heart. There were several small hemorrhages in the myocardium. There was one small area of old scar tissue. A few small vessels showed thickened walls, and a few showed obliteration of vascular endothelium.

Kidney. Here the most marked changes were seen. The epithelium of the convoluted tubules was distinctly edematous, and there was considerable degeneration and some necrosis. There was intense passive hyperemia. Interstitial hemorrhages were numerous, but not extensive. There were no chronic changes.

Suprarenal. There was marked passive hyperemia, and there were a few minute hemorrhages.

Spleen. There was moderate passive hyperemia, and there were a few small hemorrhages. Most of the smallest arteries and many of the larger arteries showed a marked edema of the wall. Eosinophils were very numerous. In one large vessel, 500 leukocytes were counted with 6 per cent. of eosinophils. In one high-power field, sixty-five eosinophils were counted, which were estimated to be 5 per cent. of the total number of cells present.

Liver. There was very marked edema involving practically all of the parenchymatous cells. There was no passive hyperemia, and there were no hemorrhages. Very few small areas of round cell infiltration were present. Many small arteries showed marked thickening of the walls. No areas of necrosis or scar tissue were seen.

#### COMMENT

This case is of special interest for several reasons:

First, because of its relation to the recently popularized desensitization method of treating those cases of asthma (and of certain other clinical conditions) which show sensitization to specific proteins. Undoubtedly, this patient should have been treated with high dilutions of serum as advocated by I. Chandler Walker instead of the undiluted serum.

Second, because of the very small amount of serum which produced death. Of the other recorded cases, probably the Langerhans case (in which 1.2 c.c. of serum were used) involved the smallest amount of serum. In one recorded instance, an infant received 20 units of diphtheria antitoxin; one adult received 300 units, and one 1,000 units, in three instances, one adult and two children, "an immunizing dose" was given. In the nonasthmatic cases that I have collected, the fatal dose has usually been larger than in this case.

Third, because of the striking similarity in appearance of the organs in this case to those in experimental anaphylaxis in animals. The enormous distention of the lungs, the intense passive hyperemia of the abdominal organs, and the occasional subserous hemorrhages are highly characteristic of experimental anaphylaxis.

Furthermore, this is the only case of death from acute anaphylaxis, uncomplicated by other morbid conditions, that I have been able to find in which microscopic studies have been made. Koch<sup>7</sup> has reported

necropsy findings in a case of anaphylactic death in a child with scarlet fever and suppurative tonsillitis; but the microscopic findings are all referable to the infection present.

Further, we are able to observe here a case in which repeated anaphylactic shocks have been experienced, and thus to study the cumulative effect of this intoxication. Undoubtedly, the repeated asthmatic attacks to which this patient was subject have not meant as severe intoxication as is usually experienced by laboratory animals in experimental work, yet it is interesting to note that the edema, degeneration and necrosis of the epithelial cells of the liver and kidneys and the thickening of the arterial walls in spleen, liver, lung and heart correspond closely to the changes that I have previously described<sup>8</sup> in experimental chronic anaphylaxis.

It has been well known for a number of years that one must exercise extreme care in giving curative serums to asthmatics. No satisfactory method of desensitization has yet been discovered to make safe the administration of serum to asthmatics with acute infections, such as diphtheria, in which time is such an essential factor in treatment. Besredka's method of "doses subintrantes"<sup>9</sup> has not justified the claims originally advanced for it; and Weil<sup>10</sup> has pointed out grave objections to its use as a routine. At best, the methods of desensitization are uncertain. In experimental work, animals sensitized with a small dose of serum can be desensitized with a small dose. Animals sensitized with a large amount of serum require a relatively large amount to effect desensitization—an amount, indeed, that would be fatal to an animal sensitized by a small dose.<sup>10</sup> Since we cannot know whether man should be desensitized by a large or a small dose, this method is unsatisfactory for practical use. The giving of a series of doses of gradually increasing size may, in some cases, produce desensitization, but in others it will bring on a fatal attack of anaphylaxis instead.<sup>11</sup> Of course, the intravenous method of administration in these cases is more dangerous than the subcutaneous. And yet in only a small number of cases is the danger great. Walker,<sup>12</sup> in an analysis of 150 cases of asthma, found that only 20 per cent. were due to horse proteins, and of these but 20 per cent. (or only 4 per cent. of the entire series) were sensitive to horse serum; the rest were sensitive only to horsehair protein. When it is desired to give a curative serum to an asthmatic, it would be well to make first the cutaneous test with diluted serum to see if he is sensitive to horse serum. If not, the therapeutic dose would probably not produce serious symptoms. For the benefit of those asthmatics who are sensitive to horse serum, it might be worth while to prepare curative serums from other animals than the horse.

#### SUMMARY

A certain proportion of asthmatics (4 per cent. in Walker's series) are sensitive to horse serum. In

these the injection of horse serum (antitoxin) may produce serious symptoms or death. As compared to nine previously recorded cases of anaphylactic death in asthmatics, an added case, in which death resulted from the intravenous injection of 1 minim of horse serum, presents an instance of the smallest amount of serum that has produced death in any recorded case. Both the gross and microscopic appearance of the organs at necropsy show a striking similarity to lesions previously described in experimental anaphylaxis. There is uncertainty in existing methods of desensitization. Asthmatics who require curative or prophylactic serums should be tested by the cutaneous method to determine their sensitiveness to horse serum. If they are not sensitive to horse serum, therapeutic doses of antitoxin are probably safe. It might be well to prepare antitoxins from other animals than the horse for use in patients sensitive to horse serum.

## ACUTE DILATATION OF POST PARTUM UTERUS AS A CAUSE OF POST PARTUM HEMORRHAGE

ITS ANALOGY TO ACUTE DILATATION OF THE STOMACH, WITH A SUGGESTION ON THE ACTION OF INVOLUNTARY MUSCLES:  
PRELIMINARY REPORT

JOHN P. GARDINER, M.D.

Obstetrician, Dispensary of the Toledo District Nurse Association  
TOLEDO, OHIO

Acute dilatation of the post partum uterus may occur: (1) during the third stage of labor in which the placenta and membranes are still in utero, and (2) in the early puerperium, uncomplicated by the placenta and membranes which have been discharged.

1. In the third stage of labor, the uterus has a function to perform: the separation and discharge of the placenta and membranes. As the child is being born the fundus follows the child until it is stopped by the bulk of the placenta which it snugly surrounds. The liquor amnii, usually clear, though it may be highly tinged with blood, is discharged, with some bright blood following. The uterus slightly relaxed, globular in shape, and situated below the umbilicus, gives good evidence of muscular tone. After a half dozen pains the placenta and membranes have become separated and are pushed down into the lower uterine segment and vagina. The fundus rises, having become pear-shaped, and is found in the median line below the umbilicus; being well contracted, its outline is well marked. The flow of blood is not great, and normally no clots are present. The average loss of blood during a normal labor is less than 500 c.c.<sup>1</sup> In contrast to this picture, acute dilatation in the third stage of labor presents a uterus which has increased in size until it may fill the abdomen. Its limits are ill defined; its walls, instead of being resilient, are soft and doughy. The placenta and membranes are still retained in the uterus, and the uterine cavity fills with blood. By vis a tergo the hemorrhage, unless blocked by the membranes in the lower uterine segment, appears at the vulva, where it is recognized as a post partum hemorrhage. The time of onset of the acute dilatation is not fixed, but it

comes on while the uterus is apparently functioning normally.

2. Acute dilatation in the early puerperium occurs usually within half an hour, though it may happen within the hour, rarely later. The normal puerperal uterus at this time is in the median line; its fundus is felt midway between the umbilicus and the pubis. The size of the individual uterus varies. Its outline is well marked, it is well contracted, and the membranes and placenta are entirely discharged. There is present only a slight lochial hemorrhage. By the end of an hour the uterus, being larger but not losing its muscular tone, has risen to or near the umbilicus. In acute dilatation, however, the uterus may extend above the umbilicus, or it may be but little larger than many post partum uteri functioning normally. Its walls are softer and they have lost their muscular tone, allowing the blood to escape from the open sinuses of the placental site. It is obvious that the bleeding is not so rapid as in the third stage, yet this post partum hemorrhage is free enough to cause death within an hour or two. Cragin,<sup>2</sup> in speaking of this condition, calls it "ballooning of the uterus with its accompanying hemorrhage." Hemorrhage from other portions of the post partum uterine endometrium must of necessity be slight in comparison to that from the placental site.

Under normal conditions after the birth of the child, the uterus contracts and retracts closing the sinuses and, following a few pains, the placenta and membranes are discharged. No unusual hemorrhage occurs. The placenta, however, in some cases is retained, and yet there is no hemorrhage. That retention of the placenta in itself is not deleterious is shown by the fact that articles appear from time to time issuing a word of warning against any mechanical interference with the uterus, as with the Credé method, before the placenta has had time to separate. The most common danger of retained placenta and membranes or portions of them is that they may become splendid culture mediums, causing puerperal infection.<sup>3</sup>

When an excessive quantity of blood appears at the vulva after childbirth, the place from which the hemorrhage is coming must be determined. If hemorrhage from the cervix, circular sinus,<sup>4</sup> or lower birth canal can be excluded, it is a post partum hemorrhage from the placental site. Hemorrhage from the placental site is due to the lack of pressure which should control the flow of blood from the uterine sinuses. Serious bleeding may occur even after the expulsion of the placenta. Williams<sup>5</sup> and other writers state that "the danger of hemorrhage does not end with the expulsion of the placenta, as the uterus sometimes relaxes during the hour immediately following" labor.

Acute uterine dilatation must not be confused with uterine inertia.<sup>6</sup> If there is retention or delayed sep-

aration of the placenta without hemorrhage, uterine inertia is present. If there is retention of the placenta with hemorrhage, exclusive of birth injuries and other pathologic uterine conditions, acute uterine dilatation is present.

The three cases outlined herewith illustrate the different types of acute post partum uterine dilatation:

#### REPORT OF CASES

**Case 1.**—Mrs. B., secundipara, had spontaneous labor, the second stage of which was short. The child weighed 10½ pounds. The placenta and membranes were discharged intact fifteen minutes after the birth. The uterus was well contracted, and there were no injuries to the birth canal. The lochial hemorrhage was normal. Fifty minutes after the birth, the uterus extended above the umbilicus; its walls were soft and doughy. There was a profuse hemorrhage, and the patient was nearly exsanguinated. Under active bimanual stimulation the uterus contracted to midway between the umbilicus and pubes. Recovery was uneventful.

**Case 2.**—Mrs. McN., secundipara, after normal labor gave birth to a child weighing 10 pounds. The uterus contracted down on the placenta after the birth. Within ten minutes the uterus had increased in size until the fundus was midway between the ensiform cartilage and the umbilicus, filling the abdomen. The uterine wall had lost its muscular tone. The woman showed signs of hemorrhage, though none appeared at the vulva. By bimanual compression and the Credé method the uterus contracted, expelling intact the placenta and membranes and many clots, until the fundus was 10 c.c. above the pubes. The cervix and lower birth canal were not the seats of any hemorrhage, only a small perineal laceration being present. The patient made a good recovery.

**Case 3.**—Mrs. S., secundipara, after labor, the first stage of which was prolonged, owing to a unyielding cervix and the second stage was very short, owing to a relaxed perineum, was in apparently good condition thirty minutes after the birth, when I saw her: the skin was of good color, the pulse was 100, and the fundus was midway between the pubes and the umbilicus. The membranes and placenta were discharged entire about ten minutes after the birth. Forty-five minutes after the birth the patient showed signs of hemorrhage the skin was pale, the lips were blanched, and air hunger was present. There was some vulvar hemorrhage present, but it hardly seemed enough to account for the severe symptoms, and as there were no injuries to the birth canal, and as the uterus appeared contracted, other signs of the hemorrhage were quickly looked for with no result. Further examination revealed that there had been considerable oozing of blood through the vulva. Then the uterus was grasped and under the Credé method it contracted down behind the pubes to the size of a two months pregnant uterus. Further recovery was not interfered with.

#### COMMENT

The uterine muscle is an involuntary muscle and possesses the characteristic of involuntary muscles—rhythmic contraction. Of the physiologic action of involuntary muscles little is known.<sup>9</sup> What is known has been gained chiefly from the experiments on the uterus, ureter, bladder and retractor penis. It is revealed that dilatation of a voluntary muscle causes a system of contraction to travel to each end of the fiber, but no farther. As a rule, a stimulus applied to any part of a sheet of involuntary fibers may travel all over the sheet, just as if it were a simple fiber, as in the heart, stomach, and in the contractions of the uterine muscle. The most important form of mechanical stimulation is that produced by tension. The effect

of increasing tension on involuntary muscle may be twofold: First, if produced slowly, as in the gradual filling of the urinary bladder, relaxation is the result; second, sudden excitation produces increased contractions. The Lewises<sup>9</sup> reported that the power of rhythmic contraction exists in involuntary muscles in the culture growths of the chick amnion, as an inherent property of the protoplasm of the involuntary muscle, and may be exhibited either by a bundle of cells, by an individual cell, or by a part of a single cell. This is a great advance in pointing out that the movements of involuntary muscles are not dependent entirely on their closely associated network of nerve fibers. Furthermore, they found that when this phenomenon, rhythmic contraction, ceased, it could again be instituted either by touching the cell or by the addition of calcium to the culture medium. The point which the Lewises bring forward is very timely, as many authors speak of a paralysis of the placental site as a cause of post partum hemorrhage. By their experiment, it is seen that the movements of involuntary muscles are not dependent entirely on their closely associated network of nerve fibers. In view of this fact, it appears that involuntary muscle fiber cells and even parts of cells possess the inherent property of rhythmic contraction without any demonstrable nerve control, just as in the amoeba. Here, then, one may question the assumption that a true paralysis of the placental site occurs, and affirm rather that it is an acute dilatation or, more properly, a relaxation of the uterine muscle which allows the hemorrhage from the placental site.

All hollow viscera have involuntary muscle walls and seem to possess a property which may cause them to go into acute dilatation after a period of undue stress. It is frequently noticed that an old person in his usual health, after a more than ordinary exertion during the day, may die during the following night. Here, the heart muscle has continued apparently as normal after the period of stress; then later it enters into permanent diastole. The same thing occurs in younger people, after a period of extraordinary strain, such as a sharp run or severe physical exercise, when not in training for it. The heart continues apparently normal for a time, and then goes into permanent diastole. It again occurs as a complication in operations. The stress on the heart muscle may be great enough, even before anesthesia is complete, to cause the heart to enter into permanent diastole. Diastolic rest may also occur in postoperative cases. In severe infections, such as diphtheria, it is sometimes seen.

The involuntary muscular coats of the blood vessels also possess this common action of dilatation, as the dilatation of the abdominal vessels in fainting. This acute dilatation is seen in the vessels about local injuries and infections irrespective of their location in the body. It is possible that this acute dilatation of the blood vessels is one of the chief features in the production of that condition which is generally known as shock.

As there is an acute dilatation of the heart and blood vessels, so there is an acute dilatation of the stomach.<sup>10</sup> Two theories have been brought forward to explain

<sup>9</sup> Lewis, M. R., and Lewis, W. H.: *Am. J. Physiol.*, **44**: 67 (Aug.) 1917.

the cause of acute dilatation of the stomach: first, that there is a primary paralysis of the stomach; second, that there is a mechanical obstruction by the mesentery and mesenteric vessels. All cases of acute gastric dilatation give a history of preceding stress, as is shown in postoperative dilatation of the stomach. No matter what part of the body is operated on, dilatation may follow.<sup>11</sup> Gastric dilatation follows delivery—post partum dilatation of the stomach.<sup>12</sup> It is often a complication of acute infections, as in pneumonia. Thompson, who has studied the subject extensively, states that while in no way denying that some cases may be obstructive in origin, he is inclined to believe that a primary paralysis of the organ must be regarded as the underlying cause in the majority of cases. It is suggested that instead of a primary paralysis it is an acute relaxation of the involuntary muscles of the stomach walls which occurs.

The intestine is likewise affected: the condition is known as ileus.<sup>13</sup>

The urinary bladder is another organ which is frequently affected by acute or fatal dilatation, when the body has undergone a period of stress, as is frequently seen following operations, labor, and as a complication in infectious diseases.

From physiologic experiments we learn that involuntary muscles possess the power of rhythmic contraction, and that the walls of the heart, stomach, bladder, uterus and other hollow organs are made up of involuntary muscles and possess the function of rhythmic contraction. The involuntary muscle walls of the uterus reveal an added function during and after labor, that of retraction. Therefore, involuntary muscles under some circumstances have two functions, rhythmic contraction and retraction. Furthermore, the heart, stomach and bladder, after a period of stress, may assume a state of acute dilatation due to the acute relaxation of the involuntary muscle. This same condition I have found in the uterus, and it appears with such dignity and purpose that I have been impressed with the possibility that it may be due to an inherent quality in involuntary muscles. One may object to the dilatation of the uterus theory on the basis of a simple distention caused by the blood, coming from the placental site, accumulating in the uterine cavity and producing distention. The point in the differential diagnosis is that in a distended organ the walls possess a characteristic resiliency or muscular tone, while in acute post partum dilatation the walls of the uterus are soft and flabby, having lost their muscular tone. Williams<sup>6</sup> speaks of a relaxation of the uterine walls post partum; Cragin<sup>9</sup> of a ballooning of the uterus post partum; DeLee<sup>14</sup> mentions that dilatation of the uterus may occur during a curettage. There is, then, an acute dilatation of the uterus, and it is a function inherent in the uterine musculature which may prove rapidly fatal.

Acute dilatation may prove rapidly fatal not only in the post partum uterus but also in acute dilatation of the heart, stomach and bladder. These organs when in a state of acute or fatal dilatation show within a limited time a uniform tendency to respond to stimuli, and may recover to perform their normal function.

Several patients with acute dilatation or diastolic rest of the heart are reported as recovering by the employment of cardiac massage. Cardiac massage<sup>15</sup> is employed subdiaphragmatically, through the abdominal wound: the hand grasps the heart and compresses it a few times a minute, and indirectly massage is applied by tapping with the fingers over the right auricle. A unique report is that of Argaud.<sup>16</sup> In a decapitated man, aged 20, Argaud saw spontaneous contractions forty-five minutes after decapitation; from this time to sixty-two minutes, mechanical stimulations, particularly of the right auricle, evoked cardiac contractions. Then he opened the heart, and by electrical stimulation produced a response to the eighty-third minute. He found the most excitable region of all corresponded to the tenia of His, the Keith-Flack node, and the valve of Thebesius, the regions richest in nerve ganglions. He recommended in diastolic rest light taps by the finger tips over the right auricle at intervals of from ten to thirty seconds, watching for myocardial response. Two patients with asphyxia neonatorum<sup>17</sup> recovered by cardiac massage, artificial respiration being simultaneously practiced: one child, after an hour, the other, after three hours.

In acute dilatation of the blood vessels, there is response to stimulation. In fainting, stimulation is produced on the acutely dilated blood vessels by assuming the horizontal position; or, if the cerebral anemia is great, it is produced by the convulsion following. That pressure applied in local infections has a good effect, because of its support of the acutely dilated vessels, is well known. This is exemplified by the fact that many a one advocates the continuous administration of ergot to keep the post partum uterus (its sinuses) well contracted (regarded also as a preventive of puerperal infection). In shock, the blood vessels are acutely dilated; and the advantage of the stimulation produced by massage, bandaging the extremities and abdomen, the Trendelenburg position, and drugs (such as suprarenal extract) is also well known.

It is known that the stomach, when directly irritated, contracts; but in acute dilatation it is impossible for the stomach to relieve itself because of the two sphincters which control the outlets and probably respond to the same stimuli as the muscular walls of the stomach. In this case the only relief is the introduction of the stomach tube.

The bladder responds likewise to stimuli, but here a sphincter also prevents relief, which is obtained only by the use of the catheter.

The acutely dilated post partum uteri in the cases reported responded to stimulation and functionated normally.

This reaction from acute dilatation predicates an inherent property in the involuntary muscle walls.

#### CONCLUSION

This preliminary report points to the fact that all involuntary muscles possess, besides rhythmic contraction and retraction, the property to functionate normally for a time, after a period of stress, then to assume a state of acute relaxation, and further, within

## SUPPURATION AND GANGRENE OF THE LUNG

A STUDY OF ONE HUNDRED CASES

HARRY WESSLER, M.D.

Adjunct Attending Physician and Associate Radiographer, Mount Sinai Hospital

NEW YORK

Although abscess, gangrene and bronchiectasis belong to the rarer lung diseases, their study is acquiring a greater interest and importance, because we are becoming more familiar with their causation and also because of the increasing possibility of curing them by operative procedures.

In the textbook description of these diseases, they are usually accorded individual notice as though these three were distinct and separate conditions. In the attempt to carry out this classification in the individual case, however, the clinician at once encounters difficulties. In a large percentage of these cases—which may comprehensively be described as cases of "lung suppuration"—abscess formation, bronchiectasis and gangrene coexist, and it is not at all an easy matter to assign the predominating rôle to any one of them.

In order to make clear some of the more salient points in the pathology and etiology of these affections, it may be of value to analyze a series of 100 cases which came under my observation up to 1918.

In respect of their etiology, these cases may be classified as in Table I.

TABLE I.—CLASSIFICATION OF ONE HUNDRED CASES OF LUNG SUPPURATION ACCORDING TO THEIR ETIOLOGY

Etiology	No. of Cases
Pneumonia	1
Aspiration	5
Pneumonia (with grip)	17
Trauma (with grip)	21
Trauma	3
Aspiration	2
Aspiration (with gangrene)	2
Aspiration (with bronchiectasis)	3
Trauma to chest	1
Trauma to chest (with gangrene)	1
Trauma to chest (with bronchiectasis)	1
Aspiration	1
Aspiration	1
Aspiration	1

If we analyze the various factors that were presumably responsible for the suppurative lung condition, they may be divided roughly into two groups: (1) those due to the aspiration of septic material into the bronchi, either during the course of operations, usually on the mouth, or in states of unconsciousness, however induced, and (2) the various primary lung inflammations, including both the frank pneumonias and the cases of so-called grip which undoubtedly represent true organized pneumonias.

These two groups will account for 94 per cent. of the cases. The rest are due to rare and miscellaneous

causes. I have included no cases of metastatic lung abscess such as may occur in the course of sepsis, as they are uncommon and do not usually appear prominently in the clinical picture.

These two groups not only are distinct as to their causation, but they also show a divergence in their symptomatology and pathology. This, however, is evident only in their early stages; and in order to recognize these differences, it is necessary to observe them from their inception.

### PATHOLOGY OF ASPIRATION ABSCESS

The frequency of suppuration of the lung after tonsillectomy, and its rarity after operations on other parts of the body, cannot fail to arrest attention. It is plausible to assume that it stands in some relation to the infected condition of the tonsils. It is probable that the infectious plugs which are expressed from the tonsils during the operation are forcibly aspirated into the bronchi, where they lodge. If a small amount of blood is aspirated with them, its coagulation will seal the bronchus and produce conditions favorable for the growth of anaerobic organisms. The abolition of the pharyngeal reflex appears to be necessary, as disease developed only in those cases in which a general anesthetic was administered. A similar mechanism will probably explain the few cases which followed profound unconsciousness due either to drugs or to alcohol.

The immediate result of the lodgment of such a mass of infectious material in a bronchus is to set up a localized bronchitis. Owing to the nature of the organisms, the process is destructive and gangrenous so that there soon results a weakening and dilatation of the bronchial wall. The initial process is therefore, strictly speaking, a localized bronchiectasis which soon invades the contiguous lung tissue. The examination of such lungs excised at operation will always reveal one or numerous such irregular cavities, which may be small and still show evidence in their walls of bronchial structure; or, on the other hand, the cavity may be large and all vestige of bronchus may be destroyed. Coincidentally with the bronchial changes, the adjacent lung experiences the effects of the infectious material. A small or a large area of the lung about the necrotic focus, sometimes a whole lobe, becomes the seat of an acute or subacute pneumonitis, with consolidation. It is significant for the later course of these cases that the pneumonic process in many cases has from the beginning a tendency to organization, so that ultimately the lung undergoes induration. The latter, owing to the development of fibrous tissue about the smaller bronchi, compresses them and thus there are produced numerous small secondary bronchiectases. These secondary bronchiectases as a rule do not achieve a great size; most of them appear as bronchial dilatations only on microscopic section. On the other hand, they may be infected by the secretions of the primary bronchiectasis and breaking down, in their turn, they may terminate as larger cavities. This, in short, is the evolution of an abscess or bronchiectasis following aspiration.

It will be noted that this is primarily a bronchial disease, and in this sense may be described as a bronchiectasis. On the other hand, in all cases an abscess cavity sooner or later develops. But it must not be forgotten that a very important and essential element in the disease is a pneumonitis, which always accom-

panies it, and which, because of its tendency to induration, constitutes one of the main obstacles to its cure.

From the clinical standpoint, aspiration abscess of the lung is always an acute disease, although later it may assume a chronic form. A study of the chronology of the symptoms will show that the acuteness of the process stands in intimate relation to the development of a gangrenous type of inflammation. It is a striking fact that signs of gangrene, consisting of the expectoration of fetid sputum or of a foul odor to the breath, are invariably noted thirteen or fourteen days after operation. The same thing is true of nonoperative cases of aspiration abscess. It will therefore be seen that such cases have a definite incubation period which must stand in close relation to the biology of the infecting anaerobic bacteria. In fact, all the facts at our disposal point strongly to the presumption that postoperative and aspiration abscess or bronchiectasis is an acute anaerobic infection of the lung, which has a definite pathology and incubation period, the subsequent course of which is to a great extent dominated by the fluctuations in the intensity of the gangrenous process.

PATHOLOGY OF POSTPNEUMONIC ABSCESS

The pathology of so-called postpneumonic abscess is not at all as easily studied as the previous form. This is due, first, to its frequent insidious onset, and secondly, to the fact that under the term "postpneumonic abscess" a variety of diverse types of lung suppuration is included. If we analyze the fifty-eight cases of presumably postpneumonic suppuration which are the subject of this study, they may be divided roughly into two groups. In the first group there will be found sixteen cases in which the symptoms and other evidences of the disease, later to be discussed, differed in no wise from those in the aspiration cases. In these patients, the evidences of gangrene were always noted from thirteen to fourteen days after the onset. For reasons to be discussed later, the question will arise whether these are really cases of acute pneumonia on which a gangrenous process has been engrafted, or whether they are not primarily cases of lung gangrene and bronchiectasis. The remaining forty-two cases apparently have a different pathology. They commonly result from an attack of bronchopneumonia, which is frequently of the grip type. Instead of resolving in the normal way, the infiltration persists and acquires a fibrotic character with a resulting induration of the lung. As a result of pressure of the fibrous tissue on the smaller bronchioles, numerous cylindrical bronchiectases develop. This is evidenced by persistent fever, cough, increasing expectoration and occasional hemoptysis. The entire process is slow and subacute, and it is months before the outspoken symptoms of lung abscess develop. The relation of gangrene to these cases is variable. In many cases it appears only late and may be only a transient manifestation. In a large percentage of the cases at some time during the course of the disease, the patient expectorates fetid sputum for a few days. But at any time, it may become a major factor, and by causing a rapid breaking down of the lung tissue it may convert a relatively benign case into one that is rapidly fatal.

LOCATION OF THE DISEASE

The distinction between these two groups of lung abscess or bronchiectasis may be further noted in the

distribution of the inflammatory process in the lungs. Postoperative and aspiration abscesses are found twice as often in the upper lobes as in the lower lobes. Exactly the reverse condition obtains in the case of postpneumonic abscess of the chronic type. This is well brought out in the tabulation of ninety-nine cases presented in Table 2.

TABLE 2.—DISTRIBUTION OF INFLAMMATORY PROCESS IN LUNGS

Kind of Abscess	Location		
	Upper Lobe	Lower Lobe	Middle Lobe
Aspiration abscess	18	9	1
Nonaspiration abscess	24	44	3

A separate consideration of the cases of acute postpneumonic abscess with early gangrene shows that in these cases also the upper lobes are involved more frequently than in the chronic postpneumonic cases. It is of interest to note that in the children in this series, postoperative abscess invariably was situated in the upper lobes.

SYMPTOMS AND PHYSICAL SIGNS

In the case of aspiration abscess, the characteristic symptom is the onset after two weeks of foul expectoration. It is evident in these cases that the development of this symptom after an operation will leave no doubt as to the diagnosis. This is true also of the acute postpneumonic abscesses. On the other hand, a cough persisting for some time after a pneumonia, especially if there is only a moderate purulent expectoration, does not warrant the diagnosis of bronchiectasis. In these cases the diagnosis must usually remain in doubt for some months, until the more characteristic symptoms develop. These patients commonly have a persistent fever, and usually slight hemoptysis, which will raise a strong suspicion of an indurative pneumonia. Only the later development of multiple bronchial dilatations, with profuse expectoration, will lend certainty to the previous suspicion. The distinction from tuberculosis should offer no difficulty because of the absence of tubercle bacilli, but especially because of the usual localization of the condition in the lower lobe. The presence of club fingers, which occurred in twelve cases, may be of help in the diagnosis. They develop relatively early in the course of bronchiectasis, at times as early as six weeks, although usually in a few months. On the other hand, clubbing develops only in long standing cases of pulmonary tuberculosis.

It is a fortunate circumstance that the diagnosis of suppuration of the lung may be so readily made from the symptoms, as the physical signs are notoriously uncertain. The physical diagnosis must depend on the demonstration of an area of induration in the lung, and also, in some cases, on the disclosure of a cavity. It is surprising how few signs even a large pneumonic area may produce. Usually only a slight dullness and diminished breathing are found. At times, there may be absolutely no physical signs. In this series of 100 cases, a cavity was diagnosed only twelve times by physical examination, although roentgenographic examination showed them to be present in forty five cases. For an exact localization of the process, to determine the extent of the disease, and to a certain extent the presence of cavities, we are to a great extent dependent on the roentgenogram.

It should be emphasized that in the diagnosis of suppuration of the lung, the demonstration of one or multiple cavities is not at all essential, nor is it possible in more than a fair percentage of the cases. When cavities are buried in infiltrated lung, when they are full of secretion, and when they are small, they will elude any kind of examination. Only the larger cavities are usually discovered. These are much more frequent in the postoperative cases and in the acute postpneumonic cases. In other words, in those cases in which the gangrenous process plays a major rôle, large cavities are early formed. Their frequency is indicated in Table 3.

TABLE 3. FREQUENCY OF LARGE CAVITIES IN POST-OPERATIVE AND POSTPNEUMONIC CASES

Case	Cavity	No Cavity
Aspiration abscess	21	3
Acute postpneumonic abscess	16	0
Chronic postpneumonic abscess	13	30

#### COURSE AND PROGNOSIS

The etiology of lung abscess has a decisive influence on its course and prognosis. The prognosis is best in the postoperative cases. Of these, nine patients recovered spontaneously, eight of them being posttonsillectomy cases. In the process of cure, it is remarkable that even large cavities may disappear in a very short time. The necrotic wall of the cavity sloughs out and is expectorated, and as the surrounding pneumonia undergoes resolution, the lung once more expands and obliterates the cavity. The cure of postoperative abscess was accomplished in every case within two months of the onset. Cases which persisted beyond this time invariably went on to a chronic stage, with a resulting lung induration, and later developed the usual sequelae and complications.

The disappearance of all symptoms and physical signs in a case of lung abscess should not without more be regarded as decisive evidence of its cure. This disease is characterized by deceptive remissions during its early stages which necessitates great caution in the prognosis. A large percentage of the acute postoperative cases, after a few weeks, become quiescent or "sleepy." In these cases a roentgenographic examination will usually reveal a small area of infiltration which is below the threshold of physical examination. Sooner or later, this remnant of the disease will be stirred to activity, and the symptoms of a gangrenous abscess will be reproduced. The disease will then take its course for months or years until it is terminated by one or more of a number of complications which continually menace these patients. Among these, pulmonary hemorrhage should be first mentioned. Hemoptysis in lung abscess occurs more commonly than it does in pulmonary tuberculosis, and not infrequently it is fatal. In a few cases a superficial abscess has ruptured into the pleura with a resulting pyopneumothorax. More commonly a simple empyema develops. In three cases, septic embolism of the brain caused the death of the patient. In addition there are periodic exacerbations in the severity of the symptoms which are probably due to an extension of the inflammatory process. This may occur slowly or may develop rapidly, owing to the spilling over of the contents of a cavity into previously uninvolved portions of the lung.

The prognosis of the postpneumonic cases appears to be almost absolutely bad; but two patients recovered in this series, although the case of one of these is doubtful, at least, as he died subsequently of brain abscess. The perforation of a superficial abscess in postinfluenzal cases in their early stage appears to be a favorable occurrence. Three patients, observed last year, in which this complication occurred, recovered promptly after drainage of the pleural cavity. It appears probable that the rupture of the cavity into the pleura served the purpose of pulmonary drainage, which apparently may be an effectual method of cure before the lung has become indurated.

Most of the postpneumonic cases continue until there is a progressive induration of the lung with the formation of multiple bronchiectases. Unless the condition is fatally terminated by one of several complications, the patients may live for years. Their lot, however, is sad and hopeless. Usually, the course of the disease is punctuated by periods of aggravation of the symptoms, in which the patients are harassed by a constant cough, profuse expectoration, which is often so fetid as to require their isolation, and attacks of high fever. On the other hand, there are cases in which the patients enjoy a considerable degree of comfort for many years, their only symptom being a copious purulent expectoration which is evacuated every morning on arising. They may have no fever, and there is usually no gangrene. These cases usually date from childhood, and may result from an attack of bronchopneumonia. In these cases the disease may be purely a bronchial one, the lung parenchyma being not at all involved. The roentgenogram reveals multiple globular dilations of the bronchi, usually of a lower lobe, so that the lung has a spongy or honeycomb appearance. It is evident that the prognosis for the life of the patient in this type of case is fairly good, although a cure cannot be expected.

#### TREATMENT

The medical treatment of suppurative lung disease offers little that is encouraging. It can be only symptomatic. The disease responds favorably for a time to climatic treatment; but there is sooner or later a recurrence of the symptoms. Symptomatically, the relief of the cough is an important object to accomplish. Constant violent coughing, by projecting the infectious material farther down into the smaller bronchi, undoubtedly disseminates the disease, and also promotes the formation of bronchiectases by weakening the bronchial walls. Periodic upsetting of the patients will facilitate drainage. Irrigation of the bronchi through the bronchoscope accomplishes the same purpose and may also keep the anaerobic process in check so that the expectoration is less offensive. This procedure cannot, however, cure these patients, as it has no effect on the pulmonary infiltration.

#### OPERATIVE TREATMENT

Acute lung abscess or gangrene is usually not an operative condition. A study of the cases here recorded has shown that at least one third of the patients with aspiration abscesses recover spontaneously usually within a period of two months. For this reason any operative procedure for the cure or relief of lung suppuration may profitably be postponed for several months. Two types of operation may be applied to these cases: thoracotomy with drainage, and lobectomy of one or more lobes of the lung.

Thoracotomy can at best be but a palliative procedure. By supplying drainage of the cavities, it diverts their secretion from the upper respiratory tract, thus, to some extent, shielding uninvolved portions of the lung from infection. It may produce a distinct improvement in the condition of the patient. A knowledge of the pathology of lung suppuration teaches us, however, that the only hope of complete cure rests in a complete removal of the infiltrated lung. This, no drainage operation can accomplish. Unfortunately, lung resection is an operation fraught with the greatest difficulties; it demands the highest surgical skill, and the operative indications in the individual case are extremely narrow. They may thus be formulated: The patients must be young; the operation in those who have reached the age of 40 has a prohibitive mortality. The case must be uncomplicated, that is, the pleural cavity must be free of dense adhesions so that the lobectomy may be expeditiously performed. Operations which last much over an hour result in a high mortality. The disease must be unilateral. When the operation has been successfully performed, the patient is completely cured; and surgery records no more brilliant or dramatic achievement than the restoration to health of a person afflicted with this most dreadful and hopeless disease. Of the patients in this series, five were cured by lobectomy by Dr. Lilienthal, all of whom remain well to this day.

Of the other surgical procedures, mention should be made of artificial pneumothorax. It is difficult to see how the injection of air into the pleural cavity may be expected to cure these patients. The conditions present bear no similarity to those which obtain in tuberculosis. It is not desirable to stimulate fibrosis, as there is already a tendency to fibrosis. The collapse of a cavity, if this is possible, which is doubtful, will not bring about the removal of a gangrenous focus. Not only is this procedure of no value, but it also may be distinctly harmful. The collapse of the lung may lead to a dissemination of septic material into distant portions of the lung with a rapid extension of the disease. In two of the cases in this series in which artificial pneumothorax was performed, not only was there a marked extension of the disease, to be observed on the roentgenogram, but also both patients died suddenly, shortly after the last insufflation.

It is important to emphasize the value of bronchoscopic examination preliminary to any operative procedure. In children, especially, it is not unusual to find a foreign body in the bronchus as the unsuspected cause of a lung abscess, and unless the disease is of long standing, removal of the foreign body may result in a cure.

#### CONCLUSION

It may be worth while to emphasize a few points in the pathogenesis of suppuration of the lung. There seems to be little doubt, from a study of the cases of postoperative abscess, that the disease is bronchogenic. It is equally probable that the infection is primarily gangrenous and owes its origin to definite forms of anaerobic micro-organisms. The pathogenesis of post-pneumonic abscess is, however, not so clear. In the chronic types there is, undoubtedly, primarily a pneumonic process which is due to the usual bacteria, such as the streptococcus and pneumococcus, which have the power to incite a chronic type of inflammation. There is, however, a group of so-called acute

postpneumonic abscesses or gangrene in which, without any evidence of operation or aspiration, there is, nevertheless, a primary gangrenous inflammation. In these cases, of which there were sixteen, the onset of fetid expectoration occurred on the thirteenth or fourteenth day just as in the cases of aspiration. They resembled the latter also in the frequent involvement of the upper lobes and in the early development of large cavities. The question, therefore, arises whether these are truly cases of pneumonia with subsequent development of gangrene, or whether they are not also due to the aspiration of septic material from the teeth or the tonsils, perhaps in the act of snoring during sleep. That this is not improbable will be evident from a consideration of several of the cases in which aspiration gangrene developed during unconscious states. This occurred in one case after an overdose of morphin, and in another after alcoholic coma. In both these cases, the chronology of the symptoms and the clinical course were identical with those of postoperative cases. It is to be hoped that a clearer insight into the pathogenesis of lung suppuration will be obtained when we succeed in reproducing the disease in animals, and when systematic studies of its anaerobic bacteriology have been made.

## CONTAMINATION OF THE HANDS AND OTHER OBJECTS IN THE SPREAD OF DIPHTHERIA

OBSERVATIONS ON SECONDARY INFECTIONS IN HOSPITALS FOR CONTAGIOUS DISEASES\*

GEORGE H. WEAVER, M.D.

AND

JOHN T. MURCHIE, B.S.

CHICAGO

Crossed infections in hospitals for contagious diseases are always a matter of concern, and the technic followed in modern hospitals for these diseases has been elaborated with the special purpose of preventing such infections. Since the transfer of the infectious material is probably in most cases by direct carriage, it is most important to know just what the carrier is and to take measures to avoid its activity. It is readily imagined that the hands of nurses and others which are often in contact with patients and which frequently become contaminated by discharges from the throat, nose, ears, etc., may readily act as carriers. Our observations were made to learn if the routine followed in the hospital was sufficient to preclude such carriage by hands. Cultures were made to determine whether the hands of nurses and interns were free from the organisms which they had acquired in handling patients after the washing with soap and running warm water which we have depended on for cleaning the hands. The observations were made on a floor of the hospital principally devoted to diphtheria patients. Two forms of bacteria were sought by cultures, namely, the diphtheria bacillus and hemolyzing streptococcus. Neither of these is apt to occur except as it comes from disease secretions. Davitt and other have

\* From the Durand Hospital of the City of Chicago, Illinois, for Infectious Diseases.  
1. Davitt, D. J. *Ill. M. J.* 24: 134 (1911).

pointed out that hemolyzing streptococci do not occur on normal clean skin. Since they commonly are present in the secretions in cases of diphtheria, their presence on the hands of those caring for persons with this disease can safely be inferred to be due to contamination with patients' secretions. Similar conditions apply to diphtheria bacilli. Cultures were also made from door knobs leading to the vestibule of patients' rooms, since if they become contaminated they may soil hands that have been properly cleaned. The cultures from hands were taken after routine washing, the person not knowing when they were to be taken. Cultures from door knobs were made after they had been unwashed for several hours.

