Captain Clark, at that time attached to 1st Battalion, 60th Infantry, did, at Ponta Mousson, France, on September 25 and 26, 1918, render valuable services and show great devotion to duty and disregard for personal safety by establishing and maintaining a First Aid Station, which was constantly under heavy shell fire for about eighteen hours. At Sadeline Farm, from Oct. 14 to 17, 1918, Captain Clark again showed the same devotion to duty by remaining at the First Aid Station and attending to the wounded without rest or sleep for over seventy-two hours, and from Oct. 26, 1918, to the date of signing of the Armistice, he continually kept his First Aid Station in advanced position much of the time under heavy shell fire.

William H. Bishop, Lieut.-Col., M. C., U. S. Army, New York, who was appointed a chevalier of the Legion of Honor,

was invested with the honor in Washington, D. C., the ceremony being performed by General Colardet, Military Attaché of the French Embassy. The citation states that the proposition for the Legion of Honor is based on "exceptionally meritorious and conspicuous service with the base hospital at Orleans, France."

### HONORABLE DISCHARGES, MEDICAL CORPS, U. S. ARMY

NOTE.—In the following list, L. signifies lieutenant; C., captain; M., major; L. C., lieutenant-colonel, and Col., colonel.

#### ALABAMA

Ahnona—Kehatrick, L. A. (L.)  
Birmingham—Harris, C. S. (L.)  
Wilson, I. E. (M.)  
Winn, L. M. (C.)  
Camp Hill—Langer, W. T. (C.)  
D'Alton—Chaudron, P. O. (L. C.)  
Fitzpatrick—McLaurine, H. F. (L.)  
Fulton—Adams, B. F. (C.)  
Janson—Davis, J. H. (L.)  
Mobile—Jones, C. T. (L.)  
Perdue Hill—Broughton, W. E. (L.)

Toledo—Hatchett, W. C. (L.)  
Woodville—Hodges, R. (C.)

#### ARKANSAS

Bauks—Smith, S. (L.)  
Denville—Puel, T. J. (L.)  
Heber Springs—Matthews, J. T. (L.)

Little Rock—Bledsoe, E. P. (C.)  
Day, E. O. (L.)  
Gardiner, H. L. (C.)  
Jobe, A. L. (C.)  
Jine Bluff—Seales, J. W. (C.)  
Tevsiana—Dale, R. (L.)  
Walcott—Majors, W. M. (L.)

#### CALIFORNIA

Berkeley—Bull, E. C. (C.)  
Do—Dowling, S. R. (C.)  
Colfax—Robney, H. T. (C.)  
Los Angeles—Carter, R. A. (L.)  
Crak, C. W. (C.)  
Oakdale—Smith, C. E. (M.)  
Oakland—Kergan, J. T. (L.)  
Pomeroy, G. T. (C.)  
Pasadena—McMillan, E. H. (L.)  
San Francisco—Bell, J. L. (M.)  
Eaves, J. M. (L.)  
Gedney, F. M. (C.)  
Jones, R. A. (L.)  
Parkinson, R. H. (C.)  
Richland—G. H. (L.)  
San Gabriel—Chamley, O. D. (L.)  
Santa Cruz—Parker, C. H. (M.)

#### COLORADO

Denver—Dewey, A. W. (C.)  
Metz, C. W. (C.)  
Talbot, R. E. (M.)  
Van Meter, L. M. (M.)  
Fort Morgan—Clarke, E. R. (L.)  
Grand Junction—Stiles, F. N. (C.)  
Pueblo—Adams, E. S. (C.)  
Hein, G. E. (L.)

#### CONNECTICUT

Hartford—McManus, J. P. (L.)  
Therrien, E. J. (C.)  
Vernlund, C. F. (L.)  
Middletown—Burr, H. L. (C.)  
Naugatuck—Claffey, M. F. (L.)  
Woodford, C. N. (L.)  
New Haven—O'Shansky, A. L. (C.)  
New Milford—Day, R. S. (L.)  
Norwich—Donohue, J. D. (L.)  
Waterbury—Smith, E. L. (C.)

#### DISTRICT OF COLUMBIA

Washington—Bolton, B. R. (C.)  
Cousins, S. C. (L.)  
Ecker, L. C. (M.)  
Hall, C. L. (M.)  
Herschman, M. J. (L.)  
Ong, H. M. (L.)  
Parker, E. M. (M.)  
Fatten, W. F. (M.)  
Mariana—Campbell, D. C. (C.)  
Rice, E. F. (C.)

#### FLORIDA

Bethlehem—McCallister, A. (C.)  
Plus Creek—Dwyer, G. W. (M.)  
Jacksonville—Schlers, E. T. (C.)  
Lake City—Rivers, D. G. (C.)  
Leesburg—Randolph, T. L. (C.)  
Mariana—Campbell, D. C. (C.)  
Pensacola—Hixon, F. P. (C.)  
Tampa—Andrews, C. A. (L.)

#### GEORGIA

Agricola—Gibson, W. A., Jr. (L.)  
Athens—Swofford, J. H. (C.)  
Aulata—Dillard, J. A. (C.)  
Augusta—Oertel, T. E. (M.)  
Crawford—Deal, D. L. (C.)  
Lumpkin—Walton, M. C.  
New Holland—Maudlin, J. D. (C.)  
Pelham—Hill, R. A. (L.)  
Senosis—Tridley, J. A. (L.)  
Stapleton—Turner, J. P. (L.)  
Temple—Farmer, J. R. (L.)

#### IDAHO

Lewistown—Harris, F. T. (M.)  
Pocetello—Smith, C. T. (M.)  
Richfield Fitz, G. G. (C.)  
Troy—McCull, J. M. (L.)

#### ILLINOIS

Argyle—Farney, W. P. (C.)

### LONDON LETTER

LONDON, Sept. 24, 1919.

#### Racial Types of Man

At the annual meeting of the British Association for the Advancement of Science, Arthur Keith, president of the anthropologic section, gave an address on the "Differentiation of Mankind into Racial Types." The evolutionary machine as it is commonly understood, he said, does not supply a clue to the origin of the European, the Chinese and the negro. But nature has at her command a secret mechanism by which she works out the new patterns in the bodies of man and beast, a mechanism of which we were almost ignorant in Darwin's day, but which we are now beginning to perceive and to understand dimly. This is the internal secretions of the endocrine glands. The growth of the body may be accelerated, retarded or altered if one or more of five glands (pituitary, pineal, thyroid, suprarenal and interstitial glands embedded in the testis or ovary) become the seat of a functional disorder. The thyroid acts directly on the skin and hair, just the structures employed in the classification of human races. Abnormality, tumor, or disordered action of the pituitary gland, is associated with acromegaly, gigantism, eunuchoid condition of the body, or dwarfism. The pituitary is one of the main parts in the machinery of regulation of growth, and is directly concerned in determining stature, cast of features, texture of skin, and character of hair, all of which are marks of race. The Caucasian type shows the greatest predominance of the pituitary; the sharp face, strong superciliary ridges, prominent chin, hulk of body, and height of stature can best be explained in terms of hypophysial function. The interstitial gland of the testicles evidently plays a part in bringing about the robust manifestations of the male characters, and this sexual differentiation is more emphatic in the Caucasian than in the Mongol or negro types. The evidence of loss of suprarenal gland function, as shown in Addison's disease, leads to the inference that at least part of the function of these glands is concerned with the clearing away of pigment, and to their action may be attributed the fairness of skin in the European. Malignant growth of the suprarenals in children produces a premature sexual maturity with all its bodily characteristics, and a similar result follows disease of the pineal gland. Anthropologically the thyroid gland is perhaps the most important of all the organs of internal secretion. Apart from its immediate function in regulating the rate of combustion of the tissues which can be correlated with the selection and survival of human races, it has remoter morphogenic effects on growth and the shaping of racial characters. Cretinism, myxœdema, achondroplasia and mongolism are evidences of characters induced by the thyroid gland changes of disease, and the racial characteristics normally corresponding are dependent on the physiologic action of thyroid secretion. The endocrine glands thus possess a growth-controlling mechanism, and the respective parts played by each in its relation to the rest of the economy are dominated by hormones, which, according to the nature of the recipients on which they act, bring about the endless variety in the relative development of racial and individual features.

#### Germans Round-Headed

Dr. F. G. Parsons introduced a discussion in the anthropologic section on the "Racial Characters of the Modern Briton." He pointed out that there is still much difference of opinion as to whether or not the cranial index is a valuable clue to racial origin. There is a great weight of opinion in favor of the belief that there are three major racial types in the population of modern Europe, the Nordic, the Mediterranean and the Alpine. The latter is distinguished from the former two by a higher cranial index, that is to say, by the possession of a rounder head. The value of this distinction, as well as of others, such as the orbital index, which has been used to distinguish the Nordic from the Mediterranean, the value of stature, of eye color, and of hair and skin color, are all more or less in dispute. He believed that the cranial index was the most satisfactory test. He insisted on the contrast between the typical German population and that of the British Islands. Although there are pockets of round-headedness in Great Britain, the modern Briton has, on the average, the lowest cranial index in Europe. The Germans are typically round-headed. This

fact has long been suspected, but the Germans, in association with their pan-German views, refused to collect or to publish the evidence which showed the real facts. Methodical examination of German prisoners of war which he had been allowed to make revealed that even in Schleswig-Holstein the Germans were round-headed. As far as psychologic characters could be associated with cranial characters, he believed that the round head was slow, methodical and unwilling to take risks, and that the long head was adventurous, enterprising and imaginative.

#### A New Theory of Vision

Sir Oliver Lodge, at the Mathematical and Physical Science Section of the British Association for the Advancement of Science, outlined a possible theory of vision. A great deal, he said, is known about the ear, but little about the retina. Acoustic vibrations are of reasonable frequency, and the mechanism can respond to them; but no mechanism can respond to the ethereal vibrations at the rate of 500 million million a second. Something electrical or chemical is necessary. He suggested that, in the retina—perhaps in the black pigment—there are certain atoms which are stimulated into radioactivity by impact with waves of light of luminous frequency, and that those atoms, when they receive waves, accumulate energy of the right frequency, and stimulate the nerve. The eye is exceedingly sensitive to light, but not to any other kind of vibration. What he would like to do would be to take some of the pigment of the retina—though whether a dead eye would do or whether it would have to be a living eye he did not know—and put it on the electroscope, and illuminate it with red, green and violet light, and see whether it shoots off electrons which will stimulate the electroscope. It would be a very delicate experiment, but there are very delicate electrical instruments. If the electroscope should be stimulated, it would tend to show that the eye is an electrical organ making use of atomic energy.

#### Pearls in Tripe

In the report of the Liverpool Port Sanitary Authority, the medical officer of health (E. W. Hope) describes the discovery of small pearls in a consignment of frozen tripe from the United States. The tripe was being examined for undness, and there were found scattered over the surface of the mucous membrane of some of the stomachs certain pearl-like bodies of small size; these in certain cases were very numerous, and the impression was formed that they were the result of some parasitic infection. Specimens were forwarded to Prof. Johnstone, D.Sc., of Liverpool University, and the following is his report: "The material sent to me was imported tripe which had been cleaned, prepared and frozen. The pieces I examined contained hundreds of small, iridescent, pearl-like bodies about  $\frac{1}{16}$  to  $\frac{1}{8}$  inch in diameter. Sections were made, and these were seen to be true pearls or concretions of soft material (elastic connective tissue) with a very regular lamellar structure. Because of the distortion of the tissues caused by the boiling and freezing, it was difficult to make out much detail. The medical officer of health, however, was able to get fresh material (cow's stomach) showing similar bodies. These were true soft pearls embedded in the submucous coat. Each was surrounded by a cyst wall which consisted of flattened epithelial cells, and which appears to be the formative layer. No nucleus could be seen in these pearl-like bodies. I do not doubt, however, that they originated from very small parasitic organisms which may have been sarcosporidia, or perhaps eggs of some worm parasite. These intrusive bodies were probably carried in the blood stream, and became arrested in the capillaries of the submucosa of the alimentary canal. Irritation set up a fibrosis round them, which resulted in the establishment of a formative capsule depositing concentric lamellae of connective tissue round the irritant. The latter, whatever it may have been, is quite destroyed and unrecognizable in the specimens sent. No doubt the condition is the result of an infection. I have seen somewhat similar structures in fish, where the nucleus of the pearl-like body was recognizable as the egg or larva of a cestode parasite."

#### Marriage Pronounced Null on the Ground of Insanity

Wills are often disputed on the ground of insanity, but marriages scarcely ever. This case is therefore of interest. A gentleman had been certified as insane on and off for about ten years, and was detained in a private lunatic hospital. He became enamored of a housemaid there, who was dismissed for undue familiarity with him. He contrived to escape, and married the housemaid. He was then brought

an action, as guardian of his father, for the nullification of the marriage. A lunatic is not disqualified as such from entering into contracts. In order to upset a contract on the ground of insanity it is necessary that the madness should be of such a nature as would influence his mind in entering into it. In this case the judge held that the madness was of that character. He considered that the man "was suffering from erotic mania which influenced him and that he had not the judgment of a sane man when he went through the ceremony of marriage, nor did he recognize and appreciate the responsibilities of that particular marriage." There appears to be only one other case in which a marriage was pronounced null in recent years on the ground of insanity. It is more remarkable than the present case in that the husband was not recognized as being insane until some time after the marriage and, moreover, there was a child of the marriage at the time of the trial. The husband was a paranoiac. It was proved that his insanity existed at the time of the marriage and was of such a character as to disqualify him from entering into the contract.

### PARIS LETTER

PARIS, Oct. 2, 1919.

#### Homage to Laënnec

September 12, the centenary of the first edition of the epoch-marking work, "Traité de l'auscultation médiate," by René-Théophile Hyacinthe Laënnec, the inventor of the stethoscope, was celebrated at Quimper (department of Finistère). On this occasion, a palm wreath was placed at the foot of the statue of the celebrated physician which stands in Saint-Corentin Place, and a commemorative tablet was affixed to the house where he was born. On his burial vault at Kerlouarnec, near Ploaré, another tablet was added in the presence of delegations of the medical corps and the Société archéologique de Bretagne.

In reality, we are more than a year late in celebrating the memory of one of the greatest men of which France can boast. The fact is, it was May 1, 1818, that the first work of Laënnec on auscultation was published, and it was during the course of the same year that the two volumes of the *Traité* appeared.

#### Regulation in Regard to the Employing of Civilian Physicians by Military Authorities

The regulations affecting the army medical department of the interior provide for the eventuality of the requisition by generals in command of army corps, at the instigation of regional directors of the army medical corps, of civilian physicians, in order to assure proper service among the bodies of troops and in the military hospitals, in case there should be a lack of regular army physicians or of complement of assistants.

The necessities of the situation created in the army medical department by the demobilization of the front ranks of the medical corps have made it necessary to have recourse to the cooperation of civilian physicians, and, in this connection, the impropriety of the term "requisition" has been recognized and also the fact that the foregoing regulations are out of date; accordingly, the following order has been issued in their place:

In case of an insufficiency of medical, pharmaceutical or administrative personnel, resulting in the army medical department of the interior, physicians, pharmacists, dentists and administrative officers of the reserve or of the territorial army may be temporarily enlisted to meet the emergency. Provided military personnel and the necessary complement of assistants cannot be secured, appeal may be made, under such conditions as the minister of war shall establish, to civilian physicians, pharmacists and dentists. This appeal shall not be regarded as mandatory in principle, for requisition cannot be employed except in time of mobilization and in case of absolute necessity.

#### Remuneration of Civilian Physicians

Dr. Louis Mourier, undersecretary of state for the army medical department, has decided that civilian physicians employed as medicolegal experts in connection with applications for the granting of disability claims or retiring pensions are entitled to remuneration. A compensation of 5 francs for each man examined has been allowed such consultants, no matter whether the work performed was done at a special center established for that purpose or whether the preliminary examinations and consultations took place elsewhere. This sum pays for the physician's examination and likewise for the physician's assistance in drawing up the certificate or report that is made out following the consultation.

#### Advanced Courses in Pulmonary Tuberculosis

Three advanced courses in pulmonary tuberculosis will be given in Paris during the course of the present school year (1919-1920). Each of these courses will occupy six weeks. The first will begin, October 15; the second, April 15, 1920, and the third, June 15, 1920. The instruction given will be of an essentially practical nature and will include bacteriology, pathologic anatomy, physical diagnosis, laryngology, social hygiene and the administrative technique of dispensaries. The lectures and the work in the laboratory will come in the afternoon, and the mornings will be spent by the students at individual tasks in the hospital or in the dispensary in the services of the physicians conducting the courses.

The courses will be open to French doctors of medicine and to citizens of allied and friendly nations.

The Rockefeller Commission for the Prevention of Tuberculosis in France holds a limited number of scholarships, which are at the disposal of French physicians in charge of a medical service in an antituberculosis dispensary in France or who may be officially designated by the departmental or municipal authorities or local committees to take up the management of a dispensary.

#### Personal

A clinical chair of otorhinolaryngology has been created in the Faculté de médecine de Paris. Dr. Pierre Schileau, hospital surgeon and agrégé professor at the Faculté de médecine de Paris, has been chosen as the first occupant.

#### Preferential Milk Tickets

With a view to preventing the possibility of young children and the sick being curtailed in their milk supply, the coming winter, the prefect of the department of the Seine has decided to put in force again the system of preferential milk tickets, which was in force for a period of two years during the war and which, taking it all in all, gave satisfactory results. The representatives of the wholesale milkdealers, of the milk producers' associations and the retail milkdealers have expressed a readiness to take up again with the system. Posters will be put out indicating the formalities to be complied with in order to secure preferential milk tickets, which will entitle the holders to be supplied first in case there is ever a milk shortage.

#### The Transportation of Food Supplies

The committee appointed to study the question of ways and means in connection with the transportation of food supplies gave recently an outline of the plan decided on to secure the importation to France of 400,000 tons annually of frozen meat from foreign countries and 50,000 tons from the French colonies. Certain measures have been adopted, in accordance with the regulations of the national shipbuilding board, in order that the program of the shipbuilders may be in harmony with eventual needs.

#### Death of Prof. Louis Chevrel

The death of Dr. Louis Chevrel, professor of histology in the Ecole de Plein exercice de médecine et de pharmacie de Rennes, at the age of 70, has been announced.

#### Death of Dr. Galtier-Boissière

Dr. Galtier-Boissière, director of the *Larousse médical*, died recently at Barbizon (department of the Seine-et-Marne), at the age of 63. He is the author of numerous books, chiefly on hygiene and the diseases of the respiratory passages.

## Marriages

JACOB THORKELOSON, Anaconda, Mont., to Miss Frances Higbee of Deer Lodge, Mont., at Great Falls, Mont., October 1.

BENJAMIN MERRILL RICKETS, Cincinnati, to Miss Mary Elizabeth Holliday of Knoxville, Tenn., October 1.

FRANK LAMONT MELENEY, New York City, to Miss Helen Seelye Clark of St. George, N. B., September 17.

DELON RICHARD NOTBOHM, Warren, Ill., to Miss Matilda Heller Horn of Coplay, Pa., October 2.

ALTON BOWIE REDBICK, Sylvania, Ga., to Miss Lillian Causy of Savannah, Ga., September 21.

JULIUS ALBERT ROSSEN to Miss Florence Freund, both of St. Louis, recently.

## Deaths

**Edward Grahame Parker** ♦ Capt. (Med. Dir.) U. S. Navy, Harvard University, Medical School, 1898; aged 48; who was appointed in the Navy, Jan. 10, 1899, and whose sea service included tours of duty on the U. S. S. *Pensacola, Florida, Adams, H'cheeling* and *Buffalo*, and whose shore duty, Tutuila, Samoa, Annapolis, Md., and the U. S. Naval Hospital, New York; and who was then placed in charge of the Dispensary in the Washington Navy Yard; died suddenly in Washington, October 24, from cerebral hemorrhage.

**Max Feldman** ♦ Newark, N. J.; University of Pennsylvania, Philadelphia, 1898; aged 47; also a graduate in pharmacy; assistant to the supervisor of medical inspection in the public schools of Newark, and head of the medical department of the school clinic; physician in charge of the Elizabeth Avenue Open Air School and the open window classes; a member of the medical staff of Beth Israel Hospital; died at his home, October 8, from meningitis.

**Ira W. Porter**, Omaha, Neb.; University of Alabama, Mobile, 1892; aged 49; a member of the Nebraska State Medical Association; sovereign physician for the Woodmen of the World, since 1898; at one time acting assistant surgeon, United States Public Health and Marine Hospital Service; professor of hygiene, and lecturer on life insurance examinations in the John A. Creighton Medical College; died at his home, October 6, from heart disease.

**Charles Sanford Allen**, Rensselaer, N. Y.; Vermont Medical College, Woodstock, 1849; aged 95; during the Civil War, assistant surgeon of One Hundred and Twenty-Fifth New York Volunteer Infantry; coroner of Rensselaer County for nine years; president of the village of Greenbush, and first mayor of the city of Rensselaer; for eighteen years, school trustee, and at one time state commissioner in lunacy; died at his home, October 5, from senile debility.

**James Burry** ♦ Chicago; Northwestern University Medical School, Chicago, 1879; aged 66; for many years, chief surgeon of the Illinois Steel Company; and surgeon of the Elgin, Joliet and Eastern Railroad; who served as Captain in the Medical Reserve Corps, U. S. Army, and was honorably discharged, March 27, 1918; one of the pioneers in roentgen-ray work in the Middle West; was found dead, October 16, on the Illinois Central tracks.

**Thomas J. McCoy** ♦ Los Angeles, Calif.; Kentucky School of Medicine, Louisville, 1880; professor of ophthalmology in the College of Physicians and Surgeons in the University of Southern California; eye and ear surgeon to a number of railways; well known as a specialist on the eye, ear, nose and throat; died at his home, October 1, from angina pectoris.

**Stephen Olin Richey**, Washington, D. C.; Northwestern University Medical School, Chicago, 1886; aged 70; a specialist on diseases of the eye and ear; a member of the American Ophthalmological Society, American Otolological Society, and Congress of American Physicians and Surgeons; died at his home, October 8, from cerebral hemorrhage.

**Joseph Edwin Harris**, Marshall, Mo.; University of Missouri, Columbia, 1881; University of Maryland, Baltimore, 1883; aged 59; a member of the Missouri State Medical Association; assistant physician of the Missouri Colony of Feeble-Minded and Epileptics, Marshall; died in the Colony, October 11.

**Garvin Gilmore Weld**, Oldtown, Me.; Dartmouth Medical College, Hanover, N. H., 1889; aged 63; for three terms mayor of Oldtown; representative of Oldtown and Penobscot in both branches of the Maine legislature; died at his home, September 28.

**Cynthia A. Skinner**, Los Angeles, Northwestern University, Woman's Medical School, Chicago, 1890; aged 68; a member of the Medical Society of the State of California; was instantly killed, October 4, when her automobile was struck by a street car in Los Angeles, October 3.

**Charles Joseph Langlois**, Pittsfield, Mass.; Maryland Medical College, Baltimore, 1911; aged 31; for three years a member of the board of health of Pittsfield, and for a time its chairman; died at his home, September 30, from acute dilatation of the heart.

**Lafayette Hansen**, Galena, Mo.; Missouri Medical College, St. Louis, 1883; aged 61; a member of the Missouri State Medical Association; local surgeon of the St. Louis, Iron

Mountain and Southern system; vice president of the Southwest Missouri Medical Society; died at his home, October 2.

**George Leonard Wakefield**, Manchester, N. H. (license, New Hampshire State Board of Medical Examiners, 1897); a practitioner since 1882; aged 72; a veteran of the civil war; died in the Eliot Hospital, Manchester, October 3.

**Charles Clifton Brown**, Coker, Ala.; University of the South, Sewanee, Tenn., 1905; aged 40; a member of the Medical Association of the State of Alabama; died at his home, about September 16.

**William Adams Seibert**, Easton, Pa.; Boston University, 1885; aged 60; trustee of the State Homeopathic Hospital, Rittersville, Pa., and of the Allentown State Hospital; died at his home, October 7.

**William S. Thomas**, Woden, Tex. (license, Texas State Board of Medical Examiners, April, 1907); a practitioner since 1868; aged 69; died in a hospital in Naacogdoches, Texas, October 2.

**Robert Morton Wolfe**, Port Carbon, Pa.; Jefferson Medical College, 1913; aged 31; a member of the Medical Society of the State of Pennsylvania; died at his home, October 7, from influenza.

**Charles H. Anderson** ♦ Grand Rapids, Mich.; Detroit College of Medicine and Surgery, 1894; aged 42; died in Blodgett Hospital, Grand Rapids, October 6, after a surgical operation.

**Lewis George Smith**, Buffalo, N. Y.; University of Victoria College, Cobourg, Ont., 1885; aged 62; a member of the Medical Society of the State of New York; died at his home, October 4.

**Julius W. Alford**, Inverness, Miss. (license, Mississippi, 1890); aged 51; a member of the Mississippi State Medical Association; died in the Greenville, Miss., Sanitarium, September 17, from nephritis.

**James F. Aydelott**, McKenzie, Minn.; University of Louisville, Ky., 1878; aged 64; a member of the Tennessee State Medical Association; died at his home, September 16, from valvular heart disease.

**Sarah Catherine Martineau**, Brooklyn, N. Y.; New York Medical College and Hospital for Women, Homeopathic, New York City, 1884; died at her home, about October 9.

**John M. Toney** ♦ Vanburen, Ind.; Medical College of Indiana, Indianapolis, 1900; aged 48; while on his way to Marion, September 30, died from heart disease.

**Alonzo Thomas Park**, Gratis, Ga.; University of Nashville, Tenn., 1859; Southern Medical College, Atlanta, Ga., 1880; aged 86; died at his home, September 15.

**Henry August Dodin** ♦ New York City; Bellevue Hospital Medical College, 1882; aged 61; died at his home, September 29, from chronic interstitial nephritis.

**Samuel B. Wood**, Roan Mountain, Tenn.; Cincinnati College of Medicine and Surgery, 1891; aged 58; died at his home, September 17, from nephritis.

**Martin L. Dorman**, Taylorville, Ill.; Kentucky School of Medicine, Louisville, 1875; aged 79; died at his home, July 10, from inflammatory rheumatism.

**Thomas Irving Deacon**, Boston; Tufts College Medical School, Boston, 1906; aged 40; died at the home of his father in Cambridge, September 20.

**Charles E. Lamont**, Fairmount, Ill.; Rush Medical College, 1865; aged 82; for thirty years a druggist of Fairmount; died at his home, September 29.

**Edwin Mussina**, Austin, Tex.; Hahnemann Medical College, Chicago, 1872; aged 79; died in a sanitarium in Waco, Tex., September 30.

**P. N. Blackerby**, Falmouth, Ky.; Cincinnati College of Medicine and Surgery, 1876; aged 74; died at his home, July 12, from nephritis.

**Jeptha D. Knott**, Monticello, Ill.; Hahnemann Medical College, Chicago, 1883; aged 58; died at his home, September 12, from diabetes.

**Samuel E. Strother**, Salem, W. Va.; University of Maryland, Baltimore, 1892; aged 54; died at his home, September 25, from neuritis.

**Frank Ezra May**, Edwardsburg, Mich.; Rush Medical College, 1887; aged 53; died at his home, October 4, from cerebral hemorrhage.

**Nicholas Re**, Chicago (license, Illinois, 1889); aged 68; died at his home, October 13, from valvular heart disease.

**Albert Clemans Rhiel**, Lowell, Ill.; University of Illinois, Chicago, 1894; died at his home, September 28.

♦ Indicates "Fellow" of the American Medical Association.

## The Propaganda for Reform

IN THIS DEPARTMENT APPEAR REPORTS OF THE JOURNAL'S BUREAU OF INVESTIGATION, OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORY, TOGETHER WITH OTHER MATTER TENDING TO AID INTELLIGENT PRESCRIBING AND TO OPPOSE FRAUD ON THE PUBLIC AND ON THE PROFESSION

### P. PRESTO COMPANY

#### The Government Stops an Oregon Fraud

"P. Presto Company," also known as "The Presto Manufacturing Company" and "The Presto Company" was a mail-order concern operated from Albany, Oregon, by one Edward F. Lee. Lee is now in the penitentiary and the Presto Company has been debarred from the United States mails.

Lee's business was that of selling on the mail-order plan what he termed his "New Method Treatment for Sexual Weakness and Varicocele in Men." As a side-line he also sold through the mail certain remedies intended for women and sold "formulas" for making beer, whisky, ice and substitutes for meat and eggs! Under the name of "P. Presto Company" or "Presto Manufacturing Company" Lee got in touch with his victims by ways common to the medical mail-order faker, *viz.*, that of purchasing "sucker lists" from firms that make a business of selling names and addresses and by advertising in certain not-too-particular newspapers and magazines. A typical advertisement follows:

MEN OF ALL AGES — STOP GROWING OLD. You can recover and retain your youthful vigor and vitality without dangerous drugs and appliances. One New Mexico tells how. Send for free letter. The P. Presto Company, Albany, Oregon.

Those who answered these advertisements or those whose names Lee had purchased received a form letter in which Lee pointed out that his "treatment" was entirely unlike any other. Said he:

"Safe and sane and scientific, it is what every young, middle aged or old man should know, as our system will enlarge, lengthen and strengthen the organs, making the weak strong and the strong stronger and bring back the firmness of youth unlike any other method."

Lee further claimed that no matter what the cause of impotency nor how long the condition had existed, his "cure" was "rational, quick and lasting" and "would positively cure or benefit any case of weakness or loss of vigor." If the first letter failed to bring a response, a second letter was sent urging the recipient to take quick action and declaring that the price of the treatment was \$2.00 and would not be offered for any less. The letter concluded, however, with the statement that if \$1.00 was sent the "copyrighted new method" would be mailed and at the end of two months the recipient, if satisfied, could send in the other dollar.

Those who swallowed Lee's bait received a form letter containing his "copyrighted new method." The essential part of this letter read:

"So, to build up, to strengthen and increase the blood and nerve supply to the testicles, they should be stretched by placing one hand on each side of the scrotum (bag) above the testicles, and stretch them one centimeter away from the body, moving the hands from side to side in a swaying position while pulling.

"The above treatment frees the circulation in the many feet of arteries, veins, etc., and causes a strong flow of blood and nerve force to the parts. Stretch the penis the same way. Also stretch the skin of the scrotum strongly with the tips of the fingers. Above treatment should also be used for varicocele, but should be given quite gently 40, 1751.

"Should the impotency have been caused by prostate gland enlargement, insert the first (index) finger in vaseline or mild oil, and inserting the finger in the rectum, manipulate well the prostate gland, which lies right in front of the rectum and behind lower portion of the bladder."

The Government instituted action against this fraud and, on March 1, 1919, the United States grand jury at Portland,

Oregon, returned a true bill against Edward F. Lee charging him with using the mails to defraud in connection with the operation of this business. In June Lee was found guilty and sentenced to eighteen months in the United States Penitentiary at McNeil's Island, Washington, which sentence he is now serving. On Sept. 30, 1919, Judge W. H. Lamar, Solicitor for the Postoffice Department, recommended to the Postmaster-General that a fraud order be issued against the "P. Presto Company" and other names under which Lee did business debarring them from the use of the United States mail. The order was issued Oct. 8, 1919.

## Correspondence

### LIPOVACCINES AS INFLUENZA PROPHYLACTIC

Correction of Erroneous Statements in the Chicago Daily Tribune

To the Editor:—In the "How to Keep Well" section of the Chicago Tribune for Oct. 6, 1919, there appeared an article carrying the caption "Would Avert 'Flu' Attacks." This article is in some respects so misleading and reflects so seriously on the U. S. Public Health Service that I would request you to give this letter space in your columns.

The portions referred to read as follows (italics are mine):

There is considerable diversity of opinion as to whether vaccines need to be made from the local strains of bacteria. Since very few communities can get vaccines from local strains, they will have to use the standard strains or do without. Some state boards of health will furnish vaccines as they did last winter.

The question about lipovaccines is a difficult one to answer. The Public Health Service has refused to allow the commercial houses to sell lipovaccines. Some city and some state health departments will doubtless manufacture them and distribute them to their citizens.

The citizens who live in such communities are lucky. It looks as though other citizens will have to go without. The Army is supplying lipovaccines for the soldiers. They offer it to employees of the War Department. They have issued two favorable reports on lipovaccines as protective agents against pneumonia, one based upon thousands of vaccinations done at Camp Upton, and the other upon thousands of vaccinations done at Camp Wheeler. Not only are they behind it with their reports, but they are supplying it for the use of those for whose health they are responsible.

In civil life vaccination must be done at one sitting, or it will not be done at all. The people will not come three times at week intervals for injection. Therefore vaccination to be done at three sittings is not practicable. A great many people want to be vaccinated with lipovaccine. The commercial houses are willing and able to supply them with the vaccine. The Public Health Service will not let them.

The physicians who are dependent upon the commercial houses for their supplies will have to get along without lipovaccines. They can get the three injection vaccines. Some health departments will equip their physicians with the other kind.

The first statement objected to as inaccurate is the reference to the use of lipovaccines in the Army, the statement reading "The Army is supplying lipovaccines for the soldiers." The fact is that the Army discontinued distributing lipovaccine some months ago, and withdrew that which was outstanding.

It is also stated that the Army issued a favorable report on lipovaccines "based on thousands of vaccinations done at Camp Upton." This is incorrect. The fact is, as may be ascertained by a glance at the Camp Upton report (Cecil and Austin: *J. Exper. Med.* 28:21 [July] 1918), that a saline suspension vaccine was used. The reference to lipovaccine at Camp Wheeler is correct, so far as the preparation used is concerned.

The chief objection raised is to the coupling of the refusal of the U. S. Public Health Service to license lipovaccines with statements which imply that for this reason people are being deprived of a valuable prophylactic agent. The facts are that the U. S. Public Health Service has been and is conducting extensive clinical and experimental investigations of lipovaccines and is of the opinion that they are not now on a footing which makes them desirable for general use.

The lack at present of satisfactory potency and sterility tests for lipovaccines has led the bureau to decline to license such vaccines for interstate sale, and the evidence at our dis-

posal indicates that a saline vaccine containing pneumococci is at least as effective as an oil suspension of the organisms.

The U. S. Public Health Service has always made it a rule to license only such biologic products as are safe for general use, and within recent years has added the restriction that for original license satisfactory evidence of efficiency must be presented as well, if it is possible to secure such evidence.

Constructive and reasonable criticism is welcomed, but such an insinuation of failure of the service to perform its duties as is carried in the article referred to is unwarranted and unjust.

RUPERT BLUE, M.D., Washington, D. C.  
Surgeon-General, U. S. Public Health Service.

### A STETHOSCOPE OF INCREASED SENSITIVENESS

To the Editor:—Recently I thought of a means of making a more sensitive instrument out of a Ford or similar bell stethoscope by fitting a rubber diaphragm (such as the rubber cap from a packing strip test tube) over the bell of the stethoscope. These are inexpensive and serve the pur-

Diaphragm on bell of stethoscope, with retaining coiled spring.

pose very well. A more durable diaphragm might be made of vulcanized rubber, celluloid or metal with a retaining coiled spring of wire situated above the diaphragm on the bell, holding the diaphragm firmly in place against the bell.

JOHN B. DONALDSON, M.D., Lorain, Ohio.

### "SELF-SACRIFICE IN THE WARFARE AGAINST DISEASE"

To the Editor:—I have read with interest, pleasure and pride the editorial in your issue of Oct. 11, 1919, entitled "Self-Sacrifice in the Warfare Against Disease." It is impossible to honor too highly the nobility of the men who voluntarily, calmly, cheerfully jeopardize their lives in the conduct of an experiment undertaken to elucidate the obscurities of diagnosis and treatment: who do this with none of the inspiring features of battle and no prospect of being welcomed home as heroes if they survive, yet have had fully explained to them the risk they incur.

These men are heroes in the fullest and most beautiful meaning of the word, and we should know about them and publish to the world the story of their deeds. When such experiments are conducted on enlisted men ignorant of the exact nature of what is being done, and perhaps not appreciating the safeguards that it may be possible to throw around them, they show a sublimity of faith in science, a sublimity of love for their fellow men unequalled in any field of science and endeavor.

The annual report of the Surgeon-General of the Navy for 1919, now in press, contains the names of 138 enlisted

men of the Navy who should be remembered along with those to whom your editorial refers. When the influenza epidemic of 1918-1919 was at its height, certain experiments were carried out under the auspices of the Navy by Lieut.-Commander M. J. Rosenau, M. C., U. S. N. R. F., and Lieut. W. J. Keegan, M. C., U. S. N. R. F., and by Surg. Joseph Goldberger and Asst. Surg. G. C. Lake, both of the U. S. Public Health Service, to determine the mode of transmission of the disease. Of eighty-three enlisted men of the Navy experimented on at Boston, forty-seven gave no history of attack during the existing epidemic, and thirty-nine had never had any illness of this type in their lives. These men were inoculated with the blood of patients in the active stage of influenza, and with pure cultures of various organisms derived from influenza cases. Furthermore, both filtered and unfiltered secretions from the respiratory tract of typical *influenzal pneumonia* cases were used by spraying and swabbing to inoculate the noses and throats of the subjects. These subjects were also exposed for forty-five minutes each to infection by direct contact with influenza patients who talked, breathed and coughed into their faces. Somewhat analogous experiments, but on men who, though not previously exposed to influenza, had received inoculation with certain bacterial vaccines against the disease, were carried out simultaneously with the Boston experiments by Surg. G. W. McCoy, U. S. Public Health Service, and Lieut. DeW. G. Richey, M. C., U. S. N. R. F., on fifty members of the Navy personnel in San Francisco.

As has been stated, the experiments were performed when influenza was at its height, and the men who volunteered for them not only knew of its awful fatality but also had been witnesses of the demoralization and terror that beset communities and individuals as this public calamity garnered its thousands and tens of thousands of victims.

W. C. BRAISTED, M.D., Washington, D. C.  
Surgeon-General, U. S. Navy.

### PREVENTION OF INJURY TO PATIENTS BY FALLING FROM WINDOWS

To the Editor:—The article entitled "Fatalities in Hospitals Caused by Patients Falling from Windows (THE JOURNAL, Aug. 23, 1919, p. 604), tempts me to describe a scheme we have used in the More Hospital for a number of years to lessen the opportunities for delirious patients to escape from the hospital.

We installed a special enunciator in the main hall near the general service one. This special enunciator has a loud bell, differing in tone from the other. From this enunciator, concealed wires extend to a small copper plate in the baseboard near a corner in each room and ward. If a patient becomes delirious, his bed is rolled into the corner of the room or ward, and an electric mat about 3 by 5 feet in size is placed in front of the bed and connected by wires to the copper plate in the baseboard. Over this is placed a common rug. Any pressure, as a nurse or patient stepping on the rug, causes the bell attached to the special enunciator to ring, and is a warning to the nurses.

In a small hospital, especially, all nurses can be readily informed that there is a delirious patient in a certain room, and at the sound of the bell it is seldom necessary to go first to the enunciator to see where the call comes from. Our experience has been that the nurses are alert and respond promptly to this emergency call. I, myself, have been on the floor when the bell sounded, and have seen two or three nurses meet at the patient's bedside before he had time to leave the room. No delirious patients have escaped from the hospital or been injured.

C. W. MORR, M.D., Eveleth, Minn.

Medical Progress.—Hoppe-Seyler (1825-1895), in 1872, established the first laboratory of physiological chemistry. Von Recklinghausen (b. 1833) was studying the white blood cells, Weigert was staining bacteria with carmine, Ehrlich was staining blood. Obermeier had found the organism of relapsing fever.

## Queries and Minor Notes

## Medical Education, Registration and Hospital Service

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be printed. Every letter must contain the writer's name and address, these will be omitted, on request.

### HYOSCIN FROM HYOSCYAMUS

To the Editor.—Can you inform me as to the amount of hyoscin obtainable from one ounce of hyoscyamus?

W. K. McLAUGHLIN, M.D., Chicago.

ANSWER.—The alkaloid scopolamin (hyoscin) is usually obtained by working up the mother liquors from the preparation of hyoscyamin; but *Datura metel*, which contains about 0.5 per cent of alkaloids of which scopolamin is the chief constituent, would appear to be particularly satisfactory material from which to prepare this alkaloid.

The alkaloids of hyoscyamus consist chiefly of hyoscyamin, with a little scopolamin (hyoscin) and possible traces of atropin. The U. S. Pharmacopoeia alkaloidal standard for hyoscyamus is "not less than 0.065 per cent. of the alkaloids of hyoscyamus," but, as above mentioned, most of the alkaloidal mixture is hyoscyamin and not scopolamin. According to this standard, 1 avoirdupois ounce of hyoscyamus should contain not less than 28½ grains of the alkaloids of hyoscyamus.

The amount of scopolamin (hyoscin) in hyoscyamus is difficult to determine chemically. Its quantity being small, assays for it in hyoscyamus are not made commercially.

### THE PRESCRIBING OF ALCOHOL

To the Editor.—Kindly advise whether or not a physician is permitted to keep in stock alcohol for office use. If so, how can he secure it for this purpose, under the present law, and must he keep records? Kindly omit my name.

M.D., Columbus, Ohio.

ANSWER.—A physician may secure alcohol for professional use only by securing a permit from the collector of internal revenue of his district and giving bond to insure the proper use of the drug. A bond of \$100 permits the physician to have in his possession or in transit 20 gallons of alcohol. For regulations governing the prescribing of alcohol and alcoholic liquors, see THE JOURNAL for Oct. 4, 1919, page 1080. Permits and forms for bonds may be obtained from the internal revenue collector of the district.

### ASBESTOS JAUNDICE

To the Editor.—Does the manufacture or handling of asbestos ever cause acute or chronic jaundice in the workers with this material? Please do not publish my name.

S. L. I.

ANSWER.—We find no reports indicating that asbestos causes jaundice; asbestos does not seem to have attracted attention as a cause of any pathologic condition. It is rarely possible, however, that, like mineral wool, asbestos may be inhaled in the form of minute particles and give rise to cough and irritation of the lung which may lead to a pulmonary fibrosis.

### F. A. C. P. AND F. A. C. S.

To the Editor.—Would you let me know something about the American College of Physicians, and how one can become a F. A. C. P.? Does it correspond to the F. A. C. S.?

J. F. W. M., Brooklyn.

ANSWER.—Dr. Frank Smithies, Augustana Hospital, Chicago, is secretary of the A. C. P., and Dr. Franklin Martin, 20 N. Michigan Ave., Chicago, of the A. C. S. Write them for the desired information.

**The Infant and Prenatal Care.**—There is something so interesting, so human, so tangible, so dramatic about the new-born baby that we fail to realize that the condition of the baby at birth depends largely on the care of the mother before its birth. The pendulum is beginning to swing from babyhood to motherhood, and today we find that the first aid to the infant, the first prevention against injury, accident and disease at birth, begins from the time the mother becomes pregnant.—Jacob Sobel, M.D., *Monthly Bulletin*, New York City.

### COMING EXAMINATIONS

ARKANSAS: Little Rock, Nov. 11-12. Sec. Regular Board, Dr. T. J. Stout, Brinkley. Sec. Eclectic Board, Dr. Claude E. Laws, 803½ Garrison Ave., Fort Smith.

CONNECTICUT: New Haven, Nov. 11-12. Sec. Regular Board, Dr. Charles A. Tuttle, 196 York St., New Haven. Sec. Homeopathic Board, Dr. Edwin C. M. Hall, 82 Grand Ave., New Haven. Sec. Eclectic Board, Dr. James F. Hair, 730 State St., Bridgeport.

DELAWARE: Dover, Dec. 9-11. Sec. Regular Board, Dr. P. S. Downs, Dover. Sec. Homeopathic Board, Dr. H. W. Howell, 824 Washington St., Wilmington. Pres. Medical Council, Dr. Henry W. Briggs, 1026 Jackson St., Wilmington.

FLORIDA: Tampa, Dec. 1-2. Sec., Regular Board, Dr. Wm. M. Rowlett, Citizens' Bank Building, Tampa.

ILLINOIS: Chicago, Dec. 1-3. Mr. F. C. Dodds, Supt. of Registration, Springfield.

KENTUCKY: Louisville, Dec. 2. Sec., Dr. A. F. McCormack, 532 W. Main St., Louisville.

LOUISIANA: New Orleans, Dec. 1-3. Sec., Regular Board, Dr. E. W. Mahler, 141 Elk Place, New Orleans.

LOUISIANA: New Orleans, Nov. 4. Sec. Homeopathic Board, Dr. F. H. Hardenstein, 702 Machesa Bldg., New Orleans.

MAINE: Portland, Nov. 11-12. Sec., Dr. Frank W. Searle, 776 Congress St., Portland.

MASSACHUSETTS: Boston, Nov. 11-13. Sec., Dr. Walter P. Bowers, Room 501, No. 1 Beacon St., Boston.

NEBRASKA: Lincoln, Nov. 12-14. Sec., Dr. H. J. Lehnhoff, 514 First Nat'l Bank Bldg., Lincoln.

NEVADA: Carson City, Nov. 3. Sec., Dr. S. L. Lee, Carson City.

OHIO: Columbus, Dec. 2-4. Sec., Dr. H. M. Plattner, State House, Columbus.

SOUTH CAROLINA: Columbia, Nov. 10. Sec., Dr. A. Earle Boozer, 1806 Hampton St., Columbia.

TEXAS: Galveston, Nov. 18-20. Sec., Dr. M. F. Bettencourt, Mart, Texas.

VIRGINIA: Richmond, Dec. 9-12. Sec., Dr. J. W. Preston, 511 McBain Bldg., Roanoke.

### ORGANIZED MANAGEMENT OF A HOSPITAL

In an article under the title "The Duty of the Hospital Trustee and His Relation to the Staff," published recently, Mr. C. H. W. Foster, a trustee of the Massachusetts General Hospital, Boston, gives what he deems "a desirable procedure in the organization and management of a hospital." Mr. Foster says that formerly only the pauper was concerned with charity, but nowadays a broader view prevails—charity is a "gift in trust for promoting the welfare of the community." Each member of a community, rich or poor, should have access to the hospital equipment and organization, and it would be uncharitable to deny either rich or poor this privilege. This means that in planning the hospital plant there will be a building for people of means with luxuries to which they are accustomed, a building equally comfortable but less luxurious and expensive for people of moderate means, and a third building for the poor. The people of means will pay full price, the people of moderate means as much as they can, while the poor will pay little or nothing. Any profit made in one branch of the institution will be used to pay a deficit in another branch. By treating all classes in the community with the same medical organization, there is avoided the grading of the medical profession which might take place if the rich and poor had separately chartered hospitals. The trustee must see also that the best professional treatment that is in the physician is given to each and every patient alike, whether charity or not.

### HOSPITAL ORGANIZATION

Mr. Foster suggests three divisions for every hospital: (1) professional—treatment and direct care of the patients; (2) administrative—concerning housing, feeding and financial questions of the hospital; (3) educational—and scientific department.

The professional division will have: (a) a medical director; (b) a general executive committee; (c) a resident physician, and (d) staff nurses, orderlies, and the like.

**Medical Director.**—The medical director is appointed by the trustees, and is ex officio chairman of the executive committee, but without a vote. He should be expected to

concentrate all his professional activities at the hospital, and may receive a salary. He should be the principal adviser of the trustees as to medical policies, should represent the hospital on important medical occasions, and in general should concern himself with the medical progress and reputation of the hospital. He should have authority to order the resident physician or administrator to suspend any person or action until the matter can be referred to the executive committee or trustees. In regard to the professional activities of the hospital, he should not only be considered as having authority to investigate and interview, but should also be expected to do so—with the idea of cooperating as well as of becoming informed.

**Executive Committee.**—The executive committee should consist of two chiefs of the medical services, two chiefs of the surgical services, two special department chiefs, and a junior medical or surgical man. The latter member will hold the office only during his months of service, and the medical and surgical will rotate in filling the position. The medical director will act as chairman and the resident physician as secretary, without power of voting.

**Resident Physician.**—The resident physician should have the immediate superintendence of the medical and surgical departments, except as to the direct treatment of patients. He should admit and assign patients to the hospital, should have control of interns, externs, nurses orderlies and apothecaries, and in general should see that the rules of the trustees and the orders of the physicians as to the treatment of patients are carried out. He should give his whole time to the hospital, and will be paid.

**Administrator.**—The administrator should be appointed by the trustees, on nomination of their finance committee and treasurer, whose agent he will be in regard to all money matters and accounting. He should have charge of the plant, building operations, housing, feeding and purchasing. He should create a budget of income and expense, and keep the various department heads informed concerning their part in it.

**Staff.**—The trustees should generally ask the executive committee for nominations to staff positions, but should reserve to themselves the right to appoint any other candidate. As to the composition and duties of a staff, let us accept this form: There will be two medical services, each with its chief, and two surgical, each with its chief. One medical and one surgical will be continuous services; the others will be so-called clinical services, in which each participating physician will serve only a certain number of months per annum. The continuous service provides a better opportunity for research work and training, while the clinical service enables a larger number of men to get the hospital experience with time also to engage in private practice. To provide a living for the continuous service men, one plan is that they be given the preference in the allotment of patients of means and of the great middle class—both of which classes will pay a professional fee. In some just way the hospital should regulate the fees and collect them for these full-time physicians, and thus give them time for their professional research work. Speaking for the eastern part of the country, at least, Mr. Foster asserts that an ample living for all the continuous service and research men who might wish to work in the hospital is being lost through the failure of the hospitals to provide accommodations for people of moderate means. Hundreds of would-be patients who are suffering and avoiding treatment because they cannot afford the modern-day costs must be treated in some such cooperative way as is possible in a hospital, and in that way save professional time and other costs.

Experience seems to show, according to Mr. Foster, that it is good policy to fill vacancies on the staff by promotions, but not necessarily by seniority, and that the prestige of the hospital will fall under this plan unless the greatest care is taken in the selection of the young men and unless they are given opportunity and encouragement to develop. Answering the contention that this plan of promoting from within is liable to make a nonprogressive and self-satisfied staff and that it is stimulating to introduce new blood by an occa-

sional appointment from without, he believes that much of this stimulation might be obtained by inviting celebrated medical men to visit, lecture and operate, or that some sort of an exchange professor idea might be adopted similar to that in vogue between colleges.

**Educational and Scientific Division.**—This will include the various laboratories, roentgen-ray, and special investigation work, necropsies, record rooms, medical libraries, and the relations of the hospital to medical schools and other medical institutions. There will be a committee of men in the hospital who will study the welfare of the division and further its development. The chairman will be appointed by the trustees, and with others in this division, if continuous service men, should receive a living from the hospital. The medical director should be a member ex-officio of this committee or be in constant touch with its doings. He will find in this department the force which attracts the young men of greatest promise, and, through its discoveries, he may expect the making of a great reputation for the hospital.

**Personal Relations Between Trustees and Staff.**—The trustee should show firmness when needed, but should aid and encourage to an accomplishment the ambitions and efforts of the members of the staff. He must, with justice and consideration recognize that physicians and hospital people are human; that they are, as a rule, denied their fair share of money and recreation, and that their compensation lies largely in the success of their work. The trustee must establish standards which will create respect, which will make effort worth while, and then encourage all hands to forget themselves in the accomplishment. Then we shall have a real hospital both in name and in spirit.

## Book Notices

---

**CEREBRO-SPINAL FEVER: THE ETIOLOGY, SYMPTOMATOLOGY, DIAGNOSIS AND TREATMENT OF EPIDEMIC CEREBRO-SPINAL MENINGITIS.** By C. Worster-Drought, M.A., M.B., Captain (Temp.) R. A. M. C., Officer-in-Charge Cerebro Spinal Fever Ward, and Alex. Mills Kennedy, M.D. (Both. Price, 30 shillings net. Pp. 514, with 64 illustrations. New York: Macmillan Company, 1919.

During the past few years, much progress has been made in the bacteriology and treatment of epidemic meningitis. The excellent book now under consideration is based largely on the observations of the authors while in charge of the disease among the troops of an English military district. The recent literature is drawn on also, although one misses references to some recent American work, notably Herrick's study of general meningococcus infection. There are twenty chapters in all, and the various phases of epidemic meningitis are dealt with thoroughly and satisfactorily. The book is the best we have on its subject, and will be of great value to all who may have to deal with epidemic meningitis, whether from the clinical, bacteriologic and serologic, or epidemiologic point of view.

**MILK.** By Paul G. Heineman, Ph.D., Director of the Laboratories of the United States Standard Serum Company, Woodworth, Wisconsin. (Cloth. Price, \$6 net. Pp. 684, with 237 illustrations. Philadelphia: W. B. Saunders Company, 1919.

The foundation for this book was laid during a connection of thirteen years with the Department of Hygiene and Bacteriology of the University of Chicago, in which position the author conducted laboratory and lecture courses on "The Sanitary Aspect of Milk Supplies." The opening chapter is devoted to a brief but lucid review of the historical evolution of the dairy industry. There follow chapters which present in detail the physiology of lactation, and the physical and chemical properties of milk. The technical methods used in the physical and chemical examination of milk are described in detail, as are also those related to adulterations. There is a complete discussion of the sources and kinds of micro-organisms in milk. The subject of milk-borne infections is treated in a lucid manner with due regard to the relative importance of the different diseases. Separate chapters are devoted to certified milk, pasteuriza-

tion, and control of milk supplies. The economic aspect of milk is discussed. A valuable chapter on milk in its relation to infant feeding has been written by Drs. Isaac A. Abt and Abraham Levinson. The closing chapters deal with butter, cheese, ice cream and ices, condensed and dehydrated milk, and milk from mammals other than the cow. The value of the book has been much enhanced by the addition of a fairly inclusive bibliography at the end of each chapter. The entire book is profusely illustrated. This work should prove of much value to every one who is interested in the subject of milk, whether as physician, sanitarian, producer or student. The author has handled the topics from practical, first-hand knowledge; his experience as teacher and investigator has enabled him to make a well balanced presentation of his subject.

A TEXT BOOK OF UROLOGY IN MEN, WOMEN AND CHILDREN, Including Urinary and Sexual Infections, Urethroscopy and Cystoscopy. By Victor Cox Pedersen, A.M., M.D., F.A.C.S., Major, Medical Corps, United States Army. Cloth. Price: \$7. Pp. 901, with 375 illustrations. Philadelphia: Lea & Febiger, 1919.

The author states that this work is planned on a rather uniform discussion of the clinical side of the diseases included, for the benefit of students and general practitioners. A wealth of clinical details is offered, the presentation of which is facilitated by a large number of well selected illustrations; but it is not easy for the reader to reconcile himself to the method by which this material has been arranged. The discussion of general principles of diagnosis and treatment is placed in the middle of the book, after urethritis, acute and chronic. Cystoscopy and urethroscopy are explained in the twelfth and thirteenth chapters, while cystitis and urethrocystitis are discussed in Chapters II and III. The technic of nephrectomy is minutely described in the chapter on complications of urethritis, which is scarcely the place. The unevenness in handling the various topics is pronounced. For instance, hysterectomy indicated by gonorrhoeal infection of the uterus, hardly to be mentioned under urology, is extensively and minutely described, while the operative interferences for removal of the hypertrophied prostate are disposed of in a very few lines. The enthusiasm of the author concerning electrotherapy in urology will hardly be shared by the majority of his confrères. Inaccuracies, such as "Subphrenic abscess and perinephritis are infections," or "The symptomatology is acute, subacute and chronic," could have been easily avoided. The ponderous and involved language of the author is irksome. In view of the quality of most of the extensive material contained in this book it is unfortunate that a little more time was not taken to correct the defects of construction which have been mentioned.

## Medicolegal

### Ill Passenger Being Required to Change Berths

(*Pullman Co. v. Anderson (Miss.)*, 81 So. R. 276)

The Supreme Court of Mississippi had here an action brought by Mrs. Anderson to recover damages because, according to her allegations, when, some weeks after she had been operated on for a severe and critical abdominal trouble, she purchased a ticket for a certain lower berth from Colorado Springs to Memphis, Tenn., in a Pullman sleeping car in which she would have the companionship of a physician and of a trained nurse, she was required twice to take other berths, and later was told that the only berth that could be given her was in a car three cars back, which worried and prostrated her, until finally some women, seeing her condition, gave her their berth in that car and went to the other one; that she suffered great physical and mental pain, could not get much rest that night, and continued ill the next day. The court says that its members were equally divided on the question of the defendant's liability, but all agreed that, conceding liability, the verdict of \$2,000 that was returned in favor of the plaintiff was grossly excessive.

The decision is that, if a remittitur of all in excess of \$300 should be entered, the judgment of the court below would be affirmed; otherwise, it would be reversed and the cause remanded.

### Liability of Visiting Surgeon for Injury from Cast

(*Napier v. Greenzwieg (U. S.)*, 256 Fed. R. 196)

The United States Circuit Court of Appeals, Second Circuit, in affirming a judgment for \$7,709.57 against defendant Napier, says that the plaintiff, a boy 5 years of age, was a citizen of Russia residing in New York, and was admitted to a county hospital to be treated for bow legs. The defendant was a visiting surgeon on the hospital staff, but, as the visiting surgeons took turns in visiting the adult and infant wards, and the defendant was in charge of the adult ward when the operation was performed and the casts were put on the plaintiff, July 7, and the defendant did not see him until July 12, no fault was found, so far as the defendant was concerned, with what happened prior to July 12, when he first took charge of the case. The complaint was that, when it was apparent, July 12, that the cast or the bandages on the left leg were too tight and interfered with the proper circulation of the blood, as disclosed by the swelling of the toes and their cyanosed condition, the defendant prevented the opening of the cast and the bandages and their removal until July 16, when gangrenous conditions had set in which made amputation of the left leg a little below the knee necessary.

The ailment for which the plaintiff was treated was not of a serious nature, and a proper course of treatment thereof is not dangerous to the patient. But the treatment in this case made it necessary to amputate the left leg as stated, and this notwithstanding the fact that the experts had never known of an amputation which resulted from an operation for bow legs. So a jury might well conclude that, if in this case there was such an operation, some one was guilty either of negligence or want of skill; and the question the jury had to decide was to determine whether this defendant in what he did or did not do was at fault. There was evidence that when the swelling of the toes of the left foot, followed by cyanosis, was discovered the intern cut down the plaster around the toes and leg up a distance of 5 or 6 inches, and relief followed. But this was not sufficient, and the same conditions again asserted themselves. Thereupon the intern said that he cut the cast from the bottom to the top, and intended spreading the cast and cutting the bandages beneath, so as to eliminate the pressure from the leg; but, just as he cut the cast, the defendant appeared in the ward and told him to stop, and not to proceed further with it; and because of this order, which he was bound to obey as coming from his superior, nothing further for the relief or spreading of the cast was done until July 16, when the cast was removed by one of the defendant's assistants and a looser cast was applied. The defendant, however, denied that he directed the intern to stop the cutting, July 12, and testified that he himself proceeded to cut the cast at that time from end to end, and the bandages beneath, which he removed, having spread the cast apart like a trough. There was thus a direct conflict in the evidence, and it was for the jury, who saw and heard the witnesses, to determine what the truth was. It was said that the testimony on which the verdict was based was incredible, but, while it is the duty of a court to determine the competence of a witness, the credibility of the witness is for the jury.