The material for cultures was secured by drawing sterile cotton swabs, moistened with sterile water, beneath the nail of the right index finger, over the palmar surface of the same finger, and over the surface of a door knob. The swabs were rubbed over slants of Loeffler's solidified blood serum, and then washed off in sterile broth from which 5 to 10 drops were used in preparing blood agar plates. When organisms resembling diphtheria bacilli were seen in preparations from the culture on Loeffler's serum, pure cultures were isolated. Only those were finally recognized as diphtheria bacilli which produced typical lesions in guinea-pigs and were protected against by diphtheria antitoxin. In the blood agar plates, minute hemolyzing colonies were transferred to broth, and those strains which grew in chains and which produced a wide zone of hemolysis on a blood agar streak were listed as hemolyzing streptococci. The observations were carried out over a period of five months. The results may be thus summarized:

#### RESULTS OF EXAMINATIONS

A total of 268 examinations were made on forty-five pupil nurses, from one to fifteen examinations being made on the same individual. Of the 268 cultures from beneath the nail and from the palmar surface of the right index finger, twenty-five, or 9.3 per cent., contained hemolyzing streptococci and eight, or 3.0 per cent., diphtheria bacilli. Of the forty-five nurses, sixteen, or 35.6 per cent., yielded hemolyzing streptococci, twelve from beneath the nail, two from the palmar surface of the finger, and two from both locations. Of the same nurses, six, or 13.3 per cent., yielded diphtheria bacilli, three from beneath the nail, two from the palmar surface of the finger, and one from both locations. No individual who had ten or more cultures failed to show hemolyzing streptococci.

Similar examinations were made of four graduate nurses who had been specially trained in the care of contagious diseases, from five to twenty cultures being made on single individuals. In fifty-one cultures, hemolyzing streptococci were found but once, that is, in about 2 per cent. Diphtheria bacilli were never found. These nurses work with the sick-st patients, and their hands are especially liable to contamination. The contrast between the results in highly trained and pupil nurses is striking.

From the hands of three interns, forty-five cultures were made, seven of which, or 15.6 per cent., yielded hemolyzing streptococci, and three, or 6.7 per cent., diphtheria bacilli. Each of the three interns yielded diphtheria bacilli from beneath the nail on one occasion. In two of these the cultures were taken immediately after scrubbing the hands following the making of a necropsy in a case of diphtheria during which no

rubber gloves were worn. All of their hemolyzing streptococci were from beneath the nail.

Cultures were taken from the hands of four diet maids. Out of sixty-four cultures, hemolyzing streptococci were found beneath the nail twice, or in 3.1 per cent. No diphtheria bacilli were found.

An orderly who handled the laundry bags and waste materials yielded hemolyzing streptococci from beneath the nail four times out of eighteen cultures, but never diphtheria bacilli. Cultures from persons in the hospital office and laundry were uniformly negative.

Cultures were made from door knobs 137 times, eight, or 5.8 per cent., yielding hemolyzing streptococci, and six, or 4.4 per cent., diphtheria bacilli.

#### METHODS OF AVOIDING CROSS INFECTIONS

The significance of these findings is evident. While the streptococci may not always have come direct from patients, this can hardly be the case with diphtheria bacilli. It is evident that washing with soap and warm running water as carried out by most individuals does not entirely rid the hands of pathogenic bacteria. That it can be done, however, is indicated by the result of cultures from the hands of the specially trained nurse. The soiling of door knobs, etc., by unclean hands furnishes a means for contamination of clean hands, and so one careless person may annul the efforts of others. It would seem necessary to give special detailed instruction in the care and cleansing of the hands, especially of the nails, to all pupil nurses and interns when they begin work in a hospital for contagious diseases. They should be taught to avoid needless soiling of the hands as well as proper cleansing. They should be impressed by the great danger of the hands acting as carriers of infection to patients and to themselves.

In caring for patients when gross contamination of the hands cannot be avoided, and when performing necropsies, the difficulty of complete cleansing would suggest the use of some mechanical protection, such as rubber gloves. The routine making of cultures such as we have indicated, and which we propose to continue, might well be of value as a check on the technic of persons working about contagious diseases. Doors so constructed that knobs are eliminated would remove one means of hand contamination.

Even with the most perfect mechanical conditions, instances of cross infection can be eliminated only by intelligent, conscientious care by every person who has to do with the patients. Those who are careless should not be tolerated about hospitals for contagious diseases.

---

**Fight Against Hookworm.**—The annual report of the International Health Record of the Rockefeller Foundation states that Brazil, Central America, the West Indies, and Far East, and twelve states in the United States are enlisted in cooperative work in the campaign against hookworm. Requests for aid in combating the disease were received from Colombia, the Barbados, Curaçao, and Santo Domingo, West Indies, the Madras Presidency, India, Kelantan, and the Federated Malay States, and Mauritius. In the United States, Alabama, Arkansas, Georgia, Kentucky, Louisiana, Maryland, Mississippi, North Carolina, South Carolina, Tennessee, Texas and Virginia were added to the states actively engaged against the disease. In the West Indies, Gambia, St. Lucia, St. Vincent and Trinidad; in Central America, Costa Rica, Guatemala, Nicaragua, Panama and Salvador; in the Far East, Ceylon, China, Fiji, Seychelles, Siam and Queensland, Australia and in Brazil, the federal district of São Paulo, and Rio de Janeiro.

## ASYNCHRONISM OF THE RESPIRATORY MOVEMENTS IN LOBAR PNEUMONIA\*

WARREN COLEMAN, M.D.  
NEW YORK

The type of breathing to be described first attracted my attention some twenty-five years ago. Subsequently, it was observed with such constancy that I simply assumed it to be well known. A recent review of the literature, however, which included the more recent textbooks, various systematic discussions of lobar pneumonia, and all of the suggestive titles in the second edition of the Surgeon General's Catalogue yielded only two references to the subject. Grocco<sup>1</sup> gave a brief description of the phenomenon in 1904. Frugoni,<sup>2</sup> his pupil, included it in an extended study of pathologic changes in the respiratory rhythm in 1910.

In 1904, Hughlings Jackson<sup>3</sup> reported an isolated case of "latent pneumonia" in which there were no contractions of the intercostal muscles with ordinary breathing. The rate of the respiration was 44 per minute. The intercostals acted, however, when the patient was told sharply, "Breathe!" "There was loss of automatic movement of the intercostals with persistence of the voluntary movement of the same muscles." The diaphragm appeared not to act in the "voluntary" breathing since the epigastrium sank in. This case only remotely resembles the type of breathing under discussion. Jackson himself thought that the phenomenon was due to a circumscribed myelitis of the lateral horns, if not more, of the cord.

Asynchronism of the respiratory movements is characterized by a separation of the moment of contraction of the diaphragm and intercostal (and other thoracic) muscles by a definite, though variable, time interval. As far as my observations go, the diaphragm always contracts first; the abdominal wall is forced outward, and then, after varying intervals, the contractions of the intercostal muscles follow. Careful attention may be necessary to detect the lag in the movement of the thorax; the lowermost intercostals may contract first and the movement of the thorax spread from below upward, or the delay in the contraction of the intercostals may result in complete asynchronism. In the fully developed type of asynchronism, the diaphragm reaches the expiratory phase before the contractions of the intercostals set in, and the abdomen and chest rise and fall alternately—"see-saw" best describes the impression conveyed. The time relations of the contractions of the diaphragm and intercostal muscles with those of the auxiliary and associated respiratory muscles (for example, dilatation of the alae nasi) have not yet been determined in detail, but dilatation of the alae nasi has been observed to precede the bulging of the abdomen, which in turn preceded the movement of the thorax.

### INCIDENCE

Grocco states that he has observed asynchronism of the respiratory movements in meningitis (especially

the basilar form), typhus fever, pneumonia, heart disease, uremia, and cerebral abscess, hemorrhage, or tumors. In my experience, a slight delay in the contractions of the intercostal muscles has occurred in uremic stupor, pulmonary abscess following pneumonia, and in cases of indefinite febrile disease; but complete asynchronism has occurred only in lobar pneumonia.

### PROBABLE CAUSE AND PROGNOSTIC SIGNIFICANCE

Asynchronous breathing possesses especial interest from two standpoints: (1) its probable cause, and (2) its prognostic significance.

1. *The Cause of Asynchronous Breathing.*—The search for the cause of asynchronous breathing has suggested that the phenomenon may help to clear up problems in the physiology of respiration which have not yet been solved. For example, the time relations of the contractions of the various respiratory muscles and groups of muscles have not yet been determined with certainty, nor have the identity and respective functions of the different parts of the central nervous system concerned in the regulation of the respiratory movements.

In 1849, Hutchinson<sup>4</sup> described the normal respiratory movements:

In ordinary male breathing in man the abdomen first bulges outward; the ribs and sternum nearest the abdomen gently follow this movement until the motion, like a wave is lost over the thoracic region. In costal breathing, the upper ribs move first, and the abdomen, second. This is the ordinary breathing in women.

Without a definite statement to that effect, Keith<sup>5</sup> conveys the impression that he believes the inspiratory muscles act in unison. He found that if tracings are taken over the epigastrium and over the apex of the lung, the descent of the diaphragm precedes that of the apex; but he explains this on the ground that for anatomic reasons the apex cannot expand unless the lung descends, and that the downward piston like thrust of the diaphragm causes the lowermost part of the lung to expand first.

In Dally's<sup>6</sup> discussion of Keith's paper, he states definitely that reciprocal exciting and inhibitory impulses control the action of at least some of the muscles of respiration:

As Sherrington has shown in case of the limbs that contraction of the flexor muscle group can only take place by temporary corresponding inhibition of the extensor group, and vice versa; so during respiration I believe the diaphragm in its active downward contraction to be synergic with the powerful muscle group which produces extension of the vertebral column, while in expiration it is antagonistic to the muscles of the abdomen.

Howell<sup>7</sup> states that "the inspiration in man (in quiet breathing) is made by the diaphragm alone or by the diaphragm together with some action of the levatores costorum and the external intercostals."

Luciani<sup>8</sup> states that in sleep respiration is essentially costal, the diaphragm is virtually inactive; and that the thoracic respiration precedes the diaphragmatic.

and that in the death agony only the diaphragm is active, while the intercostal muscles are paralyzed.

Also, according to Luciani, the immediate centers for the respiratory nerves are in the gray matter of the cord; they depend on the controlling center in the bulbiformis reticularis, which is probably under cerebral control. Mossa<sup>12</sup> believes there are at least a facial, a thoracic and a diaphragmatic center for inspiration.

In discussing the question of the existence of more than one respiratory center, Luciani asks, "Do the various modes of functional association and succession of the several muscles or groups of respiratory muscles depend exclusively on the bulbar center; or do the respective spinal centers cooperate actively; or is the varying degree of excitability of these centers at the given moment when they receive impulses from the bulbar center, of account?" He does not give the answers; but the questions themselves evidently express his belief that under certain conditions the coordination of the different muscles may be disrupted.

If Hutchinson's views and the similar views of Luciani and Howell are correct, the delay in the contractions of the intercostal muscles in lobar pneumonia is merely an exaggeration of the normal dissociation. On the other hand, if the contractions of the respiratory muscles are controlled, as Dally suggests, by reciprocal exciting and inhibitory impulses, asynchronism indicates a more or less profound disturbance of the nervous control of respiration.

In this connection it will be of interest to inquire to what extent respiration in pneumonia can be brought into relation with the control of the respiratory mechanism in health.

Haldane<sup>13</sup> and his associates have shown that the discharge of impulses from the respiratory center is regulated (among other factors) by the carbon dioxide pressure in the blood and alveolar air. The reaction of the center is so delicately adjusted that fractional alterations of the carbon dioxide pressure in the alveolar air and blood call forth marked responses (an increase of 0.2 per cent carbon dioxide in the alveolar air doubles the breathing, a fall of 0.2 per cent. causes the breathing to cease). In order, however, that the carbon dioxide may be effective, the oxygen pressure must be maintained at a definite (but relatively low) level.

Prud'homme<sup>14</sup> found that the carbon dioxide content of venous blood in pneumonia is constantly diminished and that the anoxemia of the urine runs parallel with it. While the carbon dioxide content bears little relation to the severity of the disease, it tends to be lower in the more severe cases. In two unusual cases, the carbon dioxide content was normal or above normal. In one of the higher rate of metabolism in pneumonia with increased production of carbon dioxide, the diminution of the carbon dioxide content of the blood can only be explained by diminished carrying power of the blood or by its more rapid elimination through the lungs. Prud'homme also found that the oxygen content of venous blood in pneumonia was within normal limits, except in the terminal stages of fatal cases, when a progressive decrease occurs.

An interesting suggestion may be drawn from Peabody's observations, namely, that one of the modes of

death in pneumonia may be in reality the result of excessive reduction of the carbon dioxide in the blood (acapnia) with so great a fall of venous blood pressure (venodepressor effect of Yandell Henderson<sup>15</sup>) that sufficient blood is removed from active circulation (as in hemorrhage) to precipitate the fatal issue.

Peabody's results make it clear that the cause of the rapid breathing of pneumonia must be sought in other factors than the carbon dioxide and oxygen pressures of the blood.<sup>14</sup>

Porter<sup>15</sup> and his associates have studied the functional state of the respiratory center in experimental pneumonia (produced by Friedländer's bacillus) in dogs by measuring its reaction to increasing percentages of carbon dioxide in the inspired air. They found that the center was progressively depressed as the disease advanced. In view of the fact that the center was not depressed in bacteremias produced by the same organism, they concluded that the depression was not due to the action of the toxin of the bacillus on the nerve cells of the center. Similarly, by allowing the animals to breathe pure oxygen they eliminated lack of oxygen as the cause. Since section of the vagus nerves prevents depression of the respiratory center, they concluded that the depression was due to exhaustion of the center by afferent impulses from the inflamed lung. These results are suggestive, but they should be applied to pneumonia in man, caused by a different group of organisms, with caution.

It is generally believed by clinicians that the respiratory center is depressed in pneumonia; and this opinion is supported by the action of morphin in the disease. In 1890, Loewy<sup>16</sup> found that morphin raises the carbon dioxide threshold of the respiratory center in man. These experiments have been repeated and confirmed a number of times for both man and lower animals. Henderson and Scarbrough<sup>17</sup> confirmed experimentally what has long been known clinically, namely, that the carbon dioxide threshold of the respiratory center is raised by morphin to a greater extent than the afferent threshold; in other words, respiration in opium poisoning may be maintained therapeutically by afferent impulses (vigorous flagellation, etc.).

The available evidence appears to justify the belief that the respiratory center is depressed in pneumonia; but whether the depression is caused by direct action of the pneumococcus toxin on the nerve cells, or by afferent impulses from the inflamed lung, or both, must remain open questions for the present.

The complete dissociation of the contractions of the diaphragm and intercostal muscles (the one being in the inspiratory phase, while the other is in the expira-

14. Since this article was written, Stadie's work on the oxygen content of arterial and venous blood in pneumonia has appeared (Stadie, W. C.: *J. Exper. Med.* **20**: 215 [Sept.] 1919) in which it was found that a decided reduction in the oxygen content of both arterial and venous blood occurred, especially in fatal cases of pneumonia. The average "unsaturation" (oxygen content as contrasted with oxygen capacity) of arterial blood of four patients with lobar pneumonia who recovered was 36 per cent., of venous blood 44.2 per cent.; in three fatal cases, the averages were 27.6 per cent. for arterial and 59.5 per cent. for venous blood. (The normal figures are 5 per cent. and 26.8 per cent., respectively.) In the light of Stadie's results and those of Haldane, Meakins and Priestley (*The Respiratory Response to Anoxemia*, *J. Physiol.* **52**: 420, 1919; *The Effects of Shallow Breathing*, *ibid.*, p. 433), the conclusion appears warranted that the increased rate of respiration in pneumonia is due chiefly, if not entirely, to deficiency of oxygen.

tory) makes it apparent that the central nervous mechanism is unequally affected. But whether the depression is confined to the bulbar center (formatio reticularis), or affects the other centers as well cannot at present be determined. When it is recalled that the facial, abdominal and costal movements may all occur asynchronously, strength is added to Mosso's belief that a facial, a diaphragmatic and a thoracic center for inspiration exist.

2. *Prognostic Significance.*—Asynchronous breathing was first observed in patients with lobar pneumonia who were dangerously ill and who required constant attention throughout the night. As opportunity for wider observation came, it was found to occur only in the severest cases. Without having kept statistical records, I can recall only a few patients exhibiting the phenomenon, at least in a well developed form, who recovered. It usually develops late in the disease, but it may appear within the first few days, and give the first intimation of the gravity of the case. After long observation I have come to regard asynchronism as a sign of the gravest import. While patients who develop it generally die, it does not occur in all fatal cases. In the influenzal pneumonias of the recent epidemic, asynchronous breathing was comparatively uncommon in my experience.

SUMMARY

Asynchronous contractions of the respiratory muscles occur in many cases of lobar pneumonia. In the fully developed type of asynchronous breathing, the diaphragm and thoracic respiratory muscles contract alternately, with the result that the abdomen and the chest "see-saw" up and down.

The cause of the phenomenon probably lies in unequal depression of different parts of the central nervous respiratory mechanism.

The development of asynchronous breathing usually augurs a fatal termination.

EOSINOPHILOUS MYOCARDITIS IN  
DIPHTHERIA

FRANK NUZUM, M.D.  
JANESVILLE, WIS.

The presence of eosinophils in the myocardium was first noted by Straubli<sup>1</sup> in a guinea-pig with trichosis. Rindfleisch<sup>2</sup> also recorded the condition in an acute interstitial myocarditis. Freund<sup>3</sup> found eosinophil cells throughout the myocardium in high-grade blood eosinophilia following teniasis. And Wulffius,<sup>4</sup> Tanaka,<sup>5</sup> and Liebman<sup>6</sup> have described eosinophils in the myocardium after death from diphtheria.

So far as I know, recorded examples of eosinophil myocarditis are not described in American literature. The opportunity to obtain material from the Durand Hospital of the John McCormick Institute for Infectious Diseases prompted me to search for these cells in the myocardium after death from acute infection.

In sections from various parts of the auricles, ventricles and the papillary muscles, stained with various

blood dyes, eosinophils were found in seven of twenty-nine hearts of children that had died of diphtheria. I did not find eosinophil cells in the myocardium of patients that had died of various other diseases, including scarlet fever, meningitis, poliomyelitis, measles, etc.

The cells were polymorphonuclear in type with many sharply stained granules. They were so prominent in sections stained with Wright's stain as to be detected easily on glancing over the field with low power. They usually occurred in groups of from four to twelve. In one instance, sixteen were noted in one field. The cells were grouped about among the individual muscle fibers and the connective tissue stroma. They were not more frequent in the hearts showing the most pronounced degenerative changes. So far as I could determine, the myocardial eosinophilia had no relation to the severity of the clinical symptoms or to the degrees of myocarditis or the amount of serum used in treatment. The average dose of serum in our patients was 22,000 units, or about 25 c.c., with a maximum of 110,000 and the minimum 4,000. The cells were never found in the structures which make up the specific conducting system of the heart, that is, the sinus node, Tawara's node, the His bundle, and the Purkinje fibers.

In my instances of eosinophilous myocarditis, the myocardial changes characteristic of diphtheria were present, but in no wise were they different from such cases in which eosinophils were not found. In all of the hearts studied, the myocardial changes were most pronounced about the blood vessels. Vacuolization of the muscle fibers, cloudy swelling, hyperemia of the small vessels, and blood extravasation between the muscle fibers and about the capillaries were regularly present. Fragmentation was not noted. Such changes have been described many times, more recently by Aviragnet and others.<sup>7</sup>

I have studied serial sections of the sinus node, Tawara's node, the His bundle, and the Purkinje fibers to determine whether changes of the special impulse conducting system of the heart might be made responsible for the various disturbances of rhythm so frequently noted clinically. In one heart, marked extravasation of the blood was found in the His bundle. In the others there were varying degrees of cloudy swelling of the individual fibers of the His bundle. Statements sometimes made to the effect that the fibers of the His bundle are enlarged as a result of cloudy swelling, etc., are rather indefinite, and depend in a large degree on the interpreter. After study of several dozen His bundles and the related structures which go to make up the special impulse conducting system of the heart, the changes found in this group of diphtheria hearts are not considered striking. But, since the His bundle is surrounded by a firm and dense connective tissue sheath, in some species, especially the sheep, this sheath often being cartilaginous, it is possible that even slight swelling of the individual fibers of the bundle might result in an increase of pressure within the bundle of sufficient degree to inhibit the passage of impulses. This compression, with possible changes within the fibers themselves, may be responsible for arrhythmias. This affords a satisfactory explanation for the instances of heart block that occur in diphtheria. Extrasystoles are noted less frequently. Atrial fibrillation following heart block in diphtheria has been recorded only once, so far as I know.

8. Purkinje, J.: Heart 6: 13, 1912.

It is held that diphtheria toxin is responsible for the myocardial changes in diphtheria. Hume and Clegg<sup>9</sup> are said to have demonstrated that the toxin has a direct action on the bundle of His, causing both interstitial and parenchymatous changes. It is reasonable to suppose that the changes I have observed in the His bundle are due to the toxin.

Electrocardiograms were not made in the cases from which my material was obtained. However, the clinical charts of the patients show marked variations in the pulse rate from time to time, and frequently marked irregularity. The hospital cared for 805 diphtheria patients during the time that I obtained my material, and of this number ninety three, or 11.6 per cent., died. However, in 6 per cent. of the fatal cases, the patients were moribund on admission and died within twenty-four hours. The hearts I studied were about equally divided between the group of patients that died soon after admission and the group that died after several days of observation. In each instance, the anatomic diagnosis began with the item tonsillitis, acute diphtheric pharyngitis or laryngitis, etc. Frequently, acute nephritis, myocarditis, and bronchopneumonia were noted also in the record.

The degree of myocarditis varied materially in the different specimens. It was most marked in the very toxic cases in which little antitoxin had been used. It is interesting to note that in one case in which 110,000 units (about 250 c.c. of serum) were given, the myocarditis was moderate and no eosinophils were present.

There are at least three possible explanations of the disturbance of the pulse rate in diphtheria: The degenerative changes in the myocardium due to the diphtheria toxin may cause it; similar changes in the nerve plexuses, the nerve fibers and endings in the heart may be responsible; or changes in the terminal fibers of this system, as the Purkinje fibers at the point where they fuse with the individual muscle cells of the myocardium, may cause it. When heart block occurs, involvement of the His bundle is certainly present. In other instances, myocardial, nerve and bundle lesions may be associated, and each may be partially responsible.

Several explanations of eosinophilous myocarditis in diphtheria have been offered. Schlecht and Schwenker<sup>10</sup> suggest that anaphylactic reactions play a rôle and that serum therapy increases its occurrence. Kull<sup>11</sup> records an instance of severe myocarditis following the injection of 40,000 units of antitoxin. However, eosinophilous myocarditis does not seem to have been produced experimentally with serum poisoning, although it has been caused by epinephrin (adrenalin) poisoning.<sup>12</sup> Tanaka, who found this condition in four of fifteen diphtheria hearts, regards it as a symptom of subacute infection, and holds that the eosinophils have no special significance. Bubano<sup>13</sup> explains it as a local phagocytic process. Straubli,<sup>14</sup> Gruber,<sup>15</sup> and more recently Sternberg,<sup>16</sup> have regarded the eosinophils in the myocardium as having been drawn from the capillaries by a positive chemotaxis. We have no definite knowledge of the function of the eosinophils, and this renders more difficult a satis-

factory explanation of eosinophilous myocarditis. We know that these cells take a prominent part in the reaction of the body to alien protein.<sup>15</sup> In helminthiasis, an eosinophilia arises owing to a substance introduced by the parasite into the host.<sup>10</sup> This substance actually attracts the eosinophil to the precise region in the intestinal wall that is injured by the worm.<sup>17</sup> In subacute appendicitis, the lymphatic structures of the appendix may be packed with eosinophils. Likewise, in gonorrhéal salpingitis, the gonococcus causes a chemotaxis of sufficient intensity to attract large numbers of eosinophils to the tubal tissues.<sup>10</sup> In constitutional or familial eosinophilia, including hay-fever, gout, urticaria, mucous colitis, and asthma, a blood eosinophilia is often present, especially during convalescence.<sup>15</sup> Here, also, introduction of foreign protein into the body may be held responsible for the eosinophilia. Whether the eosinophils invade the tissue in these conditions is not known. In Hodgkin's disease, eosinophilic myelocytes and polymorphonuclear eosinophils are found in the lymph glands and in the blood as part of a terminal leukocytosis. These cells are morphologically slightly different from those found in eosinophilous myocarditis; but in Hodgkin's disease, the stimulus that leads to the production of eosinophilia may be so strong that disturbance of the bone marrow results with production of immature eosinophils.

In view of these conditions in which an eosinophilia occurs, and also the production of eosinophilia by the infection of alien protein, the most acceptable explanation of eosinophilous myocarditis seems to be that it results from a positive chemotaxis, some substance being present in the myocardium in response to which eosinophils migrate from the capillaries.

#### SUMMARY AND CONCLUSIONS

An eosinophilous myocarditis was found in seven of twenty-nine cases of diphtheria, but it was not present in many cases of death from various other acute infectious diseases.

The myocardial eosinophilia had no relation to the severity of the clinical symptoms or to the degree of myocarditis.

A moderate degree of cloudy swelling was found in the bundle of His and in the special impulse conducting system of the heart.

There is a possibility that the various types of arrhythmia in diphtheria are due to a compression of the fibers in the bundle of His as a result of moderate cloudy swelling or to the degenerative changes in this system.

The changes in the specific conducting system are not proportionate to the degenerative changes present in the myocardium.

In all probability, eosinophilic myocarditis is the result of a positive chemotaxis.

METHEMOGLOBINEMIA DUE TO BROMOSELTZER POISONING\*

W. S. McELROY, B.S., M.D.

PITTSBURGH

REPORT OF CASE

*History.*—A white man, aged 36, was recently presented for diagnosis exhibiting marked cyanosis, associated with pallor, which gave him a peculiar leaden aspect. Respiration was not augmented to the degree ordinarily seen with a similar degree of cyanosis when due to deficient aeration of blood. At the age of 21, the patient had experienced "stomach trouble," manifested by pain after eating, which began at the left anterior costal margin, associated with abdominal distention and belching. The condition lasted for from one to two hours. At times vomiting occurred, which gave immediate relief. The symptoms were always accompanied by severe frontal and occipital headaches. The condition grew worse, and numerous kinds of medication were tried. The patient began taking bromoseltzer in 1911, about 5 ounces every three or four days. The headaches ceased, but the other symptoms persisted.

In 1912, the bromoseltzer was discontinued, but he began taking about one bottle of sal hepatica daily.

In 1913, he resumed the bromoseltzer, taking 5 ounces every three or four days. This he continued, gradually increasing the amount, until June, 1918, when three or four 5-ounce bottles were consumed daily. In October, 1918, he became weak, nervous, dizzy and restless.

From November, 1918, to April 20, 1919, the patient took from four to five 5-ounce bottles of bromoseltzer daily. April 23, 1919, he was admitted to the hospital. The chief complaints were nervousness, severe frontal headache, dizziness, and shortness of breath on exertion.

He was put to bed and given elimination treatment, sodium bromid and iron. The mucous membranes were very cyanotic; the skin was pale and dry, and there was considerable emaciation. The reflexes were exaggerated, but none that were pathologic were detected.

From April 27 to May 26, the patient was delirious, and physical restraint was necessary. From May 26, his mind began to clear gradually until June 10, when his mentality was normal, and he was up and around. At this time he stated that he felt better than he ever had in his life. There were still present slight cyanosis of the mucous membranes, skin pallor and general emaciation. The headache and dizziness had disappeared, though slight shortness of breath on exertion persisted.

He was discharged from the hospital, June 25, in good physical and mental condition and with no evidence of cyanosis.

*Physical Examination.*—This was negative except for a pale blue color of the skin, especially of the mucous membranes, lips and nail-beds. The pulse was regular but weak. While lying in bed, the patient experienced no respiratory distress.

*Laboratory Findings.*—The urine contained a faint trace of albumin, but there was no blood pigment. The blood count, April 24, was: red blood corpuscles, 4,400,000; white blood corpuscles, 8,100. The differential count was: polymorphonuclears, 70 per cent.; small lymphocytes, 15 per cent.; large lymphocytes, 15 per cent.; transitional, 0; eosinophils, 0.

Three samples of blood were obtained from the arm vein on the first, fifth and tenth days of May. The first sample of blood was of a dark hue with a brownish tinge, and on exposure to air, did not assume the bright scarlet hue characteristic of normal arterial blood. A portion was centrifuged, and clear serum was obtained. Spectroscopic examination of the serum failed to detect the spectrum of methemoglobin even to a thick layer. A portion of the whole blood, laked by adding water, showed, in addition to the oxyhemoglobin bands, a very pronounced absorption band in the red. On the addition of ammonium sulphid, the band in the red disappeared and the

spectrum of reduced hemoglobin appeared. The position of the absorption band in the spectrum, and the reaction to ammonium sulphid, was that of methemoglobin.

The second sample, obtained five days later, was to all appearances the same as the first. The same dark hue was noted which on aeration did not readily become arterial in hue. A portion was centrifuged. The serum was blood tinged, owing to slight laking which had probably taken place after the blood was drawn from the vein. Spectroscopic examination of the serum and of the whole blood laked by adding water demonstrated the bands of oxyhemoglobin and a band in the red, which disappeared on the addition of ammonium sulphid, as in the first sample.

The third sample of blood, taken ten days after the first, still showed the dark color which, however, was less pronounced. On aeration, this sample was found to be noticeably brighter than the two previous samples, but it was still unlike normal arterial blood. The serum in this case was clear and no band of methemoglobin could be detected. Laked whole blood, however, still gave the spectrum of methemoglobin which, on the addition of ammonium sulphid, gave the characteristic reaction.

A fourth sample, obtained June 5, was to all appearances normal, rapidly becoming of arterial hue on aeration. Spectroscopically, only oxyhemoglobin could be detected.

As it is well known that many benzene derivatives, including phenacetin and acetanilid, when introduced into the body in sufficient amounts will convert hemoglobin into methemoglobin,<sup>1</sup> the presence of methemoglobin in this case is attributed to the acetanilid contained in the bromoseltzer.

The oxygen capacity was determined by the method of Van Slyke,<sup>2</sup> and the hemoglobin by the method of Palmer.<sup>3</sup> From the third sample the oxygen content<sup>4</sup> was also determined. The accompanying table shows the results together with the hemoglobin calculated from the oxygen capacity.

RESULTS OF TESTS FOR THE OXYGEN AND HEMOGLOBIN CAPACITY OF THE BLOOD

No.	Date	Oxygen Capacity, Volume per Cent.	Hemoglobin Calculated from Oxygen Capacity, per Cent.	Hemoglobin, Palmer's Method, per Cent.	Oxygen Content of Venous Blood, per Cent.	Spectroscopic Examination for Methemoglobin
1	5/1/19	14.47	88.47	112.1	7.2	++
2	5/5/19	16.06	96.81	116.5	7.2	++
3	5/10/19	17.06	102.06	115.6	7.2	++
4	6/5/19	19.00	107.55	101.0	...	Negative

In aerating the blood for the oxygen capacity determination, the persistence of the dark color on exposure to air was conspicuous, the blood remaining dark after from fifteen to twenty minutes of such aeration.

COMMENT

The difference between the hemoglobin as determined by the method of Palmer and as calculated from the oxygen capacity apparently was due to the methemoglobin, which does not give up oxygen to the vacuum but adds to the colorimetric determination. In the presence of methemoglobin, therefore, the hemoglobin as determined colorimetrically does not give the true picture of the oxygen carrying capacity of the blood.

It might be thought that the difference between the hemoglobin as determined colorimetrically and as calculated from the oxygen capacity would give the amount of methemoglobin present, but such is not the case. The amount of methemoglobin is more than indicated by the difference, as the methemoglobin is not converted quantitatively to carbon monoxid hemoglobin.

globin, and its brownish tint does not match well with the standard.

#### SUMMARY AND CONCLUSIONS

1. A man developed the bromoseltzer habit, which led eventually to the ingestion of extremely large quantities of the drug.

2. The outstanding features of the toxic effects were a persistent methemoglobinemia, associated with cyanosis and mental derangement.

3. The methemoglobinemia can probably be attributed to the acetamidil contained in the bromoseltzer.

4. The cyanosis can be explained on the basis of the change in the blood pigment. The altered pigment was shown by spectroscopic examination to be methemoglobin.

5. The oxygen capacity and oxygen content of venous blood would seem to indicate why the cyanosis was not associated with symptoms of air hunger except on exertion.

6. If the presence of methemoglobin, the determination of the hemoglobin colorimetrically does not give the true picture of the oxygen carrying power of blood, which, however, can be estimated by determining the oxygen capacity.

## ACTINOMYCOSIS TREATED WITH RADIUM

S. A. HEYERDAHL, M.D.

Senior Physician, Radium and Röntgen Section, Rikshospitalet  
CHRISTIANIA, NORWAY

In January, 1914, I demonstrated before the Medical Society of Christiania the first case of actinomycosis treated with radium.

#### REPORT OF CASES

**Case 1.**—A O., a laboring man, aged 32, was removed Feb. 10, 1913, to the radium division from the surgical section where he had been under treatment since Nov. 30, 1912, for actinomycosis with swellings in the right cheek. December 1 the tumor in the outer side of the cheek had been incised and scooped out, a small quantity of pus (together with a soft granulation tissue) being removed. A similar incision had been made on the inner side of the cheek in which a small amount of xeriform gauze had been placed. The patient, since November 7, had gone through an internal treatment with potassium iodide. He then felt better until the beginning of February, 1913, when the swelling in the cheek grew so much that the eye slit finally disappeared. Feb. 10, 1913, he was sent to the radium division of the Rikshospitalet.

At entrance the right cheek was very swollen, especially under and inside the right eye; it was strongly injected, tender, infiltrated and sensitive to touch. Close under the right eye was a fluctuating, more prominent area the central part of which was red-white. The swelling reached farther, from the upper lip to the hair and on the outer side to the ear; on the inner side to the nasal furrow. The mucous membrane of the cheek also was heavily infiltrated and thickened. The nostril was well shut up. In front of the sternocleidomastoid muscle an estimation swelling was present.

February 11 the whole of the swollen cheek was subjected to radium treatment and the patient had for three days twenty-four hours in each place 4 cg. of radium (tube preparation).

February 14, it was noted that the swelling had abated somewhat after his arrival.

April 3, the patient returned for renewed radium treatment. The swelling on the right cheek was now distinctly better, and the right eye was about half as wide as the left one; it is true that even now the cheek was red and infiltrated, but only over an area of about 4 square centimeters on the outside of and below the eye; a small abscess was seen in the center of the infiltration.

The patient was then subjected to another three days' treatment with about half as strong doses as the first time.

May 20, the patient came for further treatment; but as the cheek showed no more traces of the disease, he was released on the same day and has been well since.

**Case 2.**—A man, aged 17, came from the surgical polyclinic into the radium section, Feb. 25, 1914, on account of actinomycosis faciei and colli.

In the beginning of December, swallowing had become painful, and at the same time the left cheek and the neck under the left ear began to swell. The swelling increased slowly, and an abscess formed, from which there ran thin pus containing small granules (under the microscope found to contain actinomycetes). Later on, several abscesses formed.

When he entered the radium section, a diffuse, firm infiltration reached across the left cheek up to the zygomatic arch, and to the ear. The infiltration covered part of the neck, the skin was very much injected, and in the infiltrated area several fistulous openings were to be seen.

In the mouth, in the mucous membrane above the left canine tooth, there was a projecting swelling the size of a bean, with a center of pus. Here could be felt glands, up to the size of a bean, hard and insensitive, on the neck alongside the front edge of the sternocleidomastoid muscle and in the supraclavicular fossa.

The radium treatment began, Feb. 25, 1914. On the outside tumor 21 cg. of radium (tube preparation) with lead filter, 1 mm., were placed for twenty-four hours, and a surface preparation of 2 by 1 cm. (0.5 mm. lead filter) in the mouth for five hours.

April 19, the radium treatment was repeated with half doses to meet a possible relapse. The patient was cured at the time, and no relapse had taken place at the last inspection, one year after radium treatment.

**Case 3.**—A laboring man, aged 44, suffering from actinomycosis colli, was transferred from the surgical section to the radium division, May 4, 1915.

The illness began with a small "lump" under the skin over the right lower jaw four months before his entrance to our section. This grew little by little and developed into an infiltration, as hard as wood, of the soft part of the neck. The swelling on the right side reached the mastoid process, downward to within a few centimeters above the sternoclavicular joint and across the middle of the throat to the angle of the left maxilla. The swelling was sensitive, the skin covering it was red, and there were indications of deep fluctuation, and actinomycetes were demonstrated in the pus of the abscess.

The radium treatment commenced, May 4. In all, 20 cg. of radium (tube preparation) were used, with a strong lead filter of 1 mm., for twenty-four hours.

A repeated treatment took place, June 9, with about a half dose as compared with the first treatment, and, July 30, the last radium treatment followed (4 cg. for twenty-four hours).

**Case 4.**—A man, aged 79, a mason by trade, was moved to the radium section, Jan. 15, 1914, from the surgical section, where he had been treated for actinomycosis.

According to the history, the illness had existed for five weeks. In the surgical section, an incision had been made on the outside of the neck whereby some pus had been evacuated; actinomycosis granules were found in the pus.

On his entrance to the radium section, the soft parts of the neck on the left side were infiltrated by a flat swelling, hard as wood, in front, measuring 10 by 10 cm., which reached to within a few centimeters across the middle line of the throat and behind to the back edge of the sternocleidomastoid

<sup>1</sup> W. Heyerdahl, *Actinomycosis faciei et colli* for the determination of the oxygen capacity and a colorimetric method for the estimation of methemoglobin, *Actinomycosis faciei et colli*, *Actinomycosis faciei et colli*.

muscle, and from the collar bone to the lower jaw. The swelling was immovable on its base, the skin nodulated, infiltrated and bluish red. Pus trickled out through a fairly large incision.

It was a case of a serious, deep actinomycosis in the neck.

The patient was subjected to his first radium treatment, Jan. 15, 1915, and 10 cg. of radium (tube preparation) with lead filter of 1 mm. were used for twenty-four hours, also surface preparations.

As early as a few days after the radium treatment, a perceptible decrease of the disease was noted.

A repeated radium treatment was undertaken, March 2, with about the same doses. The swelling was by this time evidently on the decrease, stretching in front to the middle line of the throat, above to within two finger breaths below the lower jaw, below to two finger breaths above the collar bone, and behind to the front edge of the sternocleidomastoid muscle. The infiltration had become considerably flatter.

One more after-treatment with surface radium preparations was arranged. The patient was now cured and has been well since.

CASE 5.—A man, aged 18, was brought into the radium section, Dec. 8, 1915, from the surgical section, where he had been under treatment for actinomycosis of the neck and face since the last of November.

The whole of the lower right side of the face was covered by a firm infiltration, hard as wood, stretching from the zygomatic arch across the whole of the right cheek and behind to the back edge of the sternocleidomastoid muscle and downward to within two cm. above the collar bone. The skin over the infiltrated part was slightly injected, and one part round the angle of the jaw was red and inflamed. Here, an area about as big as a florin, where a fluctuation might be traced, formed a lump. There was considerable trismus. The patient was able to open his mouth to a distance of 1 cm. between the upper and lower teeth. By puncture, a few cubic centimeters of pus were obtained, in which were found typical actinomycosis granules.

On the same day, an incision of the abscess was made and about a soup-spoonful of pus was taken out. The radium treatment commenced, Dec. 9, 1915. In all 20 cg. of radium (tube preparation) were applied for twenty-four hours.