The law is well established that a surgeon or physician attending a patient is bound by his contract to possess and to give the case such reasonable and ordinary skill and diligence as surgeons or physicians in similar localities and in the same general line of practice ordinarily exercise in like cases. Inasmuch as the surgeon's obligation is imposed by law, the law requires the same degree of care and diligence of the surgeon, or of the physician, when his services are rendered gratuitously, as when he receives compensation. So no question was raised in this case as to whether the child or his father was under agreement to compensate or had compensated this defendant for his services. In cases of

alleged malpractice, the burden is on the plaintiff to establish that the defendant failed to exercise the skill which the law demanded, or that in his treatment of the case he was guilty of negligence. He must establish this by a preponderance of the evidence.

Southern Surgical Association, New Orleans, Dec. 16-18.  
Western Surgical Association, Kansas City, Dec. 15-16.

### AMERICAN ASSOCIATION OF OBSTETRICIANS AND GYNECOLOGISTS

Thirty-Second Annual Meeting, held in Cincinnati, Dec. 17, 1919  
(Continued from page 1239)

#### Prenatal Care

DR. SYLVESTER J. GOODMAN, Columbus, Ohio: The average obstetrician thinks it more important to know the technic of applying forceps and of making cesarean sections than what constitutes prenatal care. Diet, to keep the baby small and its tones elastic, is folly.

#### Fundamental Repair of Partial and Complete Lacerations of Perineum

DR. ALBERT GOLDSPOHN, Chicago: All purse-string or figure of eight sutures that engage the levator structures, and also some structures in the outer portion of the wound or the skin are wrong in principle and poor in effort. Efficient union of the most important parts (levator and urogenital diaphragm) can be secured only by direct apposition without any intervening tissues, by means of direct and transversely placed buried sutures.

#### Median Episiotomy in Primiparous Labors

DR. JAMES A. HARRAR, New York: Median episiotomy is a simple operation of valuable assistance in preventing relaxation of the pelvic floor after labor, in shortening the second stage of labor, and in reducing the number of low forceps operations. It is better than the lateral incision, as it separates chiefly muscles in the raphe rather than in their continuity. Median episiotomy wounds heal better than lateral ones or spontaneous lacerations.

#### Incidence in Malignancy in Gallbladder Disease

DR. JOHN F. ERDMANN, New York: Among 1903 patients operated on, 224 had cholecystitis, and fifteen of these had malignant disease in the gallbladder. In thirteen cases the primary focus could not be demonstrated positively, but in the majority of these cases, the point of greatest involvement was in the neighborhood of the gallbladder. In all of the cases of carcinoma of the gallbladder recorded in this communication, stones were found in the gallbladder. I have found that interference with the gallbladder, unless a complete cholecystectomy can be done, is prone to be followed by a rapid death. An established diagnosis of cholecystitis predicates the possibility of occurrence of cancer, almost double that of the possibility of a mortality in case of operation.

#### Inversion of Uterus

DR. H. WELLINGTON YATES, Detroit: The greater majority of inversions are due to faulty technic. The cord should not be dragged down, Credé's method should not be employed indiscriminately; in no instance should the fundus uteri be so pressed down that indentation is made on it; Credé's method should not be employed except when the uterus is in contraction. This is highly important. The obstetrician should

remain with the patient until a firm uterine retraction has been established. The more recent the inversion, the more surely and safely can it be reduced.

#### Cesarean Section: Its Indications and Technic

DR. ARTHUR J. KEEL, Cleveland: In many small hospitals, without a well organized surgical staff, the technic is so poor that one must question a surgeon's right to subject a patient to this uncertain factor. My preference is to operate after labor has started. The cervical dilatation thus secured permits freer drainage, less movement in the uterine wound. When a patient has had one section for disproportion, the abdominal route should be chosen for the next delivery. If the first section was for any cause except disproportion, the patient should be in the hospital with competent supervision, and the method of delivery selected as circumstances may indicate. The repeated section is by no means so simple an operation as the first one. Adhesions are the rule. This incision for the second operation is best made lower down than the first and lateral to it, going through the peritoneum first at the lower angle. In this manner one usually enters the free peritoneal cavity at once and can deal with adhesions advantageously. It has been my practice to free the uterus thoroughly, but to leave the adhesions to the abdominal wall alone, if they present no special reason for interference.

#### Prophylaxis of Gestation

DR. ASA B. DAVIS, New York: Prophylaxis of pregnancy (prenatal care) means a supervision of the pregnant woman throughout the whole nine months of gestation. It means the giving of instruction to her as to her mode of life, clothing, her occupation, exercise, sleep, diet, the attention to hygienic care of her body, bathing, the avoidance of constipation, etc. The aim should be to anticipate and avert complications, and to detect them early if they do arise, while they are yet relatively unimportant and treat them.

#### Version

DR. IRVING W. POTTER, Buffalo: Among 1,010 women, version was performed 680 times. For delayed rotation of the occiput from either the right or left posterior position, there were 545 cases; four face presentations with the chin either anterior or posterior; prolapsed cord, nine cases; arm presenting, three cases; placenta praevia marginalis, eight cases. There were forty-three stillborn children, the total fetal mortality.

#### Cystic Ovary

DR. FRANCIS REDER, St. Louis: A cystic ovary is usually discovered in the course of an abdominal operation. Resection of the cystic area and puncture of the scattered cysts alone rarely cure the condition. Proper suspension of the organ to reestablish and augment its vascular supply, together with a well regulated hygienic management of the patient, may eventually effect a cure.

#### Chronic Oophoritis and the Cystic Ovary

DR. OTTO H. SCHWARZ, St. Louis: Chronic oophoritis necessarily means a chronic inflammatory process in the ovary. It is almost always a secondary disease, secondary usually to an infection of the tubes, and therefore most frequently of gonorrhoeal origin. Periovarian adhesions with sclerotic changes in the ovary are most characteristic. In my work, cystic degeneration of the ovary was found most frequently in cases of noninflammatory nature. In a considerable majority of cases there were no changes in the ovary which could be attributed to inflammation. Small round cell infiltration, one of the usual findings in chronic inflammation, was not in evidence.

#### Adenomyoma of Ovary and Rectovaginal Septum

DR. OTTO H. SCHWARZ, St. Louis: The tumor of the rectovaginal septum represents a new growth in its earliest stage and brings up the possibility of recognizing this type of tumor clinically at this early period. Only a few well described cases of adenomyoma of the ovary have been reported in the literature. Adenomyomas of the rectovaginal septum usually start just behind the cervix, and on manual examination one can feel in this region a small, somewhat movable nodule

scarcely more than 1 cm. in diameter. The rectal mucosa can readily be made to slide over the tumor.

#### Treatment of Vaginal Discharge

DR. GEORGE F. CHANDLER, Kingston, N. Y.: I treat ordinary discharges of the vagina by a so-called dry method. Six treatments are given. The first three treatments consist of swabbing the cervical canal with pure phenol (carbolic acid) and painting the entire vaginal mucous membrane with a weak solution of iodine, after which the vagina is packed with dry sterile gauze in sufficient quantity to straighten out all the folds. The last three treatments consist of the application of a powder made of equal parts of stearate of zinc, starch and boric acid, and packing the vagina with sterile gauze.

#### Buried Loop Operation for Shortening the Round Ligaments

DR. JOHN NORVAL BELL, Detroit: The usual median incision having been made, the round ligaments are brought out through a perforation of the abdominal wall, as in the Gilliam operation. A strip of fascia from one-half to 1 inch in width is cut transversely and dissected from the rectus. The fascial flap is drawn through the loop of ligament, replaced in its original position and sutured there. The loop of the ligament is buried beneath the fascia, and cannot escape to slide back into the abdominal cavity. The flap can be cut to accommodate the length of the loop.

#### Varieties and Treatment of Dysmenorrhea

DR. J. H. CARSTENS, Detroit: Dysmenorrhea is due to obstruction, to abnormal conditions of the membrane, to inflammation of the tubes, to pelvic adhesions, and to an aberrant action of one or more of the ductless glands. Treatment should consist of dilatation and the use of the stem pessary to make it permanent; abdominal section and removal of the tubes or their restoration; breaking up adhesions, and the use of preparations of ductless glands.

#### The Stem Pessary

DR. THURSON S. WELTON, Brooklyn: In the absence of infection, a stem pessary may be introduced, provided the patient refrains from sexual relations while the stem is in place, puts herself under constant observation, and reports to her physician at the first early indication of trouble. This pessary gives excellent results in properly selected cases of dysmenorrhea; otherwise my results with the pessary have been negative.

#### Bands in the Right Upper Abdominal Quadrant

DR. WILLIAM S. BAINBRIDGE, New York: The prone position often fails to give the surgeon an exact conception of the conditions present when the abdomen is opened. The reverse Trendelenburg will be of aid in arriving at an exact diagnosis. Frequently we must also make traction downward on the hollow organs so as to picture what would be the relations if the erect posture were assumed. Early adequate attention to bands and adhesions in the right upper abdominal quadrant often makes such operations as cholecystotomy, cholecystectomy and gastro-enterostomy unnecessary.

#### Short Incisions Versus Long Incisions

DR. ROBERT T. MORRIS, New York: In operative work we are to use as short incisions and as little manipulation of the tissues as may be safest for our purposes. The operator who is not very expert requires a great deal of room for his work. He must work by sight and through an incision perhaps several inches in length, whereas a most expert operator can operate through an incision 1, 2 or 3 inches in length. In other words, a very short incision is the one which on general principles gives the smallest proportion of toxic substance and the smallest degree of destructive nerve impulse. On the other hand, what I call the mackerel incision, such as one learns in the fish-shop, is the one that gives the greatest degree of shock. Therefore, it is very desirable to use the shortest incision possible for one's work through which he may work safely and comfortably in the interest of the patient.

#### Syphilis as a Cause of Delayed Healing in the Noninfected Abdominal Incision

DR. WILLIAM EDGAR DARNALL, Atlantic City, N. J.: In my experience I can find only three cases. Two patients were definitely syphilitic and the third probably so. This evidence is enough to suggest syphilis as one of the causes, at least, of delayed healing in the abdominal incision.

#### Cancer Significance of Mammary Adenoma

DR. WILLIAM J. GILLETTE, Toledo, Ohio: Adenoma of the primary type or stage in persons under 30 years of age may be removed together with their capsule and a wide margin of the adjacent stroma and a very favorable prognosis furnished; but in women over 30 years of age, even this type should be considered potentially malignant. Cases of secondary hyperplasia should be considered as precancerous; and while they do not require so extensive an operation as the removal of the underlying muscles together with the axillary glands, yet no portion of the mammae should be left. The tertiary type is fully developed cancer and should be treated as such. With all due deference to the conservative pathologist, clinical experience proves that so-called benign adenomas of the mammary gland are often anything but benign.

### INDIANA STATE MEDICAL ASSOCIATION

Annual Meeting, held in Indianapolis, Sept. 26-27, 1919

(Continued from page 1238)

#### Meningococcus Cerebrospinal Meningitis

DR. JOHN A. MACDONALD, Indianapolis: The mode of transmission and avenue of entrance of the organism are of prime importance. That transmission, owing to the extreme fragility of the meningococcus when removed from the body and dried or exposed to light, must be through the human host, is now well established; and since no other avenue of exit or entrance to the body but by way of the secretions of the nasopharyngeal tract is known, the conclusion seems unassailable that the perpetuation of meningococcus infection depends on the human carrier. The carrier problem in the U. S. Army was the subject of careful study and exhaustive research. The result of these studies emphasized the importance, first, of rigid isolation of all meningococcus infection, and if possible the identification of the type of organism present; second, the frequent making of nasopharyngeal cultures from all attendants and contacts; third, the isolation of all carriers discovered; and what is of the utmost importance, the frequent clinical observation of these carriers for symptoms of the disease, since a not inconsiderable percentage of the carriers are already in the incubation period. In addition to intravenous and intraspinal injections, the general principles of treatment should not be lost sight of, and morphin should be used freely to combat pain and restlessness. The abundant administration of water at frequent intervals is particularly essential.

#### Meningitis: Neurologic Manifestations

DR. CHARLES D. HUMES, Indianapolis: I wish to refer especially to the undifferentiated group of cases of idiopathic epilepsy in which the history usually reveals nothing of importance, except, perhaps, gastro-intestinal colic in babyhood which seemed to provoke spasms. Because of the similarity of the spinal fluid in chronic meningitis and epilepsy, so-called, I further associate the two conditions. There is one indisputable fact in both cases, namely, that the cerebrospinal fluid in idiopathic epilepsy and in chronic meningitis does not reduce Fehling's solution. I am convinced that a very large percentage of our epileptics and mental defectives have been the victims in early babyhood or adult life of an intraspinal pathologic condition. So far as the neurologic symptoms are concerned, we can accept this general statement as a fact: that no part of the central nervous system is invulnerable to infection, so that as surely as the convexity or base of the brain is infected, any or all of the adjacent structures may be affected singly or col-

lectively with arrested function, producing any or all of the disturbances of the special senses, interrupting the reflex arcs, irritating the centers of motion, interrupting pathways of movement, and blunting or blocking the afferent pathways, interfering with the visceral functions, resulting in early or late, partial or complete loss of function in its entirety, and obscuring the entire clinical picture with a veil of mental cloudiness and profound psychic reaction.

## DISCUSSION OF PAPERS BY DRs. MACDONALD AND HUMES

DR. C. NORMAN HOWARD, Warsaw: After the meningococcus lodges on the mucous membrane of the nasopharynx in one who is not immune, it is thought that it passes into the blood stream and produces its havoc through that channel rather than up through the cribriform plate to the meninges of the brain, as was formerly the more general belief. I should like, therefore, to emphasize the need, in examining suspected carriers, of passing the cotton wound applicator through the nares clear back to the posterior wall of the pharynx. If the culture made from this secretion is positive, then the logical procedure is to isolate the carrier and eliminate from his nasopharynx the dangerous germs.

DR. A. C. KIMBERLIN, Indianapolis: When one is not able to diagnose the specific disease, and one lies in mind the nervous symptoms, one should not think they will present themselves in the same order, the same degree or with the same symptomatology, because they will not. A good laboratory is a great aid in diagnosis; otherwise, the patient should be isolated. There is only one means of prevention, and that is isolation.

## Active Mobilization in Joint Conditions

DR. E. B. MUMFORD, Indianapolis: The keynote of Willems' treatment is immediate, continuous, active mobilization. The joint is moved as soon as the patient has awakened from the anesthesia; it is moved as often during the day as the power of the muscles will permit, and even in the night the patient may be awakened to take his exercises; all motions must be made by the muscles controlling that particular joint, neither the surgeon nor nurse nor patient giving any passive motion. Drains into or to the joint are not used. The dressing is plain sterile gauze, arranged so as to give freedom of motion at the joint level. As soon as the patient has awakened from the anesthesia, the active mobilization is begun, and after that the success of the treatment depends on the patient. The pain is not the severe pain of an acutely inflamed joint, nor that caused by passive motions to break up adhesions. At the end of from twenty-four to forty-eight hours the pain is a negative factor, and at the end of a week the patient may be allowed to take a few steps each day. Fever is not a contraindication of active mobilization.

## DISCUSSION

DR. WILLIAM R. DAVIDSON, Evansville: I do not think that we can realize to what extent Willems' work is going to influence our ideas of mobilization in general. If it applies to one joint, then why not to all? Why not even to abdominal work in which there is pus?

DR. EDWARD D. CLARK, Indianapolis: This is the first time we have used rational treatment for infected joints, a treatment that will get rid of pus and prevent adhesions.

DR. GEORGE R. MARSHALL, Kokomo: While it is a great thing to be able to secure a movable joint, sometimes it is a great nuisance. A painful, unstable knee joint is certainly worse than a stiff one. This point should be discussed before we put it in practice with private patients.

DR. H. O. BRUGEMAN, Fort Wayne: If one is going to use this method, one must have the patient within twenty-four or forty-eight hours after the injury. In regard to the future of these patients, one can always stiffen a joint, but nobody can get good mobilization of a joint once it is stiffened.

DR. FREDERICK A. TUCKER, Noblesville: The time to use this method is as soon as possible after the injury, not late. If it is done early and kept up, one will have good results

**High Protein Diet Causes Bright's Disease.**—The experiments which form the substance of Newburgh's paper were undertaken with the intention of discovering whether nephritis will be produced when the kidneys have been eliminating an unusually large amount of nitrogenous material over a considerable period of time. To attain this end, rabbits were fed diets abnormally high in protein. The following results were obtained: Renal injury was very quickly and constantly noted in rabbits that ate several egg whites daily. Prolonged egg white feeding caused acute and subacute nephritis. When the nitrogenous metabolism was increased by means of casein, rabbits suffered no demonstrable renal injury from eating 15 gm. of casein daily; but when the daily intake of casein was 30 gm. and the nitrogen metabolism was about three times normal, a well marked deleterious effect on the kidney was produced. Rabbits that lived on soy beans for months regularly acquired chronic nephritis and frequently died of it. The nitrogen metabolism from this diet was about twice the normal. The renal lesion produced by feeding high protein diets was not caused by the passage of too much urea through the kidney. The data obtained by Newburgh suggest that the kidney injury is related to those digestion products of protein which vary both quantitatively and qualitatively with the type of protein eaten.

**Quinin Idiosyncrasy.** Two new cases of idiosyncrasy to quinin are reported by O'Malley and Richey. The hypersensitivity to quinin was acquired by these patients. In neither case could a similar familial tendency be elicited. The clinical manifestations were extremely suggestive of cinchousm, and it was found that neither individual reacted with any of the other common drugs where idiosyncrasies are known to occur. Furthermore, it was found that in one case the tolerance was somewhat less than 0.03 gm. quinin when given by mouth and in the other it was about 0.25 gm. quinin when given by mouth or intravenously in a 5 per

cent. solution. Both men failed to react clinically with the other alkaloids of cinchona, whereas the various salts of quinin produced a reaction in sufficient dosages. A method of desensitization described by Heran and Saint Girons proved efficacious in one case and increased the tolerance in another. The intensity of the cutaneous reaction was found to be in inverse ratio to the degree of desensitization obtained.

**Benzyl Benzoate in Protozoal Dysentery.**—The authors have employed benzyl benzoate in the treatment of eight cases of endamebic dysentery uncomplicated by bacillary infection, and have seen markedly good results in every case. All the cases were of the acute type and varied in severity. No ill effects on the alimentary or excretory tracts followed the administration of benzyl benzoate. In no case has the drug unfavorably altered the course of any case. On the contrary, its administration has always been accompanied by a marked alleviation of both the objective and subjective symptoms of the disease. It gives the patient much needed rest and permits him to sleep at night. Under the administration of the drug the endamebas disappeared from the stools in nearly every case as the general symptoms subsided. The benzyl benzoate we administered in a small amount of cold water, three times a day, after meals. The doses employed varied from 10 to 30 drops of the 20 per cent. alcoholic solution.

**Basal Metabolism in Hypothyroidism.**—Basal metabolism determinations were made by Means and Aub in three untreated cases of myxedema. All showed a definite reduction below that of normal individuals of the same age and sex. Similarly, the basal metabolism in an untreated cretin and in a case of cachexia strumipriva showed a marked reduction. In the latter case the fall in metabolism antedated the clinical appearance of hypothyroidism. In a case of carcinoma of the thyroid a moderate reduction in basal metabolism was found, both before and after thyroidectomy without clinical evidence of hypothyroidism. The metabolism of all patients studied during thyroid therapy was readily brought to normal or above by the administration of thyroid extract. The authors emphasize that the determination of the basal metabolism forms a sound and convenient method for governing the dosage of thyroid preparations in cases of hypothyroidism, and furnishes a far better guide in this respect than does the clinical picture. It is also of value as a means of differential diagnosis in obscure cases. In the treatment of hypothyroidism, doses of from 3 to 4 grains of thyroid extract, daily, should be ample to bring the metabolism to normal in two or three weeks, and doses of from 1 to 2 grains daily should usually be sufficient to keep it here. Cases of cachexia strumipriva may require larger maintenance doses than those of spontaneous hypothyroidism.

**Relation of Neurocirculatory Asthenia to Hyperthyroidism.**—Was performed the Goetsch test in a series of twenty-one consecutive cases and comes to the conclusion that it is impossible to predict, from any of the criteria we have at present, whether or not any particular case of neurocirculatory asthenia is sensitive to epinephrin or not.

**Diagnosis of Early Hyperthyroidism.**—In Lueders' opinion the laboratory affords the most reliable means toward the recognition of early hyperthyroidism. The sugar tolerance test seems an important aid in the detection of borderline or early cases of hyperthyroidism. The epinephrin test did not prove, in the study of the cardiac neuroses, diagnostic of hyperthyroidism. It seemed rather an index of the sensitization of the sympathetic nervous system. Its value as a diagnostic test is increased when blood and urinary sugar estimations are recorded with pulse rate and blood pressure. Intramuscular injections gave best results. Tests for nitrogen loss and acidosis seemed suggestive as aids in the diagnosis of toxic hyperthyroidism. Further studies are being made to discover if borderline cases or early hyperthyroidism reveal such changes. Creatinuria did seem present in the thyroid disorder group, and when taken in conjunction with the other tests, was of value in the diagnosis of early hyperthyroidism.

**Recognizing Acidosis in Diabetes.**—Stillman describes the methods employed at the hospital of the Rockefeller Institute to detect as early as possible the development of acidosis and

to prevent its progress, and typical examples are given of the procedure and results with patients of each group.

**Heart Block.**—A case is reported by Brown of a child, 11 years old, with acute arthritis, who presents a typical sinoatrial block. Changes in heart rate and rhythm by vagus stimulation and by the administration of atropin are demonstrated. It was found that atropin in small doses will eliminate the arrhythmia without producing an acceleration of the heart rate. Electrocardiographic records accompany the report and illustrate the observations.

- Pathogenesis of Pachymeningitis Due to Nasal Operations. Report of Cases. A. B. Wessels, San Diego.—p. 383.

**Hypertension in Young Drafted Men.**—Marked cyanosis of the extremities is proposed by Alvarez as an important sign of hypertension or of the hypertensive diathesis. Alvarez regards hypertension as one sign of a hereditarily defective cardiovascular renal system.

**Amino Acids and Hypertension.**—In a study of hypertension, Breed says one must reckon with not only the amino acids, but with the bacteria concerned in intestinal putrefaction. During the past three years in making observations on the flora in intestinal putrefaction Breed found it possible to change the flora at will by changing the diet, and that coincidentally with a continuous carbohydrate diet there was a disappearance from the urine of the absorption products of putrefaction. Breed has made observations on a number of patients with varying degrees of hypertension. These observations consisted of daily examination of feces, daily study of body metabolism, together with functional tests of liver and kidney. Some of these patients had lowered kidney function, others had lowered liver function, some had both, while still others had neither, but all responded promptly to a carbohydrate diet by a lowering of the blood pressure and a lessening of the products of putrefaction. Proteids were gradually and carefully added, but only up to the actual body requirements, always watching the effect on the intestinal flora, providing for normal intestinal motility and keeping the carbohydrates so much in excess that they could not all be absorbed from the upper intestinal tract, thus insuring plenty of available suitable pabulum, for the necessary energy of the intestinal bacteria.

**Hypertension at Menopause.**—Cummings has found an increased blood pressure very frequently at the time of menopause. He says that every woman should have her blood pressure taken frequently during "the change," especially if hot flashes and nervousness are present. Marked relief of these symptoms have been obtained by the use of bromids and internal secretory extracts.

**Paralysis of Esophagus.**—McNaught reports two cases due to occlusion of the right posterior inferior cerebellar artery

probably the result of arteriosclerosis. He suggests that when confronted by a case of sudden inability to swallow, the syndrome of occlusion of the posterior inferior cerebellar artery, should always be kept in mind.

**Intensive Treatment of Meningococcic Meningitis.**—Twenty cases of meningitis are reported by Frick with a mortality of 15 per cent. Intensive intravenous and intraspinal treatment was used in all cases. The seventeen patients who recovered were well on discharge and able to do duty. All the cases were of moderate severity. Fifty-five per cent. of the men had a petechial eruption; 30 per cent. had a positive blood culture and 50 per cent. were unconscious on admission. Frick suggests that all patients with positive signs and symptoms of meningococcic meningitis should be given both intraspinal and intravenous injections of serum. Intraspinal injections of from 30 to 50 c.c. should be given every eight hours for six doses and then at less frequent intervals as needed. Intravenous injections of 100 c.c. after desensitization should be given every twelve hours for three or four doses and then every twenty-four or forty-eight hours as indicated by the condition of the patient and by the findings in the blood cultures.

**Hydrogen Ion Concentration of Pneumococci.**—Thirty-nine strains of pneumococcus comprising representatives of the various immunologic types were studied by Avery and Cullen. In the majority of instances these cultures were isolated directly from the blood or sputum of patients suffering from lobar pneumonia. Some of the strains were tested immediately on isolation, others after years of cultivation on artificial media. Most of the strains were pathogenic for white mice and had been passed through these animals to enhance virulence. Cultures used for inoculation of the test medium were grown for eighteen hours at 37 C. in plain meat infusion broth of  $p_{H}$  7.8. The authors found that the optimum hydrogen ion concentration for growth of pneumococcus is  $p_{H}$  7.8. In broth cultures growth of pneumococcus continues until a final hydrogen ion concentration of about  $p_{H}$  5.0 is reached, if sufficient fermentable carbohydrate (above 0.4 per cent.) is present. Apparently this acidity is sufficient in

itself to stop growth. If less carbohydrate is present in the medium growth ceases at a lower hydrogen ion concentration, apparently because of exhaustion of carbohydrate. If no carbohydrate is present save that extracted from the meat of which the broth is made (plain broth medium), growth initiated at  $p_{H}$  7.8 (optimum reaction) ceases at about  $p_{H}$  7.0. If bacteria free filtrates of plain broth cultures in which growth has ceased are readjusted to  $p_{H}$  7.8 and reinoculated with pneumococcus, no growth occurs unless carbohydrate is added. However, if bacteria free filtrates of dextrose broth cultures in which growth has ceased ( $p_{H}$  5) are readjusted to  $p_{H}$  7.8 and reinoculated with pneumococcus growth occurs. Cultures of pneumococcus with all the carbohydrates which were fermentable under the condition used, namely maltose, saccharose, lactose, galactose, raffinose, dextrose and inulin gave identical results in the rate of reaction changes and the final hydrogen ion concentration ( $p_{H}$  5.0) attained. The different immunologic types of pneumococcus, for the limited number of strains studied, behaved alike in fermenting the carbohydrates mentioned above.

**Cause of Resolution in Pneumonic Lung.**—The relation of the pneumococcus to the production of acid in culture mediums and the acid reaction of the pneumonic lung suggest that crisis and recovery may be due to local biochemical changes in the course of which the acid death point of the pneumococcus is reached. Evidence is presented by Lord of certain factors influencing resolution in pneumonia. Three fatal cases of pneumococcus pneumonia in the stage of gray or gray red hepatization furnished the material. Evidence is given of the presence in the cellular material obtained from the pneumonic lung of a proteolytic enzyme digesting coagulated blood serum at hydrogen ion concentrations of 7.3 to 6.7 and inactive at higher; i. e., more acid concentrations. In addition, evidence is brought forward of the presence in the cellular material from the pneumonic lung of a proteolytic enzyme splitting peptone to amino acid nitrogen. This enzyme is operative at hydrogen ion concentrations from 8.0 to 4.8, but most active at 6.3 or 5.2. These findings are regarded by Lord as having a bearing on resolution in pneumonia. During the course of the disease a gradual increase in the hydrogen ion concentration of the exudate probably takes place. With the breaking down of cellular material an enzyme digesting protein (fibrin) in weakly alkaline and weakly acid mediums may be liberated. With a gradual increase in the hydrogen ion concentration of the pneumonic lung the action of this enzyme probably ceases. An enzyme capable of splitting peptone to amino acid nitrogen is probably active during the proteolysis of the fibrin and further activated when the hydrogen ion concentration of the pneumonic lung is increased to within its range of optimum activity at a  $p_{H}$  of 6.3 and 5.2. By this means it may be conceived that the exudate is dissolved and resolution takes place.

**Pneumococcus and Hydrogen Ion Concentration.**—According to Lord and Nye, in the growth and death of the pneumococcus in fluid mediums containing 1 per cent. glucose, the production of acid is the most important bactericidal factor. One per cent. glucose bouillon cultures of the pneumococcus allowed to grow and die out usually reach a final acidity of a  $p_{H}$  of about 5.1. At a hydrogen ion concentration of about 5.1 or higher the pneumococcus does not survive longer than a few hours. In hydrogen ion concentrations of about 6.8 to 7.4 the pneumococcus may live for at least many days. In the intervening hydrogen ion concentrations, between 6.8 and 5.1, the pneumococcus is usually killed with a rapidity which bears a direct relation to the hydrogen ion concentration; i. e., the greater the acidity the more rapid is the death. Cloudy suspensions of washed pneumococci in hydrogen ion concentrations, varying from 8.0 to 4.0 show, after incubation, dissolution of organism in lower hydrogen ion concentrations than about 5.0. This dissolution is most marked at about 5.0 to 6.0. Some dissolution also takes place toward the more alkaline end of the scale. No dissolution occurs at the most acid end of the scale.

**Mosquitoes and Yellow Fever.** Experiments are reported on by Noguchi which show that symptoms and lesions closely resembling those of yellow fever in man may be induced in

guinea-pigs by the bite of female stegomyias that have previously sucked the blood of a yellow fever patient or of an animal experimentally infected with *Leptospira icteroides*. With mosquitoes infected directly from a yellow fever patient the infectivity seems to become manifest after a longer period of incubation than with those infected with the animal blood. In the former, at least twelve days are said to be necessary before they become infectious, and this hypothesis seems to be borne out by the author's experiments. On the other hand, the mosquitoes which were engorged with the infected blood of the guinea-pig were found to be capable of transmitting the disease within eight days after the feeding. This discrepancy may be explained by the fact that the number of leptospira existing in experimentally infected guinea-pigs is far greater than that in human blood. The frequency with which positive transmission by the stegomyia was obtained in both instances was very small, indeed, in view of the number of mosquitoes employed. It appears that even under natural circumstances the percentage of mosquitoes that eventually become infected with the yellow fever microbe by sucking the blood may be very small. To transmit yellow fever from a patient to a nonimmune person requires 0.01 c.c. or even less. Apparently a mosquito occasionally becomes infectious by taking up the one or two organisms which happen to be circulating in the peripheral blood of man, and it is these occasionally infected few which carry the disease. The development and maintenance of *Leptospira icteroides* are indissolubly associated with the blood constituent, the serum, and this is amply supplied by the blood sucking insect. The organism is one of the most fragile of all the pathogenic parasites and cannot survive the concurrence of other less fastidious organisms, such as bacteria. The comparatively aseptic body cavity of the stegomyia furnishes a secure shelter for the parasite, which undoubtedly penetrates the zone of safety as soon as it is taken into the stomach of the insect. Unlike many other parasites this organism is capable of penetrating the intact skin or a bacterio-proof filter, and hence it is probably an easy matter for it to pierce the tissue of the visceral organs of the mosquito. Whether or not *Leptospira icteroides* can survive, and multiply only in the body of *Stegomyia calopus* and not in other varieties or genera is yet to be determined. Another interesting fact with regard to the extrinsic life of this organism is that it can multiply steadily at a temperature from 18 to 37 C. The optimum temperature at which it remains viable for many months is 26 C. The climate in most of the tropical countries offers optimum conditions both for *Leptospira icteroides* and for the mosquito which carries and nourishes it.

**Megaoduenum; Hirschsprung's Disease.**—Carr's patient, a girl, 6 years of age, had been constipated for five years and had vomited for twenty-four hours before he saw her. The child was in a condition of shock; the skin was pale, the lips and fingers were cyanosed and the eyes were staring. There was dyspnea with gasping respiration. The temperature was 97.5 F.; pulse, 120. The abdomen was greatly distended and there was a constant involuntary discharge of feces. The child died eleven hours after admission. Necropsy disclosed a marked distention of the intestines, which was particularly evident in the sigmoid colon which was bent on itself. The wall of the upper part of the rectum and the lower part of the sigmoid colon was slightly calcified and the lining mucous membrane was very granular. There was hyperplasia of the mesenteric lymph nodes. A microscopic study of the tissue from this specimen showed a complete loss of mucous membrane, and in its place was a vascularized round cell proliferation of the submucosa. There was a corresponding hypertrophy of the inner and outer muscular coats.

**How to Wean the Baby.**—When weaning a baby, Graham says, it is always a safe plan to begin with cow's milk mixture which is considerably weaker than what would be given a healthy baby of the same age who had been raised on a bottle. A fair average would be to start the milk formula at about one half the strength of what would ordinarily be given to a healthy infant that was of the same age as the baby to be weaned. If the child can digest this, the formula can be increased cautiously. It is wiser, as a rule, not to wean the baby during the hot summer months. The change from the breast to the bottle during the heated term is very likely to cause gastro-intestinal disturbances. This, of course, would not hold true in the case of infants who are taken to a cool climate during the summer months. Always, if possible, wean slowly rather than rapidly. At first give one bottle feeding a day. If this agrees in the course of three or four days a second bottle feeding may be given. In this way the breast feeding can be discontinued gradually. A baby should be weaned if the mother has any disease which she may transmit to her nursing infant, such as typhoid, or tuberculosis, or if the mother has any disease which nursing might have a tendency to aggravate, such as nephritis, tuberculosis, or acute pneumonia; if the mother becomes pregnant or is suffering from some comparatively mild disease; if mastitis develops. In most cases weaning depends on the ability of the mother to nurse her baby. If the amount of milk secreted is not sufficient for the nutrition of the infant, additional feedings of cow's milk should be given. Nursing should not be prolonged much beyond a year simply because the baby is doing fairly well. Anemia, subnormal development and failure to gain in weight is a common rule in these cases. Graham believes that it is a wise plan, if a baby 9 months old is doing well at the breast to begin giving it one bottle feeding a day. Bottle feeding is a good thing because it trains the digestive organs of the infant to digest cow's milk and it makes weaning less abrupt.

Syphilis of Mouth and Pharynx. N. S. Weisberger, Sayre.—p. 805.

**Rectal Diseases in Children.**—Brav states that hemorrhoids are rarely observed in children. Prolapsus recti frequently occurs, polypos recti is not an uncommon disease and proci-dentia recti is frequent in children. Rectal hemorrhage in girls is often mistaken for vicarious menstruation. Anal fissure is more common in infants than in older children. Fistula in ano is a very rare affection in infants and children. Fecal impaction, or coprostasis is occasionally met with in children.

**Effect of Diet on Second Dentition.**—Sinclair claims that to improve the teeth of the future generations it will be necessary to begin with the pregnant mothers and supervise their diets so that they may have a well balanced ration in excess of their usual food requirements to the end that both mother and child may not lack needed nutrient for perfect growth and development. This careful dietetic oversight and management must follow the nursing mother and her child until weaning is accomplished, after which the child must be still further properly directed from the standpoint of diet. With the appearance of the deciduous or milk teeth, such

food as will require chewing should be given to the child. Dry crusts of bread, zwieback, toasted bread, the coarser cereals, meat and meat bones, and later, green salad leaves, cooked celery, spinach, peas, cauliflower tops, asparagus tips, string beans and apples.

**Phebotomus Nienie.**—Banks directs attention to a new species of the genus *phebotomus* as a serious factor in human existence in the Philippines and as a not improbable agent in disease transmission. The term "nienie" is the Tagalog name of a "tiny fly too small to be seen."

**Cultivating Dysentery Bacillus.**—During an outbreak of bacillary dysentery in Manila in 1918, the authors had an opportunity of subjecting the methylene blue eosin lactose plate to a practical test as to its suitability in the bacteriologic diagnosis of bacillary dysentery. The stools were taken at random from hospital patients. Each stool was plated directly on litmus lactose agar and on methylene blue eosin lactose agar. An equal amount of material was smeared on the surface of each plate. Of thirty-eight stools examined, thirty-three were found positive. While the lactose litmus plate gave positive results in twenty-nine specimens, the methylene blue eosin lactose plate gave positive results in thirty-two specimens. The time necessary for the detection of *B. dysenteriae* on this medium was much shorter as compared with the labor required to confirm the positive findings on the lactose litmus plate.

**Treatment of Deep Seated Inoperable Cancer.**—Superficial malignant growths, such as epithelioma, respond rapidly to roentgen-ray and radium treatment, while deep seated malignant growths do not. The reason for this, as stated by Beck and Warner, is that the skin, fat and subcutaneous tissues which usually overlie deep seated cancer are strong filters for penetration of the roentgen rays; they absorb most of the soft rays the roentgen-ray tube and allow only the hard rays, which is a small quantity, to penetrate deeply enough to reach the growth. Small quantities of radiation instead of destroying the cancer cell are apt to stimulate it to more rapid growth. Therefore, it has seemed to the authors that if the skin and all the overlying tissue and as much of the growth as is feasible are removed and a large area left entirely exposed, and to this field is then applied either the roentgen ray or radium directly, it may be possible to obtain similar results in treating deep seated carcinoma as are usually obtained in treating superficial growths. In other words, the problem is to convert the deep seated growth into a superficial one. Cases are cited.

**Scar Tissue Tumors of Mucous Membrane of Lip.**—Bloodgood reports six cases of scar tissue tumors occurring on the mucous membrane of the lower lip after the excision of a lesion there. These tumors apparently have no relation to the nature of the primary lesion, whether it be in the mucous membrane or in the submucous tissue. Apparently, they are more apt to occur in the first instance when the primary lesion had been treated with caustics, or when the wound has healed by granulation. In all of Bloodgood's cases, in spite of the fact that no cautery had been employed and that the area was excised with a sharp knife and that with few exceptions the wound healed by primary intention, slight indurations have always formed in the wound, and some have been painful. These cases seem to present the problem clearly and to settle the method of treatment—noninterference.

**Secondary Syphilis of Uterus.**—In Gellhorn's case the initial lesion was situated on the left labium minus near the clitoris. It had healed. The cervical mucosa showed, posteriorly, an oblong patch about 0.5 cm. above the external os. Two other, smaller and more nearly round patches lay to the right of the larger lesion, and a fourth patch could be seen on the mucosa anteriorly. The secretion of these patches, examined with the ultramicroscope, showed an abundance of very active spirochetes of the typical pallida variety. Except for a slight adenopathy of the neck and groins, increased left patellar reflex and sluggish pupils, there were no secondaries present.

**Suprarenal Rests in Hernial Sac Walls.**—In six cases of inguinal hernia occurring in children, MacLennan found small nodules, one-eighth inch in diameter, embedded in the wall of the sac near but not attached to the cord. The sacs in which these rests have been found have been with one exception typically so-called acquired ones, the exception being a congenital hernia, i. e., one where the tunica vaginalis and the sac were common. A specimen has not yet been found in the corresponding hernial sac of the female. On microscopic examination these nodules proved to be "adrenal rests."

**Diverticula of the Posterior Urethra.**—Bumpus reports four cases of this kind seen at the Mayo Clinic. He says that they are generally of the acquired type. Probably the most frequent etiologic factor is a previous perineal operation. They give rise to a definite syndrome; namely, incontinence, dysuria, interrupted micturition, perineal pain and pyuria. Since they may be associated with a normal bladder they

may easily be overlooked unless the posterior urethra is carefully examined.

**Resection of Esophagus for Tumor.**—In Bengolea's case the tumor was situated in the lower portion of the esophagus. A Torek's incision was made, the esophageal resection was begun at the cardia, following the usual technic for intestinal resection. The stomach stump was closed by a Lembert continuous suture. On removal of the tumor a wooden hobbin was placed in the esophageal opening and fixed by means of a catgut purse-string suture. The portion of the stomach pulled up into the thoracic cavity was opened at the point of least traction and as near as possible to the greater curvature, and was then placed in the esophagus in which the wooden hobbin had already been placed. The patient died thirty-seven days after operation.

**Technic for Neurorrhaphy.**—The principle of Bulkeley's procedure depends on the utilization of the scar tissue in the ends of the divided nerve for the release of tension on the actual line of nerve suture. These masses of scar tissues are split lengthwise once and one half is removed. The exposed portion of nerve ends are then brought in contact and sutured together. The scar tissue is sutured on the outside of the union, thus giving support.

**Cross Buck Mattress Suture for Closure of Difficult Peritoneal Incisions.**—When it is difficult to close a peritoneal incision owing to tension or thinness and friability of the peritoneum, Jackson uses a cross buck mattress suture. First, a simple transverse suture at the lower (or upper) end of the wound is tied. It is a continuous suture. The needle on the long end of the suture is now introduced from without inward about one-eighth to one-quarter inch above the primary suture. It passes obliquely forward and is brought from within outward, at a point about the same distance forward of the point of entrance. It is now brought backward to a point opposite the beginning and introduced on the opposite side from without inward. Again, obliquely it is advanced and brought from within outward one-eighth to one-quarter inch forward of the beginning point of introduction. It is now drawn taut and the next stitch is begun. It is thus an X or cross buck mattress stitch. Where there is much tension or a very friable peritoneum, a liberal bite of muscle may be taken in each stitch. When each stitch is drawn taut it is remarkable that it does not cut out. The peritoneum is also everted, leaving no raw surfaces on the inside.

**Marking Out Varicose Veins for Operation.**—Cooperall has found brilliant green, an anilin dye, in an aqueous solution, most satisfactory. The veins should be marked out the day before operation and let dry before the clothing touches them. At the time of operation they can be painted with one or two coats of iodine. The vessels will show beautifully through the coats of iodine, as green intensifies almost all colors. After the skin has been marked with the green, it is almost impossible to wash it off with alcohol, turpentine, ether, etc. It takes several weeks for the stain to wear off.

\*Intestinal Parasites of College Students. Y. Yasaki, M. Terada, and T. Fuzui.—p. 23.

Intestinal Parasites of College Students.—The authors examined the feces of 458 students for intestinal parasites. Three hundred and fifty-four, or 77 per cent., were found to harbor one or more kinds of parasites. The following parasites were found: *Ancylostoma duodenale*, 22 per cent. of cases; *Trichostrongylus orientalis*, 7 per cent. of cases; *Ascaris lumbricoides*, 38 per cent. of cases; *Trichocephalus trichirus*, 54 per cent. of cases; *Clonorchis sinensis*, 6 per cent. of cases; *Metagonimus yokogawai*, 6 per cent. of cases. The percentage of *Ancylostoma duodenale* gradually diminished among the students of the upper classes. The parasite carriers were found to carry from one to four kinds of parasites.

\*Treatment of Diaphragmatic Hernia. A. Schwartz and J. Quénu.—p. 162.

\*Catheterization of the Esophagus. J. Guizez.—p. 165.

Operation for Diaphragmatic Hernia.—Schwartz and Quénu have been making a special study of the best technic for correcting diaphragmatic hernia, and they expatiate on the advantages of an incision in the seventh inter-space, starting at the axillary line and continued down to the umbilicus. There is no need for rib resection. The incision is carried down deep enough to open the pleura and peritoneum. The cartilaginous margin of the thorax, to which the diaphragm is attached, is cut with scissors, and the incision resulting is continued in a straight line in the diaphragm to the hernia opening. Both the thorax and the abdomen are thus opened up. The organs that protrude into the thorax are readily recognized and reduced, the diaphragm sutured, the cartilage reconstructed and a drain left in the pleura if adhesions had to be broken up. The only drawback to this technic is the operative pneumothorax, but this is regarded as of not much moment nowadays. The article is illustrated.

Catheterization of the Esophagus.—Guizez declares that both for exploration and for mechanical dilatation, the catheter has proved its value for the esophagus almost as much as for the urethra. But of course the exceptional fragility of the walls has to be borne in mind, and more must not be demanded from this method than it is able to yield. The bougie should be of soft rubber with an olive tip, flexible, and softened just before use by dipping into boiling water for a few moments. He uses a No. 26 to 30. The patient holds his head vertical or bent forward a little, to even out the abrupt curve between the sixth cervical to the first two dorsal vertebrae. He breathes deep and if necessary pulls out his tongue. Once past the opening, the bougie drops down of itself; there is only possibly a slight resistance at the cardia. If the bougie is arrested, some obstacle is evident, and we can determine its site by measuring the exposed portion of the catheter. We know that spastic and inflammatory processes locate almost invariably at the inlet or outlet of the esophagus. If the bougie is arrested at an intermediate point, the chances are 90 per cent. in favor of cancer, compression from glands or tumors being comparatively rare. If the tip of the bougie is found bent back this suggests a calcareous formation. If the head is bent back, the catheter may get into the air passages by mistake, especially if there is paralysis of the larynx. The latter should be determined beforehand. Ectasia of the aorta, painful inflammation of

the esophagus, and recent caustic action are all absolute contraindications to the use of the catheter, also the suspicion of a foreign body. The attempt to dislodge the foreign body may have dire effects—he has seen some striking instances of this. In a recent case a long sharp bone had been driven into the mucosa of the posterior wall, only 1 mm. of it protruding, and the catheter had probably been a factor in this. In another case a small bone in the esophagus was driven by the catheter into the trachea.

\*The Tongue in Stupor. Chavigny.—p. 217.

\*Bone Ankylosis after War Wounds. M. Grosset.—p. 219.

Hysterectomy by Aseptic Section of the Vagina.—Gudín found at necropsy of women who had died from infection after hysterectomy that the infectious process was almost invariably a pelvic cellulitis; peritonitis was the exception. He ascribes this pelvic process to infection from the drain in the vagina, and seeks to obviate this by suturing at once the opening in the vagina. This renders draining unnecessary as a rule. If conditions require it, he drains through the abdomen by aspiration.

A Focus of Diphtheria in a Military Hospital.—A wounded prisoner presented wound diphtheria, and the nurse tending him and two men in the ward developed diphtheria. The surgeon who operated on the prisoner became a carrier and, on a trip later, diphtheria developed in persons he met in three different cities, and then his wife developed the disease.

The "Stuporous Tongue."—Chavigny applies this term to the aspect of the tongue in cases of stupor, muscular immobility, etc., all connected with pathologic mental states. The tongue is held pressed against the teeth immovably for such a long time that the teeth leave deep imprints on it. The thin edge of the front and sides of the tongue stands up in ridges corresponding to the spaces between the teeth, forming a mold of the hollows and projections. Psychiatrists are familiar with this "stuporous tongue," and the general practitioner will find it a corroboratory sign of something radically wrong in the psychic sphere.

Bone Ankylosis After War Wounds.—Grosset discusses from the clinical and medicolegal standpoints complete ankylosis as a sequela of war wounds.

Tendon Anastomosis to Correct Radial Paralysis. Manchère analyzes the various methods of tendon plasticity in vogue, and gives an illustrated description of the technique he had found most effective in treatment of war radial paralysis. The outcome is almost sure to be satisfactory if the operation is done before extensor tendons have lost their elasticity from being stretched too long, and if the fingers are exercised early

to keep them from getting stiff. He utilizes the smaller palmar tendon along with a little of the palmar aponeurosis for the anastomosis, reaching them through a broad horse-shoe incision and taking up a fold in the stretched extensor tendons to shorten them about 1 cm. The details of the technic are shown in an illustration.

**The Biometric Method of Estimation of Varicose Conditions.**—Mabille emphasizes the importance of distinguishing between true varices from insufficiency of the valves in the vein and false varices from merely vasomotor weakness or from endocrine disturbance, etc. This differentiation permits proper treatment. It is realized by systematically recording the blood pressure in the leg and arm as the subject stands, sits, and reclines, and as he holds the leg up in the air, and by recording the viscosity of the blood in relation to the blood pressure in these four attitudes. Mabille has thus examined more than a thousand persons, and has determined the standard findings in health and the interpretation of the abnormal findings, as he describes with instances of the various types of varicose disturbance. The cases in which surgical measures are imperative can thus be recognized at once, and also the cases which require weak and prolonged thyroid and pituitary treatment or sodium citrate to reduce the excessive viscosity of the blood. Subcutaneous injections of oxygen and physical measures are often useful adjuvants. He depends on the Pachon oscillogram for the maximal and minimal pressure readings, and commends this biometric method to every practitioner.

**Rapid Diagnosis of Diphtheria Bacilli.**—Debré and Letulle expatiate on the differential importance of Babes' polar granules, shown up by double staining, in true diphtheria bacilli. Their two years of experience with this method of differentiation has confirmed its precision and reliability. The pseudodiphtheria bacilli never show these granulations at the poles when stained by the technic described, which is a modification of Neisser's first method. The specimen is incubated at 35 C. for twenty hours and each loop of the culture is spread on two slides. One slide is treated with the Gram, the other after fixation by heat is covered with a solution made by dissolving 1 gm. of methylene blue in 20 c.c. of 95 per cent. alcohol, and adding 950 c.c. of distilled water and 50 c.c. of glacial acetic acid. The smear covered with this solution is heated until it begins to steam. It is then heated a second time, and is then left in contact for five minutes. It is then rinsed rapidly with distilled water and then is covered with the second stain for ten or twelve seconds and rinsed quickly in distilled water. This second solution is made by dissolving 0.50 gm. vesuvine in 250 c.c. of boiling distilled water, filtering while still boiling. The granules clustered at the poles of the bacilli, or only in some of them, show up a black oval, and larger than the body of the bacillus. In their 800 tests they never found these polar granulated bacilli except with true diphtheria and they always found them then. They warn that one other bacillus may present these granulations, *Bacillus cutis-commune*. But they never found this in the throat in any of their tests. It differs from the diphtheria bacillus further in attacking saccharose. In case of diphtheric lesions elsewhere than in the throat, it might be advisable to test a loop on a sweetened litmus culture medium to exclude this bacillus.

The Series of Mental Phases after Commotions. A. Barbé.—p. 414.

**The Clinical Characters and the Pathogenesis of Ulnar Claw Fingers.**—Pitres and Marchand give illustrations of different types of what they call *griffes cubitales*. The thumb and the index finger are normal, but the little finger, the ring and sometimes the middle finger are flexed to a degree to amount to a deformity. They have encountered 163 cases of the kind consecutive to war wounds. This vicious attitude of these fingers is a frequent but not a pathognomonic symptom of traumatic paralysis of the ulnar nerve. It develops in about 90 per cent. of the cases of ulnar injury, but it may occur even without injury of this nerve. The fingers are held in this position at first merely to avoid pain, and then the position becomes irremediable and incurable on account of the neurotrophic lesions which develop in the tissues around the joints. In other cases the deformity is primary, the result of the functional contracture of the fibers of the flexor longus added to the symptoms proper to the lesions of the ulnar nerve. There is also a group of false *griffes cubitales* from contracture of heterotraumatic origin, or cicatricial retraction, etc.

**Para-Osteo-Arthropathies.**—Certain clinical and radiologic findings with this complication of injury of the spinal cord have already been published by this trio of workers, and they now describe with illustrations several out of sixteen specimens of P. O. A. as they call this type of ossification in the tissues around a joint after injury of the spinal cord.

\*Tuberculosis in its Action on the Mind and Character. O. Amrein.—p. 1300.

Tuberculosis in Rodents. B. Galli-Valerio.—p. 1309.

**Action of Tuberculosis on Mind and Character.**—In this long study of the change in tastes and character under the influence of tuberculosis, Amrein warns among other things of letting the patients develop "thermometer-mania." One of his patients left the dinner table once to insist on having his temperature taken, and as the hot soup had warmed his mouth, the thermometer reading sent him to bed "very ill," expecting hemiplegia at once. Another patient routed out by a fire at night saved only his thermometer and fever chart. Amrein comments on the evils of excesses of all kinds in games, dancing, drinking, etc. A single dancing party or drinking bout may undo months of patient sanatorium treatment. One of his patients had a tuberculous cavity rupture during a lively dance, with fatal outcome. The long separation from home and occupation, the opportunities, he says, for *das Flirten* are reinforced, he thinks, by a direct stimulating influence from the tuberculosis toxins on the sexual appetite, especially at times of higher temperature. This applies particularly to patients with a long subfebrile temperature, 37.5 to 37.8 C., and they also seem peculiarly liable to irresponsibility in general. Many physicians have noticed how much more sensible their patients seem to act after recovery, their nervous system more stable. His plea is that the physician should pay more attention to the mind and character of the tuberculous, seeking to train and guide them. This of course can be accomplished best in a well managed sanatorium, and he reiterates that this is "terribly important" (*furchtbar wichtig*) in treatment, especially of pulmonary tuberculosis. Some patients do even better without the strict discipline of a sanatorium. The physician has to individualize and treat them psychologically.

\*Syphilis as a Factor in Chorea. P. Foti.—p. 579.

Hydronephrosis in Boy of Four. Nicola Iavarone.—p. 590.

**Inherited Syphilis and Rachitis.**—Camata relates that he has been studying during the last five years the possible connection between inherited syphilis and rachitis. There were 1,285 rachitic infants among the 10,000 that passed

through the children's clinic in that period, and 37.27 per cent. of the rachitic children had inherited syphilis. Excluding those with tuberculosis or chronic skin disease, there were fifty-eight breast fed infants in whom the rachitis seemed to be connected with the inherited syphilis, and the latter dominated the clinical picture. The set of symptoms described by Marfan (craniotabes, pronounced anemia, and splenomegaly) as characteristic of rachitis with inherited syphilis, was found equally pronounced in eighteen infants under 6 months old who seemed to be free from all inherited taints.

**Vaccine Therapy of Dysentery in Children.**—Borrello gives full details of twenty-four cases of dysentery in young infants and children up to 10 years old. The disease is more common in children than generally recognized, and seems to be graver the younger the child, and in the Shiga form, but the Flexner form is liable to prove fatal also, especially when secondary to other disease. Treatment is principally with the specific vaccine, and this is more effectual the earlier it is begun. Its efficacy is most striking in the Shiga form which without it is almost invariably fatal.

**Essential Enuresis in Children.**—Provincioli reviews the various theories that have been advanced to explain essential enuresis, and states that in eight out of ten children of this category roentgen examination revealed anomalies in the lumbar-sacral portion of the spine. In only two were these parts of normal aspect. The children with these anomalies did not show any other appreciable signs of degeneracy or only in a proportion much less than in adults. As the children usually outgrow the enuresis in time, he urges roentgen examination of their spines to see if it might not be possible to detect the nature of the anatomic changes which put an end to the enuresis. He protests against the assumption of dysplasia in the spinal cord or roots, as this would entail quite another set of symptoms, more in the line of neuralgia or paralysis.

**Pathogenesis of Chorea.**—Foti relates that syphilis was unmistakable in 13 out of the 17 cases of chorea given treatment at the children's clinic at Naples during the last five years. It was probable also in 3 others, and only one of the 17 children seemed to be entirely free from the taint in every way. He insists that this 95 per cent. must be more than the mere coincidence which Comby thinks it is. He regards it as a predominating influence in the pathogenesis of chorea as the principal predisposing factor, entailing such instability of the nervous system that the most diverse causes, infections, emotional stress or metabolic disturbance may bring on the chorea.

\*The Normal Intestinal Flora in Adults. N. Pane. p. 686.

\*To Enhance the Sensitiveness of Indicators for Acids and Alkalies. E. Pittarelli. p. 692.

Fracture of Anterior Tuberosity of the Tibia. R. Mosti. p. 693

Differentiation of Hysterical and Organic Anesthesia. A. Iappelli. p. 697.

**Toxic Action from Intestinal Flora.**—Páne is director of the Istituto di Batteriologia of the University of Naples, and he here presents comprehensive data confirming the presence in the intestines of toxic facultative anaerobic and aerobic bacteria which by their products may gradually in time thoroughly intoxicate the organism. This is especially liable when much meat is eaten. By modifying the diet, conditions may be so changed that the toxic bacteria no longer find the environment favorable for their proliferation, and the production of their toxic products ceases. This is the explanation, he continues, of the benefit from restriction to milk in chronic intestinal and liver disease. The milk in the diet favors the proliferation of the bacteria of acid fermentation, and these crowd out the toxic bacteria. Milk in itself does not seem to have any antitoxic action. He cultivated in milk some of the toxic bacteria and their virulence seemed to be permanently increased. All his patients were between 50 and 60 and all had indican in the urine. He does not place any reliance on yoghurt as, although this answers the purpose while the yoghurt is being taken, yet as the lactic acid bacilli do not form part of the customary flora of the

adult intestine, they soon die out when the yoghurt is discontinued. The acidophilus and the bifidus, on the other hand, are encountered regularly in human stools.

**To Enhance the Sensitiveness of Indicators.**—Pittarelli refers to the indicators for alkalies and acids and discusses their application to the qualitative and quantitative analysis of acetone.

August, 1919, 36, No. 674

The Delirium with Peruvian Verruga; Two Cases. Hermilio Valdizán. p. 263.

\*Trigeminal Neuralgia. M. Sixto Chávez. p. 273.

\*Remote Disturbances from Ovarioectomy. R. Mendoza. p. 283.

**Trigeminal Neuralgia.**—Chávez refers to cases of trigeminal neuralgia in which syphilis, malaria, anemia, tuberculosis, diabetes, gout or rheumatism could be incriminated as the principal factor causing the neuralgia. He describes also local and reflex trigeminal neuralgia, and reports a case in which supra-orbital neuralgia of long standing disappeared after removal of a fibromyomatous uterus. In another case the agonizing right supra-orbital neuralgia developed at the third month of pregnancy in an otherwise healthy woman of 30. As no relief was obtained from the usual measures, the whole of the right supra-orbital nerve was resected, but the pains continued with even greater intensity until delivery. Then the neuralgia vanished completely and the woman has been in good health since. Syphilis should always be suspected with neuralgia, especially when the pains are worse early in the night, a dull ache keeping up all the time with occasional paroxysms of pain, never very violent. If the neuralgia is bilateral, this in itself renders a syphilitic origin almost certain, even when there are no other symptoms from it. The co-existence of neuralgia elsewhere is also significant, as is the case likewise with lymphocytosis in the lumbar puncture fluid, with not very severe neuralgia. In the third stage of syphilis the neuralgia is usually due to mechanical irritation, and it passes from the phase of pain to that of paralysis and then to trophic disturbances. If treatment for the syphilis does not rapidly improve the neuralgia, some other explanation for the latter will have to be sought.