Jan. 22, 1916, a renewed radium treatment was applied with 20 cg. of radium, lasting twenty-four hours.

January 23, it was recorded that infiltration of the right cheek had considerably decreased; it now covered an area of 4 square centimeters below the ear and round the angle of the jaw. Over the angle a small fistular opening was seen. The redness had decreased.

The radium treatment was repeated, March 1, 1916, with 14 cc of radium for twenty-four hours.

CASE 6.—E. R., a farmer, aged 27, entered the surgical section, Feb. 2, 1916, because of actinomycosis colli. An extract from the history runs:

A month before pain in the throat also started difficulty in swallowing; he was hoarse and felt weak.

About a fortnight before, the neck began to swell on the right side just below the lower jaw. The swelling spread little by little over the right half of the face upward and downward to the jugulum. During the last days, the difficulty in swallowing had increased, and breathing had become difficult.

Feb. 2, 1916, the patient had difficulty in speaking. The temperature was 38.1 C. (100.6 F.). The tongue was strongly coated, and there was fetor ex ore. The right side of the neck was considerably swollen, the swelling covering the right half of the face upward to the lower edge of the orbit and to the right nasolabial furrow. Downward it reached 23 cm., over the sternum and a little beyond the middle neck line, backward to the upper back edge of the sternocleidomastoid muscle.

On the right side of the neck upward, the tissue felt firmly infiltrated. The skin was tight and bluish red. Farther down, below the lower jaw, fluctuation could be felt, and at the upper of the middle line under the throat a lump the size of a large walnut was seen, which fluctuated strongly. The

mouth and the fauces could not be examined, as the infiltration prevented the opening of the mouth.

Immediately after the patient's entrance into the surgical section, three incisions were undertaken, and pus was removed from a large abscess. In the offensive pus were found actinomycetes. Radium treatment was started, Feb. 12, 1916. In all, 20 cg. of radium (tube preparation) with a lead filter of 2 mm. thickness were applied outside on the neck for twenty-four hours, and in the month 2 cg. of radium with a lead filter of 1 mm. thickness were applied for twenty-five hours.

The repeated treatment took place, March 28, with application of the same doses as the first time.

A slight thickening was still to be seen round the incision scars. The patient was permanently cured.

## THE DIAGNOSIS OF CHRONIC CHOLECYSTITIS COMPLICATING CARDIAC LESIONS

ROBERT H. BABCOCK, M.D.

CHICAGO

Although I do not wish to reflect invidiously on the judgment of other practitioners, still I think I am not making an extreme statement when I say that there is a tendency among some physicians to attribute to a discovered cardiac lesion most, if not all, of the symptoms of which the patient complains. This is illustrated by precordial pain. If opinion is sought by the patient because of pain in the region of the heart, and if the physician recognizes the existence of a valvular defect, for instance, the symptom is likely to be attributed to the heart and treatment instituted accordingly. If the pain is evoked or intensified by exercise, this is considered proof positive of the correctness of the conclusion, and the patient may be ordered to bed or at least told to keep quiet. Soreness of the pectoral muscles or tenderness of the intercostal nerves may not be recognized or may be ignored, and no careful attempt may be made to differentiate between myositis or simple neuralgia and angina pectoris, or to search for some focus of infection in the throat, mouth or digestive tract that may be responsible for the pain, irrespective of the cardiac lesion. That in some cases an indirect connection may exist between the pain and the state of the heart is admitted; but it is an error of judgment in most instances to conclude that the latter is the cause, and the former the effect.

What has been said of pain about the heart applies with equal, if not greater, force to certain symptoms pertaining to the digestive system. Acute attacks of indigestion, or especially what is termed "chronic stomach trouble," when complained of by a cardiac path, is very likely to be ascribed to the heart disease whether valvular or myocardial.

That persons with pronounced circulatory embarrassment are prone to disturbance of digestion is granted, in consequence probably of sluggish circulation, and therefore more or less pronounced venous stasis and altered gastric and intestinal secretion. Such digestive disorders generally show themselves as accumulations of gas causing eructation with or without fermentative acidity, and as annoying flatulence. But not infrequently, cardiac patients complain of attacks of pain, generally in the epigastric, which they ascribe to their stomach. Others may speak of "spells of biliousness" with soreness, especially of pressure either in the median line below the cardiac

cartilage or at either side, more frequently the right. If on examination the physician detects enlargement and tenderness of the liver, he is very likely to conclude that the symptoms are due to passive hepatic congestion, and the latter to defective circulation in consequence of the heart disease.

#### CHOLECYSTITIS AND CARDIAC DISEASE

In 1909, I<sup>1</sup> pointed out the injurious influence of gallbladder disease on the heart, and cases were cited of serious cardiac incompetence even to the production of dangerous edema, a condition corrected wholly or in part by drainage of the gallbladder. Since that time I have never failed to pay special attention to the possibility of cholecystitis in every person with heart disease of whatever nature who complains of indigestion or subdiaphragmatic pain, and frequently I have detected evidence of gallbladder disease.

The history is rarely diagnostic, but is often very suggestive. From an etiologic standpoint, typhoid fever either in life may furnish a clue; but even when that is wanting, the history of inflammatory rheumatism or of some other streptococcal infection may be significant, since Rosenow's investigations have proved the presence of streptococci in the mucous membrane of the infected gallbladder more often than of the typhoid bacillus. Then, if the patient lays stress on symptoms referable to the digestive tract rather than to respiratory difficulty, or if attacks of palpitation occur at night or without such provocation as exercise or excitement, and especially if such attacks are accompanied by epigastric distress, attention should be directed to the abdominal organs, that is, the gallbladder and appendix. And here it may be stated that the appendix is not seldom the offending structure, a fact to be considered in some future paper. Duodenal and gastric ulcers also must be borne in mind, but their symptomatology is so unlike that of cholecystitis that the physician need rarely be confused. Their differentiation need not be discussed here.

Gallstone colic when severe is not apt to be overlooked and is likely to be mentioned by the patient in relating his history. It is chronic cholecystitis with or without the formation of calculi sufficient to excite violent pain, but is the real subject of this discussion. Therefore, in studying the anamnesis and symptomatology, the physician should not disregard data, no matter how insignificant they may seem to be.

It should be kept in mind, however, that pain of a severe nature from intense hepatic colic is a frequent symptom, and that its character may be different. The pain may be referred to, is rather more a feeling of soreness or distress than an agonizing colic, and may be due to distention of the inflated viscera instead of its emptying or spasm, or to the passage of a stone along the cystic or the common duct. When due to distention of the gallbladder or to congestion of the liver, the distress is likely to be more continuous and not so markedly agonizing as that caused by colic. The location of the pain may be various and referred to the epigastrium or to the umbilical region, or it may radiate upward over the anterior or posterior aspect of the chest to the ribs.

According to my observation, nausea and vomiting need not be prominent features, very more than if jaundice. When these do occur they are very apt to

be attributed by the sufferer to acute indigestion especially if succeeded by cessation or decided diminution of pain. These are the symptoms so commonly regarded and mentioned as "attacks of biliousness."

That the differential diagnosis of chronic cholecystitis is often a matter of great difficulty is readily admitted. It requires not only a discriminating study of the history, possible etiology and symptomatology, but also a careful examination of the abdominal contents. By the last is meant a painstaking and precise palpation of the liver. In most instances of cholecystitis, this organ is plainly palpable, the degree of its enlargement depending chiefly on the acuteness of the gallbladder infection and the frequency, as well as the intensity of the symptoms produced.

The liver is not ordinarily palpable, or at most only its thin, smooth, regular lower edge can be felt during forced inspiration; therefore distinct enlargement of this organ is significant of some unusual influence brought to bear on it. In cases of cardiac disease, enlargement of the liver is the result of passive congestion and is so frequently observed that, when due to chronic cholecystitis in a cardiopath, one may very naturally attribute its increase in size and tenderness to stasis in consequence of impeded circulation. It is this very circumstance that renders the diagnosis of gallbladder infection difficult as a complication of cardiac lesions.

The following points are of great aid in arriving at the diagnosis: in passive hepatic congestion from heart disease, the organ preserves its natural and characteristic outline unless this is prevented by adhesions or by changes produced by cirrhosis, the chronic indurative cirrhosis of long-standing portal stasis. When not cirrhotic, but merely swollen by congestion, the left lobe is palpable and tender as well as the right, and one can detect the notch separating the two lobes. This is a point of great importance in cases of cardiac, particularly valvular disease. Furthermore, when secondary passive congestion of the liver exists one is very likely to find evidences of venous stasis in other organs and tissues. Consequently, the physician should search for these before concluding that the liver changes are the result of passive congestion merely. These being absent and the symptoms being referable to the abdomen rather than to respiratory embarrassment, suspicion should be attached at once to the liver, not to the heart.

#### RIEDEL'S LOBE

When cholecystitis is responsible for enlargement of the liver, it causes a characteristic alteration in the form of the right lobe first described by Riedel<sup>2</sup> in 1892, and hence known as Riedel's lobe. As a rule, the more acute the gallbladder infection, the more pronounced is this change in the outline of the liver; and yet this may occasionally be very pronounced in cases of chronic cholecystitis. This alteration consists in a convex enlargement of the right hepatic lobe downward, so that the edge of the organ curves downward toward the right for a variable distance and then upward to or shortly below the margin of the ribs. In some cases, this convex bulging may be small and obscured by the right rectus muscle, while in others, Riedel's lobe may reach from the median line nearly or quite to the extreme limit of the liver at the right. It may be noted also by careful palpation that the portion

<sup>1</sup> Journal, A. M. A., October 2, 1909, p. 4. A. C. S. J. M. 1910, p. 10. J. A. M. A. 52 (1919), June 12, 1919.

<sup>2</sup> Riedel, R. M. C. L.: Erfahrungen über die Gallensteinkrankheit. *Centralblatt für Chirurgie*, Ed. 8, Berlin, W. Graun, 1892, p. 11.

of the viscus lying to the left of the median line is not at all, or only indistinctly, palpable.

In pronounced instances, there may be an appreciable bulging of the part of the liver overlying the gallbladder, so that in well-marked cases it gives the impression of a round mass like an orange beneath the liver. If the liver or the gallbladder is sensitive to pressure, the right rectus muscle is apt to stiffen in distinct contrast to the corresponding muscle on the left side. If Riedel's lobe is small, it may be obscured by the rigid muscle, and yet by careful palpation the liver may usually be detected at either side of the rectus, and with the characteristic convex shape described.

In many cases on deep inspiration, the hand can detect the softer and exquisitely tender gallbladder itself extending slightly below the lower edge of Riedel's lobe, while in others the hand must be thrust sharply upward underneath the edge of the liver in order to come in contact with the gallbladder and elicit evidence of pain. This procedure causes the patient to cry out and shrink from the hand, and is followed by unmistakable rigidity of the right rectus muscle.

Palpation of the liver in these cases is a fine art. Not only should the knees be elevated so as to relax the abdominal walls, but the flank should be raised either by the examiner's left hand or by a firm cushion; and the physician should avoid too firm and rough palpation since by so doing he is likely to frustrate his own object. I have frequently been able to feel the lower edge and the shape of Riedel's lobe by merely resting my flat hand lightly on the abdomen and allowing the patient to breathe regularly and with moderate force. By so doing, pain is avoided, the abdominal walls remain relaxed, and the lower hepatic border can be perceived to glide back and forth beneath the hand. If this procedure is performed at each side of the median line alternately, the state of the two rectus muscles, as well as the outline of the two hepatic lobes may be compared.

Another sign of gallbladder disease of corroborative value in some cases is the so-called Ewald's area of cutaneous hyperesthesia on the right lower back. When this is present, simultaneous stroking of the two sides behind, from above downward, just internal to the posterior edge of the scapula, will elicit more or less sensitiveness of the skin at the right, over the course of the tenth and eleventh intercostal nerves. This sign has seldom been absent in cases of well marked cholecystitis as shown by the evidence obtained by palpation of the liver.

The degree of systemic disturbance, as shown by the temperature and leukocytosis, depends on the intensity of the gallbladder infection. If the cholecystitis is chronic, revealing its presence chiefly by digestive disorder and only moderate pain, the body temperature may be but slightly, if at all, raised, and may not even attract the patient's attention, while during the intervals between attacks of acute distress the temperature is likely to be quite normal. Indeed, it may be said that the freedom from febrile or other systemic disturbance furnishes one reason why these chronic cases are apt to escape detection.

The leukocyte count in like manner is subject to slight deviation from normal. In strictly chronic cases without marked symptoms, the leukocytes are not likely to show an increase of over eight or nine or possibly ten thousand with, of course, no pronounced preponderance of the polymorphonuclear elements. One

should be careful not to regard slight increase in temperature and white count in a given case of valvular disease as indicating an exacerbation of a chronic endocarditis. Except in acute instances of cholecystitis, more information is to be obtained by history, subjective symptoms, and painstaking manual examination than by study of temperature and leukocytes or even roentgenologic examination unless, of course, the roentgen ray is so fortunate as to disclose the presence of stones.

#### REPORT OF CASES

CASE 1.—Mrs. J. H., aged 54, the mother of nine children, on examination in November, 1917, was found to be corpulent and to display dyspnea on exertion, this together with some edema of the left leg, bleeding hemorrhoids, and cough constituting the symptoms for which she sought relief. There was a history of inflammatory rheumatism, typhoid fever, pneumonia and an attack of heart collapse a year and a half prior to my examination.

The pulse was accelerated and irregular, of the type due to auricular fibrillation. The systolic pressure was 140 mm. as nearly as could be determined, while the diastolic stood at 90 mm. The apex beat was  $4\frac{1}{2}$  inches to the left of the median line, and the transverse dullness seemed to be fully 6 inches. The mitral first tone was indistinct because of a soft systolic murmur, and the pulmonic second tone was accented. The liver was palpable and tender, but not uniformly so, as the left lobe was rather larger than was the portion to the right of the median line. The lungs were negative, and the single specimen of urine examined in the office was also negative.

The diagnosis was myocardial incompetence with mitral insufficiency, hepatic congestion and obesity. Digitalis, cathartics, rest and light diet were prescribed. During the succeeding year, this patient was seen only two or three times. At these times she showed very little improvement despite continuance of treatment.

In April, 1919, she suffered an acute stomach disturbance, and was seen by another physician who diagnosed acute cholecystitis. As the symptoms subsided after a few days of treatment, I did not see the patient until July, 1919, when she appeared because of aggravation of the original complaint. The heart was as before, except perhaps rather more arrhythmic and rapid. On going over the liver, we were at once struck by the distinctness of Riedel's lobe, and by the circumstance that directly beneath and below its inferior margin there could be felt a soft, very tender mass that was evidently the gallbladder. During 1918, suspicion had been aroused regarding the existence of a chronic cholecystitis, though the characteristic alteration in the outline of the liver did not become distinct until after the acute attack in April, 1919.

The advice to have the gallbladder drained was heeded, and when the gallbladder was opened, hundreds of small stones were discharged. A drainage tube was inserted, and the viscera was allowed to drain for a number of weeks. The patient's condition is now greatly improved. Her heart is still irregular, but the systolic pressure has increased twenty points which, taken in connection with the lessened dyspnea, the loss of stomach symptoms and her ability to attend to household duties daily, is taken to signify increased strength of the myocardium.

Here was a case thought to be one of heart disease alone, but which was complicated by a gallbladder infection which, as the operation has proved, was in reality the factor most responsible for the symptoms for which relief was sought.

CASE 2.—Miss A. B., aged 34, first seen in December, 1918, was tall and thin, having lost 45 pounds during the previous six months. There was a history of inflammatory rheumatism, several "krip attacks," and in the preceding January what was thought to be pleurisy on the right side with fever, nausea and vomiting. She complained of great shortness of

breath, cough and stomach trouble. Physical examination disclosed a feeble, irregular pulse of the fibrillating type, a very low pulse pressure, the systolic being 110 mm. as nearly as could be determined because of the great arrhythmia, and the diastolic about 100 mm., pulsating jugulars and a markedly dilated heart with the characteristic rumbling murmur of mitral stenosis, while the tender lower border of the liver extended to the level of the umbilicus. This organ was engorged generally, and yet its right lobe suggested a Riedel lobe. The lungs also showed congestion, and the urine contained albumin.

The condition was regarded so serious that she was confined to bed, and of course given other suitable treatment. Constipation was a marked and very obstinate symptom. The condition did not improve much, and in February, 1919, she rather suddenly developed unmistakable signs and symptoms of acute cholecystitis, namely, and high temperature, so that an operation became urgently indicated. This was successfully performed under local anesthesia, and two stones were removed from the cystic duct. Bile did not flow for ten days, but then came freely, and improvement followed promptly. At present this patient is so well that she is at work daily. The gallbladder must be kept draining, for as soon as the opening closes, the heart begins to grow more irregular and rapid, and the patient soon thereafter displays perceptible features. From a purely surgical standpoint, cholecystectomy is indicated; but it is doubtful whether her heart would enable her to survive the operation. We are content, therefore, to let well enough alone.

This case illustrates the difficulty of recognizing chronic cholecystitis complicating a decompensated cardiac lesion. The acute attack in February, 1919, was so typical in the spasmodic pain running up into the right back and shoulder, the nausea, vomiting, and twenty-four hours later the intense icterus, that one does not understand how it could be overlooked. Yet the patient herself recognized its features as identical with the attack in January, 1918, which was pronounced pleurisy and was followed by the cardiac incompetence for which advice was sought in the following December. It is my opinion that had I given more attention to the history of the supposed pleurisy, and examined the greatly engorged liver more carefully, I might have recognized the existence of the gallbladder infection before it made itself so obvious by its acute exacerbation. It strengthens my belief that in every case of cardiac disease with a history or symptoms of abdominal disturbance, minute attention should be paid to the gallbladder and appendix, the latter in many cases being the chief offender, as I hope to show in some future communication.

NOTE.—Mr. S. B. , seen first in 1916, reappeared in March, 1919, with the statement that he had been in bed for nine weeks because of broken compensation. He was cyanotic, and very restless, much from dyspnea and cough. Physical examination disclosed a hypertrophied heart in consequence of aortic regurgitation, numerous murmurs at the base of the right lung behind, and a palpable tender liver. The leukocytes numbered 10,000, and the urine contained albumin.

On being again sent to a hospital and placed under medical treatment, with the result that at the end of a week of ten days the fever had become free of rales, and he no longer complained of dyspnea. The pulse also had greatly improved in rate and rhythm. But he now complained a heavy sense of trouble about the stomach. Catarrhs and the red and hard nodular results of the hepatic congestion, so that on palpation one could detect very early a Riedel lobe, this portion of the liver being very sensitive to pressure. Underneath could be detected what seemed to be the softer and yet more tender gall bladder. As all symptoms referable to the respiratory system had abated, and as the circulation was satisfactory, and as the digestive disturbance interfered with proper rest, he was informed of the cholecystitis and

advised to have the gallbladder opened and drained under a local anesthetic. To this, however, he would not consent, and he left the hospital abruptly for his home. No report from him has been received since his departure.

This case, like the preceding, illustrates the difficulty of recognizing the existence of chronic cholecystitis in a person suffering from the distressing symptoms of broken compensation of a coincident cardiac lesion. But it also emphasizes how serious may be such a combination in its effect on convalescence, that is, restoration of cardiac efficiency, and how important is a close study of the hepatic condition. It is so natural to regard the obvious circulatory embarrassment as responsible for the phenomena that unless each organ is scrutinized daily, we may overlook complications capable of turning the scales against recovery.

30 North Michigan Avenue.

## ALLEVIATION OF DISTRESSING DIGESTIVE SYMPTOMS IN "CARDIORENAL DISEASE"

SOME SUGGESTIONS

GEORGE M. NILES, PH.G., M.D.

ATLANTA, GA.

All practitioners of medicine, particularly those specializing in gastro-enterology, have patients with so-called "cardiorenal insufficiency" who complain of indigestion, of distressing flatulence, of sensations of epigastric fullness after eating, and of a general feeling of digestive discomfort. These patients may present valvular lesions in various stages of compensation; there may be arrhythmia or myocardial inefficiency or tumultuous heart action. The urine may be loaded with albumin, may show granular or hyaline casts or both, or at times it may be fairly normal. The questions of actual cardiac and renal pathology will not be discussed in this study, but rather the methods of steadying the heart's action, of aiding compensation, of allowing more physical space to the thoracic and abdominal organs, so that they may be less handicapped in performing their functions, and of lightening the work of the kidneys.

As a cardiac "steadier" plus a diuretic, I have much confidence in the *infusion* of digitalis—more, perhaps, than in any other preparation of this drug. However, the infusion must be fresh and must be made from fresh and dependable digitalis *leaves*, otherwise the results will be disappointing. It is my custom to give one-half ounce, four times the first day, especially if the pulse is accelerated. After that I have found 2-teaspoonful doses, four times daily, a sufficiency. It is well to omit it altogether every fifth day, and if the pulse becomes rather slow, to omit it every fourth, or even every third day. This minimizes the danger of a cumulative effect. Unless the bowels are loose, which is seldom the case, I employ, with good effect, this prescription:

R Magnesium sulphatis  
Pulvis ferri tritatus (C. P.).....aa ʒiij  
Triturata finely.  
M. Sig. Two teaspoonfuls in one-half glass of water on arising.

This prescription should produce two or three free watery stools, but the dose may be varied to obtain that result. In some instances, when the watery move-

ments seem to cause debility, this prescription may be given on alternate mornings, or even three days apart.

For the distressing accumulation of gas in the stomach, which so embarrasses the heart's action, this prescription has proved most helpful:

R. Spiritus anisi ..... ʒiij  
Zinci phenylsulfonatis ..... ʒiijss  
Magnae magnesiae ..... ʒiijss  
Aqua ..... q. s. ad ʒiijss  
M. Sig.: One teaspoonful every fifteen to thirty minutes as needed for gas.

This can be repeated almost ad libitum. It can produce no bad effect, unless the magnesia acts as a hydragogue cathartic, and generally it promotes the free expulsion of the disquieting gas, of which the patient complains so bitterly. In many of these uncompensated cases there is frequent dyspnea, coming on after slight exertion or without apparent cause, or deepening in intensity during the hours of night.

The following combination, while it unfortunately possesses an odor both foul and fierce, has to many sufferers under my observation afforded a most grateful succor for this distress:

R. Spiritus ammonii aromatici ..... ʒiijss  
Elivir ammonii valerianatis ..... ʒiijss  
M. Sig.: One teaspoonful in water every fifteen minutes to one hour as needed for difficult breathing.

This, like the previous prescriptions, may be repeated quite a number of times.

Dietetic restrictions and regulations are most important, as they tend to diminish intestinal flatulence, to encourage intestinal peristalsis, to lighten the eliminative burden of the kidneys, and to promote general nutrition.

In the suggestive dietary herein offered, it will be noted that sweets and fats are avoided, so far as possible, and that vegetables containing only 5 and 10 per cent. of carbohydrates are allowed, while the starchy foods are for the most part prohibited. Fresh lean meat may be eaten freely, but must be broiled, baked or roasted. The string beans, squash, onions, turnips, etc., may be cooked, but the green vegetables, usually eaten raw, may be cut up into a combination salad and flavored with lemon juice instead of the ordinary condiments. A limited amount of fresh buttermilk is admissible, and a small amount of cereal for breakfast, if the patient insists on it, as sometimes is the case. When cereals are eaten, a very scant amount of sugar may be permitted.

SUGGESTIVE DIET LIST

FOODS ALLOWED

Lettuce; cucumbers; spinach; asparagus; sauerkraut; beet greens; greens (turnip, mustard or collard); celery; tomatoes; Brussels sprouts; peas; cauliflower; egg plant; cabbage; radishes; beets; onions; string beans; pumpkin; turnip; squash; beets; carrots; ripe olives; grapefruit; lemons; oranges; unsweetened pickle; clams; oysters; liver; lean fresh meat of any kind, as beef, mutton, pork, chicken; fish or game; coffee or tea as sparingly as possible; and fluids, only enough to quench actual thirst.

FOODS TO AVOID

Sweets of all kinds; fats, as fat meat, butter and cream; sweet milk, eggs, and starchy foods, as breads, rice, grits, potatoes, dried beans or peas, and macaroni.

This diet will seem quite a revolutionary change to many patients, and some will for a while complain at the prohibition of breads and sweets especially. In a short time, however, in a majority of cases, the intestinal flatus will markedly diminish, the dyspnea will lighten, the heart will become more steady and efficient in its action, and the albuminous content in the urine will lessen or entirely disappear.

This dietary does not promote a gain in weight. On the contrary, there is generally some loss; but this is not prejudicial to the invalid's welfare. As general

improvement progresses, certain variations or modifications in the daily regimen may be allowed; but any inclination to increased dyspnea or inefficient heart action should indicate the necessity for a prompt return to the strict diet and regular medication.

There will, of course, be found some persons who lack the mental stability required for the successful advancement of this method; then, too, there will be found both hearts and kidneys seemingly beyond the power of compensation or recuperation.

Nevertheless, in a liberal proportion of these melancholy and long-suffering "cardiorrenal cases," the brief, but practical suggestions herein offered will be found decidedly helpful.

CUTANEOUS REACTION TO QUININ  
IN QUININ IDIOSYNCRASY\*

B. M. EDLAVITCH, M.D.

FORT WAYNE, IND.

Some individuals are susceptible to the action of certain foreign substances. The urticarial rashes brought on by strawberries, the eczematoid dermatoses due to various proteins or food products, the asthma caused by pollens of plants or by inhalations of animal emanations or derivatives, the skin reaction to tuberculin, and the various symptoms following the use of certain drugs are specific examples of such idiosyncrasies. Symptoms commonly observed in hypersensitive individuals are: (1) urticarial or eczematoid rashes; (2) gastro-intestinal disturbances; (3) those characterized as asthma, or (4) those indicating exaggerated pharmacologic action of the antigenic drug.

Among the drugs to which man manifests this idiosyncrasy is quinin. This fact has long been known.

An attempt to develop a specific skin reaction to quinin was successfully made by Boerner.<sup>1</sup> By applying quinin bisulphate to a skin scarification made on himself and a colleague—both of them susceptible to quinin—he was able to obtain a definite and well marked local reaction in each case. Similar skin tests in non-susceptible individuals gave no reactions whatever. Boerner<sup>1</sup> concluded, therefore, that this reaction was specific and was most pronounced when using a 10 per cent. solution of quinin bisulphate.

O'Malley and Richey<sup>2</sup> tried out this method in two cases of quinin idiosyncrasy under their observation. They used 10 per cent. quinin bisulphate and obtained definite reactions, thus confirming Boerner's observation. They also obtained an equally well marked local reaction with a 5 per cent. solution of quinin dihydrochlorid. With emchonin or emchonidin sulphate, and with various other drugs tested, they could get no reactions whatever. In twelve non-susceptible persons no reactions could be obtained with quinin sulphate. These observers concluded, therefore, that this skin reaction is a good index of hypersensitization to quinin.

In the case here with presented, which recently came under my observation, this skin reaction was tested out with the idea of determining its value.

\* Read before the Tenth District (Indiana) Medical Society, Fort Wayne, Ind., Nov. 11, 1911.

## REPORT OF CASE

Mrs. T. S., aged 54, entered St. Joseph's Hospital for a test cure. On the day of admission she was given 1 dram of the tincture of iron, quinin, and strychnin (N. T.), which contained one-fourth grain of quinin. Immediately after taking this dose she felt a peculiar "drawing in" sensation over the middle of the chest, which lasted several minutes. She promptly asked whether there was any quinin in the medicine she had just taken, and when informed that there was, she said that she had never been able to take that drug.

About an hour later a weltlike exanthem appeared over the entire body except the face. With the exanthem, there was intense itching. The exanthem and itching were worse over the back under the arms and on the lower extremities. When seen several hours after the skin manifestation presented the appearance of a severe eczematoid dermatitis. It began to fade from sixteen to eighteen hours, and disappeared completely at thirty-six hours.

The patient said that about twenty-seven years before she had had an acute attack of grip for which she was given quinin. After several doses—the size of which she did not know—a rash and severe itching came on all over her body, and lasted from four to five days. On at least two other occasions she had been given quinin, and each time the same symptoms occurred within a few hours. So far as she knows she is the only member of her family who manifests any reactions after taking this drug.

## REACTION TEST

The opportunity thus presented itself to test out the cutaneous reaction already described. Accordingly, October 19, and again, November 5, the skin of the forearm was scarified in two places about 3 inches apart. Over the proximal abrasion 10 per cent. quinin solution in aqueous solution was applied. The distal scarification served as a control. Within a few minutes the patient began to feel an itching sensation around the scratch into which the quinin had been rubbed. A few minutes later an edematous papule began to appear around this scarification. It reached its maximum size, about 0.75 cm. in diameter, in about one-half hour. Surrounding this area of edema was a bright reddish patch of erythema measuring about 3.5 cm. in diameter. The reaction began to subside after the first half hour, and at the end of a few hours had completely disappeared. Around the distal or control scarification, nothing worthy of note occurred other than the usual normal reaction following traumatism of that kind.

The cutaneous reaction described was striking and unmistakable. It was tried out twice in this case, and the reactions were exactly identical. Evidently the cutaneous reaction to quinin is not only very definite but also rather characteristic, and can really be considered as a specific allergic phenomenon.

## SUMMARY

1. The test of desensitization to quinin afforded heretofore further confirms the skin reaction to quinin, caused first by Morner<sup>1</sup> and confirmed by O'Malley and Barber.<sup>2</sup>
2. This reaction is observed only in individuals who are hyper-sensitive to this drug, and can be obtained on any side of the body, and on the arm.
3. It seems to be a specific reaction, analogous to the other allergic reactions already known.
4. As a method for testing out hyper-sensitization to quinin, this test too seems to be very reliable and of great value of very great value.

1919 (Quin. Ther.) 1919.

## THE MAXIMUM NONFATAL OPENING OF THE CHEST WALL

F. VARTS A. GRAHAM, M. D.

Professor of Surgery, Washington University Medical School  
ST. LOUIS

In a previous article, by the present writer in conjunction with R. D. Bell,<sup>1</sup> evidence was presented to show that in the normal thorax the pressure relationships are always practically equal in both pleural cavities and that therefore the prevalent conceptions of collapse of one lung and maintenance of respiration with the other in the condition of open pneumothorax are incorrect. In the same article also, it was shown that a bilateral open pneumothorax in a normal chest is practically no more dangerous to life than a unilateral opening unless the combined areas of the openings on both sides are greater than the area of the single opening on one side. Both theoretically and experimentally effects of practically the same severity result in the case of one or more openings into one pleural cavity as follow the creation of a double pneumothorax, provided that in each case the combined areas of the various openings are equal. Moreover, it was shown that the maximum opening in the chest wall compatible with life in the normal adult (that is, without pleural adhesions or induration of the mediastinum) could be approximated by means of the mathematical expression:

$$X = \frac{R_1}{R_2} \frac{T}{C} \sqrt{\frac{V}{T}}$$

in which  $V$  is the vital capacity

$R_1$  is the rate of respiration before the opening is made

$R_2$  is the rate of respiration after the opening is made

$T$  is the tidal air (approximately 500 c.c.)

$C$  is a factor less than 1 (assumed to be 0.8).

$X$  is the area of the glottis (about 2.25 sq. cm.)

In the substitution of numerical values, 3,700 was used to represent the vital capacity.<sup>2</sup> This was the commonly accepted average vital capacity, and on the basis of it a value for  $X$  was obtained of 51.5 sq. cm. (8.1 square inches). In other words, the computation was made that an opening of 51.5 sq. cm. in the chest wall was the maximum for which compensation could be made. At that time we were not acquainted with the work of Peabody and Wentworth<sup>3</sup> on the vital capacity. In their study it was found that in general the vital capacity of men is greater than that of women, and that an approximate relationship exists between the height of the individual and his vital capacity. In men, for example, the average normal vital capacity is 4,633 c.c.; but in men 6 feet or more in height, the normal vital capacity is 5,100 c.c., and in one man it was found to have the very high value of 7,180 c.c. The accompanying tables are quoted from their article. It is at once obvious that whenever the value of  $V$  in our mathematical expression changes, the value of  $X$  will also change in the same direction, that is, if  $V$  becomes greater, the value of  $X$  will also be increased, and vice versa. If in substituting numerical values in our equation we insert 4,800 for  $V$  (the normal vital capacity of men with a height of from 5 feet 8 1/2

1 Graham, F. A. and Bell, R. D.: Open Pneumothorax, Its Relation to the Treatment of Empyema, *Am. J. M. Sc.* 156:1:839 (Dec 1 1918).

2 Hays, J. *Textbook of Physiology*, Philadelphia, 1911, p. 646.

3 Peabody, E. W., and Wentworth, J. A.: Clinical Studies of the Respiration. IV. The Vital Capacity of the Lungs and Its Relation to Height, *Am. J. M. Sc.* 20:1:41 (Sept 1 1912).

inches to 6 feet), instead of 3,700 we obtain a distinctly larger value for  $X$ . If we assume as before that  $R_1$  (the rate of respiration before making the opening) during complete rest is 15 per minute and the maximum rate,  $R_2$ , for the greatest possible depth of respiration is 60 per minute, then:

$$X = \frac{4800 - 125}{125} = aC - 37.1 - 1.8 \quad \text{or}$$

$$X = 67.32 \text{ sq. cm., or } 10.4 \text{ sq. inches.}$$

Criticism has been made of the incorrectness of our mathematical expression on the ground that the value obtained for the maximum opening compatible with life, which was published in our previous article, was too small when compared with what was sometimes found clinically to be possible in connection with both war and operative wounds of the chest. But it should be remembered that the value of 51.5 sq. cm., which was previously given, represented merely an average value based on what was commonly considered as the average value of the vital capacity. As found in the

individuals of some of the other factors, as for example,  $C$ .

The validity of the statement in our former article that the value of  $X$  would be diminished by the presence of toxemia, infection, or any other cause which increases the level of metabolism, as well as by any condition which reduces the available breathing space of the lungs, has been confirmed at least in numerous observations on acute emphyema by other observers as well as ourselves. Also, Peabody and Wentworth have found that in nine patients with pleural effusions, the vital capacity varied between 74 and 42 per cent. of the normal. One patient with a massive pleural effusion had a vital capacity on two successive days of 48 and 40 per cent. Immediately after the aspiration of 2,200 c.c., his vital capacity was only 46 per cent. On the two following days it had risen to 69 and 68, and three weeks later it was 74 per cent. This observation is of particular interest in showing that the mere withdrawal of a pleural effusion is not sufficient to increase the vital capacity immediately, and it is therefore in direct opposition to a common belief that in cases of a true emphyema, the danger of an open pneumothorax created for drainage can be disregarded because the withdrawal of the effusion will in itself immediately relieve the patient sufficiently to make an open pneumothorax safe.

Obviously, this mathematical expression does not hold good for conditions in which the mediastinum has become more or less immobilized by induration or by adhesions.

TABLE 1.—VITAL CAPACITY OF THE LUNGS IN NORMAL MALES

usual type of war surgery, this value was probably somewhat too small because of the fact that, as Peabody and Wentworth have shown, the average vital capacity of men is greater than that of women and is therefore greater than the general average vital capacity. Obviously also in the exceptionally large man of athletic build, as for example in the case of the man Peabody and Wentworth mention, who had a vital capacity of 7,180 c.c., a relatively enormous opening in the chest wall can be compensated for. In such a case, for instance, the value of  $X$  in our equation would be 101.3 sq. cm., or 15.6 square inches. It should be remembered also, as stated in our previous article, that what are often apparently very large operative openings in the thoracic wall are actually smaller than they seem to be because of the presence in the incision of a lung which has been delivered out, gauze sponges, instruments, fingers of the operator, etc., all of which tend by their plugging to reduce the area of the opening and the amount of air which is sucked in at inspiration. On the other hand, it should be borne in mind that the value of  $X$  represents the approximate maximum opening compatible with life only so long as the respiratory muscles can maintain a maximum respiratory movement, and in addition, that it is only an approximation because of the variability in different

### IDIOSYNCRASY TO ALCOHOL

WILLIAM W. CADBURY, M.D., CANTON, UTAH

In prescribing tinctures and elixirs, one is too prone to forget that they contain alcohol and to think only of the drug which forms the main constituent of the medicine.

I have been able to find no reference in textbooks to systemic media and therapeutics to susceptibility of patients to alcohol given in minute doses. The case reported below is unique, therefore, because of the patient's marked idiosyncrasy to alcohol even in very small quantities.

#### REPORT OF CASE

Chen C., aged 28, Chinese, whose previous history was unimportant, when seen, Nov. 21, 1918, reported that six months previously, after giving birth to a child, she developed a cough with hemoptis. Physical examination disclosed advanced pulmonary tuberculosis. The disease progressed steadily until the patient was last seen in June, 1919, at this time both lungs were extensively involved and a final summation of the disease appeared to be near at hand. Her first visit I prepared.

For expectorant I prescribed the following:  $C_1 = \frac{C}{10}$   
 1/2 Ampule of 10% solution of  $C_1$  in 100 cc. of water  
 1/2 Teaspoonful of 10% solution of  $C_2$  in 100 cc. of water

In estimating the amount of alcohol in a mixture that 97 per cent. alcohol was used in preparing the elixir, we find that 15 c.c. of the mixture there would be about 14.55 c.c. of absolute alcohol in solution. The patient's husband estimated when I next saw him that each time after giving medicine his wife's face became flushed and she developed a symptom of alcohol intoxication. The systematic course of the medicine in controlling the cough led me to continue the administration from time to time. On June 15, 1920, I prescribed a small quantity of alcohol.

A number of other prescriptions were also given during the course of the disease, each one containing small amounts of alcohol, and all were invariably followed by symptoms of alcoholism, flushing of the face, vertigo and even at times mild delirium. These symptoms were somewhat mitigated by diluting the dose with a large amount of water.

The husband informed me that his wife had never been able to drink even the weak Chinese wines containing only about 4 per cent. of alcohol without showing symptoms of intoxication so that eventually I took pains to give all medicines as powder or pill or in nontoxic liquid solutions.

A number of nonalcoholic remedies were given, but in no case was there evident any sign of intoxication following their administration.

#### A CASE OF CANCER FOLLOWING A SULPHURIC ACID BURN\*

DANIEL R. MERRILL, New York

So much is yet to be discovered concerning the circumstances surrounding the cause of cancer, that any new facts seem worthy of being reported. With this point in view, the following case, seen in a city clinic, is submitted.

##### REPORT OF CASE

C. M., a man, aged 57, employed in a dye factory, presented himself at the clinic with a prominent tumor on the dorsal surface of his right hand. Seven months prior to this, his hand had been burned by a few drops of sulphuric acid in a factory accident. Previously, the tissues in this region had, according to the patient, always been normal. The initial burn left a small ulcerated surface about the size of a pea which gave little pain, but which refused to heal. Three months later the patient noticed an increase in the size of the lesion, both in diameter and in height. Growth continued for the next four months.

Examination revealed a mass about  $1\frac{1}{2}$  inches wide and three-quarters inch high, presenting a reddish, ulcerated surface and a distinct red border. In the center, there was an orifice of a sinus from which a slight yellow discharge exuded, emitting a disagreeable odor. Pain was confined to the periphery, where it had been continuous for the past few months, increasing in intensity day by day. The axillary lymph nodes were not palpable at the time of examination.

The patient had been a man of regular habits, employed at outside work previous to obtaining his position at the dye factory, two years before. He had always enjoyed good health and his family history was negative.

The growth was excised by Dr. Van Ness of Newark, N. J., and a portion of the specimen were made. Healing was slow at first, a black crust underlaid with pus and sloughing material having formed. However, six weeks after the operation the area started to fill in with healthy pink granulation tissue, which slowly obliterated the excavated area. A subsequent examination revealed the fact that the tumor was made up of growing squamous cell carcinoma, the diagnosis being confirmed by Dr. Francis Carter Wood of the Coecker Research Laboratory. When the patient was last seen, the hand had almost entirely healed, but a small irregular, freely attached mass, about the size of a pea's mass and occupying part of the inner anterior part of the right hand, probably a metastasis involving the articular tissues, still remained. The new growth had started three months after the original tumor had been removed, and had rapidly increased during the past five weeks. The patient was seen at the hospital for further treatment.

##### COMMENT

A great many other chemical irritants have been reported as factors in producing a site for the occurrence of a malignant growth. Tar and paraffin, for example, sometimes cause an acute eczema followed by a hyperplasia of the tissues which frequently form a starting place for cancer. Soot by irritating the skin may cause an ulcer which later may

develop into chimney-sweep's cancer. Tobacco in its combustion gives off certain irritant products which may lead to ulcers of the lip or tongue, and a resultant malignant growth. Workers handling guano and anilin dyes often get sores on exposed parts, which, in time, may become cancerous. Recently Pflüger has experimentally produced cancer of the stomach in animals as a result of chronic irritation by nematodes; and Yamagiwa has developed epithelioma of the skin in rabbits with tar.

In all these cases, as well as in the present one, the cancerous condition followed a chronic, slowly healing ulcer, which, in turn, was produced by the chemical irritation. It appears that the healthy cells are in some way altered by the ulceration so that if a predisposition to cancer is present, the malignant condition will follow. It is very unlikely in the present case that the acid itself was the etiologic factor in the production of the tumor, as thousands of sulphuric acid burns never become cancerous. A suggested explanation is that the acid burn and subsequent ulcerating condition merely provided a place of lowered resistance, which, combined with a certain predisposition and the "cancer age" of the patient, led to the development of the malignant growth.

#### CEREBRAL GAS EMBOLISM OCCURRING DURING ADMINISTRATION OF ARTIFICIAL PNEUMOTHORAX

J. D. THOMAS, M.D., MOUNT VERNON, OHIO

*History.*—W. W., aged 37, white, machinist, native of Scotland, who had been in the United States four years, was admitted to the Ohio State Sanatorium for Incipient Pulmonary Tuberculosis, May 27, 1918, and his condition classified as moderately advanced (Turban II). He gave a history of having had tuberculosis ten years before, with several pulmonary hemorrhages at that time. He had recovered with no recurrence until April 1, 1918, when he developed a heavy cold which persisted. On admission he weighed 166 pounds, which was normal. He was 5 feet, 5 inches tall, stockily built, had a short, thick neck, and was of the typical apoplectic type.

*Examination.*—The sputum was positive for tubercle bacilli, May 31, July 23 and Dec. 10, 1918, and Jan. 4, 1919. The urine was negative on several different examinations. August 17, the sputum was streaked. On admission, the temperature ranged from normal to 99.4 F. until the middle of August, when it subsided to normal until October 8. At this time, the patient had an acute exacerbation ranging to 99.8 F. for a few days, when it again became normal. The pulse rate was always low, ranging from 54 to 70. The appetite was good, the bowels regular, and the patient felt comfortable all the time. There was considerable cough and expectoration. It was not possible to develop any stable degree of exercise, even under the most careful system of gradation.

*Treatment and Result.*—December 30, physical examination revealed evidence of a cavity formation in the right upper lobe which was confirmed by the roentgen ray. It was then decided to perform artificial pneumothorax. January 2, this was done, 350 c.c. of nitrogen gas being given in the fourth interspace, midway between the nipple and the sternum. The patient showed no disturbance and experienced no discomfort except slight soreness at the point of puncture. Cough and expectoration materially diminished after the first treatment. Subsequent treatments were given, as follows: January 2, 300 c.c.; January 18, 300 c.c.; January 25, 600 c.c.; February 5, 650 c.c.; February 17, 600 c.c., and March 3, 600 c.c. The patient was feeling very well and showed unmistakable signs of improvement.

March 14, after the usual procedure and with a manometer reading of from —3 to —7, about 100 c.c. of gas had been introduced, when the patient turned his head slowly, far to the right, saying, "There is something wrong." The face became cyanotic; the pupils were strongly contracted; the chin was drawn over the right shoulder; breathing was slow and stertorous; the eyes were drawn to the right; the entire body became quite rigid, with complete loss of consciousness and with tonic convulsions and frothing at the mouth. After

\*From *Columbia University College of Physicians and Surgeons*.

about eight minutes of convulsive movements, he relaxed and subsided into a semicomatose condition. Whenever aroused, he had a staring expression and would immediately relapse into a comatose state. There was complete loss of sensation and reflexes. The pulse rate was 54; respiration was 18, and was somewhat labored. During the night following this experience, the patient was quite restless, involuntarily throwing the bedding, moaning and sighing aloud, and frequently calling out and beating the bed with the right fist. Left side movements were wholly uncontrolled. He tried to get out of bed, but he could not coordinate his movements.

During the day of the fifteenth, he was still unconscious and very restless, moaning and talking incoherently all the time. He made an attempt to get out of bed, but fell on the floor and had to be lifted back. He had three involuntary actions of the bowels, and voided urine frequently and involuntarily. Toward evening, he became more quiet and seemed to show some return of consciousness. He had a quiet and restful night, and in the morning he was perfectly rational. The second day after this, he was allowed to get out of bed for a short time. The third day, he was up for all meals, and was about the cottage. On the fifth day, he was allowed to go to the general dining room, feeling as well as usual. He showed absolutely no untoward results from the experience and was discharged, April 27, as "quiescent."

REPORT OF A CASE OF VOLVULUS OF AN  
INTUSSUSCEPTION

E. L. ELIASON, M.D., PHILADELPHIA

*History.*—I. A., a negro, aged 22, was admitted to the hospital, July 3, complaining of pain in the right iliac region. On the preceding February 26, the patient had been operated on for acute appendicitis, and on June 17, for abdominal adhesions which were found and freed. On admission, July 3, 1916, the temperature was 97 F., the pulse 84, and respiration was 24. The abdomen was flat and soft. No tender areas and no masses were found. There had been no vomiting, and the bowels were regular and had moved the previous day. The patient stated that he had been having the same type of pain ever since his operation for adhesions, sixteen days before. He was given a simple enema  $\frac{1}{32}$  grain of physostigmin (eserin) and morphin, with good results. The following day he felt relieved and was discharged.

*Clinical Course.*—July 13, the patient returned to the dispensary complaining of severe abdominal pain. He was again admitted and given  $\frac{1}{16}$  grain of morphin with no relief. Two hours later, he was given 10 grains of barbital, and a sterile water hypodermic by the resident physician, who suspected a hysterical element in the condition. The patient obtained relief and slept.

July 14, the temperature was 98, the pulse 80, and the respiration 24. The leukocyte count was 8,100. The patient's bowels had moved, and he had voided urine normally. He did not vomit or feel nauseated, but, on the contrary, ate soft diet with relish and asked for more. The abdomen was soft, showed no distention, and auscultation elicited normal peristaltic sounds. The urine showed no blood, but did show marked indican reaction. The bowels moved as a result of a soap-suds enema, and were normal macroscopically.

July 15, the night nurse's report for 1 a. m. was to the effect that the patient was quiet and had been sleeping most of the night. His temperature was 98.2 F., and pulse 80. The nurse's 2 a. m. report stated that the patient was having severe pains and was tossing about the bed, groaning and perspiring profusely. The patient later got out of bed in the nurse's absence and was found in the hall on the floor, crying out with pain. When I saw him for the first time at 10 a. m., he gave every evidence of being hard hit by some abdominal catastrophe. The skin was cold and clammy. The temperature 96 F., and the pulse 120. He was groaning with pain and was in a state of collapse. Abdominal examination revealed a tender mass in the left iliac fossa.

*Operation.*—A midline incision was made, and a mass was delivered which proved to be a volvulus of the ileum, under-

going gangrene. When the volvulus was untwisted, the loop was found to consist of an intussusception of the ileum, the intussuscepting loop being glued tightly with well formed adhesions to the intussuscepted loop. These adhesions were too firm to separate. Owing to the extreme condition of the patient, the diseased intestine was excised and the two ends of the normal ileum brought out of the wound and left open. The wound was closed. The patient died ten hours later.

COMMENT

Examination of the removed intestine revealed beginning gangrene of the enveloping loop of the volvulated intussusception. The inner loop was in the last stage of gangrene and just ready to slough off into the bowel. Nature had made a firm anastomosis at the point of entrance of the one loop into the other. Judging from the advanced decomposition of the inner loop, the conclusion had to be drawn that the intussusception had existed for days, probably since his first symptoms seventeen days before, while the outer loop showed only evidence of strangulation of hours' duration. In all probability the volvulus occurred at 1 a. m. of the morning of the operation, thus accounting for the patient's sudden collapse.

730 South Sixteenth Street.

AN ETHER DROPPER

I. E. HILL, M.D., HARRISBURG, Pa.

One of the petty annoyances of the anesthetist is the arranging of a satisfactory dropper for the ether can.

Every one who gives many anesthetics, at some time or other, has wished for a device of some sort that would do

FIG. 1.—Top of ether can, with dropper.

away with the inserting of the wick of gauze safety cap or similar makeshift dropper, and at the same time deliver the ether from the can in a suitable manner.

FIG. 2.—Front and rear views, showing the position of the wick.

The experimenting was many directed. I have made up a number of contrivances which are well classified, all the same, but at the same time add a touch of originality, and give a finished result, so other administrators.

The dropper is made of thin light metal and is transparent, the glass covering half the mouth of the can. The base of the metal is a fine spring from which a wick is usually applied or removed. Whether one wants to see ether pour out or to hide completely, is left to the operator, and is easily controlled.

AND OTHER REMEDIES IN THE TREATMENT OF DISEASE.

### USE AND ABUSE OF CATHARTICS\*

(Continued from page 1885)

#### SENNA

As a purgative, senna is more powerful than cascara sagrada, and often acts when the latter fails. It requires from four to eight hours for action. Large doses are therefore better given in the morning; small doses may be administered at bedtime. It is much more prone to produce griping, and in some patients to cause a feeling of abdominal soreness. On the principle that the mildest is the best, cascara is to be preferred to senna, especially for prolonged use. When, however, a single prompt, thorough evacuation is aimed at, senna is the superior.

Roentgenoscopic examination has demonstrated that senna exerts its chief effect on the large intestine. The movements of stomach and small intestine are not markedly changed; but, the moment the bismuth meal passes the ileocecal valve, it traverses the colon in great haste. This makes senna useful to complement the action of duodenal purgatives, such as the mercurials, and shows the rationale of the old prescription of blue mass at night and "black draft" in the morning.

From therapeutic doses there is little tendency to hypercatharsis, inflammation, or to constipation after its use. However, as senna is the most drastic of the purgatives, it is particularly contraindicated in spastic constipation and in conditions of intestinal inflammation. For patients with hemorrhoids it should be prescribed with caution and only in small doses.

We must remember that the coloring matter of senna gives to and urine a deep yellow color, and that this urine becomes red under the influence of alkali. The later appearance might give rise to the false fear of the presence of hematuria. Some of the cathartic principle is eliminated into the milk of nursing women. Hence, purging the mother may also purge the nursing.

The taste of senna, though bitter, is not nearly as intense as that of cascara sagrada; and it is more easily digested. Thus the official *syrup of senna*, containing 25 per cent. of the fluidextract and flavored with coriander, is sufficiently pleasant for most children to take without protest. The *aromatic syrup of senna* of the National Formulary is still more pleasant and only of half the strength (12.5 per cent.), though it also contains, and probably unnecessarily, 5 per cent. of jalap, 17 1/2 per cent. of rhubarb, and 30 per cent. of alcohol. It is flavored with cinnamon, cloves, nutmeg and lemon. A teaspoonful of the official syrup or two teaspoonfuls of the aromatic would be sufficient to act on a sensitive adult or an older child. A 1-year-old babe would be acted on by 15 drops of the National Formulary preparation. As these syrups are readily available, it is surely, to say the least, inexpedient to prescribe such nostrums as "castoria" and "syrup of figs," which owe their value chiefly to senna.

In coffee or prune juice the taste of senna is hardly noticeable. It is recommended that senna leaves (2

gm.) be added to ground coffee (8 gm.) and infused with 90 c.c. each of hot coffee and hot milk; or else a teaspoonful of senna leaves be tied up in a small muslin bag and stewed with 250 gm. of prunes, in either case adding sweetening to taste. Senna forms the laxative ingredient of nearly all the various "herb teas," so much used by grandmothers. In these days of the automobile and the aeroplane, however, the slow and tedious, even though economical process of domestic extraction, is bound to become obsolete. Coffee or prune juice may more readily be made purgative by the addition of a dose of syrup or of fluidextract of senna.

The most pleasant way of taking senna is to use the powdered leaves, letting the alimentary tract do its own extracting. Thus, the *compound powder of glycyrrhiza* owes its popularity to its rather pleasant taste. It contains 18 per cent. of senna, glycyrrhiza and sugar for sweetening, and oil of fennel for flavoring. The sulphur contents (8 per cent.), would probably not be missed if it were deleted from the formula; for sulphur is a very feeble agent as compared with senna. The dose of compound powder of glycyrrhiza for an adult is a teaspoonful or more stirred up with water. For children, the dosage given in the accompanying tabulation may be employed.

#### DOSE OF COMPOUND POWDER OF GLYCYRRHIZA

Age of Child	FOR CHILDREN	Gm.
6 months	.....	0.60
1 year	.....	0.90
2 years	.....	1.20
3 years	.....	2.00
5 years	.....	3.00

The *confection of senna* was very properly deleted from the present pharmacopœia. By no stretch of the imagination could it have been called a confection in the modern sense. A more pleasant preparation can be made in any household after the subjoined formula, which will yield a candy medication of approximately the same strength and dose as the compound glycyrrhiza powder.

#### LAXATIVE FRUIT CAKE

Senna leaves	.....	} Of each, equal parts
Figs	.....	
Dates (freed from stones)	.....	
Prunes (freed from stones)	.....	
Raisins (seedless)	.....	

\* Chop fine in a chopping bowl, mix by kneading, roll into cylinders as thick as a thumb.

Dose: 1 slice, larger or smaller according to size of the patient.

Perhaps the very pleasantness of this preparation is a disadvantage, as it may invite unnecessary use, and thus lead to the pernicious practice of habitual catharsis.

The *fluidextract of senna* might be used in a manner similar to that of cascara sagrada and for the same purpose—to increase intestinal irritability—in the curative treatment of chronic constipation, in doses of from 0.5 to 1 c.c. several times daily, and progressively reduced; or else in dose of from 2 to 4 c.c. for a single thorough evacuation. The addition of from 0.25 to 0.50 c.c. of tincture of belladonna to each dose, to antagonize griping, is suggested, though the patient may object to the dryness of the mouth and the impairment of vision produced thereby.

Little can be said in view of the old abominably tasting "black draft," the *compound infusion of senna*, excepting on the score of its efficiency. It is a relic of the days, fortunately now past, when nauseous medicine was given by the teaspoonful. The combination of senna (6 per cent.), which is chiefly a stimulant to per-

\* This is the title of a series of articles on the pharmacology, physiology and practical application of the common laxatives and cathartics. The first article appeared October 18.

istalsis, with magnesium sulphate (12 per cent), which keeps the feces fluid but does not have much effect on the musculature, is an instance of good synergism. The manna (12 per cent.), on the other hand, is too feeble in activity and in taste to be of much value either as an adjuvant or as a corrective. Fennel is used as flavoring. The average dose of 120 c.c. of this preparation will open the bowels, if it is within the power of any cathartic to do so. It might be remembered as a last resort, when other cathartics have failed and intestinal obstruction is probably not present. When it fails, a strong suspicion of mechanical interference with intestinal evacuation may be entertained. Of course, when intestinal obstruction is known to be present, this powerful agent is decidedly contraindicated, as it is more dangerous than the surgeon.

(To be continued)

## New and Nonofficial Remedies

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES OF WHICH THE COUNCIL RESERVES ITS ACTION WILL BE SENT ON APPLICATION.

W. A. PUCKNER, SECRETARY

### BENZYL BENZOATE (See N. N. R., 1919, p. 53).

**Benzyl Benzoate for Therapeutic Use**—Van Dyk and Company.—A brand of benzyl benzoate which complies with the N. N. R. standards.

Manufactured by Van Dyk and Co., No. U. S. patent or trademark.

**LUMINAL**.—Phenobarbital.—Phenyl Ethyl-Barbituric Acid.—Phenyl-Ethyl-Malonyl-Urea.

2,4,6-trioxy-5-phenyl-ethyl pyrimidin. Phenobarbital (luminal) differs from barbital (veronal) in that one ethyl group (C<sub>2</sub>H<sub>5</sub>) has been replaced by one phenyl group (C<sub>6</sub>H<sub>5</sub>).

**Actions and Uses.**—It is claimed that the introduction of the phenyl group increases the hypnotic power of luminal (phenobarbital) over that of barbital.

Luminal is said to produce sleep in the cat and dog with a satisfactory range between the effective and lethal doses, affording a deep, quiet sleep, without injury to the respiration or circulation. Very rarely a period of excitement precedes sleep.

It has a sedative action on respiration, lessening the frequency of breathing, although the volume of each respiratory is increased. It kills by respiratory paralysis. It is eliminated by the kidneys, a certain portion being probably decomposed in the organism. No renal injuries or gastric disturbances have been observed.

Luminal is claimed to be a useful hypnotic in neuralgic insomnia and conditions of excitement of the nervous system.

**Dosage.**—From 0.2 to 0.3 Gm. (3 to 5 grains) increased if necessary to 0.8 Gm. (12 grains). A maximum dose of 0.8 Gm. (12 grains) should not be exceeded. Small doses are sometimes efficient.

Manufactured by the Winthrop Chemical Co., Inc., New York, U. S. patent No. 1,021,872 (May 7, 1912; expires 1929); U. S. trademark No. 87,327.

**Luminal Tablets 13 grains.**—Each tablet contains luminal 8 grains. Luminal is a white, odorless, slightly bitter powder. It is insoluble in cold water, slightly soluble in hot water, and in alcohol, ether and chloroform, and in a kerosene solvent. It dissolves from boiling water in hot, toxic tablets, and a precipitate is formed by acids from its alkaline solutions. An aqueous solution of luminal has an acid reaction to litmus.

Luminal melts not below 172°C. Shake about 0.1 Gm. of luminal for a short time with 10 c.c. of normal sodium hydroxide and 2 Cc. of water, filter the filtrate into two portions and add measured volume solution to one and silver nitrate test solution to the other. A white precipitate is given in each case.

Boil about 1 Gm. of luminal for 5 minutes in 10 Cc. of a 1 per cent solution of sodium hydroxide. Ammonia is evolved. Dilute about 1 Gm. of luminal in 5 Cc. of normal water, hydroxide and heat the solution for four hours on a boiling water bath, replacing the evaporated water from time to time. Crystals of phenyl-ethyl-barbituric acid are formed on cooling. After removing the filtrate from above alcohol these crystals melt at 147°C. Dissolve about 0.1 Gm. of luminal in 1 Cc. of concentrated sulphuric acid. The solution is colorless. Incubate about 0.5 Gm. of luminal accurately weighed. The ash amounts to not more than 1 per cent.

**LUMINAL-SODIUM.**—Phenobarbital Sodium.—Sodium Phenyl-Ethyl-Barbiturate.—Luminal Soluble.—Na(C<sub>6</sub>H<sub>5</sub>CH<sub>2</sub>CO)<sub>2</sub>.—The monosodium salt of phenyl-ethyl-barbituric acid.

**Actions and Uses.**—The same as those of luminal.

**Dosage.**—For hypodermic injection luminal-sodium is used in the form of 20 per cent. solution, prepared by dissolving the salt in boiled and cooled distilled water; 2 Cc. (30 minims) of the solution contain 0.4 Gm. (6 grains) of luminal-sodium. The dose of luminal-sodium is 10 per cent. greater than that of luminal.

Luminal-sodium may be given hypodermically in doses of 0.1 to 0.3 Gm. (1½ to 5 grains).

Manufactured by the Winthrop Chemical Co., Inc., New York, U. S. patent No. 1,025,872 (May 7, 1912; expires 1929); U. S. trademark No. 87,327.

Luminal-sodium is a white, bitter, powdery, very soluble in water, slightly soluble in alcohol, practically insoluble in ether and chloroform. An aqueous solution of luminal-sodium has an alkaline reaction to litmus. On long standing or prolonged boiling of the aqueous solution 1 m. mole of carbon dioxide is liberated and 1 m. mole of methyl urea is precipitated after recrystallization from dilute alcohol its substance melts at 147°C.

Incubate about 0.5 Gm. of luminal-sodium. The residue responds to tests for sodium carbonate.

Accurately weigh a solution of luminal-sodium with hydrochloric acid and shake with ether. Evaporate the solvent. The residue responds to tests for luminal (which see).

On 1 Gm. of luminal-sodium, dissolve without residue 9.20 Cc. of alcohol (distilled) from barbituric sodium, which requires more than 500 Cc. of alcohol for solution.

Dry about 1 Gm. of luminal-sodium accurately weighed to constant weight over sulphuric acid. The loss does not exceed 5 per cent.

**SAJODIN.**—Calcium Monoiodobenenate.—(C<sub>6</sub>H<sub>4</sub>IOO)<sub>2</sub>Ca.—The calcium salt of monoiodobenzoic acid.

**Actions and Uses.**—Sajodin is used as a substitute for iodides. The iodine of sajodin, being longer retained, is perhaps better utilized. It is also less liable to produce gastric disturbances.

**Dosage.**—From 1 to 3 Gm. (15 to 45 grains) daily.

Manufactured by the Winthrop Chemical Co., Inc., New York, U. S. patent No. 839,241 (Dec. 25, 1906; expires 1924); U. S. trademark No. 61,730.

**Sajodin Tablets 8 grains.**—Each tablet contains sajodin 8 grains.

Sajodin is a colorless or slightly yellow powder, odorless, tasteless, non-toxic to the touch, insoluble in water, very slightly soluble in cold alcohol and in ether, and freely soluble in warm chloroform. When heated it chars and gives off violet vapor of iodine and finally a residue of calcium oxide remains.

Shake 0.5 Gm. thoroughly with 10 Cc. of hot water and filter. The filtrate is neutral to litmus (limb) and gives, with a drop of sodium hydroxide nitrate solution (soluble a drop). Five Cc. of the filtrate when evaporated leave no weighable residue (limb).

Dissolve 0.5 Gm. in 10 Cc. of warm chloroform. The solution is colorless but slightly opalescent and only a trace of solid matter precipitates on cooling.

Shake 0.5 Gm. of sajodin. The residue dissolves completely in hydrochloric acid and the solution made alkaline with sodium hydroxide precipitates on addition of ammonium carbonate. Strongly ignited about 10 per cent. of the residue remains.

Dry about 1 Gm. of sajodin accurately weighed to constant weight over sulphuric acid. The loss is not more than 1 per cent.

Ignite thoroughly in a crucible weighed to 0.001 Gm. The residue is dry at 100°C. It reacts with a solution of calcium hydroxide to form calcium iodide and calcium carbonate.

Shake 0.5 Gm. of sajodin with 10 Cc. of water and filter. The filtrate is colorless and gives, with a drop of sodium hydroxide nitrate solution (soluble a drop). Five Cc. of the filtrate when evaporated leave no weighable residue (limb).

Dissolve 0.5 Gm. in 10 Cc. of warm chloroform. The solution is colorless but slightly opalescent and only a trace of solid matter precipitates on cooling.

Shake 0.5 Gm. of sajodin. The residue dissolves completely in hydrochloric acid and the solution made alkaline with sodium hydroxide precipitates on addition of ammonium carbonate. Strongly ignited about 10 per cent. of the residue remains.

Dry about 1 Gm. of sajodin accurately weighed to constant weight over sulphuric acid. The loss is not more than 1 per cent.

Ignite thoroughly in a crucible weighed to 0.001 Gm. The residue is dry at 100°C. It reacts with a solution of calcium hydroxide to form calcium iodide and calcium carbonate.

## CHLORINATION OF WATER SUPPLIES

The chlorination of water supplies is probably the most important contribution made by this country to the art of water purification. In fact, this process stands out as the most useful procedure yet devised for insuring the safety of a municipal water supply. The results that could be achieved by adding calcium hypochlorite to water were first demonstrated in some experiments by G. A. Johnson at the Union Stock Yards in Chicago. Immediate publicity was given to this work by the treatment of the Jersey City supply at Boonton and the celebrated lawsuit that followed. The next few years witnessed a rapid development in the installation of plants using calcium hypochlorite, approximately 500 of these being in operation at the end of 1911. Disadvantages in the use of the lime salt soon appeared, due primarily to the lack of uniformity in the strength of the commercial product and also to the loss of germicidal efficiency, following storage of this chemical. These disadvantages were in large part overcome by the introduction of liquefied chlorine gas, or "liquid chlorine." Greater precision and uniformity of application became possible through this means, and the use of the liquid chlorine cylinders has practically displaced the bleaching powder. It is estimated that at the end of 1918 approximately 2,500 water purification plants in the United States were being operated with the use of liquid chlorine.

While few sanitary engineers believe that chlorination is a substitute for filtration, there is general agreement that, as an adjunct to the filtering process and in most emergency conditions, chlorination is almost indispensable for many supplies. The expense of hypochlorite amounts to only about 40 cents per million gallons of water treated, or, for a municipality of 5,000, only about \$150 a year, including depreciation.

The principal objection to water chlorination has been the occasional production of disagreeable odors or tastes. This is partly a matter of psychology; in many places where chlorination has been practiced and where newspapers have not taken up the matter in a sensational way, there has been no material objec-

tion on the part of the consumers. The interesting experience of the city of Milwaukee<sup>1</sup> shows that the occurrence of unpleasant odors in a water supply may be chargeable only in part to the chlorine. In that city it was found that the sewage was laden with coal tar derivatives and that the odor was primarily due to these substances, perhaps acted on by the chlorine. The extremely disagreeable taste in the Milwaukee water vanished altogether when sewage from a coke plant was diverted from the lake, although chlorination was continued. It seems likely that in other cases in which the chlorine itself has been accused, the presence of other substances, especially the coal tar derivatives, has been essentially responsible.

The remarkable decline in typhoid fever in American cities in the last ten years has been clearly set forth in the annual statistical summaries published by THE JOURNAL; and some sanitarians, especially waterworks engineers, have been inclined to attribute this improvement solely to water chlorination. This is probably an extreme view, since other factors, such as the growth in milk pasteurization, have been operative during the same period to reduce typhoid prevalence. Even, however, if it is impossible to ascribe all the credit for typhoid diminution to water chlorination, it is enough to say that this procedure has had a large share in the improvement effected. If it were still more widely used, especially in the smaller towns and cities using surface water without filtration, there is no question that a further impetus would be given to the work of typhoid prevention in the United States.

## IS ALCOHOL A STIMULANT?

Until comparatively recently, alcohol was regarded as a respiratory and cardiac stimulant. Whisky was probably the most popular domestic remedy for such occasional upsets as fainting, in which stimulation was presumably required. The popular idea that alcohol is a tone stimulant has so often proved to be untenable on the basis of scientific evidence that it seems almost superfluous to refute the mistaken notion anew. No one will deny that a feeling of relief often follows the use of alcohol in conditions in which stimulation seems to be indicated. In such cases, however, it has been shown to act merely as an irritant to the mucous membranes of the mouth and throat, promoting thus a beneficial local reaction before the alcohol has had time to be absorbed and stimulate in any way the depressed function.

There would be little occasion to refer again to the subject at this time had not a layman of prominence, Mr. G. E. Flint, recently, in a fiery volume,<sup>2</sup> vigorously defended alcohol as a stimulant. Any tyro in physiol-

1. J. Am. Waterworks Assn. 4: 515, 1919.

2. Flint, G. E.: *The Whole Truth About Alcohol*, with an Introduction by Dr. Abraham Jacobi, New York, the Macmillan Company, 1919.

ogy can find contradictions in Flint's book which, as a recent reviewer<sup>3</sup> remarked in *THE JOURNAL*, "sometimes quotes confidently as fact what is absolutely not true." Consider, for example, this statement (page 155):

That alcohol is very easily digested is proved by the fact that the carbohydrates cannot be digested as such, but only after they have been changed into sugar and finally into alcohol.

To the author of such statements, seemingly endorsed by a medical expert, alcohol is distinctly a "heart stimulant." And then there is further instruction: "That alcohol is not a stimulant has never been proved."

In animal experimentation the use of anesthetics, which are commonly employed to insure painless effects in such studies, may interfere with the interpretation of the observations in which alcohol, itself a narcotic, is concerned. Lately, satisfactory methods of investigation without the use of the anesthetic when alcohol is being tested have been devised. Hyatt,<sup>4</sup> who has given the most recent report, found that when alcohol is given by mouth there is a rapid rise in blood pressure followed by an immediate return to normal. This is a purely local effect due to irritation of the gustatory nerves and swallowing movements. The same result can be obtained with dilute acids. When the alcohol was introduced directly into the circulation without preliminary contact with mucous membranes, there was either no effect or a fall in pressure. An anesthetic dose may actually be given by introduction in this manner into the circulation, to which it must find its way in any mode of administration, without any stimulation of the heart or respiration. Even when moderate doses of 40 per cent. alcohol are introduced into the stomach slowly by the use of a gastric sound, no change in pressure is produced.

These experiments confirm the earlier studies of the same sort which Brooks<sup>5</sup> has described in *THE JOURNAL*. Why need the subject receive further argument? In refuting the claim that alcohol is in any sense a direct stimulant of the heart, a distinguished British committee reporting to the Central Control Board thus formulated<sup>6</sup> the status of the controversy:

The fact that the beneficial effect appears almost immediately and long before any significant amount of alcohol can have been absorbed and carried to the heart, is evidence for this local and indirect nature of the action. Its use in these circumstances is, therefore, comparable with that of smelling salts, or the irritating fumes of burnt feathers, traditionally employed for the same purpose. When, in conditions of more protracted weakness of the heart, the administration of alcohol has a beneficial effect, this must be attributed mainly to its mildly narcotic and sedative action, relieving the centers which

modify the action of the heart from the disturbing influence of pain and anxiety. The promotion of a patient's comfort, the relief of mental strain, may be an essential element in the treatment of disease, and an important factor in recovery. It does not, however, justify the description of alcohol as a "stimulant" of the heart.

#### THE DETERMINATION OF RACIAL RELATIONSHIPS BY MEANS OF BLOOD

The question of the relationship of different races to one another is a matter of considerable interest. Up to the present, morphologic criteria have been used almost exclusively in attempts to decide what this relationship is. Various anthropometric tests have been devised, for example, the so-called cranial index, the facial angle, and similar tests. These tests are in a sense as obvious as differences in stature, and such striking differences in conformation as the peculiarities in the eye slits which characterize the oriental races. With the advent of immunologic knowledge, the methods of serology were applied to the study of racial peculiarities. In the early days of serology, the precipitin test was used to demonstrate the blood relationship between man and the higher apes. The possibility of differentiating groups within the same species was not apparent until some time after serology became well established. Indeed, it was not until Landsteiner demonstrated the fact that serologic differences occurred among individuals of the same species that the possibility of using serologic methods became apparent.

In certain fields of operation in connection with the recent war, extraordinary opportunities were offered for the study of different races on account of the bringing together of military units from various parts of the world. In the British campaign in Mesopotamia, particularly, an extremely cosmopolitan group was collected. Advantage of this was taken by L. and H. Hirschfeld,<sup>1</sup> two Swiss serologists, who made extensive studies of the blood of soldiers of different nationalities and of the population of Mesopotamia. The type of blood test chosen was that in every day use in connection with the transfusion of blood, namely, the determination of the group into which individuals should be placed with reference to the presence of iso-agglutinins. The method as ordinarily used places individuals in one of four groups. The Hirschfelds tested English, French, Italian, Serbian, Greek, Bulgarian, Russian, Arabian, Turkish, Senegalese, Amhara and Indian soldiers, and also tested the blood of Jewish refugees.

As the result of a great many tests, the observer were able to divide the nationalities into three groups: a European type, which contained the English, French, Italian, Greeks, Bulgarian, and Serbian; and which

according to the studies of Landsteiner and von Dün-  
gern, would also contain the Germans and Austrians;  
an intermediate group containing the Arabs, Turks,  
Russians and Jews, and an Asio-African group con-  
taining the negroes, East Indians, and natives of Indo-  
China and Madagascar. The authors draw the con-  
clusion that these results are suggestive of a dual  
origin of the human race. According to this concep-  
tion, the European type and the Asio-African type  
originated independently, and the intermediate type  
represents the fusion of the other two types. The  
validity of these conclusions may, of course, be ques-  
tioned; but the studies are certainly of interest not  
only on account of the immediate results but also  
because they suggest further studies of different races  
along serologic lines.

#### HEMOGLOBIN DETERMINATION

The method for the determination of the hemoglobin  
content of the blood introduced by Sahli is probably  
one of the most commonly used today. The method  
is fairly reliable and the apparatus required is not  
complicated; it consists of a simple color standard  
(usually acid hematin) and a calibrated tube in which  
the measured amount of blood is treated appropriately  
for comparison. Clinical chemists have recognized,  
however, that the Sahli method is open to certain  
objections: the inaccuracies due to the variations in the  
calibrations and in the construction of the tubes; the  
fading of the standard; the variations of the readings  
in different lights, the delay in the development of the  
permanent color, and the "personal equation."

About two years ago, Palmer<sup>2</sup> suggested converting  
the hemoglobin to carbon monoxid-hemoglobin and  
comparing this with a standard solution of like com-  
position. The comparisons were made in a colorimeter,  
a modification that enhanced greatly the accuracy and  
ease of the determination. Since then Cohen and  
Smith<sup>3</sup> of the Yale Station of the Chemical Warfare  
Service have shown that the Palmer method is deficient  
in one particular: Palmer recommended artificial  
gas for his source of carbon monoxid; Cohen and  
Smith noted that the standard made at New Haven  
deteriorated, most likely owing to the use of an  
inferior quality of illuminating gas. Hence they have  
proposed a modification of the Palmer method by  
reverting to the original Sahli standard but retaining  
the valuable technical features of the Palmer proce-  
dure. By means of check determinations, for which  
the complex Van Slyke<sup>4</sup> apparatus was used as a

control, the Sahli-Palmer modification was shown to  
be accurate within 2 per cent., even in the hands of  
relatively inexperienced workers. Its limitations are  
that a special form of colorimeter is required, and  
due time must be allowed for the full development  
of the acid hematin color.

Berman<sup>5</sup> has just proposed an acid hematin method,  
modifying the Sahli procedure slightly in two respects:  
Instead of diluting the hemoglobin standard with part  
water and part tenth-normal hydrochloric acid solu-  
tion, the dilution is made entirely with tenth-normal  
acid solution, and after dilution, the acid-hemoglobin  
mixture is boiled one minute to hasten the formation  
of the maximum depth of the acid hematin color.  
According to the author's data, the accuracy of the  
latter method may be kept within 3 per cent. It is  
doubtful whether the many laboratory users of the  
Palmer method will wish to return to the brownish acid  
hematin color in preference to the beautiful and easily  
contrasted pink color of the carbon monoxid-hemo-  
globin; perhaps the difficulty may be solved by a  
refined method of securing a satisfactory grade of  
carbon monoxid.

### Current Comment

#### A REMINDER

A blue slip to be used in remitting subscriptions and  
Fellowship dues for 1920 is inserted in THE JOURNAL  
this week. Last week we explained its use under the  
heading "Will You Help?" The use of this slip by  
Fellows and subscribers will result in a considerable  
saving for the Association on the cost of sending indi-  
vidual statements. In each of the several years past,  
more than 20,000 subscribers and Fellows utilized sim-  
ilar slips, and it is hoped that even a larger number  
this year will give their cooperation in this matter.  
Little things promptly performed constitute most of  
life's courtesies.

#### INFLUENZA AND TUBERCULOSIS

The reappearance of influenza a year ago led to the  
prediction by many writers that a marked increase in  
active pulmonary tuberculosis was sure to ensue. Fol-  
lowing the epidemic of 1889-1890, a number of articles  
appeared in which the statement was made that influ-  
enza frequently caused a lighting up of quiescent tuber-  
culosis. This view became current with the medical  
profession and led to the foregoing prophecy. Some  
recent observations of Fishberg<sup>6</sup> seem to indicate that  
a decided revision of our views is necessary. Fishberg  
points out that when a patient with tuberculosis states  
that the onset of his disease followed influenza, it is  
very necessary to determine just what the patient  
means by influenza. The terms "grip" and "influenza"

are used so loosely by both the layman and the physician that what the patient describes as influenza is frequently not true epidemic influenza at all but an ordinary upper air passage infection such as is likely to occur at any time. Furthermore, the early symptoms of tuberculosis itself may take the form of just such an upper air passage infection. The question is also complicated by the fact that many of us have not yet learned to differentiate pulmonary tuberculosis from the postinfluenzal pulmonary lesions that simulate it. Fishberg's conclusions, and they are supported by evidence from other observers, rather indicate that patients with tuberculosis are as resistant to influenza as the average individual, that they develop pulmonary complications possibly less frequently than the non-tuberculous, and that the ultimate effect of an attack of influenza, in most instances, is not to cause the tuberculosis to light up. Fishberg's article is timely and calls attention to the necessity for a critical analysis of the late complications of influenza. We are inclined to believe, however, that it is as yet somewhat early to decide whether as radical a change of opinion is warranted as his article would indicate.

#### A QUARTER CENTURY OF SERUM THERAPY IN DIPHTHERIA

In a recent address before the Académie de médecine of Paris, Louis Martin<sup>1</sup> recalled that in September, 1894, Roux communicated to a medical congress in Budapest the results of his pioneer studies on the serum therapy of diphtheria. To physicians of the present generation it seems long ago that Behring and his collaborators, Kitasato and Wernicke, definitely showed that the cell-free blood serum of animals immunized with diphtheria toxin acquires the power to protect other animals of the same and different species against the poison. Yet, in the quarter century that has elapsed since Roux put to the test of human clinical experience the treatment discovered by Behring, what enormous practical advantages to mankind have been derived from these brilliant scientific investigations. The outcome with the first larger group of diphtheria patients who received no other medical treatment than administration of antidiphtheric serum was so striking that the procedure found prompt recognition from clinicians. Serum therapy in diphtheria became an accepted method. It is unnecessary to dwell on the fact that the mortality in this disease has been reduced from 30 per cent. or more to 8 per cent. or less in practice. The beneficent results can be learned from the experience of every community in the civilized world. The maximum of therapeutic efficiency has not yet been reached. With speedier diagnosis, with more direct methods of introducing the antitoxin, with better concentration and preparation of the latter, and with more heroic dosage in emergencies, the results seem destined to become even more favorable than they have been in the past. Now that the war is over and men can once more turn their

thoughts to activities that are worth while, let us remember that the discovery of diphtheria antitoxin was not an overnight affair or a chance find. Only patient, laborious researches brought ultimate success. In the study of diphtheria, by which such brilliant results have been achieved, the laboratory and the clinic have worked hand in hand. Looking forward to further great discoveries in the domain of medicine, let us not fail to encourage in the case of other diseases likewise this fruitful collaboration between science and practice.

#### THE ORIGIN OF MACROPHAGES

In his earliest explanations of cell ingestion, or phagocytosis, of foreign particles, Metchnikoff pointed out that the process is quite comparable to what takes place in the intracellular digestive functions among unicellular forms of life. In the lowest animals the single cell must perform all necessary functions, whereas in the course of evolution to the higher forms a division of labor has taken place, which is expressed by a differentiation in structure and activity. Bearing in mind the evolutionary history of the cells, we should not be surprised if various types of cells besides the specialized leukocytes could, if occasion arose, assume the primitive function of cell ingestion. Metchnikoff<sup>2</sup> has, indeed, distinguished between the "motile" and "fixed" phagocytes, the former the leukocytes of the circulating blood, the latter certain connective tissue cells, endothelial cells, cellular elements in the lymph nodes and spleen pulp; in fact, all phagocytic cells that are ordinarily confined to some definite locality in the body. Among phagocytic cells Metchnikoff further distinguished between "microphages," by which he designated the polymorphonuclear leukocytes of the circulating blood, and "macrophages." The latter include the fixed cells mentioned, together with the large mononuclear elements of the blood. Following his conceptions still further, we may regard the macrophages as concerned primarily with the engulfing of cellular detritus and foreign particles, whereas the microphages are more commonly engaged in the resorption of bacteria. The origin of these phagocytic cells, between which no sharp division of classification can be drawn, has been the subject of considerable speculation. Are they derived from connective tissue, endothelium or lymph cells, to all of which they have at times seemed to bear some relation? What is the identity of the various phagocytic cells which have received a diversity of new names in recent years and which seem to be so important in the defense against certain pathologic processes in the organism? With respect to some of them, several investigators have reached the conclusion that, as lymphocytic cells do not possess the power of phagocytosis, the macrophages are derived from connective tissue. Recently, however, Foot<sup>3</sup> has championed the view that the macrophages of the loose connective tissue are in

<sup>1</sup> A discussion of this subject can be found in Zinner, H., *Infection and Resistance*, New York, The Macmillan Company, 1914, p. 117, on phagocytosis.