With a malarial origin, the almost constant localization in the frontal branch of the trigeminal is suggestive, and also the periodicity of the pains, sometimes accompanying or taking the place of the chill and fever. The neuralgia usually occurs mornings, at the same hour, and the region aches a little in the intervals, and there are liable to be vasomotor disturbances, conjunctivitis and epiphora. If quinin does not cure malarial neuralgia in three or four days, it does no good to keep it up indefinitely. Anemia is a frequent cause of neuralgia, especially trigeminal. "The nerve is shrieking for a more nourishing blood." The neuralgia in diabetes is

usually but not always symmetrical. When neuralgia resists all other measures, it might be well to try a course of anti-diabetic diet. With neuralgia in gout or rheumatism, tincture of colchicum or the salicylates are indicated; the neuralgia in these conditions moves about from joint to joint and may alternate with psoriasis or hemorrhoids or with the heart attacks. When alcohol or tobacco is an important factor, benefit follows their disuse. The trigeminal neuralgia with hysteria does not yield to the ordinary measures, including hydrotherapy, bromids, valerian, psychotherapy or electricity, while organic neuralgia usually is more or less modified by these. In the exceptional cases in which benefit has followed operation for hysterical trigeminal neuralgia, there has usually been some slight lesion in one of the branches of the trigeminal nerve, and the removal of the latter favorably modified the neuralgia.

**Remote Disturbances from Ovariectomy.**—Mendoza remarks that in Peru ovariectomy has always been associated with hysterectomy. He reviews the various disturbances that may follow castration, and describes the application of organotherapy, ovarian extract, corpora lutea, etc. The benefit sometimes observed after giving extract of corpora lutea may be due to the fact that the castration was not as complete as supposed, and that enough tissue had been left behind to regulate the function. This may explain also the success of certain ovary-grafting operations. In Peru, Carvallo has done some operations of the kind, and J. Voto Vernales has found ergot useful in warding off symptoms from ovarian insufficiency, especially the vasomotor disturbances. Juvenal Denegri has reported fine results from administering in successive two-day periods thyroid, pituitary and ovarian extracts in turn; others, from arsenic and mineral waters with arsenic and iron. Mendoza ascribes the benefit from these to the regulating action on the thyroid as the latter is always an important factor in the disturbances from loss of the ovaries.

Supracervical Vaginofixation. Rosendo Amor.—p. 109.  
The Lange Colloidal Gold Test. Jesús Arroyo.—p. 113.

**Cholecystostomy.**—Velázquez reviews two recent cases of cholecystostomy done for gallstones and one for empyema of the gallbladder. He extols the advantages of this simple conservative operation, for the debilitated and elderly in particular. Two other patients followed for years have never presented any further symptoms from their cholelithiasis since the cholecystostomy. As this operation is so simple, it can be done early and before the diagnosis is absolutely certain, thus saving many patients from becoming addicted to morphin to which they may otherwise be driven. It has the further advantage that it facilitates removal of gallstones later if this becomes necessary.

**Serotherapy in Typhus.**—Paz gave the serum by the vein once a day, and compares his tabulated results with those reported by others in which the subcutaneous route was used. There were no complications in any of the eleven cases, and recovery was rapid in all but one instance in which it was "slow." The disease was grave in all and the injections were commenced from the fifth to the ninth day. The serum used was a few hours up to 2½ months old. It was drawn from convalescents from ten to fifteen days after defervescence. The total injected ranged from 36 to 125 c.c. according to the clinical aspect of the case. The results obtained, he says, confirm and surpass those realized by Treille and Legrain in 1911.

**The Colloidal Gold Reaction in the Cerebrospinal Fluid.**—Arroyo's article is accompanied with four colored plates to show the minutest details of the Lange reaction as determined in sixteen cases. He gives charts showing the response in various conditions and especially in general progressive

paralysis, in which the test is most instructive. It is not definitely settled yet, however, whether the reaction occurs exclusively in this.

Heart Action and Nervous Disturbances in Schoolchildren. Alvarez Sierra.—p. 94.  
Iodin as an Alterant. A. Sobrino Alvarez.—p. 95.

**Vacuum Extraction of Cataract.**—Barraquer now has a record of 1,000 cases of suction extraction of cataract in the capsule, or *jacocrosis*, as he calls it. The suction apparatus is known as the *crisifaco*. Visual acuity of from 07 to 1 was regained in 69.4 per cent, and from 0.3 to 0.7 in 24 per cent. Simple extraction was realized in 219 cases; in 530 the periphery of the iris had to be slit, and in 251 iridectomy was necessary. There was luxation of the crystalline lens in 3 cases and infection in only 2 of the 1,000. He does not include in this series the cases of his first tentative period. His method was described in THE JOURNAL, Dec. 8, 1917, p. 2006.

**Heart and Nervous Disturbances in Schoolchildren.**—Alvarez insists that when disordered heart action is noted in a child at school this may be from some congenital defect, and ordinary school work and play may aggravate it beyond repair. Or it may be merely the effect of the fatigue of the brain, sustained attention inducing greater afflux of blood to the brain, modifying the respiration and making the heart beat noticeably loud. A child presenting these symptoms should be taken out of school at once; conditions may then right themselves. When he returns to school, the teacher and physician should plan his studies. When a previously good scholar grows indolent and inattentive, this warns of brain fatigue. It is common with an inherited neurotic or alcoholic taint. Sleepiness or dizziness are also signs of irritation of the brain in such children. Too close or too prolonged attention by a child fatigues the brain, and its deleterious influence in time becomes manifest in grave circulatory and nervous disturbances. When these develop, the physician is liable to attribute them to everything but the right cause, the strain of school life. He declares that none of the diseases to which children are liable act so directly and with such dire effects on the general condition in the course of time, as this strain from school life.

Typhus. Arturo Atria.—p. 432. Cont'n.  
Bilateral Hysterical Amblyopia after Trauma of Face. Carlos Charlín C.—p. 365.  
Cancer of Appendix. Ernesto Greene O.—p. 369.  
Cancer of Lung. E. Prado Tagle and C. Garces.—p. 372.

**Normal Beef Serum in Treatment of Anthrax in Man.**—The success of Kraus and his co-workers has been repeatedly mentioned in these columns, as for instance, July 20, 1918, p. 234. Kraus here brings the subject down to date in this address which he delivered at the University of Chile. He reiterates that normal beef serum has proved as successful as any other known measure so far. He injects it subcutaneously in doses of from 30 to 50 c.c. and repeats the injection in

twelve, twenty-four or thirty-six hours as indicated. Very seldom are more than two or three injections required. In the extremely severe cases he advises to inject the serum by the vein. The serum is heated twice to 56 C., and it only exceptionally induces serum sickness. Even when the case seems mild, he warns not to use a smaller dose than 30 or 50 c.c.

**Cancer of Appendix.**—The appendix was removed on account of acute flaring up of a long chronic appendicitis in a woman of 34, and a fibro-adenoma was found at the tip. It showed traces of malignant degeneration.

**Primary Cancer of Lung.**—In the case reported by Prado and Garces the man of 52 for nine months had been having intense pain at times at the base of the right lung, with a cough and progressive expectoration. The sputum was mucous at first but gradually showed more and more blood, and there were also attacks of hematuria, precordial distress and palpitations. Necropsy nearly eight months after the first symptoms revealed a primary cancer in the right lung with metastases in the left lung and in the right kidney, with compression from metastases involving the cervical roots from the third to the seventh.

### Semana Médica, Buenos Aires

July 3, 1919, 26, No. 27

- \*Therapeutic Prohibition of Meat. A. D'Alessandro.—p. 1.

- Infant Welfare Work. Ernesto Gaing.—p. 12.
- The Pandemic of Quackery. Juan A. Massa.—p. 14.
- \*Calculi in Children. R. A. Rivarola.—p. 18.
- Early Diagnosis of Brain Tumors in Children. Id.—p. 19.
- History of Organized Prophylaxis of Venereal Disease in Latin America. Emilio R. Coni. p. 22.

**Prohibition of Meat.**—D'Alessandro protests against the routine direction to patients to refrain from eating meat. This therapeutic sarcophobia as he calls it is unphysiologic, and patients are too apt to continue indefinitely any specific order like this, intended for some transient condition such as acute fever or acute gastro-intestinal derangement. Not much meat should be eaten by persons inclined to gout, joint disease or nephritis, but it should not be forbidden entirely. He adds in conclusion that in diabetes, meat is indicated only in the first stage.

**Welfare Work for Infants.**—Gaing is in charge of the Instituto de Puercultura No. 1 at Buenos Aires, which includes a well baby clinic, dispensary and infants' hospital. He here reiterates the importance of giving prizes for the babies that are thriving most. When this is not done, the only women who profit by the well baby clinics are those who get artificial food there for their infants. The nursing women soon tire of bringing their babies merely to be told that they have increased so much in weight. In this way the premium is put on artificial feeding, the very opposite of what is intended. This can be remedied by giving small prizes for the infants that are thriving best. The woman's pride in being recognized as the model mother is a greater stimulus than the prize itself, so the expense of the prizes need not be large. He suggests monthly distribution of \$40 in five prizes of \$5 each and five of \$3. He relates that breast milk is provided also at the institution in his charge, 905 bottles being given out in 1914; 246 in 1915, 969 in 1916; 4001 in 1917, and 2859 in 1918. This milk is ordered for infants who are impatient, but when more is available than needed, it is given out for use in the home. It is supplied by four wetnurses in the institute and, as is obvious, it represents much effort, but the benefits realized have been enormous. He expatiates on the wisdom of this arrangement and its application on as large a scale as possible. The infant thrives on this bottled breast milk just as well as if it suckled the breast. Each district with an institution of this kind should have a commission appointed from among the neighbors for aid and propaganda of the welfare work.

**The Pandemic of Quackery.**—In the course of this discussion on charlatanism in general and its present unprecedented extension, Massa remarks that even a qualified physician is an *charlatan en latencia* if he applies any one single therapeutic method in treatment of all diseases.

**Calculi in Children.**—Rivarola ascribes to abnormal persistence of the uric infarcts, found in the kidneys of the newly born, the development of a calculus, either in the kidney or bladder or their outlets, as the child reaches the age from 3 to 5. This lithiasis is not rare in Argentina although far less frequent than has been reported from Hungary and elsewhere. He emphasizes the necessity for watching over the child after removal of the stone to ensure rigorous hygiene, trying to modify the calculus producing tendency. He has had no mishaps from crushing or cutting out calculi in children, but in some cases there was recurrence.

- \*Fatal Acute Leukemia in Young Woman. D. González Marmol.—p. 123.
- Organization of the Fight against Tuberculosis in the School. L. Mather.—p. 131.
- \*Hemiosalemesis; Two Cases. C. M. Desvervigne.—p. 134.

**Acute Leukemia.**—In less than a month after a normal childbirth, the young woman developed headache, lassitude and tenderness in the occipital region, and infarction of glands, with a pseudomembranous process in mouth and throat from which only pus cocci could be cultivated. The diagnosis of leukemia was confirmed by the 91.33 per cent. mononuclears. Then conditions improved the twelfth day, the fever subsided, the liver and spleen returned to normal size, and the woman seemed to have recovered. But the thirty-third day the symptoms returned and grew rapidly worse, with death in nine days.

**Hemiosalemesis.**—Desvervigne reports two cases of profuse vomiting of a blood-stained fluid, without general disturbances of any kind. The vomiting attacks occurred every two or three months in the first case, in connection with the menstrual periods, which were regular. The vomiting had occurred first two years before. There was no nausea or cough with the vomiting, merely a sensation of retrosternal constriction. The vomit showed the three strata characteristic of hysteric "pink hematemeses," and the woman presented other signs of hysteria. Such were evident also in the second case in which there was rapid swelling of the palate, tonsils and base of the tongue. The hemiosalemesis in this case developed at the close of a period of profuse menorrhagia. The hemorrhages in both cases seemed to have occurred by diapedesis as there were so few erythrocytes in the vomit. In the first case the husband of the woman began to vomit too, in much the same way, except that there was no adreberia. The couple could not be convinced that the vomiting in both was not due to hemipneumonia of inter-uterine origin.

## OBSERVATIONS ON THE CEREBRO- SPINAL FLUID OF ACUTE DISEASE\*

W. W. HERRICK, M.D.

NEW YORK

AND

A. M. DANNENBERG, M.D.

PHILADELPHIA

The anatomy of the meningeal-choroid complex, or, as it may conveniently be termed, the subarachnoid system, is quite well understood; its physiology and pathology are shrouded in a large measure of uncertainty, while recognition of its clinical importance is recent and, even yet, not very general.

For a summary and an extension of our knowledge of the development, structure and function of this part of the envelop of the central nervous system, we are indebted to Weed,<sup>1</sup> to whose writings the reader is referred for details and the literature.

It seems to be established that the cerebrospinal fluid is largely a product of the choroid plexus of the cerebral ventricles, with small, probably insignificant, accretions from the general ependymal cells and the capillaries of nervous tissue itself, through their perivascular channels; that it exists in an amount of from 60 to 150 c.c., and that its formation is rapid and its circulation active, particularly in the upper or cranial portion of the system of channels through which it circulates.

The route taken by the major part of the fluid is one which leads from the lateral ventricles through the foramina of Monro to the third ventricle, and then through the aqueduct of Sylvius to the fourth ventricle. From this chamber it escapes by the median foramen of Magendie and the lateral foramina of Luschka into the cisternae lying in the cerebello-vertebral angle, where, contained between arachnoid externally and pia internally, the fluid is distributed in the communicating spaces, subarachnoid spaces and to the cerebral and cerebellar spaces as a capillary layer, except where the enclosing membranes are separated by wider intervals, as at the choroid.

Absorption is chiefly by the great venous sinuses, largely through the pacchionian bodies, which are but augmented arachnoid villi, with lesser drainage into the lymphatic system surrounding certain cranial nerves and vessels. Drainage is largely a physical

process determined by the difference in pressure existing in this subarachnoid system and in the venous sinuses—a matter of undoubted clinical importance.

This system may, in a sense, be conceived of as an accessory or specialized circulation between the vascular choroid plexus and the venous sinuses. That the fluid exchange here is great, there is no doubt.

Frazier<sup>2</sup> estimates the total amount of fluid secreted in twenty-four hours to be from 360 to 720 c.c., and is of the opinion that the entire amount—from 60 to 150 c.c.—is replaced every three hours. He cites also the fact that within two hours of the injection of phenylsulphonephthalein into the ventricles, 60 per cent. is recovered from the urine, and that the subarachnoid spaces of a dog will absorb about 500 c.c. of physiologic sodium chloride solution per hour, the rate of absorption being in direct ratio to the pressure.

Flexner and Amoss<sup>3</sup> have made the most thorough recorded experimental study of the normal and pathologic physiology of the meningeal-choroid complex, establishing the fact of its role as a barrier to the passage of the virus of poliomyelitis from the blood to the central nervous system, and the fact that this barrier is broken down under the influence of inflammation excited mechanically or chemically.

This principle has been found applicable to other injurious agents than that of poliomyelitis.

Austrian<sup>4</sup> demonstrated in rabbits the importance of subarachnoid infections of serum, with resulting inflammation, in determining the localization of meningococci in the meninges in meningococcal sepsis. Wood, Wegeforth, Ayer and Fallon made similar but more extensive studies, which emphasize the effect of lumbar puncture in exciting inflammation and thus increasing permeability.

That similar conditions govern the permeability of the meningeal-choroid complex for chemical substances was shown by Viron in 1833 and by Jordan in 1838 for arsenic.

The complexity of the problem is brought out by Amoss and Flexner,<sup>5</sup> who discuss the variability in Austin's conditions.

These observations, however, and the same experimental evidence, to show, that the meningeal function of

meningococci in rabbits given serum by the thecal route, when a meningococcus bacteremia exists, is the result of injury from the needle rather than of increased permeability consequent on the local effect of serum on the leptomeninges. They also found it impossible to direct the meningococci circulating in the blood into the cerebrospinal meninges of monkeys either with or without aseptic meningitis. It is admitted, however, that because of the high insusceptibility of the monkey to infection with the meningococcus, these experiments have little or no clinical bearing.<sup>9</sup>

The physician can supplement the laboratory studies thus briefly summarized. Since Quincke introduced lumbar puncture in 1890, an appreciable amount of clinical data has been set down. It is worth while to collect and sift this, to add a fairly extensive series of observations of our own, and to evaluate the whole from a clinical point of view. In order to keep within limits, consideration of meningitis in the ordinary acceptance of the term is omitted. We shall take account of the participation of the meninges (meningitis serosa Dupré) as revealed by study of the cerebrospinal fluid only in those diseases that ordinarily are not supposed specifically to involve the central nervous system.

That the meninges participate in the systemic reaction to a variety of infections not as a rule giving rise to meningitis has not had wide recognition. For example, Frazier,<sup>10</sup> in a paragraph on the spinal fluid of acute infections, is content with the statement that "definite pleocytosis which may reach very high counts is found in a large number of cerebrospinal diseases—particularly the infectious meningitides, meningococci, pneumococci, tuberculous and cerebrospinal syphilis, paresis, tabes dorsalis, brain abscess and herpes zoster."<sup>10</sup>

Symptoms of meningeal irritation, headache, delirium, irritability, hyperesthesia and exaggerated reflex activity are accepted as a matter of course as inaugural symptoms of perhaps the majority of the acute infections of any degree of severity. Only when these symptoms persist and become intense are they ordinarily deemed of enough significance to suggest lumbar puncture. Furthermore, if this lumbar puncture shows a "clear fluid," additional study is usually omitted, the cell count and the globulin determination are neglected, and the meningeal features of the picture are suppressed in the clinician's consciousness. A result of this has been that the cerebrospinal fluid of diseases other than the various forms of meningitis and poliomyelitis has been little considered. No broad study of the meningeal phase of acute febrile diseases, based on the character of the cerebrospinal fluid in any extensive series of miscellaneous cases, has rewarded our search of the literature. One finds, in fact, evidence of much confusion of ideas in the conflicting statements v. e. r. t. e. d.

We quote from a few typical statements set down since Dupré,<sup>11</sup> in 1904, coined and defined the term meningitis.

Connal<sup>12</sup> examined the "fluids of a large number of cases other than those of meningeal irritation. Cases

of scarlet fever, enteric, whooping cough, erysipelas, cerebral tumor, epilepsy, tetany, acute lobar pneumonia, bronchopneumonia, gastro-enteritis, uræmic coma and various minor ailments were punctured." The centrifuged sediment was found in each instance to contain very few cells—one to every two or three fields—generally mononuclears.

Blatteis and Lederer<sup>13</sup> state that "when the cerebrospinal symptoms were due only to irritation the fluids were found to be absolutely normal in every way."

Abramson<sup>14</sup> experiences no difficulty in determining fluid from a case of meningism, as it uniformly in his experience "shows no increase in cells, no albumin-globulin and a prompt and heavy reduction of Fehling's solution."

DuBois and Neal<sup>15</sup> remark that in meningismus pressure of the cerebrospinal fluid is increased, there are "very few cells," and globulin is  $\pm$ .

Heiman<sup>16</sup> finds that "in intoxication cases no variation from the normal spinal fluid occurs."

Johnston<sup>17</sup> found that cases with meningism showed "no pleocytosis except in one instance." He also makes the useful observation that a negative globulin test may occur in a pathologic fluid.

At variance with the statements quoted above are these:

Warrington,<sup>18</sup> in common with Hutinel,<sup>19</sup> Jean and Cardamatis,<sup>20</sup> and others, considers that just as "there is no essential difference between the pathogenesis of purulent meningitis, and of serous meningitis or ependymitis, so there is no true pathologic demarcation between meningism and serous meningitis, though examination of the cerebrospinal fluid is a most valuable means of determining the degree of the process."

Lucas<sup>21</sup> believes that in pyogenic infections the reaction in the meninges resembles that in the true serous membranes. He cites a single case of meningismus in which the number of cells in the spinal fluid varied from 10 to 80, and concludes that there are many conditions giving the same cytologic findings in the spinal fluid: (a) encephalitis; (b) epidemic myeloencephalitis; (c) meningismus; (d) tuberculous meningitis, and (e) syphilis of the central nervous system.

Plaut, Rehm and Schottmüller,<sup>22</sup> without citing any series of observed cases, make the statement that lobar pneumonia, pertussis, scarlatina, measles, mumps, enteric fever and sepsis with cerebral symptoms (meningitis serosa—Dupré) may have a cerebrospinal fluid under heightened pressure, with globulin and an increase in cells, in some instances amounting to several hundred in a cubic millimeter.

MENINGEAL REACTION IN ACUTE DISEASES

The cerebrospinal fluid of certain acute diseases has been studied with varying degrees of thoroughness.

**Lobar Pneumonia.**—The most complete study is that of Voisin,<sup>23</sup> whose thesis is a catalogue of the literature up to 1904. Forty-nine lumbar punctures were made in forty-five cases of lobar pneumonia or bronchopneumonia in which meningeal symptoms were observed. Cellular increase was found in the cerebrospinal fluid in eight, the cells numbering from 11 to 66 per cubic millimeter. The patients, in all cases but one, had purulent otitis media. Sixty-four lumbar punctures were made in thirty-eight cases in which there were meningeal symptoms. In fifteen of these there was no abnormal reaction in the spinal fluid. Of the twenty-three cases showing modifications, nineteen had a leukocyte reaction more or less marked. Of these, 60 per cent. showed albumin. The patients in most of these cases had suppurative otitis, which raises the question as to whether these cases can properly be classed as mere meningitis. Only six patients in these thirty-eight cases recovered. Voisin concludes that in pneumonia there may be every gradation of meningeal reaction, from a slight increase in pressure to purulent fluid. Litchfield<sup>24</sup> finds it the rarest exception for cases of pneumonia with meningeal irritation not to present positive findings on lumbar puncture, and reiterates what has already been found true in meningococcus meningitis;<sup>25</sup> that clear normal fluid may be obtained by lumbar puncture, though there is purulent inflammation of the meninges located at higher levels. In this connection, the work of Cushing<sup>26</sup> may be recalled, which brings out the difference in composition of the ventricular and subarachnoid fluids in sugar and albumin content, and in bactericidal and other immunologic properties.

**Scarlet Fever.**—Several reports establish a meningeal reaction in at least some cases of this disease. Hutinel,<sup>27</sup> who was perhaps the first to grasp the general clinical significance of the changes in the cerebrospinal fluid of a variety of acute diseases, finds that the exanthems with which meningism is a frequent associate are often accompanied by a lymphocytosis of the spinal fluid. He suggests that a common origin of the meninges and the skin in the ectoderm may be a not altogether satisfactory explanation of the tendency to the invasion of the spinal and cerebral coverings in the same manner as that of the skin by the unknown infective agents of the eruptive fevers. Porter<sup>2</sup> has expressed a similar point of view, as has Sharpe,<sup>28</sup> who cites a case of scarlet fever with spinal fluid under great pressure and containing much globulin which, at autopsy, revealed edema of the leptomeninges. Kirchheim and Schröder,<sup>29</sup> in a paper in which the anatomic basis of meningism has had careful study, report definite meningeal reaction in three cases of

scarlet fever which came to necropsy. Gauss<sup>31</sup> examined the spinal fluids of fifty patients, aged from 1 to 14 years, having scarlet fever or associated exanthems. All cultures were sterile. The cell count averaged eight, but eleven fluids contained between 10 and 20 cells, from 80 to 90 per cent. of them lymphocytes.

**Mumps.**—Meningitis is one of the rarest complications of parotitis. However, if one studies a series of several hundred cases, an opportunity possible in large military hospitals, he will be impressed with the frequency of meningeal symptoms.

Chauffard and Boidin<sup>32</sup> cite two cases of mumps with meningism, associated with well marked lymphocytosis of the cerebrospinal fluid, which came and went with the meningeal symptoms, and which in one case was so marked that the fluid was quite turbid. Larkin<sup>33</sup> reports a lymphocyte increase in the cerebrospinal fluid in several cases. In 1902, Monod<sup>34</sup> practiced lumbar puncture systematically in infants with parotitis, and found lymphocytosis of the cerebrospinal fluid six times in eight cases. Ackert<sup>35</sup> has given a very complete summary of the observed facts in mumps meningitis, in which he cites the findings of Sicard, Chauffard and Boidin, Dopter, Netter, Comby, Hutinel, Nobecourt and Brelt, and Feliciant, confirming the presence of lymphocytosis in the cerebrospinal fluid in parotitis with nervous symptoms. This feature of parotitis seems, therefore, quite established.

**Influenza.**—Observations of meningism accompanying influenza are an everyday bedside experience. Gendre and Terrien<sup>36</sup> give an account of a case of this kind in which there was pleocytosis of the cerebrospinal fluid, with recovery.

**Gastro-Enteritis.**—Meningism is a very common accompaniment of the gastro-enteritis of children. Hutinel<sup>27</sup> has pointed out the frequency of a subarachnoid reaction in this condition. Blatteis and Lederer<sup>13</sup> state that cases of "intestinal autointoxication" with meningeal symptoms may yield fluids chemically and cytologically resembling tuberculous ones.

**Rabies.**—Abramson<sup>11</sup> found the cerebrospinal fluid in a case of rabies opalescent, with a large number of polymorphonuclear leukocytes, and without organisms on smear or culture. Deniges and Tabrazes<sup>37</sup> report a case in which the cerebrospinal was under high pressure, contained 0.2 gram of albumin per liter, and had very few cells.

Lochelouge<sup>37</sup> reports the finding of pleocytosis in the cerebrospinal fluid withdrawn from patients in individual cases of Malta fever, diphtheria with paralysis, tetanus, plague, malaria and trypanosomiasis. In the same monograph will be found references to positive findings in the fluids of cases of uremia, alcoholism, saturnism and herpes zoster, observed by various writers.

REPORT OF PERSONAL OBSERVATIONS

Our own series of observations on the spinal fluid of miscellaneous acute diseases is a by-product of the study of the early phases of meningococcus meningitis

made at the base hospital at Camp Jackson, South Carolina. Many other acute infections with meningismus came under suspicion in the attempt which was made to recognize meningococcus meningitis during the premeningitic stage of meningococcus sepsis. Lumbar punctures were made in over 100 of these varied medical cases. All counts and globulin estimations were made by thoroughly competent persons having no knowledge of the special study in progress, and no instructions except that every precaution tending toward accuracy should be regarded. For the care with which the laboratory work was done, we are indebted to Marshall A. Barber, Major, S. C., U. S.

the degree of the meningeal irritation and of the severity of the more general symptoms present, and, in many instances, the number of leucocytes in the blood and the differential count. The amount of cerebrospinal fluid withdrawn is given, also a rough estimate of the pressure without manometric readings. The cell count, the globulin determination by the butyric acid method, and the result of the test for reducing bodies is shown.

By this tabulation the relations of the reaction of the subarachnoid system, as shown by changes in the cerebrospinal fluid, to some clinical and laboratory features of acute disease are made available for study:

Army, Chief of the Laboratory, Base Hospital, Camp Jackson, S. C.

The study is not complete, differential counts, the colloidal gold test and other elaborations having been omitted in the press of work. Several cases showing more than a single Wassermann reaction are omitted from this report, as are all instances of meningitis of any form, poliomyelitis, mastoiditis or other disease process tending specifically to involve the central nervous system. The seventy-six cases tabulated are therefore those with meningismus not resulting in meningitis at any stage of their progress.

ANALYSIS OF TABLES

In the accompanying tables are shown the diagnosis, the temperature at the time of the lumbar puncture,

1. *Relation of the Subarachnoid Reaction to the Degree of Meningeal Irritation.*—No very direct relation is apparent. As stated by Voisin,<sup>24</sup> cases without meningeal irritation may show pleocytosis and a globulin increase in the cerebrospinal fluid. The opposite is also true. The tables show that it is not always the case that the highest degree of meningismus gives the greatest variation from the normal, or even any variation at all, in the cerebrospinal fluid.

2. *Relation of the Subarachnoid Reaction to the Clinical Estimate of the Severity of the General Symptoms, Including Temperature.*—Again, no constant relation appears.

3. *Relation of the Subarachnoid Reaction to the Leukocytic Reaction in the Blood.*—The study of this

point also gives negative conclusions. Many cases with pronounced leukocytosis are without significant alterations in the cerebrospinal fluid, and vice versa.

4. *Relation of the Subarachnoid Reaction to Prognosis.*—In general, it may be said that a pleocytosis and a globulin increase in the cerebrospinal fluid in an acute disease do not in themselves make the prognosis more grave. In our judgment, they have no prognostic value, except in the rare instances in which an oncoming meningitis is indicated.

THE CEREBROSPINAL FLUID OF CERTAIN ACUTE INFECTIONS

The character of the cerebrospinal fluid in certain acute infections is shown in the tables.

1. *Lobar Pneumonia.*—Of twelve cases of lobar pneumonia, in seven there was a cellular reaction in the

a great increase in pressure; globulin was present, and there were 20 cells. This finding suggests an explanation of the headache, vomiting, delirium and lumbar pain that are initial features of smallpox. Hutinel's theory,<sup>27</sup> already cited, gains support from this observation and from our single case of measles with 16 cells.

Of twenty-eight miscellaneous pathologic conditions in which there was meningismus, and from which spinal fluid was withdrawn, there was pleocytosis in seventeen, while in only four of the instances in which the cerebrospinal fluids were examined was a globulin increase revealed.

COMMENT

The results of the examination of the cerebrospinal fluid in this quite large and varied group of acute

cerebrospinal fluid of from 12 to 200 cells; in eight there was a globulin increase. Four patients in the twelve cases died. Three patients among the seven with spinal fluid pleocytosis died.

2. *Bronchopneumonia.*—In fourteen cases, lumbar puncture was made. In five of these cases there was an increase in cells varying from 12 to 30. Only one of these five patients died, while eight cases of the entire fourteen were fatal.

3. *Influenza.*—Fourteen patients in cases with meningismus recovered. Of these, five had cerebrospinal fluid pleocytosis of from 14 to 40 cells. Only three had a globulin increase.

4. *Miscellaneous Cases.*—In all three cases of acute follicular tonsillitis with meningism, there was pleocytosis and a globulin increase. The cells numbered from 12 to 172. None of these patients died. It is of interest here to recall like findings already cited in the case of scarlet fever.

In two cases of sepsis there was a significant subarachnoid reaction. In one case of variola there was

diseases confirm and perhaps slightly extend the observations of others. There is no question that the meningeal-choroidal complex shares in the systemic reaction to the toxins or the infective agents of a very considerable number of acute diseases, and that the cerebrospinal fluid of meningismus is not always, or even usually, normal.

Of no slight clinical moment is the comparative permeability of the meningeal-choroidal complex to various infective agents and their toxins. Of the accepted pathogenic organisms, the meningococcus finds readiest access to the subarachnoid system. In our experience,<sup>28</sup> this penetration takes place in about 95 per cent. of meningococcus septicaemia. If Liebermeister's<sup>29</sup> statement is true, that in 25 per cent. of the cases of pneumonia there is distinct suppurative inflammation in the membranes of the spinal cord, even though their gross appearance is unchanged, the pneumococcus and its toxins have an even stouter

<sup>28</sup> Herrick, W. W. Extra-meningeal Meningococcus Infection, Arch. Int. Med. 24: 471 (April 1914).  
<sup>29</sup> Liebermeister, quoted by Hirschfeld (abstract 24)

affinity for the meninges than ordinary clinical experience would suggest.

The tubercle bacillus and *Spirochaeta pallida* also readily pass the meningeal-choroidal barrier; less readily, *B. typhosus*, the influenza bacillus and the gonococcus, or their toxins.

Other pyogenic organisms than those mentioned—notably the streptococcus and staphylococcus—rarely penetrate the subarachnoid system, except by direct extension from some focus of suppuration immediately adjacent to the meninges. That the toxins of the streptococcus may have an effect on these structures is shown by the changes in the cerebrospinal fluid disclosed in the examples of sepsis studied in the series tabulated.

Of the more doubtful etiologic agents of infection, that of poliomyelitis penetrates the structures in question with the highest facility. The virus or toxins of scarlet fever, measles, parotitis, variola and epidemic influenza may give rise to reaction within the subarachnoid space. That many of these viruses are filtrable is perhaps not without significance. All this has diagnostic value, both positive and negative.

It is obvious that it is unsafe to rely too greatly on the presence of a slight or moderate increase in cells or globulin in the cerebrospinal fluid in the diagnosis of meningitis or poliomyelitis. The diagnosis of these serious infections from the mere presence of fever, meningismus and the spinal fluid findings mentioned is not justifiable. Abortive poliomyelitis is a dangerous diagnosis, and until the recognition of the etiologic agent has been placed on a basis useful clinically, had best be made with the greatest caution. Cases with less than 100 cells in the cerebrospinal fluid and without paralysis should be viewed with skepticism in the absence of very strong epidemiologic, clinical or immunologic evidence.

Of late, much has been said and written from a laboratory point of view of the dangers of lumbar puncture. After an experience with some 5,000 lumbar punctures in a large military medical center, in all sorts of medical conditions, we are not impressed with its clinical dangers. In none of the cases tabulated did true meningitis develop. Animal experiment has indicated possible dangers, under very special conditions, but its results cannot always be wisely translated bodily into terms of human pathology. Until convincing clinical proof is at hand, the skilled clinician need have no hesitation in removing from 5 to 8 c.c. of cerebrospinal fluid through a small needle, drop by drop. The removal of larger amounts, under any conditions, except for therapeutic purposes in meningitis, is unwise. The heightened pressure in the subarachnoid system in the early stage of so many infections may well be a protective reaction, and care must be taken not to reduce the pressure to a point which would promote undesirable filtration from the blood stream. There is clinical evidence at hand tending to show that the meningeal-choroidal complex consolidates its defenses after sepsis has existed for some time, and that the release of spinal fluid is fraught with less danger at a later than at an earlier period of sepsis.

#### CONCLUSIONS

1. A review of the literature and a personal study of seventy-six cases not re-sulting in meningitis show beyond question that the cerebrospinal fluid often gives evidence in increased pressure, pleocytosis and heightened globulin content of a reaction on the part of the

leptomeninges to the infective agents or toxins of a large number of miscellaneous acute diseases, not ordinarily causing true meningitis.

2. These diseases are lobar and bronchopneumonia, influenza, tonsillitis, the exanthems, scarlet fever, measles, variola; herpes zoster, parotitis, typhoid fever, sepsis, arthritis, pleurisy, migraine, reaction to typhoid inoculation and others.

3. The cerebrospinal fluid shows variation from the normal in about one third of the cases studied.

4. Most, but by no means all, of the patients with subarachnoid reaction have clinical meningismus (meningitis serosa Duprè). On the other hand, many examples of meningismus are without pronounced changes in the cerebrospinal fluid.

5. The greatest caution should be used in making a diagnosis of meningitis or poliomyelitis from fever, meningismus and the changes in the cerebrospinal fluid mentioned. Cases with less than 100 cells should be viewed with skepticism, unless clinical, epidemiologic or other laboratory evidence is decisive.

49 East Fifty-Third Street.

#### ABSTRACT OF DISCUSSION

DR. CHARLES G. KERLEY, New York: This paper is valuable in establishing something definite in our knowledge of the relation of pathogenesis to the cerebrospinal fluid. It was known there was an increased cell count and a positive globulin in pneumonia, scarlet fever and mumps. Knowledge in reference to the spinal fluid in many other conditions was very indefinite. The finding of a cell count of 172 in tonsillitis, of 200 in pneumonia, and of more than forty in a large number of other disorders must have a very direct clinical value. It was of great importance to know that there must be a much larger cell count than had hitherto been thought necessary before deciding that one was dealing with a particular disease. This knowledge would have been of the greatest value in the late epidemic of poliomyelitis when it was given out that a cell count of over ten established the diagnosis of poliomyelitis. A tonsillitis with a cell count of 173 would have landed the patient in a poliomyelitis hospital. There was no doubt that during the epidemic, many cases of poliomyelitis were wrongly diagnosed because of the lack of just such information as had been given by the authors.

DR. ISAAC A. ABT, Chicago: It seems to me that we have just begun to study the chemistry, the cytology, bacteriology, etc., of the cerebrospinal fluid. A vast field is opened up. There are vast possibilities, and a great deal is to be learned. I think that will possibly explain some of the difficulties which Dr. Kerley encountered with the various health boards. We have not said the last word about the cell content of cerebrospinal fluid in health or in disease, certainly not in disease. With reference to the meningismus or the meningismus as spoken of here, we ought to define clearly in our minds what we mean so that we do not confuse it with an incipient or beginning meningitis. Many of us have seen cases which we can definitely say are cases of meningismus. In typhoid fever, particularly, a child will start with meningeal symptoms lasting one, two or three days. The meningeal symptoms disappear, and the typhoid runs the usual course. The same is true of pneumonia. The doctors speak of these cases as apical pneumonia or meningeal pneumonia. They begin stormily with perfect meningeal symptoms. These symptoms soon subside, the pneumonia becomes more apparent in the lung, and the case runs the course of an ordinary pneumonia. In those older cases and in some of the more recent cases the spinal fluid presents some slight or insignificant changes but never the changes that occur in true meningitis.

DR. WALTER R. RAMSEY, St. Paul: It has been shown that there is an increased intracranial pressure causing symptoms of meningitis, both where you find a real infection and

where you do not. Several years ago we had an epidemic of poliomyelitis in St. Paul and Minneapolis. I had just been abroad and they had had a big epidemic in Norway and Sweden. At first the doctors generally did not know what they had, and I remember reviewing and translating from the German an article by a Swedish physician, wherein he demonstrated and pointed out a variety of forms of poliomyelitis. One he designated as meningitis serosa. I remember in trying to diagnose these early cases we found one or two among a large number that manifested all the symptoms of meningitis with severe pressure, and after lumbar puncture the fluid removed was sterile and the symptoms disappeared at once. Whether that was one of the forms of poliomyelitis which gave pressure symptoms as the result of the irritation was a question; probably it was. The most practical point is this: they have demonstrated that in all sorts of diseases you may get this increased pressure. About two or three years ago I remember seeing a child who had measles and became quite convalescent from that but gradually went into a coma, manifesting all the symptoms of meningitis. I had no doubt that this was a case of tubercular meningitis. I did a lumbar puncture. The fluid was perfectly clear, and the next day gave no reaction of any kind. In two or three days that child was running about and had no other symptoms at all. Another child ate many green apples and then was ill for two or three days, going into a condition of coma. I had no doubt at that time that the boy had meningitis. To clear up the situation, I did a lumbar puncture, found a large amount of perfectly clear fluid which gave no reaction at all. The next day he went home. Those cases demonstrate that intercranial pressure may cause all the symptoms of meningitis which cannot be differentiated except by lumbar puncture.

DR. ALFRED F. HESS, New York: The most interesting part of this discussion has been the question of meningism. Dr. Josephine Neal, who is the head of the Bureau of Laboratories, Department of Health of New York City, in an examination of six or seven hundred cases of this kind, found that the cell count was normal in almost all the cases and that the chemical examination was almost normal. There are exceptions, one of which is when there have been convulsions, for instance, convulsions associated with whooping cough; another exception is when there has been some pyogenic infection with meningism, such as mastoiditis, and third, she found it true with the cases which are not acute and recent. If the case was chronic, if it had lasted a week or ten days, then the cell changes which Dr. Herrick described occurred. I think that these tables should be rearranged on the basis of the acute and the chronic cases.

DR. H. L. F. LOCKE, Hartford, Conn.: I was particularly interested in what has been said regarding meningism or meningism. We found that in meningism the cell changes were usually very minor, but that in cases where lumbar puncture was delayed for five, six or seven days, due to delay in diagnosis, there was usually a moderate increase in the number of cells and a slight increase in the amount of globulin. Where the punctures were made fairly early, we rarely found any changes in cases of meningism. I believe the explanation, as Dr. Neal also believes, lies in the gradual development of cerebral congestion which causes an infiltration of cells into the spinal fluid and also delays normal absorption. The factor of time is most important. The longer these cases go on without puncture the more apt we are to find changes in the cerebrospinal fluid.

DR. HERMAN SCHWARZ, New York: During the poliomyelitis epidemic of 1916 and since that time we have taken every opportunity of puncturing in acute cases that had any resemblance at all to meningism or meningitis, and we have found regularly that when the fluid is examined immediately after puncturing the cell count is not increased, except when there is some definite lesion of the meninges or of the brain or cord. In a large group of cases of so-called meningism, the cell count was regularly below twenty. The count of 172 described in the paper as occurring in a case of tonsillitis is certainly very curious. I should like to see many more cases reported before quite overturning our idea

that the cell count of fifty or sixty or more has not some real value in the diagnosis of an inflammatory condition of the nervous system. It might be of interest to report to you that in some studies of the sugar content of the spinal fluid, this substance was regularly increased in real inflammatory conditions of the spinal cord and meninges.

DR. FRITZ B. TALBOT, Boston: There is one point which has been brought out very clearly, and it is an important one. We should first study the normal before we study the pathologic. It is very encouraging to see so much normal data recorded and I hope this tendency will spread.

DR. W. R. SISSON, Boston: During the past year, in one of our southern camps, we have had an experience with spinal fluids similar to that which Dr. Herrick described. This was especially true during the epidemic of mumps. Many patients with this condition had a most fulminating type of infection and frequently manifested meningeal symptoms. Lumbar puncture was performed in most of these cases and a pleocytosis was almost invariably found. So frequent were these findings that we came to look on "mumps meningitis" as a not uncommon complication. I feel that if routine spinal punctures are performed on children with other acute infections we would find pathologic fluids even more often than Dr. Herrick has noted. It is interesting in this connection that one of the first types of cells we found in the spinal fluid, even before an actual invasion of the meninges has taken place, is the small mononuclear endothelial cell which is unquestionably a phagocyte.

DR. W. L. MOSS, Baltimore: I wish to ask Dr. Herrick if cultures were made from the spinal fluids which showed these rather remarkable increases in cell count. It seems probable that in many of the infections which we think of as local, a few organisms may get into the blood stream where they may not multiply or even persist very long or give rise to any very appreciable symptoms. If they reach the blood stream may they not sometimes reach the sub-arachnoid spaces? In support of this suggestion, I may refer to an experience in the A. E. F. during the early days of the influenza epidemic. At first some of us did not recognize the disease as influenza and in our efforts to make a diagnosis we made many blood cultures and a considerable number of lumbar punctures with cultures from the spinal fluid. Dr. Roger Kinnicut and Dr. Carl A. L. Binger, working in Base Section No. 2, found meningococcus Type C (French classification) in a considerable number of cases, both in the blood stream and in the spinal fluid. In the complicated cases showing bronchopneumonia and in some of those which showed an exudate over the brain at necropsy these findings are not remarkable, but I wish especially to emphasize the fact that in some of the cases in the early part of the epidemic when the disease was commonly called "three day fever," before we recognized any complications and at a time when the mortality from the disease was nil, we occasionally found the meningococcus in the blood stream and in the spinal fluid. If meningeal symptoms were present in these cases, they did not reach the level of clinical manifestation. In the light of this experience, I suggest therefore, that micro-organisms may sometimes get into the blood stream and even into the spinal fluid without giving rise to clinical symptoms of septicemia or of meningitis, but may cause a reaction on the part of the meninges which would account for such cell counts as Dr. Herrick has reported.

DR. ARTHUR M. DANNENBERG, Philadelphia: As to Dr. Hess' question with regard to the cell counts of spinal fluids in acute infections taken at the onset of the disease and later on. In all these cases from which spinal fluid was obtained, lumbar puncture was made within from fifteen minutes to one hour after the patient was admitted to the hospital. This was an invariable rule. We did these lumbar punctures in order to make an early diagnosis of meningitis. Only after it was realized that we had this wealth of material did it occur to us to tabulate, correlate and present the results to you.

DR. W. W. HERRICK, New York: British and American physicians seem to be behind the French and Germans in recognizing that the cerebrospinal fluid of so-called meningismis

may show variations from the normal. The work of the latter shows definitely that in a variety of acute infections a positive reaction in the cerebrospinal fluid may be found. I want to say again that in only about 30 per cent. of the cases examined did we find this reaction, that the larger percentage of our cases with meningisms were without these changes in the cerebrospinal fluid. The cases were all acute and were examined early in the course of the disease. It may be of interest to add that the sequence of changes in the cerebrospinal fluid in meningococcus meningitis is as follows: Blood stream invasion, the appearance of isolated organisms in the fluid, globulin, then increase in cells, usually mononuclears at first, then polymorphonuclears and pus. The work of Dr. Levinson is important in pointing out the possibilities of detailed study of the physical and chemical properties of the cerebrospinal fluid. For practical clinical purposes, however, I believe we must still be largely dependent on the demonstration of the etiologic agent in the diagnosis of meningitis and allied conditions.

### FAMILY DEGENERATION OF THE MACULA LUTEA\*

ROBERT BLUE, M.D.

Assistant Clinical Professor of Ophthalmology, Northwestern  
University Medical School  
CHICAGO

In the American literature there has recently appeared the report of several cases of macular degeneration occurring in two or more members of the same childship, of a type originally described by R. D. Batten and subsequently by Stargardt, Jennings, Lutz, Darier and Pusey.

In all, nine families unquestionably suffering from this familial affection have been reported, the entire number of individual cases in these families totaling twenty-six.

The most striking feature of this disease is that it is familial; conformity to Bolling's law of heredity has been complete in all reported cases. The lesion is macular in the beginning and is rather closely confined throughout the course of the disease to this area and its immediate vicinity. Subjectively, this is evidenced by a central scotoma with no restriction of the peripheral field. The disease in all reported cases to date begins in early childhood; the fall in central vision is rather rapid to the point where reading is laborious. From the subjective standpoint it is slower from this point forward, and after reaching a certain grade may remain stationary for years. Blindness never supervenes. Mental deterioration does not occur. Those afflicted with it are of average intelligence and health, the only abnormal feature being the visual disturbance and the macular and perimacular lesion.

In view of the fact that the number of reported families afflicted with this disease is so small and that its status is still unsettled, I feel that it is not presumptuous to present a family case and to analyze from the standpoint of classification previously reported cases.

The case I here present is of peculiar interest in that it is the first reported which departs from Bolling's law of heredity—it occurs in two generations. Moreover, the late onset in the father would make the classification of this case in its present category not

only questionable, but wholly impossible, were it not for the fact that the history and findings in the daughter's case parallel the history and findings of all the typical cases reported.

#### REPORT OF CASE

*History.*—The family is one of intelligence and comfortable circumstances. The childship consists of two members, both girls—one 18, the other 10—the elder of whom, Antoinette, is affected. Born, Feb. 27, 1901, she saw perfectly as a child. She found no difficulty in seeing the blackboard from the rear seat in school or in reading her school books until reaching the seventh grade. While in the seventh grade, at the age of 12 or 13, vision began to fail. She first noticed that she was unable to see the blackboard work from the rear of the school-room. She was transferred to the front row and soon could not see well from this position. While she was in the eighth grade, the teachers began to demand that her eyes be examined. At present she can read the newspaper slowly—picking out the words—by holding the paper about 6 inches from her eyes. She says that it takes an hour to read a column of the newspaper. She began studying music six years ago (in 1912). Until three years ago she could see the notes with the music in its proper place on the piano. She now holds the sheet of music close to her eyes and memorizes it. She thinks her vision a little better than it used to be.

Her previous history contains nothing to attract attention. She had measles and whooping cough in childhood.

At present (February, 1919) she is not feeling up to par. Dr. John M. Lilly, whom she consulted, reports that she is somewhat anemic, has lost weight during the past few months, and is somewhat "run down." He attributes the condition to overwork at school. She is extremely ambitious to finish school, and under the visual handicap the work in third year high school is excessive. It has been her habit during the year to study until 11 p. m. and arise at 7. The Wassermann test has not been made.

*Examination.*—These are the salient features of the eye examination: Vision is 6/60 in each eye, scarcely improved by the correction of the low grade refractive error present. The visual fields show a relative negative scotoma at the center; the ophthalmoscope, a lesion at the macula.

*Family History.*—Ceclia, sister, aged 10, born, Oct. 14, 1908, is normal in all respects; vision 6/6 in each eye; fields normal; no fundus lesion. Examined in January, 1918.

W. H., the father of the foregoing childship, aged 43, was born in Posen, Feb. 14, 1876; Polish; no Jewish blood; one of a childship of six—four boys and two girls; no consanguinity in parents; father died at 40 plus of "paralysis of intestines," not robust; had indigestion for years; the father's father died at 85; the mother died at 49 of pneumonia; she was not robust; she was confined to bed five or six months following one childbirth; the mother's mother died at 80 plus; the youngest sister died of tuberculosis of the cervical glands. The father can give no information as to the vision of the other members of his childship, as he came to America at the age of 19.

Until eight years prior to present examination he could read the finest print with ease. Suddenly, in 1911, his vision began to fail and fell rather rapidly to a point at which the recognition of faces was uncertain. Particularly annoying was his inability to read except by the greatest effort. He now reads the newspaper as he did when I first saw him two years ago (1916) by holding it about 8 inches from his eyes and looking through a small magnifying glass. He cannot note any change in his vision in recent years. It may be a little worse, but of this he is not certain.

His previous history, while of interest, is not illuminating. Nineteen years ago he began suffering with indigestion. Fourteen years ago he underwent an operation for appendicitis with no resulting benefit. Six years ago he consulted Dr. Charles Louis Mix, who, after exhaustive examination, discovered an ulcer of the duodenum. For the past five years he has lived on a diet of milk, cereals and eggs which has resulted in marked improvement.

\* Read before the Section on Ophthalmology at the Seventieth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

 8. In this family, two generations were affected; in the other families, one.

The eye examination shows the following points of interest: vision, O. D. 6/30; O. S., 6/60; no material improvement by correcting the low grade refractive error present. The visual fields show relative negative scotomas at the centers. He is blind for green and red at the center. The peripheral fields are not contracted. The ophthalmoscope shows a lesion at the macula in each eye.

Mrs. W. H., mother of the foregoing childship, was born in Alsace-Lorraine in 1881. Her mother died at 80, her mother's mother at 76; her father at 80.

#### COMMENT

The literature covering this subject shows a tendency to consider only those cases typical of family degeneration of the macula lutea which conform to a rather restricted preconceived type. This conception is based on the reports of a relatively few individual cases and a still smaller number of family groups. We are, in truth, almost within the bounds of fact when we say that the present concept is based on the one family reported by R. D. Batten in 1897 and circumscribed by the opinion of Stargardt expressed on presenting two similar families in 1909. A further tendency to consider those cases atypical which do not conform rigidly to this concept is apparent.

On the other hand, there is apparent a strong tendency to broaden the classification to such an extent as to include such dissimilar conditions as amaurotic family idiocy, cerebral degeneration associated with macular lesions and the cases under discussion in a single clinical concept.

Now it seems to me that neither the one nor the other concept is logical under our present knowledge. But would it not be logical to broaden our concept of the disease to include the so-called atypical cases? Is it not apparent that a disease with a history so characteristic, with a lesion so definite, and a prognosis so certain merits consideration as a separate clinical entity? Other conditions may resemble this one in certain features which seem to bind them together into one group; but they differ so greatly in other points that plain lines of cleavage exist. Recognition of these lines of cleavage amounts practically to differentiating one clinical entity from others which resemble it in certain features.

To my mind the most potent argument for an inclusive classification is the fact that a familial factor is present in all the so-called types of the disease. The case presented introduces a hereditary factor. This basis for classification, however, is so broad that it is quite evident that its use would necessitate the inclusion of other and still more diverse conditions.

It is alluring to group together those conditions which show in common a lesion at the macula, particularly if they present other common characteristics or resemblances. This very natural tendency leads to the placing of too great emphasis on the location of the lesion as a binding factor. To guard against this tendency, careful consideration must be given to the anatomy of this region which makes it peculiarly vulnerable to pathologic processes and to the physiology which early throw these lesions into prominence. Diverse, indeed, are the known conditions producing lesions at the macula. So diverse are they that the term macular lesion has the same significance as the term corneal lesion—it locates the lesion.

From the unquestioned cases of symmetrical disease of the macula of R. D. Batten; symmetrical degeneration

at the macula of Jennings; progressive familial macular degeneration of Stargardt, and family degeneration of the macula lutea of Pusey, the accompanying table has been compiled. In very few instances a perfectly obvious conclusion, though not mentioned in the text, has been incorporated. From the data supplied by these cases we may reconstruct our conception of family degeneration of the macula lutea to conform with all the features of the disease as amplified by constantly accumulating facts.

Family degeneration of the macula lutea is a disease of unknown etiology. It usually attacks several members of a single childship. The parents of the afflicted childship commonly show no abnormality of the eyes and are otherwise normal. It is unusual for it to affect more than one generation, but it may.

Both Jew and Gentile are attacked—the latter with much the greater frequency. Race cannot be said to be a positive factor in its occurrence.

Sex does not appear to play any considerable rôle in its occurrence. Of the total number of cases reported, more have been of the female sex than of the male. On the other hand, where the complete childships have been recorded there is a preponderance of females in these childships. In certain childships the males seem notably immune to the disease, and the females notably susceptible, making it difficult to escape the conviction that the female is more susceptible to the disease than the male. Statistics, however, do not admit of this conviction being recorded as a fact.

The disease is bilateral. It manifests itself between the ages of 7 and 35. The majority of cases develop between the ages of 10 and 14. The period of adolescence corresponds with the time in life during which the disease most frequently develops. The cases that develop before and after puberty differ in no way from those that develop during this epoch of life.

A slowly progressive course characterizes the disease. After the rather rapid initial onset, evinced by the comparatively rapid initial fall in vision, long periods of arrest may occur during which visual acuity remains stationary or is diminished by imperceptible gradations. It may finally progress to central, that is, macular, blindness. Here it halts. The periphery of the retina is spared. Blindness, idiocy and death do not occur.

Objectively, the findings are those characterizing a lesion at the macula lutea. Externally the eye appears normal. The pupils may be a trifle wide. They react to light and accommodation. But when the light is thrown directly on the macula, the pupillary reaction may be relatively sluggish. This lowered sensitiveness to light at the macula facilitates greatly the ophthalmoscopic examination of this portion of the fundus oculi. The objective findings are complete when a lesion at the macula and temporal pallor of the disk are observed and a central scotoma is demonstrated. In the beginning, the scotoma is relative; later, it may become absolute. Pallor of the temporal half of the disk depends on the completeness of the macular degeneration.

#### ABSTRACT OF DISCUSSION

DR. SAMUEL D. RISLEY, Philadelphia: Since the cases discussed in this paper lie entirely outside of my personal experience, it is possible that I may have overlooked, or not recognized, the family character of certain macular diseases. I am not prepared to accept the hereditary aspects of this case without more elaborate study of the family conditions

even in the family of the patient whose case is presented. All of us have seen many examples of macular disease of various origins, and many times I have been unable to discover why the central blind spot existed. We see this in cases of strabismus, in which the strabismus is seemingly due to the apparent blind spot in one eye. I have oftener seen it monocular than binocular. Some years ago Dr. Adams called my attention to the fact, and subsequently published a paper in which he contended that these central blind spots are often associated with adenoids in the upper pharynx. He published quite a group of cases in which he had demonstrated the presence of the blind spot in children with large adenoids. It is not going far afield when we associate diseases in that locality with the sphenoid sinuses, and we all know the relation between the roof of the mouth and the optic nerve itself, which runs right over the roof of this sinus. In this way we may often account for the existence of the central blind spot. Until we have excluded the possibility of systemic origin in all these cases we should hesitate before placing these cases in the hereditary group. The fact that they have occurred in fathers and daughters may be incidental or coincidental, rather than hereditary. We must have a fair record before we include the case in the distinct type of family diseases.

DR. WILLIAM ZENTMAYER, Philadelphia: I have seen two cases of family blindness with macular changes, as to the proper classification of which I am in doubt. To bring all types of family disease presenting macular lesions into one class would be faulty because the macula and the macular fibers, by reason of their highly specialized function, fall within the Erdinger dictum, and are, in Dr. Blue's words, "particularly vulnerable to pathologic processes." Yet the difficulties in properly assigning a given case are evident. Certain groups of cases which resemble one another in their general symptomatology and course are in contrast as to ophthalmoscopic findings. This is true of juvenile amaurotic family idiocy and the type for which Clarke proposes the term macutocerebral degeneration. Other groups are allied ophthalmoscopically but differ in their general aspect, as, for example, the two forms of macular degeneration, one of which is associated with cerebral degeneration. Furthermore, Gifford states that Hicene has recorded a family history in which one child had the Tay-Sachs' type, another the Voigt type and the third the Stargardt-Batten type. According to Clark, who presented an admirable paper on macular degeneration with and without dementia, before this section last year, the first type differs from the second in that the onset occurs at, or about, the time of second dentition instead of at puberty. Cerebral changes begin at the same time as those in the macula, but there is a greater terminal impairment of vision. Ophthalmoscopically, the changes are identical but optic atrophy is more common in the type with dementia. Stargardt and Stock assume that in both types the degeneration, which Clark believes to be in the neuro-epithelium of the retina, is due to an auto-cytotoxin that has an affinity for the neuro-epithelium of the retina and in some cases for certain brain cells. In this connection it is of interest to note that Sajous believes the suprarenal secretion to be at fault and responsible for amaurotic family idiocy and evidence is accumulating which tends to substantiate Hisler's view that Leber's disease (hereditary optic nerve atrophy) is due to dyspituitarism. I recently saw, through the courtesy of Dr. Homer Rhoad of Reading, Pa., a family of three children, two of whom were either born blind or became so in the first months of life, while the third, a baby 2½ months of age, appeared to have but a slight amount of vision. They were all too young to permit of a thorough study of the ocular conditions or to determine their mentality. All three presented at the macula changes which, so far as could be determined, were not unlike the whitish areas of circinate retinitis, but bearing no likeness in the grouping of the lesions. The affected area seemed more or less oval and covered a surface several times the diameter of the disk. The disks were partly atrophic and the vessels were small and somewhat tortuous. There had been no inflammation in the eyes of any of the children, and there was no blindness in the

families of either parents. The external appearances of the eyes were normal except for the searching movements of the globe. In January, 1917, I saw a boy, aged 9 years, and his sister, aged 10 years, both having very low visual acuity associated with retinal degeneration. There were grouped about the macula and along the course of the superior and inferior temporal arteries white or yellowish white disciform lesions, mostly discrete but sometimes confluent, varying in size from two to four times the diameter of the main trunk of the central artery of the retina. In the right eye of the boy the foveal lesions were somewhat pigmented. The children were healthy, well developed and mentally sound. The girl had a slightly positive Wassermann.