<sup>2</sup> Foot, N. C., *Studies on Endothelial Resorption: The Macrophages of the Loose Connective Tissue*, J. M. B. A., **10**, (1913), p. 17.

<sup>3</sup> Martin, Louis. *Vingt cinq années de sérothérapie antidiphthérique*. *Bull. de l'Acad. de méd.*, **82**: 173 (Oct. 14) 1919.

reality of endothelial origin. From studies conducted in the department of pathology at the Harvard Medical School, he concludes that they do not originate in the epithelium or the connective tissue cells, or from lymphocytes. According to Foot they are probably derived from the proliferating vascular endothelium in the immediate vicinity of the lesion that calls them forth, rather than from the vascular endothelium in general.

#### NEW NURSING LEGISLATION PROPOSED FOR NEW YORK STATE

Since the influenza epidemic of last year with the accompanying shortage of nurses, much discussion has ensued relative to proposed reforms in nursing legislation in order to make available an adequate supply of nurses, not only for ordinary times but also for times of stress. *THE JOURNAL* has received a copy of a bill which it is proposed to introduce into the 1920 legislature of New York as an amendment to the present law covering nursing. The main features of this bill are the statement of definite qualifications for those carrying the title R. N., and an annual re-registration. A new class to be known as trained attendants, with the designation T. A., is created; it is to include persons over 18 years of age holding a certificate from a school for trained attendants connected with any institution, properly licensed, giving a course of at least nine months, including six months of practical experience. Trained attendants are also to re-register annually. In addition to those licensed as trained attendants with the qualifications mentioned, the regents may license any one who pays a fee of \$5 and submits satisfactory evidence that she is more than 18 years of age and of good character, that she has had two years' experience in the care of the sick and is qualified to practice as a trained attendant. Such candidates must also be certified to by three licensed physicians who have personal knowledge of the applicant's qualifications. Finally, there is a saving clause, which states that nothing contained in the bill shall prevent any person from engaging in nursing, provided that he or she does not assume the title of trained, certified, graduate or registered nurse or trained attendant.

#### SUPERVITAMINS

This from a recent issue of *Physiological Abstracts*:

Three rats fed on the same diet with the addition of 2 mg. per cent "Orypar," a commercial vitamin, lived for 100 days, and retained their desire for food for a much longer period.

With the present high cost of food-stuffs, one may question the wisdom of taking anything that will prolong the thirst for food after death. Nevertheless, the same physiologic achievement evokes one's admiration. Science is, indeed, wonderful.

**Hematogenous Peritonitis.**—Of the serum germ which causes the peritonitis by the blood stream and produces a fatal peritonitis in the pneumococcus is the best known. There is a strong probability that this germ can enter the peritoneum by passing inward along the fallopian tubes with the possibility of a secondary reaction in the tubes.—*W. H. Burt, Clin. Jour. Oct. 1, 1919.*

## Medical News

(PUBLISHERS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

### CALIFORNIA

**Illegal Practitioner Fined.**—Shew Ping, a Chinese herb doctor of San Francisco, was found guilty of practicing medicine without a license and was fined \$200.

**Chiropractic Act on Ballot.**—An act providing for the creation of a board of chiropractic examiners apart from the state board of medical examiners will be on the 1920 California ballot.

### ILLINOIS

**Society Organ Resumes Publication.**—The *Bulletin*, a monthly publication, the official organ of the Montgomery County Medical Society, which was suspended during the war, resumed publication with the November issue.

**Physician Acquitted.**—In the case of Dr. Horace Reddish, Jerseyville, charged with the murder of his father and a domestic in their home near Jerseyville several months ago, the jury, December 10, found the defendant not guilty.

**Indicted as Illegal Practitioners.**—According to report, Miss Victoria Japa of 4423 Walton Street, Chicago, was arrested by the department of registration and education for practicing as a midwife without a state license, and was fined \$50 and costs. Andrew Garratt of East St. Louis was arrested for practicing medicine without a license and was fined \$50 and costs. He could not pay the fine and was committed to the county jail for two months. Carl E. Schulte of St. Louis was also arrested by the department for practicing medicine in Illinois without a state license. Schulte was fined \$50 and costs, the total amount being \$83.40, which he paid.

**Chiropractors Fined.**—For the third time in eighteen months Mrs. Emma Calvin of Monticello has been fined for practicing as a chiropractor without a state license. The fine in each of the former convictions was \$150 and costs, and for the third conviction the fine is \$200 and costs and ten days in jail. This is said to be the first jail sentence the Illinois Department of Registration and Education has been able to secure against a chiropractor for practicing without a state license. Mrs. Calvin graduated from the Palmer School of Chiropractic at Davenport, Iowa, and claims that by reason of such graduation she is entitled to treat human ailments without regard to any law on the subject. H. N. Mettler of Rock Island, another chiropractor, has been fined \$200 and costs for practicing without a state license. Mettler is also a Palmer graduate and, like all other chiropractors who are not licensed, claims that the law does not apply to him. On a former occasion, Mettler was fined \$150 for violating the medical practice act, paid the fine, and started right to practicing again.

### Chicago

**College of Surgeons Secures Home.**—The Nickerson residence on East Erie Street has been purchased by the Chicago members of the American College of Surgeons and turned over to that organization to be used as an administrative home.

**More Money Asked for Speedway.**—In order to complete the Speedway Hospital it will be necessary to ask Congress to appropriate at least \$2,500,000, bringing the cost of the project up to \$5,500,000. The Surgeon-General, U. S. P. H. S., reported to favor the project.

**Washingtonian Home Closed.**—The Washingtonian Home, which has been in existence for more than half a century and is said to have a record of 50,000 cures, will close its doors, January 1, on account of the decrease in patronage from 100 patients a month to twelve or fifteen. It is expected that the energies of the organization will be devoted to the treatment of drug addicts.

**Grant for Medical Research.**—At the annual meeting of the Committee for Grants for Research of the American Association for the Advancement of Science, the sum of \$400 was awarded to Leslie B. Argy, Ph.D., of Northwestern University Medical School in support of his study of the origin, growth and fate of giant cells or osteoclasts which have usually been held responsible for bone dissolution.

**Former Assistants Honor Professor LeCount.**—December 17, former assistants of Dr. Edwin R. Le Count, professor of pathology in Rush Medical College, tendered him a banquet and presented him with two paintings as a recognition of esteem and gratitude. The presentation address was made by Dr. Frank R. Nuzum, Janesville, Wis., who presided. Addresses were also made by Drs. Herman A. Brennecke, Aurora; George E. Clements, Crawfordsville, Ind.; William H. Burmeister, George H. Coleman, Arthur H. Curtis, Morris Fishbein, Edward H. Hatton and James P. Simonds, Chicago.

**Physician Convicted.**—Dr. Lillian Hobbs Seymour, also known as Dr. Lillian R. Hobbs, is said to have been convicted of murder by abortion, December 16, by a jury in Judge Scanlon's court and to have been sentenced to imprisonment for fourteen years in the state penitentiary. This is the second time Dr. Hobbs was placed on trial in the same case. In 1916, she was found guilty and sentenced to fourteen years imprisonment, but later was granted a new hearing on technicality. The conviction is said to have been based on antimotem statements of the two young women on whom she is said to have performed an illegal operation.

INDIANA

**Personal.**—Dr. Augustus R. Schaefer, Alexandria, was found insensible and almost frozen at his home, December 10, and is under treatment in the Alexandria Hospital.—Dr. Benoni S. Rose, Evansville, was elected president and Dr. J. S. Stephens, secretary, of the Medical Service Club of Evansville.—Dr. Milton C. Wilson, Lafayette, has been appointed physician for the county farm and county jail.—Dr. William C. Dunscombe, Lafayette, has resigned as superintendent of the Wabash Valley Sanitarium, Lafayette.—Dr. George S. Bliss, superintendent of the Indiana School for Feeble-Minded Youth, Fort Wayne, has resigned.

MARYLAND

**National Guard Item.**—The Adjutant-General of Maryland has been authorized by the War Department to organize a field hospital company (motorized) for the national guard of the state.

**Libraries to Be United.**—According to plans now being considered by the authorities of the Johns Hopkins University, the libraries of the hospital, the school of hygiene, and the medical school ultimately will be collected under one roof in a new library building to be erected in the hospital group.

**Health Wardens Named.**—In naming the health wardens for Baltimore city, Health Commissioner C. Hampson Jones made but five changes among the twenty-eight wardens now connected with the department. Those appointed were: Drs. Maurice Feldman, J. Walker Thomas, Roscoe Z. G. Cross, H. J. Carrick and W. Edward Grempler.

**Appointments in Baltimore City Health Department.**—Health Commissioner C. Hampson Jones, inaugurating the merit system in the Baltimore City Health Department, has reappointed Dr. John F. Hogan, assistant commissioner of health, in charge of the bureau of communicable diseases, and Dr. Marion B. Hopkins, chief of the bureau of food and dairy inspection.

**Joint Meeting.**—A joint meeting of the Maryland Psychiatric Society, Baltimore County Medical Association and State Lunacy Commission, to which the members of both the State and Baltimore City Bar Association were invited, was held December 17, at the Spring Grove State Hospital at Catonsville, to discuss the question of the care of the criminal insane. Addresses were made by Dr. V. P. Herring, secretary of the Lunacy Commission, and by Dr. John Oliver. Plans to be laid before the legislature for 1926 were considered.

**Appointments to Baltimore Health Department.**—Giving further evidence of his intention to put the health department on an efficiency basis, Dr. C. Hampson Jones, health commissioner, has reappointed the following: Dr. William Royal Stokes, chief bacteriologist; Dr. Mary Sherwood, head of the bureau for the prevention of infant mortality; Dr. Mary C. Willis, assistant to Dr. Sherwood; Dr. C. L. Ewing, assistant bacteriologist, and Dr. John E. O'Neill, superintendent of the tuberculosis dispensary. In addition he has appointed: Dr. Howard J. Maldeis, city medical examiner; Dr. Standish McCleary, assistant medical examiner, and Dr. Bartus T. Baggett, assistant physician in the tuberculosis dispensary.

MISSOURI

**Bill for New Marine Hospital in St. Louis.**—Congressman J. C. Dyer of Missouri has introduced a bill (H. R. 11,333) in the House of Representatives authorizing the Secretary of the Treasury to sell the present marine hospital site and to acquire a suitable and sufficient site in or near St. Louis for the construction of "a complete hospital plant for the treatment of beneficiaries of the War Risk Insurance and Public Health Service." It was referred to the House Committee on Buildings and Grounds.

NEBRASKA

**Personal.**—Dr. Ira H. Dillon, Auburn, has been appointed chief of the bureau of public health of Lincoln.—Dr. Alfred E. Westervelt, Omaha, is in Manchuria working against cholera under the central division of the Red Cross.—Dr. David G. Griffiths, formerly superintendent of the Beatrice Hospital for the Feeble-Minded, has been appointed superintendent of the Lincoln State Hospital for the Insane and has been succeeded at Beatrice by Dr. Samuel J. Stewart, Hastings.—Dr. Philip H. Bartholomew, Blue Hill, has been succeeded by Dr. Richard T. Leeder as representative of the government in the office of the state board of health.

NORTH CAROLINA

**Personal.**—Dr. Joseph A. Speed has been appointed college physician of Trinity College, Durham.—Dr. Harry Q. Alexander, Pineville, has resigned as president of the North Carolina Farmer's Union, and will resume practice.

**New Sanatorium.**—Dr. Watson S. Rankin, Raleigh; Richard M. King, James E. Smoot, Joe A. Hartsell, William D. Pemberton and William H. Wadsworth, all of Concord, have purchased the Wagoner Grove and will erect on this site a hospital, to be known as the Caharrus Sanatorium, at a cost of about \$60,000.

**Plans for Health Work.**—Dr. Watson S. Rankin, secretary of the state board of health, Raleigh, November 22, held a conference with Drs. E. F. Long, Davidson County; A. C. Bulla, Forsyth County, and J. L. Smith, Wilson County, in order to map out plans for the fifteen cooperating counties of the state for health work during the next year.

**New Officers.**—Guilford County Medical Society, at its annual meeting held in Greensboro, December 4, elected Dr. Charles W. Banner, president; Dr. Robert A. Schoonover, vice president, and Dr. Frederick J. Pate, secretary-treasurer, all of Greensboro.—Physicians of the Tenth Congressional District met in Asheville, November 12, and organized the Tenth District Medical Society. The following officers were elected: president, Dr. Clyde E. Cotton, Asheville; vice presidents, Drs. John R. McCracken, Waynesville, Macon County; Percival R. Bennett, Bryson City, Swain County; Fred L. Siler, Franklin, Macon County, and Benjamin L. Ashworth, Marion, McDowell County, and secretary, Dr. Wilham J. Humeccut, Asheville.

PENNSYLVANIA

**Gorgas in Pittsburgh.**—January 8, Gen. William C. Gorgas, formerly Surgeon-General, U. S. Army, will deliver an address on "Yellow Fever," in Pittsburgh, under the auspices of the Society for Biological Research of the University of Pittsburgh.

**Field Hospital and Ambulance Companies Authorized.**—The Adjutant-General of Pennsylvania has been authorized by the War Department to organize four field hospitals (motorized) and one headquarters, and four ambulances (motorized) and one headquarters for the national guard of the state.

**First Social Disease in Quarantine in Pennsylvania.**—The first quarantine for social disease in Pennsylvania was enforced by the Harrisburg department of health and the state health department. The victim, after being warned, broke quarantine and was arrested and sent to jail and her cell quarantined. State and city health authorities visited the house and placed a big yellow placard on the door with the name of the disease prominently displayed as a warning to the public. The same regulations apply to the quarantine as in smallpox. The woman left the house less than two hours after the quarantine was established.

Philadelphia

**Gift to Hospital.**—Seven acres adjoining the Chestnut Hill Hospital has been presented to the institution by Henry A.

of the City of Columbia Hill. Mr. Laughlan made the donation in memory of his wife, Mary Red Laughlan. Through this gift it is possible for the hospital to continue on its present basis. If necessary, funds can be raised to make contemplated improvements, and the hospital will meet the demands of Columbia Hill residents for additional accommodations. Lewis Wharton and Joseph C. Fraley have each pledged \$1,000 toward the new project.

**Army Equipment for Hospital.**—Improvements and equipment valued at nearly \$75,000 has been offered to the Philadelphia General Hospital by the United States Army which is a part of the institution. A lease hospital during the last year. The army authorities had a contract with the city by which they got the use of part of the hospital at a rental of \$1 a year on condition that when they left the institution they would put it in its original condition. Thousands of dollars were spent in painting and renovating the wards, putting in a modern kitchen, improving plumbing and installing the equipment which the city had on hand at the institution, and the "putting back in original condition" by the army would have meant the destruction of most of these improvements, according to Director Krusen of the Department of Public Health and Charities. In addition the city was able to buy for \$251 a Red Cross building, erected by the War Department at many times that cost. This is expected to be one of the most useful additions to the city's hospital.

**Personal.**—Dr. J. A. Lichty, Pittsburgh, delivered an address on "The Treatment of Thyroid and Other Endocrine Disturbances as Viewed by an Internist," before the section on general medicine at the College of Physicians, December 17.—Dr. H. H. Finkle has been elected medical director of the Charity Hospital succeeding Dr. W. Krusen, resigned.—Dr. Harvey Cushing delivered the second of the series of Nathan Lewis Hatfield lectures at the College of Physicians, December 16. His subject was "The Major Hereditary Neurologias and Their Surgical Treatment."—George M. Kohler of Washington delivered a lecture on "Opportunity in Relation to Tuberculosis," before the section of industrial medicine and public health of the College of Physicians, December 17.—Dr. Wilmer Krusen will be the guest of honor at a testimonial dinner given by the physicians of Philadelphia at the Bellevue-Stratford Hotel, December 30.—Dr. C. Lincoln Furbush, incoming director of the Health of Philadelphia, will be the guest of honor at a reception held in the Hotel Adelphia, January 9, and given by the Northern Medical Association to celebrate its twenty-fourth anniversary.—Dr. S. S. Woody of the Philadelphia Hospital for Contagious Diseases, has just returned from Georgetown, Del., where he went at the request of the state board in the fight against smallpox. According to Dr. Woody, the cases at Georgetown, while many, are not serious, and the local medical authorities have the matter under control. General vaccination has been ordered and arrangements for other county hospitals should necessarily require it.—Dr. C. L. Hensinger has been appointed director and in charge of the new pathologic laboratory of the Philadelphia General Hospital by Dr. Wilmer Krusen of the Department of Public Health and Charities.

### SOUTH CAROLINA

**Hospital Note.**—The total Samaritan Greenville (Spartanburg) hospital was 1,000 for 1919 patients to cost \$60,000. An additional 1,000 inpatient cases has provided \$2,500.

### SOUTH DAKOTA

**District Officers Elected.**—At the annual meeting of the South Dakota Medical Society, December 2, at Sioux Falls, S. D., the following district officers were elected: president, Dr. George W. Benson, Pierre; first vice-president, Dr. Samuel A. Smith, Rapid City; second vice-president, all of Sioux Falls.

**Personal.**—Dr. John W. Freeman, Lead, and Robert D. Stone, Aberdeen, have been elected members of the State Medical Association.—Dr. G. J. E. Zimmerman, Sioux Falls, has been appointed health examiner for young children at the Industrial, Normal and Industrial School, Aberdeen.

### TENNESSEE

**Branch Laboratory Established.** The first branch laboratory of the state board of health has begun work in West Tennessee. This work has been undertaken by the University of Tennessee Medical School, and will be carried on by

the laboratories of the departments of bacteriology and public health at the University.

**Hospital Notes.**—Drs. Charles P. Edwards and Enoch W. Lupton have purchased from the city of Kingsport the Community Hospital which was founded in 1918 for checking influenza. Announcement is made that Vanderbilt University has taken over the Galloway Memorial Hospital, Nashville, and will immediately complete it and put it in operation.

**Vanderbilt Gets Four Million Dollars.**—It has just been announced that the General Education Board, New York, has appropriated \$4,000,000 to enable Vanderbilt University, Nashville, to reorganize completely its medical school. This amount is said to come from the general funds of the board and not out of Mr. Rockefeller's recent donation of \$20,000,000 for the promotion of medical education in the United States.

**Harrison Law Violator Sentenced.**—In the case of Dr. Ben Freidman, Memphis, who is said to have been convicted of violating the Harrison Narcotic Law, and who appealed to the district court of appeals and then to the Supreme Court of the United States, the decision of the lower courts has been sustained and the defendant, who had been sentenced to imprisonment for two years in the federal penitentiary, Atlanta, was taken to Atlanta, December 6, to begin his term.

**Personal.**—Dr. Walter S. Nash has been appointed chief of the medical staff of the Knoxville City Hospital.—Dr. Clarence B. A. Turner, Newbern, has been appointed president of the Dyer County Board of Health, succeeding Dr. Stanley B. Sharpe, Dyersburg, resigned.—Dr. Iverson L. Lofton, Nashville, is reported to be seriously ill as the result of a cerebral hemorrhage.—Drs. Worcester A. Bryan, Lucas E. Burch, and Robert W. Grizzard, Jr., have been elected as the executive committee of the medical staff of the Woman's Hospital, Nashville.—Dr. Herbert L. Baugh, Flynnshick, has been appointed registrar of vital statistics for the state board of health.

### TEXAS

**Convalescent Home Honor.**—The Red Cross Convalescent Home, Fort Bliss, in which about fifty returned soldiers were being cared for, was destroyed by fire, December 6. All the patients were removed in safety.

**Health Department Plan Adopted.**—The county health department plan has been inaugurated in Wichita and Bell counties, and will be inaugurated in Wilson, Tarrant, and Jefferson counties by January 1.

**Memorial Hospital for Cooper.**—A movement has taken tangible form to build at Cooper a hospital to cost not less than \$50,000 as a memorial to the soldiers from Delta County who fell in the world war.

**Clinics at Dallas Hospitals.**—Medical clinics were held in Dallas, November 24 and 25, by Drs. Llewellyn F. Barker, Baltimore; Joseph C. Bloodgood, Baltimore; George W. Crile, Cleveland, and Drs. Rudolph Matas and Isadore Dyer, New Orleans. The clinics were held at the St. Paul and Baptist sanatoriums, and the City Hospital.

**Personal.**—Dr. Beverly T. Young, San Antonio, superintendent of the Southwestern Insane Asylum for several years, has resigned and has been succeeded by Dr. Job G. Springer, Elmendorf.—Dr. Lane B. Kline has resigned as city health officer of Houston, and has been succeeded temporarily by Dr. Carl B. Young.—Dr. Gustavus A. Spivey has been appointed assistant health officer of Dallas County and has resigned as a member of the staff of the Emergency Hospital, Dallas.

### CANADA

**Personal.**—Dr. Neil Macphater, Calgary, Alta., was operated on recently at the Presbyterian Hospital, Chicago, for glaucoma of the right eye, and is reported to be doing well.

**Hospital News.**—The N. C. O's and men of No. 3 Canadian General Hospital (McGill University) have taken steps to form a permanent club to be composed solely of members of the unit. Brig.-Gen. H. S. Birkett, C.B., commander of the hospital in France in 1915, presided at the initial meeting.—The hospital at Summerland, B. C., was destroyed by fire on Dec. 16, 1919. The patients and staff escaped unharmed. The loss totals \$12,000.

**Medical Societies.**—At its recent annual convention, the Manitoba Medical Association elected the following officers:

president, Col. John A. Gunn, M.D., Winnipeg; secretary, Dr. Thomas K. G. Hamilton, Winnipeg; treasurer, Dr. Sidney J. S. Peirce, Brandon.—The Alberta Medical Association has elected the following officers: president, Dr. William F. Gershaw, Medicine Hat, and vice presidents, Drs. Walter S. Galbraith, Lethbridge, and Robert B. Wells, Edmonton.

**Public Health News.**—The Toronto city council having refused to issue a proclamation putting the Ontario Vaccination Act into effect as regards compulsory vaccination in that city, the provincial board of health has taken up the matter, and an order of the court is being sought to compel the city of Toronto to do its duty. The case comes up for hearing on December 23. In the meantime smallpox continues to spread in Toronto, and the total number of cases to date is more than 1,600. So far there have been no deaths.—All Ontario is now in quarantine so far as Montreal is concerned. No person traveling from the province of Ontario into Montreal, nor any citizen of the United States entering Montreal via Ontario, will be permitted entrance into that city unless able to produce certificate of vaccination within seven years. Failing such, or immediate vaccination by vaccinators on the trains, they must return to their homes.

**University News.**—Extension courses and lectures for graduates in medicine are being established for the practitioners of the province of Ontario by the Medical Faculty of the University of Toronto. A standing committee has been appointed to advise as to clinics and lectures. The committee will be prepared to arrange lectures to aid medical societies or groups of physicians who desire to keep up to date.—Talk has been revived concerning the removal of Queens medical faculty from Kingston to Ottawa. Members of the board of trade of Kingston and citizens recently discussed it at a largely attended meeting of that body and a resolution unanimously passed that every effort should be made to retain the medical faculty in Kingston. Principal Taylor said that if the entire medical college was to be kept in Kingston, \$1,000,000 would be needed, while if part of it were moved to Ottawa, one or two chairs would have to be duplicated. Pressure to make the move had come from the graduates of Queen's and Principal Taylor said it was not to be lightly regarded.

### GENERAL

**Society Changes Name.**—The Western Roentgen Society at its recent meeting in Chicago changed its name to the Radiological Society of North America.

**Industrial Nursing.**—The industrial nurses of the National Organization for Public Health Nursing plan to form an industrial nursing section in the National Organization at the meeting in Atlanta, Ga., next April. The object of this section will be the formation and maintenance of high standards for service in industry.

**Hygiene and Prohibition Help Health.**—Surgeon-General Rupert Blue states that the improvement of the health conditions in the United States during the last year has been due partly to prohibition and partly to the lessons of hygiene learned in the war. The relief from war strain also was a factor in the reduction of illness.

**Bequests and Donations.**—The following bequests and donations have recently been announced:

Mount Sinai Hospital, Chicago, \$4,000, the proceeds of a musical pageant given in Chicago, December 7.

Children's Hospital, Boston, and Convalescent Home of the Childrent's Hospital, Boston, each \$10,000; Baldwinville (Mass.) Cottage Hospital for Children, \$5,000, by the will of Caroline S. Freeman, Weston, Mass.

Pasavant Memorial Hospital, Chicago, \$100,000, the proceeds of the Atlantic City Board Walk, the second week in December.

**Bill for Examination by Physicians of Pension Bureau.**—A bill to empower examining surgeons now employed by the Pension Bureau to make medical examinations for the War Risk Insurance Bureau and Federal Board of Vocation Education has been introduced in the House by Congressman Louis C. Crampton of Michigan. It is understood that the measure contemplates economy and the reduction of duplication of effort in performing examinations. The measure has been referred to the House Committee on Interstate and Foreign Commerce. It is H. R. 10,972.

**Sioux Valley Physicians to Meet.**—Sioux Valley Medical Association will hold its twenty-fourth semiannual session at Sioux City, Iowa, January 21 and 22, with headquarters at Hotel Martin, under the presidency of Dr. Alfred E. Spalding, Luyven, Minn. The banquet will be held on the

evening of the first day at which Col. Robert M. Culler, M. C., U. S. Army, will deliver an address on "Medical Memories of the War," and Dr. Donald Macrae, Jr., Council Bluffs, Iowa, formerly colonel, M. C., U. S. Army, will speak on "Who Won the War."

**Personal.**—George A. Lung, Captain, M. C., U. S. Navy, who has been for a long time in command of the U. S. Naval Hospital, Brooklyn, and has recently been transferred to the command of the Naval Hospital, Newport News, Va., was given a farewell dinner and theater party, December 8. After the theater, Captain Lung was the guest of a supper party at Hotel Astor.—Dr. William J. Mayo, Rochester, Minn., and Dr. Franklin H. Martin, Chicago, will leave for the Argentine Republic and other South American countries, January 7.—Dr. Robert H. Crawford, Rock Hill, S. C., has been awarded the Greek Medal of Military Merit.

**Seaboard Physicians Hold Meeting.**—The twenty-fourth annual meeting of the Seaboard Medical Association of Virginia and North Carolina was held in Norfolk, Va., December 2 to 4, under the presidency of Dr. William L. Harris, Norfolk, Elizabeth City, N. C., was selected as the next place of meeting, and the following officers were elected: president, Dr. Cyrus Thompson, Jacksonville, N. C., vice presidents, Drs. Edward C. S. Taliaferro, Norfolk, Va.; Zenas Fearing, Elizabeth City, N. C.; Thomas B. Luford, Princess Anne, Va., and Stuart M. Mann, Moyock, N. C.; secretary, Dr. Clarence Porter Jones, Newport News, Va., and treasurer, Dr. George A. Caton, Newbern, N. C.

**Deficiency Appropriation for Public Health Service.**—Both branches of Congress have passed an urgent deficiency appropriation measure which carries the sum of \$2,000,000 to be expended by the United States Public Health Service. This amount is to be expended "for medical, surgical, and hospital services and supplies for war risk insurance patients and other beneficiaries of the Public Health Service, including necessary personnel, regular and reserve commissioned officers of the Public Health Service, clerical help in the District of Columbia and elsewhere, maintenance, equipment, leases, fuel, lights, water, printing, freight, transportation, and travel, maintenance and operation of passenger motor vehicles, and reasonable burial expenses." The measure also provides for the completion of the government hospital at Broadview, Cook County, Illinois, and authorizes the Secretary of the Treasury to submit additional estimates up to \$2,500,000 for making it a "complete working hospital." The measure has gone to the President for approval.

### FOREIGN

**Honor to British Admiral.**—Surgeon Vice-Admiral Sir Robert Hill, medical director general of the Royal Navy, has been awarded, in the name of the U. S. Navy, the Distinguished Service Medal.

**Prize Offered for Cure of Foot-and-Mouth Disease.**—The *Policinco* states that the Federation of Dairies in the Cremona district has offered a prize of 100,000 lire for any means that will arrest the damage wrought by epizootic foot-and-mouth disease.

**Prize to Swedish Physiologist.**—The Swedish Medical Association has awarded its jubilee prize this year to Dr. Hans Gertz of the physiology laboratory of the Karolinska Institute for his work on the functions of the labyrinth. It was published in the *Nordisk Medicinskt Arkiv* in 1918.

**From Palace to Hospital.**—The Charlottenburg royal residence at Berlin has been transformed into a large hospital and vocational school for the wounded soldiers. Barracks have been erected in the grounds to supplement the buildings, and provide workrooms for making artificial limbs, etc.

**New Quarantine Hospital at Newchwang, China.**—A new quarantine hospital is being built at Newchwang under the auspices of the Manchurian Plague Prevention Service at a cost of 40,000 taels, the money to be drawn from the local customs. Dr. Wu Lien-teh, president of the National Medical Association of China and editor of the *National Medical Journal* of China, has been appointed to have charge of this hospital.

**Chinese Physician Goes to Johns Hopkins School of Hygiene and Public Health.**—Dr. Lim Chong Lang, M.P., B.S. (Hongkong), for the past two years senior medical officer of the Peking Central Hospital, has obtained a Rockefeller fellowship and will proceed to Johns Hopkins University to enter the School of Hygiene and Public

Habit, where he expects to work for his PH.D. (1949) to obtain a third degree.

**Chinese Students in America.**—According to the Chinese Students' directory published by the Chinese Students' Alliance of America there are 1,124 Chinese students now studying in various colleges in the United States. Of chiefly professional studies, medicine comes first with fifty-eight students; mechanical engineering is a close second, with 107—seven students; pharmacy claims eleven students, dentistry one, bacteriology three and sanitary engineering two.

**Professor Murri's Gift to Hospital.**—Prof. Augusto Murri in the chair of clinical medicine at the University of Bologna some years ago presented the children's seaside sanatorium of the district with 200,000 lire and he has recently given the sanatorium another 200,000 lire. In his gift letter he remarks that although these sums are not large they represent sixty-six years of professional work in the Bologna district, as he had no inherited fortune. The authorities have decided to call the sanatorium in future the *Allegro Maria Ospizio Marino*.

**Medical School Construction in China.** The Rockefeller Foundation has delayed work on the medical school which is to be built at Shanghai until the completion of the Peking Union Medical College. The increased cost of labor and materials has made it necessary to increase the estimated cost at Peking to \$5,000,000. Work is being pushed vigorously, the faculty at Peking college is being recruited and contributions toward the maintenance of various mission hospitals are being made. The China Medical Board has allocated \$2,141,588 in 1918, including \$1,610,000 for the land, buildings and equipment of Peking Union College and \$515,753 for scholarships.

**The Medical History of the War in Italy.**—The military authorities in Italy are compiling records and collecting data for the museum connected with the Scuola di applicazione in S. Maria militare; specimens, photographs, radiograms, projectiles extracted, plastic models of wounded regions and illustrations from wounds and freezing, prostheses, photographs of surgical stations in different zones of the country, notes and reports of medical officers and other data on war surgery, epidemiology and prophylaxis of infectious diseases, etc. All the medical officers have been asked for contributions of this kind for the museum to make it a comprehensive historical and scientific record of the world war.

**Italian Internal Medicine Society.**—The annual meeting of the Società italiana di Medicina interna was held in Trieste at Trieste. The subjects discussed were mainly the venereal diseases during the war in our knowledge of disease of the nervous system, heart and kidneys, and of typhoid, sprue, malaria, etc. The presiding officers for the coming year are Professor and Sena and E. Maragliano of Genoa, Prof. V. A. Vassallo of Rome and Prof. L. Lucatello of Padua, Director of the *Clínica di Poli. Ospedale*, with Dr. G. Gallavotti. Professor Astoli is chairman of the committee of organization for the next meeting to be held at Rome. The subjects proposed for discussion are bronchial asthma and the *typho-rheumatoidosis*.

**Anniversary Celebration of the Milan Instituto Sieroterapico.**—The anniversary of the twenty-fifth anniversary of the foundation of this well known institution at Milan was recently celebrated with much ceremony. Among the speakers who participated in this success are Prof. Giuseppe Agazzi, Milan; Nigam, and the creator professor, Alessandro Galvani of Genoa. Prof. Leo Carcano described some years ago to laboratory infection contracted in the service. The committee in charge of Professor Galvani and Giuseppe Galvani presented him with a bronze bust and a certificate of appreciation for the personnel. At the same time an all portrait of Galvani was presented. The ceremony was presided over by a message to the 300 persons present at the institution.

**Honor for Professor Pittres.**—The French government has recently conferred the title of commander of the Legion of Honor on the professor of classical medicine and dean of the Faculty of Medicine at Bordeaux, Dr. J. A. Pittres. This honor was first conferred in 1903, and his friend, professor J. A. Pittres, also with a portrait medallion. His name is well known around the world by his *opur du sang* and other works on work on malaria, on the changes in the shape of the heart from playing long in bed, on the phthisis-like form of malaria, etc. To this title is due the degree of "doctoral honor" now conferred by the university, and the founda-

tion of the museum of ethnography and colonial research. As he has reached the age limit, this is his last term as acting professor.

**Foundation of Swedish Association for Medical Research.**—On the initiative of Professors Forsner, Forssell, Holmgren and Dr. Key of Stockholm, and Professors Quensel and Petérén of Uppsala and Lund, a meeting was held recently to organize the Svenska Sällskapet for medicinsk forskning to promote scientific research in Sweden. Already 160 members are enrolled and the officers elected. They include a number of prominent laymen, directors of banks, consuls and others besides leading professors in the medical sciences. Professor Quensel in the opening address emphasized that the rapidly changing world has brought the necessity for new orientations and the blocking out of new routes, and he cited the saying, "If the human race can be perfected, it is in the medical sciences that the means for this must be sought." The aim of the new society is to provide funds for medical research, and the treasury starts with a donation of 5,000 crowns from a legacy. Full details of the organization are given in *Hygien* for October 31, p. 833.

**Status of Public Health in Hongkong.**—Although Hongkong has made wonderful strides in an economic way under the guidance of the British Empire, the same success has not been achieved in public health matters, according to the *National Medical Journal*, September, 1919. Epidemics of smallpox and bilious plague occur almost yearly. Tuberculosis reigns unchecked. There is still no hospital worthy of the name where the Chinese could see with their own eyes the great advances which modern medicine has made during the past decade. The Tung Wa Hospital is still run on primitive lines. Under so-called "native" treatment, the mortality, as shown in the medical and sanitary reports for 1918 issued by the British colony of Hongkong, was 35.9 per cent., whereas under "western" treatment, the mortality was only 17.1 per cent. It is suggested that if the Cantonese could be given the example of an efficiently managed modern hospital to which the Hongkong University could send its medical students, the prejudices of the Cantonese would disappear.

## LATIN AMERICA

**Medical Students in Chile.**—During the year of 1918 there were in the medical school of Chile 948 students, fifty-eight of whom were women. There were 233 students studying pharmacy.

**New Quarantine Station in Peru.**—There was established recently in Peru the quarantine station of San Lorenzo at which first and second class passengers will be isolated when suspected of having diseases that may threaten the public health.

**Railroad Hospitals in Mexico.**—The railroad medical department of Mexico has at present seventeen railroad hospitals located at strategic points and provided with the necessary equipment. During the year September, 1918, to August, 1919, there were treated 2,217 hospital patients and 4,983 outpatients.

**Memorial to Dr. Hernandez.**—As a memorial to Dr. José Gregorio Hernandez, a prominent physician who died recently at Caracas, Venezuela, the Students' Scientific Center has just created for indigent patients a clinic which will be named after him and will be connected with the society Amparo Infantil.

**Monument to Dr. Finlay.**—Among recent appropriations made in Cuba there is one providing \$225,000 to remodel the Hospital Las Américas of Havana and erect a monument to Dr. Carlo Finlay at the entrance of the hospital. Other appropriation provided \$380,000 for three years in succession for sanitary improvements in the city of Guantanamo; \$8,000 to drain the lands that surround the town of Camanera, \$125,000 for the construction of the national university of a building for the school of pharmacy, and in building a department devoted to teaching the manufacture of serum and vaccines; and \$24,000 and \$60,000 for the construction of hospitals in the cities of Nuevitas and Havana respectively.

## CORRECTION

**"Differential Diagnosis of Hyperthyroidism."**—In the abstract of Dr. G. W. McCaskey's article on this subject which appeared in *THE JOURNAL*, Dec. 13, 1919, p. 1855, the line next to the last should read "below 140 mg. of sugar in 100 cc. of blood," etc., instead of 1,000 cc.

## Government Services

### Personnel of the Medical Department

For the week ending December 19, there were on duty in the medical department 2,212 medical officers, including 1 major-general, 2 brigadier-generals, 163 colonels, 162 lieutenant-colonels, 528 majors, 836 captains and 520 first lieutenants. The medical reserve corps contained 4,183 officers, an increase of 74 from the previous week, which included 2 brigadier-generals, 74 colonels, 254 lieutenant-colonels, 1,125 majors, 1,753 captains and 890 first lieutenants.

### MEDICAL OFFICERS, U. S. NAVY, RELIEVED FROM ACTIVE DUTY

ARKANSAS	MISSISSIPPI
Nashville—Nelson, C. H.	Raymond—Hagaman, F. H.

### Report of the Surgeon-General, U. S. Navy

The annual report of the Surgeon-General of the Navy for the fiscal year 1919 reveals the efficiency which has always been characteristic of the Navy. The report includes health statistics up to the close of the calendar year 1918, and operations of the Medical Department of the Navy to June 30, 1919, practically completing the record for war work, except as regards the return of the Army sick and wounded from abroad, and the efforts for the reeducation and rehabilitation of the disabled of the Navy and Marine corps.

The main concern of the Bureau of Medicine and Surgery has continued to be the health of the Navy and of the millions of soldiers committed to its care on the Atlantic in home and foreign waters.

The transportation of Army troops to and from Europe by the Navy and the return of the sick and wounded stand out among the most brilliant achievements of the war. This work was conducted by vessels constituting an integral part of the Navy, the cruiser and transport service and the Army transport service. The number of sick and wounded to be returned was far too great to be carried by the naval hospital ships, and therefore an arrangement developed by which Navy transports on the westward passage would serve to the limit of capacity for the return of Army sick and wounded, and this plan was worked out with great credit to the service. Before the armistice was signed, about 100 Army patients were returned home on each return voyage, as this was all that could be evacuated quickly and safely in case of accident. After the removal of the submarine menace, about 650 patients were carried on each voyage, and this required new organization and an increase in the hospital corps complement. During the fiscal year 1919, seventy-six hospital corps men were received and given instruction in laboratory work before assignment to duty.

The transportation of sick and wounded after the signing of the armistice necessitated an increase in the transport service from thirty-eight to 129 vessels. Many of these ships were provided with adequate sick bays for healthy troops, but not infrequently sick and wounded were sent on board each vessel a medical department adequate to meet exceptional demand, and for this purpose there was a commissioned medical personnel of more than 500 men. Between Nov. 11, 1918, and June 30, 1919, 1,235,933 troops had been returned by this service from Europe, and of this number 11,522 were classified as sick or wounded.