DR. MARCUS FEINGOLD, New Orleans: It is difficult to class one group of macular degeneration in any one of the several groups referred to here; but it has been an acknowledged fact, except in very rare instances, that macular degeneration will have more or less the same type in a given family. In the case reported the father was injured. He acquired the disease rather late in life, and at the same time the daughter acquired the disease early in life. In other words, while it is difficult to differentiate and define the different types of macular degeneration, we have in one family the two types of it, and it has appeared in two generations—an interesting fact. Next is the fact that we have no appearance of several members of the same childship, having the macular degeneration. This is a factor also which must be borne in mind if we are to consider these as macular degeneration.

The patients whose cases I reported three years ago are holding their own; the condition has deteriorated only in the most progressed case. No degeneration is evident except for some nervous symptoms.

DR. ROBERT BLUE, Chicago: I am aware of the unsettled condition of this question. I have expressed my personal opinions in the paper and will let it rest on its merits. In the father, the normal marks of the macula are found, while in the daughter they are obliterated. In the father they are pigmented, not around the borders of the lesion, but scattered through it. It can be described as a moth-eaten appearance. The lesions are not alike. I judge this from the pictures and the descriptions. The paper shows the lesions at various stages. My reason for not mentioning the lesions is that the appearance does not seem to be the same in the various descriptions, even though the histories are typical, and the discussion of that subject would have made too long a paper to present here.

## UVEITIS

WITH SPECIAL REFERENCE TO THE ETIOLOGY  
AND TREATMENT IN THE CHRONIC AND  
MALIGNANT TYPES\*

A. EDWARD DAVIS, A.M., M.D.  
NEW YORK

Although much has been written on this subject in the last few years, and although many scientific investigations have been made as to etiology and numerous methods of treatment tried, unfortunately in many cases the cause or causes of the disease remain obscure, and the treatment unsatisfactory. In this country de Schweinitz, in particular, has given the subject of uveitis, in its various forms, much attention; he has made special investigations as to the etiology, and has by his many valuable contributions and discussions done much to clear up a complex problem. A valuable symposium on the subject of uveitis was presented before the Section on Ophthalmology of the American Medical Association in 1902, de Schweinitz, Woods, Friedenwald, Hensell, Wilder, Woodruff and

\* Read before the Section on Ophthalmology at the Sixteenth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

Marple contributing.<sup>1</sup> Irons and Brown, Reber, Zentmayer, Frances, Bordley and Dwyer and others have made valuable contributions on the subject. In England, Stephenson, Mayo, Butler, Dunn, Campbell and others have contributed to the subject; while on the continent, among many contributions to this subject in the last few years, Elschnig's papers, perhaps, have attracted most attention, because of the anaphylactic theory of sympathetic iridocyclitis which he also applies to nonsympathetic uveitis. Bordley's and Percy Dunn's contributions to this subject, wherein they lay stress on hypothyroidism as a factor in cases of iridocyclitis and uveitis, and dwell on the clinical value of the administration of thyroid extract in these cases, have not received so much attention, perhaps, as they deserve.

ETIOLOGY

Stephenson and de Schweinitz are of the opinion that most probably every case of uveitis (iridocyclitis) is of septic or toxic origin. In a general way, the causes of uveitis may be grouped under three headings: (1) those that are associated with or produced by infectious diseases, as syphilis, tuberculosis, gonorrhoea, influenza and "rheumatism"; (2) those in which there is perverted metabolism, as in gout,

arthritis (so-called uric acid diathesis), diabetes, nephritis, anemia and hyperthyroidism, and (3) those cases of autointoxication from focal infections, which may be situated in the gastro-intestinal tract, nasopharynx, nasal accessory sinuses, teeth and alveolar processes, tonsils, genito-urinary tract, or the skin.

In investigating the etiology of uveitis, it is interesting to compare the causes as given by the older writers with those given by men who have had the advantage and use of modern laboratory methods of investigation. In the good old days, syphilis and "rheumatism" held the leading rôles, while gout, malaria, diabetes, tuberculosis, scrofula, gonorrhoea, etc., were given secondary consideration. Take in contrast the statistics of de Schweinitz, Reber, Irons and Brown, who have availed themselves of all the latest methods of investigation as to the etiologic factors in these cases. To begin with, an accurate history is taken; then a physical examination is made; and the roentgen ray and various laboratory tests, as the bacteriologic and serologic, are utilized to arrive at, if possible, an approximate cause of the eye trouble.

It is interesting to note the opinion expressed by the late Dr. Reber on the value of the older methods of ascertaining the etiologic factors in cases of uveitis. After reviewing the statistics of numerous authors,

based on clinical findings, and noting the wide discrepancies therein, he came to the conclusion that these statistics amounted to "precisely nothing." While admitting the value of clinical findings and the history of the case, Reber strongly urged the use of modern laboratory methods, such as the complement fixation test, for detecting *Spirochæta pallida*, gonococci, pneumococci, streptococci, the postinfluenzal group, staphylococci and *Bacillus coli*, the first five having been shown to have a causative effect in diseases of the iris.

Following the latest methods, Brown and Irons<sup>2</sup> reported 100 cases of iritis, the causative factors of which (traumatic cases excluded) are given in the accompanying table.

These authors found it not an easy task to treat these cases when the etiologic factors were multiple, as it proved difficult to decide which factor played the important part in causation. Knapp<sup>3</sup> cites Mayo to the effect that "there are three kinds of bacteria which usually cause cyclitis, and that these are usually present in the aqueous humor. Among thirty cases, he finds the tubercle bacillus in thirteen, the staphylococcus in ten, and the spirochete in five. He suggests as a routine method of examination, first, the Wassermann test, second, the von Pirquet test, then paracentesis and examination of the aqueous."

As to the uric acid diathesis; although laboratory methods have induced us to give up the blanket term "rheumatic" to cover a multitude of affections, and to substitute therefor "toxicemic" or "autotoxemic," as suggested by Harrison Butler,<sup>4</sup> we cannot, as suggested by Knapp,<sup>5</sup> give up the rheumatic tendency entirely, and from a therapeutic standpoint the study of the eye patient's diathesis is of importance. Knapp also cites Girard to the effect that among the causes of eye diseases the arthritic diathesis occupies the first place; second, syphilis; third, tuberculosis; and de Schweinitz,<sup>6</sup> commenting on rheumatoid arthritis, says:

In these polyarthritic conditions, the toxin, bacterial or metabolic, or the bacterial element itself comes, in all probability, in general terms, from the digestive system, beginning in the mouth, and including the pharynx, tonsils, intestines, etc. The patient begets uveitis or iridocyclitis, not because he is "rheumatic," but this is one of the manifestations of the toxemia or infection of which he is the subject, while his muscle, joint, and fibrous tissue pains and lesions are other manifestations of the same cause.

In regard to intestinal infections, Dwyer recently has called attention especially to the hyperacidity and hyperalkalinity of the intestinal contents as a factor in eye diseases, including chronic uveitis. He states that either hyperacidity or hyperalkalinity of the bowel contents in these cases destroys the colon bacillus; and at the same time he noted that in such specimens the indol and skatol content was high and that there was always a high percentage of indican in the urine. In such cases intestinal intoxication occurs, and eye affections may follow.

Elschnig has laid great stress on indican in the urine as an indicator of intestinal intoxication, but de Schweinitz has called attention to the fact that indicanuria is not a reliable test of intestinal toxemia; that, in

6. De Schweinitz: Pathogenesis of Chronic Uveitis, Tr. Internat. Cong. Med., 1913.

fact, the patient may be toxicemic without the presence of indican in the urine, and, vice versa, may not be toxicemic though indican is present.

A final point in etiology to which I wish to call attention is that of hyperthyroidism, a factor perhaps which has not received sufficient notice. Dunn<sup>7</sup> calls attention to the influence of the thyroid gland in metabolic processes. He says:

Metabolic processes as a whole depend on the controlling influence of the thyroid gland, and that owing to its extreme vascularity, the ciliary body is very responsive to blood changes. . . . There is the primary stage, represented by auto-intoxication, arising, as we may assume, in the intestines. To combat the toxemia, so called, the thyroid gland, through its secretion, is called on to make strenuous efforts under the influence of excessive stimulation. For a time these efforts are successful. Later on, however, the thyroid fails in its mission. Then follows the second stage, namely, hypothyroidism. With this begins a pervading uncontrolled toxemia. Accompanying this, and dependent on it, is the last stage—that of diminished resistance of the tissues, thus rendering them a prey to bacillary infection.

Dunn reports some remarkable cures from the administration of thyroid extract, and reaches this conclusion:

The main purport of this paper is to lay stress on hypothyroidism as a causative factor in cases of iridocyclitis and on the usefulness, clinically, of its recognition. That the ciliary body, so sensitive to toxicemic influence, should readily respond to thyroid treatment is a natural sequence to the vascularity of its structure. Thus is placed in the hands of the ophthalmic surgeon a means of relief, yielding results which can be obtained in no other way. The dose of the extract employed by me for children beyond 5 years of age and for adults is 3 grains twice daily, and from this dosage I have never seen any ill effects.

In a second communication on the same subject, Dunn<sup>8</sup> adds further evidence of the value of thyroid extract in the treatment of deep-seated eye affections.

James Bordley, Jr., of Baltimore has made two communications on the value of thyroid extract in the treatment of malignant uveitis, and has reported seven cases. In four out of five cases,<sup>9</sup> first reported in 1915, the patients are entirely well<sup>10</sup> without return of symptoms to June, 1916, and in the last two cases reported the patients have been entirely relieved of all symptoms of inflammation. Bordley states that he does not claim that thyroid extract is a panacea for all types of malignant uveitis or, indeed, for any special type, and says further that it will take treatment of many cases to prove its usefulness. It is his opinion that, uveitis being due to an infection and the eye not having sufficient defensive power to protect itself, thyroid extract furnishes the offensive energy, and in this way, a cure is brought about. Bordley gave 2½ grains of iodothyryn from one to three times a day.

#### TREATMENT

The foundation of all treatment, of course, rests on finding the cause and if possible removing it. However, as Bordley states relative to malignant uveitis, it must be remembered that the mere finding of a focus is not proof of its causative relation, and that malignant uveitis once established becomes an entity and

not a symptom. It goes without saying that in all doubtful cases the Wassermann and tuberculin tests should be made. In syphilitic and tuberculous cases, the indication for treatment is plain, and intensive treatment should be used. In those cases due to focal intestinal intoxication, the services of an internist must be utilized and laboratory methods employed to get at the underlying cause. De Schweinitz<sup>11</sup> has reported a series of such cases. Lately, Dwyer has made some investigations in cases due to intestinal intoxication, especially in reference to the part the colon bacillus played in these cases. Dwyer found that in many cases of deep-seated eye infection, including intractable uveitis, the colon bacillus was absent, owing to a hyperacid or a hyperalkaline condition of the bowel contents, the colon bacillus not being able to survive in either condition. Dwyer's method of treatment<sup>12</sup> in such cases is briefly as follows:

In the highly acid specimens, an endeavor was made to alkalinize the contents by the use of irrigations of a 1 per cent. sodium carbonate solution and then to practice colon transplantation in order to approach the normal. At the same time the patients were put on rather free diet, cutting out those foods that were completely assimilated, such as meat. In other words, the tolerance for the three fundamental foods was established as far as possible. In the highly alkaline specimens, irrigations with lactose were given and then the colon bacillus was transplanted. At the same time the Bulgarian bacilli were given by mouth, the whole idea being to approach the average normal. Lactose was also administered by mouth in such cases to provide a suitable pabulum for the colon bacilli.

Dwyer reports some remarkable cures when all other treatment had failed.

But even with the removal of foci of infection and elimination of toxicemic conditions in the alimentary tract, the arrest or cure in many of the chronic and malignant cases of uveitis is not to be had. It is in this type of case, when other methods have failed, that Bordley and Dunn call into use thyroid extract. Although my own experience with the use of thyroid extract in these cases is very limited (being confined to two cases) and not of happy result in either, from the reports of Bordley and Dunn I think the method should be thoroughly tried out. Even the cure of one such case would justify its trial in many cases.

#### REPORT OF CASE

By way of foreword, I may say that the following complement fixation tests were made: 1. Wassermann, for *Spirochaeta pallida*, several times, always negative. Spinal puncture was not made, as the patient refused it. 2. For gonococci; negative. 3. For staphylococci; negative. 4. For streptococci; positive for the viridan type. Also examination for the presence of colon bacilli was made, their absence noted, and appropriate treatment given after the method suggested by Dwyer.

*History.*—S. J. D., man, aged 38, consulted me first, May 13, 1910, for an acute iritis in the right eye, which was of one week's duration when he came under my observation. I found the pupil contracted and somewhat irregular, the iris muddy and edematous in appearance, but only with a slight exudate present, the anterior chamber was deep, and the aqueous hazy; there were marked circumferential injection and redness, and great pain and photophobia. The patient's father died at the age of 74 years, of cancer; his mother died at the age of 50, of Bright's disease; one brother, older than himself,

7. Dunn, Percy: Some Aspects of the Ciliary Body in Health and Disease, *Lancet*, 1: 1129 (May 29) 1915.

8. Dunn, Percy: *Brit. J. Ophth.*, January, 1919.

9. These cases were presented before the American Ophthalmological Society in 1915.

10. Bordley, James, Jr.: Thyroid Extract in the Treatment of Malignant Uveitis, *J. A. M. A.* 67: 112 (Aug. 5) 1916.

11. De Schweinitz: Pathogenesis of Chronic Uveitis, *Tr. Inst. Cong. Med.*, London, 1913.

12. Dwyer, J. G.: Focal Infection of the Eye from the Intestine, *J. A. M. A.* 71: 916 (Dec. 21) 1918.

died of Bright's disease, at the age of 36; he had also suffered with "rheumatism," and had had one attack of iritis one year before his death; another brother and sister were in good health; the patient himself, though not robust, had enjoyed good health, never having had any serious illness.

There were no symptoms of syphilis, unless the inflamed eye should be so considered. Many subsequent Wassermann tests have all proved negative; the patient had had two attacks of gonorrhoea, but was apparently entirely cured of this, and subsequent complement fixation tests have proved negative. Roentgenographic tests of the sinuses have shown them to be entirely normal until recently; urinary tests proved negative, except for excess of indican, now and again.

In the last eight years that the patient has been under my observation, he has had ten attacks of iritis, first in one eye and then in the other, until this last attack, when both eyes were involved, the right eye, first, in November, 1917, which still continues, and the left, May 10, 1918, acutely following injections of *Streptococcus viridans*. The shortest attack lasted ten days, and the longest, eight weeks, previous to the present one, which has now lasted for sixteen months, the whole uveal tract becoming involved. All former attacks of iritis yielded to the usual local treatment of atropin, ethylmorphin hydrochlorid (dionin), hot fomentations, leeches, etc., and to antirheumatics given in full doses, both by mouth, and by rectum in mucilaginous suspension. The patient has been to the hot baths in Michigan several times, and once to Arkansas. In 1913, while taking the baths in Michigan for an attack of iritis, in the fifth week of his stay he developed an acute arthritis in his left knee, the knee swelling to almost double the usual size, and it has remained in this condition, since, except for short intervals, though he has had hot air baths, and all other approved and unapproved antirheumatic treatment for the condition. In 1917, following the removal of submerged tonsils by my brother, Dr. George E. Davis, the swelling of the knee almost completely subsided within forty-eight hours, but inside of ten days, the swelling returned, and so remains. I may say also, in this connection, that *Streptococcus viridans* injections have caused acute swelling in the knee, and rendered it painful.

*Treatment and Course.*—Diagnostic tuberculin tests proved negative, both for the von Pirquet and subcutaneous injections of the O. T. solution, though the latter were carried up to 5 mg. These tests were repeated after a year's interval, and were again negative. In January, 1918, examination of the bowel contents detected the absence of colon bacilli. The reactions in this case were alkaline. After due preparation, these beneficial bacilli were reimplanted, locally, and also the Bulgarian bacilli were given by the mouth, and proper diet instituted, but all without benefit to the patient.

As it was not known what else to do, and as other treatment failed to give relief, for diagnostic purposes a course of mercurial inunctions combined with pilocarpin sweats was given for a period of four weeks, but without improvement of the condition.

The history concerning the teeth is of particular interest in this case as a possible etiologic factor. The patient, when 15 years of age, had a swelling about a capped lower molar tooth on the right side. This swelling lasted two years, and subsided without treatment. In 1912, after the patient had had two attacks of iritis, an abscess formed around this capped tooth, and the tooth was removed with a portion of the alveolar process. The patient had no other trouble with the teeth until 1917, when he had one lower molar on the left side removed. In the fall of 1918, after consulting two competent roentgenologists, one of whom pronounced the teeth all right but the other pronounced them diseased, the patient had two right upper molars, and one left lower molar removed, and also a small piece of the root from the site of the right lower molar which had been removed six years previously, on account of abscess. *Streptococcus viridans* was found, and autogenous vaccine was given biweekly, beginning with an initial dose of 2,500,000,000 and carried up to 8,000,000,000. After these injections, the right eye had slight reaction, followed by some clearing; following the ninth injection, there was slight circumferential flushing in the left eye, which had been quiet, and after the tenth injection,

a decided reaction followed, with redness, pain, photophobia and lachrimation; and in two days, a very severe iritis developed in the left eye. The right eye had also become slightly worse, and injections were discontinued for one week, and then begun with the same size dose as the tenth injection, which apparently had little effect on the eyes, one way or the other. Altogether, forty-three of the streptococcal injections were given, the last dose, as stated above, being 8,000,000,000, but without improvement.

The patient was then put on thyroid extract (Rogers residue<sup>13</sup>), 3 minims five times a day, for several weeks, but without improvement. A second series of injections of *Streptococcus viridans* was given biweekly, being rapidly increased until 40,000,000,000 were given at a single dose (Dr. John H. Richards gave these injections); but as the patient did not improve, the injections were given up altogether.

Roentgenoscopy of the sinuses seemed to show some sphenoidal involvement, and accordingly, March 12, 1919, Dr. E. R. Faulkner opened up and drained these cells, a submucous resection of the nasal septum being done as a part of the operation. The operation showed signs of an old cicatrization, parts of the bone being ivory hard. There was but slight reaction from the operation, and what effect it will have on the patient's condition is a matter of speculation.

The present condition of the patient's eyes is: R. V., 5/200 not imp. L. V., 4/200 not imp. Almost complete posterior synechia of the iris to the lenses, incipient cataract with the vitreous full of floating membranes in each eye. Deposits on Descemet's membrane, T. 12 mg. each. I may say that at no time, even in the attacks of iritis, has there ever been a plus tension. The fields of vision remained normal until the vision was markedly reduced, when peripheral contraction was manifest to a slight degree.

The patient has a marked arthritis in each knee which has not been improved by any treatment, and altogether he is in a bad way, both as regards his eyes and his joints.

#### ABSTRACT OF DISCUSSION

DR. GEORGE S. DE SCHWEINZ, Philadelphia: The advance made in the management of these cases depends on the widely accepted statement that practically all cases of uveitis are of septic or toxic origin. Second, it depends on the recognition of the fact that uveitis must be considered as a complication. And in the third place, in the management of these cases, we have learned that the finding of one source of focal infection does not necessarily mean that we have found the cause in its entirety. In other words, the toxemia may come from several sources. These various sources we ordinarily call the areas of focal infection, or sepsis, and those most in our mind are in the tonsils, intestines and teeth, or more accurately, the buccal mucous membrane. The relation of the teeth to the eye has been recognized for years. Forty years ago Nettleship reported the relationship between various teeth and choroiditis. Seven years ago I sent out 700 questionnaires to Americans and Canadians on this subject. Of 100 replies seventy-four were available and among these only nine surgeons reported a relationship between infected teeth and uveitis. Next year Mr. Lang reported 215 cases, with 139 attributed to tooth infection. I think we have learned, too, that extensive tooth infection is not at all necessary, and that the smallest blind abscess is liable to be the seat of infection. In like manner the so-called innocent tonsil is often a virulent source of danger. I wish to emphasize the importance of buccal sepsis in its relation to uveitis, and to call attention not only to ordinary pyorrhea alveolaris, but to "blind abscesses," apical abscesses, in devitalized teeth, and to the fact that no dental examination is complete without roentgen-ray examination. I would urge insistent exploration of the tonsils, even though they are innocent looking. I shall not discuss the treatment from the medicinal, dietetic and vaccine standpoints; it is well

13. Rogers residue is that which remains from the thyroid gland after acetic acid has been added and the proteins have been extracted. The residue is a liquid and supposedly nontoxic. Three minims of this were given five times a day.

known. But I urge the importance, in addition to these measures, of repeated paracentesis of the anterior chamber in uveitis, especially where there is rise of intra-ocular pressure—a not infrequent complication. Naturally, the fluid obtained should be examined bacteriologically.

DR. E. L. JONES, Cumberland, Md.: I have seen results in uveitis, which I believe indicate that we are on a trail that in some cases at least will lead to better results than we could obtain heretofore. The etiology of this affection has been said to be due to infections, syphilis, faulty metabolism, etc. But many causes combine in some cases. The effect of infections, syphilis and faulty metabolism is strong to disorganize the ductless glands; therefore we supply thyroids in addition to the other treatment. It enables antisyphilitic treatment to cure when that treatment alone would not cure; and so with infections and faulty metabolism.

DR. A. EDWARD DAVIS, New York: The point Dr. Jones made has been brought out also by Dr. Dunn, that even in specific cases there is always something beyond, and that by giving attention to this, using thyroid extract, as he has, we secure results not obtainable before.

## EXPERIENCE OF AN AREA CONSULTANT IN FACIAL SURGERY

IN THE ZONE OF ADVANCE \*

GEORGE C. SCHAEFFER, M.D.

Major, M. C. U. S. Army  
COLUMBUS, OHIO

The work of the maxillofacial service began properly with the mobile and evacuation hospitals, and in both the zone of advance and the hospitals of the advanced section, the work of our department was largely one of prevention. We had to deal with all injuries of the face and neck, exclusive of brain injuries. Those injuries involving the eye, the nose and the ear which did not involve other parts of the face came directly under their respective departments; but as these injuries were almost invariably associated with injuries of other parts of the face, most of them came directly under the care of the maxillofacial department.

It was the original plan to have installed in each mobile, evacuation and base hospital a maxillofacial team, composed of a surgeon who had had some special training in this class of work, a surgical assistant and a dentist. The surgeon was to be the head of the team. The dentist was expected to do the splinting or wiring of the jaws, working in cooperation with the surgeon. With this in view, several schools in this country had given special oral and plastic courses to surgeons and dentists, to prepare them in sufficient numbers for the work. Unfortunately, however, this plan was not practicable, not because of the shortage of surgeons and dentists in our army, but because they could not be transferred abroad in sufficient numbers. Another reason was that it was not always possible to have the cases properly classified in the triage and sent to special teams. So a compromise plan was adopted. A dentist was secured for each hospital, and it was arranged that he be called to assist the general surgeon to whose table the case happened to go, in caring for all jaw fractures. By this plan, the dentist was on call twenty-four hours a day, and often had to work steadily during the entire period.

The care of soft parts and the general supervision of the case devolved on the general surgeon, who spent most of his time at general surgical work and who often had had no special training for the maxillofacial work. This was not the ideal plan, but it produced some very good results, and seems to have been the best one possible under the circumstances.

For the guidance of surgeons and dentists in caring for maxillofacial cases, the chief surgeon, A. E. F., on the recommendation of the chief consultant in maxillofacial surgery, issued some bulletins of instruction.

The essential features of these bulletins were as follows:

1. All maxillofacial wounds shall undergo thorough mechanical cleansing.
2. There shall be no débridement of face injuries.
3. No bone fragment having any soft tissue attachment shall be removed.
4. Immediate steps shall be taken to arrest hemorrhage, and to prevent secondary hemorrhage.
5. There shall be immediate fixation of all jaw fractures.
6. Adequate inferior drainage shall be established in all fracture cases.
7. As much primary suture of face tissues shall be done as is consistent with good surgical principles.
8. Cases shall be evacuated to the base hospitals as quickly as possible.

It will be seen that in several respects these instructions ran counter to those that were sent out for the guidance of general surgeons in the handling of war wounds. One of the first requirements of these general instructions was that there should be a thorough débridement of all gunshot injuries. The second was that there should be no primary suture of these cases. This was essential and well advised in the handling of general surgical cases. The danger of general infection, and particularly the danger of infection from the gas bacillus, required that all gunshot wounds should be thoroughly debrided, particularly shell, shrapnel and hand grenade injuries. In the handling of face cases there were two reasons why we should not follow these general rules: In the first place, thorough débridement of all face injuries would have meant the sacrifice of an immense amount of facial tissue which never could have been adequately replaced, and which, if removed, would have necessitated a great amount of unsatisfactory secondary plastic surgery. In the second place, it was shown that there was practically no danger from gas infection in face wounds, no case to my knowledge having been reported.

By thorough mechanical cleansing of the soft tissues and careful suture of these shreds of skin and mucosa into their normal position, much tissue was saved which, otherwise, would have roped up into hard scar tissue and have been absolutely useless in the reconstruction of the face.

As was to be expected, much of this primary suture broke down, but even in these cases, no damage was done by the suture, and the tissues had been brought into some semblance, at least, of their normal position, which they retained to a greater or less degree.

Bone fragments, with some soft tissue attachment, were retained to serve as grafts from which new bridges of bone were to be regenerated. Many of these were lost, of course, but in a good percentage of cases, they served their purpose admirably, and no damage resulted from their retention.

In the matter of fixation of the jaws, it was necessary to allow the dentist considerable latitude for the

\* Read before the Section on Stomatology at the Seventieth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

exercise of his own skill and judgment. Materials for this purpose were very scarce, and the dental men were often forced to resort to extremely crude methods. A great deal of ingenuity was evidenced by many of these men, and some excellent results were obtained.

An open bite emergency splint had been devised and was eventually supplied to the advanced hospitals. This consisted of double trays of aluminum filled with modeling compound. The jaws were to be put in the best possible position, the modeling compound softened in hot water, the splint placed in the mouth, the teeth pressed into this softened compound, and the jaws held in that position until the compound hardened. A chin cup and bandage completed the work. This was intended to serve only until the patient reached the base hospital, where permanent splinting could be done. Some of these splints were used with good results. In many cases, however, they were not found practical, and some other method was used. Probably the most common form of fixation used at the front, and one which gave very good results, was that of interdental and intermaxillary wiring. Villain's anchorages were used in a few cases. Arches of heavy silver wire, with interdental wiring, were also used. A few men made swedged splints, and one or two made some cast silver splints, using for this purpose the crudest sort of home-made casting apparatus. As silver and aluminum were hard to get, some of our dentists used frane pieces from their own pockets for this purpose. Block tin was also used in some cases and made very good splints. The ingenuity of the American dentist is such that he can be trusted to find some way out of almost any difficulty, and the lack of equipment and materials never daunted him. In the preparation for another war, should such a misfortune befall us, I have no doubt that some standardized method of procedure will be adopted and carried out; but should we ever be caught again as unprepared as we were this time, it is very comforting to know that we have dental men who can be depended on to meet the emergency as efficiently as they did in France during the later months of the war.

Too much cannot be said of the work done by the dental men in the advanced hospitals, and there is no doubt that much subsequent bone grafting of ununited fractures has been prevented by the early and efficient fixation secured by these men.

As these cases had to be evacuated very quickly, only the most temporary measures could be instituted. We had to depend on the base hospital staffs for the more permanent appliances to the jaw and for the real plastic work.

The arrest of primary hemorrhage was often a difficult matter, and taxed the ability of the surgeon to the utmost. Concealed hemorrhage from a mouth, very much swollen, made its control a very perplexing problem. Ligation of the common carotid was found necessary in a few cases. The prevention of secondary hemorrhage resolved itself largely into a question of the prevention of sepsis. Adequate inferior drainage in fractures of the mandible went far toward controlling the sepsis that almost invariably followed these injuries. This was secured by making a free opening below the border of the mandible at the site of the fracture. In the fractures of the maxilla, the wound itself almost always provided inferior drainage—either externally or into the mouth.

As the consultant in maxillofacial surgery for the advanced section and zone of advance, it was my duty to organize our forces and resources for the accomplishment of our aims. Our forces in surgeons and dentists were meager, and our resources in materials were still less. On my first visit to the advanced hospitals I found practically no plastic surgeons, only a limited number of dentists, and no equipment for caring for face cases. It was necessary to secure dentists to supply the hospitals that were without them. This was done through the chief dental surgeon of the A. E. F. Directors of surgery and commanding officers of hospitals had to be shown the necessity of having some systematized plan of handling our cases. They had to be convinced of the wisdom of the maxillofacial rules of treatment, and as these differed essentially from those governing other cases, this was no mean task. It was only with difficulty that many of them were induced to consent to calling in the dentist to help splint jaw cases, but it was very gratifying on later visits to find dentists and surgeons working in close cooperation. The securing of materials with which to do our splinting was a hard problem. Modeling compound, ligature wire, heavy silver wire for arches, emergency splints, silver, aluminum, silver solder—these and many other things very necessary for the proper splinting of bad fractures, had to be obtained wherever and however we could, and they had to be taken to the men in the hospitals, so that the consultant reminded himself oftentimes of a sample man for a drug or instrument house. It was a part of the consultant's job to gather ideas from all sources, and to impart them to others. It was a work of education of the consultant and by the consultant.

After seeing the work in British and French hospitals, later in our own hospitals in France and now in our reconstruction hospitals at home, where I am now seeing many of the same cases that it was my fortune to see in France, I am convinced of the wisdom of the original plan of work and the rules laid down for the guidance of surgeons and dentists in the treatment of maxillofacial injuries.

**The Prevention of Blindness.**—The fourth annual report (1918) of the National Committee for the Prevention of Blindness is devoted largely to ophthalmia neonatorum. Since reporting is still defective, new cases of blindness from ophthalmia neonatorum can be determined only after the children enter schools for the blind. From this source it is found that 614 new pupils were enrolled in 1917-1918 in forty schools for the blind, and of this number, ninety, or 14.7 per cent., had become blind through the disease named. In 1917 the percentage reported was 18.4, and the year before that, 19. In 1915 it was 15.1. The percentage reported in 1918 is the smallest, therefore, since statistics were gathered. In the forty-one schools for the blind reporting on the subject, there were enrolled in 1917-1918, 4,109 pupils, and of these, 937, or 22.8 per cent., became blind through ophthalmia neonatorum, a decrease since 1907, when it was nearly 30 per cent. Massachusetts had the first organized class, and ten are now being conducted for the benefit of children who would otherwise be a neglected group in the school system. Virginia, Louisiana and Georgia in 1918 enacted laws for preventing blindness by ophthalmia neonatorum, and Kentucky and Rhode Island passed laws on other phases of the committee's work. Twenty-four states have carried forward prevention of blindness work. The report, in addition to the detailed reports of Edward M. Van Cleve, managing director, and Winnifred Hathaway, secretary, gives many other details of the activities of the committee during the year. The headquarters of the committee is at 130 East Twenty-Second Street, New York.

## RECONSTRUCTION WORK IN WAR INJURIES OF THE FACE AND JAWS\*

ROBERT H. IVY, M.D., D.D.S. (PHILADELPHIA)  
Lieutenant-Colonel, M. C., U. S. Army

JOSEPH D. EBY, D.D.S. (ATLANTA, GA.)  
Major, Dental Corps, U. S. Army

AND

ROY M. BODINE, D.D.S. (INDIANAPOLIS)  
Captain, Dental Corps, U. S. Army

TAKOMA PARK, D. C.

As has been pointed out many times before, the successful treatment of maxillofacial injuries depends on teamwork between the surgeon, the dental surgeon

is not going to take place spontaneously. These require bone grafting. In others, when the nonunion is due to infection or lack of fixation, the application of splints and removal of all sources of infection will often result in new bone formation and eventual solid union.

4. Healed scars involving the soft tissues alone, requiring plastic operation, excision of scar tissue and obliteration of the deformity by flap sliding, fat transplantation, etc.

5. Fractures associated with more or less extensive destruction or laceration of the soft tissues of the cheek, lips or chin. These, of course, require fixation of the fracture and correction of the soft tissue deformity (Figs. 5 and 6). Frequently the upper and lower buccal and labial sulci are partially obliterated by adhesions of the mucous membrane to the bone. These are best treated by division of the bands of scar tissue and the covering of the raw surfaces with epidermic grafts placed on modeling compound inlays attached to prosthetic appliances. Many of these injuries are accompanied by trismus, which requires treatment by jaw stretching and other measures.

6. Cases presenting perforation of the hard palate or having openings between the buccal cavity and

and the dental prosthetist. We desire to outline the practical application of this cooperation at the Walter Reed General Hospital.

The patients arriving from overseas belong, in general, to the following groups:

1. Compound comminuted fracture of the mandible in process of consolidation. These may or may not have been splinted before arrival, and require observation until union is complete.

2. Compound comminuted fracture with delay in union and healing of the soft parts due to the presence of sequestrums, infected teeth in or near the line of fracture, foreign bodies, etc. These require incision and drainage, removal of sequestrums, teeth, foreign bodies, etc., and general treatment of sepsis, in addition to splinting.

3. Ununited fracture with loss of substance. In many of these cases the tissues have been healed for some time, and there is evidence that union

the maxillary sinus, requiring operative or prosthetic closure.

7. Miscellaneous cases of injury of the nose, orbit, external ear, etc., requiring plastic operation.

In every case a thorough survey of the mouth is made, clinically and roentgenographically, to eliminate any factors that may be keeping up infection. All teeth in or near the fracture lines are extracted, bone cavities drained, and sequestrums and foreign bodies

removed. The splints employed in fixation of fractures are as simple as the nature of the case will permit. For many of the uncomplicated cases with many teeth and good occlusion, in which maintenance of reduction is easy, intermaxillary wiring of the teeth has proved efficient. For the majority of cases we employ the cast silver cap splint. When there are firm teeth on both

quently necessary to prepare a saddle extension to cover the anterior surface of the ramus (Fig. 14). By means of a screw rod running from the upper splint to the saddle at an angle of 45 degrees to the line of the upper teeth, backward propulsion of the ramus may be brought about. In this backward propulsion, as the ramus rotates on the condyle, the change of position is accommodated for by a compensating hinge connection of the screw rod with the saddle. The saddle is made of vulcanite lined with a layer of velum rubber.

Various other mechanical appliances are invaluable as supports in plastic operations. Attachments are made to vulcanite plates and splints for holding modeling composition plumpers to bring out the lips to their normal contour and to form supports for epidermic grafts to replace mucous membrane on raw surfaces of the mouth (Figs. 3 and 4). External and internal nose conformers may be attached to the upper denture, as supports in nose plastics. Check supports held in this way are generally more satisfactory than those depending on the head band.

Fig. 7 (Case 3)—Wound received, Oct. 4, 1918. Depressed scar, right cheek.

sides of the fracture it may be necessary to splint only the lower jaw, thus permitting mastication. For other cases the upper and lower teeth are splinted separately, the two splints being locked together in occlusion with a removable bolt on each side. While we can conceive of the advantage of early application of open bite splints in certain cases coming to us late with trismus, we have rarely seen a case in which the late application

Fig. 9 (Case 4)—Wound received, Oct. 1, 1918. Ununited fracture, left body of mandible, 2 cm. loss of substance.

Fig. 10 (Case 4)—Loss of substance as result of wound.

Fig. 11 (Case 4)—Pedicle bone graft, performed March 26, 1919. Examination, June 10, 1919, after removal of splint, shows perfect union.

of the open bite splint would have any particular advantage over the closed bite splint. Especially is this true in early and late cases in which the patient has no teeth in the posterior fragment and in which the use of the open bite splint may result in union in malposition. For these fractures in or near the angle, particularly when ununited, preparatory to bone grafting, it is fre-

Two methods of bone grafting have been employed. In two cases of ununited fracture of the body of the mandible with loss of substance of not more than 3 cm., we have used the method of Cole, removing a piece of the lower border of the anterior fragment, with a pedicle of muscle and fascia attached to it below for nourishment, sliding it back to fill the gap, and

attaching it to the ends of the fragments by means of silver wire (Figs. 9, 10 and 11). Most of our cases have been unsuitable for Cole's method, either being too extensive, or situated at or behind the angle. In one case there was a defect of 10 cm. In the cases of the eight remaining patients operated on so far, we have employed the osteoperiosteal method of Delage-

which a hematoma occurred, followed by some sup-puration and extrusion of small shreds of bone from the graft. Even in this case, guided by the experience of Delagenière himself, it is hoped that union will occur. In the earlier cases, there is good evidence that union is taking place. The splints will not be removed for at least two months and a half.

Free abdominal subcutaneous fat has been employed several times to fill in marked depressions left by excision of adherent scars or when underlying bone has been lost (Figs. 7 and 8).

Costal cartilage transplants are used for correcting depressed nasal bridges. As a rule the entire thickness of the sixth cartilage is used.

The anesthetic most commonly employed is ether, given intrapharyngeally through nasal tubes. The bottle containing the ether is attached to an oxygen tank, and the bubbles of oxygen carry the ether to the patient, there being thus no necessity for a foot bellows or motor pump. Ordinarily it is not necessary to warm the ether. Regional and infiltration anesthesia with 1 per cent. procain-epinephrin is very useful for many of the lesser plastics.

Fig. 12 (Case 5).—Wound inflicted Sept. 26, 1918. Ununited fracture, right body of mandible, 3 cm. loss of substance. Appearance of patient before operation. Keloid scar of neck and chin.

Fig. 13 (Case 5).—Appearance of patient after plastic and osteoperiosteal graft operation, performed March 31, 1919.

nière. This consists of first exposing the ends of the fragments and preparing a pocket beneath and over each by stripping back the periosteum and soft tissue for a distance of about 1 cm. The graft is made by the removal of a thin shaving from the antero-internal surface of the tibia with a chisel, leaving the overlying periosteum attached. One piece of this is inserted in the pockets under the ends of the fragments and another over the fragments, with the bony surfaces of

Fig. 15 (Case 5).—Loss of substance of mandible as result of wound.

Fig. 16 (Case 5).—Osteoperiosteal graft in place, May 3, 1919.

the grafts facing each other. It is necessary that the grafts be in contact with the previously freshened bone ends (Figs. 12, 13, 14, 15, 16). No fixation is used beyond suturing the deep tissues over the grafts, the jaws, of course, being splinted and locked in occlusion the day following the operation. It is early yet to report as to the final outcome in these cases. Primary union followed the operation in all cases except one, in

Careful records of cases are being preserved by means of photographs, color sketches, diagrams of operations, roentgenographic prints, plaster casts and wax models.

**Ventilation.**—Rooms having a window area equal to or greater than 21 square feet per person do not require mechanical ventilation.—*Bulletin*, State Board of Health of Rhode Island, August 1919.

## CAMPHORATED OIL TUMORS\*

W. H. MOOK, M.D.

AND

W. G. WANDER, M.D.

ST. LOUIS

This paper is an abstract of a preliminary report on a series of important cases we have lately been observing in increasing numbers in which tumors resulted from the injection of camphorated oil. They are from the skin service of Engman and Mook at the Barnard Free Skin and Cancer Hospital, at the Washington University Clinic, and in their private practice. We have heard of other cases, and in view of the great quantities of camphorated oil injected during the epidemic of influenza last year, as well as its common use in operating rooms as a stimulant, a word of warning may not be amiss.

## REPORT OF CASE

Following is a typical case:

Miss A. R., aged 32, had been in good health until the middle of December, 1918, when she had had influenza followed by a severe pneumonia, and had received at the critical time in her illness, when partially unconscious for about five days, about eight injections of camphorated oil in the right arm and three or four in the left. For some time afterward, the right arm was weak, and the sites of the injections were tender, but she had no actual pain. She paid no attention to her arms until June, six months later, when she consulted her doctor about the "lumps" on them. He said they were not due to the injections, because there was a tumefaction on the inner surface of the right arm, and he had not injected in this area. The tumors were increasing in size in both arms, but there was hardly any perceptible redness. The latter part of June, or six and one-half months after the injections, they began to increase rather rapidly in size, and became red and inflamed and somewhat painful on pressure. They continued to get larger and more inflamed until now, in September, nine months after the injections, the entire anterior, outer and posterior portions of the right arm are a mottled bluish red, swollen, hard and very infiltrated. The local temperature is considerably higher than that of the normal skin. The mass is lobulated, and around the periphery the edges are linear and very sharply differentiated from the adjacent tissue, with distinctly marked angles, instead of merging gradually into the normal tissue. The inner aspect of the arm is represented by a wide, circular, reddened band of infiltration, and here the inflammation is a little more acute. The whole process completely encircles the arm just above the elbow in an infiltrated band, and has so interfered with the return circulation of the arm as to produce edema of the hand and the forearm.

The left arm has a similarly inflamed tumor mass, just above the elbow, but it is very much smaller and only on the outer aspect.

Extending downward over the external surfaces of both elbows and forearms to a distance of 8 cm. on the right arm

and 6 cm. on the left, are the same doughy infiltrations, with angular edges, triangular in shape, the apexes pointing downward. They are slightly reddened, but not as inflamed as the earlier arm lesions. Small, beadlike chains of little tumors may be felt in long strands around the periphery of the tumors proper, and they also extend upward toward the right axilla, like metastatic malignant tumors growing along lymph channels.

These processes are obviously the result of the seeping of the oil along nonresistant paths, such as the lymph channels, or between muscle fibers.

The right upper chest and supraclavicular space are somewhat swollen, but show no tumor process. The superficial, dilated veins indicate this swelling to be secondary to the circulatory obstruction in the arm.

In our first case, diagnosed in 1914, a piece of inflammatory tumor was excised, and the diagnosis from the pathologist was tuberculosis, probably owing to the tumor's granulomatous character, with many giant cells. This led us, at first, to believe that the tumors belong to the sarcoid class. In a later case, with practically no clinical inflammation, a piece was excised and the true nature of the lesions discovered.

The term sarcoid has been used by Darier and Boeck to differentiate subcutaneous tumors that are granulomas, due in some instances to tuberculosis, while the origin, in others, is unknown. In some clinical aspects, the tumors described in this report might at first be so classified, in that the inflammatory tumors are granulomas, too; but now that their etiologic factor has been clearly established, they are no longer to be classed with the sarcoid group, for they are known now to be mechanically produced inflammatory tumors.

Ever since paraffin has been injected subcutaneously to remedy various defects, we have been well acquainted with the possible subsequent tumor development and activity. In most instances, no difficulty is experienced in the diagnosis of these tumors, for generally the patient is aware, when he applies for treatment, that they are due to paraffin.

The tumors due to the subcutaneous injection of camphorated oil greatly resemble the paraffinomas in their slow development, their peculiar concrete-like type of infiltration, and the time in which they develop after injection. Their location, however, is so totally different from that of paraffinomas as not even to cause suspicion that they are of the same nature and due to the same cause, namely, the subcutaneous injection of an oil, probably mineral.

An analysis of the cases shows a series of six patients who developed tumors in the arms, some also in the thighs, all with practically the same history and lesions of the same characteristics; namely, the appearance of deep tumors, following the injection of camphorated oil for a previous severe illness, situated generally on the outer aspects of the lower third of one

Fig. 1.—Inflamed tumors in arm, resulting from injection of camphorated oil. They began to grow one month after the injections. The photograph was taken four months later.

\* From the Barnard Free Skin and Cancer Hospital.

• The full report, of which this paper is an abstract, will soon be published in the *Journal of Cutaneous Diseases*.

or both arms and occasionally in a shoulder, thighs or breasts. They are of months' duration, and if not inflamed they have a doughy or concrete-like infiltration that may be from the size of a walnut to the size of an orange, and is usually lobulated. The size of the tumor depends on the amount of oil injected and the extent of the individual reaction. Instead of being rounded in outline, they are linear, with definite, sharp angles marking them off from the normal connective muscular tissue which is adjacent. Beadlike infiltrations of the same nature, but smaller, may be traced toward the axilla or around the periphery, simulating the metastasis of a malignant growth along lymph channels. The skin surface may or may not be elevated or discolored, and some tumors are discoverable only on palpation. They are practically always deep in the muscle or connective tissue. They may or may not be painful, or even tender. The early discomfort is generally slight.

If they are inflamed, the process is of long duration and the skin will be of various hues, varying from a red to deep purple, the color depending on the congestion and the amount of inflammation. The local temperature in inflammatory tumors is higher, of course, than that of the surrounding normal skin. In none of our cases has necrosis occurred, such as occurs in paraffinomas; but this may be due to two factors: First, the character of tissue involved, which allows the oil to move in various directions, whereupon the inflammation occurs up and down the arm between muscle fibers, the fascia and the lymph spaces. No doubt, if the oil was to be injected in the face, necrosis would occur as in paraffinomas, owing to the difference in tissue character, that of the face favoring necrosis instead of subcutaneous distribution. Second, the factor of time. Since some of our most marked cases are of recent observation, not enough time has elapsed to let us see the end-results. In one instance, at least, necrosis has been expected two or three times, and the constriction of the tumors has so interfered with the arm circulation as to produce edema and to suggest the possibility of an amputation if the obstruction becomes more complete.

The microscopic sections demonstrate the encapsulated oil cavities, virtually the same as seen in paraffinomas.

The necessarily inert and stable character of the oil in the globules from excised tissue suggests at once that the oil may be a mineral or paraffin oil. Parallel staining reactions between oil from the tissue and liquid petrolatum strengthen this suggestion; both stain with sudan III, but fail to stain with osmic acid.

In at least two instances, the camphorated oil used was manufactured by a well known drug manufacturer, and in one the oil we obtained was part of a quantity

bought by the local druggist. The camphor was put up in a mineral oil and in all respects reacted to the same tests as the oil recovered from the tissue excised from one of the patients.

In the case in which the oil was a part of a quantity bought by a local druggist, it failed to saponify on boiling with a solution of potassium hydroxide, and there was no soap demonstrable in the resulting product, indicating—and more or less conclusively establishing—that liquid petrolatum was the vehicle used in the camphorated oil injected.

From our studies thus far, it appears apparent that liquid petrolatum may remain as an inert foreign body in tissue, whether injected as paraffin to correct facial defects or as camphorated oil when injected in the arms, thighs or breasts as a stimulant during an operation or in any very severe illness.

The inflammatory tumors that may result from either are more or less serious, and the use of camphorated oil as a stimulant should be discontinued until researches show that it can be made innocuous with a vegetable or an animal oil, or a vehicle that will be absorbed immediately after injection, with no ultimate bad effects.

The study reveals other possibilities of bad results from the use of liquid petrolatum as a vehicle in the mixtures of mercurials, such as the salicylate and calomel, in the treatment of syphilis. Deaths from emboli after such injections occur often enough to make one a little apprehensive in their routine use.

Emboli of the lungs from oil have been known to occur.

We have reached the conclusion that it is dangerous to use liquid petrolatum as a vehicle for any remedy to be injected in subcutaneous tissue. This fact has been well established in regard to paraffin injections, and the tumors resulting from the injection of camphorated oil made with liquid petrolatum strengthen the conclusion.

Fig. 2.—Histologic section of camphorated oil tumor, showing cavities and tissue containing the oil. It is very typical and resembles paraffinoma tissue.

**Fads in Treatment.**—Further, you must

avoid, like the devil, all fads in treatment. Fadery lies in wait all through professional life. It does not matter so much what pathological fads you hold; that is only a disorder of belief. But when you carry those fads into action and treat people on "faddy" lines, you are guilty of disorder of conduct, and disorder of conduct is insanity. There have been many eminent persons in our profession who have succumbed to the vice of faddism, and they become in their treatment, in certain respects, insane, and, therefore, in a practical sense, they are a real danger to the community. Watch out, then, for the earliest indications of faddism in yourselves. It was said by Sir James Paget, one of the wisest men who ever practiced our profession, that as you begin to get older you tend to write the same prescription for everything. The man who does that is an incipient faddist.—Robert Hutchison, *Some General Principles of Therapeutics, The Practitioner*, September, 1919, p. 164.

## RECONSTRUCTION AND AFTER-CARE OF OLD UNREDUCED POTT'S FRACTURES \*

WILLIAM L. SNEED, M.D.  
NEW YORK

The most frequent disability following in the wake of Pott's fractures is flat foot. This is often exaggerated and rendered painful and persistent by a slight posterior displacement of the foot on the tibia or a widening of the ankle joint, due to a rupture of the tibiofibular ligament. Of course, there is a large percentage of Pott's fractures in which the tibiofibular ligament is not ruptured. These will have a normal ankle joint mortise. There is another factor in the reduction of a flat foot. Often after a Pott's fracture the foot is put up at right angles but in valgus position, and the muscles which support the arch of the foot are put on the stretch; the patient is allowed to walk in the support with the foot in this faulty position and a flat foot develops, the result, largely of loss of muscle tone.

In the treatment of these cases the degree of disability and probable end-results are the main factors to be considered. The age of the patient and the traumatic inflammatory changes, whether vascular, lymphatic, osseous or of the soft parts, should always receive careful attention before operation. The operative procedure varies in each individual case, depending on what is necessary for the establishment of the normal anatomy of the foot. In the after-care, one method may apply to all cases.

I have selected a case for consideration giving the following history:

A laborer, aged 35, weighing 180 pounds, fell 20 feet, in March, 1917, sustaining an injury of the left ankle. Inspection showed the foot in position of equinovalgus, marked traumatic flat foot, posterior displacement of the foot on the tibia, and a widening of the ankle joint. The patient walked with a marked limp and was able to stand or walk for only a little while. A roentgenogram taken at the Hospital for Ruptured and Crippled, in January, 1918, ten months after the injury, disclosed an ununited fracture of the internal malleolus at the base, a rupture of the tibiofibular ligament, a fracture of the fibula  $3\frac{1}{2}$  inches above the joint, a displacement of the tarsal bones as found in third degree flat foot, and posterior displacement of the foot.

### OPERATIVE PROCEDURE

First. The foot was grasped between the hands and knees and forced around into varus, overcorrecting the pes planus and reestablishing the normal relation of the tarsal bones as near as possible.

Second. An incision was made over the internal malleolus, the fibrous tissue removed, and the ends of the fragments freshened by chiseling. An inlay of bone was slid down from the tibia into a groove prepared in the malleoli, and this was sutured into place.

Third. An incision was made over the fibula and the fibula divided transversely about 1 inch above the ankle joint. Then with a curet the fibrous tissue with

Fig. 2.—Equinus with posterior displacement of foot. The position is equinovalgus.

periosteum was removed from between the tibia and fibula from the ankle joint up to the fracture line.

Fourth. The Achilles tendon was divided by the "Z" method, and the foot was forced up into dorsal flexion. This reduced the posterior displacement. The foot was then pulled around into slight varus, approximating the fracture of the internal malleolus to the tibia and forcing the raw surfaces of the tibia and fibula together. The wounds were then closed.

The foot was put up in plaster of Paris in corrected position and held so for six weeks. A roentgenogram taken at this time revealed a reestablishment of the mortise in the ankle joint by union of the tibia and fibula, a union of the internal malleolus, and an all-round reconstruction of the bony anatomy of the foot.

### AFTER-CARE

The after-care consists of: first, continual support; second, baking and massage; third, exercises and manipulations. The support of the foot was of two types: first, plaster of Paris for eight weeks, then adhesive plaster strapping for two or three weeks longer, and finally a Whitman arch support with a raise of shoe of one-quarter inch on the inner border of the heel and toe. The exercises and manipulations are those for reestablishing muscular power of weak feet in general.

In one case, photographs showing the relative contour of the injured and the uninjured foot reveal less deformity on the injured side, or left foot, than there is on the right side, or uninjured foot. This is accounted for by the forced correction of the flat foot on the injured side while the existing flat foot on the uninjured side was merely supported and not corrected.

FIG. 1.—Ununited fracture of internal malleolus; marked widening of mortise of ankle joint; ruptured tibiofibular ligament; fracture of fibula  $3\frac{1}{2}$  inches above joint.

\* Read before the Section on Orthopedic Surgery at the Seventieth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

This man returned to work twelve weeks after operation and has been at work since that time, wearing a Whitman brace with his shoe raised one-quarter inch on the inner border of the heels and toes.

OTHER CASES

I have had two other cases which needed operation. In one only the flat foot and posterior displacement needed correction, necessitating the lengthening of the Achilles tendon. The other patient had a rupture of the tibiofibular ligament. The fibula had healed in a faulty position, and there was a widening of the mortise of the ankle joint. This patient was first seen six weeks after injury. An osteotomy of the fibula and a lengthening of the Achilles tendon, pulling the foot in varus and dorsal flexion, and using the after-care described in the case first mentioned, restored the normal function of this foot, so that the patient has been able to resume his former vocation, which was moving and lifting heavy boxes of goods, without discomfort.

A CAUTION

It is very important that the normal mortise of the ankle joint should be restored. If it is not there will be too much play at the ankle joint. The astragalus will be allowed to rotate, and the foot will be permanently weakened. Special stress is laid on this point, as too little attention has been given to this aspect of the lesion both in recent and old cases of Pott's fractures.

ABSTRACT OF DISCUSSION

DR. ZABDIEL B. ADAMS, Boston: To reduce these fractures simply means restoring normal conditions as far as possible. The method described originally by Dr. Pott is not carried out in general. In the classical Pott's fracture the procedures that have been

a result as if the deformity had been prevented in the first place. So much change takes place in the articular surfaces of the bones, and there is so much play on the ligaments, that a perfect result cannot be looked for. I am quite in agreement, however, with the general lines of treatment laid down by Dr. Sneed.

DR. WILLIS C. CAMPBELL, Memphis, Tenn.: The one fact that has been shown in this paper is that these fractures can be rebroken and reduced, the result in many instances being anatomically and functionally perfect, without the necessity for any internal splints. Dr. Sneed used, in one instance, the sliding graft, on account of the ununited fracture. The

Fig. 4.—Relative contour of both feet eighteen months after operation. Notice long scar over internal malleolus of the left foot and the lesser degree of flat foot on the injured side.

average Pott's fracture is not complicated by nonunion at the point of the mesial fragment, as in his case. Consequently, the raft is unnecessary. I have operated in two cases within the last six months, both being of exactly similar displacement, except that union was perfect. In both cases there was long union between the tibia and the fibula for a considerable distance. This necessitated chiseling between the two bones before replacement. After replacement in proper position, putting the foot in inversion in a plaster cast, I used the simple Thomas heel in shoe, and found it unnecessary to employ any other form of support. Both these cases occurred in young people. The restoration was practically perfect, and I felt that long after-treatment was unnecessary. In old atypical cases, long continued support with the Whitman, or some other form of arch support, would be necessary.

DR. JAMES W. SEVER, Boston: There is one point that I should like to have Dr. Sneed speak of in closing the discussion. That is in regard to the articulation between the tibia and fibula and the rupture of the tibiofibular ligament. In cases in which there is definite injury to the joint, there is a great deal of disability and widening between the two bones. The condition clinically looks like a fracture, but apparently it is not. The adequate treatment of these cases should be discussed, because it is overlooked, the condition being treated as a sprain.

DR. HARRY E. STEWART, New Haven, Conn.: An interesting point has been brought up about the treatment by means of orthopedic gymnastics and massage. We should not confine a man, after a surgical operation, to an artificial support like a plate, but follow up the procedure with treatment designed to bring back the tone of the muscles and ligaments. We should look in the arch plate as we would on any other splint, to be worn while necessary, and discarded as soon as possible.

DR. CHARLES M. JACOB, Chicago: I consider it a great mistake to immobilize the joint for many weeks as is now being done whether the joint was, or was not, operated on. It is my custom to apply a plaster cast for about ten days; at the end of this time passive motion is used each day for a certain period of time; following which a posterior molded splint is used.

DR. FRED J. GAENSELEN, Milwaukee: Very frequently there is a breaking of the lower and anterior portion of the tibia; and if the fracture is of long standing, this misplaced frag-

Fig. 3.—Six weeks after operation. Union of internal malleolus; a re-anchored tibia; posterior reduction of posterior displacement; almost at right angle.

mented out in this paper are the ones that must be resorted to in order to get a perfect result. If they are carried out, one can, in most of these cases, get a very marked improvement, if not an almost complete cure.

MR. ERNEST W. HEY GROVES, England: The keynote of the whole situation here, as in most orthopedic surgery, is prevention. When a Pott's fracture has remained unreduced for any considerable period of time, we can never expect, even by the most ingenious operation, to produce as good

ment acts as a definite obstacle to the reduction of the fracture. In most cases, it would be necessary to remove the fragment or loosen it, so that it would not interfere. Another point is that it is wise to reduce these fractures with the knee in acute flexion. This position relaxes the Achilles tendon avoiding the necessity of tenotomy so that reduction may be accomplished with ease. The plaster may be removed to just below the knee at the end of two weeks, without danger of relaxation.

DR. WILLIAM L. SNEED, New York: There is no doubt that many of these cases, as viewed from a roentgen ray standpoint, do not show any fracture. It is possible to have a rupture of the anterior lateral ligament and of the tibio-fibular ligament that will give a widening of the joint and injury on the inner side that does not go as far as a fracture, having no bony lesion, but that gives the same symptoms as in Pott's fracture without the deformity, other than a widening of the joint. There is a large percentage of cases in which the tibiofibular ligament is not ruptured. Of course, these cases need no consideration. These patients come to us, maybe one year or two years after the injury, and we must consider them in the light of what can be done at that time, and what it is wise to do, taking into consideration the bony and ligamentous deformity, the muscle degeneration, and the presence or absence of lymph or blood vessel changes. Sometimes it is unwise to do anything at all, as when there is infection in the tarsal bones. I have not known of any case in which it was necessary to carry the support about the knee. We all try to get rid of any mechanical support. If we can restore the normal anatomy, and it needs no support, we do not use it. It is only in the cases in which we cannot restore the normal anatomy that we need to use the support.

### ARSPHENAMIN IN PNEUMONIA WITH DELAYED RESOLUTION IN SYPHILITIC SOLDIERS

GEORGE DOUGLAS HEAD, M.D. (MINNEAPOLIS)

Major, M. C., U. S. Army; Chief of the Medical Service,  
Base Hospital

AND

JOHN L. SEABLOOM, M.D. (RED OAK, IOWA)

Captain, M. C., U. S. Army

CAMP WHEELER, MACON, GA.

In some individuals an acute disease will so derange the protective mechanism of the body that an old infection lying apparently dormant will be reactivated thereby.

Medical officers stationed during the war in Southern camps where malaria was prevalent not infrequently observed instances of renewed malarial infections in soldiers sick with pneumonia. These soldiers gave old histories of malarial fever with chills, fever and sweats, in some instances years prior to their entrance into the army. The symptoms of malaria appeared usually in the early part of convalescence from pneumonia. The chill and fever were typically periodic. The spleen was usually enlarged. Tertian organisms were found in the blood, and the paroxysms of fever responded promptly to quinin. Several such instances occurred at the base hospital at Camp Wheeler during the epidemic of pneumonia in the winter of 1918-1919.