July 1, 1919, the total of the Medical Corps on active duty numbered 592 officers of the reserve forces, 865 officers of the permanent medical corps, 315 officers holding temporary appointments, and eighty-two former pharmacists commissioned as assistant surgeons. At present there are 301 vacancies in the Medical Corps of the regular establishment. As 104 resignations have been received up to date from officers holding permanent commissions, the size of the vacancy list is giving the bureau considerable concern. It is recom-

mended that Congress provide means whereby officers holding temporary appointments in the Officers Reserve Corps may enter the permanent corps, and that in view of this fact the present statutory age limit be waived and one of 40 years substituted. This will insure to the government twenty-four years of prospective service before retirement on account of age would become operative.

Much thought has been devoted to the provision of an educational program in the specialties for officers of the regular establishment, and it is suggested that a course be mapped out at the United States Naval Medical School which will extend for a period of about three months, during which each officer will be carefully observed to determine his special fitness. It would then be desirable to arrange special courses in one of the larger medical centers. After such courses, these young officers would be available for assignment as specialists in the naval hospitals, in addition to their duties as general medical officers.

The assignment of female nurses to ships, a practice that was inaugurated during the war, has proved satisfactory; and the character of the professional work, the manner and bearing and general adaptability of the nurses have been most favorable, and the influence has been good. The interests and efficiency of the nurses assigned to the Philippine Islands, Guam, Samoa and Haiti in the developing training schools in their own work, and also the development of training schools for native women, is most praiseworthy.

Many hospital men served independently of medical officers on transport service ships, destroyers and other vessels, and acquitted themselves most creditably. For the training of hospital corps men the medical department maintains one training school at Newport, R. I., one at Great Lakes, Ill., and one at San Francisco, with a capacity of 300 each, and an advanced hospital corps school also with a capacity of 300 at the United States Naval Operating Base, Hampton Roads, Va. The difficulty of maintaining a sufficient proportion of hospital corps men is emphasized. If the Navy is recruited to its allotted strength of 191,000 men, or 218,400 including the Marine Corps and Hospital Corps, at least 7,500 men will be required. Since January, 1919, there have been only 493 reenlistments, and of these 400 are eligible for release; and during the same period more than 8,000 men have been discharged.

Casualties in the Medical Department on duty with the Marine Corps include one commissioned officer and twelve enlisted men killed, eight commissioned officers and 101 enlisted men wounded or gassed, and one enlisted man taken prisoner.

The medical personnel of the Naval Aviation Forces in Europe consisted of seventy-two medical officers, fifteen dental officers, four pharmacists and 264 enlisted men, and their commander reports most favorably on the professional ability and devotion to duty of these men.

The most general complaint of officers and men on duty on submarines was with reference to the ear, with the syndrome of middle-ear catarrh. A number of cases of eye strain prevailed toward the end of the series of patrols. These were believed to have resulted chiefly from excessive use of the eye, defective lighting, refractive errors, and glare. The majority of the personnel were constipated during the patrol; it was not practicable during the patrol to provide facilities for men to get into open air on deck. Gradual deterioration of officers and men developed as patrols proceeded. This, in general, was not of a serious nature, and in the great majority of cases complete recovery followed.

June 30, 1919, there remained a total of 14,891 available beds under Navy control in hospitals on this continent. During the year the hospitals abroad at Leith, Queenstown, Strathpeffer, London, Gibraltar, Genoa, Lorient, Cardeth, Pauillac, Plymouth and Corfu, and one hospital at Brest, were discontinued.

During the year there were twelve commissioned officers and forty-five enlisted men cited for the Distinguished Service Cross, seven commissioned officers and sixteen enlisted men cited for the Croix de Guerre; sixteen commissioned officers and sixty-three enlisted men were awarded the Croix de Guerre, thirteen commissioned officers and twenty-nine enlisted men were awarded the Distinguished Service Cross, eleven commissioned officers and twenty-two enlisted men were recommended for the Distinguished Service Cross, ten commissioned officers and thirty-three enlisted men were recommended for the Croix de Guerre, one commissioned officer was cited for the Medaille Militaire, and eleven commissioned officers and twenty-four enlisted men were mentioned in general orders.

There were 9,507 deaths in the Navy during 1918. Of these, 5,388 were due to disease, 1,158 to accident and injuries, and 2,961 to casualties in action. The death rate for all causes was 18.47 per thousand, and for disease only 11.78 per thousand. Of the 5,938 deaths from disease, 5,027 were due to pneumonia in one form or another. Influenza and pneumonia were responsible for 1,158 of these deaths. Could pneumonia have been eliminated this year, the death rate of the Navy from disease would have been only 1.80 per thousand. The value of the report is much enhanced by numerous illustrative plans and graphic charts.

The problems of demobilization are considered at length. It is believed that this is the time to make a careful study and tabulation of findings in regard to demobilization, so that the essential facts may be on record for use should the contingency of war again confront the country. Plans for demobilization should be incorporated with the legislation enacted at the time of expansion to a war footing, and should be deliberately calculated in advance so as fully to serve the best interests of the nation. The medical and hospital corps must be the last to demobilize after the war.

The Surgeon-General pays an eloquent tribute to the patriotism of the men who left their civilian employment and professions to enter the Naval Medical Reserve Forces.

### The Medical Strike of Jerez de la Frontera

The town of Jerez de la Frontera, which has just witnessed the first general strike of physicians. This strike originated because the municipal authorities, disregarding all statutory provisions and trusting to political influence, failed to keep their pledges, and the salaries due the employees finally amounted to 1,000,000 pesetas (about \$200,000). When the physicians became tired of seeing that, in this period of extraordinary compensation for labor, they were the only ones who could not bring home the wages they had earned, they unanimously decided to go out on strike. The mayor and the members of the town council were very indignant at this time, their arguments running somewhat as follows: "It is very strange that the physicians should be so rebellious, and especially now, when the town council has just spent several thousand dollars for celebrations and bull fights, thus doing our desire to please the people and attract foreigners. The physicians do not bear in mind the fact that we cannot pay their salaries, since to do so would be to show partiality in their favor; in a place where no one is paid, it is an indignity to ask for money. If we have spent so much for celebrations, it has been only because the bull fighters and the crowd would not have come otherwise; but every one understands that if we could have got out of paying them, we would not have paid them either." These reasons did not convince the physicians who suspended all official relations with the municipal authorities, and who, while continuing to do their share of the work, refused to submit any reports, would not accept of any certificates, or attend the municipal disbursements, and let public opinion and the government decide the matter. At first the local authorities threatened the physicians, but when this failed was Dr. Aranda, one of the most prominent surgeons of Andalusia. The physicians proved themselves equal to all this, and the pressure that was brought to bear on them for over a month. At last the government decided to force the law, it dismissed the municipal council and appointed new members to assist in solving the situation. The result was that the physician will immediately receive the wages of the amount due them, and the balance of the strike. This is the first medical strike that ever occurred in Spain. It has received support not only in the town of Jerez, but also at the hands of the government.

### Medical Syndication

The labor movement has come to be one of the most important subjects to be the subject of the medical profession in this country. This subject has been the object of much discussion in all parts of Spain, and especially in Madrid. Many articles and speeches have been delivered both for and against the creation of a syndicate of physicians. The syndicate would naturally have for its model the working

men's syndicates, which are responsible for the social revolution which is stirring in Barcelona at present.

In the Colegio Médico (medical guild) several meetings have been held to discuss the subject of syndication, and a program has been prepared. When a syndicate of physicians was first proposed, 500 Madrid physicians endorsed the idea; but after seeing the program, up to November 18, only sixty-seven had signed. It seems that Section 6 of the first article is the part to which many physicians object. It is here provided that the physicians can join the workmen to achieve some of their ends.

Dr. Medinaveitia, the gastro-enterologist, and considered one of the most advanced leaders of Spanish anarchism, delivered a lecture a few days ago. After making many radical statements, he attacked medical syndicalism and medical strikes. It is his opinion that physicians should not shirk their duties. In the same place, another physician, the laryngologist, Dr. Hinojar, attacked Dr. Medinaveitia's statements, and advised medical syndicalism.

Dr. Lafora, a neurologist, has published in one of the newspapers an article in favor of medical syndicalism, saying that the time had come for the physician to consider himself just a laborer.

Professor Pittaluga and Dr. Juarros have also delivered speeches favoring syndicalism. The journal *La Medicina Libre* is advocating it, while the dean of the medical press, *El Siglo Médico*, is against it.

### The Medical Meeting at Malaga

A meeting of Andalusian physicians was recently held at Malaga. Physicians from other provinces, including Madrid, also attended. The most characteristic note of the meeting was the protest against politicians and the government. This is explained by the fact that the physicians are losing all hope of improvement, seeing that cabinets succeed each other, and still the municipal physicians are left at the mercy of local authorities without receiving the protection to which they believe themselves entitled. The medical classes now think they have found a remedy for this condition, i. e., in the payment of their salaries by the national government. Lately, however, a new political element in favor of political autonomy is attacking this measure. It is a fact that Spanish physicians have not taken part in politics as physicians but as individuals belonging to different parties. Although they have tried to improve national sanitation so far as they had the power to do so, they have always been handicapped by the indifference and ignorance which the politicians display toward sanitary matters.

### Death of Dr. Rodriguez Méndez

Dr. Rodriguez Méndez, former president of the University of Barcelona, and professor of hygiene of the Barcelona School of Medicine, died shortly after receiving news of his retirement because of having reached the retirement age. He was in perfect health before his death, and it is asserted that his death was due to grief over his enforced withdrawal from public life. Dr. Rodriguez Méndez was a scientist whose career was marked by enthusiasm for medical teaching, love for humanity, and healthy patriotism. The bitter struggles that have convulsed Barcelona could not alter his devotion to Spain, or his love for the city of Barcelona, where he fought epidemics and assisted all sanitary improvements with such eagerness and tireless activity that he had no enemies and was admired by all for his achievements.

### The Parliamentary Elections and Social Hygiene

In the numerous political platforms that have seen the light of day in connection with the election campaign preceding the parliamentary elections, questions pertaining to social hygiene have not occupied, it must be confessed, a very conspicuous place. However, I wish to call attention to a manifesto which emphasized the necessity of improving French birth records both quantitatively and qualitatively and of protecting large-sized families. At the head of the list of candidates who signed this manifesto stood the name of Dr. Pinard, former professor of clinical obstetrics on the Paris Faculty of Medicine. Pinard has been one of the well known promoters of the child welfare movement in France.

The Ligue nationale contre l'alcoolisme, of which Protes or Deloche, former dean of the Paris Faculty of Medicine, is president, has sent to the various political parties the following declaration:

## TO THE FRENCH PEOPLE

France, though victorious, is almost exhausted. There rests, therefore, on us the paramount necessity of recuperating our strength. Our industries that have been destroyed by the invader must be built up again. Our domestic and foreign commercial relations, which are the source of our normal economic life, must be reestablished. By means of industry and thrift our exhausted stocks of merchandise must be replenished. And, what is still more important, we must regain our vital equilibrium after the terrible bleeding to which we have been subjected.

But there can be no industry; there can be no commerce; there can be no toil; there can be no thrift; there can be no health, so long as alcohol shall remain the master of France, ruming production, paralyzing trade, diverting labor from its proper channels, devouring the savings of the people, and generating disease, folly and crime. We are now facing a different kind of a struggle—an enemy so implacable that the British prime minister has publicly announced that a world crisis has been reached which is even more threatening than that imposed by the Germans.

Vote! The nations round about us, neutrals as well as allies, though not so deeply affected as ourselves, have comprehended the danger. Norway, Sweden and Belgium have imposed on themselves severe restrictions. The United States has prohibited all intoxicating beverages.

Is France alone incapable of renouncing its appetizers and its liquors?

Demand of your candidates that they shall take a definite stand as advocates of the immediate prohibition of beverage alcohol or at least declare themselves disposed to prepare the way for such prohibition by voting for: (1) the radical suppression of the privilege of private stills; (2) a marked reduction in the number of places licensed to dispense intoxicating beverages; (3) an increase of the tax on beverage alcohol with a corresponding reduction of the duties on alcohol used in the industries; and (4) denial of wine merchants of a license to conduct a tobacco store in connection with a wine shop.

Refuse to vote for those who give you a negative or evasive answer. Voters: remember that if France does not suppress alcohol, alcohol will suppress France.

## Antituberculosis Propaganda

The various representatives of the societies in the United States, Great Britain and France that are concerned with the world-wide antituberculosis campaign held a meeting here recently under the chairmanship of M. Léon Bourgeois, president of the Comité national de défense contre la tuberculose. It was decided that a conference should be held in Paris next year in October for the purpose of drawing up the constitution of an association to be composed of the delegates of the national antituberculosis societies of the different countries that constitute the league of nations.

## A Resolution of the Surgical Congress

The Congrès de chirurgie, at the instance of its president, Dr. Walther, has unanimously adopted the following resolution:

WHEREAS, The Congrès français de chirurgie is fully aware that: (1) the indigent sick in hospitals (formations hospitalières) are entitled to receive such care as will secure to them all the physical guarantees of safety that compare with present medical standards; and (2) a large number of surgical services are still inadequately equipped and lack the indispensable equipment for the examination and treatment of the sick—often even the necessary apparatus for the sterilization of instruments, etc.; therefore, be it

Resolved, That in all these hospitals (formations hospitalières) the surgical services shall be provided with: (1) such equipment as will absolutely guarantee the sterilization of instruments, water and all forms of dressings; (2) a complete roentgenographic outfit, including the instruments of fluoroscopy; and (3) a laboratory suitably equipped to perform histologic and chemical examinations and to carry out bacteriologic researches such as become constantly necessary in the course of the examination and treatment of patients.

## A Move to Protect Pedestrians Against Mud-Splashing Autos

M. Georges Lemarchand, in a letter to the chief of police, has pointed out the advantages that would accrue if an order could be issued requiring all automobiles, and especially motor trucks, to be fitted with fenders similar to those used on the autobuses of the Compagnie générale des omnibus. On account of the bad condition of the streets owing to their being neglected during the war, M. Lemarchand thinks that pedestrians ought to be protected against mud splashes, which not only damage clothing, so expensive at this time, but also constitute a menace from the hygienic standpoint.

## The Attendance at Swiss Universities During the War

According to the Economiste français, in the school year 1913-1914 there were 8,110 students matriculated at the Swiss universities, 6,775 of whom were men and 1,335 women. In 1918-1919 the total had fallen to 7,307, a reduction of 10 per cent., but there has been a still greater change in the relative representation of the sexes; 6,430 men against 877 women. The number of men was reduced only

5 per cent., while the number of women had decreased 34 per cent.

A study of the proportion of different nationalities develops some interesting facts. In 1913-1914 there were 3,925 Swiss in attendance as compared with 4,185 foreigners. In 1918-1919 the figures had become 5,328 and 1,979, respectively, which was an increase of 36 per cent. in the Swiss representation and a decrease of 56 per cent. in the number of foreigners. The great decrease in the foreign representation was brought about chiefly by the Russians, the number of whom (Poles are included) fell from over 2,000 to 480. The Hungarians decreased from 527 to 78, and the Germans from 528 to 320.

Swiss universities, in recent years, have been unusually well attended. Before the war they had 21.3 students (including those who had merely visiting privileges) per 10,000 inhabitants; France had only 11.6; Austria, 9.4; Germany, 9.2, and Italy, 6.8.

## Personal

At one of its recent meetings the Academy of Medicine elected three foreign correspondents: Professor Banti of Florence, Dr. Van Ermengem of Ghent, and Dr. Pawinski of War-saw.

## LONDON

Nov. 26, 1919.

## Refutation of Lombroso's Theories in Official Work on Criminology

The most important work on criminology that has appeared in this country, or indeed in any country, has just been issued by the government. In 1901 Dr. Griffiths, deputy medical officer of Parkhurst prison, formed the idea of subjecting a large number of prisoners convicted of certain similar offense to measurements to ascertain whether they showed any deviation from what might be regarded as the normal, or noncriminal type. The suggestion commended itself to his superiors, who recommended that the observations should be extended to the general body of convicts, so that the existing theories of criminology, particularly those of Lombroso, might be tested. In conjunction with the medical officers of the chief convict prisons, a scheme was drawn up and the data were tabulated by the late Dr. Charles Goring, deputy medical officer of the prison service. In order that they might be subjected to study by modern statistical methods, the aid of Prof. Karl Pearson, director of the biometric laboratory at University College, was obtained, and Dr. Goring was detached from duty to work under him. The main conclusions are as follows:

The criminal type marked by physical and mental stigmata as described by Lombroso, does not exist. As individuals criminals possess no characteristics, physical or mental, which are not shared by all people. Criminality is not a morbid state akin to physical disease which can be diagnosed and established by pure observation. On the other hand, the "criminal" man is to a large extent a "defective" man, physically and mentally, and this "defectiveness," like many other human qualities, is determined more by nature than by nurture. A "criminal diathesis," a composite of mental and physical defectiveness, is recognized. Like other constitutional characters, it is subject to heredity. The influence of parental "contagion" is inconsiderable in comparison with the influence of heredity and mental defectiveness, which are the most important factors in the production of crime.

Dr. Goring's work illustrates the unreliability of conclusions drawn from rough observations. Three hundred criminals classified into three grades of intelligence were observed to discover if there were any appreciable association between height of forehead and intellectual capacity. Their foreheads were classified as low, medium or high. Of the intelligent group, 20.5 per cent. had low foreheads and 20.5 per cent. high foreheads, of the unintelligent group, 35.7 per cent. had low and 8.3 per cent. high foreheads, and the weak-minded group the corresponding figures were 50 and 8 per cent. The conclusion seemed to be that brain development was associated with intelligence. Two years later, however, the same 300 criminals were included in a group of 800 criminals whose head contours were measured, and a series of precise measurements of the head and heights were thus obtained. The verdict of the new method was different. There was little, if any, appreciable relationship between height of forehead and intelligence.

No evidence was obtained of the existence of a particular criminal type such as described by Lombroso and his followers. But English criminals are markedly below the general population in stature and body weight. They contribute of violence to the population about equal to an average

source of strength and of constitutional soundness considerably above the average of the other criminals and of the law-abiding class. Thieves, burglars and incendiaries, who constitute 90 per cent. of all criminals, are inferior in stature and weight, and are puny in their general bodily habit in comparison with other criminals and with the law-abiding population. These are the sole facts on which the theories of criminal anthropology rest.

First convictions show a predilection for the age period from 15 to 25, which Dr. Goring concludes to be significant. Comparing this fact with the age incidences of liability to various diseases, he is inclined to interpret the facts as evidence that a mental constitutional proclivity is the primal source of the habitual criminal's career. "Alcoholism, epilepsy, sexual proclivity, and insanity in their relation to crime are accidental associations depending on a high degree of relation between defective intelligence and crime. It cannot be assumed from the evidence that defective intelligence is correlated with the defective physique. English criminals appear to be selected from the noncriminal population by two independent factors: a mental constitution and a physical constitution, each, however, differing from that of the general population in degree and not in kind. Moreover, elaborate examination of the data shows that crime, at least in this country, is due only in a trifling extent (if in any) to social inequality, adverse environment, or other man-festations of what may be comprehensively termed the "forces of circumstances."

#### The Prevention of Venereal Disease

The prevention of venereal disease continues to be the burning question in the lay press. The National Council for the Eradication of Venereal Disease has published a letter to the *Limes* stating that it is as firmly opposed as ever to any general distribution of prophylactic packets to the civil community. The council holds that the prevention of venereal diseases is a large sociomedical problem. In the first line of attack, ample facilities for treatment and instruction of the public occupy the first place. Concerning personal disinfection after risk is taken, the council has always acknowledged the value of cleansing and disinfecting material applied early and thoroughly in diminishing the risk of disease. Abstention from exposure to infection is the only certain safeguard against the ordinary risk of the diseases. Continence is to be encouraged by every means. No person who has indulged in promiscuous sexual intercourse can be certain that he is not infected. He or she should therefore seek means of cleansing at the earliest possible moment. For this purpose a thorough application of soap and water is of great value, followed, if possible, by the use of mild disinfectants as may be recommended by a physician. While such applications sensibly reduce the risk of infection within four hours of exposure, they afford no absolute security. In the case of women, satisfactory self-disinfection is practically impossible; medical attention at the earliest possible moment is necessary.

#### Drunkenness as a Defense in Trial for Murder

A trial for murder has been quashed under peculiar circumstances in the west of appeal. A man was convicted of manslaughter for strangling a girl of 13 while violating her. The defense was that the man was so drunk when he committed the crime that the jury should find a verdict of manslaughter. During a discussion of the law, the judge said that if a man is strangling a woman and he defends himself and then she sees something which kills her, to prevent her from strangling or struggling, he commits manslaughter. The defense of drunkenness could prevail only if it was proved that the accused did not know what he was doing and that fatal violence done in furtherance of a criminal intent was an unintended murder. As to manslaughter, the judge said that the crime of murder to manslaughter, the crime of manslaughter, for this to succeed the accused must be proved to be affected by drink that he was incapable of knowing that what he was doing was fatal violence. In the direction of the judge in the present case was less favorable to the accused. He had applied the law applicable to cases in which the defense was insanity. Had he applied the proper test it was impossible for the court to say what the verdict would have been. The court therefore concluded that the verdict must be reduced to manslaughter. The crime was of the gravest character, and the sentence would be of the severest kind—penal servitude for twenty years.

## Marriages

FRANCIS EDWARD THIBAUEN, Marshfield, Wis., to Miss Gertrude Breitlow of Winona, Minn., November 28.

EDWARD NEWMAN PACKARD, Saranac Lake, N. Y., to Miss Mary Bissell Lettis of New York City, November 27.

ARTHUR GIBSON KELLEY, Greenville, S. C., to Miss Louise Dolbs of Inman Park, Atlanta, Ga., November 18.

CLARENCE HENRY BOREN to Miss Gertrude Elizabeth Mueller, both of Marinette, Wis., November 22.

FREDERICK WALTER MASON, Great Neck, L. I., N. Y., to Miss Edith Bowron of Flushing, L. I., recently.

JOHN HUGHES DUNNINGTON to Miss Genevieve R. Parker, both of New York City, November 26.

ALBERT E. CAMPBELL, Springfield, Ill., to Miss Carrie Roberts of Decatur, Ill., November 26.

ROY J. HOLMES, Wadley, Ga., to Miss Esther Smith of Bartow, Ga., at Wadley, November 12.

BENJAMIN APPELEGATE FURMAN to Miss Helen Pryor, both of Newark, N. J., September 27.

WALTER JAMES SULLIVAN to Miss Katherine Agnes Keith, both of Chicago, November 29.

LUMIR ROBERT SAFARIK to Miss Madge Dunnell, both of New York City, October 18.

JOHN DANNA THOMSON to Miss Ruth Arnold, both of Atlanta, Ga., November 15.

JAMES LEONIDAS KING, Macon, Ga., to Miss Grace O. Ide of Baltimore, November 26.

RAYMOND FRANCIS WIVELL to Miss Anna Conley, both of Pittsburgh, November 27.

ROBERT ELLIS WEAVER to Miss Ruby Scott, both of Hope, Ark., November 22.

WILLIAM JOHN SCHOLDS to Miss Myrtle Bonnet, both of Chicago, recently.

## Deaths

Robert B. Wilson, Montreal; McGill University, Montreal, 1893; aged 53; for many years superintendent of the Western Hospital, Montreal; a pioneer in roentgenology and electrotherapy; lieutenant-colonel, C. A. M. C.; who went overseas with the first Canadian contingent and was attached to Canadian General Hospital No. 1 in France, later to Granville Canadian Special Hospital, Ramsgate, England, from there was called to London and given charge of roentgen-ray work, and equipment of all Canadian hospitals overseas; consultant in electric and hydrotherapeutic treatment in Canada, and responsible for this equipment in all Canadian hospitals in the Dominion, with headquarters in Toronto; died in St. Andrew's Military Hospital, Toronto, November 1.

Robert Lee Randolph \* Baltimore; University of Maryland, Baltimore, 1894; aged 59; attending surgeon to the Presbyterian Eye and Ear Hospital; ophthalmic and aural surgeon in chief to the Baltimore and Ohio Railroad; chief surgeon to the Chesapeake Steamship Company; associate professor of clinical ophthalmology and otology in Johns Hopkins Medical School, Baltimore; winner of the Alverenga prize of the College of Physicians of Philadelphia in 1901; and the Boylston prize of Harvard University in 1902; died, December 9.

Robert John Sloan, Shanghai, China; University of Michigan, Ann Arbor, 1863; aged 81; assistant surgeon of the Thirtieth Missouri Volunteer Infantry, and later promoted to major and surgeon, during the Civil War; who went to Japan in 1869, and since 1877 had been located in Shanghai, China; died, June 5, from dyspepsia.

John Milton Tate, Fulton, Mo.; Bellevue Hospital Medical College, 1865; aged 77; representative from Calloway County in the legislature in 1893 and 1895; a director of the Calloway Bank, Fulton, and later of the Williamsburg Bank; died at his farm home, December 2, from cerebral hemorrhage.

Louis J. Goux \* Detroit; Detroit College of Medicine and Surgery, 1894; aged 48; a member of the American

\* Indicate "Fellow" of the American Medical Association.

Academy of Ophthalmology and Oto-Laryngology; ophthalmologist and otologist to the Eastern Michigan State Hospital, Pontiac and Grace Hospital, Detroit; died, December 1.

**Charles Arthur Vanderveer**, Phoenix, Ariz.; College of Physicians and Surgeons in the City of New York, 1840; aged 72; formerly a practitioner of Long Branch, N. J.; and then a member of the staff of the Baltimore Sun; secretary of the Phoenix Board of Trade; died, December 8.

**William Thomas Williams** \* Mount Carmel, Pa.; University of the City of New York, 1875; aged 65; local surgeon of the Pennsylvania and Lehigh Valley systems; for twelve years head of the state department of health clinic at Mount Carmel; died, December 4, from pleuropneumonia.

**Dwight Birdsill Hunt**, Otego, N. Y.; New York Homeopathic Medical College, New York City, 1873; aged 73; for many years a member and dean of the faculty of his alma mater; a member of the staff of the Homeopathic Hospital, New York City; died, December 6.

**Colon Junius Spence** \* Milford, Ohio; Miami Medical College, Cincinnati, 1883; aged 61; president of the Claremont County board of education for ten years; for several years a member of the surgical staff of the Jewish Hospital, Cincinnati; died, December 3.

**William Pinkney McKee**, Washington, D. C.; George Washington University, Washington, D. C., 1903; aged 43; a member of the Medical Society of the District of Columbia, and a specialist in ophthalmology; died, November 30, from multiple sclerosis.

**George Edwin Adams**, Worcester, Mass.; Harvard University Medical School, 1880; aged 62; a member of the Massachusetts Medical Society; died suddenly from heart disease, November 29, while making a professional call.

**William Wymond Walkem**, Vancouver, B. C.; Queens University, Kingston, Ont., 1873; aged 69; in 1894 a member of the provincial legislature from the district of South Nanaimo; died, September 29.

**Charles Franklin Updike, Capt., M. R. C., U. S. Army**, Browntown, Va.; University of Maryland, Baltimore, 1889; aged 55; a member of the Medical Society of Virginia; died, October 14, from diabetes.

**Albert Carlton Baxter** \* Oswego, N. Y.; Albany (N. Y.) Medical College, 1896; aged 45; health officer of Oswego County; consulting physician to the Oswego Hospital; died, about December 1.

**John Ellis Rodley**, Chico, Calif.; Missouri Medical College, St. Louis, 1881; aged 67; for four years local surgeon of the Missouri Pacific System at St. Louis; died in Napa, Calif., December 2.

**Joseph John Cronin**, Boston; Jefferson Medical College, 1885; died in the Peter Bent Brigham Hospital, Boston, November 30, from septicemia, due to an infected wound of the hand.

**James Casey**, Chicago; Northwestern University Medical School, Chicago, 1902; aged 68; a member of the Illinois State Medical Society; died, December 10, from chronic nephritis.

**Thomas B. Hayward**, Baltimore (license, Maryland State Board of Medical Examiners); aged 83; a practitioner for nearly half a century; died, December 9, from senile debility.

**Thomas McFadden**, Syracuse, N. Y. (license, N. Y., 1878); aged 81; for many years a practitioner of Appleton, N. Y.; died at the home of his daughter in Syracuse, December 4.

**Vernon Clayton Goodrich** \* Barre, Vt.; University of Vermont, Burlington, 1873; aged 73; postmaster of Brookfield, Vt., for four years; died, November 29, from pneumonia.

**Christopher A. Frame**, Roxboro, Philadelphia; Penn Medical University, Philadelphia, 1876; aged 73; a veteran of the Civil War; died, December 12, from heart disease.

**John D. Muters**, Ashland, Ky.; Starling Medical College, Columbus, Ohio, 1892; aged 66; a member of the Kentucky State Medical Association; died, about December 1.

**Thomas G. G. Ritchie**, Cochran, Alta.; E.R.C.S. (Edin.); 1872; who was seriously injured in a motor accident near Banff, Alta.; died in a hospital at Calgary, October 5.

**Harry Cook**, Urbana, Ohio; Chicago Homeopathic Medical College, 1894; aged 49; died in Grant Hospital, Columbus, Ohio, December 1, from organic heart disease.

**Edmund G. Shower**, Baltimore; Hahnemann Medical College, Philadelphia, 1878; aged 73; died suddenly, December 10, from neuritis, complicated by heart disease.

**Millard F. Pritchard**, Cherokee, Iowa (license, years of practice, Iowa, 1886); aged 67; a practitioner since 1874; died, November 22, from pernicious anemia.

**William R. Smith**, Pinckard, Ala.; Memphis (Tenn.) Hospital Medical College, 1886; aged 50; died in a hospital in Dothan, Ala., November 24, from dropsy.

**J. Bruce Hess**, Benton, Pa.; Jefferson Medical College, 1892; aged 58; died in the George F. Geisinger Memorial Hospital, Danville, Pa., November 28.

**Edward S. Navaun**, Detroit (license, Michigan, seven years of practice, 1900); aged 60; a practitioner since 1872 also a druggist; died, November 27.

**August A. Guglieri**, Madrona, Calif.; California Eclectic Medical College, Los Angeles, 1901; aged 60; formerly of San Francisco; died, November 30.

**Charles Schomburg Elliott**, Toronto; Harvard University Medical School, 1860; aged 80; a specialist on nervous and mental diseases; died, October 24.

**Jessie M. Green Estes**, Chicago; Saginaw Valley Medical College, Saginaw, Mich., 1902; aged 50; died, November 28, from an overdose of chloroform.

**William Charles Rutledge**, Denison, Texas; Hospital College of Medicine, Louisville, Ky., 1898; aged 58; died, November 8, from tuberculosis.

**Henry John Charles Sprehn**, Reno, Nev.; California Eclectic Medical College, Los Angeles, 1913; aged 42; died in Oroville, Calif., November 13.

**Albert Riley Cain** \* Cambridge, Ohio; Columbus (Ohio) Medical College, 1892; aged 69; died, November 30, from cerebral hemorrhage.

**William R. Eareckson** \* Elkridge, Md.; University of Maryland, Baltimore, 1890; aged 52; died, December 10, from cerebral hemorrhage.

**Alfred Raymond** \* Seattle; McGill University, Montreal, 1886; aged 59; died in Rochester, Minn., December 3, after a surgical operation.

**May E. Traece Callender**, Middletown, Conn.; New York Medical College and Hospital for Women, 1865; aged 83; died, November 1.

**Romanus M. Smith**, Manzanola, Colo.; University of Louisville, Ky., 1885; aged 65; died in Long Beach, Calif., November 24.

**James T. Sweetman**, Ballston Spar, N. Y.; University of Georgetown, Washington, D. C., 1872; aged 85; died, October 21.

**Anthony I. Hoon** \* Mercer, Pa.; University of the City of New York, 1881; aged 63; died, December 6, from heart disease.

**Charles Wesley Pillsbury** \* Saco, Me.; Dartmouth Medical School, Hanover, N. H., 1881; aged 68; died, December 3.

**Edwin H. Sims**, Columbus Ga.; Atlanta (Ga.) Medical College, 1883; aged 57; died, November 28, from heart disease.

**John W. Seatt**, Jamestown, N. Y.; Cleveland University of Medicine and Surgery, 1866; aged 80; died, November 5.

**Elbridge Simpson Pixley**, Pittsfield, Mass.; Eclectic Medical College, Philadelphia, 1878; aged 87; died, October 12.

**William Henry Mays**, Newman, Calif.; University of California, San Francisco, 1873; aged 73; died, November 30.

**George M. Overstreet**, Sylvania, Ga.; University of Virginia, Charlottesville, 1892; aged 81; died, December 1.

**William Caswell Maples** \* Sealsboro, Ala.; University of Nashville, Tenn., 1881; aged 61; died, November 24.

**Alois F. Juetner**, Cincinnati; Cincinnati College of Medicine and Surgery, 1910; aged 67; died, November 27.

**Martha Hays Pollock**, Huntington, Pa.; Boston University School of Medicine, 1833; aged 74; died, December 2.

**William A. Marner**, Miles, Iowa; State University of Iowa, Iowa City, 1885; aged 61; died, December 10.

**George H. Miller**, McDonald, Pa.; Miami Medical College, Cincinnati, 1873; aged 73; died, November 30.

**Charles S. Wight**, Marlboro, Mass.; University of Nashville, Tenn., 1880; aged 63; died, December 3.

**Bennett G. Willis**, Omaha; John A. Croston College, Omaha, 1906; aged 38; died, November 26.

**Milo Leonard Kensington**, Chicago; University of Illinois, Chicago, 1891; aged 72; died, December 4.

**William J. Humphrey** \* Union City, Pa.; University of Buffalo, 1890; aged 59; died, October 19.

## Correspondence

### "DEFECTS IN THE TEACHING OF PATHOLOGY, AND THE LAY PROFESSOR"

To the Editor—I have been both interested and instructed by the communications of Dr. Douglas Symmers (THE JOURNAL, Sept. 20, 1919) and of Dr. Francis Carter Wood (Dec. 6, 1919) relative to the regrettable falling off in the percentage of necropsies performed in our representative hospitals. As the resident medical officer of the Philadelphia General Hospital (Blockley), this fact has caused me considerable concern.

There were in our wards 3,235 deaths in 1918, 535 of this number occurring from September 23 to November 1, during the epidemic of influenza. Of this number, 6.83 per cent. were post-mortem. During the height of the epidemic, the work in the post-mortem room was at a standstill, for more pressing work demanded the attention of all. From Jan. 1, 1919, to June 30, 1919, 1,324 deaths occurred in our wards, of which 188 necropsies were performed in our hospital morgue.

Early in June, before the new class of interns reported for duty, I endeavored to discover some plan for increasing our necropsy service. It was decided that each month a post-mortem efficiency sheet should be published, in which the percentage of post-mortems and deaths in each service should be set forth in order of rank.

Each visiting physician was also to be notified on a printed form, drawn up for that purpose, of his percentage for the current month. Talks were given the intern staff on the unquestioned teaching value of comparing clinical and pathologic diagnoses. The result was indeed gratifying, as will be shown by the accompanying table for the months of July, August, September, October and November.

PERCENTAGES OF NECROPSIES

Month	Deaths	Necropsies	Average Per Cent.
July	176	41	23.06
August	162	40	24.69
September	151	44	29.58
October	117	45	38.46
November	150	36	24.00

A low post-mortem percentage can often be traced to failure on the part of the visiting physician to make known satisfactorily the fact that he expects each case studied in his ward to be post-mortem, if death occurs. But this is not enough, for there it will soon languish unless a resident hospital officer not only does all in his power to simplify the method of securing post-mortem permissions, but also continually impresses on the resident staff that a high percentage is expected of each intern, and that his efficiency record shall reflect an accurate information as to the practical results of his endeavor to secure such permissions. It is not felt at the Philadelphia General Hospital that an intern is interested in his position, and worthy of the highest commendation, unless his post-mortem percentage remains consistently high.

The difficulties encountered at the Bellevue, Boston, and Philadelphia City hospitals, are similar.

In Philadelphia, by special concession of the state anatomic board we are allowed to perform necropsies on 35 per cent. of our unattended dead from October to June, and 25 per cent. during the summer months.

The former's office does not materially increase the number of examinations held at the Philadelphia General Hospital, as permissions are required from the relatives on all coroner's cases, except those in which violence is suspected.

It has been found that the most fruitful procedure to adopt is to secure the written permission before death takes place. The verbal permission, legal in Minnesota and possibly a few other states, removes one of the great stumbling blocks

to solving this problem, and probably explains the high percentage of examinations reported from hospitals in these localities.

Finally, as is suggested by Dr. Wood, there exists a direct ratio between the perseverance and interest that the visiting and resident staffs display and the number of examinations performed. Post-mortem examinations can be secured in a large percentage of cases if intelligent and wideawake effort is persistently made.

JOSEPH C. DOANE, M.D., Philadelphia,  
Chief Resident Physician, Philadelphia  
General Hospital.

To the Editor—I have read Dr. Hammett's reply to my article on this subject (THE JOURNAL, Dec. 13, 1919, page 1852) in which he refers to my "stigmatization" of the so-called lay professor in the medical school as untimely and as showing lack of appreciation of the contributions of such men to medical progress.

I regret that my statements should have been interpreted as an effort to stigmatize gentlemen for whom and for whose accomplishments I entertain respect and admiration. I made no reference to the scientific achievements of nonmedical men which, from Pasteur onward, have been universally acclaimed, but confined myself to criticism of the value of nonmedical men as teachers in the medical school. Doubtless the nonmedical professor is a necessary factor in that stage of evolution through which the schools are now passing, since modern medicine has failed, among other things, to provide its own teachers in the more strictly scientific branches; but I venture to predict that, as time goes on, he will be replaced by an educator whose knowledge of medicine will have been developed by a broader experience than that of the laboratory alone. As it stands now, the medical curriculum is overloaded, not only in the fundamental branches, but elsewhere. In the grave responsibility of proportioning the teaching of physiology, biologic chemistry and anatomy, and in the choice and emphasis of facts to be presented to the student, I believe that we shall ultimately receive more valuable assistance from the properly trained physician than from the highly specialized products of the schools of science.

DOUGLAS SYMMERS, M.D., New York.

### "TEST FIGHT ON SOCIAL INSURANCE IN NEW YORK"

To the Editor:—There is cold comfort for the medical profession of New York in the editorial announcement in THE JOURNAL, December 6, p. 1774, of the coming effort of the governor of this state, backed by the New York State Federation of Labor, to put through the scheme for compulsory health insurance at the coming session of the state legislature.

After wrestling with this matter for four years, the Medical Society of the State of New York has definitely gone on record against it. This step was taken at a special meeting of the House of Delegates called to discuss the subject. The New York County Medical Society has long been on record as opposed to the "principles" of compulsory health insurance. Nevertheless, much of the vitality of this measure has been due to the pleas for "constructive" work and for "study" of it by the influential not to say the ruling portion of this body.

The present attitude of the county society on this question is one of unanimous disapproval. This was brought about by the exigencies of an election contest, just closed, in which both sides were compelled to declare their opposition to compulsory health insurance as a matter of safety.

In the same way, it may be stated, the state society was compelled to take a definite stand by the growth of associations, leagues and guilds of medical men organized to oppose this measure more effectually than had been done in their opinion by their local and state organizations.

For four years the medical men of New York state have been compelled to fight this battle at each session of the legislature, at a loss of time and at an expense of money which many of them could ill afford against paid public servants and others who were not losing anything by advocating a system of compulsory health insurance. At my suggestion last year, the late president of the Medical Society of the State of New York, Dr. Thomas H. Halsted, called the attention of all the county societies of the state to this matter early in the session of the legislature instead of waiting for the perfunctory hearing toward the close of the session to take action on it. Again this year I advised an active discussion of the subject by medical men with their candidates for the assembly well in advance of the date of election, instead of waiting till after this event, as was the case in its discussion by the state society.

In your article you say that New York "is an ideal state in which to discuss and test out this important subject." Judging by the facts given above, it has been tested out by medical men in this state, not only to their hearts' content, but to their hearts' sorrow. For them the discussion is closed. An official presentment of this fact by the Medical Society of the State of New York duly attested to the governor and the legislature should be the only action on their part at the coming session of the legislature in regard to compulsory health insurance. If this measure is to be enacted into law, let it be definitely understood that the great body of the medical profession of New York will have to be impressed into carrying out its medical provisions by the hand of the state, a form of compulsory medical service which the people will not be slow to recognize as one in every way inimical to their interests and unworthy of the traditions of the great medical profession.

JOHN P. DAVIN, M.D., New York.

### Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

#### GRADUATE COURSES IN PUBLIC HEALTH

To the Editor:—Please let me know if any medical school in Chicago grants a degree in public health, and if any of this work can be done during the summer.

ETTA SELSAM, M.D., Indianapolis.

ANSWER.—No medical school in Chicago gives public health courses leading to a degree. A list of the schools giving such courses and a description appeared in THE JOURNAL, Aug. 16, 1919, page 516.

**The New Netherlands Law on Narcotics.**—Although the three international conferences on regulation of the consumption of opium, etc., were held in the Netherlands (1911, 1913 and 1914), and France, England and the United States have long since passed laws, the Netherlands completed its legislation on the subject only in October, 1919. The law of Oct. 4, 1919, is said to be a model of conciseness and allows fewer loopholes for infringement of the spirit of the law than the more extensive and sometimes galling laws of the other countries. A full summary of the law is given in the *Nederlandsch Tijdschrift voor Geneeskunde*: 2:1577 (Nov. 15), 1919, with comment by Professor Muntendam. He says that the abuse of narcotics is almost negligible in the Netherlands in comparison with other countries. But the new law will prevent importation of the vice of drug addiction just as the legislation against absinthe has prevented the development of absinthe abuse. He adds that the benefit from a law depends on the way in which it is enforced and in this case much depends on the decisions of the committee who are to pass judgment on the narcotic content, etc., of "patent medicines" and other proprietaries and nostrums.

## Medical Education, Registration and Hospital Service

### COMING EXAMINATIONS

- ALABAMA: Montgomery, Jan. 13. Chairman, Dr. Samuel W. Welch, Montgomery.
- ARIZONA: Phoenix, Jan. 6-7. Sec., Dr. Ansel Martin, 207 Goodrich Bldg., Phoenix.
- COLORADO: Denver, Jan. 6. Sec., Dr. David A. Strickler, 612 Empire Bldg., Denver.
- DISTRICT OF COLUMBIA: Washington, Jan. 13. Sec., Dr. Edgar P. Copeland, The Ruckingham, Washington.
- HAWAII: Honolulu, Jan. 5-8. Sec., Dr. J. R. Judd, Honolulu.
- INDIANA: Indianapolis, Feb. 10-15. Sec., Dr. W. I. Gott, 84 State House, Indianapolis.
- KANSAS: Topeka, Feb. 10. Sec., Dr. H. A. Dykes, Lebanon.
- MINNESOTA: Minneapolis, Jan. 6-9. Sec., Dr. Thos. McDevitt, Loomis Bldg., St. Paul.
- MISSOURI: St. Louis, Jan. 12-14. Sec., Dr. George H. Jones, State House, Jefferson City.
- NATIONAL BOARD OF MEDICAL EXAMINERS: St. Louis and Chicago, Feb. 18-25. Sec., Dr. J. S. Rodman, 1310 Medical Arts Bldg., Philadelphia, Pa.
- NEW MEXICO: Santa Fe, Jan. 12-13. Sec., Dr. R. E. M. Bridg, Las Cruces.
- NEW YORK: New York City, Albany, Buffalo, Syracuse, Jan. 27-31. Asst. Professional Examinations, Mr. H. J. Hamilton, Albany.
- NORTH DAKOTA: Grand Forks, Jan. 6. Sec., Dr. George M. Williamson, Grand Forks.
- OKLAHOMA: Oklahoma City, Jan. 13-14. Sec., Dr. J. M. Byrum, Shawnee.
- OREGON: Portland, Jan. 6. Sec., Dr. Frank W. Wood, 559 Morgan Bldg., Portland.
- PENNSYLVANIA: Philadelphia, Jan. 13-17. Pres., Dr. John M. Baldy, Harrisburg.
- RHODE ISLAND: Providence, Jan. 2-3. Sec., Dr. B. U. Richards, State House, Providence.
- SOUTH DAKOTA: Pierre, Jan. 13. Sec., Dr. Park B. Jenkins, Wanbury.
- VERMONT: Burlington, Feb. 10-12. Sec., Dr. W. Scott Nay, Underhill.
- WASHINGTON: Spokane, Jan. 6-8. Sec., Dr. C. N. Suttner, 415 Old National Bank Bldg., Spokane.
- WEST VIRGINIA: Charleston, Jan. 13. Sec., Dr. S. L. Jepson, Masonic Bldg., Charleston.
- WISCONSIN: Madison, Jan. 13-15. Sec. Dr. John M. Dard, 220 E. Second St., Ashland.

### GRADUATE MEDICAL EDUCATION IN GREAT BRITAIN AND FRANCE

LOUIS B. WILSON, M.D.  
ROCHESTER, MINN.

At the meeting of the Executive Committee of the Council on Medical Education of the American Medical Association, Feb. 3, 1918, the Committee on Graduate Medical Degree appointed the previous year was continued, and its duties enlarged to include a study of the entire problem of graduate medical instruction in this country and in the countries of our allies. The personnel of the committee is as follows: Louis B. Wilson, chairman; N. P. Colwell, secretary, and Isadore Dyer, John M. Dodson, A. C. Eycleshymer, William Pepper, Jr., Victor C. Vaughan, J. M. T. Finney, Edward Jackson, and James Fwing.

The chairman of the committee was intrusted, should he be ordered to military duty in Europe, to make such observations and collect such information concerning graduate medical education there as time and opportunity would permit. It so happened that he was stationed in London during April, 1918, and in France from April, 1918, to June, 1919, except for a brief visit again to England in April, 1919. During this time he had conferences with Sir William Osler, chairman of a committee representing the London medical schools, with Sir George Makin, Prof. Arthur Keith, and Sir Arbuthnot Lane of London; Sir Berkeley Moyle, and Leech, Sir Robert Jones of Liverpool, Sir Harold Stiles, and Sir William McCormack of Edinburgh, Col. I. G. Adams of the Canadian Medical Service, and with Sir Walter Morley of the Medical Research Committee of France, similar conferences were held with Prof. Henry Roger, head of the Faculty of Medicine of the University of Paris, and Georges Dubouché, secretary of the faculty of

Calmette, one of the directors of the Pasteur Institute; Dr. A. Bécélère, president of the Association médicale de Hôpitaux de Paris; Prof. A. Polcarol of the Lyons Medical School, and numerous other French medical officers met incidentally. Conferences were also held with Mr. George H. Nettleton, director of the American University Union in Europe, and Dr. George F. Maclean, acting director of the British branch of the American University Union. No opportunity was afforded for the study of the graduate medical situation in Italy, although incidental information would indicate that in certain of the schools there are opportunities for Americans to work to advantage, particularly in laboratory subjects. The results of the observations in Great Britain and France are herewith presented as an interim report in the hope that the information may be of use to some of the many Americans now seeking opportunity for graduate medical study.

#### GREAT BRITAIN

The numerous three months' courses in medicine which were attended by about 300 medical officers of the American Expeditionary Forces after the armistice furnished many suggestions to the instructors, particularly in the London and Edinburgh medical schools, concerning the kind of work desired by American graduate medical students. They also demonstrated to American medical students the high quality of work to be had even under the adverse conditions then existing. On the basis of this experience, Sir William Osler's committee has formulated, with the cooperation of the twelve London undergraduate medical schools, the four existing postgraduate institutions and many hospitals, a plan for lectures in the fundamental medical subjects, clinical teaching in cases in wards and outpatient departments, and practical instruction in roentgen-ray diagnosis, pathology, chemistry, bacteriology, clinical microscopy, post-mortems, etc. The cooperation of the British medical schools of London will probably soon be secured. Special research work and clinical assistantships are also available to selected men. Many of these courses will be most excellent and American graduates in medicine will greatly appreciate them.

The central organization consists of a council made up of representatives of all the participating teaching institutions, and representatives of the board of education, the Medical Research Committee, the donations, and American universities. This governing body assists in the organization of courses, establishes a uniformity of fees in the various schools, and furnishes detailed information concerning courses. Ultimately the association will have a building in central London not only containing offices of the organization, but also serving a meeting place for medical graduates of the entire and allied nations. American students desiring detailed information concerning the courses available should correspond with the director of the American University Union, 10 Pall Mall East, S.W. 1, London, or with Sir William Osler, 13 Norfolk Gardens, Oxford.

Recently a loan has been accomplished between the Osler group for graduate study and the American Hospital of London. The latter institution, which was developed largely through the activities of Sir Arthur Lane, has the financial support of a number of industrial Americans and Englishmen in London. It is proposed to build a large hospital and general laboratory for the care of patients but also for clinical teaching and laboratory research work. The patients may be derived from any available source. The attending medical officers will be recruited from among the most members of the London members of the medical profession, since the basic officers, interns and graduate students will be made up of Americans. Any one desiring information concerning the opportunities offered in the hospital should

inquire of Mr. Phillip Granklin, No. 1 Wimpole Street, S. 1, London.

Information at present is not at hand concerning the graduate courses in medicine actually open to American medical students in the British medical schools outside of London. It is known, however, that there are such opportunities, particularly at Edinburgh and Liverpool. Information concerning these may be obtained direct from the secretaries of the faculties.

American medical students, of course, will find great variation in the kind and quality of the teaching by the individual instructors in Great Britain. In general, however, they may expect to find the British medical man a thoroughly trained clinician, a sturdy advocate of the unvarnished truth, not taking kindly to unsupported hypotheses, without much reverence for supposedly established medical "authorities," and in criticism likely to hit to the line, let the chips fly where they may. His personal atmosphere contains no "London fog," and is delightfully "bracing."

#### FRANCE

In France, though all medical education is under the general control of the minister of education, each medical school has its own peculiarly individual plan of work. During the war the French medical schools were almost completely disorganized, but they have made rapid progress at reorganization since the armistice. Perhaps the graduate work most readily available to American medical students in France at present is that offered by the Association des Hôpitaux de Paris, of which Dr. A. Bécélère, 122 Rue la Boétie, is president. This organization, which was formed in 1907, contains a large number of the most prominent physicians, surgeons and specialists in Paris, who have associated themselves together for the better utilization for teaching purposes of the clinical material which they control in the various hospitals. The courses offered by the different members of the association are announced annually in a bulletin which may be obtained from the president of the association. Whatever divergence of interests may have previously existed between the teachers of this association and the School of Medicine of the University of Paris has now been corrected, and the two are working together in harmony for the development of graduate medical education.

In cooperation with these French organizations is the American University Union in Paris and the "College of the United States of America." Mr. George H. Nettleton, director of the American University Union, Paris, during the war interested himself not only in the purpose for which the American University Union was primarily formed, that is, "to meet the need of American university and college men and their friends who are in Europe for military or other service in the cause of the Allies," but also in the promotion of a broad basis of better relationships between the educational interests of the United States and France. Through M. André Tardieu, Commissaire Général des Affaires de Guerre Franco-Américaine, and M. Coville, director of higher education, he did much to bring about an understanding of the need of American university students and of what the United States has to offer to French university students. The American University Union has been given a grant of land in Paris on which to place a building for its general headquarters. Funds for the erection of such a building are now being obtained. This building will no doubt become a general meeting point and source of information for university students in France. Graduate medical students desiring information concerning the courses available should correspond directly with the American University Union at 8 Rue de Richelieu, Paris.

"The College of the United States of America," which is incorporated under the laws of the State of West Virginia,

with its principal office at 24 Boulevard des Capuchines, is supported by a number of wealthy Americans resident in Paris. It announces that "the object of this organization is to create in Paris an institution of learning to promote intellectual rapprochement between France and the United States, to constitute a clearing house for the exchange, discussion and dissemination of ideas in all the various branches of education, science and learning, and finally to constitute a sort of administrative home for students in France. It proposes by way of beginning to establish immediately in Paris an office or bureau as the headquarters of the new institution where may be found a complete list of the teaching facilities of France with the names of all the well known savants willing to accept graduate students in their classes, clinics and laboratories."

Outside of Paris, probably the best opportunities for graduate study of medicine in France will be found at the medical schools of Lyons, Lille and Strasbourg. All of these are in the process of reorganization and will soon be able to offer good opportunities for graduate study.

An American graduate medical student who has command of the French language will find study in France most inspiring. The Frenchman has none of the wearying, plodding methods of the Teuton, but he arrives at his conclusions across lots, apparently by intuition, actually by the subconscious guidance of wide clinical experience and a wonderfully clear mental vision, which is a racial characteristic.

French university undergraduate medical teaching in some places has not materially advanced since the days of Louis, Oliver Wendell Holmes' great instructor; but the Frenchman is an intense individualist, and the American medical student who seeks inspiration in almost any clinical specialty or in research by search can find some great teacher in France who is sure to give him a new and original point of view. Mention may be made of the special excellence of French work in the roentgen ray, diseases of the nervous system, skin and venereal diseases, and ophthalmology.

EXPENSES

The expenses of American graduate medical students in England and France, except for the ocean travel, should not be materially greater than in the United States. It is to be hoped that endowed traveling fellowships for study in these countries, paying at least as high a stipend as those provided for graduate medical study in the United States, may soon be greatly increased in number.

THE INSTITUTE OF INTERNATIONAL EDUCATION

This article would be incomplete without mention of the Institute of International Education, 421 117th Street, New York City, under the patronage of the Carnegie Foundation, which is now promoting an extensive plan of exchange of instructors between the United States and allied countries, and which later, I believe, expects to develop a similar plan for the exchange of students.

New Mexico April Examination

Dr. R. E. McBride, secretary of the New Mexico Board of Medical Examiners, reports that eight candidates were licensed by endorsement of their diplomas, and one candidate was licensed by reciprocity at the meeting held April 14-15, 1919. The following colleges were represented:

College	ENDORSEMENT OF DIPLOMA	Year Grad	
Copper Medical College	.....	(1912)	
Atlanta College of Physicians and Surgeons	.....	(1891)	
Chicago Medical College	.....	(1891)	
University of Maryland	.....	(1914)	
Harvard University	.....	(1886)	
University of Michigan Medical School	.....	(1910)	
Marion Sims College of Medicine	.....	(1891)	
Jefferson Medical College	.....	(1908)	
College	LICENSED THROUGH RECIPROcity	Year Grad	Reciprocity with
University Medical College of Kansas City	.....	(1906)	Missouri

Book Notices

THE HEALTH OF THE TEACHER. By William Estabrook Chancellor. Cloth. Price, \$1.25. Pp. 302. Chicago: Forbes & Company, 1919.

According to the notice on the cover, this book discusses every question of hygiene associated with the teaching life "in a clear, practical way by a recognized authority." One of the four reasons given in his preface for the preparation of the book is that "such books as have appeared for adult teachers have not been written by men with medical training and experience, but by teachers of hygiene who have considered the subject pedagogically rather than medically." The author also states that the book is the outgrowth of early studies in physiology and hygiene and medical training followed by thirty years of educational experience.

While not a graduate of a medical school, the author has apparently read widely along medical lines. The book is a queer mixture of practical advice and common sense with sweeping generalizations and unwarranted statements on pathologic and hygienic questions. Evidently the author has been deeply impressed with the present day discussion of the ductless glands and their functions, and is unable to separate the working hypotheses of physiologic research workers from accepted scientific fact. His physiologic views may be gazed by a few extracts. "Meats seem to stimulate all the ductless glands. Conversation, public speech, social relations, serious reading, hard exercise such as horseback riding, tea, coffee, chocolate, the alcoholic stimulants . . . and sugar, one and all stir up these glands, especially the suprarenals." A deficiency of pituitary gland secretion "causes one to develop thin, blue flesh and fat and to be nervously weak, while an excess of its secretion causes thick, red flesh and fat and high passions." The human race is divided into five different "temperaments," namely, ideomotor, sinewy-motor, muscular-motor, vital corpulent and anemic sedentary, and the various mental, moral and physical peculiarities of each class are laid down with a definiteness and minuteness that reminds the reader of a "patent medicine" almanac or a popular handbook of astrology. Dementia is "loss of mind from fret and misunderstanding and brooding." There is no mystery about cancer. It is simply "a natural growth gone to mad excess." Tight collars are "very bad for the thyroid gland." Diabetes is due to a "liver distorted and almost separated into two parts from tight dressing in early youth." The "cases" that are reported as proof of the various theories advanced are most interesting. Patient 3 was "twice turned over as dead, once at 25 years of age and the second time at 40 years." The second collapse was due to the wearing out of the organs of secretion. It was not, however, "due wholly to errors of diet, but in part to a concussion of the spine at the point of exit and entry of the kidney nerves. Massage, pediatrics, and physiological rest have cured the spine at this point." Evidently there are brilliant results to be secured by the use of "pediatrics" in the treatment of a 40 year old patient, even in one whose "kidney nerves" are concussed. Patient 10 "drank enormous amounts of seltzer, so enormous that his skin was bleached and his kidneys bloated by excessive water." The reader is advised to purchase a blood pressure machine which "an teacher can learn to operate." A case of severe and prolonged typhoid fever could not be accounted for until an unaltered soil pipe joint was found "directly below the clothes closet" of the victim.

The fact that this book has been published by a well known firm which is evidently under the impression that it is reliable and authoritative on medical questions only makes it the more dangerous. If all of the advice contained in it were bad, it would defeat its own purpose. As it is, the good and the bad are so thoroughly mixed that it is impossible for the lay reader to separate them. Professor Chantrelle should leave the preparation of books on hygiene to those qualified by training and experience to write them and should at least have his manuscript revised by a competent authority before publication.

## Medicolegal

### Loss of Time Partly Under Influenza Regulation

(Newman v. Garofalo et al. (N. Y.), 176 N. Y. Supp. 573)

The Supreme Court of New York, Appellate Term, First Department, in reversing a judgment that was rendered in favor of the plaintiff says that he was employed under a written agreement to work for the defendants a period of twenty weeks at the rate of \$27 a week. The hours of labor were from 8 in the morning until 6 at night, with time out for lunch and a half holiday on Saturday. In other words, the week consisted of forty-nine hours of labor. Loss of time was deducted on a pro rata basis at so much an hour. In the course of the contract period the city was visited by the epidemic of influenza, and the board of health passed a resolution fixing the hours of employment in the defendants' factory from 9:30 a. m. to 5:30 p. m. One of the defendants testified that he called the workmen together, and that they agreed to change the hours from 9:30 a. m. to 7:30 a. m. He also testified that thereafter they flatly refused to continue work at night, and that the plaintiff regularly went home at 6 o'clock. This continued over a period of four weeks, and the plaintiff's time was deducted accordingly. In this action he sued to recover the amount of payment thus withheld, and was awarded a verdict for the full amount, on the theory that he was ready, willing and able to do the work at the rate of forty-nine hours a week. Yet by his own testimony he voluntarily left the factory an hour and a half before quitting time because, as he said, "there was not enough work for us to do." This evidence demonstrated that he took the hour of departure into his own hands, and that the breach of contract, if any, was of his own part. The judgment in his favor is therefore reversed, with \$30 costs, and the complaint dismissed on the merits.

### Physician Not Liable for Burning of Patient

(Mason v. Graham, 117, 172 N. W. 2, R. 785)

The Supreme Court of Wisconsin, in affirming a judgment of the circuit court, which reversed one for \$300 and costs that was rendered in favor of the plaintiff, says that the main question was whether the evidence was sufficient to support a verdict finding the defendant guilty of negligence. The defendant was called to perform an operation on the plaintiff's child. At the time of the operation a Mrs. Lengua was in the company of the plaintiff, or of his wife, to take care of the patient's children, and at the request of the defendant placed the stove lid in the bed to warm it, which it was assumed would warm Mrs. Malkowki's feet. Mrs. Lengua was a married woman 25 years of age, had two children, was married to the plaintiff, and was an intelligent, competent person, but had had no experience as a nurse. There was no testimony in the record that the defendant told Mrs. Lengua to place the iron on the feet of the patient. Giving the defendant the most favorable construction for the plaintiff, it was held that the defendant told Mrs. Lengua to place the irons on the bed at or around the patient's feet, not on her feet. Moreover, Mrs. Lengua was as competent to judge whether the stove lid would be hot enough to burn as was the defendant, and was not considered to be guilty of negligence because she did not know that it was hot enough to burn. It was held that the evidence in the case was sufficient to support a verdict in favor of Mrs. Lengua's knowledge and belief that the stove lid would not place the iron as to burn the patient. Moreover, the iron was not hot enough to burn was within the common knowledge of any person of the intelligence and competence of Mrs. Lengua. The negligence, if any, on the part of the defendant was the negligence of Mrs. Lengua, not the negligence of the defendant. It was insisted that Mrs. Lengua was not the defendant, and that the relation of doctor and patient existed, but the evidence did not support that theory. Mrs. Lengua was in the employ of the plaintiff or of his wife. It was further claimed that the physician was negligent in ordering Mrs. Lengua to place the hot iron in the bed. But the most that could be said in favor of the plaintiff, through the evidence was that the

defendant told the person in charge of the patient and her children to keep her warm by placing warm or hot stove lids in bed with her, and, construing this evidence in the most favorable light for the plaintiff, it could not mean that the iron was to be placed so as to burn the patient. Clearly the defendant could not anticipate that anything of the sort would be done; hence one of the essential elements of proximate cause, namely, reasonable anticipation, was wanting in the proof. The defendant could not have anticipated that an ordinarily prudent and intelligent person would so place the iron as to cause the injury complained of; and, when there is no evidence to support the essential element of reasonable anticipation, proof is not sufficient to make a case. In order to charge the defendant with damages in this case, it must appear from the evidence that the defendant ought to have anticipated that the persons in charge of the patient would place the iron in the bed at such a heat and temperature and in such a position against the body of the patient as to burn her. On this point this court is of the opinion that there was no evidence sufficient to support a verdict for the plaintiff, and hence that the defendant was not guilty of negligence.

### Information as to Attendance and from Necropsy Not Privileged

(Chadock v. Beneficial Life Insurance Co. (Utah), 181 Pac. R. 448)

The Supreme Court of Utah says that in this action on a policy of life insurance, where the defendant alleged that the insured had in his application for insurance falsely answered certain questions asked him by the medical examiner, a physician called as a witness was asked as to whether he had been consulted by the insured prior to his application for insurance, and he answered, "Yes." He was then asked if he had been consulted on more than one occasion and, over the objection of the plaintiff, was permitted to answer that he had. The ground of the objection was that the witness was prohibited by statute from answering. The Utah statute prohibits physicians, without the consent of their patients, from testifying in a civil action as to any information acquired in attending a patient which was necessary to enable the physician to prescribe or act for the patient. The question asked did not call for the disclosure of such information, but was limited entirely to the fact as to whether the witness had been consulted by the insured. It was not within the statute, and under the issues the testimony was properly admitted.

The same witness later in his examination, against the objection of the plaintiff, was permitted to testify that he performed a necropsy on the body of the insured a day or two after his death, and found that he had died of tuberculosis of the spine. He testified also as an expert, in substance, that the disease and conditions were such that the insured would know he was not in good health for two and a half months before his death. As the policy was applied for about the last of May and the insured died on the 13th of August next following, this testimony was elicited manifestly for the purpose of showing that the insured must have known that he was afflicted with disease when he applied for insurance. The statute above referred to was invoked and relied on in support of this objection. The grounds of the objection were untenable from every point of view. The privilege claimed does not exist at common law. It was conferred by statute. In order to be available the claim of privilege must be brought within the clear meaning and spirit of the statute. Just how information acquired by means of a necropsy can be said to have been acquired to enable the physician to prescribe or act for the patient presents to the mind of the court an insoluble question. When the patient is dead he is no longer a patient. The only functionaries that can thereafter be said to act for him are the undertaker and the gravedigger, and as to them the statute is silent. If it had been necessary for the witness to supplement the information acquired at the necropsy by information he acquired during his attendance on the patient, in order to determine the cause of his death, a different question would be presented.

## Current Medical Literature

### AMERICAN

 Quantitative Studies on Growth of Skeleton of Albino Rat. H. W. Donaldson, Philadelphia, p. 237.

#### American Review of Tuberculosis, Baltimore

November, 1919, 3, No. 9

- Larger Field in Tuberculosis. A. K. Krause, p. 513.  
 Influenza and Tuberculosis. M. Fishberg, New York, p. 532.  
 Classification of Laryngeal Tuberculosis. J. Dworzetzky, Liberty, N. Y., p. 544.  
 Continuous Injection Method in the Treatment of Experimental Tuberculosis. J. H. Lewis and L. M. Dewitt, Chicago, p. 548.  
 Fate of Bacteria Introduced into the Upper Air Passages. A. L. Bloomfield, Baltimore, p. 553.

**Influenza and Tuberculosis.**—Fishberg believes that influenza has no etiologic relation to tuberculosis and cannot be considered as a reactivator of a dormant lesion. Tuberculosis patients are not unusually susceptible to influenza, nor is the latter disease more severe in them. The pulmonary sequelae of influenza are quite generally nontuberculous and do not require tuberculosis treatment.

**Treating Experimental Tuberculosis by Continuous Injection Method.**—Lewis and Dewitt applied the Woodyatt continuous injection method to the treatment of experimental tuberculosis. Various concentrations of methylene blue, 1 between 1:500 and 1:3,000, were used. On rabbits the local toxic action of the drug was disastrous, while dogs treated for six hours with 0.2 c.c. per kg. body weight per minute of a 1:500 solution usually died in twenty-four hours. The blood of these dogs drawn immediately after the injection inhibited on glycerin agar the growth of the same strain of bovine tubercle bacilli used in the experiments. The authors believe that the continuous injection method is deserving of further consideration and experimentation.

 Renographic Studies in Gout. C. W. McClure and F. D. M. Carty, Boston, p. 63.

**Intensity of Heart Sounds.** In this study the heart sounds over the apex region, aortic and pulmonary areas were recorded simultaneously or in pairs by the direct sound recording capsules described by Dean and Wiggers. It was found that the intensity of the first sound is not related to the volume of blood discharged by the ventricles, e.g., during slowing of the heart, when the systolic discharge is increased, the first sound is reduced in intensity. The intensity of the first sound over all regions varied directly as the systolic tension developed within the ventricles and with the tension developed during the isometric period of systole. The intensity of the second sound increases or decreases

the pressure (aortic or pulmonary) at the beginning of diastole. When the pressures at the beginning and end of systole increase, particularly in one circuit and relatively little in the other, an accentuation occurs, predominantly in the sounds referred to the circuit in which the changes predominate. In circulatory conditions where the pressures at the beginning and end of systole vary in opposite directions in the greater and lesser circuits, the intensity of the pulmonary and aortic sounds changes in opposite directions. Direct experimental evidence supplements the anatomic basis for believing that sounds heard over the second left intercostal space are transmitted from the right heart and lesser circuit, while those heard over the right second intercostal space and apex have their origin in the left heart and greater circulation. When reserve and caution are exercised, a change in the intensity of the first sound over any area is good evidence of a change in tension developed during systole of the ventricles, while a change in the intensity of the second sound over the aortic and pulmonary areas may safely be used as an index of a change of pressure at the beginning of diastole in the greater and lesser circuits, respectively.

**Wilson's Disease.** The anatomic diagnosis in the case cited by Howard and Royce was: cystic degeneration of the basal ganglia; cirrhosis of the liver, colloid cystic degeneration of the parathyroid glands; bacteremia; uniform congestion of the lungs. The histologic diagnosis was: progressive degeneration of the neuron and glial elements of the basal ganglia, most extensive in the lenticular nucleus but involving the optic thalamus, caudate nucleus, internal capsule and red nucleus and, to a slight extent, the white matter just beneath the gray matter of the cortex; chronic interstitial hepatitis; lymphoid hyperplasia manifest in spleen and retroperitoneal lymph nodes; acute congestion of spleen and kidneys; colloid cystic degeneration of the parathyroid glands. A later more careful examination of the brain, after it had been hardened in liquor formaldehydi, disclosed the changes in the lenticular nuclei characteristic of Wilson's disease, a bilateral symmetrical cavitation and atrophy. The cavitation is not sharply confined to the lenticular nucleus itself, but involves, although to a lesser degree, the internal capsule and optic thalamus on both sides. There is a slight grayish discoloration of the globus pallidus.

**Energy Index.**—The S. D. R. index as a guide to abnormalities in function of the cardiovascular system in a series of 26,396 cases examined by Barach was correct in 99.95 per cent. In cases referred for special cardiovascular examination, i.e., in the clinically doubtful case, the S. D. R. index proved a correct guide in 78 per cent. Of the 22 per cent, in which the index failed, more than three fourths of the cases were tachycardias. The index does not indicate "heart disease" or "decompensation" or "physical fitness." It designates the amount of effort which the circulatory system is putting forth at the time. A high index means increased cardiovascular effort, either the action of the heart and blood vessels is accelerated because of inability to accomplish their work at a normal rate of activity, or they are fully capable of doing their work, but the resistance to their functioning is great. Either condition is pathologic, and the variation of the index from the normal calls attention to this. A low index means either that the circulation is accomplished with little effort or an inability to expend the necessary effort. Minor changes in the circulation, such as are produced by the slightest alteration in the bodily functions, the effect of drugs, etc., may be detected by the S. D. R. index.

**Meningococcus Meningitis.** Of thirty-one cases of meningococcus meningitis studied by Haden, twenty-one, or 67.7 per cent, showed unmistakable evidence of a general infection before there was a localization in the meninges. The mortality of the entire series was 22.6 per cent. During the period of intrathecal treatment alone and combined intrathecal and intravenous treatment the mortality was 37.5 per cent., during the period in which intrathecal and intravenous therapy was employed, the mortality was 0.6 per cent. One case is reported in which an acute localized infection in the meninges recovered only after intravenous therapy alone.

**Cholesterol in Blood in Jaundice.**—In cases of obstructive icterus due to cholelithiasis, the authors have almost invariably encountered a hypercholesterinemia of a rather severe grade. The degree of jaundice bore a definite relation to the amount of cholesterol in the blood, indicating that this hypercholesterinemia is due to the obstruction of the bile duct. However, an occasional exception was encountered. In other conditions associated with icterus, such as cirrhosis of the liver, acute yellow atrophy, pernicious vomiting of pregnancy, etc., the cholesterol bears no relation to the intensity of the icterus. These facts suggest that in severe disturbances of hepatic function, there is a selective retention of the pigments, while the cholesterol is not retained. In one case the bile was obtained at necropsy, and showed a rather low amount of cholesterol, 0.12 per cent., against a normal content of 0.8 per cent. In other conditions associated with icterus, such as primary or secondary carcinoma of the liver, or biliary abscesses, as seen in polyplebitis, the cholesterol content of the blood is not proportionate to the intensity of the jaundice.

**Renal Glycosuria.**—The observation of three cases of renal glycosuria as compared with thirty seven cases of true diabetes, and the increasing number of reports in the literature as blood sugar analyses are more employed, the authors here indicates that "renal" glycosuria is not as rare as was once supposed, and probably is much commoner than other glycosurias, such as pentosuria or levulosemia. The etiology was unknown in two cases. In one case severe trauma was either the primary or, at least, the exciting cause. There was no indication of nephritis or renal abnormality in any one of the three cases, except a slightly subnormal phenol-sulfuric acid estimation. The excreted substance in one of the three cases seemed to be an unknown sugar, distinguished from glucose by the absence or incompleteness of hydrolyzation. This may be the most important observation in the present study and suggests the desirability of closer examination of the fresh urine in such cases for accurate identification of the sugar.

**Serotherapy of Pneumonia.**—In sixty-one cases Tenney and Seaman injected 100 c.c. of autogenous serum intravenously at eight-hour intervals, day and night, until the normal temperature registered 100 F. or lower, or evidence of consolidation or impending death made it advisable to stop the treatment. Thirty patients recovered by crisis, twenty-two by lysis and nine died, a mortality of 14.7 per cent.

**Hemoglobin Determination.**—A rapid, accurate determination of hemoglobin is made by Berman with the acid hematin method. The blood is obtained with a carefully calibrated pipette, preferably when the patient has not yet had the first meal of the day. It is diluted with tenth normal hydrochloric acid and a reading is made at the end of one minute. The dilution is then calibrated and is carefully boiled for one hour for one minute. After permitting it to cool for one minute it is again diluted with tenth normal hydrochloric acid and a final reading is made. A standard solution, standardized with a known normal blood should be used, and be made freshly daily to avoid error due to oxidation.

**Roentgenograms of Gout.**—A detailed report of the roentgenograms in twenty cases of gout is made by McClure and McGee. All the patients had tophi from which sodium urate could be extracted. One case which was clinically thought to resemble the purpura of gout was. The findings indicated that this type of arthritis may occur in gout patients even when the apparatus in the roentgenogram, by the usual roentgenographic findings in even the most characteristic form of gouty arthritis may be regarded as entirely by innocent arthritis that these urates cannot be considered as more than precipitates of the diagenesis of uric acid. The focal areas of decreased density in the roentgenogram which demonstrate urate crystals to be due to tophi, according to the authors, are probably very often merely focal areas of absorption of bone mass. These focal areas are found in from 10 to 12 per cent. of the monoarticular arthritides and are therefore not diagnostic of gout. Their absence is of more

diagnostic value than their presence, since they are almost invariably found in some of the bones of the wrists, hands, ankles or feet in true gout.

**Clinical Picture of Pneumonia in a Boy Aged Two Years Who Subsequently Passed Three Hundred and Seventy Round Worms.**—W. W. McKibben, Worcester—p. 665.

**Adequate Reduction and Care in Colles' Fracture.**—Cotton's method consists in, first, traction and rocking, with the hand a little extended (backward) so as to free the displaced radial fragment and the dislocated ulna; then, with the thumb under the ulna, making it a fixed fulcrum, drag the hand down into flexion and pronation, keeping up traction combined with this flexion and rotation. Flexion is best held in plaster, preferably applied as strip-splints of eight to ten layers of plaster of Paris, bandage, one on the back, from elbow to finger knuckles, one in front, from upper forearm to palm. These are caught with a few turns of plaster-of-Paris bandage. Splinting of three weeks' duration is enough and, from the time of reduction, splints should never immobilize the fingers.

**Scarlet Fever Wave in 1919.**—Osborn urges that quarantine of the scarlet fever patient should be carried out for twenty-eight days from the onset of the disease and thereafter until infective discharges from the nose, throat, ear and abscesses have ceased.

**Repetition of Materia Medica and Therapeutics in Modern Medical Teaching.**—S. L. Dawes, New York—p. 667.

**Influenza.**—A review of the literature on influenza leads Hurler to the belief that mixed bacterial vaccines, including streptococci and pneumococci isolated from fresh cases, are useful and worthy of trial in the prophylaxis of the disease, and that the results derived from wearing gauze face masks, particularly those made of three-ply buttercloth, are such as to justify their use as a preventive measure not only by those in direct contact with the sick, but by all persons, mandatorily, during the presence of an influenza epidemic. However, the gauze face mask should not be depended on as a sole protection, but as an adjuvant to all other measures of prophylaxis.

**Repudiation of Materia Medica and Therapeutics in Modern Medical Teaching.**—The practical abandonment of the teaching of materia medica and therapeutics in the medical schools is regarded by Dawes as being a grave and serious defect in modern medical educational methods. He says that the pendulum has swung far, indeed, from the day when a knowledge of drugs and the treatment of symptoms occupied first place in the curriculum, from the period of polypharmacy and "shotgun prescriptions," so far that it may soon commence a backward movement to stop ultimately in a middle zone.

Prevention of Influenza and Allied Diseases. W. F. Dugas, Tulsa.—p. 321.  
Two Cases of Traumatic Asphyxia. F. S. Clinton, Tulsa.—p. 323.

**Glucose in Pneumonia.**—Rucks says that at Fort Sam Houston Base Hospital they gave 250 c.c. of a 10 per cent solution of glucose intravenously in the pneumonia case

with good results. The acidosis suggested its use and the results were that, after its administration, several hours of quiet rest ensued, the cyanosis was diminished, the evidence of edema lessened, the heart strengthened and elimination increased. To avoid the chill that sometimes followed they almost habitually added one-eighth grain morphin to the solution; also if digitalis was indicated it was added.

**Etiology and Pathology of Spanish Influenza.**—On the basis of his postmortem observations Turley feels justified in holding the belief that there is a separate disease entity commonly called the Spanish influenza, but which is more properly a hemorrhagic pulmonitis or a pulmonary phlebitis. He thinks the infective etiologic factor is most probably a very minute ultramicroscopic organism, possibly *Streptococcus pandemicus* or the filtrable micrococcus of the English investigators. The characteristic lesions are in the vascular system of the lungs rather than in the parenchyma of those organs, and the picture seen at necropsy can best be explained on this basis.

**Vessel Endothelium and Hemorrhage.**—Thrash believes that so-called idiopathic capillary hemorrhages, purpura, angioneurotic edemas, petechial hemorrhages, all result from the changing from flattened tube-forming structures to mitotic globular cells for the purpose of defending the economy against an invading enemy in the form of chemical, bacterial, animal or endogenous poisons, and (b) this way disintegrating the capillaries, arterioles and venules, leaving them in such a state that through their walls serum may transude to produce edema, red cells may pass out by diaporesis to produce purpura and from their ends blood may flow to produce frank hemorrhage.

**Anomaly of Kidney.**—Dunavant reports a case of complete fusion of the right and left kidney, found in a patient operated on for fibroids of the uterus. On a level with, and to the right of the promontory of the sacrum, was a rounded mass about 3 inches in diameter, retroperitoneal and below the bifurcation of the aorta, which was displaced upward. Examination of the right and left kidney less revealed an abnormality of the kidney from its normal bed on each side. The peritoneum was incised over the kidney mass revealing a triangular renal fatty capsule and characteristic color and appearance of kidney substance. No further investigation of the kidney was made as there was nothing in the history or appearance to indicate the presence of a pathological condition in it.

- Venereal Disease Control. H. C. Ladd, Waco, Texas, p. 169.
- Treatment of Gonorrhoea in Women. E. W. Turner, Houston, p. 173.

**Treatment of Gonorrhoea in Women.**—Turner prescribes the same treatment and office treatment in these cases. The former consists of douching and tamponing. At first he prescribes potassium bichromate, two daily (teaspoonful of powder dissolved in 2 quarts of hot water, to be used only in the recumbent position and with care). This is 5 per cent. protargol vaginal cone is so inserted as to rest against a tampon previously inserted. A 5 to 10 per cent. argyrol ointment is applied to the vulva, covering the urethra, labia and parts. A well fitting soft pad is applied and worn constantly. The office treatment is applied three times daily. The vulva is carefully washed with mercuric bichlorid solution, the patient is cauterized, the cauterizer heated and at least 4 drams of solution (a 25 per cent. argyrol or 1 per cent. protargol) is instilled into the bladder. A vaginal speculum is inserted and if the cervix is not covered a large woolen tampon, dipped in glycerin and saturated with argyrol crystals, is applied directly to the cervix. If the cervix is involved, a large cotton applicator is applied to the cervix to remove the mucous sheets about the part. If the sheets do not readily come away a soda solution is used to remove it. Tincture of iodoform is applied cautiously to the external os and a small amount inserted in the orifice with a small applicator. The glycerin and argyrol tampon is inserted directly to the cervix. Argyrol crystals are applied to the external wall external to the tampon, the parts are dressed with prepared ointment and the vulva pad is applied.

The writer of this report, gonorrhoea Turner orders the following:

	Gr.	or	℥.
1. Potassium bichromate	16		5 iv
2. Potassium permanganate	16		5 i
3. Glycerin	16		5 iiss
4. Mercuric bichlorid	16		5 iv

Use 2 teaspoonful to each quart of water as a douche. This is repeated every day, with increasing strength of solution, as a stimulating douche (from 1:1,000 to 1:200). Tincture of Iod. 1 dram to the quart of water, is used externally with a tampon to relieve soreness is required. The vaginal cones are increased in strength until they reach 10 per cent. strength.

**Experimental Treatment of Fractures.** The object of this experimental work was to study the operative treatment of fractures by the use of steel plates. There were three types of experiments done on dogs, using the latex plates and their experiments in which small pieces of ivory, cow's bone and wood were used. Briefly, the results have

shown that if operative treatment for malunion of a fracture is required, bone grafting, though more difficult, usually gives better end results than the use of a steel plate.