A severe attack of pneumonia will sometimes weaken or break down the protective cell forces in or about old pathological lesions in the lung. Pulmonary tuberculosis offers an instance in point. Pneumonia not infrequently lights up an old apparently healed or

latent tuberculosis lesion, and the patient who supposed himself cured of tuberculosis is brought face to face in a life and death struggle with his old enemy, the tubercle bacillus.

We are not aware, however, that the attention of the profession has been called to the fact that syphilis may act to prolong or delay the reparative process in the lungs of persons who have had pneumonia, and that syphilitic persons with pneumonia are liable to exhibit signs of delayed resolutions for weeks or months of time. The healing process in these cases does not progress as in the normal individual, and the usual methods of treatment are of no value, while in the cases we have observed, specific treatment has been effective.

The following three cases observed at Camp Wheeler during the epidemic of pneumonia, occurring between Oct. 5, 1918, and Feb. 1, 1919, illustrate the effect of syphilis in causing the delayed resolution of pneumonia and the prompt effect of arsphenamin in clearing it up.

#### REPORT OF CASES

CASE 1.—J. J., aged 22, colored, single, soldier in labor battalion, with a negative family history, had measles, mumps and whooping cough as a child, malarial fever in 1914, and smallpox in 1917. He denied having syphilis, but admitted having gonorrhoea. Nov. 14, 1918, when going to drill, he developed severe pains in his left side and had a chill. He was admitted to the base hospital the next day with high fever (104), delirium, rapid breathing, dyspnea and marked cyanosis.

The examination of the chest revealed dullness over the entire left lung with bronchial breathing but no râles. A diagnosis of lobar pneumonia of the left lung was made.

From November 14 to the 24th, the man was very sick with pneumonia, his temperature ranging between 102 and 106.8. He had marked delirium, bloody sputum and high leukocytosis, and a Type IV pneumococcus was isolated from the sputum. November 25, his crisis occurred, and the temperature dropped to normal and remained so until his discharge, March 3, 1919.

In spite of the patient's improved condition, the left lung remained dull to percussion. Crepitant râles and bronchial breathing continued to be heard in the affected area. Roentgen-ray examination revealed an unresolved pneumonia of the left lung. Exploratory puncture of the pleura was made for possible fluid but none was found.

December 30, six weeks after the onset, the lung showing no signs of clearing, the blood was taken for a Wassermann test, and a ++ report was returned. Since the lung remained consolidated and the usual therapeutic measures had proved of no avail, it was decided to try arsphenamin. The patient was given 0.4 gm. intravenously beginning January 14, two months after the onset, and continuing one injection every seven days until five injections had been given. After the second injection of arsphenamin a rapid change in the lung condition took place. The signs of consolidation promptly subsided and the râles disappeared. By February 2, nineteen days after the arsphenamin treatment was started, all signs of lung involvement had cleared.

CASE 2.—James R., aged 25, colored, single, soldier, with a negative family history and with no history of chancre, was admitted to the base hospital, Dec. 5, 1918, complaining of headache, cough, chills and stupor. He stated that three days prior to admission he commenced to feel a pain in his left chest and had a cough. He felt chilly and thought he had fever. On the second day of his sickness he began to cough up some bloody looking sputum and was then sent to the hospital.

The examination on admission revealed nothing of importance outside of the lungs. Over the right lung posteriorly many crepitant râles could be heard on cough or deep breath-

ing, the percussion note was not impaired, and no bronchophony or tubular breathing could be detected. Over the left lung posteriorly, the percussion note was impaired with some increase of bronchophony, tactile fremitus and many fine crepitant râles. His temperature was 103, leukocytes 7,300. The urine showed a trace of albumin and a few hyaline casts. The diagnosis of bilateral bronchopneumonia was made.

From December 5 to January 11, the patient was examined from day to day; and while his temperature dropped to normal, December 16, the physical signs persisted in both bases and would not clear up. Roentgen-ray studies revealed unresolved bronchopneumonia of both lungs. A blood examination, December 8, gave a ++ Wassermann reaction. The failure of the lungs to clear after six weeks of observation and expectant treatment, the ++ Wassermann reaction and the experience in Case 1 with arsphenamin warranted a trial of the same treatment in this case. The note of January 7 read: "Crepitant and a few sibilant râles heard in the base of both lungs behind. These do not clear up. There has been no appreciable change in the physical signs for weeks."

January 14, about six weeks after admission, 0.4 gm. of arsphenamin was given, and the same dose was repeated thereafter every seven days until five doses had been given. One week after the first dose of arsphenamin was given the physical signs began to show improvement, and after the second injection a marked clearing of râles was noted, while after the third injection of arsphenamin all the lung signs and cough had disappeared and the patient was in excellent condition, and was discharged.

CASE 3.—Thomas S., aged 21, colored, single, labor battalion, with a negative family and past history, and who denied

that resolution of the lung takes place under serocellular processes the nature of which is not known, and that the resolution so promptly brought about in the cases here recited may be explained on the grounds of a natural termination of the disease rather than the arsphenamin effects. However, the impression received in watching from day to day the physical signs and clinical manifestations in these three stubborn cases of unresolved pneumonia in syphilitic soldiers has fully convinced us that the arsphenamin had a specific effect in clearing the lungs, and we advise its use in cases of unresolved pneumonia in syphilitic subjects.

THE BLOOD VASCULAR SYSTEM IN  
A PARIETAL CRANIOPAGUS \*

WILLARD M. SONNENBURG, B.S.

MADISON, WIS.

The craniopagus shown in Figure 1 was delivered at the Madison General Hospital, May 5, 1919, in a case attended by Dr. Walter H. Sheldon. The twins weighed 11 pounds and 1 ounce at the time of birth. The faces and bodies were practically in vertical alignment. One of the twins, which I shall hereafter refer to as A, was a well developed female; the other, which I shall refer to as B, had an imperforate anus and an

Fig. 1.—Craniopagus, with bodies in practically vertical alignment.

venereal disease, was taken sick, Oct. 26, 1918, with headache, malaise and fever, and was sent into the base hospital three days later. A diagnosis of bilateral bronchopneumonia was made and a Type IV pneumococcus isolated from the sputum.

The man was very sick with pneumonia from October 30 to November 7, when his temperature dropped to normal and remained so until he was discharged. A Wassermann test, taken December 1, showed a ++ reaction.

On Jan. 8, 1919, nine weeks after admission, the lung findings were as follows: "Posteriorly over the right lung, the percussion note is impaired from the angle of the scapula downward and forward to the midaxillary line. Showers of râles are heard over this area and bronchophony is slightly increased. Sibilant and fine crackling râles can be heard behind over the base of the left lung. There has been very little change in this man's lung condition for the past six weeks."

The clinical diagnosis was: bronchopneumonia, bilateral, unresolved. Roentgen-ray studies confirmed the clinical diagnosis of an unresolved bronchopneumonia.

January 14, the lung condition showing no evidence of clearing and the man giving a ++ Wassermann reaction, an injection of 0.4 gm. of arsphenamin was given intravenously, and one injection was given every seven days until five injections had been given. January 30, two weeks after the first injection of arsphenamin, all physical signs had cleared in both lungs and the soldier was pronounced well and ready for discharge.

COMMENT

We are fully aware of the fact that both lobar pneumonia and bronchopneumonia are self-limited diseases,

imperforate "penis" as large as a normal infantile penis. Subsequently, at a postmortem examination, Dr. C. H. Bunting found that the internal genital organs of A were apparently normal. B had normal ovaries, but its uterus was four times the normal size. In B, furthermore, the sigmoid colon, greatly distended, emptied into a cloaca. The left umbilical artery in B was either

very small or was absent. In A, both umbilical arteries were present. Microscopic studies of the umbilical cord have not as yet been made. No other noteworthy abnormalities in either specimen were seen, except in the region of the cranium.

The accompanying table gives some of the chief measurements of each twin.

\* From the Anatomic Laboratory, University of Wisconsin, Medical School.

The cords came off the same placenta at the center, about 2 cm. apart. The placenta was almost circular, being 22 by 23 cm. in diameter, and had a V-shaped notch on the periphery, 4 cm. deep and 7 cm. wide. The membranes were intact, and the cotyledons normal and intact.

The birth occurred at 9: 50 p. m. A began breathing thirty seconds after birth, B, fifteen seconds later. Within five minutes, both cried vigorously. In the course of a few days it became obvious that there was no close functional correlation in the activities of the nervous systems of the twins. One would sleep soundly while the other was awake or cried. Furthermore, as shown in the accompanying table, the respiratory and pulse rates varied in the two individuals. Both fed normally, although B soon showed signs of discomfort because of the imperforate anus. Its abdomen became greatly distended and, on the seventeenth day, its "penis" was noticed to be distended. A probe was then pushed into the base of the "penis," and following this there was a discharge of fecal matter. On the ninth day, B became comatose, and A showed signs of discomfort, began crying, and continued to cry until its death, May 15, at 5 a. m. A died fifteen minutes after B.

The fact that the death of one twin was followed so soon by that of the other indicated that there was probably some circulatory connection between the two bodies, in spite of independence of pulse rate. To determine this, the arterial system of the normal twin, A, was injected through the abdominal aorta with a mixture of 40 per cent. glycerin, 40 per cent. alcohol (95 per cent.) and 20 per cent. phenol (carbolic acid), in which 175 gm. of barium sulphate per gallon was suspended. Stereoscopic roentgenograms were then taken of the specimen by Dr. Howard Curl, roentgenologist at the university clinic. These roentgenograms, one of which is reproduced in Figure 2, showed an apparently normal arterial system in A and no gross connection between the arterial systems of A and B.

In Figure 3 the arteries of Specimen A at the right may be seen to terminate fairly abruptly at the line of junction of the heads of the individuals.

Some of the injection mass in A, however, passed through the capillaries into the veins. This occurred most readily in the brain, where the injection mass, in part, passed over into the venous sinuses. There was a communication between these sinuses in A and B, and from the venous sinuses of B, the injection mass

passed to the right side of the heart and into the veins of the liver and into the pulmonary arteries (Fig. 4). For the first injection, a pressure of one-half pound was used. After the roentgenograms were taken, the arteries were injected again, under 4 pounds pressure, without any notable difference in results.

Subsequently, an injection under 4 pounds pressure, made into the arteries of B through the abdominal aorta, showed that the arterial system in this specimen was apparently normal. An injection into the inferior vena cava of A under 3 pounds pressure served to increase the amount of opaque material in the hepatic veins and pulmonary arteries of B, partly filled by the first injection, described above.

Following the completion of these injections, the scalp was cut opposite the line of junction between

Fig. 2.—Apparently normal arterial system in A, as shown by a stereoscopic roentgenogram taken after injection into the arterial system of a mixture of alcohol, phenol and glycerin, in which barium sulphate was suspended.

the two heads. It was then seen that the bones of each skull, frontals, parietals and occipitals, met symmetrically but did not fuse. When the skull was opened, it was found that the two brains were enclosed within a common dura mater. At the line of junction between the two skulls, a circular venous sinus common to the two brains was enclosed in the dura mater, but the dura did not extend far inward between the two brains from this sinus. The falx cerebri of one brain was fused to that of the other, and at the line of junction there was a venous sinus corresponding to the superior longitudinal sinus, and common to the two brains. The brain of each child was covered with pia mater. Where the brains projected against one another the pia mater of one brain was in part fused to that of the other brain. The plane of meeting of the two brains was not a flat one, at least,

after the specimen had been hardened in formaldehyd solution. In places, one brain projected slightly above the level of a flat plane, in places the other brain.

#### REVIEW OF CASES REPORTED IN THE LITERATURE

The specimen here described belongs to a rare type of human monsters. I have been able to find described in the literature only four cases of parietal craniopagus in which the countenances of the two individuals faced in the same direction. These cases, in all of which the teratism was female, with the possible exception of that of von Baer, are cited by Ahlfeld:<sup>1</sup> 1. The first case, after Blainville, is from the catalogue of the Hunterian

1. Ahlfeld, F.: Die Missbildungen des Menschen, 1880.

Museum. The monster was born at Bruges, May 6, 1682, and was living at the time of observation. The twins showed independent individualities. One might sleep while the other cried. 2. The second case is after Otto, 1841. The fetuses were aged 5 months. The superficial blood vessels of the head were anastomosed. Only the smaller branches of the intracranial arteries appeared to anastomose. The brains were completely separated by pia mater. Other organs were normal. There was only one umbilical artery in each umbilical cord. 3. The third case is after von Baer. The monster lived one and one-half days. 4. The fourth case is after Badger.<sup>2</sup> The monster was stillborn, in Jamaica, in 1869. There was no necropsy.

A case in which the two heads faced nearly in the same direction is cited by Ahlfeld, after Naranowitsch.<sup>3</sup> The twins were females, born in St. Petersburg, in 1855. They had independent individualities, and lived six weeks, dying of an acute infection. The brains were enclosed in a common dura mater. There was a common falciiform process and superior longitudinal sinus.

There have been a number of parietal craniopagi described in which the dorsoventral diameter of one twin was an angle, usually of about 90 degrees, to that of the other, so that the nose of one was above the right or left ear of the other. Of four such cases, two of the monsters were females; one, a male, and in one the sex is doubtful: 1. The first is cited by Ahlfeld, after Sannie. The monster was born in Holland, in 1752. The nose of one twin was over the right ear of the other. While the text calls the twins females, the illustrations appear to show male genitalia. 2. The second case is cited by Ahlfeld, after Uecelli. The twins were females, born at Florence, in 1823. The angle between the ventrodorsal axes was 45 degrees. Between the two brains was a common dura mater, in which there was an opening through which the brains might have communicated. 3. The third case is cited by Ahlfeld after Klein and Harless. The twins were males, born in Wurtemberg, in 1799. The nose of one child was over the left ear of the other. The monster lived sixty-four hours. The child first born lived a half hour longer than the other. The individualities were independent. The brains were fully separated by membranes. 4. A fourth case is cited by Baudouin,<sup>4</sup> and also by Bernbach.<sup>5</sup> The twins were females, born near Frankfort-on-the-Main, in December, 1911. They were alive at the time of description. The nose of one was over the right ear of the other. They had independent individualities. There was an apparent anastomosis of the superficial blood vessels.

There are also four cases described in which the countenance of one child faced opposite or nearly opposite to that of the other child. 1. One is cited by Ahlfeld, after Albrecht. The monster was born in 1733. The sex is in question. The heads were united by the right parietal bones. The monster lived at least several months. 2. Another case is cited by Ahlfeld, after Villeneuve. The twins were males, born in 1829 in Paris, at about the seventh month. The brains were fully separated by dura mater. There were two cords inserted into one placenta. 3. A third case is cited by Kissinger.<sup>6</sup> The twins were males, born, March 24, 1907. They died of icterus neonatorum, March 30, 1907. There was no dura between the brains, but they were separated by pia mater. The convolutions of the brains were irregular. 4. A fourth case is cited by Ziematzky.<sup>7</sup> The sex, in this instance, was apparently female.

A number of other cases of craniopagy have been reported in which the heads were united in the occipital or in the frontal regions, or irregularly, as by joining of the frontal to the parietal regions. Cases have also been reported in which a fairly well formed head was united to the head of an otherwise normal child. Of

Fig. 3.—Passage, in part, of the injection mass, through the capillaries in A, over into the venous sinuses.

these cases, the best known and most interesting is that of Home.<sup>8</sup> The child was born at Bengal, in May, 1783. The parasitic head, which terminated above in a conical protuberance in place of a neck, was fused below to the head of the host, a female, with an angle of 90 degrees between the dorsoventral diameters of the two heads. The child lived for two years,

and was then killed by a snake bite. The parasite had the power of moving its eyes, but could not converge them. The lid reflex was defective, and tears were constantly forming. The pupils showed a light reflex, but only on passing from the dark into strong light. The eyes of the parasite at times remained open, while those of the host were shut. The lower jaw was small, but mobile. The ears were defective. The parasite made sucking movements at six months. When seen at 2 years of age, secretion of saliva was active in the mouth of the parasite when the host ate. The parasite is said to have expressed grief when the host cried and satisfaction when the host smiled. If the parasite was pinched, however, the host showed little or no pain. After death, the heads were sent to England. It is stated that a study showed that the nutrition of the parasite must have taken place through the dural or pial vessels. It was not clear from the specimen as to whether or not the two brains were completely separated by membranes.

## CONCLUSION

From this brief review of the literature, it is evident that:

The rare form of double monster known as parietal craniopagus usually is of the female sex.

The head of one individual as often faces laterally or backward or in the same direction as that of the other.

There is usually considerable independent individuality in the reactions of the twins.

The brains are nearly always, if not always, separated by pia mater, and sometimes also by dura mater.

The chief vascular connection appears to be in the venous sinuses of the skull, but at times other vessels anastomose.

Fig. 4.—Roentgenogram of B, demonstrating a communication between the sinuses of A and B by disclosing passage of the injection mass to the right of the heart in B, and into the veins of the liver and into the pulmonary arteries.

It is probable that there must have been some arterial anastomosis in the case of the parasitic head of Ilome, described above.<sup>9</sup>

**Health Center in Massachusetts.**—It is strongly urged by the state department of health that the following standard for the protection of the health of Massachusetts children be kept in mind by all those who are working for the betterment of our children: A health center, where special attention will be given to maternity and infant care, for each community or group of communities; public health nurses specially trained for the work, averaging 1,000 to 2,000 of population.—*The Commonwealth* 6:120 (May-June), 1919.

INTRAMEDULLARY BEEF-BONE SPLINTS  
IN FRACTURES OF LONG BONES\*

EDWIN W. RYERSON, M.D.

Major, M. C., U. S. Army  
CHICAGO

It is occasionally of great importance to be able to fasten securely certain fractures, particularly those of the femur and the humerus and those in which both bones of the forearm are broken. The inlay autogenous bone graft is admirable in many cases, but has the disadvantage of being technically difficult and of not affording a very high degree of immediate stability. The intramedullary dowel or peg, on the other hand, is easy of application and furnishes great strength. Clinical evidence has proved conclusively that such a graft does not interfere with the regeneration of bone tissue, and that fractures operated on by this method unite as readily and as rapidly as by any other method. It is probable that an autogenous peg, made from the patient's own tibia, is the ideal material to use, but circumstances may easily be imagined when it would be undesirable to remove a strip of the tibia. In fact, if a universally adaptable material could be developed, no operator would desire to use his patient's tibia, but up to the present time no claims can be made that there is anything quite as good as the autogenous graft. This is especially true in fractures of long standing, and in the case of elderly persons.

In fresh fractures and in reasonably young persons, however, heterogenous bone pegs may be used with safety and with the assurance that bone growth will not be inhibited. Beef-bone and ivory nails, screws, and intramedullary grafts have been used for many years by a small number of operators, but for some reason have not attained a wide degree of attention. Gallie<sup>1</sup> of Toronto has even gone so far as to use beef-bone grafts for the production of fixation of the vertebrae, after the method of Albee, but I do not feel like advising so radical a procedure as this. For fractures of long bones, however, such as those mentioned above, it is well for the operator to have at hand a ready and simple technic in case of need. It is not always easy to insert an intramedullary peg, especially if it is a long one. The proper alinement of many fractures, however, may depend on the length of the peg, so it is important to be able to insert a long peg with a minimum of difficulty. Hey Groves<sup>2</sup> describes a method which is ingenious, and which suggested the following technic:

## TECHNIC

Beef-bone splints of various sizes are cut from the long bones of slaughtered cattle. It is possible to procure from a butcher's shop pieces of the tibia or femur 5 or 6 inches long, and these are split with a saw into suitable sizes. They are then turned in a lathe or filed with a wood-worker's rasp or run through a dowel cutter so as to be round or nearly round. Those for use in the femur should be about 5 inches long by three-fourths inch wide, for adults, and several smaller sizes should be ready in case the medullary canal

\* Read before the Section on Orthopedic Surgery at the Seventieth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

2. Groves, E. W. H.: *On Modern Methods of Treating Fractures*, New York, William Wood & Co., 1916.

should be unusually small, or for use in children. Splints for the humerus should be about three-eighths inch wide, and those for the radius and ulna one-fourth to five-sixteenths, and three inches long. The ends of the splints are rounded off, and a hole is bored through near one end like the eye of a needle. These splints are then sterilized by fractional sterilization, and kept in containers. When it is desired to use them, they are boiled with the instruments.

The technic of their use is as follows:

The fracture is exposed with as little removal of periosteum as possible. The beef-bone splint is pushed into the longer fragment until it is completely within the bone, a long piece of heavy chromic catgut having been previously threaded into the eye of the splint. This double thread hangs out from the end of the bone. An eighth-inch drill is now used to bore a hole in the other fragment, distant from the fracture about half the length of the splint. The hole slants a little toward the fractured end. A piece of wire, bent at the middle to form a sort of probe, is now passed into the hole, and out through the fractured end of the bone. The two ends of the catgut cord are then threaded into the wire probe, and the wire is pulled back through the hole, bringing the catgut with it. The over-riding ends of the fracture are now reduced, either by a Murphy bone skid or by leverage or traction, the catgut cords being tightened at the same time so they will not become caught or pinched. When the bones are in position, the catgut cords are pulled on, and the splint will glide half way from one fragment into the other, so that it will be at exactly the proper point.

The catgut can be threaded into a needle, and sewed into the periosteum or muscle at its point of exit, which will secure the splint so that it will not slide out of position up or down the medullary canal.

Such a splint cannot, of course, fit the canal very tightly, and it is not necessary that it should fit tightly, provided that it is prevented from sliding out of place, and this is accomplished by the catgut.

This method involves less exposure of the bone than any other mode of artificial splinting with which I am familiar, and in the four cases in which it has been used in human beings, the fixation obtained has been very satisfactory. If autogenous splints are desired, as in old or ununited fractures of long standing, it is easy to make the splints from the patient's own tibia.

#### ABSTRACT OF DISCUSSION

MR. ERNEST W. HEY GROVES, London, England: I have been extremely interested in Dr. Ryerson's paper, and in his description of a method that I described some years ago. As he said, the intramedullary peg has been used for a number of years. I should like to compliment and criticize this method in one or two particulars. In the first place, the method is excellent, provided that its exact limitations and its details of application be borne in mind. In regard to its limitations, there are two points that should limit it, if good success is to be obtained from its use. First, the fracture must be clean; and second, it must be approximately transverse—or, at least, not comminuted. The type of fracture that is especially liable to give rise to unsatisfactory results is the very common type of fracture in which there is a little third fragment. In such a case, if you do use the intramedullary peg, it is better to cut that little triangular fragment out and bring the two ends of the long fragments together. I think that the use of the intramedullary peg

should be restricted to transverse fractures without comminution. If you employ it for a comminuted fracture, you separate the triangular fragment, which forms an indolent piece of tissue that does not form union. Dr. Ryerson did not describe the principles of what I have described as the long and the short peg. It is quite clear that, however short the peg is, it prevents lateral movement of the fragments on one another. That is the main thing you want. The essential principle of the long peg, four or five inches long, extending a considerable distance, is that it prevents angulation. I believe, however, that it is far better to get the fixation and prevention of angulation by the use of an external splint; because mechanically an intramedullary peg is a great disadvantage. If you have to secure immobilization of the femur by such a long splint, it has to be so long and strong that it is inconvenient to employ. I have personally given up the use of the long peg altogether. I use quite short pegs. Fitting the peg accurately is much more important than Dr. Ryerson gave us to understand. With all due respect to him, I do not think that any method by which a peg is pulled by a thread from one fragment to another gives a sufficiently firmly fitted peg to be satisfactory. I had

Upper part of illustration: splint threaded with catgut and pushed into medullary canal. Lower part: wire loop passed through drill hole ready to pull catgut back through drill hole.

rather have a method by which a short peg is fitted in one fragment, when the two ends are separated; and then the other end is brought over, and the two are snapped together by muscular contraction. As to the comparison of dead and living bone, I think it has been amply proved that when a piece of bone is used as a nail or as a screw, provided that it be driven like a nail or a screw into an accurately fitting hole in the piece of living bone, there is absolutely no difference between the behavior of dead and living bone; and those who believe that autogenous bone acts differently under these conditions are under obligation to bring forward some evidence sustaining their position, which has not yet been done. I am not speaking of grafts as a whole. That is quite another matter. Within six weeks the cells from the living bone grow into the dead peg as far as into the living bone. Therefore, I am convinced that when it is a case of using a nail, the dead bone nail is as good as the living; and it is far easier to prepare and make fit than is a living, autogenous bone nail.

DR. HORACE R. ALLEN, Indianapolis: Dr. Ryerson has very ably presented another new modification of the bone peg. Down in Fort Oglethorpe I built a museum of modern war injuries and their surgical treatment. In this collection I made a model of the bone peg operation. Major Levinson

ct San Francisco told me of his peg operation. The model showed a rectangular opening in the side of the shaft of the bone of sufficient size to permit a bone peg to be worked along inside the canal of the broken bone past the line of fracture. He informed me that the piece of bone should not be removed but should be pushed into the canal and then used as a bone peg. In turn I suggested the use of transverse pegs at the ends of the long peg to prevent its slipping up or down. This modification of his suggestion has since proved very useful. Concerning the length of bone pegs it should be born in mind that a long peg not only equals a short peg in preventing the lateral shearing or displacing element but it also tends to hold the bones in alignment better than a short peg. If only one bone is broken in a leg or forearm there is always difficulty in bringing out the fractured ends. If a short peg will prevent the lateral shearing or lateral displacement the angularity can readily be taken care of by the wire loop method. It consists of a wire suture passed over the angular apex, its free end being attached to an outside straight edge.

DR. ROBERT M. E. SCHLAFFLER, Kansas City, Mo.: The hard ivory pegs last too long. In some cases in which we had a perfectly firm union of the fragments, there would be a little piece of dead bone or two on the edge; and, consequently, a persistent little sinus. In these cases, after a perfectly firm and satisfactory union, the sinus would not heal; and we had to cut down and get out this little piece of quite hard bone. It showed that the medullary splint was lasting too long. When you cut these medullary splints yourself, you are apt to take the hardest part of the beef bone, file it, and give it a fine edge; but when made commercially, they do not do as well as when they are cut a little rougher. The bone should also be left a little porous and not polished so nicely. They should not be prepared too far in advance. These somewhat rougher looking pegs of not too highly polished bone give as good results and last long enough, and when they are used secondary operations are almost unknown.

DR. JOSEPH E. ROOT, Hartford: With all due respect to Dr. Ryerson's very ingenious method, it is too complicated. Remember, all that we have to do, or the main thing that we are after is to secure perfect apposition. All that is necessary in the femur is to obtain perfect apposition, so as to get perfect length. I began by taking the ordinary long bone splints and endeavoring to get them into place by traction, but I have given that up. I have also used the autogenous grafts referred to by other men. All that is required is to hold the fragments together at the point of fracture, and it seems useless to have an intramedullary graft longer than that required for the purpose of perfect apposition. If the bone is in straight, it will stay so; then you can put on ordinary external splints or plaster. To hasten the time of the operation, instead of having a graft with a square end, I saw a semicircular or pointed graft about one and one-half inches long, driving it half way into the medullary space of one end and fitting it into the other. This affords all the necessary fixation at the point of the fracture. By relaxing all the muscles—they can be separated without cutting the fibers—the fragments can be brought out through the hole. Simply bend the limb sharply at the point of fracture, drive the peg into one end, fix the graft in the center of the other fragment and straighten the limb out, thereby locking both fragments. A long external splint, or preferably a plaster spica, will keep the bones in line and enable the patient to get out on crutches the second week. As far as operation time is concerned, it can be reduced greatly by an assistant who takes out the bone graft from the other leg, while you are exposing the bone fragments. In the majority of cases there is a triangular fragment which, of course, becomes loose and detached in some cases. At first, I hesitated about replacing it, but now I replace it. I have noticed in my roentgenograms that a superabundance of osteoblasts were thrown out with a resultant large and long callus.

DR. FRED S. WILLIAMS, Bridgeport: Speaking of snapping the bone back in place, wherever there is a square break, it will do that; and you do not need any peg to hold it.

DR. E. W. RYERSON, Chicago: I do not want to have Major Hey Groves assume that no external fixation was to be applied, because that is the most important feature in treating fractures—the external fixation, and not the internal. Of course, we use the best means at our command for this, using splints, apparatus and plaster of Paris for this purpose, as may seem desirable. Regarding the length of the peg, I would say that a long peg is not necessary in transverse fractures of the femur. That is self-evident. Where you do need it is in fracture of both bones of the forearm; and any man who has had much experience with these fractures will feel better satisfied, if he puts in a long peg, so that the bones will not become bent and approach each other to form a synostosis. We have had many cases in the army in which this has happened, and in which loss of pronation and supination has resulted. It is extremely valuable, in my opinion, to have a sufficiently long splint in these cases to maintain the alignment; because the line of the ulna and that of the radius are different, and in some cases you cannot maintain them by external fixation. I feel very comfortable when I have a long splint in the radius and in the ulna that will maintain them in alignment. Also, in comminuted fractures of the femur, it is well to have a long splint. I have not had the experience of having the small keystone-shaped fragments make trouble, but I undoubtedly shall some day; and I am glad to have had it brought to my attention. The peg method described by Dr. Allen was described by Dr. E. J. Høglund, a number of years ago. It was published in exactly the same form shown by Dr. Allen, except for the two little drill holes in the bone, which Dr. Allen has described. I think that it is difficult to put a peg in, slide it through, find the holes, and put the catgut through them. It may be easy, but it looks difficult to me. The method of putting wire around these fragments and pulling them in line I have not tried. I do not know that I should be willing to try it. The idea of having a short peg and getting the bones into line is possible; and the statement made that if the fragments come into line and are securely locked, they do not need other fixation, is sometimes true, but by no means always true. I have been led astray by this idea that when I had good splints applied, no displacement would occur; but it has happened to me on several occasions that after I had done this and thought that the fragments were locked, the roentgen ray showed displacement and overriding a week or two later. There is nothing that is fool proof in this world; and if you can make it as nearly fool proof as possible, it is a good thing. Major Groves' statement that this must be done in an aseptic field is true. It is bad to put a peg into a field where there is sepsis, but sometimes one can get away with it. It sometimes works, but not often. No fracture should be treated in this way when the field is septic, if any other means can be employed to attain the end desired.

**The Age of Insects.**—We call the present the "age of man." Zoologically, however, it is the age of insects. There is but one species of man—*Homo sapiens*. Over 300,000 insect species have been described, and it is estimated that there are no less than 10,000,000 in the world. Naturally, a sharp edge in the struggle for life falls between mankind and this vast hoard composed largely of foes which seek to devour his person, his cattle and his fields. Our yearly insect tax for damage to agriculture and forest products alone rises millions over the billion-dollar mark—\$1,018,000,000. Add to this destruction of household goods, clothing, carpets, furs and woollens and causation of disease, malaria and yellow fever, typhoid, hookworm, dysentery and the whole list of filth diseases, and the tax which insects lay on the people of this country must rise well toward the two-billion-dollar mark. . . . We howl when we pay this tax. . . . We lay the blame on the railroads and the trusts when we ought to take most of it to ourselves for not having sense enough to study insects, protect our birds and control our cats. . . . A pair of flies, beginning in April, might be progenitors, if all were to live, of 191,010,000,000,000,000 flies by August.—C. F. Hodge.

LUXATION OF A LUMBAR VERTEBRA  
AT BIRTH

REPORT OF A CASE

EMILE HOLMAN, M.D.

Resident Medical Officer, Children's Hospital School  
BALTIMORE

In his *Cyclopedia of the Diseases of Children*, Keating records a statement of Scanzoni that he "had never met with luxations in the newly born, yet they occur, sometimes as congenital lesions, sometimes and not very seldom, at the hip as the result of powerful traction on the lower extremities." The dislocation of one vertebra on another is mentioned by medical writers as a possible cause of birth palsy, but a survey of the literature reveals no description nor report of a case. A brief account is recorded here of a case which may undoubtedly be considered a luxation of the first lumbar on the second lumbar vertebra, occurring at birth and causing a subsequent permanent deformity and permanent flaccid paralysis of both lower extremities below the knees.

## REPORT OF A CASE

*History.*—Delmar R., aged 4 years, 8 months, was admitted to the Children's Hospital School in November, 1918, with the complaint of curvature of the spine.

The mother, aged 28, was very small of stature. She had had four pregnancies, the patient being the only living child. The first child was carried seven months, when labor was induced because of typhoid fever contracted by the mother.

The child weighed 4 pounds and lived only a few hours. The second child is the patient, who was also carried seven months when spontaneous rupture of the membranes occurred without preceding pains. A version and breech delivery were performed under chloroform anesthesia, with considerable laceration of the mother and child. The skin was torn from both limbs of the boy, and the mother noticed a marked version of 14th feet. The estimated weight of the child was 2½ pounds, and the attending physician was greatly astonished to find him alive on his next visit. The child had been wrapped well in cotton by his grandmother, and for the first two weeks of life thrived on whiskey and crackers! At the end of that time he was able to take the breast, and thereafter made excellent progress. At one month the mother noticed a "sinking in" of his back, which became worse as the child advanced in growth. She also was aware that his legs were motionless, and apparently paralyzed below the hip.

The mother's third pregnancy terminated at seven months, the child dying after two weeks with jaundice.

During the fourth pregnancy, the mother's pelvis was found by examination and by measurement to be distinctly below

normal in size. Accordingly, in the mother's language, the child "was taken from her" at four months, and her "tubes were cut" to prevent further pregnancies.

The patient's history to the present is not of particular interest. There was apparently considerable retardation in development; his first tooth appeared at 18 months, and he did not talk until 30 months of age. Massage and passive exercises of the legs were begun early, and at 18 months this treatment had overcome the outward rotation. At 2 years the Achilles tendon on the right was divided to overcome contracture. The mother reported that the child had no control of micturition, and only slight control of defecation.

*Physical Examination.*—The patient was a well nourished, though underdeveloped, white child of 4 years and 8 months. The head exhibited a narrow, elongated configuration. The eyes and ears were normal. The mouth was negative except for hugely hypertrophied tonsils, and the nasal speech and obstructive breathing indicated the presence of excessive adenoid tissue. There were numerous palpable, enlarged glands in the suboccipital region and at the angle of the jaw. No other glandular enlargements were present.

The lungs were clear and the heart was normal. There was a markedly protuberant abdomen, but no abnormal masses were made out. The external genitalia were considerably retarded in development, and only the right testicle was descended.

An examination of the reflexes revealed the absence of the abdominal and cremasteric responses, an exaggeration of the knee kicks, with absence of both the ankle jerks and plantar responses on the two sides. The upper extremities were very well developed, exhibiting extraordinary power as compared to the legs.

On examining the lower extremities, one was struck by the fairly well developed thighs as compared to the helpless-looking, flail-like feet, and the puny, underdeveloped calf muscles. There was a bilateral foot drop, both feet lying in extreme equinus. A slight power of plantar flexion on the right was the only movement present below the knees. Extension at the knee was normal, but flexion was decidedly weak. The biceps femoris was absent on both sides, though the internal hamstrings were present.

At the hip all movements were present, the flexors more powerful than the extensors, resulting in a flexion deformity of 30 degrees, with extreme tightening of the fascia lata on both sides, a condition frequently met in neglected paralyseis following anterior poliomyelitis.

In examining the trophathic and epicritic systems some difficulty was found, owing to the age of the child, in securing any accurate delimitation of alterations in sensitiveness. The skin above the knee was of normal appearance, but below it was blue and definitely cold to the touch. The recognition of light touch was unimpaired, but there was a definite diminution in the sensitiveness to pinpricks, although it was not entirely absent. This diminution was most marked on the lateral aspects of both lower legs over the fifth lumbar

Fig. 2.—Patient erect. This illustration, with Figure 1, shows the marked and irreducible deformity.

Fig. 1.—Patient in sitting posture.

nerve distribution. The sensations of heat and cold were well appreciated on the left, but on the right the sensibility was markedly impaired over the distribution of the fifth lumbar and first sacral nerves.

The back showed a remarkable lordosis (Figs. 1 and 2), with its apex at the level of the first and second lumbar vertebrae. There was present also a definite scoliosis, with its convexity to the right in the lumbar region, and with a rotation of the vertebral bodies to the right in the lumbar region and to the left in the dorsal region. In spite of the absence of superficial or deep-seated pain, the back was held fairly rigidly, and all movements were resisted. The scoliosis in the lumbar region could be corrected with force, but the lordosis in the sitting posture resisted complete reduction, and was not entirely corrected by flexing the thighs strongly against the abdomen.

By supporting himself on a chair, the child was able to stand, but on a very broad base. In the erect position, the lordosis was greatly pronounced, and had the appearance of a right-angled back. With help, a certain amount of progression was possible.

A roentgenogram, taken, to be sure, four years after the injury, showed anteroposteriorly a scoliosis of medium degree. Laterally, one might distinguish a distinct break in the normally regular alinement of the bodies of the vertebrae, occurring between the first and second lumbar vertebrae, exactly opposite the apex of the lordosis. By accentuating the contrasts on the roentgenogram plate this break in alinement was well shown (Fig. 3). There was no spina bifida.

*Treatment.*—Souttar's operation to correct the extreme flexion at the hip was performed, and the child was provided with a combined spinal and long paralytic brace designed by Dr. George E. Bennett. The brace should, with practice, enable the child to get about with considerable ease.

#### COMMENT

Considering the difficult delivery at birth, the very early recognition of the deformity of the back, the persistence of that deformity, the presence of a bilateral paralysis, and the fairly definite roentgenographic findings, the diagnosis of dislocation of the first lumbar on the second lumbar vertebra is almost inevitable. The elasticity of structures at birth would lead one to consider this a pure dislocation without fracture but at this late date there is no evidence for or against an accompanying fracture. Because of the close interlocking of the processes and the strength of the ligaments, the possibility of the occurrence of pure dislocation of the lumbar vertebrae was long considered doubtful. The report of two authentic cases by Blasius<sup>1</sup> has, however, dispelled this doubt. Brewer<sup>2</sup>

and other authors state that pure dislocations of the spine are rare, and, of the few occurring, five sixths are in the cervical region.

As to the cause, extreme flexion or hyperextension are cited by authors as adequate methods for producing such a dislocation. A difficult breech delivery through a definitely undersized birth canal would no doubt provoke either or both of these insults.

The symptoms remaining at the present time do not correspond exactly to a lesion following dislocation of the first on the second lumbar spine. The residual symptoms point to permanent injury to the fourth and fifth lumbar and first sacral nerves, although some fibers even of these nerves seem to have escaped or recovered from injury. In fracture dislocations of the lumbar region several points of anatomy must be borne

in mind: (a) The spinal cord ends opposite the lower border of the first lumbar vertebra; (b) the five lumbar nerves arise from the cord opposite the eleventh and twelfth dorsal spines, and the five sacral nerves arise from the cord opposite the first lumbar spine; (c) the lumbar and spinal nerves emerge from the vertebral canal considerably below their origin, and find their exit through the intervertebral foramina just below the corresponding vertebrae. Accordingly, an injury between the first and second lumbar vertebra is apt to leave the cord itself uninjured, but may involve (1) the cauda equina in whole or in part, or (2) may damage the nerve as it makes its exit from the vertebral canal through the intervertebral foramen. In either case, a partial or complete regeneration of the nerve roots might reasonably be expected, and that is probably what has occurred in this instance.

A survey of the literature reveals no mention of a similar birth injury in which the victim survived. No doubt, they have occasionally occurred with fatal consequences, and quite naturally have not been recorded. Kleinberg<sup>3</sup> reports a somewhat similar case which he classifies as "congenital anterior curvature of the spine." The case was also a difficult breech delivery with considerable injury to both thighs, the left femur being fractured, and for ten days following birth the child did not move either lower limb. The most prominent feature was the marked lordosis, but a lateral roentgenogram revealed no luxation. Kleinberg says, "As the condition was observed in the first few weeks

Fig. 3.—Definite break in regular alinement of vertebral bodies, four years and eight months after birth.

1. Blasius: *Vierteljahrsschrift für praktische Heilkunde*, **102**, 103, 1869.

of life, and then very resistant, we are warranted in considering this a genuine congenital deformity." Is it possible that this might also have been a fracture dislocation, though partially reduced, as the result of a violent manipulation at birth?

Concerning the scoliosis, it would seem that this, too, must be attributed to the injury. There is no roentgenographic evidence of the presence of any of the anomalous conditions mentioned by Bohm<sup>4</sup> following developmental error occurring in embryonic life, nor is there any evidence of the wedge-shaped supernumerary vertebrae reported by Fitzwilliams<sup>5</sup> and by Norbury.<sup>6</sup> Apparently one must add injury at birth to the causes of so-called congenital scoliosis.<sup>7</sup>

### THE DELETERIOUS EFFECT OF THE ALKALIZATION OF INFANTS' FOOD\*

ALFRED F. HESS, M.D.

AND

LESTER J. UNGER, M.D.

NEW YORK

At the present time little regard is paid to the reaction of the milk preparations that are fed to babies. It is considered quite immaterial, for example, whether

being not specifically mentioned. This is true of American, English, French and German textbooks. This neglect is all the more remarkable as for some years it has been appreciated that the salts play an important rôle in infant feeding; indeed, in every effort to construct an artificial food approximating mother's milk, the salt factor has been given particular consideration.

We wish to point out that it is by no means immaterial whether we render the baby's milk more or less alkaline. What effect an addition of alkali has on proteins and other caloric food factors it is impossible, in the present state of our knowledge, even to surmise; but that this alteration has a decided effect on the vitamins is susceptible to proof. In a previous article we have shown<sup>4</sup> that orange juice, the prototype of antiscorbutics, and the one most relied on in infant feeding is essentially damaged within twenty-four hours by being rendered twentieth normal alkaline to phenolphthalein. In fact, orange juice of this faintly alkaline reaction was found to have lost its power to protect guinea-pigs against scurvy. It is evident, therefore, that the antiscorbutic vitamin is peculiarly sensitive to alkalization. We may add that this vitamin seems to be more sensitive to various physical and chemical influences than either the water-soluble or the fat-soluble vitamin. There is at present some difference of opinion as to the vulnerability of the

Chart 1—Human scurvy: weight curve of a baby that developed scurvy on a diet of malt soup (Period 1). During Period 2 the flour and malt soup were omitted from the diet, the same amount of milk and potassium carbonate being continued. The disorder did not abate. The only change in Period 3 was a discontinuation of the potassium carbonate. This brought about a gain in weight and cure, showing the destructive effect of the alkali on the vitamin.

sodium bicarbonate is added to a milk formula, or whether a proprietary food is more or less alkaline in reaction. To such an extent is this the case that in stating the composition of proprietary foods, the textbooks on children's diseases content themselves with a statement of the protein, fat and carbohydrate content of the various popular preparations, giving no consideration whatsoever to their reaction. In such tables the salts are expressed in terms of percentages of total ash, the nature of the inorganic constituents

water-soluble vitamin to the application of heat in an alkaline medium. There is no question, however, that this reaction renders it more susceptible to destruction.<sup>8</sup>

This subject was forced on our attention by the experience that milk formulas containing malt soup have an exceptional tendency to bring about scurvy in infants, unless an antiscorbutic foodstuff, such as orange juice or canned tomato, is added to the dietary. As has been brought out elsewhere, this undesirable effect might be the result of one or more of the following conditions: (1) that the formulas contain an amount of milk insufficient to protect fully; (2) that the preparation is boiled as well as frequently prepared from pasteurized milk; (3) that there is a period of aging between the initial pasteurization and the boil-

 3 Malt soup is prepared by dissolving the alkaline malt soup extract in water, and mixing wheat flour with milk. These two mixtures are then boiled together for about three minutes. According to some directions, 11 ounces of milk are used; according to the formula followed by us, 16 ounces were employed.

ing of the milk and the flour; (4) that an alkali is contained in the malt soup, and finally (5) that a considerable amount of carbohydrates in the form of flour and of malt sugar is added to the food. It seemed important, when an opportunity presented itself, to analyze this question, to determine which of these factors is at fault.

Chart 1 shows the weight curve of a baby that was receiving a diet of malt soup and cereal, with the addition of three teaspoonfuls of cod liver oil a day. It developed scurvy. The symptoms were those commonly associated with this disorder; namely, pallor, hemorrhages of the gums, tenderness of the femur, irritability, and lack of gain in weight. In view of this occurrence, an attempt was made to cure the scorbutic condition by eliminating the carbohydrate from the diet, by omitting the flour and malt sugar from the formula. In order to accomplish this, a pint of milk was prepared with the addition of sucrose and the same amount of potassium carbonate as is contained in the malt soup formula.<sup>4</sup> This milk, which was fresh and of excellent quality, and contained no malt or flour, was boiled for five minutes. There are many who believe that the carbohydrates, especially the starches, are of great importance in bringing about the so-called deficiency diseases, because they require a considerable amount of vitamin for their metabolism, and lead therefore to such disorders as scurvy or beriberi, if present in relatively high amount. It was found, however, that the harmful influence of the malt soup preparation could not be attributed to its high carbohydrate content, as the exclusion of the flour and the malt did not bring about an alleviation of the symptoms, or, as will be seen (Chart 1), lead to a gain in weight. As this form of treatment proved unsuccessful, it was determined to discontinue the addition of the potassium carbonate, so that the baby received a pint of milk that was boiled for five minutes without the addition of alkali. The sucrose, the cereal and the cod liver oil were continued. The result was striking. Not only did the infant gain in weight, as will be seen from the chart, but there was a marked change in its general condition and a disappearance of the various signs and symptoms enumerated above. It seems, therefore, quite evident that the alkalization of this food, which contains a limited amount of antiscorbutic material—merely that which is contained in a pint of boiled milk—was sufficient to render its antiscorbutic quota insufficient.

As the result of this experience, an experiment on guinea-pigs was instituted. It had been shown in previous experiments that guinea-pigs weighing about

200 gm. very rarely develop scurvy when given daily 80 c.c. per capita of fresh milk. Accordingly the same percentage of potassium carbonate as is contained in malt soup was added to this amount of milk, and its effect was noted on the weight and on the clinical condition of the guinea-pigs. Ten c.c. of an 11 per cent. solution of the alkali were mixed with raw certified milk, which was then boiled for a period of five minutes. It will be seen from Chart 2 that scurvy developed in all the pigs. That this disorder was not attributable to the alkali itself is shown by the prompt response and alleviation of symptoms, when 3 c.c. of orange juice were added to the dietary, notwithstanding the fact that the potassium carbonate was still continued (Chart 2).

These results have an application far wider than their relation merely to malt soup. Investigation brought out the fact that an alkaline potassium salt is added to the greater number of our proprietary foods for infants. This is done for one of two reasons: In the first place, because it renders the food less subject to acid fermentation,

and second, because the addition of potassium counterbalances the relative poverty of this salt in cow's milk. In the majority of instances, potassium bicarbonate is added in the ratio of from 2 to 2.5 per cent., instead of the carbonate, as in malt soup in a much lower percentage. In view of the clinical and experimental results that we report, the danger of this practice is evident. In many instances it is unnecessary, as a salt such as potassium citrate probably could be substituted to supply the potassium deficiency. In cases, however, in which the object is to change the acid reaction, such a substitution would, of course, not be practicable.

#### CONCLUSIONS

With the realization that foods contain not only caloric factors but also accessory food factors or vitamins, it is incumbent on us to revise our standards and to reconsider their entire preparation from this new point of view. It is clear that the antiscorbutic vitamin in milk is rapidly destroyed by alkalization associated with heating, and that by the thoughtless addition of alkaline proprietary foods we are robbing the infant of much of this essential foodstuff.<sup>5</sup> The question may be raised in this connection whether, in a similar way, we are heedlessly destroying the potency of other vitamins. It has been shown, for example, that cod liver oil is rich in at least one vitamin, the fat-soluble factor, and that it is almost a specific in

5. In a discussion published soon after infantile scurvy had come to be recognized, it was asserted by a member of the Berlin Medical Society that "Riche's albumose milk" induced scurvy. This was a popular preparation to which 0.4 gm. of potassium carbonate was added in order to change the albumin to albumose. No further attention ever was paid to this observation (Meyer, E.: *Berl. klin. Wochenschr.* 22: 85, 1896).

Chart 2.—Guinea-pig scurvy: All four guinea-pigs developed scurvy on a daily diet of hay and 80 c.c. of milk to which had been added the same percentage of potassium carbonate contained in the ordinary malt soup preparation and which had been boiled for five minutes. After the disorder had developed, two of the pigs (776 and 906) were given orange juice. They recovered and gained rapidly in weight in spite of the continuation of the alkali in their diet, thus proving that we were dealing with scurvy. The other two (28 and 143) were not given orange juice, and lost weight and showed marked signs of scurvy during life and at necropsy.

4. This is stated as 0.44 gm., or 6.79 grains, to the fluidounce, and is measured by adding 10 c.c. of an 11 per cent. solution of potassium carbonate for each liter of prepared malt soup.

the treatment of rickets. We have found that this oil, originally acid owing to its considerable content of organic acids, is alkaline in many of the proprietary emulsions commonly employed. It is quite possible that this alteration in reaction is not immaterial in relation to the efficacy of this valuable therapeutic agent.

16 West Eighty-Sixth Street.

#### ABSTRACT OF DISCUSSION

DR. HARRY LOWENBURG, Philadelphia: I should like to ask the doctor if he said that the addition of orange juice while he was administering the carbonate of potassium prevented the development of scurvy? Dr. Hess's work is very interesting and very enlightening, if it can be verified. However, it appears quite rash, on the face of it, to draw as sweeping a conclusion as he does from the study of only one sick baby and from the protocols of only four experimental guinea-pigs, in the light of vast clinical experience with many feeding cases wherein the alkalization of milk has produced no harmful effects. I have yet to see the development of scurvy in these cases. I feed many infants on malt soup extract; I never feed orange juice, although I commence the administration of comminuted green vegetables and stewed apples and prunes early. It is very difficult, indeed, to consent to have one's convictions swept aside by the meager data offered by this single case and these four experiments. I should like to see this work carried out further and confirmed. Until then I must continue to add alkali to milk mixtures where I believe it to be indicated. This is said not in the light of destructive criticism. The essayist has not provided us with sufficient data. Hence hasty conclusions may not be drawn nor accepted. It is illegal to conclude from the doctor's statements that those who are using malt soup extract and alkalis should have an abundance of scurvy in their practice. This has not been my experience.

DR. JULIUS H. HESS, Chicago: When Keller first gave us the formula for making malt soup, he warned the profession against feeding this mixture for too long a period, because of the danger of developing scurvy. I have had the misfortune of placing infants on Keller's malt soup, and notwithstanding instructions the parents have remained away for from two to four months and returned with the infants showing evidences of scurvy. This has occurred three or four times. One proprietary infant's food on the market is recommended to be fed in amounts as high as three to four ounces daily. This food contains 2 per cent. of potassium bicarbonate which would result in the feeding of from 30 to 45 grains of the alkali to the quart, while the potassium bicarbonate in Keller's malt soup equals about 16 grains to the quart. A great many babies come under my observation who have been on this food for a considerable period of time, and I must confess that I have never seen a case of scurvy develop on the diet, even though it is a very one-sided one. These facts lead one to wonder why we do not see more scurvy in babies fed on the infants' foods containing potassium bicarbonate.

DR. C. G. KERLEY, New York: I have been feeding alkalis of different kind for many years and I have had only an occasional case of scurvy, and these cases are nearly always associated with the diet of some cooked milk product and not with fresh milk. Children given fresh milk do not have scurvy whether alkalis are added or not. There must be something else, therefore, than the presence of alkalis that interferes with the vitamin content of the food. Malt soup mixtures are more apt to produce scurvy than any other diet. I never use this method of feeding without prescribing orange juice at the same time.

DR. J. P. CROZER GRIFFITH, Philadelphia: Let me call your attention for a moment to what is in a way ancient history, but no less important and true now, since conditions have not changed. I refer to the published investigations of the American Pediatric Society some years ago, as to the effect of the feeding of different kinds of food in the

production of infantile scurvy. In that publication you will find that infantile scurvy followed oftener on the use of many of the proprietary infant foods of various sorts than after any other regimen. In fact, one manufacturing company was so disturbed about the matter that they made a claim that the scurvy was due to the fact that the milk mixed with the food had been boiled. It is undoubtedly true that the boiling of milk is followed by the development of scurvy in some cases, but not nearly so often as in the use of the commercial foods. I am not referring in any way to malt soup, which is not advertised to the laity but to the profession. Dr. Hess's paper is a very valuable and interesting one. He seems to have proved in the case reported that rendering the food alkaline produced scurvy. I do not think, however, that this is convincing proof that alkalis used as a routine measure are to be feared on this account. In the American Pediatric Society's report there were mentioned ten cases of scurvy occurring in infants fed solely on breast milk. That would not prove that breast milk is to be avoided. I have fed hundreds of infants with malt soup preparations, since it is a very favorite food with me, but I have yet to see a case of scurvy following its use. It should be said, too, that in many cases the pasteurizing or sterilizing of milk serves such a very useful purpose and tends to prevent diseases so much more serious and common than scurvy, that it would be foolish to avoid its use, especially since any tendency which it may have to produce this disease can readily be obviated by the administration of orange juice. Indeed, the fact that scurvy is uncommon, considering the vast number of babies artificially fed on boiled milk, pasteurized milk, alkaline foods, and many other foods, is an indication that we do not yet know all there is to know about the etiology of this disease.

DR. ST. GEORGE T. GRINNAN, Richmond, Va.: Some of you have said that scurvy is rare. It certainly is not in Richmond. I was in New York about two years ago and heard Dr. Hess read a paper and Dr. Kerley discuss it. I went back and looked up the subject of scurvy more than I had before, and I have seen more cases in the last two years than I had in the ten years before. I found that there was a very large sale there of a certain proprietary food, and I found many cases of scurvy in the babies fed with this food.

DR. JOSEPH GROVER, Boston: I feel sure that scurvy is not a rare disease. In the Children's Hospital in Boston we see one case every two, three or four days. I think boiled or pasteurized milk causes it a great deal, but the dry foods cause it more frequently still. The use of certain dry proprietary foods over a period of two or three months is fairly sure to bring on the first symptoms of scurvy.

DR. LEWIS HILL, Boston: I have used the food to which Dr. Grinnan referred a great deal and I have never seen a case of scurvy develop while it was being fed. This food is only carbohydrate with a little vegetable protein and salts. It should not be called a food. It is malt sugar and should be used as malt sugar, to which is added a reasonable amount of milk, orange juice or cereal, or some other food. I believe it is a good preparation and no more likely to produce scurvy than any other sugar is.

DR. EFAA V. DAVIS, Chicago: I am rising to voice my protest against condemning a malt sugar which happens to be called a food. It is malt sugar made from wheat. We have been discussing corn syrup; dextrimalose is now made from corn. It was formerly made from potatoes. I think we may as well face what is being placed on the market and understand it first hand, rather than condemn a thing on theory. I have tried the "malt food" in the modifying of raw milk for the past two years in my nursery, where I have from ten to fifteen artificially fed infants, without the development of scurvy. I know there is a certain percentage of potassium carbonate in the food. About six months ago, my attention was called to the fact that sodium bicarbonate added in the usual housewife's method of cooking beans destroyed the vitamins. From that hint I began to drop it in making bean soup, which I give my babies in their second year as well as the early use of antiscorbatic elements, such

as vegetables, fruit juices, etc., from the seventh or eighth month. To go back ten years is a little ancient. We made other mistakes then which affected our results, such as feeding every two hours, for example. I think the alkalinity of infants' food is still an open question.

DR. EMANUEL C. FLEISCHNER, San Francisco: It seems to me that we are losing sight of what Dr. Hess wishes to bring before us. I do not think it is his purpose to pass on the entire etiology of scurvy. I have seen a large number of his experimental animals, and I think no one can doubt he has demonstrated thoroughly, that with a certain fixed amount of raw cow's milk he is able to determine in an exact manner that he can keep guinea-pigs free from scurvy. Giving animals the same amount of cow's milk which under ordinary circumstances keeps them free from the condition, and by alkalinizing this food to a certain extent, he has shown that the antiscorbutic vitamin is destroyed. In other words, our attention must be directed toward the fact that a high percentage of alkali in artificial foods, if we are giving a quantity of milk which is just sufficient to prevent scurvy, can destroy a sufficient amount of the vitamin in that milk to produce the disease although it may be in a very mild state. It does not seem to me that in his paper he has tried to convey to us that all cases of scurvy are due to highly alkaline foods, and I am sure that he has not tried to prove that proprietary foods are always responsible for the disease. All of us know that we can use proprietary foods of practically all types, even with high alkaline content, if we are giving these children a large amount of raw milk. In other words, they are getting enough vitamin to prevent the development of scorbutus, notwithstanding that the alkali destroys a portion of the antiscorbutic element. It seems to me that Dr. Hess has developed a very interesting and scientific fact in this connection.

DR. F. C. NEFF, Kansas City, Mo.: I should like to ask Dr. Hess one question. Within the past year a sugar to which potassium carbonate was added was marketed with the definite statement that it was to be used instead of other preparations for the relief of constipation. I want to ask what the findings are with regard to that. I have seen no effect whatever on constipation by the addition of potassium carbonate.

DR. A. F. HESS, New York: I do not see how we can do that, especially with the malt soup and some of the other things. Dr. Lowenburg said that he had never seen scurvy develop on malt soup. I think Dr. Kerley has answered that. If I put a hundred children on malt soup without any antiscorbutic I will get almost 100 cases of scurvy. By scurvy I do not mean the active cases that sometimes are waited for, with the bulging red gums and the hemorrhages. I mean the mild cases with pallor, loss of weight, tenderness, irritability, and a few petechiae. Those cases will develop more frequently on malt soup than on any other food. Malt soup, according to the way it is made in the final preparation, contains 0.1 per cent. potassium carbonate. It is quite different from the others, and that explains why malt soup is so prone to produce scurvy. As regards the animal experiments I described only four, but I could have described many more. I do not know of any essential particular in which animal scurvy differs from human scurvy. I have never found any. An antiscorbutic for the guinea-pig is antiscorbutic for humans. I have tested many hundreds of guinea-pigs in the last few years, and found that what will produce scurvy in the guinea-pig leads to it in the baby, so that we can accept, as far as I know, animal scurvy for interpretations of human scurvy. As to the dry food, I do not think that it is the drying of these proprietary foods that leads to scurvy, because, as I have recently shown, dry milk, subject to a temperature of 240 F., for two or three seconds still retain its antiscorbutic property and when made up to the equivalent of fresh milk is able to protect guinea-pigs against scurvy.

**Trained Nurse.**—A trained nurse does not always enjoy being a sanitary policeman, but some one must do it if the treatment is to be carried out.—*Bulletin*, State Board of Health of Rhode Island, August, 1919.

## IMPROVISED ORTHOPEDIC EXERCISING APPARATUS\*

RUDOLPH S. REICH, M.D. (CLEVELAND)

Captain, M. C., U. S. Army

FORT SHERIDAN, ILL.

During June, 1918, at Camp Cody, New Mexico, the camp orthopedic staff was confronted with the necessity of carrying out, on a large scale, many specialized corrective gymnastic exercises for soldiers and recruits among whom were found all of the whole gamut of orthopedic defects: weak feet; contractures of the finger, wrist and larger joints; limitation of motion of various joints incident to recent fractures, etc. For this work, the medical department provided the orthopedic staff absolutely nothing in the way of ready-made orthopedic apparatus, such as Zander

Fig. 1.—Hurdle for exercising ankle and knee.

machines, and at that time the principles of vocational reconstruction had not made such appliances available. The schedule of gymnastics included specialized calisthenic exercise without apparatus, supplemented by a general daily routine suited to the individual needs of the men. Although excellent results were secured, it seemed to me that the end results might be augmented by the employment of apparatus designed to assist in corrective and developmental work.

### APPARATUS FOR THE LOWER EXTREMITY

Realizing the need of apparatus to facilitate flexion and extension of the foot and knee, we devised wooden steps, having a rise of 6 inches and a tread of the same dimension, arranged in such a way

that the patient walked up four and down the same number. Wooden hurdles, 8 inches high, were made (Fig. 1). These were placed at variable distances, and each man stepped over them in such a way that his foot passed directly over the hurdle, necessitating flexion and extension at the knee, and extension of the foot.

The success of this simple device, which was no doubt partly due to its novelty, encouraged us in attempting other appliances. We tried to procure an old sewing machine to stimulate dorsal and plantar flexion by pedaling, but were unable to do so, and decided to build its equivalent. Through the courtesy of the reclamation and conservation officer, we obtained a fly-wheel of a washing machine. Short pieces

\* Read before the Section on Orthopedic Surgery at the Seventeenth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

of various sizes of lumber were obtained through the courtesy of the construction quartermaster. A frame, 36 inches high and 24 inches square (Fig. 2), was constructed out of two-by-fours. An offset was attached to the right side, and in the inside of the frame, to which was attached the fly-wheel, 24 inches in diameter. The foot-pedal, which was the chief mechanical feature, made of 2 by 10 lumber, rested on an elevation from the base, which was similar to that of a sewing machine, and it was joined to the fly-wheel by means of a wooden connection rod. The patient's seat was built to the frame, and his feet were strapped to the pedal. The efforts to force the fly-wheel gave the desired dorsal and plantar flexion with resistance, which was graduated by an adjustable brake.

Another machine, similar to the one described, was constructed, in which the pedal was hinged to the frame in such a way as to bring the fulcrum at the far end of the pedal, and in this way a wider range of dorsal and plantar flexion was obtained.

Fig. 2.—Pedaling machine for exercising ankle and knee.

Fig. 3.—Bicycle for exercising ankle and knee.

Fig. 4.—Foot exercising board.

The Red Cross obtained for us an old bicycle, which included the frame, saddle, sprocket, chain, and rear axle and gear only. This was fixed upright on the floor by means of a wooden frame (Fig. 3), and a rear wheel was constructed entirely of wood. Pedals, which were 10 inches long, also had to be improvised of wood. The feet were strapped to them, and, by putting the pedals into motion, flexion and extension of the hips and knees, as well as dorsal and plantar flexion, were obtained. Resistance was graduated as in the other apparatus, by means of a brake.

For patients afflicted with weak feet, with abduction and pronation, we used boards (Fig. 4) on which men received systematic exercises in their bare feet. Short strips of 2 by 10 lumber, 12 inches long, were cut down into double inclined planes of 120 degrees, with the apex upward. The distal end of the board was cut to a point forming an angle of 120 degrees, and this point was notched out into a semicircle. In this way, dorsal and plantar flexion were easily obtained from the metatarsophalangeal joint, when the man stood on the board with his feet parallel and 3 inches

apart, and his toes over the distal end of the board, while the incline placed the feet in adduction and supination.

For the same purpose, a long runway was constructed in the shape of a double inclined plane, with the apex pointing upward at an angle of 120 degrees, and the men were instructed to walk along this incline with feet parallel, or toeing slightly inward.

APPARATUS FOR THE UPPER EXTREMITY

In considering apparatus for the upper extremity, we first attempted to construct exercisers. The available materials consisted of discarded pulleys, rope and old shell casings filled with sand for weights. Handles were made from broom sticks and No. 6 galvanized iron wire. Three types were constructed: The first, in which the pull was from above downward and required only two pulleys, firmly attached to the ceiling, over which the rope was suspended with the weights and handles on either side. The second, in

which the pull was on a horizontal plane and required four pulleys. The first two were attached to the wall, 4 feet from the floor, and 2 feet apart. The second two were suspended from the wall 3 feet above and 6 inches to the outside of the vertical plane of the lower pair. The rope extended from the handles through the lower set of pulleys, then through the upper set, and to the shell casings. In the third type, the pull was from below upward, and also required four pulleys. The first two pulleys were attached to the floor at the junction of the wall and 3 feet apart, and the second two were attached to the wall 6 feet above and 6 inches to the outside of the vertical plane of the lower ones. From the handles, the rope extended first through the lower set of pulleys, then through the upper set, and finally to the weights.

For exercising the deltoid muscle and for producing circumduction of the shoulder joint, we employed a large fly-wheel, 30 inches in diameter, salvaged from a washing machine (Fig. 5). This wheel revolved on an axle which was fixed at one end to a metal bracket, a part of the original washing machine. It was mounted

on a wooden offset 5 feet from the floor, and in such a way that the axle projected horizontally at right angles to the wall. A wooden handle was inserted into the rim, and a wooden brake was applied against the rim, the pressure being regulated to suit the needs of the patients.

An apparatus for pronation and supination exercise of the forearm was thus constructed: A piece of two-by-four about 20 inches long was trimmed down at each end to leave two cylindrical projections like the handles of a rolling-pin (Fig. 6). It was mounted on a pair of wooden brackets fastened to the wall, 30 inches from the floor, in a position similar to that for a roller towel rack, and was then perforated in the center at right angles to its long axis, a hole being made of the right size to receive snugly the shaft of a sawed-off shovel handle, which was pushed through it with the handle on its near side, and the shaft projecting toward the wall. Two wooden pins driven through the shovel handle, one on either side of the crosspiece, fixed the

carpometacarpal joint rested on the edge of the support. The patient grasped a discarded screw driver in his hand, and placing the shaft between the spokes, propelled the wheel. Thus, the desired circumduction was obtained.

#### APPARATUS FOR GENERAL EXERCISE

For the purpose of obtaining general exercise, a rowing machine was suggested. Two uprights were built to the floor out of two-by-fours 30 inches high, 4 feet apart and 4 feet from the wall (Fig. 8). Oars were constructed out of two-by-fours, 3 feet long, the ends of which were whittled down for handles. The oars were pivoted to the uprights through their centers by means of discarded motor valve stems. Two pulleys were fastened to the wall at the same height and immediately behind the distal ends of the oars, and two more placed 3 feet above and 6 inches outside of the vertical planes of the lower set. Ropes were tied to the distal ends of the oars and extended through the

Fig. 5.—Shoulder circumduction machine.

Fig. 6.—Pronation and supination apparatus.

Fig. 7.—Wrist circumduction apparatus.

shovel handle in this position without preventing its free rotation in the hole. At the distal end of the shovel handle, and at right angles to it, there was attached a stout lever arm 6 inches long, and from this a weight was suspended. Whereas this machine was devised merely for pronation and supination exercises by rotating the shovel handle, the roller bearing permitted an adjustment for the height of the man.

We constructed another appliance, similar in every detail to the pronation and supination machine, with the exception that the shaft of the shovel handle moved in a large oval opening, thus giving the handle a wider range of movement.

To produce circumduction at the wrist, we mounted a wheel with its axle on a wooden bracket in the same position as the wheel in the shoulder circumduction apparatus, with the exception that the axle was 3 feet high (Fig. 7). The wheel was 12 inches in diameter, and it also was obtained from the reclamation department. A wooden arm support was mounted on a level with the axle, at right angles to the plane of the wheel, and 12 inches away from it. The arm was fixed to the support by means of straps in such a position that the

lower pair of pulleys, then through the upper pair to the two shell casings filled with clay as weights. A seat was mounted behind the oars with three foot-rails in front. Four rollers attached to the bottom of the seat permitted free backward and forward motion on a wooden track. The novelty of this device proved to be quite attractive to the men, and they took great advantage of it.

#### COMMENT

The purpose of this brief review of the practical application of well known scientific principles in the crude apparatus devised will be served if I have been able to demonstrate the early approach thereto to the larger field which concerns us now as orthopedic surgeons, namely, the application of the principles of vocational training and reeducation to the wounded soldiers returning to our reconstruction hospitals. It is believed that the success attained in the service at Camp Cody will be encouraging to those who may be called on to make an effort at rehabilitation in centers where modern means of vocational training may not be readily available.

## ABSTRACT OF DISCUSSION

DR. ZABDIEL B. ADAMS, Boston: I had an opportunity of going to a school in France, just outside of Paris, where the French were reclaiming the men who had been slightly wounded or who had been discarded in the draft; and there, the apparatus used was very much the type that has been described in the paper—that is, apparatus that was made out of practically anything found on the premises. They had a few things that have not been thought of, apparently, in this country—at least, not described in this paper—which were original and simple. One of these was a double inclined plane, which they used to increase the flexion of the hip, knee and ankle. It consisted of a plane made of two boards, about ten or twelve inches wide, sloping up to 33 cm. in the center, and about eighteen feet long. The men took hold of a rail attached to the wall and, putting one foot on this inclined plane, and keeping the other on the floor, would start with the foot at a low level on the plane, and gradually push the lame foot up and swing back and forth; so that when they got to the top of the inclined plane, they would have complete flexion of the knee, ankle and hip. Then they had a very fine apparatus for limbering up the hand, consisting of a wooden bottle; and for supination and pronation, a machine something like that described here, with a handle like a shovel, which they twisted. They used, also, the chest weights and rowing machine.

Fig. 8.—Rowing machine.

DR. RUDOLPH S. REICH, Cleveland: We had a great many other devices there that I did not describe. We felt that by improvising apparatus we could construct almost anything that the condition we happened to be dealing with might require. We could improvise apparatus that would be applicable to any condition that we were confronted with. Another thing that I should like to mention is the practical application of this to civilian orthopedic work. Many hospitals cannot afford to buy expensive apparatus; and very good articles can, I think, be constructed, which will serve the purpose very successfully, although they may, perhaps, not be quite so elaborate as the purchased apparatus.

**The Rat.**—A recent bulletin of the U. S. Public Health Service discusses the increasing deprivations of rats. It is estimated that there is one rat at least for every person in the United States. The annual cost of the rodents is probably \$180,000,000 per year. However, the rats are not only a severe economic loss, but also a public health menace, since they have been incriminated as carriers of several diseases; for example, plague and more recently tsetse-hemorrhagic spirochetosis. Rats are frequently found infected with intestinal parasites, such as tapeworm and with trichina. It is stated that there are three kinds of rats in this country included in the survey. Chief of these is the brown or Norway rat, which has largely superseded the other varieties. The primary measure suggested for destroying rats is the rat-proofing of buildings.

## Clinical Notes, Suggestions, and New Instruments

### A MODIFICATION OF ANDREW'S BOTTLE OPERATION FOR HYDROCELE

DEWELL GANN, JR., A.M., M.D., D.Sc., LITTLE ROCK, ARK.  
Visiting Surgeon, City Hospital

This modification differs from the original only in the skin incision, evacuation of the contents of the sac, and delivery of the testicle. Some time ago it occurred to me that an incision beginning over the cord, near the spine of the pubis, extending outward and upward along the ligamentum inguinale, might have certain advantages over the usual anterior scrotal incision of the older operations:

1. With this procedure it is not necessary to hold the scrotum in the gloved hand in order to draw the skin tense over the hydrocele while making the skin incision. Since, because of its very nature, the scrotal tissue is difficult to sterilize properly, this lessens the liability of infection. Some infected wounds of scrotal tissue heal readily; some do not. If the incision is made in such a manner as not to involve the scrotal tissue, the convalescence may be more rapid.

2. The incision over the cord obviates the careful dissection necessary when approaching the hydrocele through the scrotal tissue. When the cord is exposed, slight traction with gauze will bring the funicular portion of the sac into the lower angle of the incision. Gentle pressure with the index finger will indicate a point of fluctuation. A needle is introduced at this point without danger of injury to the cord, testicle or epididymis. The contents of the sac are withdrawn, and the testicle and sac, of any size, may be delivered without the least difficulty. If the needle is left in the sac during and after its delivery, the identification of the tunica vaginalis testis resolves itself into a simple matter.

3. The operation is completed in accordance with the technique of the usual Andrew bottle operation, and the testicle is returned to its former bed.

### EXFOLIATIVE DERMATITIS, COMPLICATED WITH CELLULITIS, OBLITERATIVE ARTERITIS AND GANGRENE OF TOES, DUE TO ARSPHENAMIN(?)\*

HENRY A. JONES, M.D., HOWARD, R. I.  
Superintendent, State Infirmary

S. J., colored woman, aged 28, married, was arrested, Oct. 30, 1918, and sent to the house of correction for six months on a charge of lewdness and wantonness. She was a strong, robust young woman without any special organic trouble. Her blood gave a Wassermann test of ++++ by cholesterin and ++++ by alcoholic extract of guinea-pig's heart. Specific trouble of any known character was denied. Nov. 15, 1918, she was given 0.3 gm. of arspenamin intravenously, in the left arm, and some of the drug entering into the adjoining tissues set up a marked local inflammation, with contraction of the tendon of the biceps. This condition of contraction called for energetic treatment by massage and mechanotherapeutics, such as carrying a weight in the hand and daily increasing the load to overcome the tendency to contract. In connection with this local infection she had severe systemic disturbance. The second injection was given, Jan. 31, 1919, and no severe reaction was noted, nor was there from the third and fourth. February 24, she reacted badly to the fifth injection, and the left arm showed a neuritis and inflammation. After the sixth treatment of 0.3 gm. of arspenamin, March 7, the patient showed an eczema of the skin, which gradually became more marked, and showed desquamation of the skin in large flakes, especially about the

\* Case presented at the Clinic held at the State Infirmary, Howard, R. I., for the Annual Meeting of the Kent County Medical Society, June 19, 1919.

hands and feet. The skin previous to the desquamative process was of a glowing, dusky red, and a sharp rise in temperature was noted. A diagnosis of exfoliative dermatitis was made and corroborated by Major Harry W. Kimball, member of the Public Health Service and director of venereal clinics at Rhode Island. Between the dates of March 7 and April 6, the patient had suffered greatly from pain in both feet resembling rheumatism, and a marked cellulitis made its appearance. The face, hands and feet were the worst affected. This trouble finally cleared up with medication of alcohol dressings. The pain and numbness in the limbs became localized in the right foot; numbness and tingling were prominent with a marked puffiness of skin over half of the dorsum of the foot, involving the proximal ends of the toes. A darkened, fan-shaped area developed, spreading over the skin of the four greater toes. This became more boggy, and broke down with the tissues beneath looking gangrenous. In spite of medicaments, this process became more firmly localized, involving the four larger toes, and the tip of the little toe.

The gangrene soon assumed the characters of the dry type with a fair line of demarcation at the metatarsal joint. May 1, the four toes were amputated. The tissues of the foot were gangrenous and "porky" in character, and hardly any hemorrhage occurred. No hemostatic forceps were needed. The flaps were sutured with catgut, and heat was applied to the feet. We were under the impression at the time of operation that a secondary or Listerian operation would have to be performed because of the bloodless condition of the tissues, even beyond the line of demarcation. During etherization the patient had a peculiar tremor which was most marked in the lower limbs, and more especially the left, and the opinion was that this might be epileptic in character, as the patient seemed to be of a neurotic type. The tissues, since the operation, have healed very slowly, responding best to an ointment containing red mercuric iodid, other dressings causing a painful burning sensation of the stump. At this date (July 16, 1919), she can get about with the aid of a cane, is in good physical condition apparently, and on April 6 her Wassermann test proved negative.

## COMMENT

In looking up the causes of the obliterative arteritis, which in this case evidently took place in the dorsalis pedis artery, we find that authors consider this condition rare. Allbutt<sup>1</sup> says:

"In amputations that have been practiced it has been noticed that the arteries do not bleed and the wound heals with difficulty unless the amputations have been made high above the seat of mortification. . . . The condition is rare; syphilis in some of the cases appears to have been the principal etiologic factor. The symptoms are various according to the arteries affected and the rapidity of the process of occlusion; if it be gradual there is time for the establishment of collateral circulation, and there is no functional defect."

In the case herewith recorded, the process was fairly rapid and the destruction of tissue complete. In those cases of obliterative arteritis that are mentioned by various authors, larger vessels are as a rule affected. We were inclined to believe this condition might have been due to syphilis, as suggested by Allbutt; but in the discussion that followed the presentation of this case to our clinic, Dr. Kimball gave it as his opinion that the obliterative process was caused by the

ingestion of arsenic in the circulation and tissues, and the case as reported by Latham<sup>2</sup> would bear him out in this statement; also the last Wassermann test of the patient, which was made, April 6, 1919, gave a negative reaction. This would lead us to the supposition that the cause was not syphilitic, but a case of arsenical deposition in the system.

## THE EASY PENETRATION OF URETHRAL STRICTURES

OPERATING URETHROSCOPE OF THE GERBINGER TYPE

MAXIMILIAN STERN, M.D., NEW YORK

It is a mistake to make repeated and protracted efforts to penetrate an inflammatory stricture of minute caliber with filiforms and sounds, in a patient suffering with acute retention of the urine. He is generally in an anxious and desperate state, in consequence of hours of futile efforts on his part to void, and frequently because of the efforts of others to pass instruments.

To have at hand an instrument with which the penetration of a stricture becomes certain of accomplishment is a great comfort. This operating urethroscope consists of an ordinary endoscopic tube, slightly longer than those in ordinary use, into which the three essential working parts are inserted in one compact bundle. This bundle comprises the telescope, which is of the direct vision type, the light carrier, and the cannula or instrument channel. The bundle fits into the tube accurately by means of a water-tight sleeve, so as to permit of focusing backward or forward with the telescope and also the rotation of the inner bundle in efforts to catheterize a stricture from various angles, without the loss of water at the ocular end. This is an important feature, water pressure within the tube being essential. Dilatation of the stricture orifice with water makes it easy of identification and instrumentation, especially when bands or a cribriform opening

are present. The cannula is so constructed that the catheter or filiform is always directed toward the center of the field, so that by revolving the inner bundle while holding the tube firmly against the face of the stricture, one can approach it from any angle with a catheter. This is an advantage, because the lumen may be tortuous and the orifice eccentric.

The fact that all the moving parts are included in the inner bundle makes the necessary manipulations possible without changing the position of the tube against the face of the stricture.

I have selected a urethral catheter rather than a filiform so that it may be fixed to the glans penis and be allowed to remain in the bladder for twenty-four or forty-eight hours. In this way, drainage into a receptacle is accomplished and the patient can obtain hours of undisturbed sleep.

The instrument here illustrated is also applicable to all the purposes of a direct vision cystoscope.

BATHS FOR BURNS

DAVIS FORSTER, M.D., NEW SMYRNA, FLA.  
Resident Surgeon, Forster Sanatorium

REPORT OF CASE

A boy, aged 16, burned in an explosion on a gasoline launch and having come through fire to make his escape, was brought by automobile 50 miles, wrapped in a sheet, to the hospital, and was admitted at midnight, July 13, 1919. He was burned on the brow, both ears, the face, nose, mouth, neck, left forearm and hand, right arm, forearm and hand, including the axilla and across the back, down to and on the buttocks and posterior surfaces of the thighs, abdomen and the anterior surfaces of the thighs to the knees. It will be seen that the only uninjured parts by which the patient could be handled were his right arm, both legs below the knee, and his hair, of which he had a large mop. He was well saturated with a hypnotic, and when aroused was delirious.

He was cleansed with surgical solution of chlorinated soda (Dakin's solution), wrapped in packs of this constantly renewed, and after finally being dried, was coated with paraffin applied with a cotton mop. Parts were covered with large meshed paraffin gauze, which was found unsuccessful, as the constant rolling of the patient caused the stiff wax-laden gauze to become detached. Therefore a light meshed dressing gauze was substituted with better results. The patient was dressed daily with the paraffin, encouraged to drink water freely, was kept on a strictly milk diet, administered every three hours, and had one-fourth grain of morphin sulphate as his condition required.

He voided scantily at twelve hour intervals, the urine being of a syrupy consistency. The bowels were moved by enema. He gradually became more and more septic, the stench being overwhelming. Green flies gathered on the screen outside of his window. The temperature went to 102, pulse 146, respiration 39.

On the fifth day, acting on a suggestion for hot boric acid fomentations, we decided to place the patient in a bathtub full of warm 2 per cent. boric acid solution, which we maintained at a temperature of between 90 and 100 F., warming to the patient's desire and cooling when he seemed exhausted.

He remained in the bath one hour, and on being removed, voided 16 ounces of urine. We felt that he had absorbed a large amount of fluid through his denuded tissue and that the flushing of the kidneys was a happy accompaniment of the mechanical cleansing. When he was taken from the solution, the bleeding parts, particularly the buttocks, were coated with an ointment having a petroleum base, while the rest was treated with paraffin after drying. If the surface is not dried, the application is very painful.

The results of the immersion were so favorable that the next day we kept him in the solution three hours, detaching dead skin and large sloughs. The baths continued daily, changing from boric acid solution to physiologic sodium chlorid solution. The sloughing on the right side of the neck was so extensive that it was feared that a permanent contracture would hold the head in the one-sided position the patient constantly maintained; but gradually the condition improved.

It was remarkable to see the skin come in over the raw surfaces, growing as much as an inch in a day to cover a surface as large as two spread hands. The immersion assisted in detaching adherent particles of dressing and debris, thus avoiding the rubbing which would have detached tender growths of epithelium.

At the end of three weeks the patient was on his feet, walking in the sunshine, and in four weeks was discharged "rough healed" with only the right ear malleated, which had an abscess of the cartilaginous structures.

We have since treated a less severe case with as satisfactory results.

ACCIDENTAL PERFORATION OF THE UTERUS DURING  
CURETTAGE, WITH LACERATION OF THE  
SMALL INTESTINE

REPORT OF CASE WITH OPERATION AND RECOVERY

JOHN T. WILLIAMS, M.D., BOSTON  
Assistant Visiting Surgeon, Boston City Hospital; Assistant in Gynecology, Medical School of Harvard University

Accidental perforation of the uterus during curettage is undoubtedly of frequent occurrence, but for obvious reasons it is seldom reported. It may happen at the hands of a skillful surgeon, and if proper asepsis has been maintained, and the perforation is recognized immediately, harm seldom results. If, however, the perforation is not recognized as soon as it is made, the operator may continue to curet through the perforation, bringing down a loop of intestine (usually ileum), and, as in the case to be reported, severing the bowel from its mesentery before identifying it.

REPORT OF CASE

Mrs. R., aged 27, had had several previous miscarriages. The Wassermann reaction was + + +. June 29, 1919, being about three and a half months pregnant, she started to miscarry. She was curetted at her home by a local physician, who perforated the uterus, drew down a loop of small intestine, severed it from its mesentery, and tore it completely across before he recognized what he had done.

The patient was admitted about one hour later to the gynecologic service of the Boston City Hospital, where I saw her. She was in good condition, not bleeding, but had several inches of lacerated intestine protruding from the vulva. The abdomen was immediately opened, and the conditions found were these: The ileum was completely torn across about 12 inches from the cecum. The proximal portion had been separated from its mesentery for a distance of 12 inches and passed down through a ragged opening about 1 inch in length in the fundus uteri near the right cornu. The free edge of the mesentery was lacerated, ragged and bruised in appearance. There was a small amount of bloody fluid free in the peritoneal cavity, but no feces.

The loop of ileum that had been separated from its mesentery was resected, the part that passed through the perforation being tied off and withdrawn from below to avoid contamination of the peritoneum by dragging up through the abdomen the portion that had projected from the vulva. The lacerated distal end of the bowel and the bruised margin of the mesentery were trimmed away to get clean-cut tissues to bring together. An end-to-end anastomosis was done, the Connell suture of catgut, reinforced by a continuous suture of Pagenstecher to the peritoneum, being used. The edges of the rent in the uterus were trimmed away into clean tissue, and the perforation was closed with interrupted catgut (one layer). A perforation in the distal portion of the ileum about the size of a pinhead was found and closed by a purse-string suture of Pagenstecher. The peritoneum was carefully cleaned by gentle mopping with moist sponges. A cigaret wick was passed to the pelvis. The abdomen was closed.

As the absence of bleeding was taken to indicate that the uterus was empty, nothing was done to the uterine cavity, and the patient was quickly put to bed and the Murphy-Fowler treatment instituted. She made an uninterrupted recovery. The drain was shortened on the fourth, fifth and sixth days, and was entirely removed on the seventh. There was no drainage from the wound except serum, and the patient left the hospital on the eighteenth day, well except for a granulating sinus at the site of drainage one-half inch in depth.

483 Beacon Street.

**Public Health Nursing.**—Although a visiting nurse began work in Liverpool sixty years ago, as late as 1901 there were only fifty-three visiting nursing associations and 136 visiting nurses in this country. In 1915 there were 2,066 associations and 4,893 visiting nurses.—*Bulletin*, State Board of Health of Rhode Island, August, 1919.

## Therapeutics

A DEPARTMENT DEVOTED TO THE IMPROVEMENT OF THERAPY,  
A FORUM FOR THE DISCUSSION OF THE USE OF DRUGS  
AND OTHER REMEDIES IN THE TREATMENT OF DISEASE.

### THE NEW PHARMACOPEIA

In May of 1920, work on a new revision of the United States Pharmacopeia will be commenced. Now is the time to gather information for use on that occasion. Physicians are invited to call attention, through this department, to changes that should be made in the next Pharmacopeia. In the past, physicians have taken altogether too little interest in pharmacopeial revisions. They have permitted pharmacists and laboratory workers to model the pharmacopeia, and then the practitioners have complained when they did not find the official book to their liking. Let us have a more general participation of the medical profession in the coming revision.

### PRACTICAL CLINICAL PROGRESS

If every busy practitioner would publish once or twice in his life some fact—not opinion—in therapeutics, not generally known and that he has established beyond the possibility of any doubt, what a mine of practical information would accumulate! A tremendous amount of knowledge of the greatest possible importance to suffering humanity is lost, because it is buried with its possessors. This is not due to lack of altruism on the part of the medical profession—for who of all men is more altruistic than the doctor—but to the fact that the rank and file of physicians is literarily inarticulate. While some write too much, many publish too little.

### USE AND ABUSE OF CATHARTICS\*

(Continued from page 1287)

#### CATHARSIS AS A CAUSE OF CONSTIPATION HABITUAL CONSTIPATION

In the cure of habitual constipation, cathartics, if properly used, are of help. While some who do not accept patients unwilling to submit to a regular course of treatment covering a period of from six to seven weeks, may well say that they have not used medicines in the curative treatment of constipation for many years, and that the results obtained from the non-medicinal plan—which includes diet, mechanotherapy, hydrotherapy and electrotherapy—have been vastly superior to those accomplished by drugs, yet many patients are unable or unwilling to undertake such prolonged courses of treatment. The knowledge that descending dosage of cathartics, accompanied by appropriate regulation of hygiene, will often cure habitual constipation without recourse to physical therapy, is of practical importance. For this purpose cascara sagrada is the remedy *par excellence*. The treatment amounts to a gradual weaning of the patient from the cathartic habit, as contrasted with the sudden breaking in on this habit by the acathartic method.

Cases that resist the gradual dose reduction might still be cured by recourse to physical therapy, which should be offered as soon as it becomes evident that the simpler method failed, but not before. To speak of this to the patient earlier would be a tactical error, as it would undermine much of the patient's confidence in the treatment, and with this its psychotherapeutic value. It must be admitted that there are cases in which all these methods fail. This intractable form must be treated along the line previously mapped out for constipation of the disabled individual.

#### CATHARTICS IN "INTESTINAL TOXEMIA"

That cathartics must be of value to promote the elimination of disease-producing poisons from the intestine is self-evident. No one disputes this proposition. The dispute arises over the question: When does the intestine harbor such poisons? The intestinal tract is endowed with wonderful safeguards against intoxication, not the least among which is the inspissation of the intestinal contents and the formation of scybala from which absorption practically does not occur. Indeed, to whatever extent cathartics interfere with the formation of scybala they contribute to intestinal toxemia, not only because absorption from liquid or semifluid contents is much more active than from solid material, but also because such contents form better culture mediums for bacteria, partly by reason of their fluidity and partly by reason of the fact that they are richer in nutritive material for bacteria. The doctrine of Adolf Schmidt,<sup>22</sup> "No diarrhea with increased peristalsis without secretion of a decomposable fluid by the intestinal membrane," applies to diarrhea produced with therapeutic intent as well as to diarrhea occurring from other causes. It is a well known clinical fact that intoxication phenomena are much more prominent in diarrhea than in constipation, and that there are people who feel weak and miserable, as though poisoned, for a few days after purgation. Of course, this increase in auto-intoxication may be merely temporary, to be followed by improvement, for, as Herschell and Abrahams<sup>23</sup> say, both castor oil and saline purgatives greatly increase auto-intoxication for some hours, the excretion of ethereal sulphates rising very considerably. It then commences to fall until it is reduced much below normal. The explanation is, of course, that the purgative stirs up the intestinal contents, and the poisons are absorbed into the circulation.

The theory that toxic intestinal contents are responsible for disease has been so abused as a "cloak for ignorance" that the terms "biliousness" and "auto-intoxication" are practically taboo in strict scientific discussion. "Biliousness," which once was considered a well established disease entity, the successful treatment of which, by the use of "chologogues," was one of the cherished dogmas of medicine, has become so unpopular of late that one searches in vain for even the word "biliousness" in the index of modern books on gastro-enterology or on the practice of medicine. Adami<sup>24</sup> concludes that the term "gastro-intestinal auto-intoxication" is pernicious, and not to be employed by any self-respecting member of the medical pro-

24. Adami, J. G.: Chronic Intestinal Stasis, Brit. M. J. 1:183 (Jan. 21) 1914.

\*This is the third of a series of articles on the pharmacology, physiology and practical application of the common laxatives and cathartics. The first article appeared October 18.

fession, save for so limited a set of conditions that for ordinary purposes it may safely be expunged from the medical vocabulary. Still, it remains a clinical fact, abundantly substantiated, that a very large number of symptoms have been relieved by catharsis. With many a physician it is a rule of practice when in doubt to "open the bowels." Alvarez,<sup>25</sup> who rejects the doctrine of the chemical causation of these symptoms, admits that symptoms such as mental haziness or "dopiness," malaise, headache, spots before the eyes, coated tongue, and poor appetite, are often instantly relieved by a bowel movement. He explains these symptoms as due to the effect of afferent nerve impulses, coming from a distended overactive or wrongly acting bowel, on a particularly sensitive nervous system. According to him, also, ripples of reverse peristalsis carry more than the usual amount of bile back into the stomach and up into the mouth, depositing gastric and perhaps intestinal contents on the back of the tongue, and giving rise in this way to the coat on that organ—sometimes even bile-stained—the bad taste and the bad breath. He believes that the relief obtained by taking calomel is not due to any action on the liver, but to a restoration of the normal downward currents in the intestine. Be that as it may, we must conclude that cathartics do frequently relieve symptoms due to abnormal conditions within the bowel, and that they must therefore be looked on as an important diagnostic aid in our hands. Of course, the proper curative treatment of the symptoms due to chronic intestinal stasis is that of the accompanying constipation, and this requires differentiation of type and etiologic treatment, rather than chronic catharsis.

#### CATHARTICS IN DIARRHEA

In the treatment of diarrhea, cathartics play, at most, a minor rôle. Of course, they might "assist nature" in certain cases, especially of stercoral diarrhea, that is, diarrhea due to retained fecal masses, and in the fermentative form. On the other hand, in gastrogenic and in nervous diarrhea they are useless and may be harmful. Before using cathartics in diarrhea we should, therefore, ask ourselves, first, whether the cause is located in the intestine; and, secondly, whether nature requires our assistance. Hill's<sup>26</sup> common sense statement regarding purgation in infantile diarrhea also has decided bearing on the treatment of diarrhea in the adult:

It is a mistake to give a purge as a routine in every diarrheal disease. If there is any harmful material in the intestine which is not coming out as fast as it should, a purge ought to be given; otherwise not. It is not rational to purge a baby which is already having a good many loose stools a day, and whose intestine is emptying itself of toxic material as fast as it possibly can. In such cases, castor oil or calomel adds insult to injury. On the other hand, a baby who is seen at the onset, who has fever, and who has not yet been emptied by diarrhea, ought to be purged at once; and it is often striking to see how the temperature will drop and how much more comfortable the baby will be after a good cleaning-out.

#### CONCLUSIONS

1. With the average adult, a daily bowel movement is not a necessity for a state of health.

2. Cathartics are habit-producing drugs, admissible only in case of temporary disturbance due to harmful material in the intestine, and in those suffering from an intestine disabled by local or general disease or debility, who in default of curative measures may have to be provided with a habitual evacuant. Especially obnoxious is the habitual use of purgatives in childhood.

3. Mild laxatives and enemas should replace the more drastic drugs. The mildest is the best, and the patient should be carefully fitted with the cathartic he needs.

4. Acute abdominal pain, unless accompanied by diarrhea, contraindicates catharsis. On the other hand, some patients with a chronic tendency to abdominal pain may keep themselves comfortable by suitable catharsis.

5. Cathartics are useful as a means of diagnosis for the determination of the degree to which symptoms are due to disturbance within the intestine.

6. Routine purgation, be it preoperative, postoperative or postpartum, be it employed in the treatment of diarrhea, apoplexy, dropsy or uremia, is undesirable.

(To be continued)

## New and Nonofficial Remedies

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

W. A. PUCKNER, SECRETARY.

**ALBUTANNIN.**—Tannin Albuminate Exsiccated.—A compound of tannic acid and albumin, thoroughly exsiccated, and containing about 50 per cent. tannic acid in combination. It was first introduced as tannalbin.

**Actions and Uses.**—Albutannin is astringent. Its use is based on the assumption that the tannin compound would pass the stomach largely unchanged and thus the astringent action be exercised in the intestine where the compound would be decomposed by the intestinal fluid, slowly liberating the tannic acid. It is not likely to produce gastric disturbance. It is used in diarrhea, particularly in that of children, and in phthisis.

**Dosage.**—From 1 to 4 Gm. (15 to 60 grains) in powder or tablets followed by water. For infants the dose is from 0.3 to 0.5 Gm. (5 to 8 grains) in gruel or other mucilaginous liquids.

Albutannin is prepared by precipitating 1 part of a 10 per cent. solution of egg albumin with 6.5 parts of a 10 per cent. solution of tannic acid, washing the precipitate with water until the washings run only faintly to ferric chloride, drying it on porous tiles, powdering and heating the product to about 110 C. for six hours.

Albutannin is a creamy yellow or light brown, odorless, crystalline powder, containing about 50 per cent. of tannic acid. It is practically insoluble in water or alcohol, but slowly soluble in alkaline fluids, which decompose it into its components.

Shake 0.1 Gm. of albutannin for one-half minute with 10 Cc. of water and filter. To the filtrate add one drop of ferric chloride test solution. Only a light blue coloration is produced (*see tannin acid*). Incinerate 0.5 Gm. albutannin. Not more than 6 per cent. of ash remains.

**Albutannin-Calco.**—A nonproprietary brand complying with the standards for albutannin.

Manufactured by The Calco Chemical Company, New York. No. 175 patent or trademark.

**Albutannin-Merck.**—Merck and Company have adopted the name albutannin for the product accepted as tannin albuminate exsiccated Merck (*see JOURNAL A. M. A., March 1, 1919, p. 653*).

## SOME EFFECTS OF FOOD RESTRICTIONS IN EUROPE

In an elaborate review of the effect of war-time food conditions in Germany on the nutrition and health of her people, Professor Determann<sup>1</sup> concludes that the most significant consequences of the war diet are chargeable to its small fuel value. Emaciation, weakness and decreased resistance to present or acquired disease have increased mortality and morbidity in an amazing degree, especially among older persons and in large cities. In confirmation of the untoward effect of the lowered calory intake we now have the added testimony of Professor Loewy<sup>2</sup> of Berlin, who admits that the outcome of the enforced dietary conditions has demonstrated that the views accepted with respect to the metabolism of energy in peace time apply with equal truth during war.

What were the outstanding features of the rations supplied to the people of the Central Empires toward the end of the war period? They were low in protein. During prewar days the nitrogenous foods formed a liberal component in the German dietary, approaching the standards of 100 gm. and more a day that have been observed to exist in most civilized countries. At the end of three years of war, Loewy found that the poorer classes in Berlin were reduced to a protein consumption of less than half this figure, though in the rural districts better conditions prevailed despite the monotony of the country diet, in which bread and potatoes predominated. The diet was also poor in fats, which were largely replaced by carbohydrates. Whereas in peace time the latter constituted scarcely more than 60 per cent. of the calories of the ration, by April, 1916, they had increased to 68 per cent., on the average, and amounted to 70 per cent. or more in April, 1917. A diet of this composition is inevitably largely vegetable in origin, rich in cellulose, devoid of stimulating properties and, as further details show, in the present instance, limited in variety.

War edema, presumably associated with insufficient food and particularly with deficiency in the protein intake, has been widely observed. Hernias and displacements of internal organs have been a frequent consequence of emaciation. Lactation has been unsatisfactory among child-bearing women. Gastro-enteric disorders, rickets, deficiency diseases and delayed growth have affected the welfare of children. Tuberculosis has increased its ravages. Eclampsia is reported by Determann to have become less frequent in occurrence; diabetes and cancer also have not increased under the war-time restrictions. All in all, however, it is a sinister picture that each new report presents, for the truth is no longer camouflaged to mislead an enemy.

## THE INFECTED WOUND

The result of the intensive study of war wounds has been a better insight into the biology of infected wounds, which, in turn, has led to improvements in methods of treatment. Although most of the really important factors were known before the war, the great emergency brought them into practical general knowledge in a way that would otherwise have been impossible. For the first twelve to twenty-four hours following injury, the so-called preinflammatory stage, infecting organisms are confined to the surface of the wound. If, during this period, the wound surface can be excised (débridement), healing by primary intention is the rule and chemical treatment is useless at this stage. The importance of this phase of treatment has recently been emphasized by Duval,<sup>3</sup> who has shown that wounds of joints, once considered the most vulnerable of all tissues to infecting organisms, may be safely closed without drainage after débridement.

When wounds are seen after the preinflammatory stage has passed and the bacteria have penetrated deeply into the tissues, there is no known short cut by which they may be eliminated. This factor, recently discussed by Flemming,<sup>2</sup> furnishes a fertile field for investigation. It appears to have been demonstrated that the two important natural agencies combating infection are the blood and tissue fluids and the leukocytes. The blood and tissue fluids exert their influence because of their alkalinity and their antitryptic power. The importance of the alkaline reaction of the fluids is well illustrated by the fact that Welch's bacillus grows a thousand times better in "acidosed" serum from a gas gangrene patient, that is, a serum which has lost nearly all its alkalinity, than it does in normal serum. The influence of the antitryptic power of the serum also may be readily demonstrated. In serum of normal or raised antitryptic power, streptococci alone grow freely when planted in small numbers; staphylo-

3. Duval: Treatment of War Wounds of Joints, *Surg., Gynec. & Obst.* 29: 222 (Sept.) 1919.

2. Flemming, Alexander: The Action of Chemical and Physiological Antiseptics in a Septic Wound, *Brit. J. Surg.* 7: 99 (July) 1919, Hunterian Lecture, Feb. 12, 1919.

cocci and some diphtheroids multiply to a lesser extent. Serum of reduced antitryptic power, however, furnishes a suitable culture medium for an abundant bacterial flora.

The ability of leukocytes to destroy bacteria has been repeatedly demonstrated, and they are probably the chief agents in the removal of bacteria from infected wounds. They appear to exert a twofold influence: They are strongly antibacterial; yet, when they emerge on the surface of a wound, they readily disintegrate, setting free a proteolytic enzyme which, in turn, neutralizes the antitryptic properties of the wound liquids, thus making them better culture mediums for bacteria. At first sight, this appears to be distinctly detrimental. As a matter of fact, the liberation of proteolytic enzymes in this manner is of salutary benefit; it is nature's method of performing débridement. It is largely through the activity of the leukocytic protease, derived probably from the neutrophil granules of the polymorphonuclears,<sup>2</sup> that necrotic tissue and blood clots are cast from the wound. With the separation of the sloughs, the wound is bathed in exudate of a degree of alkalinity and an antitryptic titer approaching that of normal serum. The serosaprophytes, therefore, rapidly disappear. The leukocytes, no longer caused to disintegrate *en masse*, cease to reduce materially the antitryptic property of the wound liquids, and exert their maximal antibacterial power, the wound becomes relatively aseptic, and healing progresses at the maximal rate. The influence of infection on the rate of healing has been graphically demonstrated by Carrel and Hartmann<sup>3</sup> and by Du Noy,<sup>4</sup> These authors found that the curve representing the diminution in the size of an aseptic wound while it cicatrizes is regular and geometric; the intervention of an infection in such a wound greatly decreases the rate of healing and may stop healing entirely.

The third factor is the character of the walls of the wound. When they are overhanging and noncollapsible, as is the case frequently in compound fractures, and especially when the tract of exit is narrow and the wound cavity relatively large, infection persists and can be permanently eradicated only by operative obliteration of the cavity.<sup>5</sup> Of course, sequestrums require removal; but if sequestromy is not accompanied by wide removal of the unyielding wall of the cavity, so as to permit its being filled by the collapse of surrounding soft tissues, healing will be difficult.

The rôle of antiseptics in the treatment of wound infection is problematic. Flemming believes that all solutions that are at all effective have no appreciable bactericidal titer in the wound, but that they act as mild tissue irritants leading to increased leukocytic

emigration and to more abundant flooding of the wound with normal tissue fluids, in this way hastening the separation of sloughs and the elimination of bacteria. He regards the antiseptic method of Carrel, for instance, as fundamentally dependent on the same principles as that of the so-called physiologic method of Sir Almroth Wright. It is perhaps too early to consider the question settled, but the data and the arguments based thereon in support of this idea are exceedingly attractive.

#### INFECTIOUS ABORTION IN CATTLE

Since Bang's discovery of a characteristic microorganism associated with so-called "contagious abortion" in cattle, it has become customary to attribute the disease to *Bacillus abortus* described by him. The assumption that this is the sole or even the predominant etiologic agent concerned with a malady that occasions enormous economic losses has diverted attention away from the microbial cause and toward prevention or cure. Aside from the indirect interest that bovine disease represents in relation to human welfare, and particularly when the milk supply is involved, the bacillus of contagious abortion in cattle has lately been discussed as a possible agent of more direct menace in childhood.

The newer studies at the Department of Animal Pathology of the Rockefeller Institute for Medical Research, Princeton, N. J., under the leadership of Theobald Smith,<sup>1</sup> bring unexpected evidence that contagious abortion may involve something more than Bang's bacillus. They include the discovery of a spirillum of definite morphologic and cultural characteristics designated by Smith as *Vibrio fetus* and found associated in a considerable series of cases with what is commonly known as infectious abortion in cattle. He properly maintains that the isolation in pure culture of a definite morphologic entity, a vibrio, with practically the same biologic characters, from a series of cases of the same clinical complex establishes a presumption in favor of the specific identity of the organism and also in favor of the inference that such organisms are etiologically related to the diseased condition. It might be assumed that *Vibrio fetus* found in the fetal membranes is merely an invader from the more external genitalia or from the blood after the fetus has been damaged by other agencies. However, the fact that disease of the fetal membranes has been produced experimentally by injection of pure cultures of the vibrio strengthens the presumption that it may be a true cause of infectious abortion.

The new investigations indicate that many cases of abortion in cattle occur without evidence of the pres-

ence of Bang's bacillus. In general, *Bacillus abortus* is associated with first pregnancies, and its presence rapidly diminishes in frequency in later ones. Apparently an immunity to this bacillus may become developed in cattle, whereupon *L'ubrio fetus*, and, perhaps to a far less degree, miscellaneous septic and pyogenic micro-organisms, may become the inciters of abortion in later pregnancies. If these conclusions become substantiated by further studies, it will become clear that abortions in cattle are attributable to a variety of infections and noninfectious agencies. Even now it seems established, however, that the udders of a relatively high percentage of cows become infected with *Bacillus abortus*, probably during their first abortion disease. In this way the relation of this micro-organism to the milk and consequently to human health is worthy of consideration.

### HOSPITALS FOR CONTAGIOUS DISEASES

The general attitude toward hospitals for contagious diseases seems to be undergoing a gradual evolution. We are getting away from the idea that such hospitals are "pest houses" and "necessary evils," whose chief function is to serve as a place of confinement for persons who might endanger the public. We are coming to look on them more as places where sick persons may secure needed care, which would not be possible in their homes, as is the case with noncontagious medical and surgical cases in a general hospital. Usually conditions that make impossible proper isolation at home also preclude suitable medical and nursing care there. Hospitals for contagious diseases are specially designed for those with very limited means and for those living in hotels, boarding and rooming houses. The value of hospitals as a means of eradicating contagious diseases through isolation has made a strong appeal to sanitarians everywhere. However, experience in England and in this country has led such authorities as News-holme, Chapin and others to conclude that the hospitalization of persons with contagious diseases has failed to reduce their incidence materially. Chapin<sup>1</sup> says:

Hospitals are useful for protecting the family, for checking outbreaks in institutions, for receiving cases from lodging houses and hotels, for furnishing better medical service, and for relieving the overworked housewife in the families of the poor. It is an unnecessary expense to provide hospital accommodations for all cases of scarlet fever and diphtheria, or for 50 per cent. or even 80 per cent. That half or two thirds of the cases of these diseases can, for all practical purposes, be equally well cared for at home, is not unlikely.

In a hospital for contagious diseases, an occasional instance of crossed infection will occur even though every human effort is made to avoid it. This will be always one reason for home isolation and treatment, whenever they can be carried out satisfactorily.

In view of these facts, the statement of Stokes<sup>2</sup> in his interesting discussion of the organization and

methods of contagious disease services, that a hospital for contagious diseases is, like the police, a necessary evil whose principal justification is the convenience and safety of the well public, is only partly true. The ancient idea that a hospital for contagious diseases is a "pest house" and a source of danger to those living near it has largely influenced the location of such institutions in a community. Abundant experience has shown that the same considerations should determine a convenient and central location for a hospital for contagious diseases as for any hospital for acute illness. An intimate connection with a general hospital is economical from an administrative and operative standpoint, and except when the contagious disease hospital is very large, it may properly be located in one building of a general hospital group. Such a location enables the patients in emergencies and complications to benefit by the services of specialists, and has a tendency to raise the level of the character of the medical work in the hospital. In contrast to this, a hospital for contagious diseases that is situated in an isolated place, near the edge of a large city, operates under very serious disadvantages, both from an economic and a scientific standpoint. Hospitals for contagious diseases were formerly constructed on the same principles as general hospitals, and were often brought into disrepute by the frequency with which a patient entering with one disease contracted others in the institution.

Richardson<sup>3</sup> recently presented an able discussion of the construction of modern isolation hospitals. In efforts to combat mixed infections, the barrier and cubicle systems were introduced and are useful in old buildings with large rooms, but should not find a place in a building newly constructed at this time. The ideal hospital for contagious diseases consists of small rooms that accommodate single patients. This is insisted on by those who, like Richardson<sup>3</sup> and Wilson,<sup>4</sup> have had practical experience in hospitals for these diseases. The initial cost of providing toilet and bath tub for each room is more than offset by the advantage from the use of baths in treating patients and by the saving in work required of nurses and attendants. Each room should be supplied with a lavatory with mixed hot and cold water controlled by the foot. The liberal provision of windows and the introduction of glass into partitions prevents a building constructed in this manner from being unduly dark. With single rooms, cross infections can be practically eliminated, and diseases of various sorts can be cared for at the same time in varying proportion. All the space becomes available at all times. As with general hospitals, so those for contagious diseases should serve as training places for physicians and nurses. The medical graduate and the nurse are not fully prepared for the practice of their professions if they have had no practical experience in the treatment of contagious diseases. The con-

<sup>1</sup> Chapin: Sources and Modes of Infection, 1910.  
<sup>2</sup> Stokes, J. H.: Pennsylvania M. J. 12: 729 (Aug.) 1919.

<sup>3</sup> Richardson, D. L.: Mod. Hosp. 12: 108, 1919.  
<sup>4</sup> Wilson: Pub. Health Bull., 1918, No. 95.

tagious diseases furnish the medical student with as great a variety of medical experiences as do those of a general hospital. Without a careful training in contagious diseases, a nurse is not qualified for institutional or public health work and her field of activities is necessarily limited. Pupil nurses should receive this part of their training toward the end of their course, after they are familiar with aseptic technic. No pupil who is careless in her work should be allowed to continue. Before a person enters on this work, diseased tonsils should be removed; serious organic disease of any kind would naturally exclude any person from the work. By immunizing those who are susceptible to diphtheria, as determined by the Schick test, and by the use of gauze masks, rubber gloves and aseptic methods, the danger of contracting the diseases with which the nurses are associated is largely eliminated. To repeat. It is important that the profession and the laity should appreciate that the hospital for contagious diseases is not a nuisance but an institution of real service; that it furnishes innumerable problems for solution by the research worker, and that its clinical material should be utilized for the instruction of medical students and nurses so that patients suffering with contagious diseases among the people may receive prompt and efficient medical and nursing care, at the same time that effective measures may be instituted for protecting the well from infection.

#### THE STYLES IN SUICIDE AND HOMICIDE

Primitive man, when stirred by some primeval instinct to remove himself or some neighbor permanently from the community, adopted the means at hand. His body, or that of his neighbor, shortly after he had entered on the resolution, would be found at the foot of some cliff, from which it had fallen; or perhaps he would disappear into the depths of the sea, or, as with the Hawaiians, into the fuming crater of a volcano. With the coming of science, methods began to be refined. It is reported that the ancient Egyptians were skilled in securing the deadly prussic acid from the peach; Nicander (204 B. C.) described the use of snake venom, opium, henbane and other popular methods of seeking the Great Beyond. Socrates drank the hemlock, and Cleopatra succumbed to the sting of the asp. In more modern times arsenic became popular, reaching the height of refinement in the seventeenth century. At this period the infamous Fofana at Venice prepared vials of arsenous oxid for general sale, and herself concocted weird and unusual combinations for the secret use of arsenic by those high in political and ecclesiastical circles. Since the advent of firearms, these have steadily maintained a reasonable popularity as suicidal and homicidal agencies in view of their notorious ease of procurement and increasing facility of operation. The adoption of hanging—a rather

awkward procedure requiring four ingredients, a victim, a noose, something to hang it from and something to step from—is rather common. And we must not forget asphyxia, which the statistics list separately from hanging. Here we have an increasing vogue, although the advent of electric light in place of gas makes the method not so generally available. Modern man, in place of leaping from a cliff, sometimes seeks the easily available upper floors of city skyscrapers and thence projects himself into eternity. However, poisoning has lost but slightly in popularity. In ancient days the fame of poisoner and poisons was spread by word of mouth. The newspapers establish the style in modern times. Every one remembers when phenol—popularly called carbolic acid—was the deadly elixir of choice. Domestically used to aid the unesthetic bedbug to shuffle off this mortal coil, it sometimes found its way to the family medicine chest and was available for human extermination. The demise and the method were duly recorded in the daily press, thus increasing the popularity. Latterly, since the advent of mercuric chlorid for certain domestic uses, this poison is conveniently at hand. Not only is it convenient but there exists for it an alluring propaganda. Thus, when a Georgia banker took mercuric chlorid by mistake and lay dying, the anxious reporters hung around the lethal chamber ready to report each new development in the struggle. Through the tremendous notoriety given to this case, mercuric chlorid was introduced as an available poison. It became one of the six best sellers. Pharmaceutical houses wrote "danger" on the bottle, put the tablets on strings, put warning attachments on the cork and tried other safeguards. And when the case of the Georgia banker faded from memory it seemed that these safeguards had had the desired effect. Now suddenly comes another intimate tragedy for yellow-journalistic fancy. Reams of paper are filled with the weeping of the hysterical journalistic sob sisters—sobsyterical writing, one might call it. And do the safeguards placed around the drug have any effect? Not a bit. The styles in suicides and homicides, as even styles in dress, are influenced by newspaper publicity.

---

#### THE CAUSE OF INFLUENZA AND ITS BEARING ON TREATMENT

The striking thing about the etiologic studies of influenza which were made last year was the lack of uniformity in the results obtained. Reports that filtered through from Germany indicated that Pfeiffer himself was unable to find constantly the bacillus which he first discovered in 1894 and which had been generally regarded as the cause of the disease. While some investigators still regarded as favorable the evidence that the bacillus of Pfeiffer was the etiologic factor, others were unable to find it constantly in any large percentage of patients. Most physicians who observed the characteristic clinical picture presented by the disease and reflected that the bacillus of Pfeiffer had been found every year since its discovery in uncharacteristic, upper air passage infections, became skeptical as to its etiologic relationship to true epidemic influenza. Exten-

sive inoculations with preventive vaccines prepared from the Pfeiffer bacillus led to somewhat discordant results, but, on the whole, the results supported the view that the vaccination with this organism did not produce immunity to influenza. During 1918, Nicolle and Lebaillly stated that they had discovered a filtrable virus in influenza cases, and later on, certain British observers confirmed this finding. The work of Bradford, Bashford and Wilson<sup>1</sup> is the most extensive and the most convincing that has appeared on this subject. These observers were able to obtain a filter-passing virus from patients with influenza; they were able to cultivate it outside the body, and succeeded in reproducing the disease in the lower animals and in continuing the transmission beyond the first generation. They thus complied with all the postulates of Koch. Attention is now again called to their work, because opportunities will be afforded this fall and winter for a careful test. The discovery and the propagation of the micro-organism causing a disease is not always the most difficult step in reaching satisfactory treatment, but it is essential, and is likely to be the turning point in the conquest of the disease.

#### THE NATIONAL HOME FOR LEPERS

In January, 1917, Congress passed a law providing for a national leprosarium, and made an initial appropriation of \$250,000. The law provided that the leprosarium should be under the control and supervision of the United States Public Health Service. A commission was immediately appointed by the Service to select a site for the institution. After spending many months in investigating suggested sites in various parts of the country, it selected an island lying off the coast of Florida, in the Gulf of Mexico. From all accounts the location is ideal in every respect. Now Florida is tremendously excited over the fact that that state has been selected, although the actual site is on an island and therefore isolated from the mainland. According to the newspapers, the governor of the state is taking the lead in the opposition and, apparently, is fathering an active crusade against the project; he has even threatened to remove from office certain local officers who favor it. Headed by the governor, a delegation has been to Washington to protest against the selection. Of course, all this foolish opposition is based on the idea that the leprosarium will injure the state as a health and pleasure resort, disregarding, evidently, the fact that a leprosarium which has existed for some time in California has not eliminated that state as a pleasant and attractive place to live in. The old biblical horror of leprosy dies hard. While it is true that leprosy is mildly contagious, the disease is easily controlled by segregation. It is safe to assume that the commission did not select the location without due consideration, and it is hoped that the government will not be stampeded from its choice by a popular prejudice based on ignorance of the facts concerning the disease.

## Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

### CALIFORNIA

**Poison Act Violation Charged.**—Four additional charges of violation of the State Poison Act were said to have been placed against Dr. Paul R. Lanz, Oakland, October 1, by operatives of the Pharmacy Board. The complainants alleged that Dr. Lanz forged their names to prescriptions used by him to obtain narcotics from the local drug stores. Dr. Lanz was released under bonds of \$6,000.

**Personal.**—Jean J. A. Van Kaathoven, Major, M. C., U. S. Army, who commanded Base Hospital No. 35, Los Angeles, has been cited by General Pershing for "exceptional meritorious and conspicuous service, overseas."—Dr. Etta G. Gray, Los Angeles, president of the Medical Women's National Association, has been sent to Serbia and the Near East to investigate conditions and arrange for the establishment of hospitals where needed.—Dr. Paul E. Bowers, Whittier, has been appointed superintendent of the Northern Indiana Hospital for the Insane, Logansport.

### CONNECTICUT

**Intensive Mental Hygiene Campaign.**—The Connecticut Mental Hygiene Society, the first organization of its kind in the world, is conducting an intensive campaign for the amelioration of mental health. The staff has been completely reorganized and Dr. William B. Terhune, New Haven, has been placed in charge as medical director. He is assisted by several social workers with psychiatric training, and clinics are being conducted in New Haven, Waterbury and Hartford. The work is rapidly being extended and other clinics will be opened in the near future.

**Society Meetings.**—The twelfth semiannual meeting of the Connecticut State Medical Society was held in connection with the semiannual meeting of the Tolland County Medical Society at the State Training School and Hospital, Mansfield Depot. The chief addresses were on "The Care of the Feeble-minded," by Dr. Charles TenEyck LaMoire, superintendent of the Training School, and "Some Remarks on the Diagnosis of Mental Defects" by Dr. Arnold Lucius Gesell of Yale University.—The welcome-home reception to the medical men of Middlesex County who served their country during the great war was held by the Middlesex and Central County Medical Association, in Middletown, October 9. Seventeen members of these associations were in the military service.

### ILLINOIS

**Hospital Name Changed.**—The German-American Hospital, Chicago, changed its name, October 20, to the Diversey Parkway Hospital.

**Personal.**—Dr. Thomas J. O'Malley, Chicago, after an extended service as major, M. C., U. S. Army, at Camp Merrit, N. J., has been discharged from the military service.

**Institute of Medicine Meeting.**—At the meeting of the Institute of Medicine of Chicago, October 30, the program was devoted to the presentation of the results of new research by some of the younger research workers of Chicago.