- \*Case of Multiple Epulides. W. W. James, p. 151.

**Dietetic Treatment of Adenoids.**—Campbell claims that faulty intestinal digestion causes adenoids. The chief fault lies with cereal foods, which are consumed in a spongy, pappy, and pulraceous form. We eat too much spongy (non-crusty) bread and pulraceous pudding, and too little raw vegetable food in the shape of salads and fruit. As a result of this kind of diet the maxillary apparatus (including the nasal passages, nasopharynx and salivary glands) does not develop properly; the local flow of blood and lymph is not adequately stimulated; starchy foods do not undergo adequate salivary digestion; and an excess of wholly non-digested starch (as well as of sugar) passes into the bowel, there to give rise to indigestion and putrefaction (as shown by the malodorous motions). Then follow toxemia, malnutrition, diminished resistance to infection catarrh, and adenoids.

**Abdominal Sarcoma with Metastases in Skull.**—In Cautley's case the primary tumor was situated in the lumbar region. Between the two kidneys and in the middle line there was a bilateral growth as big as a small orange, firmly adherent to the periosteum of the spine, and compressing the kidneys, more especially the left one. The growth extended along the spinal column downward and branched off into each iliac fossa, where large nodules were formed in connection with the periosteum. The inguinal glands were enlarged. In color the growth was dirty blue, and in consistency spongy in parts. Microscopically it proved an alveolar sarcoma.

**Case of Multiple Epulides.**—James' patient, a girl, aged 11 years, suffered from the growth of a fibrous epulis associated with each tooth of the temporary and permanent series which had erupted. Removal of the growth alone was followed by recurrence, which does not take place when the teeth are also removed. Up to the present all the temporary and eight of the permanent teeth have been extracted.

**Pathologic Changes in Testes in Mental Diseases.**—Macroscopically, sections of fresh or hardened testes revealed pathologic changes in a majority of the asylum cases studied by Mott; the converse was noticeable in the adult hospital cases. In the asylum cases the most marked deviation from the normal condition was found in two groups of cases, namely, (1) general paralysis, (2) dementia praecox. There was no correlation between the macroscopic cortical changes in the brain in general paralysis and the morbid changes in the testes. As a general rule the degree of morbid macro-

scopic change of the testes in dementia praecox conformed to the duration of the mental disease and the clinical signs and symptoms of the mental decadence rather than to any obvious macroscopic changes or defects in the brain. In general paralysis, the dementia corresponds in great measure to the degree of cortical destruction; nevertheless, there is no correlation in this disease between the brain atrophy and the testicular atrophy. With the exception of cases of senile dementia and congenital imbecility with epilepsy, the testes in other fatal asylum cases did not, as a rule, show any marked departure from the normal, for example, cases of epileptic insanity, Korsakoff psychosis, paranoia and manic depressive insanity.

**Enlargement of Thyroid in Malaria.**—Although the frequency of occurrence of marked thyroid enlargement noted by Hume is probably not greater than from 5 to 10 per cent.—the cases with some very slight temporary enlargement immediately after an attack of malaria might probably represent an additional 10 per cent.—he is inclined to believe that the changes in the ductless glands in malaria may be far more marked than present knowledge shows. These changes may be due to sporulation of the parasites in the capillaries of the gland, analogous to the condition in cerebral malaria. This would cut off the supply of iodothyronin from the blood stream, and upset "thyroid equilibrium." To regain this, compensatory hypertrophy takes place, and equilibrium is regained in the course of time. The remaining thyroid swelling becomes purely a hyperplasia; or there is a compensatory hypertrophy of the other ductless glands. On the other hand, enlargement of the thyroid may be compensatory for the exhaustion of other parts of the endocrine system. Degenerative changes have been described in the suprarenals in malaria; and disturbance of these glands may be the cause of the "algid type" of malaria, which, clinically, injections of epinephrin are most valuable in combating. The low blood pressure, and the subnormal temperature, which often lasts for days after an attack, both indicate a condition of hypo-adrenia. The loss of sexual power frequently observed after attacks of both treated and untreated malaria is likely also to be due to the effect of the disease on the testes.

- Case of Wernig-Hoffmann Type of Progressive Spinal Muscular Atrophy. E. A. Barton, and H. Ingley.—p. 923.
- Case of Extreme Esophagectasia. H. B. Shaw.—p. 923.

**Methods of Choice in Immunity.** In this paper Shera discusses this axiom: Against an exotoxin a serum should be employed; against an endotoxin a vaccine should be used. Against a combination of both exotoxin and endotoxin both a serum and a vaccine should be used, as bearing on the treatment of streptococcus infections.

**Treatment of Lupus Vulgaris.**—In McKenna's opinion the method *par excellence* for the treatment of lupus affecting the mucous membranes, either of the nose or mouth, is cauterization with the electrocautery. To use this method effectively, it is advisable to make a series of punctures all over the affected mucous membrane at short distances from one another.

**Wernig-Hoffmann Paralysis.**—The case cited by Barton and Ingley differs from those previously recorded in that nystagmus was a pronounced symptom and was probably due to the morbid condition of the oculomotor nucleus; also there was profuse sweating almost from the first. A complete postmortem report is given.

**Case of Extreme Esophagectasia.**—Shaw claims that on the basis of five symptoms a diagnosis can be made in this condition without the aid of the roentgen ray: (1) The taking of solid food causes pain at the epigastrium; (2) this pain is accompanied by what the patient calls vomiting, but is

really regurgitation of food; (3) the act of taking the solid food soon provokes a cough; (4) it sometimes happens that the patient becomes breathless, and this is particularly so after attempting to take more solid food than usual; (5) liquid food causes none of these symptoms.

**Cyclopan Eye.**—Van Duyse's study of a cyclopan single eye throws light, he says, on the pathologic anatomy and pathogenesis of such malformations and on the embryology of the eye in general.

**Stuttering an Endocrine Disturbance.**—Da Costa's clinical experience at Lisbon has revealed morphologic, physiologic and psychologic evidence that stuttering is only one manifestation of a general endocrine disturbance, which the physician is often able to modify and thus cure the stuttering. He here reports the pulse findings in two stutterers which reveal that there is a tendency to a neurosis of the sympathetic system. This is presumably of endocrine origin, and, most probably, the thyroid is primarily responsible.

**Spontaneous Rupture of a Varicocele.**—Van den Branden relates that the young man was shaving when he suddenly experienced such pain in the scrotum that he swooned, and the operation two days later showed a hematocele. There were no traces of venereal disease, but treatment had been given eight years before for acute varicocele. Palet's compilation lists only five cases of spontaneous rupture, and these were all in elderly men.

- Multiple Relapsing Phlebitis. A. Roux.—p. 593.
- Mongolian Blue Spot in Brazil. C. Ferreira. (S. Paulo).—p. 597.

**Deficiency Diseases in Children.**—Weill and Dufourt relate that nine cases of scurvy developed in a group of children from 2½ to 6 years old recently repatriated from the regions occupied by the Germans. Enteritis and dysentery had been diagnosed, and although the gingivitis was extreme and painful, and the children cried day and night, the true diagnosis was not suspected. The enteritis had lasted from three to ten months in some of the children, and fruit and green vegetables had been dropped completely, as tending to aggravate the bowel disturbances. Weill changed all this at once, and had the gums painted with lemon juice. The prompt improvement when the antiscurvy diet was given soon convinced the most skeptical. All the children were completely cured within a month.

**Diabetes Mellitus in Children.**—Nobécourt reports a case in which diabetes mellitus developed in a girl of 11½. Although the glycosuria was pronounced and it proved impossible to reduce it, the general health had kept comparatively good during the seven months, except that the child was backward in her growth. On an antidiabetic diet, signs of acidosis became apparent, and she was then allowed to eat the ordinary hospital food, with 50 gm. of sugar in addition, and under this the diacetic acid content of the urine grew less. When sugar was suppressed, the signs of acidosis returned, but they subsided anew when the sugar was resumed. It had thus a distinctly favorable action in this case. The dietic restrictions cannot be as severe for children as for adults. The outlook is always grave with this form of diabetes in children; he describes two cases in which the girl of 15 and boy of 9 died in coma two months and thirteen months after the first symptoms, the coma coming on after a brief period of remission. The onset of

... is generally considered the common factor of the beauty of the eye and the anterior chamber. These factors may exist without causing a marked hyperopic error. The following test for the elastic acid may reveal a latent error if established.

tremor and other symptoms. In the majority of cases, a few weeks of thyroid treatment abolish temporarily or permanently these minor signs of thyroid insufficiency. It may tone up the thyroid so that a tendency to myxedema may be thrown off. With actual myxedema, the thyroid treatment, he says, should be given twenty days each month throughout life. Treatment of pluriglandular insufficiency does not require strictly specific organ extracts. On account of the synergy of the endocrine glands, one extract may prove effectual when others fail, even when the new organ extract does not seem to have anything to do with the symptoms observed, continuing the treatment possibly for months, and alternating or combining the organ extracts according to the results obtained. If there is any tendency to a positive Wassermann reaction, mercurial or arsenical treatment should supplement the organotherapy. In any event, organotherapy of any kind requires medical surveillance.

### Bulletins de la Société Médicale des Hôpitaux, Paris

Oct. 24, 1919, 42, No. 29

- \*Pleuropulmonary Vasomotor Reactions. D'Oelsnitz and L. Cornil. —p. 861.

- \*Different Forms of Nephritis. Hélouin. —p. 889.
- \*Chloro-Azotemic Nephritis. Hélouin. —p. 893.

**Vasomotor Reactions with Lesions in Pleura and Lungs.**—D'Oelsnitz and Cornil state that in different pathologic conditions in one side of the chest, the arm on that side shows various vasomotor disturbances. The latter differ with different forms of pleuropulmonary disease. They can be detected best with the oscillogram, and they are evidently due to irritation of the cervical sympathetic. They have been studying these phenomena with epinephrin, amyl nitrite, mechanical heat and other tests, elastic constriction of the arm, and compression of the eyeball. The findings suggest that oscillogram tests of the corresponding arm may prove a useful diagnostic measure to supplement the routine measures with latent intrathoracic foci.

**Mixed Meningitis.**—The man of 54 presented the clinical picture of meningococcus meningitis following meningococemia, with joint lesions. Slight improvement followed serotherapy but it was transient, and tubercle bacilli were cultivated along with the meningococci from the spinal fluid and from the sylvian region of the brain after death.

**Shock After Transfusion of Blood.**—Only 40 c.c. of citrated blood had been transfused in treatment of post typhoid septicemia in the young woman, but an extremely violent shock followed at once, and with convulsions, the sixth day and then coma for four days, with final recovery. The transfusion had been made very cautiously, but the hemoglobinuria testified to the hemolytic action of the transfused blood although no incompatibility between the blood of donor and recipient had been detected in the test tube. This extremely grave reaction to such a small amount of blood transfused with the utmost precision of technique was a painful surprise, but it is possible that this excessively violent albuminoid shock may have turned the scale in favor of recovery in the otherwise fatal septicemia. In conclusion the writers cite Lewisohn's warning against transfusion in very acute septicemia, on account of the alarming reaction which may follow. But they are convinced that the septicemia would have proved fatal without it. The father was the donor.

**Syphilitic Meningomyelitis.**—Nicaud reports a case of sudden complete flaccid paraplegia, with pronounced sensory disturbances, the tenth year of syphilis. Under neo-arsphenamin recovery was practically complete in three months.

**Jaundice and Neo-Arsphenamin.**—Sicard and his co-workers present evidence to prove that the drug is responsible for the jaundice that develops during arspheamin treatment. They have had five instances of it among their 100 cases of chronic

syphilitic disease of the nervous system treated by their method of small frequent (every day or every second or third day) intravenous injection of 0.15 gm. of (French) neo-arsphenamin to a total of 30 or 50 injections. The drug was suspended when the jaundice developed in all but one case, and this case was the only one that proved fatal. In two of the five cases the drug was being given for some pathologic condition other than syphilis, there being nothing to suggest either inherited or acquired syphilis. Among the other arguments presented is that the azotemia slowly and progressively increases under the neo-arsphenamin and for some time after its suspension. A further argument is offered by Mbatucci's recent cases in which fatal hemorrhages followed a course of neo-arsphenamin, accompanied in one case with jaundice. These symptoms developed six weeks after the course (total dose 8.50 gm. in six weeks at five day intervals). Necropsy revealed acute yellow atrophy of the liver. They denounce Milian's assertion that the syphilis is responsible for the jaundice, and they point to their success with frequent small doses with never any signs of anaphylaxis, as the most reliable and harmless means for administering a given amount of the drug in a given period, far safer than by weekly injections. Milian replied to this by asking them to transfer to his service the next case of what they consider toxic jaundice. He reiterated that with the present technique there is no arsenical toxic jaundice; 95 per cent. of the cases are the work of syphilitic hepatitis roused from slumber by inadequate treatment. The other 5 per cent. are exceptional coincidences, catarrhal jaundice, gallstones, etc.

**Different Forms of Nephritis.**—Hélouin expatiates on the importance for treatment of an exact diagnosis of the form of the nephritis, and lists nine different types aside from the tuberculous, syphilitic and pylonephritis forms. He outlines the treatment for each according as the kidney is or is not permeable for chlorids, urea or water.

**Chloro-Azotemic Nephritis.**—Hélouin applies this term to nephritis in which there is retention of chlorids and urea but not of water. The symptoms are slowly progressive lassitude, lack of appetite, headache, dyspnea on exertion and gastro-intestinal derangement, but no fever or chills. The dyspnea gradually grows permanent, and edema appears. The urine is scanty and contains much albumin but little chlorids or urea, and the blood pressure and the Ambaré constant are high. If the patient is allowed nothing but water for a time, all these symptoms subside in the mild cases. In the graver cases, acute pulmonary edema is liable to develop at any moment. It might be brought on by administering salt for the classic test of alimentary chloriduria. Treatment of this type includes venesection and drastic purgatives, restriction to water, and abstinence from milk, albuminoids and chlorids. As this form of nephritis improves, the azotemia subsides, but not until the urea content of the blood approximates normal does the chlorid content fall. The chloridemia seems to persist to defend the tissues against the azotemia. The edema persists as long as the retention of chlorids lasts. First the azotemia has to be got out of the way, then the chloridemia subsides, and along with this the edema. If the kidney is damaged too much for complete restitution the Ambaré constant and the azotemia figure keep high, and a new wave of azotemia is liable to entail fatal pulmonary edema.

- \*Surgical of Otorhinolaryngology Course. P. Sebléan.—p. 385.
- \*Laryngeal Meningitis. G. Roesenthal.—p. 397.

**The Otorhinolaryngology Course.** This is the first lecture of the newly founded *Clique otorhino-laryngologique* which has had a long period of gestation since its conception in 1907. A large pavilion at the Lariboisière hospital is devoted to the clinic, and Sebléan expressed his hope that it might attract students from at home and afar and prove not only a center for lively scientific activity but a *foyer d'unité confraternelle*.

**Influenzal Meningitis.** Roesenthal reports two cases in which recovery followed lumbar puncture with two cases

lavage. It was repeated four times in one case and eight in the other. The fluid is injected through the lumbar puncture needle in a cannula. The emerging fluid escapes between the needle and the walls of the cannula. By this means there can be no overpressure. He injected 100 or 200 c.c. of plain saline except that for two injections he added 5 c.c. of a 2 per cent solution of collargol. The fluid was opaque rather than actually purulent, and no bacteria could be detected in it.

Local Treatment of Tuberculosis. S. Sime.—p. 705.

Thrombophlebitis of Sinus Cavernosus. P. Gilberti.—p. 715.

Thrombophlebitis of Sinus Cavernosus. P. Gilberti.—p. 754.

Erythema Nodosum and Tuberculosis.—De Stefano tabulates the literature on the subject, and reports a case of nodose erythema which occurred in a 12 year old. The tuberculin skin test showed a positive reaction in every case, exceptionally pronounced in this. The feature that forms in response to the skin test is held to be abnormal in every respect with the nature of the tuberculin used.

One young Myositis. De Stefano reports a typical case of multiple myositis in a 12 year old in a girl of 8 with a positive tuberculin skin test. He discusses the nature of the disease and its relation to the tuberculin test, and the fact that the tuberculin skin test is normal in every instance except in the tuberculous form. He queries whether a localized tuberculous myositis might not be responsible for the cases of Pernion that are regarded as a factor in cancer. He concludes that the disease is a disease without results. The tuberculin skin test is positive death generally occurring in consequence of metastases of the vocal cords and secondary in those cases in which the tuberculin test is of the type. The tuberculin test is the extreme range.

Pernicious Anemia in Infant. In this and in three cases previously published by the author (Mar. 1913), the aplastic

anemia accompanied inherited syphilis; plus tuberculous in one case. The anemia seemed to be secondary in all.

\*Preventive Vaccination against Scarlet Fever. L. Spolverini.—p. 1081.

\*Obstruction of Intestines by Clump of Ascarides. G. Aperlo.—p. 1086.

Vaccine Prophylaxis of Scarlet Fever.—Spolverini writes from the children's clinic at Rome to confirm the development of specific antibodies in the serum of children inoculated with anti-scarlet fever serovaccine, made according to Di Cristina's technique (described in these columns, March 1, p. 687). He reports further that he constantly obtained a positive response to the deviation of complement test, applied with an alcoholic extract of recently desquamated scarlatinal scales. The ten children given the prophylactic vaccination mingled freely with scarlet fever children, some for as long as two months, and even wore the others' garments sometimes, but none contracted scarlet fever. Their blood showed the constant presence of the antibodies. He ascribes the success of this preventive vaccination to the active immunity conferred by the scales rather than to the passive immunity from the serum from the scarlatinal blood. He is now engaged in research to verify this assumption.

Obstruction of Intestines by Clump of Ascarides.—Aperlo removed a mass of sixty ascarides from the ileus. The intertwined helminths had completely obstructed the bowel in the boy of 7. The loop of bowel was sutured to the abdominal wall for fear it might be necessary to operate again, and this loop ulcerated, so that three months later this segment had to be resected. The ascarides may act by mechanically obstructing the lumen, or by irritating the bowel so that spasm is induced, which closes the lumen likewise.

Sept. 21, 1919, 26, No. 38

\*Hypertonic Solution in Treatment of Certain Bone and Joint Tuberculous Lesions. L. Durante.—p. 1105.

Treatment of Tuberculous Bone Lesions.—Durante has had charge of large numbers of tuberculous soldiers and he here expatiates on the fine results he obtained in 400 cases of cold abscesses. He filled them with a hypertonic solution to induce by osmosis profuse secretion of lymph and attract lymphocytes to the focus. The solution that proved most effectual was a 2.5 per cent. solution of magnesium chlorid in distilled water with 10 drops of liquor formaldehydi per gram, added when cold. It clears out the abscess, rinses and fills the cavity with this solution about every four days, using from 10 to 40 c.c. of the fluid.

Aug. 15, 1919, 26, Surgical Section No. 8

Modern Treatment of Gunshot Fractures and Wounds of Joints. R. Bompiani.—p. 249. To be cont'd.

Thrombophlebitis of Sinus Cavernosus. P. Gilberti.—p. 268.

\*Bone Complications of Typhoid. Umberto Tassone.—p. 274.

Thrombophlebitis of Sinus Cavernosus.—Gilberti reports the cure after multiple resections in a case of thrombophlebitis in a young soldier. It was evidently secondary to an infectious process on the lip, by way of the facial vein. The exophthalmos, chemosis, edema of the conjunctiva and optic changes in the fundus evidently resulted from the disturbance in the return circulation, but direct nerve damage was responsible for the paralysis of the third, fourth and sixth nerves, and the branch of the ophthalmic nerve that runs in the rear wall of the sinus. The general symptoms were mainly those of pyemia, while headache and slight delirium testified to meningism, and the extreme prostration suggested the typhoid form. In three similar cases he has encountered, two of the patients died in less than two days from the first symptoms. Operative treatment is the only resource, but healing is usually such a slow process that the eye on that side is irrevocably lost, as in the case described. Four operations were required and antistaphylococcus serum was given freely, with local measures. First the jugular vein was ligated after aspiration of 80 c.c. of blood, and later the facial vein, and veins in the scalp were resected or incised and cauterized as they showed signs of severe thrombo-

phlebitis. The man was in the hospital for three months. When he left he was in good condition except for the total blindness in that eye. Vision in the other was good.

**Bone Complications After Typhoid.**—Tassone comments on the predominance of young persons, between 11 and 20, among those that develop bone complications after typhoid. He suggests that the greater liability to bumps and knocks in the young may explain this. The bone complications may be merely pains suggesting rheumatism but terminating in spontaneous resolution, or there may be actual acute or chronic osteomyelitis, with suppuration, or a chronic form without suppuration, with a tendency to exostosis production. Months and years may pass before the complication develops, and any rise in the temperature after typhoid, especially during convalescence, should suggest the possibility of complicating bone disease. In a case described the young man had lively pains all over his body during convalescence from typhoid. The pains subsided in a few days except in the left ankle where a suppurative process developed. It spread to the knee, and the fistula in the ankle kept suppurating for a month. There was also pain in one ear and discharge for a month. The lids also swelled but returned to normal after two weeks or more, and the left eye was left totally blind. The crippling of the left leg entailed by the long suppurative process was corrected by an operation when the inflammation had entirely subsided. The multiple suppurating foci, the extensive and profound destruction of bone and the hyperplastic tendency thereafter were notable features of this case.

- \*Frequency of Cancerous Degeneration of Gastric Ulcer in Spain. L. Urrutia.—p. 579.
- \*Determination of Diastase or Amylase in Body Fluids. J. Luis Yagüe y Espinosa.—p. 586.

**Malignant Degeneration of Gastric Ulcer.**—Urrutia relates that in 17.7 per cent. of 158 cases of gastric cancer of which he has full records there was a history of stomach disturbances from three to fifty years before the cancer. In 20 per cent. the cancers had the aspect of an ulcer—cancer and 12.5 per cent. of the hard, boring ulcers showed signs of malignant degeneration. His personal experience, therefore, has been that from 15 to 20 per cent. of chronic callous ulcers develop cancer. He cites similar statistics from other countries; they range from Fenwick's 3 per cent. in England, to 80 per cent. at the Mayo Clinic, and 100 per cent. in Zenker's service in Germany.

**Determination of Diastase and Amylase in Body Fluids.**—Luis-Yagüe gives some tables for ready computation of the amount of amylase in the fluid being examined, and gives directions with which any physician can estimate the approximate content of diastase and amylase in the saliva, urine, blood and feces. He adds to 1 c.c. of the saliva or other fluid being examined from 0.1 to 0.5 c.c. water, using a set of test tubes and then pours in each tube 1 c.c. of a 5 per cent. solution of starch, cooked slowly until transparent. He interprets the findings with the different body fluids as a little iodine is added.

- \*Pathologic Anatomy and Clinic of M. Tuberculosis. F. Prado.—p. 111.
- \*Tuberculosis in Children. A. Muñoz y del Bravo Fria.—p. 115.

**Tuberculosis in Children.**—Muñoz y del Bravo Fria found tuberculosis in 195 of 3,000 children from 1 to 3 years old at a Madrid asylum and they examined 105 tubercular child cadavers. The tuberculin tests showed 6.3 per cent tubercular at this early age, and the tubercular cadavers formed 9.3 per cent. of the total. The thorax was primarily affected in the overwhelming majority. They encountered one case of unmistakable congenital tuberculosis. In only one of all the cadavers was the primary lesion in the intestine. They describe the clinical picture, and remark on the rarity of hemiptyosis in children. They observed it in only two cases.

- Roentgen Study of the Circulation in the Brain. A. Herrera Calmona.—p. 57.

**Topography of Liver and Right Kidney Tumors.**—Serés comments on the difficulty in certain cases in distinguishing between a tumor in the liver and in the right kidney. The liver may sag so that it may present in the lumbar region, or be in contact with the abdominal wall, and the kidney may likewise be in either of these positions. He gives a number of illustrations showing the conditions aiding to distinguish a kidney tumor from an extrarenal tumor, and explain the displacement of the liver liable with either.

**Abdominal Carcinomatosis.**—In Salgado's case the man of 45 died in four months from the first symptoms. The viscera and especially the liver presented cancerous degeneration to an unprecedented extent. The article is illustrated.

**Kidney Anomalies.**—Three large views are given of some kidney anomalies which might puzzle the surgeon. One kidney shows three large arteries. A specimen from another case shows egg-shaped kidneys with multiple arteries.

**Action of Stovain on Heart and Blood Pressure.**—The experiments on dogs reported confirm the action of stovain on the sympathetic nervous system. Nothing was observed comparable to the fall of the blood pressure in man under stovain. The blood pressure was not modified in the dogs, but small doses by the vein induced a negative chronotropic action in the heart, along with a positive inotropic action. Larger doses reversed this, accelerating the rate of cardiac contraction while weakening the force of the beat.

**Pneumococcus Peritonitis.**—Juaristi discusses some of the problems presented by pneumococcus peritonitis, especially the best way to drain. In four of his own ten cases the disease had been mistaken for typhoid, and the surgeon had not been called in till the third week. In some of the other cases puncture during the second week averted the operation, in others the pus spread to the wall outward to a growth. One girl had three of these spontaneous fistulae. This girl died, as also two of the adults, although ample laparotomy had apparently improved conditions the tenth day and the third week. He warns of the transference of this communicable form from the mother and the twelfth day. Then the symptoms flare up again unless the abdominal cavity is thoroughly drained. He experimented on his calaver and found that a hole 1/2 inch to the sacrum, through the greater sacrotuberous ligament, effectively drains the abdomen without injuring any of the viscera. He suggests the utility of draining in this way introducing a trocar from without or from within, working down from the sacrum at the lower inner margin of the greater sacrotuberous ligament in the right-hand fossa as preferred. With proper drainage thus effected the laparotomy incision might be avoided. His drainage tube

**CLEARING** of surface, as  
health measure, 1386—M  
**CLIFF FOOT**: See Talipes  
**COLIC** for physicians in Berlin, 1779  
Congress of International Infection,  
[Santos Fernández] 728  
**COEFFICIENT** of robustness, 711  
**COLD**, and comfort, [MacKay] 55—C  
social limitations to protect public  
health, 934 M  
**COLD**, method of treating atrophic  
rhinitis, [Benians & Hayton]  
729  
**COLLECTUM**, [Taylor] 795  
**COLITIS**, milk in, [Luis y Yagüe]  
729  
tuberculous, diagnosis of, 340—E  
tuberculous ulcerative, early renal  
diagnosis of, [Brown &  
Sampson] 477  
**COLLAGEN**, closed, 514  
renal administration in, 1533—E  
medical, description of, 523  
medical, existing and extinct, 507  
"COLLOSOL"™, an americal Eng-  
lish endorsement, 1218 E  
**COLOMBIA**, medical education and  
licensure in, 630—ME  
**COLON**, acute diverticulitis of trans-  
verse, colon with resection of  
bowel and recovery, [Vetlaeot]  
793  
and saline catharsis, 610—E  
**COLON**, Vaginal, 601  
cancer of, [Sherrill] 558, [Des-  
marest] 647, [Okinezy] 1859  
diffuse suppuration in walls of re-  
sected, ascending, without perfora-  
tion, [Henson] 1902  
dilatation of, congenital, [Carr]  
1312  
**COLORADO** medical news, 202, 1220,  
1419, 1761  
state board July examination, 1590  
**COLORADOANS**, immunity of, to  
pulmonary tuberculosis, [White-  
head] 1871  
**COMMUNICABLE DISEASES**: See  
Contagious Diseases  
**COMPENSATION** for both injuries  
and malpractice, 157—M  
**COMPLEMENT**, hemolytic, and anti-  
bodies in oxalated plasma and  
serum, comparative study of,  
[Watanabe] 721  
**COMPLEXION FIXATION**: See  
Siderosis  
**CONCUSSION** from severe explo-  
sions, [Chavigny] 561  
**CONGRESSES**, annual neurologic re-  
sults, 545  
First National Congress of Medi-  
cine in Spain, 297  
for physiotherapy, 921  
French Surgical, 593  
French Urologic, 703  
International Congress on Physiol-  
ogy, 703  
Latin American Medical, 208  
medical gatherings in Scandinavian  
countries, 924  
medical, in Chile, 777  
of French orthopaedists, 1793  
of French-Speaking gynecologists  
and obstetricians, 622  
of French surgeons, 622  
of Newfoundland internists, 1780  
of ophthalmologists, 1850  
of urologists, 1782  
on medical radiology, Italian, 350  
trennial of medicine, 1810  
**CONJUNCTIVA**, subconjunctival hem-  
orrhages, [Basterra Santa]  
1792, 947  
**CONJUNCTIVITIS** of fornix, [Santos  
Fernández] 800  
**CONNECTICUT** Homeopathic Medical  
Examining Board report of July  
Examinations, 593  
medical news, 992, 1220, 1368, 1775

**CONNECTICUT** social insurance com-  
mission, report of, 1092 ME  
state board July examination, 1174  
**CONSTIPATION**: See also Intestine,  
Stasis  
**CONSTIPATION**, catharsis a cause  
of, 1213—T, 1362 T  
chronic, and vagotomy, [Udaondo]  
346  
chronic, treatment of, [da Silva  
Mello] 457  
contraindication of catharsis in  
acute painful constipation, 1285  
1604  
diet with diarrhea of, [Roux] 617  
**CONSTITUTION**: See Tuberculosis,  
Pulmonary  
**CONSTITUTIONAL DISEASE**, children's  
pavilion for, [Peet] 202  
contamination of hands and other  
objects in spread of diphtheria  
and other infections, [Weaver &  
Murchie] 1921, 270  
epidemiology of, [Lindenberger]  
1389 ab  
hospitals for, 1560—E  
immunity of city bred recruits,  
916—E  
in Army, some lessons from ex-  
periences with, 900—E  
**CONTRACTS**, inability to take treat-  
ments contracted for, 1874 M  
**CONTRACTURE**, Dupuytren's, de-  
scription of operation, [L] 790  
reflex, and functional impotence,  
[Barbé] 1560  
reflex, and paralysis, [Chavigny &  
Boveri] 650  
**CONVULSIONS**, ENCE, normal, duration  
of, [Bridgman] 363  
**CONVULSIONS** after casting, [Blech-  
mann] 475  
in infancy and childhood, relation  
of, of epilepsy to, [Morse]  
139 ab, 571  
with high blood pressure without  
arteriosclerosis, [Auhertin] 798  
**COPPER**, normal, in toxicology,  
[Palet] 1909  
**CORPUS** luteum and ovarian ex-  
tracts, action of, on pupil of  
frog's eye, [Macht & Matsumoto]  
450  
luteum and ovarian extracts, phar-  
macologic study, with reference  
to contractions of genitourinary  
organs, [Matsumoto & Macht]  
358  
luteum extract in vomiting of pr-  
pregnancy, [Auhertin] 798  
Luteum if Hister-Wilson, de-  
cated, 607  
**CORTEJARENA**, Francisco, death of,  
610  
**COTARIN** salts (styptein and  
stypotin), omission of, from  
N. R., 1626 P  
**CRACKED** pot sound, superimposed  
on possible cause of,  
[Walsh] 1636  
**CRANIOPAGUS**, parietal, blood vas-  
cular system in, [Sonnberger]  
1245  
**CRANIOTOMY**, value of graft of  
bone, cartilage or fascia in  
closure of cranial defects caused  
by wounds in war, [Primrose]  
615  
**CRANIOTOMY** dural separator and  
bone elevator for, [Hanson] 875  
**CRANIUM**, cartilage implant in,  
[Bostes] 1742  
deformity, acquired, [Brett] 451  
extraction of intracranial and in-  
tracranial projectile, 350  
fracture of, by neurologic manifes-  
tations, [Widersky] 1469  
fractured, ophthalmalms following,  
[Arganatz & del Valle] 1909  
injuries, surgical intervention in,  
[Gott] 1909 ab  
meningeal hemorrhage after con-  
tusion of, [Catalina] 560  
steepic skull and springovella,  
[Leric & Le] 1041  
tuberculous lesion in, perforat-  
ing, [Roger] 1247  
value of graft of bone, cartilage  
or fascia in closure of cranial  
defects, [Primrose] 612  
value of wounds of brain and, [Grog-  
gion] 602  
wound, primary suture for [Chau-  
vin] 1807  
**CREATININ** of blood in nephritis,  
prognostic value of, [Myers &  
Katz] 1909  
**CREDULITY** and cure, [Peterson]  
177  
**CRESSY WILLIAM H.**, returns to  
1084 M  
**CRIME** insanity that is a defense to  
1084 M

**CRIMINAL**, responsibility, [Lavinle-  
Lavalette] 1647  
**CRIPPLES**: See also under Soldiers  
**CRIPPLES**, industrial service mutil-  
ated man can render, 758  
proposed national scheme for cri-  
ppled children, [Jones & Gridle-  
stone] 1554  
society for assistance of war cri-  
ppled, 125  
treatment of crippled children, 1713  
**CROUP**, influenza, [Lynch] 1239  
ab  
**CRYPTORCHID**, an undescribed dis-  
ease, [Bousfield] 4017  
**CUBA**, history of medicine in, [Cas-  
tellanos] 801  
**CULTURE MEDIUM**: See Medium  
**CULTURE LAC**, 767  
**CUPPING** glass test in eruptive dis-  
ease, [Dohelsitz] 70  
**CURIE**, and fertility, [Peterson]  
1737  
**CURETTAGE**, accidental perforation  
of uterus during, with laceration  
of small intestine, report of case  
with operation and recovery,  
[Williams] 1381  
with cancer of uterus, [Gonin]  
187  
**CURIE**, Mme., returns to Warsaw,  
1622  
**CYANOSIS**, arterial and venous oxygen  
saturation, and its rela-  
tion to, [Stadie] 638—ab  
factors involved in, 1216—E  
false, or erythrosis, [Lundsgaard]  
93  
primary causes of, [Lundsgaard] 936  
**CYCLOSPAN** eye, research on, [Van  
Duyse] 1963  
**CYST**, Echinococcus: See Echino-  
coccus  
**CYSTICERCUS** of vitreous, [de  
Schweinitz & Wiener] 1187  
**CYSTITIS**, drug, in typhoid, [Roger]  
64  
with hematurias, [Castaño] 1733  
**CYSTOCLE**, etiology and treatment  
of, [Neel] 1243  
**CYSTUR**, 019, further applications  
of, [Carre] 365

**D**

**DARIN'S SOLUTION**: See also Car-  
rel and Dakin Solution; Dicho-  
ramine—T  
**DAMAGES**, terms of judgment en-  
dorse requirements, 1746 M  
**DEAFISM**, [Vega] 566  
**DEAFNESS**, war, 268  
**DEBILITY** and atrophy, congenital,  
[Ehrlich & Kourilanski] 797  
**DEBRIDEMENT**, [Lewis] 477  
**DEDEREATION**, cerebral function  
in partially decerebrated rats,  
[Franz & Lashley] 722  
partial, retention of habits by rat  
after, [Franz & Lashley] 722  
**DEGENERATIONS**: See under Medical  
60  
**DEIOD**, honors to, 1580  
retirement of, 1171  
**DEIR FLY FEVER** or Pahvat Val-  
ley plague, 1687—ab  
**DERFELD** Water misbranded, 1459  
P  
**DEFECATION**, urination and men-  
struation by return, [Keen] 297  
**DEFECTIVES**: See Feeble-mindedness  
**DEFICIENCY DISEASES**, [Scala]  
1478  
pathogenesis of, and effects of de-  
privation of B" necessary food  
factors, [McGarra] 794  
**DEGENERACY**: See Feeble-minded-  
ness  
**DEGRESS**, honorary, in public  
health, 29 E  
**DEIRINE** endowment, 173  
**DEIRWARE**, state board June exam-  
ination, 61  
**DEIRBET'S "PIPE"** for general ana-  
esthesia by pharyngeal intubation,  
[Dubouffant] 1398  
**DEIRINGERS**, caring for, [Healy  
& Kroner] 1690  
**DELIVERE**: See Labor  
**DEMENTIA**, parietal, spirochetes in,  
[Hil] 11  
primary in twin, [Hoffert] 1471  
traumatic, [Brenn & Leifer] 1906  
**DEMYERIALIZATION**, treatment of,  
[Hoffmann] 1019  
**DEMO**, 114, death of, 61  
**DENTAL**, outfit, surplus sale of, by  
war department, 1622  
**DENTISTRY**, teacher and sister edu-  
cation of dental, 1081 M [T]  
111 867  
1084 M

**DERMATITIS**, exfoliative, [Ludy,  
Coggswell & Hunt] 1088  
exfoliative, due to arsenamine,  
[Latham] 114, [Jones] 1359  
factors complicating, hysterical  
neurosis, [Astrey] 1838  
oil, [Blum] 370, [Brox] 401  
ragweed, [Sutton] 1433  
**DEIRATOLOGY** and associated dis-  
orders of mucous membranes,  
[Focster] 653  
radium in, [Morrow & Lee] 9123  
**DEIRMOID** cyst in child, [Rumford]  
1604  
cysts, some urologic aspects of,  
[Quincy] 1045  
mediastinal, report of case, [Har-  
ris] 938  
**DEIRANTIS** Gout Pills, 213—P  
**DEIROCARMA**, false, [Guarini]  
477  
**DEIRITES** INSIPIDUS and pituitary,  
[Keunaway & Mottram] 67, 1615  
—E, [Lerehoullet] 1731  
and pituitary insufficiency, [Mara-  
non & Gutierrez] 1619  
in girl of 10 years from stand-  
point of endorbal involvement  
[Towle] 835  
pituitary treatment of, [Lerehoul-  
let] 1905  
visual disturbances in, in child,  
[Bameno] 1020  
**DEIRITIS**, MELLITUS, acidosis in,  
[L] 194, [Lobkowitz] 1963  
Allen's treatment of, [Eitz &  
Beck] 866  
bone complications of, [Bonorio  
& L] 1650  
control of acidosis in treatment of,  
[Soliman] 1310  
cost of food of diabetes in hospi-  
tal, [L] 1650  
dietetic helps in, [Dunk] 225  
duration of, [Heiber] 1736  
in infancy and childhood, [Abel-  
1] 194, [Lobkowitz] 1963  
juvenile report of 3 cases, [Hart-  
witz] 864  
lean, [Burkhan] 72  
milk, [L] 1650, 796  
pancreas of, [L] 1650, 1092  
prognosis and treatment of, [Carre]  
1252  
relation of exophthalmic goiter to  
diabetes and, [Williams]  
1092  
relation of pancreas to diabetes  
in rat, [Ervin] 1161  
results of, [L] 1650, 948  
results in modern treatment of,  
[Geyelin] 1202  
sugar content of blood in, [L] 1650  
blood, 1650  
**DEIRITIS**, blunders in, [Alvarez]  
365  
clinical, as compared with neuro-  
psychic findings, [Krisner & others]  
1906  
control and cost of modern  
1617 E  
erroneous, responsibility for, 58  
MI  
group medicine, 57, [Dew] 696  
ab  
mistakes in, reviewed for high thor-  
ough examination, [Dew] 696  
1906  
**DEIRPHAGIA**, anomaly of, with gas-  
tric and intestinal obstruction  
[Dew] 222 ab  
**DEIRRHEA** and arsenic treatment  
[Luis y Yagüe] 729  
and niacin, [Job & Hirtman]  
1017  
diet with constipation of, [Roux]  
647  
probably due to sphincter, [Dew]  
780  
sugar in formula for in infant  
1906  
summer blood culture in, [Wol-  
fson] 142  
**DEIRYASE**, determination of aniline  
and in body fluids [Luis Yagüe]  
1967  
**DEIRYRMY** in gonorrhoeal dis-  
ease, [L] 1650, [New] A V  
[L] 1650, [Herd] 1755  
in other five cases, 0 630, 124  
[L] 1650, [L] 142  
**DEIRYRMY** and gonorrhoea, [Luis  
Yagüe] 729  
**DEIRYRMY** in gonorrhoea, [Luis  
Yagüe] 729  
postoperative, [L] 1650, [L] 144  
1650  
**DEIRYRMY** in gonorrhoea, [Luis  
Yagüe] 729  
**DEIRYRMY** in gonorrhoea, [Luis  
Yagüe] 729