**Illegal Practitioner Fined.**—Miss Agnes Sewczyk of 4542 South Laflin Street, Chicago, was arrested by the Illinois Department of Registration and Education for practicing midwifery without a license and was fined \$25 and costs.

**Harrison Act Violators.**—Victor Modine was held for October 11, by Judge Carpenter, Chicago, under bond of \$5,000 on charges of violating the Harrison Narcotic Act. Modine was arrested in 1917, and while released under bond of \$3,000 fled to Canada. He was recently expelled from Canada and arrested when he crossed into the United States.—Louis Deryer, alias James B. King, was arrested, October 25, on the charge of selling opium, and was released under a cash bond of \$10,000.

**Venereal Disease Peril.**—Drs. Harold N. Moyer, Hugh T. Patrick, Harry A. Kraus, Gustav Kolischer, James Whitney Hall, John Leeming, William O. Krohn and G. Frank Lydston appeared before Judge Joseph P. David in the superior court to testify in a habeas corpus suit brought to obtain the

<sup>1</sup> Bradford, Bashford and Wilson: *Quart. J. Med.*, 12: 259 (April) 1919.

release of two girls arrested by members of the morals squad and held in the Lawndale Hospital. All of these physicians agreed that venereal diseases should be subject to the same regulations as other contagious diseases.

#### KANSAS

**Health Car.**—The health car Warren, belonging to the Kansas State Board of Health, has been taken from Topeka to Manhattan, and thence will go to Clay Center, Clyde, Cuba and other towns. Dr. Caroline A. Carr is in charge.

**Medical Society Organized.**—At a meeting held in Garden City, September 19, the Finney County Medical Society was organized and a charter was applied for. The following officers were elected: president, Dr. William J. Stilson; vice president, Dr. Charles Rewerts; secretary, Dr. Ronald M. Troup, and treasurer, Dr. Theodore F. Blanke, all of Garden City.

**Drive to Secure Medical School.**—Business men of Rosedale, headed by Dr. Clifford C. Nesselrode, Leneza, have inaugurated a campaign to raise \$32,000 to buy suitable land for administration building, laboratories and lecture halls for the medical department of the University of Kansas, in order to guarantee the retention and continue the use of the gift of Dr. Bell.

#### MARYLAND

**Personal.**—Dr. J. Fred Hempel, Baltimore, in charge of the Pasteur department of the state board of health, has been appointed assistant commissioner of health, to succeed Dr. William T. Howard, who will go to the Johns Hopkins School of Hygiene as an instructor. Dr. Hempel assumes his new duties, November 1.—Dr. William G. MacCallum, Baltimore, professor of pathology in Johns Hopkins Hospital, has returned after several months spent in Peru, Panama and the West Indies in the study of malaria and other tropical diseases.

**Campaign for Healthier Schoolchildren.**—Under the direction of Dr. E. V. McCollum of the Johns Hopkins School of Hygiene and Public Health, a campaign for healthier schoolchildren has begun in Baltimore. Three women skilled in child betterment work in the public schools of other cities began the work of weighing and measuring 10,000 children in seven Baltimore public schools. The effect on them of a special program of eating, sleeping and care of the body will be noted and they and their personal records of gain in weight and general health will be pointed to as evidences of what science can do for a whole community. It will also demonstrate the value of the School of Hygiene and Public Health, of which Dr. William H. Welch, Baltimore, is president. The results will then be published for the benefit of the rest of the 80,000 schoolchildren of the city. The actual business of improving the condition of the children will not begin for a month as it will take at least that long to weigh and measure the entire 10,000 and record the figures on individual charts. It is planned to continue this work for one year, and Dr. McCollum hopes to demonstrate the supervision of the instruction of all schoolchildren in food values just as they are taught to read and write will be of advantage to the city.

#### MASSACHUSETTS

**Ether Day.**—The seventy-third annual exercises of Ether Day were held at the Massachusetts General Hospital, October 16, the address being delivered by Dr. Richard C. Cahot, Boston.

**Personal.**—Dr. Robert Bayley Osgood, Boston, has been appointed instructor in surgery for three years; Edward Allen Boyden, Ph.D., assistant professor of comparative anatomy for five years, and Dr. William Lorenzo Miss, Baltimore, assistant professor of preventive medicine for one year, in Harvard University.

**New Officers.**—Holyoke Medical Association held its first meeting since the war, October 8, and elected Dr. Irvin H. Farr, Holyoke, president; Dr. Robert E. Cleary, Holyoke, vice president, and Dr. Frederick A. Mead, Williamansett, secretary-treasurer.—At the annual meeting of the Northern Berkshire Medical Association, Dr. George L. Curran, North Adams, was elected president, and Dr. George H. Thompson, North Adams, secretary.

#### MISSOURI

**Typhoid Epidemic.**—It is asserted that an epidemic of typhoid in Concordia, Sweet Springs and other towns in that vicinity resulted from the use of ice taken from ponds contaminated by neighboring cesspools.

**New Association Organ.**—The Missouri Tuberculosis Association announces the appointment of Mrs. Emily Newell Blair as director of the newspaper publicity service of the association and editor of a monthly magazine to be called "Fairplay" which the association purposes establishing early next year.

**Medical Library Donated.**—Dr. Herbert S. Hill, Springfield, has presented his medical library to the Greene County Medical Society. This is the second donation of medical works received by the Greene County Medical Society, the late Dr. H. L. Porter of Seneca, having directed that his medical library be given to that society.

**Personal.**—Dr. Cardinal B. Woolsey, Braymer, is completing a new building for the Woolsey Hospital.—Dr. Ralph H. Major of Kansas City, professor of pathology and bacteriology in the University of Kansas School of Medicine, has accepted a position on the staff of the Henry Ford Hospital at Detroit.—Dr. M. C. McMurry, Paris, was operated on for appendicitis in the Woodland Hospital, Moberly, recently. He is now convalescent.

**Veneral Disease Division Established.**—A division of venereal diseases has been established by the state board of health and placed under the direction of Dr. Richard L. Russell, Humansville, who has had much experience in this work. He will shortly begin a campaign against venereal diseases and will visit many communities throughout the state to organize clinics and direct effectual measures to combat the venereal disease menace.

**Medical Legion Post Organized.**—Walter Reed Post No. 136, of the American Legion, composed largely of members of the medical and dental professions, was organized at St. Louis, October 3. The officers are: Drs. Fred W. Bailey, St. Louis, post commander; William T. Coughlin, St. Louis, vice post commander; John F. Hardesty, adjutant, and Clyde P. Dyer, finance officer. Drs. Major G. Seelig, St. Louis, and J. P. Harper were elected delegates to the state convention.

**Major Gilles in St. Louis.**—Major H. D. Gilles of the British Medical Corps was the guest of the Association of Surgeons of St. Louis and the St. Louis Dental Society, October 17, and spoke of the work done in plastic surgery in treating wounds of the face during the great war. The lecture was illustrated with lantern slides showing the operations and methods of treating the injuries. Major Gilles was in charge of one of the largest reconstruction hospitals in the British army during the war.

**Postgraduate Meeting.**—The postgraduate meetings inaugurated by the council of the Missouri State Medical Association this season have proved very satisfactory. The meeting at Springfield was held in conjunction with the Southwestern Missouri Medical Association, and that at Cape Girardeau with the Southeastern Missouri Medical Association. Meetings were also held at Excelsior Springs and at Moberly. The attendance has been very encouraging and the programs have roused great enthusiasm for this method of exchange of thought. Each meeting represented a councilor district comprising from three to ten counties, invitations being extended to surrounding counties in other districts, and was held under the immediate direction of the councilor for the district.

**Mental Hygiene Survey.**—The survey of the state to ascertain the status of the insane and feeble-minded has begun. At the request of Governor Gardner, sponsored by the Missouri State Medical Association, the Missouri State Mental Hygiene Association and other bodies, the National Committee for Mental Hygiene has secured the services of Dr. Samuel W. Hamilton of New York to make the survey, and he has arrived to begin the work. His headquarters will be located in the state house at Jefferson City. He will investigate every phase of the question and make the information gained accessible to the governor so that the policies of the state toward the care of the insane and feeble-minded may be based on ascertained fact. It is estimated that about a year will be consumed in making the survey.

#### NEBRASKA

**Northwestern Physicians Meet.**—The Northwestern Nebraska Medical Society met at Valentine, September 25, for the first time in two years, and reorganized, electing the following officers: president, Dr. Robert H. Foster, Norfolk, vice president, Dr. Alfred G. Rasek, Valentine, and secretary-treasurer, Dr. William B. Ely, Ainsworth. The next meeting will be held at Norfolk.

**Personal.**—Dr. Ira H. Dillon, Auburn, has been appointed chief of the bureau of health by the secretary of the department of public welfare of Nebraska, succeeding Dr. William F. Wild, Lincoln, resigned.—Dr. James D. Case, superintendent of the Lincoln State Hospital for the Insane, has resigned and has been succeeded by Dr. David G. Griffiths, at present superintendent of the Institute for Feeble-Minded Youths, at Beatrice. Dr. H. B. Stewart, Hastings, has been appointed to succeed Dr. Griffiths.

### NEW YORK

**Personal.**—Dr. Henry L. K. Shaw, Albany, formerly director of the division of child hygiene, has been appointed a consultant of the New York State Department of Health.—Dr. Matthias Nicoll, Jr., New York City, has been appointed a member of the advisory committee of the International Exposition of Municipal Equipment, recently established at Grand Central Palace, New York City.

**Health Scoring Among Cities Resumed.**—Last year the health department prepared a score card for the health activities of the various cities of the state. Dr. Charles C. Duryee, Schenectady, state sanitary supervisor, was detailed to interview health officers and mayors of cities for the purpose of scoring this work. The results are most gratifying. Great interest has been aroused and many improvements have been instituted. The score card has been improved and it is proposed to make a second round of interviews with mayors and health officers.

**Mobile Child Welfare Station.**—In order to stimulate interest in child welfare and other health work the Westchester County Chapter of the American Red Cross has equipped a model welfare station in the interior of an auto truck and has sent this exhibit to a large number of towns in Westchester County. When it arrives in a community it is placed under the direction of the local public health nurse, the state and county health nurses attached to the exhibit acting as her assistants. In this way great interest is stimulated in the various localities. Meetings are held in the evenings at which health films are shown and at which the health officer in the community is the speaker. Little Mothers' leagues have been organized in nearly every town visited.

**Sanitary Supervisors' Conferences Resumed.**—The conferences of sanitary supervisors and health officers in the various districts of the state, which it was impossible to continue during the past two years on account of the war activities, have been resumed this fall. During September and October the fifteen sanitary supervisors held in their districts one or more conferences with their health officers. One of the aims of the conferences has been to urge the 750 municipalities which have adopted the uniform sanitary code to adopt certain amendments which will bring the code up to date. Another measure presented at these conferences was the uses that could be made of the public health nurse in rural districts.

**Pneumonia a Reportable Disease.**—Dr. Hermann M. Biggs, commissioner of health, has sent an open letter to the physicians of this state reminding them that the Sanitary Code requires that all cases of pneumonia shall be reported to the local health authorities as soon as diagnosis can be made. In the reports, lobar and bronchial pneumonia should be differentiated. The letter calls attention to the fact that recent reports of deaths indicate that many deaths are recorded where no cases have been reported. The state department of health, while it does not expect a recurrence of respiratory diseases such as was experienced last year, believes many cases of pneumonia will occur and asks the cooperation of physicians in reporting cases so that the department and local health authorities will be in a position to take prompt action.

### New York City

**Personal.**—Dr. Simon Flexner was the principal speaker at the first fall meeting of the New York Association of Biology Teachers held, October 24.—Dr. Jose Castillo, Jr., Sao Paulo, Brazil, is visiting New York for the purpose of studying health organizations.—Harry H. Warfield, Capt., Sanitary Corps, U. S. Army, and until recently attached to the base hospital at Camp Meade, Md., has been appointed superintendent of the Peck Memorial Hospital, Brooklyn.

**Red Cross to Keep Base Hospitals.**—The Metropolitan Committee of the Red Cross Roll Call announces in connection with the third Red Cross Roll Call which begins on November 2, that it will keep the eight base hospitals which it organized in this city during the war. It is pointed out

it can only be prepared to meet the great disasters of peace such as floods, earthquakes, epidemics, etc., by a fully organized and equipped series of base hospitals. Eight New York City base hospitals were organized at the following institutions, most of which have given assurance that they will be kept intact for emergency: Bellevue, Presbyterian, Mount Sinai, New York Post Graduate, Roosevelt, Lenox Hill and the Metropolitan.

**Hospitals Seek Million Dollar Fund.**—The United Hospital Fund announces that during the week of November 17 an intensive campaign will be conducted from the new headquarters of the fund, at 261 Madison Avenue, to raise \$1,000,000 to help meet the deficit of the forty-six hospitals that participate in the fund. The money will be divided among the hospitals on the basis of the free work carried on in these institutions. The money is to be apportioned by a committee headed by the mayor and composed of the presidents of the chamber of commerce and the Merchant's Association, Otto T. Barnard, Cornelius N. Bliss, Jr., Arthur Curtiss James and James Speyer. A recent report of the United Hospital Fund shows that the hospital facilities of New York are such that only one person in ten seriously ill in this city is getting hospital care. The report also reveals the fact that 2,000,000 New Yorkers, half of them with serious ailments, needed hospital treatment last year which they were unable to obtain on account of the underequipment of the city.

### NORTH CAROLINA

**Hospital Notes.**—Dr. Robert T. Ferguson, Gaffney, announces that he is to build a private hospital in that city to be known as Dr. Ferguson's Private Sanatorium.—A modern hospital to be known as the Wilmington Hospital will be built in Wilmington by Drs. J. T. Haggard and John F. Miller. The building will have fifty rooms, each with a private bath, and will be fireproof.

**State Bureau of Infant and Maternal Hygiene.**—The state board of health will establish in a short time, with the cooperation of the American Red Cross, a bureau of infant and maternal hygiene, the expense of which will be born jointly by the state and the American Red Cross. This bureau will be an enlargement of the department recently conducted by the board under the direction of Mrs. Kate Brew Vaughan. The personnel will consist of a state director of nursing, and two assistant supervising nurses with the necessary clerical help.

**Personal.**—Dr. Benjamin K. Hays, Oxford, formerly secretary of the State Board of Medical Examiners and for the last four years secretary of the state medical society, has accepted service with the National Association for the Prevention of Tuberculosis and will engage in field work designed to instruct the discharged soldiers now in civil life outside of institutions, how to best conduct their fight against the disease.—Drs. L. C. Todd and Hamilton W. McKay have been appointed members of the staff of the Crowell Urological Clinic, Charlotte.—Dr. Edward Jenner Wood, Wilmington, has sailed for England, where he will study for a degree in tropical medicine.—Dr. S. Westray Battle, Asheville, entertained the members of the Buncombe County Medical Society at a dinner, October 20.—Dr. Kemp P. Neal, Monroe, has returned from service abroad and has located at Raleigh.—Dr. Benjamin E. Washburn, Raleigh, who has been for three years supervisor of rural sanitation in North Carolina, will leave the state, January 1, to take up his new duties in Jamaica under the International Health Commission.

### OHIO

**Professor Dreyer in Cleveland.**—Prof. Georges Dreyer, professor of pathology in Oxford University, delivered a lecture at the medical library, Cleveland, October 27, under the H. M. Hanna lecture fund of the Western Reserve University School of Medicine.

**New Regulations for Sanatorium.**—Under a law which has just gone into effect, the board of governors of the Mount Vernon State Sanatorium are privileged to accept anywhere from \$5 to \$25 per patient for board, room and medical services. Under the old law, \$5 was the only weekly fee that could be accepted. The per capita cost at the present time is \$14.10 a week.

**Trachoma in Scioto County.**—An antitrachoma campaign, conducted by the state board of health, has been completed in Scioto County. During this campaign, 10,577 schoolchildren were examined, about evenly divided between the schools in the city of Portsmouth and those in rural districts.

Of these, 179 were said to have been suffering from trachoma. About five sixths of these cases were found in the rural schools.

**Personal.**—Dr. Clarence W. Russell, Springfield, is reported to be seriously ill with heart disease at the home of his sister in Burton.—Dr. Lloyd D. Trowbridge, Piqua, slipped and fell, October 1, fracturing his left leg at the ankle.—Dr. Emmett L. Hooper has been appointed first assistant physician, Dr. Freeman A. Osborn, second assistant physician, and Dr. Andrew F. Holmes, third assistant physician of the Athens State Hospital.

**Hospital Notes.**—The trustees of the Masonic Home, Springfield, have accepted plans for a new \$500,000 hospital with a capacity of 175 patients. An auditorium with a capacity of 150 wheel chairs will be a feature.—The Hinde-Ball Mercy Hospital, Mount Vernon, was opened to the public, September 15.—Lancaster Municipal Hospital opened a training school for nurses, October 1.—The Toledo Newsboys' Association has rented a private room at the Toledo Hospital for the use of any member of the association who is sick or hurt.

**Grading for Health Work.**—The grading of 102 health districts of the state for the purpose of fixing the salary to be paid to the district health commissioner has been established by the state civil service commission in compliance with the Hughes act, which revises the local health administrative organization. Salaries will increase automatically after specified periods of efficient service. Applications for non-assembled, competitive examinations for health commissioners of the general districts will be received until noon, November 15. Of all municipal districts, Cleveland is the only city in Grade 1, and the health commissioner will receive a salary of \$6,000. There are four Grade 2 districts in which a salary of \$5,000 will be given. In Grades 3, 4 and 5 the salaries are respectively, \$4,000, \$3,000 and \$2,000 a year.

**Smallpox.**—The state department of health in a current circular states that smallpox is more prevalent in Ohio than in disease-ridden Serbia. Through medical aid from other countries, Serbia is now free from smallpox for the first time in five years; Ohio reports 119 cases in September. From January 1 to October 1, 3,292 cases were reported, and others have been added this month. "Ohio is in need of methods similar to those pursued in Serbia," said the department's statement. "Smallpox is one of the most easily preventable diseases. Our records show that a case in a person who has recently been successfully vaccinated is exceedingly rare. Any community which desires to rid itself of smallpox, as war-ravaged Serbia has done, can accomplish this result in a month by general vaccination of the population."

## PENNSYLVANIA

**Typhoid Fever.**—There have been reported on the Fourth Street Extension, West Newton, nineteen cases of typhoid fever, said to have been contracted from the use of water from an old well.

**Authorities on Insane Meet.**—The association of trustees and medical superintendents of state incorporated hospitals for the insane and feebleminded of Pennsylvania met in Pittsburgh, October 17. The following officers were elected: Dr. Clyde R. McKinniss, Bridgeville, president; Dr. Ralph L. Hill, superintendent of the Allegheny County Hospital, vice president, and Dr. Q. N. Copp, physician-in-chief and administrator of the Pennsylvania Hospital Department for Mental Diseases, Philadelphia, secretary.

**Personal.**—Dr. Charles W. Sheldon, Tioga, has been appointed district medical director with supervision over the counties of Tioga, Potter, Bradford, Lycoming and Sullivan.

—Dr. J. Bruce McCreary, Shippensburg, has been appointed supervising medical director for Perry, Franklin, Adams and Cumberland counties. Dr. McCreary has also been appointed medical director of the Mount Alto Sanatorium, succeeding Dr. Frederick C. Johnson, who has been granted leave of absence.—Dr. Raleigh K. Huggins, Pittsburgh, has been appointed dean of the faculty of the School of Medicine of the University of Pittsburgh, succeeding Dr. Thomas S. Arlathout, resigned.—Dr. George Burton Stull has been appointed surgeon to the Harrisburg Hospital and medical director of the Harrisburg public schools.—Dr. Samuel P. Longstreet, Scranton, who has been seriously ill with pneumonia, is reported to be convalescent.—Dr. John A. Hawkins, Pittsburgh, Lieut.-Col., M. C., U. S. Army, after twenty-six months in the army, of which thirteen months were spent in France, has returned home.—Drs. Calvin L. Johnstonbaugh, Bethlehem, and Irvine D. Metzger, Pitts-

burgh, have been reappointed by Governor Sprout, as members of the bureau of medical education and licensure.—Dr. William L. Estes, South Bethlehem, has been appointed chief of the genito-urinary dispensary of South Bethlehem.

## Philadelphia

**Plant Memorial Trees.**—Six red oak trees were planted, Saturday, October 24, at the Pennsylvania Hospital in memory of members of Base Hospital No. 10, who gave their lives in France.

**Medical Club Reception.**—The Medical Club of Philadelphia gave a reception in honor of Hon. William C. Sprout, governor of the state of Pennsylvania, October 17, at the Bellevue-Stratford Hotel.

**Medical Society Gives Dinner.**—A testimonial dinner to Dr. Henry D. Jump, president-elect of the Medical Society of the State of Pennsylvania, was given by the West Philadelphia Medical Association at the Hotel Rittenhouse, October 28.

**Sugar for Druggists.**—The shortage of sugar has been seriously affecting the compounding of medical prescriptions in which sugar is used, so that Dr. Wilmer Krusen, medical director of Public Health and Charities, has issued an appeal to dealers and wholesalers in sugar to permit for medical purposes a 100 per cent. allowance to druggists.

**Dispensaries Reopened.**—After being closed for more than a year, the Medico-Chi dispensaries have been reopened to the public in conjunction with the state dispensaries. Cooperating with the state dispensaries through Dr. Edward Martin, head of the state department of health, and Dr. Alexander C. Abbott of the hygiene department at the University of Pennsylvania, the Medico-Chi clinics have been improved with new and up-to-date equipment.

**Personal.**—Dr. Edwin S. Cooke has been appointed first assistant of the State Genito-Urinary Dispensary.—Dr. Samuel T. Orton has been secured as head of the new psychopathic hospital at Iowa City, which is being erected at a cost of \$150,000.—Dr. Charles J. Hatfield has been reelected chairman of the Southeastern Chapter of the American Red Cross.—Dr. William Harvey Perkins sailed for Chiang-Moi, Siam, October 30, to do medical missionary work in the Presbyterian Hospital there. During the war Dr. Perkins was a lieutenant in the medical corps, stationed at Base Hospital No. 20, France.

**Occupational Therapy School Opens.**—The opening session of the School of Occupational Therapy was held in its new quarters, 2131 Spruce Street, October 19. This is the only institution of its kind in the state for the training of aides in the new profession of "healing by occupation." There are courses in weaving, stenciling, block printing, modeling, bookbinding, woodcarving, toy making and basketry. Through the cooperation of the Philadelphia General Hospital and the Pennsylvania Hospital the students are insured good hospital training under skilled supervision, and further prepared for their work by a course of lectures by eminent physicians, surgeons and psychologists.

## SOUTH CAROLINA

**New County Officers.**—At the annual meeting of the Lexington County Medical Society, held in Lexington, October 6, Dr. John H. Mathias was elected president, Dr. Daniel R. Kneccc, Pelton, vice president, and Dr. James J. Wingard secretary (re-elected).

**New Training School.**—At the opening exercises of the present session of the Medical College of South Carolina, the addition of another school was announced to be designated as the Training School of Nurses of the Medical College of South Carolina. This is an entirely new feature and is expected to attract many students.

**Scholarship Awarded.**—The governor has announced the award of scholarships in the Medical College of South Carolina, Charleston, to the following appointees: Ashley B. Haight, Charleston; John D. Bunch, Clarks Hill; Arthur Kennerly, Greenwood; M. C. Patton, Fountain Inn; W. M. Jones, York; John Melver Wilcox, Darlington, and James Furman Herbert, Columbia.

**Hospital Notes.**—It is understood that a new hospital to be known as the Orangeburg Hospital will be opened by Dr. Charles A. Molliey, formerly assistant to the surgeon at the Fennell Infirmary, Rock Hill.—The Mullins Hospital has been incorporated with a capital stock of \$50,000 by Drs. French A. Smith, Frank L. Martin, Johnson H. Smith and Lonnie M. McMillan, all of Mullins.

**Personal.**—Dr. Robert H. Crawford, Rock Hill, has been awarded by the King of Greece the Medal of Military Merit for distinguished services with the American Red Cross in combating an epidemic of typhus fever.—Dr. Henry B. Malone, Chester, has been appointed chief of the internal medicine department of the Pryor Hospital.—Dr. Frank D. Mower, Newberry, has been commissioned lieutenant-colonel on the staff of Governor Cooper.

**Veneral Disease Prevention.**—A venereal clinic has been established in Columbia under the care of Dr. Charles V. Akin. It will take over the work previously done at the Columbia Hospital. The clinic will be located on the second floor of the old police station.—During the fiscal year of 1919-1920, the state board of health will expend \$32,953.42 in combating venereal disease in South Carolina. One half of this sum has been appropriated by the general assembly and the other half by the federal government. Of this amount, \$28,600 is to be devoted to the treatment of cases, \$1,926 for administration, \$1,200 for repressive measures, and \$1,227.42 for education and publicity.

#### CANADA

**Federal Health Department Created.**—A bill recently has been passed by the Canadian House of Commons creating a federal department of health and providing for a minister of health and advisory committee. The authority of the department will extend to all matters affecting health within the jurisdiction of the Dominion of Canada.

**Personal.**—Dr. Robert R. McClenahan, Hamilton, Ont., district officer of health from Toronto to Niagara Falls, has been appointed medical officer to take charge of the venereal diseases campaign in Ontario with headquarters in Toronto, under the provincial board of health.—Dr. Wilfrid T. Grenfel, C. M. G., the Labrador medical missionary, has recently been in Toronto.

**Hospital News.**—The method of caring for the insane in the province of Manitoba is now undergoing a radical change. Persons suspected of being mentally unsound will be admitted to psychopathic wards of general hospitals to receive immediate expert treatment. Subsequently, these patients, if found suitable, will be sent to either the hospital for the insane at St. Kirk or to Brandon. Specially trained nurses and interns will be provided and reports of each case will be forwarded to the superintendent of hospitals in Winnipeg.

**Canadian Medical Association.**—By a new arrangement the *Journal of the Canadian Medical Association* loses the services of Sir Andrew Macphail as editor, and substitutes an editorial board. Dr. Alexander D. Blackader, Montreal, is the chairman of this board; Dr. William W. Francis, assistant editor, and Dr. Maude E. S. Abbott, acting editor. Besides, there is a subeditorial board appointed by provincial associations. The former publisher has been bought out, but the journal will still be issued from Toronto.

**Some Drug Importations Into Canada.**—In 1915 Canada imported 80 ounces of cocaine. This advanced from year to year until in the official year 1919, there were imported 12,333 ounces at a cost of \$142,123. The morphin importations in 1915 amounted to 259 ounces; in 1919, 30,087 ounces at a cost of \$179,195. Crude opium imported amounted to 7,248 pounds in 1915; in 1919, 34,263 pounds, at a cost of \$534,555. Every province the last three or four years has enacted prohibitory liquor legislation; and a year or two ago manufacture and importation of alcoholic liquors was prohibited. A bill has recently been introduced into the Canadian House of Commons controlling drug importations.

#### GENERAL

**Western Surgical Association Change of Meeting Date.**—The time for the next meeting of the Western Surgical Association which will be held at Kansas City, Mo., has been changed to December 5 and 6.

**Southern Medical Association Meeting.**—The annual meeting of the Southern Medical Association will be held in Asheville, N. C., November 10 to 13, under the presidency of Dr. Lewellys F. Barker, Baltimore.

**Honorary Fellowship for Surgeon-General.**—It is announced that the Royal College of Surgeons of Edinburgh has conferred a honorary fellowship on Major-Gen. Merritte W. Ireland, Surgeon-General of the Army.

**Women Physicians Pass Resolutions Favoring Prenuptial Physical Examinations.**—The International Conference of Women Physicians in session in New York, at its meeting,

October 24, passed resolutions advocating that couples contemplating matrimony present themselves for physical examination before wedlock. A resolution asking the conference to denounce tobacco smoking as an evil was voted down.

**Appropriations for Maternal and Infant Care.**—Senator Morris Sheppard of Texas has introduced a bill in the United States Senate carrying large appropriations for the public protection of maternity and infancy, and authorizing the Children's Bureau of the Department of Labor to cooperate with the various state health agencies in the promotion of maternity and infancy care. Several similar bills are pending in the Senate and House, but no action has been taken.

**No Action on Public Health Legislation in Senate.**—Efforts to get action on public health legislation in the United States Senate during the past week were unsuccessful. The Senate called up a measure to create a department of tuberculosis in the United States Public Health Service, a bill to appropriate \$1,000,000 for the prevention and study of influenza, and a bill to appropriate funds for caring for drug addicts. By failure to obtain unanimous consent, the measures were passed by for consideration later.

**Eye, Ear and Throat Men Elect Officers.**—At the twenty-fourth annual meeting of the American Academy of Ophthalmology and Oto-Laryngology, held recently in Cleveland, the following officers were elected: president, Dr. Lee M. Frazer, Buffalo; vice president, Dr. Hal Foster, Kansas City, Mo.; secretary, Dr. Luther C. Peter, Philadelphia; treasurer, Dr. Secord H. Large, Cleveland, and chief of directors, Dr. Clarence Loch, Chicago. The twenty-fifth annual meeting will be held Oct. 14-16, 1920, at Kansas City, Mo.

**Amendments Offered for Control of Venereal Disease.**—An effort to add amendments to House Bill 5123 to prevent transmission through the mails of advertisements relating to the treatment of venereal diseases and certain sexual disorders is to be made in the House of Representatives. The amendments would extend the prohibitory mailing features of the measure to other diseases such as kidney diseases, bladder trouble, skin and blood diseases. The measure was introduced by Congressman Halvor Steernerson of Minnesota.

**New Mississippi Valley Officers.**—At the annual meeting of the Mississippi Valley Medical Association, held in Louisville, October 21 to 23, Chicago was selected as the place of meeting for 1920, and the following officers were elected: president, Dr. Frank B. Wynn, Indianapolis; vice presidents, Drs. Chauncey W. Dowden, Louisville, and Frank Smithies, Chicago; secretary, Dr. Henry Enos Tuley, Louisville (re-elected), and treasurer, Dr. Samuel C. Stanton, Chicago (re-elected).

**Bequests and Donations.**—The following bequests and donations have recently been announced:

City Hospital, Winston-Salem, N. C., \$240,000 for improvements in the hospital, including a five-story fireproof building, by the will of R. J. Reynolds, Winston-Salem.

Columbia, Pa., Hospital, \$1,000, by the will of Benjamin F. Hiestand, Marietta, Pa.

Methodist Home for the Aged and Infirmary, Bala, Pa., \$3,000 and a residence; Methodist Orphanage, Philadelphia, \$3,000, and Methodist Hospital, Philadelphia, \$500, by the will of Elizabeth E. Kilburn.

Christ Church Hospital, Philadelphia, \$30,000, by the will of Mary Wright.

**New Officers for Railway Surgeons.**—At the sixteenth annual meeting of the American Association of Railway Surgeons, held in Chicago, October 12-17, the following officers were elected: president, Dr. Robert McConaughy, York, Neb.; vice presidents, Drs. Isaac F. Harter, Stronghurst, Ill.; Paul E. Gardner, New Hampton, Iowa; George W. Thompson, Winamac, Ind.; treasurer, Dr. Henry B. Jennings, Council Bluffs, Iowa (re-elected); secretary-editor, Dr. Louis J. Mitchell, Chicago (re-elected), and executive board, Drs. Samuel C. Plummer, Chicago, and David Y. Roberts, Louisville, Ky.

**Mayo Clinic Physicians Meet.**—The second annual meeting of the Association of Resident and Ex-Resident Physicians of the Mayo Clinic was held at Rochester, Minn., October 8 and 9, under the presidency of Dr. Harold L. Foss, Danville, Pa. The following officers were elected: president, Dr. Clarence G. Toland, Los Angeles; vice president, Dr. Francis G. Aud, Cecilia, Ky.; secretary, Dr. Harold L. Foss, Danville, Pa.; assistant secretary, Dr. Archibald H. Logan, Rochester, Minn.; treasurer, Dr. Arthur H. Sanford, Rochester, Minn., and board of governors, Drs. Edward S. Judd, William F. Braasch and Donald C. Balfour, all of Rochester, Minn.

**Clinical Congress Elects.**—At the annual meeting of this organization, held October 23, the following officers were

elected; president, Dr. George E. Armstrong, Montreal; vice presidents, Drs. Rudolph Matas, New Orleans, and Horace Packard, Boston; regents for term expiring in 1921, Drs. Alexander Primrose, Toronto; Albert J. Ochsner, Chicago; George W. Crile, Cleveland; Harvey Cushing, Boston; George L. deSchweinitz, Bethlehem, Pa., and William J. Mayo, Rochester, Minn.; regents for term expiring 1922, Drs. John M. T. Finney, Baltimore; James B. Eagleston, Seattle; Charles H. Mayo, Rochester, Minn.; J. Bentley Squier, New York, and Dr. Walter W. Chipman, Montreal.

**Women Physicians Organize.**—As a result of the conferences of women physicians that have been in session in New York City from September 15 to October 25, a permanent organization has been formed, called Medical Women's International Association. The headquarters for the present will be at the office of Dr. Esther C. P. Lovejoy, 637 Madison Avenue, New York City. The following officers have been elected; president, Dr. Esther C. P. Lovejoy, New York City; vice presidents, Dr. Christine Murrell, London, L. Trillier-Landry, Paris, and Kristine Much, Christiania, Norway; corresponding secretary, Dr. Martha A. Welpton, San Diego, Calif.; recording secretary, Dr. Marie Feyler, Lausanne, Switzerland, and treasurer, Dr. Ellen C. Potter, Philadelphia.

**New Electro-Therapeutic Officers.**—At the annual meeting of the American Association of Electro-Therapeutics and Radiology, held in Philadelphia, September 9-12, under the presidency of Dr. Frank B. Granger, Boston, the following officers were elected: president, Dr. William Martin, Atlantic City, N. J.; vice presidents, Drs. Virgil C. Kinney, Wellsville, N. Y.; S. St. John Wright, Akron, Ohio; Mary L. H. Arnold Snow, New York; William T. Johnson, Philadelphia, and John H. Burch, Syracuse; treasurer, Dr. Emil Heuel, New York (re-elected); secretary and registrar, Dr. Byron Sprague Price, New York (re-elected), and trustees, Drs. J. Willard Travell, New York; Frederick DeKraft, New York; Frank B. Granger, Boston; Frederick H. Morse, Boston; William L. Clark, Philadelphia, and Edward C. Titus, New York.

**Bacillus Botulinus Poisoning in Detroit.**—Cases of botulism have been reported in Detroit causing the deaths of five persons and severe illness of two others. At a dinner party, October 18, infected olives were eaten by four diners and a waitress. Of this group one guest and the waitress died. The hostess and another guest became ill and one guest escaped entirely. The olives were also eaten by three members of the household, and of this group all died. The bacillus botulinus was recovered from both the liquor and the olives. The Detroit Department of Health found that the "Curtis Brand" of ripe olives were at fault. On the basis of this information food inspectors immediately placed a ban on the sale of this particular brand. Some 7,000 jars were seized at once and the eighth jar of this lot examined was found to contain a similar organism. On the basis of this finding the entire supply of this brand of olives in Detroit was condemned as unfit for food. Nearly 20,000 jars have been attached.

**Distinguished Service Medals for British Surgeons.**—At the convocation of the Clinical Congress of the American College of Surgeons, October 24, Major-General Ireland conferred distinguished service medals on Sir Anthony Bowlby of London and Sir Robert Jones of Liverpool, after reading a letter from Secretary of War Baker in which he regretted that the President's illness made it impossible for him to make the presentation himself. The citations accompanying the awards were as follows:

Sir Anthony Bowlby: For exceptionally meritorious and distinguished services to the United States. An eminent consulting surgeon, and while serving with the British Expeditionary Forces in France with untiring zeal he devoted his time and energy toward cooperating with and unreservedly placing at the disposal of the American Expeditionary Forces his eminent talent, broad experience and knowledge of general principles in preventing wastage among our forces from wounds and disease. His research work in wound bacteriology and vaccination resulted in the saving of many lives among our sick and wounded.

Sir Robert Jones: For exceptionally meritorious and distinguished services to the United States. An eminent orthopedic surgeon and chief of the division of orthopedic surgery in the British Army service, he placed at the disposal of the medical service of the American Expeditionary Forces his eminent talents and broad experience in standardizing methods of treatment of the sick and wounded, and took an active personal interest in class instruction of American medical officers in this very important branch of surgery.

**Prohibition Enforcement Act of Interest to Physicians.**—The prohibition enforcement act, to make effective the prohibition constitutional amendment, carries sections of interest to the medical profession. It provides that no one but a

physician holding a permit to prescribe liquor shall issue any prescription for liquor. This must be after physical examination of the patient if this procedure is possible and, if this course is impracticable, the prescription can be issued on the best information obtainable that the liquor is necessary as a medicine for the ailment. Not more than a pint of spirituous liquor to be taken internally can be prescribed for use by the same person within a period of ten days. No prescription can be filled a second time when spirituous liquor is included in it. Official blanks for filling these prescriptions are to be provided, and these blanks must be used in all cases, except in emergencies. Physicians are to obtain licenses from the Internal Revenue Service. The use of liquor is also permitted in the manufacture of medicinal preparations manufactured according to stated formulas: "patent," patented and proprietary medicines unfit for beverage purposes; toilet, medicinal and antiseptic preparations unfit for beverage purposes; flavoring extracts and syrups unfit for beverage or intoxicating purposes. Permits are required to manufacture these articles but not to sell them. Substantial fines are prescribed for violations, which are increased with recurring offenses.

## FOREIGN

**Personal.**—Dr. Edward Hindle, Kingsley Lecturer and Bye Fellow of Magdalene College, Cambridge, assistant to the Quick Professor of Biology, has been elected to the chair of biology in the School of Medicine, Cairo, Egypt.

**French Gratitude Medal for American Physicians.**—The *Journal officiel* of Sept. 24, 1919, publishes a list of American physicians and surgeons to whom the silver Médaille de la Reconnaissance française had recently been awarded. The list is reproduced in the *Presse médicale* of October 4.

**New Medical Building in Spain.**—The Physicians' Association of Madrid has under consideration the building of a new eight story building which will serve as a home for the different medical societies of Spain. The estimated cost of this Palacio de Ciencias Médicas, as it is to be called, is about \$1,300,000.

**Deaths in the Profession Abroad.**—Dr. E. Bonardi, professor of medical pathology at the University of Pavia and member of the lower house of parliament.—Dr. N. Berend, professor of children's diseases at the University of Budapest, killed in a riot.—The *Nederlandsch Tijdschrift* mentions also the death of Prof. F. Niszl of the Institute for Psychiatric Research at Munich.

**The Dejerine Endowment.**—The widow of the late Professor Dejerine of Paris and Mlle. Dejerine have endowed a fund in charge of the Société de neurologie at Paris in memory of the eminent neurologist who was one of the founders and long president of the society. The income is to be devoted to promote scientific research, clinical or experimental, in the field of neurology, especially to aid those who have distinguished themselves by original research to publish their works with the desirable extent and illustrations, or to facilitate further research by better instrumental or experimental equipment. The funds disposable are to be given exclusively to works the first results of which have been previously communicated to the society. The research worker may or may not be a member of the society, or have worked in collaboration with some member of the society. A further provision states that the funds disposable may be attributed year after year to the same work at the discretion of the society. The candidates may apply for aid from the fund directly or through the intermediation of some member of the society. The works may be published by the society in its official journal, the *Revue Neurologique*, or independently, within two years, and the works may compete for prizes offered elsewhere. It is anticipated that the fund will be increased later by donations or appropriations. The first award will consist of 2,000 francs. Application should be made to the Commission du fonds J. Dejerine de la Société de neurologie de Paris.

## LATIN AMERICA

**Sanitary Works in Uruguay.** A cablegram from Montevideo announces that the secretary of public works has proposed that an American company be given the contract for the execution of a plan of sanitary works for the whole country. It is estimated that the cost will amount to \$19,000,000.

**Fiftieth Anniversary of Mexican Medical Society.**—The Sociedad Médica Pedro Eschericho of Mexico City held a gala session, August 4, to commemorate the founding of the society fifty years before. The president, Dr. José Truete

y R. A., spoke on the life and work of the physician's wife, and Dr. A. Lopez Hernandez on the progress in medicine during the half century since the society was founded. The society publishes a journal, *El Observador Médico*, which has just entered on its third series of volumes. The editorial staff consists of Drs. R. Lopez, Santiago Ramirez and L. S. Viramontes. An editorial in a recent number, signed by Dr. Ramirez, laments the free rein given to quacks of all kinds in Mexico and urges the necessity for organized resistance on the part of the public. The publishing of a popularly written journal to educate the public in regard to the dangers of quackery is suggested. Dr. Ramirez added: "The medical education of society should be initiated; the need for it is great, from the millionaire to the minister. Society in Mexico is absolutely ignorant of medical culture. For the public, the physician, the cook, the tradesman, all rank alike as regards medicine." There is some agitation in favor of founding a physicians' club, the Casa del Médico. The editorial adds that if this should become a fact, "it should be born with a whip in its hand to lash the commercialists. It is rumored that certain commercialists were already on hand at the meeting to discuss arrangements for the proposed club."

## Government Services

### MEMORIAL DISCHARGES, MEDICAL CORPS, U. S. ARMY

NOTE.—In the following list, L. signifies lieutenant; C., captain; M., major; L. C., lieutenant-colonel; Col., colonel.

#### ALABAMA

Birmingham—Dabney, W. C. (M.)  
Edmundson, H. C. (L.)  
Rosen, G. W. (M.)  
Sniard, E. C. (L.)  
Barnsville—Walker, L. M. (L.)  
Cullman—Culpepper, R. A. (L.)  
Fairhope—Godard, C. G. (L.)  
Mobile—Sleeker, E. S. (M.)  
Tuscaloosa—Dixon, R. E. (L.)  
Tuscumbia—DesPrez, L. W. (C.)

#### ARKANSAS

Rush—Drennan, S. A. (M.)  
Scranton—Blair, A. A. (C.)

#### CALIFORNIA

Alcatraz—Yemans, H. W. (M.)  
Downey—Zindon, D. B. (L.)  
Fresno—Williams, J. C. (L.)

**MEXICO LETTER**

MEXICO CITY, Oct. 19, 1919.

**The Mexican Medical Association**

The Mexican Medical Association held recently a general meeting at which the directing officers presented the by-laws that they have prepared pursuant to the powers conferred on them. The work of the association will be divided into five sections; namely, medical ethics, scientific publications, mutual protection, social and physical culture, and propaganda. All physicians duly licensed and practicing their profession in good faith are eligible to membership. Those that signed the proceedings at the first session will be considered as founders. It was decided that the homeopath could not belong to the association, not because it was intended to display any sectarianism, but because this belonging to that school here are generally very ignorant. The meeting was attended by physicians from the different states who represented the physicians of their respective localities. The president Dr. Gregorio Mendizábal, delivered an address in which he advised that Mexico should follow the methods through which medical education has reached the wonderful development it has attained in the United States, with which development he is personally acquainted through his various visits at the universities of that country. In view of the number of applications for admission already received and those that are expected from the different

states, the creation of the National Medical Association may already be considered a success.

#### Tabardillo (Typhus Fever) Transactions

The transactions of the Congreso Nacional del Tabardillo, which met here last January, have been published in a 457 page volume. This publication is due to the interest displayed by the president of the congress, Dr. Terrés, who has even advanced some funds for this purpose. The proceedings have already been distributed to the members who paid the membership fee and in addition will be sent to anybody forwarding the price of the book, namely, 15 pesos (about \$7.50). Orders should be addressed to the treasurer, Dr. Ernesto Cervera, Avenida Uruguay, No. 77, Mexico City. This rather high price should not cause surprise in view of the fact that book publishing is very expensive here, among other reasons because of the import duties on paper.

#### Journal Resumes Publication

The organ of the society "Pedro Escobedo," *El Observador Médico*, which had been suspended for several years, has recommenced publication. The manager of this journal is Dr. Santiago Ramirez, 4 a. calle de Hidalgo, 129.

#### Yellow Fever

It is reported from the peninsula of Yucatan that new cases of yellow fever have occurred in the city of Merida. As a result of this, notwithstanding the repeated requests made by the merchants of that region, the quarantine established against the port of Progreso has not been raised. It is not known whether any investigations have been made to confirm the etiologic rôle of *Leptospira icteroides* or whether any trials have been made of the merits of curative and preventive serotherapy, or whether neo-arsphenamin has been tried as was done in the northern part of Brazil (*THE JOURNAL*, Sept. 27, 1919), although it would seem advisable to do all of these things.—The sanitary authorities of Cuba, according to the newspaper *El Día* of Havana, have sent Dr. Mario Lebreto to our country so that he may make some studies, taking advantage of the opportunity presented by this epidemic.

There are rumors, not confirmed as yet, that there have been cases of the same disease in the port of Manzanillo on the Pacific coast, which would tend to make the situation more serious.

#### Regulating the Practice of Medicine

A large group of students belonging to the law, engineering, medical, odontology and military medical schools have presented a petition to congress advocating the passage of a law governing the exercise of the liberal professions, so that only those duly licensed may practice them. While it may seem strange, there have been some newspapers that have defended the alleged rights of the "amateurs" to practice the different professions, including medicine, which is the one that would seem most dangerous in the hands of the ignorant.

#### The Academy of Medicine

The Academy of Medicine held, October 1, the first session of this year, under the presidency of the president of the university, Dr. Macías; after the usual report by the secretary and the address of the retiring president, new officers were elected as follows: vice president, Dr. G. Diaz Lombardo (of the section on urology) who will occupy the presidency during the year 1920-1921, and second secretary Dr. Jesus Arroyo (of the section on internal medicine). According to the law-lays, Dr. Emilio Montaño, of the section on ophthalmology, became president for this year. To celebrate this event a banquet was held which, in addition to the members of the academy, was attended by the honorary members, Drs. Liccaga, Mendizabal, Villada, Ramirez de Arellano and Soriano.

In the meeting held, October 8, Dr. González Uruña presented a paper on the use of carbon dioxide snow for the treatment of lupus erythematosus and acne rosacea, presenting two patients nearly cured (one of lupus and the other of acne). Uruña, after mentioning the experiences of Swedish and American authors and his own, advocated this method of treatment for these diseases.—In the session held on the 15th, Professor Cordero, of the section on natural history, read a paper on the yeast of pulque which he has been able to isolate and grow, and which, when planted in unfermented maguey, produces an alcoholic aromatic liquor that does not possess the disagreeable smell and taste of pulque. He suggested the possibility of preparing a kind of

pulque that would be less harmful than that consumed at present by the poorer class of Mexico, and pointed out the possibility of using for therapeutic purposes the yeast of pulque instead of that of beer. Cordero exhibited also a sample of alcohol which could be used for pharmacologic and industrial purposes and is obtained through the fermentation and distillation of the maguey penecas. These are the waste products which are left after pulque is manufactured and which are now thrown away.—The academy appointed as honorary member Dr. J. Ramón Icaza, who has belonged to the academy for more than forty-five years.—The department of sanitation has extended the courtesies of the bacteriologic laboratory to those members who wish to take advantage of the opportunities for research thus available.

#### The President of the University of Madrid

The newspapers have mentioned the fact that Dr. J. Rodriguez Carracido, a noted chemist and president of the University of Madrid, is a member of a Spanish delegation leaving soon for the United States. If this is true, the Spanish colony in Mexico will invite him to come to this country and deliver some lectures.

#### Monument to a Physician

Some steps have already been taken to erect a monument in honor of Dr. Belisario Dominguez in one of the cities of Chiapas, the state in which he was born. Dr. Dominguez was murdered in 1914 when he represented his state in the senate and public opinion has ever since attributed his murder to the dictator Huerta and some of his ministers.

#### LONDON LETTER

LONDON, Oct. 2, 1919.

#### Opening of the Medical Schools

The first opening of the session at the medical schools after the war, which is about to take place, marks a new epoch in medical education in this country—the inauguration of research clinics in the London hospitals. In previous letters this innovation has been described at the London Hospital (*THE JOURNAL*, April 12, 1919, p. 1091) and at Guy's Hospital (September 13, p. 849). At University College Hospital, Dr. T. R. Elliott has been appointed director of the medical clinic, and at St. Thomas', Sir Cuthbert Wallace. At St. Bartholomew's Hospital, Sir Archibald Garrod will preside over the medical, and Mr. G. E. Gaske over the surgical research departments. At Charing Cross Hospital, an institute of pathology for teaching and research has been established. It will have a staff of five medical teachers and investigators, of whom the principal will be Dr. W. W. C. Topley. The institute will carry on investigation and research in connection with the hospital, and give the medical students in the final years of their course a thorough grounding in pathology and bacteriology before they proceed to their specialized studies in medicine and surgery. Research work will have a foremost place in the activities of the institute, and the members of the staff will devote their full time to this and to teaching. In order that they may do this, their salaries have been arranged on a scale which will enable them to carry on their work without financial worry or anxiety.

It is anticipated that the number of students who will enter the medical schools will be greater than ever. This is due to two principal causes: A large number of youths have passed directly into the army from the secondary schools without the opportunity of choosing a profession, and the survivors are now in a position to select one. The government has undertaken to make generous grants toward the expenses of ex-service men who will take up medicine. This will induce many who might have done otherwise to take up the profession. The second principal cause of the influx is the return of those who had registered as medical students in 1914-1915 but had not attained a sufficiently advanced standard to entitle them to exemption from conscription. In a lesser degree the opening of most of the London medical schools to women students has tended to increase the roll. Of the twelve London medical schools, the only ones now not open to women are the Middlesex, Guy's, St. Bartholomew's and St. Thomas'. During the war, the shortage of male medical students and of male physicians in civil practice greatly increased the number of women students. The numbers of entry at the various medical schools cannot yet be given, but it may be stated that the new entries at the London Hospital are already more than 100, as against an average

of between seventy and eighty. During the second and third years of the war, fears were expressed that in four or five years there would be an insufficiency of physicians in the country, owing to conscription; but it is now considered that this will not occur. The Irish and Scottish medical schools were full of students all through the war. In the case of Ireland, this was due to exemption from conscription. In the case of Scotland, the reason was more creditable. It was due to the fact that Scottish boys at 16 are generally as advanced as English boys of 17 and 17½, and are thus in a position to begin professional studies at an earlier age. Not only is it believed that there will be no shortage of physicians, but it is feared by some that there is a possibility of the profession's being overcrowded—a condition that existed before the passage of the insurance act.

#### Reunion of the Tip of the Nose

Remarkable reports have been published from time to time of reunion of severed fingers, but few cases appear to have been recorded of reunion of a severed nose. Mr. J. O. Skevington, F.R.C.S., has reported a case in the *British Medical Journal*, which has also attracted attention in the lay press. A man was admitted to King Edward VII Hospital, Windsor. While he was grooming a restive horse, a skylight fell and, breaking, cut off the end of his nose. In addition to the tip, the part missing included about one third of the left ala and two thirds of the right ala, besides the lower part of the septum and a small portion of the upper lip. A messenger sent to the stable succeeded in finding the missing part, and about an hour after the accident it was sutured into place. Under a dressing saturated with physiologic sodium chlorid solution, primary union took place, and the resulting effect is very good.

#### Increased Fees of Physicians

The great increase in the cost of living and in the expenses of medical practice, such as the maintenance of cars, gasoline and chauffeurs' wages, has led to an increase in physicians' fees. This has taken place gradually first at one part of the country and then at another. The amount of the increase varies, but may be taken to average 50 per cent. Some consultants have raised their fees from \$10 to \$20. The question of an amended rate of remuneration for panel physicians is to be considered by a meeting held under the auspices of the British Medical Association. In London the ministry of health has decided to pay a war bonus to panel physicians on the following basis: (a) a payment of 30 per cent. of the physicians' insurance capitation fees for treatment (up to a maximum of \$750) in the case of every physician who shows that his total net professional income from all sources does not exceed \$2,500 a year; (b) a payment of 20 per cent. (up to a maximum of \$1,500) when the income exceeds \$2,500 but does not exceed \$6,000; (c) a payment of 15 per cent. (up to a maximum of \$1,300) in all other cases.

### PARIS LETTER

PARIS, Oct. 9, 1919.

#### The Advisory Committee of the Army Medical Corps

M. Clemenceau, minister of war, has decided to appoint a number of civilian physicians on the advisory committee of the army medical corps. He is moved to do this by reason of the eminent services that the civilian physicians rendered the army during the course of the war. In the selection of civilian physicians to act on the advisory committee such physicians, surgeons and pharmacists will be chosen as are well known and whose works are authoritative, even though they may not have acquired the highest rank from a strictly military standpoint.

#### Reorganization of the Special School of the Army Medical Corps

An order has been issued providing for the reorganization of the Ecole du service de sante militaire de Lyon. The purpose is to develop a maximal efficiency among the physicians, surgeons and pharmacists of the army medical corps.

In accordance with this order, the selection of candidates for this school, as provided for by competitive examinations, will henceforth be made from among students of all grades of scholarship. The youngest students may be enrolled in the army medical corps, and yet continue their studies in their original medical schools, which are thus called on to compete in the training of army physicians. The presence of approved candidates will not be required at Lyons except during their last years of study. New rubings facilitate also

their admission to externships and internships in civilian hospitals, and permit them to perform these duties under the same conditions as their civilian associates. As a recompense for those students who shall have been admitted to an internship in a hospital, they will be entitled to certain special privileges as affecting their career. Thus, prospective army physicians and pharmacists will in all respects have the benefit of the same educational advantages and of the same scientific resources as the civilian students. Students promoted to the rank of *medecins aides-majors* will no longer, on leaving the Ecole de Lyon, proceed directly to the Ecole d'application de medecine et de pharmacie militaires du Val-de-Grace, as they did formerly, for their further training, but will first spend a year of service in the large military hospitals. It is thought that after they have participated in real military life for a certain length of time they will be better prepared in every respect to profit by the specialized instruction of the Ecole d'application du Val-de-Grace.

#### Organized Endeavors to Increase the Birth Rate of France

The Congrès de la natalité française, organized under the patronage of the presidents of the French chambers of commerce, convened at Nancy, September 25 to 28. At this inaugural meeting, M. Auguste Isaac, honorary president of the chamber of commerce of Lyons, set forth in detail the working program of the society. Dr. Jacques Bertillon, president of the Alliance nationale pour le relèvement de la natalité française, gave some very impressive statistics in support of the conclusions of M. Isaac.

Among the reports presented to the various committees of the congress we note especially the reports on the campaign against tuberculosis and insanitary dwellings, on infants' nurseries and day nurseries for working mothers in factory towns, on the propaganda against depopulation, on the creation in each community of a birth rate promoting bureau and of study centers, presided over by competent persons, with a view to improving moral and social standards, and on the necessity of making a special appeal to all associations that are interested in contributing to this movement for the uplift of France. Other subjects that came up for discussion were: the different forms of legislative action; the question of indemnities for excessive family burdens; military service; aid to unmarried mothers, and the law pertaining to succession.

#### Enlargement of Medical School

The minister of public instruction has filed a bill with the chamber of deputies providing for an appropriation of 5,500,000 francs for the securing of suitable territory and for the erection of buildings required by the Faculté de médecine de Paris in its plan of enlargement.

#### Men Disabled by the Loss of Limbs in the War

An assembly of men who have become disabled through the loss of limbs in the war, and of men who have received medical discharges for other reasons, together with war widows, took place recently at Bar le Duc, under the presidency of M. Maginot, of the chamber of deputies, and a number of resolutions were passed, the principal ones of which demand that (1) a certificate showing the nature and origin of war wounds must be furnished at any time to those who may require such a certificate, if occasion should arise, also a duplicate must be furnished; (2) a time limit shall be established within which a pension case referred to a court of appeal must come to trial, in order that the payment of pensions in such cases may be accelerated.

In the same connection, M. Constant Verlot, deputy from the department of the Vosges, has filed a bill with the chamber of deputies which has in view the granting of special concessions to military pensioners and to civilian victims of the war who may wish to acquire small rural holdings. This bill provides that they shall be granted loans at 1 per cent. under the usual rate.

#### Changes in the French Population in 1918

The minister of labor has completed the birth and mortality statistics for France for the year 1918. These statistics show that the civil population of France decreased during the year 1918 by 389,575 not counting the war losses.

These statistics, based on civil records, continue to cover only the seventy-seven departments that were not directly affected by military operations. This is the same as it was during the first four years of the war. It will be the same

for the year 1919, and not until the beginning of 1920 will the statistics of all French territory, made complete by accession of Alsace and Lorraine, be included. If one compares the statistics of the years 1917 and 1918, for the seventy-seven departments of which account was taken, one will note that last year shows not only the persistence of an excess of deaths over births, but even an increase of the excess over that of the preceding year. In 1917, the population of the seventy-seven departments not invaded decreased 269,838, whereas the decrease in 1918 has risen to 389,575. This result is due to the considerable increase in the number of deaths during the second half of 1918, ascribable to the influenza epidemic; for the number of births showed a slight increase over 1917. A comparison of the statistics of the years 1917 and 1918 is given in the accompanying table.

DEMOGRAPHIC STATISTICS FOR THE YEARS  
1917 AND 1918

	1918	1917
Births	399,041	343,310
Deaths	788,616	613,148
Excess of deaths over births*	389,575	269,838
Marriages	177,872	158,508
Divorces	8,121	5,572

An analysis of the table reveals the fact that in 1918 there was: (1) an increase in the number of marriages; (2) a corresponding increase in the number of births, and (3) an increase in the number of deaths. This increase in mortality affects exclusively the second half of last year. During the first half of 1918, 316,077 deaths were recorded, as compared with 354,554 during the first half of 1917; and during the second half of 1918, 472,539 deaths were registered, as against 258,594 in 1917. According to the preceding figures, the number of civil victims claimed by the influenza last year may be placed at approximately 200,000.

Pupils of the Marine Medical Department

The auxiliary officers of the medical corps (physicians and pharmacists), and students of the Marine Medical Department, who entered the Ecole principale du Service de Santé de la marine de Bordeaux in 1913, who have not finished a year of military service and who have not finished their studies, will be debarked and sent immediately to the Ecole de Bordeaux, where they must report not later than Nov. 1, 1919.

Franco-American Amity

Mrs. William Astor Chanler, president of the "French Heroes' La Fayette Memorial Fund," and John C. Moffat, chairman of the executive committee of this society, recently received, at one of their offices, certain representatives of the French press, to whom they set forth the new plans and purposes of the American welfare societies, which intend to form a federation in order to concentrate their efforts and thus make them more effective. Mrs. Chanler and Mr. Moffat have been appointed as special delegates in France to acquire into the needs of the hour and to ascertain the best means of meeting the situation.

American Physicians Decorated

Among the physicians recently decorated with the Médaille de la Reconnaissance française for services devoted to the care of the wounded during the war appear the names of the following Americans: Drs. Charles Leach, Edward Case, William Johnston, David Edmond Smith, Alfred Malabre, Basilius Valdes and James Wyant.

Personal

M. Eugène Brieux, member of the French Academy, has been made, on the recommendation of the minister of war, commander of the legion of honor, with the following citation:

Exceptional distinctions: He devoted himself wholeheartedly, during a period of four years, to those blinded in war. He created and organized throughout the country numerous schools for their reeducation.

Death of Dr. Michel Gangolphe

Dr. Michel Gangolphe, agrégé professor at the Faculté mixte de médecine et de pharmacie de Lyon, formerly chief surgeon of the Hôtel-Dieu Hospital of this city, is dead at the age of 61. Gangolphe, who was one of the most brilliant pupils of Ollier and of Poncet, was known by his works on bone surgery and especially by a work, which has become an authority, on "Les maladies infectieuses des os" (Infectious Diseases of the Bones).

Deaths

Henry Weightman Stelwagon \* the eminent dermatologist of Philadelphia; aged 65; died in Philadelphia, October 18, from angina pectoris. He was born in Philadelphia, and was graduated from the medical department of the University of Pennsylvania in 1865. After a term as intern in the Philadelphia (Blockley) Hospital he spent two years in Vienna and Berlin. He was physician in charge of the Philadelphia Dispensary of Skin Diseases from 1880 to 1890; instructor in dermatology in his alma mater from 1885 to 1890; clinical professor of dermatology in the Woman's Medical College of Pennsylvania, Philadelphia, from 1898 to 1907, and professor of dermatology in Jefferson Medical College since 1890. He was dermatologist to the Philadelphia Hospital from 1888 to 1915, and since that date consulting dermatologist. He was a member of the American Dermatological Association and president in 1900; also a member or honorary member of many dermatologic societies in this country and abroad. In addition to Dr. Stelwagon's textbooks on "Essentials of Diseases of the Skin," which first appeared in 1890, and his "Treatise on Diseases of the Skin," which appeared in 1901, he translated and edited Mraček's "Atlas of Skin Diseases." Dr. Stelwagon's death while in the full vigor of manhood is greatly to be deplored.

Stephen Henry Lutz \* Brooklyn; Dartmouth Medical School, Hanover, N. H., 1895; aged 47; president of the Kings County Medical Society; a member of the American Otological Society; American Laryngological, Rhinological and Otological Society; and American Academy of Ophthalmology and Oto-Laryngology; surgeon to the ear department of the Brooklyn Eye and Ear Hospital; otologist to the Bushwick Hospital; consulting laryngologist to the Bedford Dispensary; died at his home, October 17, from heart disease.

James Frederick Smith \* New York City; College of Physicians and Surgeons in the City of New York, 1882; aged 62; a fellow of the New York Academy of Medicine; a specialist on diseases of the eye, ear, nose and throat; assistant surgeon of the eye department of the Manhattan Eye, Ear and Throat Hospital, and a member of the staff of the Post-Graduate Nose and Throat Hospital; died at his home, October 18, from pneumonia.

James Perry Duckett, Anderson, S. C.; Jefferson Medical College, 1874; aged 68; a member of the South Carolina Medical Association; for several terms a member of the city council of Anderson, a member and for a time chairman of the local board of health; for fifteen years a member of the board of trustees of the city schools; and for several terms physician of Anderson County; died in the Anderson County Hospital, October 10.

Matthew Charles McGannon \* Major, M. R. C., U. S. Army, Nashville, Tenn.; McGill University, Montreal, 1885; aged 62; professor of surgery and clinical surgery in Vanderbilt University, Nashville; chief surgeon of the Woman's Hospital; and attending surgeon at the Vanderbilt Hospital and Nashville City Hospital; recently appointed surgeon-general of Tennessee; died at his home, October 9, from heart disease.

Ernest Eugene Roberts \* Sawtelle, Calif.; Marion-Sims College of Medicine, St. Louis, 1899; aged 49; who had served for about four years in the Philippine Islands as a contract surgeon, and was afterward commissioned lieutenant and captain, Medical Reserve Corps, and was honorably discharged, Feb. 17, 1919; was shot and killed in Los Angeles, October 11.

Martin D. Foster, Olney, Ill.; Eclectic Medical Institute, Cincinnati, 1882; Hahnemann Medical College, Chicago, 1894; aged 58; mayor of Olney in 1895 and 1902; for six terms congressman from the Twenty-Third Illinois District, and thereafter a member of the government commission to adjust war mineral claims in the Western states; died at his home, October 20.

Alfred William Anderson \* Lakewood, Ohio; Cleveland Homeopathic Medical College, 1902; aged 40; formerly chief officer of Lakewood; who was honorably discharged as first lieutenant, M. C., U. S. Army, Jan. 3, 1919; a member of the staff of the Lakewood Hospital for eleven years; died in that institution, October 12, from cerebral hemorrhage.

\* Indicates "Fellow" of the American Medical Association.

**Cornelius S. Van Riper**, Pasadena, Calif.; College of Physicians and Surgeons in the City of New York, 1859; aged 82; for forty years a practitioner of Paterson, N. J.; for three terms president of the Passaic County (N. J.) Medical Society and consulting surgeon to the Passaic and Paterson General hospitals; died at his home, October 9.

**Thomas Finlie Miller**, Glasgow, Ky.; University of Louisville, Ky., 1909; aged 34; a member of the Kentucky State Medical Society; who was honorably discharged as first lieutenant, M. C., U. S. Army, May 29, 1919, after having served with a medical unit in France; died at the home of his father in Tompkinsville, October 12.

**Porter Farley**, Rochester, N. Y.; College of Physicians and Surgeons in the city of New York, 1874; aged 79; a member of the Medical Society of the State of New York; a veteran of the Civil War; coroner of Monroe County, N. Y., in 1877 and 1883; twice president of the Rochester Historical Society; died at his home, October 18.

**Cushman Allen Sears**, Portland, Conn.; New York University, New York City, 1862; aged 79; a member of the Connecticut State Medical Society; medical director of Grand View Sanitarium, Windsor, Conn., in 1902; a member of the medical staff of Middlesex Hospital, Middletown, Conn.; died at his home, October 20.

**Matthew J. Rodermund**, Madison, Wis.; Bennett Eclectic Medical College, 1887; aged 65; notorious because of his expressed belief that smallpox was not contagious; died from heart disease, October 12, on a train near Chippewa Falls while en route to his home.

**John Jacob Lindsay**, Manchester, Iowa; Bellevue Hospital Medical College, 1883; aged 61; for ten years a member of the school board of Manchester and for a portion of that time president of the board; died in the State Hospital, Independence, Iowa, October 6.

**Harvey D. Hockenberry**, West Sunbury, Pa.; University of Wooster, Cleveland, 1879; aged 68, a member of the Medical Society of the State of Pennsylvania; for ten years medical inspector of Butler County for the state board of health; died at his home, October 8.

**Joseph Nicéphore Aubin**, Peshtigo, Wis.; Ecole de Médecine et de Chirurgie, Montreal, Que., 1894; aged 54; a member of the Wisconsin State Medical Society; died in St. Joseph's Hospital, Peshtigo, October 12, from pleurisy complicating typhoid fever.

**Albert Jefferson Peterson**, Goodwater, Ala.; Vanderbilt University, Nashville, Tenn., 1889; aged 60; a member of the Medical Association of the State of Alabama; secretary of the Coosa County Medical Society in 1910; died at his home, September 21.

**Charles M. Faulkner**, Montra, Ohio; Cincinnati College of Medicine and Surgery, 1883; aged 59; a member of the Ohio State Medical Association; died in the Cincinnati Sanitarium, College Hill, Cincinnati, October 5, from cerebral hemorrhage.

**William W. Robertson**, McComb, Miss.; Vanderbilt University, Nashville, Tenn., 1886; aged 55; postmaster of McComb; died on an Illinois Central train, while returning home from New Orleans, September 29.

**Joseph Hoyt Mosher**, Tuxedo, N. Y.; Fordham University, New York City, 1913; an intern at the White Haven (Pa.) Sanatorium in 1916 and 1917; died in that institution, October 17, from pulmonary tuberculosis.

**James Donat Graber**, Limerick Centre, Royersford, Pa.; Bellevue Hospital Medical College, 1870; aged 74; a member of the Medical Society of the State of Pennsylvania; died at his home, October 6, from heart disease.

**John F. Simmons**, Pine Bluff, Ark.; Jefferson Medical College, 1865; aged 86; a Confederate veteran; organizer and first president of the Simmons National Bank, Pine Bluff; died at his home, October 1.

**William Wilbur Williams**, Hilton, N. Y.; University of Buffalo, N. Y., 1881; aged 66; a member of the Medical Society of the State of New York; died at his home, October 16, from arteriosclerosis.

**Henry Washington Stephens**, Anaconda, Mont.; St. Joseph (Mo.) Medical College, 1893; aged 57; a member of the Medical Association of Montana; mayor of Anaconda in 1900; died at his home, October 12.

**Andrew Uren**, Hollywood, Calif.; University of Michigan, Ann Arbor, 1895; aged 61; for many years physician for the Montreal Mining Company, Montreal, Wis.; died at his home, about October 7.

**Joel Taylor Barker**, Danville, Ind.; Bellevue Hospital Medical College, 1870; aged 71; a member of the Indiana State Medical Association; died at his home, October 11, from arteriosclerosis.

**William F. Work**, Charlestown, Ind.; Eclectic Medical Institute, Cincinnati, 1875; University of Louisville, Ky., 1887; aged 69; died at his home, October 7, from cerebral hemorrhage.

**Daniel Peck Cook**, Clay Center, Kan.; University of Michigan, Homeopathic Medical School, Ann Arbor, 1881; aged 67; died at his home October 2, from cerebral hemorrhage.

**Thomas A. Pope**, Cameron, Texas; Louisville, Ky., Medical College, 1870; aged 73; a veteran of the Civil War; twice postmaster of Cameron; died at his home, October 5.

**Charles William Fox**, Philadelphia; Long Island College Hospital, Brooklyn, 1865; aged 71; died at his summer home in York Harbor, Me., October 8, from myocarditis.

**William J. Rogge**, Portland, Ore.; Medical College of Ohio, Cincinnati, 1891; aged 64; died at his home, September 19, from cerebral hemorrhage.

**Samuel C. Hewitt**, Chatham, Ill. (license, years of practice, Illinois, 1878); aged 84; a veteran of the Civil War; died at his home, October 6.

**James M. Schee**, Halbur, Iowa; College of Physicians and Surgeons, Keokuk, Iowa, 1881; aged 59; died at his home, September 19.

**William Johnson Hurt**, Waynetown, Ind.; Rush Medical College, 1873; aged 69; died at his home, October 8, from pneumonia.

**Edward Calvin Ballard**, Greenville, Ohio; Eclectic Medical Institute, Cincinnati, 1871; aged 70; died at his home, October 1.

**William Finley Semple**, Chicago; Rush Medical College, 1881; aged 58; died at his home, October 12, from angina pectoris.

**James Truman Dewey**, Cayesville, Mo.; Missouri Medical College, St. Louis, 1888; aged 68; died at his home, September 15.

## Marriages

**HARRY ARTHUR STECKEL**, Kings Park, N. Y., to Miss Carolyn E. Moon of Binghamton, N. Y., at Lake Mohawk, N. Y., September 29.

**HUGH J. DAVIS**, Capt., M. C., U. S. Army, Austin, Texas, to Miss Grace Reynolds Douglas, at Wilkes Barre, Pa., October 18.

**BENJAMIN PRESCOTT BURPEE**, Manchester, N. H., to Miss Marguerite Rose Burke of Greenfield, Mass., October 11.

**LAWRENCE OSMOND CRUMPLER**, Schoolfield, Va., to Miss May Paec Tallott of Danville, Va., October 15.

**FRANK THOMAS BRENE** to Miss Bessie Pearl Millard, both of Iowa City, at Red Wing, Minn., October 15.

**EDGAR ARTHUR DRAPER**, Cape May, N. J., to Miss Pauline Elizabeth Gaskins of Philadelphia, October 18.

**ROBERT LUCAS OZLIN**, Dundas, Va., to Miss Bertha Marjorie Kelly, at New York City, October 15.

**RICHARD LEE SILVESTER**, Washington, D. C., to Miss Susette Parran, at Port Republic, Md., October 25.

**LEO RAYMOND GOZMAN**, Reading, Pa., to Miss Katherine McMullen of Catasauqua, Pa., October 11.

**SANFORD B. HOOKER**, Boston, to Miss Lillian Augusta Osgood of Claremont, N. H., October 11.

**DANA FLETCHER DOWNING**, Wilmings, Wis., to Miss Rose Emma Akus of Warren, Ill., October 18.

**FLOYD WILCOX McRAE, JR.**, Atlanta, Ga., to Miss Eleanor Deming Stott of Chicago, November 1.

**JAMES SAMUEL MITCHNER**, Edenton, Va., to Miss Bessie Williams of Arvonia, Va., October 16.

**ROY LAFAYETTE OWENS** to Miss Mary Veronica Murphy, both of Chicago, October 1.

**LELAND EGGLETON COFFER** to Miss Lujsita Leland, both of New York City, October 15.

**CHARLES ALLEN STONE**, St. Louis, to Miss Sylvia Lora of Toledo, Ohio, October 22.

**CORNELIUS JOSEPH CORORAN** to Miss Dora Kalk, both of Milwaukee, October 15.

## The Propaganda for Reform

IN THIS DEPARTMENT APPEAR REPORTS OF THE JOURNAL'S BUREAU OF INVESTIGATION, OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LARGELY BY THIS BUREAU WITH OTHER MATTER TENDING TO AID INTELLECTUAL PRESERVING AND TO OPPOSE FRAUD ON THE PUBLIC AND ON THE PROFESSION.

### PINEOLEUM ADVERTISING METHODS

#### Capitalizing the Name and Position of the President of the American Medical Association

To the Editor:—Enclosed is a postal card which a physician in Oklahoma has sent me together with thirty-six cents in stamps. The envelope was addressed to me at the address of the Pineoleum Company. The post-office corrected the address and sent it to me. It is evident, therefore, that the physician in Oklahoma thought that I was sending these postal's as an employee of the Pineoleum Company, or, at least, was endorsing their products.

Kindly do me the favor to publish this letter in THE JOURNAL as a protest against the dishonesty of this method of advertising. What is quoted from an article that I wrote appeared originally in the *New York State Journal of Medicine* and was abstracted in THE JOURNAL of the American Medical Association of August 2, 1919. The obvious inference to be drawn from this postal is that I referred to the products of the Pineoleum Company in that article. I did not have the products of the Pineoleum Company in my mind. I never have used their products and never prescribed them.

This form of advertising is done with intent to deceive and did deceive the doctor in Oklahoma. It was therefore a successful falsehood, its success depending on the false use of the name of the President of the American Medical Association to bolster up the sale of the product.

I resent the use of my name in connection with the quack advertising of nostrum venders. The low, vulpine cunning of the method used is on the same level as the deceit and dishonesty which use this form of advertising to the injury of my name and reputation. As President of the American Medical Association I must insist that you protect me by publishing this letter in THE JOURNAL, giving it as widespread publicity as possible.

ALEXANDER LAMBERT.

[COMMENT.—"Pineoleum" is a "patent medicine" advertised in the cheapest and most effective way—by the aid of the easy going and complacent physician. In 1906 Pineoleum was being marketed by the Winslow Laboratory of New York City, which also put out three or four other nostrums—"Mormuloh," "Egeriol," "Digestylin," and "Ford's Nucleo-Peptide." Pineoleum was advertised to the public then as it is advertised now, via the medical profession. Physicians are circularized and are offered a petty graft in the form of a cheap nebulizer and a sample bottle of Pineoleum. Some time ago the company seems to have developed a scheme whereby physicians could make money "dispensing Pineoleum nebulizer outfits at more than 140 per cent. profit." The Pineoleum concern for years has also polluted the stream at its source by attempting to get the secretary of the senior class of every medical school to distribute its free nebulizer outfits to members of the class and receive therefor 5 cents for each outfit distributed! The life history of Pineoleum is that of the typical nostrum. Epidemics, of course, are utilized as opportunities for pushing the product. In 1911 a card was sent out featuring "A Special LaGrippe Offer"; in 1916 the profession was circularized recommending Pineoleum as "The Ideal Prophylactic" in infantile paralysis; during the past year influenza has again been the selling point.

The case described by Dr. Lambert is not the first example of the misuse of names and statements of physicians. Last December the Pineoleum concern was sending out an advertising card in which Dr. McCoy of the United States Public Health Service was quoted as recommending Pineoleum as the "bulwark of prevention" and "battery of relief" in influenza. Of course, Dr. McCoy never said anything of the sort. A protest against this particular falsehood resulted in another card being sent out several months later by the Pineoleum people purporting to explain and apologize for the misquotations and putting the blame on the printer. The "apology" ended with a postscript (in larger and bolder face type than the body of the card) that urged physicians to "secure our liberal introductory advertising proposition on improved oil nebulizer outfits." From the standpoint of publicity for Pineoleum, the "explanation and apology" was doubtless as good an advertisement as the original card of misrepresentation.—En.]

### LAVORIS

#### Report of the Council on Pharmacy and Chemistry

Lavoris was considered by the Council in 1913, and its proprietors—the Lavoris Chemical Company—were advised that the preparation was inadmissible to New and Non-official Remedies because of conflict with Rules 1, 4, 6, 8 and 10. No report was published at that time. As the preparation is still widely advertised to physicians, the Council has again examined Lavoris and authorized publication of the following report. W. A. PUCKNER, Secretary.

In recent years Lavoris has been widely advertised as "THE IDEAL ORAL ANTISEPTIC" particularly to the dental profession. A printed card sent out by the Lavoris Chemical Company in 1913 read: "LAVORIS, the Pyorrhea Remedy. The Original ZINC CHLORIDE Mouth Wash. One grain zinc to each ounce."

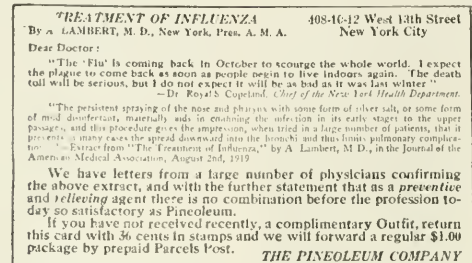

The card also gave a "formula" to the effect that each pint of Lavoris contained:

Zinc Chloride .....	1.040
Resorcin .....	0.520
Menthol .....	0.400
Saccharin .....	0.195
Formalin .....	0.195
Ol. Cassia Zeyl .....	0.780
Ol. Caryophyl .....	0.195

Advertisements now appearing in medical journals repeat the older "formula" except that resorcin is omitted. The formula while seemingly frank and open is in reality indefinite and misleading in that no denomination of weight is given for the various constituents. It is uncertain, for example, if the figures in the formula are intended to represent grains, grams or percentages of the several constituents. In view of the indefinite statement of composition, a chemical examination of Lavoris was undertaken in the A. M. A. Chemical Laboratory. The report of the laboratory follows:

**Zinc.**—This was determined electrolytically. Fifty c.c. gave 0.026 gm. zinc and 100 c.c. gave 0.0531 gm. zinc. The average is 0.0526 gm. zinc in 100 c.c. This is equivalent to 0.1102 gm. anhydrous zinc chlorid in 100 c.c.

**Chlorid.**—After decolorizing some of Lavoris with chlorid-free animal charcoal, the chlorid was determined by the Vollard method. Twenty-five c.c. Lavoris required 4.328 c.c. tenth-normal silver nitrate solution equivalent to 0.01535 gm. chlorid (chloridion) or 0.0614 gm. in 100 c.c. A second 25 c.c. of Lavoris required 4.112 gm. tenth-normal silver nitrate solution equivalent to 0.01458 gm. chlorid (chloridion) or 0.05832 gm. in 100 c.c. Average is 0.05985 gm. This is equivalent to 0.1150 gm. zinc chlorid in 100 c.c. This agrees closely with the foregoing zinc determination.

Postal card capitalizing the name and position of the President of the American Medical Association.

**Resorcin.**—The method of the U. S. Pharmacopoeia was used. The total bromin absorption of 25 c.c. Lavoris was 3.68 c.c. tenth-normal bromin solution. This would be equivalent to 0.00675 gm. resorcin in 25 c.c. or 0.02700 gm. in 100 c.c. In a duplicate test, 25 c.c. Lavoris required 3.8 c.c. tenth-normal bromin solution equivalent to 0.00697 gm. resorcin or 0.02788 gm. in 100 c.c. Since oil of cinnamon absorbs bromin, 50 c.c. of Lavoris was boiled until very little or no odor of the oil was noted, keeping the volume nearly constant by adding a little water from time to time, and the bromin absorption then taken. In one experiment, 0.30 c.c. of tenth-normal bromin solution was consumed, and in a duplicate no bromin was absorbed. This shows the absence of resorcin.

**Residue.**—On evaporating 25 c.c. Lavoris on a steam bath and subsequent drying of the residue at 100 C., 0.455 gm. of residue was obtained. This is equivalent to 0.1820 gm. in 100 c.c.

**Saccharin.**—Saccharin was detected in the residue and ether-extract of the residue by its intense sweet taste when a little sodium bicarbonate was added to it.

**Formaldehyd.**—This could be detected by the Jarrison test. The color was not very pronounced and the quantity of formaldehyd was small.

**Oil of Cinnamon.**—The odor and taste of Lavoris is characteristic of cinnamon.

**Menthol and Oil of Cloves.**—The odor of menthol and of oil of cloves could not be detected, but no tests were made to demonstrate their presence.

The analysis thus indicates that the Lavoris of today contains no resorcin but does contain a small amount of formaldehyd, a little saccharin, and oil of cinnamon (menthol and oil of cloves could not be detected by the odor, but were not tested for). The analysis showed that the principal constituent of Lavoris is zinc chlorid, of which there is about 0.1 gm. per 100 c.c. (about  $\frac{1}{2}$  grain to the ounce).

The amount of zinc chlorid given in the published formula, i. e., 1.04, is meaningless because the unit of weight or measure is not given; furthermore the analysis shows that it is inaccurate for any unit of weight that might be assumed from the published figures. Since the amount of the most active medicinal ingredient is both indefinite and inaccurate, the composition of the preparation is essentially secret. Lavoris is indirectly advertised to the public by having included in the package a circular giving a list of diseases for which the preparation was recommended. The combination of zinc chlorid, formaldehyd and oil of cinnamon (assuming the menthol and oil of cloves to be present as flavors) in a mixture is irrational and likely to lead its users to ascribe a false and exaggerated value to the preparation. The name is objectionable in that it does not indicate the composition of the potent ingredients of the mixture, but instead suggests its use as a mouth wash.

From a standpoint of public safety, the most serious objection to Lavoris, however, lies in the many unwarranted therapeutic claims and suggestions. It is generally held that zinc chlorid solutions which possess a strength of from 1 to 200 up to 1 to 500 exercise a weak antiseptic action. The strength of zinc chlorid in Lavoris is approximately 1 to 1,000. The directions for its use recommend that Lavoris should be diluted. A dilution of 1 to 4 is recommended for a variety of mouth conditions while for cystitis irrigations and as a vaginal douche, it is recommended that one tablespoonful be added to a quart of warm water or salt solution. The strength of zinc chlorid in the last suggested dilution would approximate 1 to 64,000. It is evident that no antiseptic action could be expected from such dilutions.

The recommendation that diluted Lavoris be used for the treatment of coryza, nasal catarrh, hay fever, inflamed eyes, hemorrhoids and leucorrhoea is objectionable and irrational. Especially dangerous is the recommendation that members of a family exposed to diphtheria or scarlet fever should use Lavoris freely as a preventive. Such recommendations can but give a false sense of security and lead to the neglect of proved methods for preventing the spread of these diseases. Equally unwarranted is the recommendation that in gonorrhoea one teaspoonful of Lavoris to eight of warm water be used with a blunt end syringe.

The use of Lavoris as recommended would not only prove valueless in many instances but might lead to serious consequences because really valuable methods of prevention or treatment might be neglected. For these reasons the preparation is in conflict with Rule 6.

The Council declared Lavoris ineligible for New and Nonofficial Remedies.

## Correspondence

### "SELF-SACRIFICE IN THE WARFARE AGAINST DISEASE"

*To the Editor:*—On reading the letter of the Surgeon-General of the Navy in THE JOURNAL, October 25, with its account of the eighty-three enlisted sailors who, during the height of the terrible influenza epidemic in Boston, subjected themselves voluntarily and after having the danger fully explained to them, to experimentation with a view of promoting medical research which might help the surgeons in finding a remedy, I feel deeply impressed with the thought that honors should be conferred on these men—at least honorable mention of their names in THE JOURNAL or in some permanent public record. I do not know whether they would be entitled to the Carnegie hero medal, but no one could be more worthy of it. I hope the Surgeon-General can be interested in the matter. He pays a deserved tribute to the surgeons of the navy in this connection and truly calls these men "heroes in the fullest and most beautiful meaning of the word." Of course, the men should be consulted as to the making public of their names, and any who did not wish to be thus mentioned need not be. I am assuming there is no rule in the Navy against such action.

RICHARD DEWEY, M.D., Wauwatosa, Wis.

### METABOLISM AND SEX

*To the Editor:*—A recent editorial (THE JOURNAL, Aug. 23, 1919, p. 612) emphasizes the relationship obtaining between basal metabolism and sexual expression, as evidenced by Miles' account of the diminished sex activities of a group of men on a reduced ration experiment. As Miles intimates these results have been foreshadowed by Riddle-Riddle (Theory of Sex, Science, N. S. 46:19-24 [July 6] 1917; J. Washington Acad. Sc. 7:319, 2, 1917, for references to earlier papers) has revived the metabolic theory of sex through extensive experiments on pigeons in which he has affected the metabolism of the germs (egg yolks) through such measures as reproductive overwork and hybridity, thereby producing abnormal sex ratios, while the dietetic factor has been held constant (An excess of females is produced by overwork, and an excess of males from wide crosses.) He has further shown that when these sex reversals take place they are quantitative in nature (as measured by sex behavior and gonad size), just as chemical and calorimetric analyses of the ova show quantitative changes in the storage metabolism, coinciding with the severity of the method used to produce the change in sex ratios.

Drummond (Biochem J 12:25, 1919) has observed in his feeding experiments that when rats are kept on a diet deficient in water soluble B (vitamin) that the males exhibited a lowered sex activity, and indeed were sexually impotent, the testes showing degeneration. More recently Osborne and Mendel (J. Biol. Chem. 38:223, 1919) have observed that when yeast is given to rats as the only source of protein and water soluble B, the males thus fed, although grown vigorously to adult size, were with very few exceptions sterile.

R. McCarrison (Indian J. M. Res. 6:275 [Jan.] 1919; 550 [April] 1919) has measured the change in weight of the organs of pigeons on diets adequate except for water soluble B. His results are based on seventy-two control and 168 experimental pigeons, and the data show that the testes lose 93 per cent. of their weight, while the ovaries lose only 69

per cent. In simple manition when the birds die in twelve days or less, the loss in testes weight is 61 per cent. against 11 per cent. for the ovaries.

The nutritive deficiencies mentioned seem to affect the testes much more than the ovaries.

That the experiments also permit of a metabolic explanation seems evident from Dutcher's recent work: He has been able to alleviate, to a considerable degree, the symptoms of beriberi by therapeutic agents such as thyroid extract, tethelin and pilocarpin, which are known stimulants of metabolism.

It seems highly improbable that water soluble B, per se, is necessary in the formation of reproductive tissue, else we should expect to find it in these organs, but it is lacking. A more likely explanation is that its deficiency results in a level of metabolism insufficient for the differentiation and maintenance of male reproductive tissue, and if this level is sufficiently reduced, also for ovarian tissue.

That a change in metabolism due to internal secretions may convert differentiating ovarian tissue into testicular tissue has been brought out most beautifully by the work of Tandler and Kellar, and of Lillie in their studies on the freemartin, in which the hormones of the male fetus circulate through the female fetus, owing to an anastomosis of the blood vessels. If the juncture occurs later in fetal life, the female exhibits only masculine secondary characteristics and sterile ovaries; if earlier, the ovary itself contains testicular tissue, and it is probable that in cases in which the testicular hormone circulates through the female previous to the development of the ovary, a complete sex reversal may be effected.

But the effect of diet on sex is not restricted to a change in secondary sexual characteristics of the differentiated organisms, for if it is applied properly it can effect a true reversal of sex. As Lusk and others have shown that the ingestion of an abundant diet, and of protein foods in particular, leads to an increase in metabolism (specific dynamic action), we should expect that a change in diet which would yield a higher metabolic rate should also result in an increased production of males; and, indeed, such has been found to be the case in the lower forms of life.

Whitney, and Schull and Ladoff (*J. Exper. Zool.*, series of papers from 1914 on), demonstrated in *Hydatina senta* that it is the diet acting on the grandmother which determines the sex of the grandchildren. A continuous diet of the colorless flagellate, *Polytoma*, causes female grandchildren to be produced; and when an abundant supply of the active green flagellate, *Dunaliella*, is supplied, approximately 95 per cent. of the daughters became male producers. This work has been confirmed on five species of rotifers, and in every case the giving of an optimum food and in greater abundance has yielded similar results.

It may properly be asked at this point why it is, then, that feeding experiments on mammals with this object in view have in some cases yielded apparently positive results, but perhaps even more frequently negative results, so that the effect of nutrition and, in truth, the metabolic theory, have until recently been discredited among scientific men.

In answer to such criticisms it seems well to point out that Nature has protected herself against the effects of sudden change in sex ratio by environmental causes by setting aside an organ (the ovary) which resists any change in its metabolism except by unusual or prolonged pressures. The results in rotifers show that the diet does not affect the sex of the daughter, but only of the ova which are to differentiate and develop in the daughter's ovary. How, then, are we to expect significant changes in the sex ratios of higher forms in which the metabolism is more stabilized through the agency of internal secretions, by performing a feeding experiment lasting only a comparatively short time on, at most, a single generation? Riddle has been successful in the first generation, because his methods attack directly the metabolism of the ovary and the developing ova both previous to and during the chromosomal maturation period; and it is for this reason, in addition to others, that he has been compelled to abandon the chromosome theory as a causal explanation of his results. He considers the sex chromosomes as associated

phenomena in the determination of sex, developed possibly for the maintenance of the necessary metabolic levels.

The evidence at present would seem to indicate that the older experiments designed to test the nutritive factor must be repeated in view of our newer knowledge of nutrition relating to the physiologic values of the different amino-acids and the rôles played by the vitamins or food hormones. By approaching the problem in this manner we may possibly hope to explain the varying sex expressions of the different nationalities and the changed sex ratios which seem to follow war.

VICTOR K. LAMER, A.B., New York.  
Research Assistant, Food Chemistry, Columbia University.

#### "DESENSITIZATION OF PERSONS AGAINST IVY POISONING"

*To the Editor:*—As additional evidence supporting Dr. Schamberg's desensitization of persons against ivy poisoning (*THE JOURNAL*, Oct. 18, 1919, p. 1213), the following experiment tried on myself may not be without interest: Ever since reaching college age and living in cities, I have been very susceptible to dermatitis by contact with poison ivy plants during country excursions, and once was confined to the house for two weeks.

In 1910, before the outdoor season began, for about two months, twice a day, I took gradually increasing doses of tincture of rhus toxicodendron, starting with one drop and ending with a number now forgotten. I never had enough confidence in the possible immunization to come purposefully in contact with poison ivy, and previous experiences were too unpleasant to risk repeating, if avoidable. However, during that summer in portaging a canoe my bare arms unavoidably came in contact with much foliage of the plant. Contrary to previous experiences, no sign of dermatitis developed. Lack of opportunity for outdoor life prevented me from repeating the experiment in other summers.

One or two laymen of intelligent type have told me that they have seen ingestion of poison ivy leaves effect a cure and immunity from dermatitis venenata.

Dr. Schamberg's term "desensitization" implies that more is known of the mechanism of ivy poisoning than many admit. I am more inclined to think that his treatment increases one's "tolerance," whatever that may be, much as one becomes tolerant to nicotine, caffeine, alcohol, or even the sun's rays. Following one attack in a season, I have never experienced a second that same year. When a boy and living mostly in the country with plenty of poison ivy around, I was seemingly immune, though never purposefully handling the plant.

Frequently during the time I was taking tincture of rhus toxicodendron I experienced slight pruritus ani, either as a real effect of the drug, a psychic phenomenon, or just a coincidence.

M. W. LYON, JR., M.D., South Bend, Ind.

*To the Editor:*—The theory of establishing an immunity toward ivy poisoning by giving extractives of the plant internally, as recorded by Dr. J. F. Schamberg (*THE JOURNAL*, Oct. 18, 1919, p. 1213) is not new. Chewing the leaves of poison ivy has long been practiced by laborers (Dakin: *Am. J. M. Sc.* 4:98, 1829) and others in the belief that it would establish immunity against poisoning; many references are made to it in the literature. Some years ago Williams (*M. World* 20:482, 1902) advanced the conception of an antitoxin to rhus poisoning by giving the drug. He writes:

A decoction of the leaves of the plant, say about half a dozen leaves at a dose (or they may be simply chewed and swallowed), will cause an eruption of blebs, or water blisters, which contain an antitoxin that neutralizes the poison in the blood when the serum from them is resorbed. One or two doses is usually sufficient. . . . The remedy immunizes against the possibility of future poisoning by the plant.

Ford, as long ago as 1907 (*J. Infect. Dis.* 4:542, 1907), stated that he had established an immunity to rhus poisoning in guinea-pigs and rabbits by administering small but increasing doses of fluidextract of poison ivy. He found that from ten to twenty times the fatal dose could be given to immunized animals.

However, after long study of the subject I have little faith in any theory of immunity against ivy poisoning. The active substance in poison ivy (and poison sumach) is a brownish-red, liquid, nonvolatile resin, 0.001 mg. of which is sufficient to cause symptoms (Pfiaff: *J. Exper. Med.* 2: 192, 1897). The poison being soluble in alcohol, biologic tests with it may easily be made, the degree of irritation being controlled by variance in concentration and duration of application. The technic is simple and the patient's discomfort trifling. I have applied the purified resin from the poison sumach on one so-called immune, and the individual was poisoned (*Pharm. J.* 83:563, 1909), though it appeared that the skin of this subject was somewhat less sensitive than mine, my arm having been used as a control.

L. E. WARREN, Chicago.

**STANDARDS FOR BLOOD PRESSURE APPARATUS**

*To the Editor:*—In response to requests from several sources, the Aeronautic Instruments Section of the Bureau of Standards is undertaking the establishment of standard tolerances for blood pressure gages. In this connection, we are anxious to obtain the opinion of medical authorities as to what allowable error can be permitted in using these instruments.

It should be remembered that no instrument can be made absolutely accurate, and that even if it could, the personal equation of the user would still be a source of error. Consequently, some definite standard of accuracy should be established to be met by the manufacturer.

The information that the gages should be "as accurate as possible" will be of little assistance to us. What we should like is a statement that an error of a certain number of millimeters of mercury in the reading can be reasonably allowed.

We should appreciate also any general information which your readers can furnish on the subject of blood pressure gages, especially as to the principal difficulties encountered in their use and as to the type of gage which is preferred.

S. W. SLATTON, Washington, D. C.

Director, Bureau of Standards, Department of Commerce.

**THE RELATION OF THE NEUROLOGIST TO GROUP DIAGNOSIS**

*To the Editor:*—The ever increasing advances in medical science have placed such a burden of responsibility on the profession that a physician attempting a diagnostic study on his patient, alone and unaided, may well feel appalled and helpless. To overcome this apparent paradox, diagnostic clinics or groups are coming into being whose functions are to relieve the physician of the perplexities associated with cases of a difficult nature. The sick have accepted the idea without equivocation. Physicians will do likewise as soon as they fully appreciate its beneficent influence.

I am, of course, aware that physicians avail themselves of the aid given them by the laboratory and the specialist. This readily serves its purpose in a great many cases when the condition is obvious and interpretation simple. What I have in mind, in particular, is the vast number of patients presenting ill defined, vague clinical states who trudge wearily from specialist to specialist. Each specialist's own narrow point of view is injected into the case, and the relief which these patients seek, and which is their due, is more elusive than ever. Group diagnosis obviates the narrowness and correlates all diagnostic data, so that final correct interpretation is possible. The medical profession will be spared the just censure and mistrust of the patient, and the ever growing crop of cults and quackeries will cease to exist.

What is the relation of the neurologist to group diagnosis? I consider this to be a highly important one from several points of view. As a result of the great war, the prestige of the neurologist has been enhanced immeasurably. His opinion was eagerly sought in the great mass of organic disturbances that were the direct results of injuries, and for that

type of disorder, largely functional, and grouped under the misnomer "shell shock." His deductions were obviously of manifest importance, for it was he who had the final decision in hand to which side a certain type belonged. In civil practice, his rôle is no less important for we are all cognizant of the innumerable conditions that simulate visceral organic diseases, and which, in the final analysis, are caused directly by organic nervous diseases. Group diagnosis will prevent a patient with a tabetic crisis from being operated on needlessly; and this holds true for a large number of nervous affections whose onset and course are characterized by pains largely confined to the visceral organs. Repeated operations for a condition that does not exist will, naturally, be obviated. The neurologist himself, as the result of group study, will avoid the pitfalls that might otherwise cause him to interpret falsely a patient's complaint. He will not dismiss a case as functional, and then, very much to his chargin and humiliation, find that some one else has cured "functional" affection by proper operative procedures.

I realize that I have but briefly touched on the relation of the neurologist to group medicine. It is not the purpose of these notes to thrust unduly into the medical limelight the neurologic specialist. Each member of the diagnostic group has an equally important function to fulfil. His deductions in a given case bear a definite and important relation to the group as a whole. Inferentially, the deductions of the other members of the group either add greater value to his interpretations or repudiate them altogether. The manifest educational value of such an exchange of opinion hardly needs extended comment.

I trust that I have not created the impression that the conception of group diagnosis is largely the product of my own originality. On the contrary, there exist in the profession today forceful pioneers who have within recent years preached this radical innovation. The success of their endeavors is a matter of record. I have merely attempted to emphasize its importance to the medical profession, and to the ill who entrust themselves to their care.

CHARLES ROSENHECK, M.D., New York.

Neurologist, Hospital for Deformities and Joint Diseases, New York Diagnostic Clinic

**Queries and Minor Notes**

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

**COMPARATIVE VALUE OF ACETYL-SALICYLIC ACID AND ACETANILID AS ANALGESICS**

*To the Editor:*—There has been some controversy in our country medical society about the depressant effect of acetylsalicylic acid and about giving it for the relief of pain. I have been giving it in preference to acetanilid or antifebrin or any of the acetanilid compounds. I would like to have your opinion on this subject.

A. J. MYNART, M.D., Lanier, Mo.

ANSWER.—There is no doubt that acetyl-salicylic acid has decided analgesic value. As it is more anodyne than sodium salicylate, some of it must be absorbed and act as the undecomposed acetyl compound. The mean toxic dose of acetyl-salicylic acid, that is, the dose at which either gastric or auditory disturbance is produced, was found by Hanzlik, in a clinical study, to be 165 grains for males and 140 grains for females, which might be roughly averaged at 120 grains. Depression of the circulation (collapse) or of the nervous system (coma) was not observed with such doses. A fatal case of what perhaps was aspirin poisoning is reported by F. W. Lewis, in which a dose of about 200 grains taken by an influenza patient in the course of six hours, on an empty stomach, was followed by death in two days, the cause of death having been hemorrhage from the small intestine, which was profusely and extensively inflamed and ulcerated. Vomiting and anemia, rather than primary depression of the circulation or of the nervous system, were the prominent symptoms during life. We must, therefore, conclude that acetyl-salicylic acid does not have a marked tendency to

produce depression. Assuming the average analgesic dose of acetylsalicylic acid to be 10 grains (though 5 grains often suffice) and the average dose at which toxicity is usually noted to be 140 grains, the figure 13 (10:140::1:14; 14-1=13), might represent the therapeutic zone; while 19 might be considered the margin of safety, if 200 grains be the minimal fatal dose of this drug. Of course, this does not take into account the unusual reaction to acetylsalicylic acid, characterized by the appearance, from ten to fifteen minutes after ingestion of 5 or 10 grains of the drug, of edema of the larynx or violent bronchial asthma—almost amounting to asphyxia in some cases—and of urticaria or angioneurotic edema. Though they are uncommon, a considerable number of such cases have been reported. We must conclude that acetylsalicylic acid does not have a tendency to produce depression, and that it is a comparatively safe drug; for, even in those cases of allergy in which alarming symptoms appeared, recovery invariably took place.

This cannot be said of acetanilid, which is a treacherous drug. While as much as 60 grains have been tolerated without ill effect, the same dose has frequently been followed by serious collapse, and in some cases by death. A dose of 10 grains would certainly represent a maximum therapeutic dose, for such amount has repeatedly produced toxic effects and may have contributed to a lethal result (even 5 grains are alleged to have caused death). While the analgesic dose of this drug, which might be placed at 2½ grains, is smaller than that of acetylsalicylic acid, and though acetanilid is therefore four times as powerful an analgesic as acetylsalicylic acid, its therapeutic zone is very much smaller: 3 vs. 13, and its margin of safety is relatively smaller still.

We may conclude, therefore, that the preference of acetylsalicylic acid over acetanilid, for the relief of pain, is well founded.

TREATMENT OF BURNS WITH PARAFFIN FILMS

To the Editor:—Please write me the details of the treatment of burns, by the Ambrine method, particularly as regards its use in a spray. Is a hot air drier essential? Kindly state equipment necessary and usual cost, also where to purchase.

R. M. WILEY, M.D., Salem, Va.

ANSWER.—The secret proprietary "Ambrine" was found to consist essentially of a plastic form of paraffin with a small amount of a fatty oil and an asphalt-like body (Ambrine and Paraffin Films, THE JOURNAL, May 19, 1917, p. 1497). "New and Nonofficial Remedies, 1919," lists two forms of "Paraffin for Films"—"Parresine," which retails for about 75 cents a pound, and "Stanolind Surgical Wax," which is less expensive. The lesions are carefully washed with some antiseptic solution, such as the hypochlorites or chloramin-T. They are then dried by blotting with gauze or by means of a jet of hot air. Meantime, the solid paraffin (or mixture) is heated and cooled to about 50 C. The melted paraffin is applied by means of a fine brush (or sprayed by a specially devised atomizer) directly on the wound and on the adjacent unwounded surface, forming a thin film. (In some cases in which there is much pain, Sollmann and Beiter state that it may be more advisable to substitute a heavy coating of liquid petrolatum for the first paraffin film.) Over this is placed a fine layer of cotton, and it is coated with the paraffin. This in turn is covered with another layer of cotton, followed by a gauze bandage, which may be sealed by paraffin. Subsequently the lesions are cleaned in the same manner and again dressed. Sloughs and dead tissue are removed as found at the daily dressings.

The sprayers may be obtained from Max Woehner and Son Company, Cincinnati, the Abbott Laboratories, Chicago, or the DeVilbiss Manufacturing Company, Cleveland, who can supply current price quotations.

A reprint of certain articles on this general subject, from THE JOURNAL, will be sent on receipt of ten cents in stamps.

Mental Test of Sex Offenders.—Mental statistics for the first 900 persons examined by the social service department of the venereal disease division of the Michigan department of health illustrate that a large percentage of sex offenders are subnormal mentally. Of the whole number, 214 were feeble-minded and needed institutional care; 538 were feeble-minded but needed only supervision; twenty-seven were either insane or epileptic; ninety-four were normal; two were superior adults; in twenty-five cases the diagnosis was not completed.—*Social Hygiene Bull.*, October, 1919.

Connecticut July Examination

Dr. Edwin C. M. Hall, secretary of the Connecticut Homeopathic Medical Examining Board, reports the written examination held at New Haven, July 8, 1919. The examination covered 7 subjects, and included 70 questions. An average of 75 per cent. was required to pass. One candidate was examined, and passed. Three candidates were licensed on credentials. The following colleges were represented:

College	PASSED	Year Grad.	Per Cent.
New York Homoeo. Med. Coll. and Flower Hosp. ....	(1916)		78
LICENSED BY ENDORSEMENT OF CREDENTIALS			
College	Year Grad.	Certificate from	
Hahnemann Med. Coll. and Hosp. of Chicago ....	(1904)	Mass.	
Atlantic Medical College .....	(1909)	Penna.	
Boston University .....	(1906)	New Hamp.	

Kentucky July Examination

Dr. A. T. McCormack, secretary of the Kentucky State Board of Health, reports the written examination held at Louisville, July 1-3, 1919. The examination covered 10 subjects and included 100 questions. An average of 70 per cent. was required to pass. Of the twenty-five candidates examined, 21 passed and 4 failed. Eight candidates were licensed through reciprocity. One candidate, a graduate of Rush Medical College in 1918, was licensed on presentation of a certificate from the National Board of Medical Examiners. The following colleges were represented:

College	PASSED	Year Grad.	Per Cent.
University of Louisville (1916) 81, (1919) 81, 82, 83, 84, 84, 85, 85, 85, 86, 86, 87, 87, 87.			
University of Michigan .....	(1917)		91

## Social Medicine, Medical Economics and Miscellany

### MEDICAL INSPECTION OF SCHOOLS

Taliaferro Clark, in a discussion on the medical inspection of schools (*Public Health Reports* 31:2013 [Sept. 5] 1919), outlines the potent advantages and the minimal requirements of an acceptable health supervision of school-children. All endeavors to raise the standard of health of a given community naturally begin with the children. The value of medical inspection lies not only in the detection of remediable defects in the schoolchildren, but much more in the detection of remediable defects in the sanitary conditions with which the children are surrounded—ventilation, lighting, heating, construction of the individual desks, seating capacity of rooms, playgrounds and playground apparatus.

An outline is given of what an effective system of health supervision should provide, namely: (1) thorough sanitation of all buildings used for school purposes; (2) intelligent supervision of classrooms to detect and correct conditions injurious to the health of the pupils as soon as they arise; (3) full-time services of medical inspectors qualified to discharge the sanitary and medical duties of the school physicians; (4) full-time services of school nurses; (5) facilities for dental inspections; (6) provision whereby necessitous children may receive free treatment best suited to their needs, and (7) examination of all children who fail to progress normally in school work.

At times one hears objections made against medical inspection of schools on the ground that it is an interference with the rights of physicians, with the rights of parents; that it is the cause of an unwarranted increase in the tax rate and that it encourages parents in shifting to others responsibilities that they should bear themselves. Dr. Clark shows that the experience of the communities that have given health supervision of schoolchildren a full trial refutes any such charges. Interest in matters of health is greatly increased by the inspection; parents awake to the needs of the situation; the average number of years of instruction required per pupil is lessened owing to the greater efficiency of the pupils, and there is a gain all along the line, which more than compensates for the slight additional expense.

The scope of an effective and efficient medical inspection should include (1) examination for the presence of physical or mental defects which make it inadvisable for certain children to attend school; (2) the measuring and weighing of all children to determine the average physical development by sex and one-year age periods, and the utilization of such standards as an index of nutrition and as a guide to the discovery of harmful causes in the case of children who do not develop normally; (3) the discovery, removal and prevention of defects of dentition, hearing, posture and vision that hamper children in school work and retard their physical and mental development, and (4) aid to the health authorities in the control of communicable diseases.

An acceptable school physician should meet the following minimal requirements: 1. He should devote his full time to the supervision of the health of schoolchildren. 2. He should be skilled in medical diagnosis, and able to advise with and assist the family physician when it is so desired. 3. He should have a knowledge of bacteriology sufficient to enable him to take cultures, detect "carriers," and otherwise assist the health authorities so that it may be unnecessary to close schools during epidemics of communicable diseases. 4. He should be well grounded in the principles of personal and general hygiene, and have the ability to apply them to school purposes. 5. He should be competent to prescribing suitable exercises in individual cases to overcome postural defects, and advise with regard to regulated group exercises designed to promote the best physical development of normal children. 6. He should notify all parents of the presence of physical defects in their children as soon as these defects are discovered, and make reasonable efforts to have his recommendations carried out.

A full-time, specially qualified physician is needed for the work, and 2,000 schoolchildren constitute the average number that can be adequately served by one physician. A card index system with an inspection card for each pupil should be introduced. The pupil should receive a thorough examination on first entering school, and the results should be carefully recorded and filed. The inspection card should be sufficiently large to permit of adding notations from time to time as the pupil passes through the various grades of the school. Comparisons yearly (or more frequently) as to weight and height are valuable as indicative of proper or defective nutrition or of the onset of disease.

### STATE CONTROL OF VENEREAL DISEASES IN AUSTRALIA

Australia, which has served the world as an experimental field in social and economic affairs, is developing much advanced medical legislation. The serious attempt it has made at state control of venereal diseases is described by J. H. L. Cumpston, director of quarantine, in Service Publication 17, published recently at Melbourne.

Definite statutes directed at venereal disease control, and embodying the recommendations of a special committee appointed by the government in 1916, have become a part of the law of Tasmania, Queensland and Victoria. Western Australia already had on its law books an act passed in 1915. Legislation had followed rapidly in the three other states to protect the country from a wholesale spread of infection, feared from the discharge from the army of 55,000 men suffering from venereal diseases—comparatively few of whom had been diseased before entering the army, and many of whom would return to country districts, spreading the infection in regions hitherto almost free from it.

Among many detailed provisions of the legislation enacted are these:

1. It is obligatory on persons with venereal diseases to apply at once for treatment, and to continue treatment until given a physician's certificate of cure.

2. A record must be sent by physicians to the central authorities each time a patient appears for treatment. Neither the patient's name nor his address is included in this record of the disease, but must be obtained by the physician, and are forwarded later if the patient stops treatment before he is cured.

3. Notice is then to be served by the government, directing such patients to continue the treatment.

4. All prisoners with venereal disease may be detained in jail until cured.

5. Official examination must be submitted to by any person formally accused by another of having venereal disease.

6. Marriage may be annulled, in one state, if one of the parties to the contract has a venereal disease in an infectious stage and has not informed the other of his condition.

7. For one person to infect another, knowing he has venereal disease, is a serious and punishable offense.

8. Persistence by a diseased person in an intention to marry justifies warning being given by the state to the other party.

9. Proprietary medicines and appliances for the generative organs may not be advertised or sold.

10. It is recognized that free clinics must be established, as well as regular hospitals, for the care of venereal cases, and the central government offers financial assistance to the states on a dollar for dollar basis.

It is not expected that this legislation will result in complete eradication of venereal diseases; but it is expected that it will approach that ideal, and will put an end to great loss of life, insanity, sterility, destruction of family life, inefficiency and economic waste. The object of the legislation is that the disease shall be treated as a disease. All confusion with moral questions is avoided.

Knowledge of the source of infection is felt to be a matter of primary importance in attacking the condition. Investigation indicates that half of the venereal disease in Australia is contracted from women who are not professional prostitutes. It also appears that the disease is five times as prevalent among single as among married men.

About 1,619 notifications of applications for treatment have been received from physicians since the passage of the laws in 1917. This is considered as demonstrating a considerable measure of success, though prediction of ultimate complete success is hardly hazardous, for "in the present state of public opinion it is not possible to attempt the rigid enforcement of the law."

## Medicolegal

### Cleaning of Surface Closets as Health Measure

(*Rat. v. City of Gastonia et al. (N. C.), 99 S. E. R. 21*)

The Supreme Court of North Carolina, in affirming a judgment dissolving an order restraining the selling of a lot for charges for cleaning a surface closet in it and other closets owned by the plaintiff, holds valid the city ordinance under which the city was acting. The ordinance provided that each and every surface closet or privy in the city used in connection with a dwelling should be cleaned and inspected under the supervision of the city, for which a charge of 30 cents a month should be made, to be paid by the owner of the property, a penalty of 50 per cent. to be added in case of nonpayment, the charge to be a lien on the real estate, enforceable in the same manner as the lien for taxes. The court holds that this ordinance was a valid exercise of the power reposed in the town authorities for the protection of the health of the people of the town, and that it was fully authorized by the powers expressly conferred by the provision of the general statute of 1917, in regard to cities and towns, that the governing body, or officer or officers who may be designated for this purpose by the governing body, shall have the power summarily to remove, abate or remedy, or cause to be removed, abated or remedied, everything in the city limits, or within a mile of the limits, which is dangerous or prejudicial to the public health; and the expense of such action shall be paid by the person in default, and, if not paid, be a lien on the land, and be collected as unpaid taxes.

The court says that the town authorities not only have the power to impose such duty on the land for the necessary protection of the health of the citizens, but they would be derelict in their duty as such officials, and in proper cases liable to indictment for failure to protect the health of the public by such necessary regulation. Even if there had not been precedents sustaining such authority, the act of 1917 confers the power, and it may be that the authority would exist, even without the statute, as a necessary inference from the requirement and duty imposed on the town authorities to protect the public health. The enforcement of such regulations as this by an officer appointed by the city, directly through its officers and employees, not only is more economical, but it is the only method of making it efficient.

The necessity of sanitation is fully recognized and is becoming of more and more importance with the knowledge which we obtain of the causes of disease and death. Doubtless the time is not far distant when by statute all manufacturing establishments or industries employing more than a certain number of people will be required to institute sewerage in their tenement houses, even when located outside town limits, in order to protect the health of the employees and of the neighborhood as well. In most towns of any size, surface closets are abolished, and sewerage is required. In view of the advance of medical science and regard for that sanitation which must be universal in order to be at all effective, there must be an extension of the requirements which by experience have been demonstrated as necessary for the protection of the public health.

The public health is a matter of importance to the entire neighborhood, and especially to all the inhabitants of a town or city, for the indifference or ignorance or neglect of one man will nullify the precautions taken by all others in that locality. Such an ordinance as is here in question is a necessary protection, which will be extended in its scope

with the increase of knowledge, and can never be diminished. The requirement of sewerage will be better than such an ordinance as this, which is the minimum.

### Quarantine for Gonococcus Infection

(*Ex parte Johnston (Calif.), 180 Pac. R. 644*)

The District Court of Appeal of California, Second District, Division 1, says that, on the petitioner's application therefor, the supreme court issued a writ of habeas corpus returnable to this court after its denial of a similar petition. The writ, no doubt, was granted on the argument that she was not and never had been afflicted with the infection, which, if true, would entitle her to be discharged from custody; but the return to the writ and evidence taken at the hearing conclusively established the fact to the contrary; and she was remanded to custody.

The adoption of measures for the protection of the public health is universally conceded to be a valid exercise of the police power of the state, as to which the legislature is necessarily vested with large discretion, not only in determining what are contagious and infectious diseases, but also in adopting means for preventing the spread thereof. The legislature, having determined the character of the disease in question, imposed on the health department of the city the duty, when having knowledge that one is afflicted therewith, of taking the necessary measures to prevent its spread. In the absence of any showing to the contrary, this court must, on the evidence before it, assume that the petitioner was, when subjected to quarantine regulations, and was yet, afflicted with and suffering from gonococcus infection, which, by Section 2979 A of the Political Code, is, with leprosy, smallpox, typhus fever, and a number of other diseases, declared to be contagious and infectious. The sole question thus presented was the right of proper authorities to isolate and place her in quarantine. By the section of the code just cited it is made the duty of the health officer, knowing of the existence of any such contagious or infectious disease, to take such measures as may be necessary to prevent the spread thereof. The isolation of one afflicted with a contagious or infectious disease is a reasonable and proper, indeed, the usual, measure taken to prevent the increase and spread thereof.

It appeared that the petitioner was originally taken into custody without a warrant, and, basing his argument on such arbitrary action, counsel drew a lurid picture of what might result from maladministration of the law by those charged with the duty of enforcing it. But the fact that the authority so delegated may, in a given case, be abused, is no legal reason for denying the power to quarantine summarily in a case in which grounds therefor concededly exist. Possible maladministration of the law was no concern of the petitioner, unless such administration thereof was shown to have affected her. Nor could her arrest without a warrant, after which, and while being illegally held, an examination was made with her consent which disclosed the existence of the infection, avail her in this proceeding. Assuming the action of the police officer arbitrary and unjustified, she was not restrained of her liberty by reason thereof, but on account of a disease with which she was subsequently found to be afflicted, and in the ascertainment of which fact there appeared to have been no arbitrary or unlawful action taken.

There was no merit in the contention that the infection with which the petitioner was afflicted was noncommunicable except by actual contact, which contact in such cases must be predicated on the assumption that an offense cognizable by law would be committed. Assuming that grounds existed for the petitioner's contention, no evidence tending to establish such fact was presented, and it is not a matter as to which the court may take judicial notice.

Counsel cited no authorities in support of the contention that one afflicted with a contagious disease cannot be subjected to quarantine regulations until it is first judicially established by some proceeding in court that he is so afflicted. Manifestly to uphold such contention would render laws for the protection of the public health nugatory.

### COMING MEETINGS

American Child Hygiene Association, Asheville, N. C., Nov. 11-13.  
Southern Medical Association, Asheville, N. C., Nov. 12-13.  
Southern Minnesota Medical Assn., Mankato, Dec. 1-2.  
Society of American Bacteriologists, Boston, Mass., Dec. 30-31.  
South-ern Surgical Association, New Orleans, Dec. 16-18.  
Western Surgical Association, Kansas City, Dec. 15-16.

### MEDICAL SOCIETY OF THE STATE OF PENNSYLVANIA

Sixty-Ninth Annual Meeting, held at Harrisburg, Sept. 22-25, 1919

The President, DR. FREDERICK L. VAN SICKLE, Olyphant, in the Chair

#### Community Sanitation as Based on Knowledge of Camp Sanitation

DR. WILLIAM G. TURNBELL, Cresson: To secure for the communities the results obtained in camp sanitation, there must be centralization of authority; sanitary officers trained by the central health authority—to which body they must be responsible; employment of only licensed health officers—the salary to be sufficient to attract capable men and a pro rata share of such salary to be borne by the central authority, and a comprehensive campaign of health education that the cooperation of the public may be secured—such campaign to begin in the lowest grade of the public schools and to reach all ages and all walks of life.

#### Work of Sanitary Engineer in Pennsylvania Department of Health

MR. C. A. EMERSON, JR., Chief, Engineering Division: The principal work of the sanitary engineer is included under water supply, sewerage, waste disposal, milk supply and housing. The provision of a pure water supply constitutes the most important element of the work. We have 136 filter plants in Pennsylvania supplying pure water to over 4,000,000 people. Long time storage and filtration are the two well defined methods of water purification. To these may be added the chlorination of water as a protection against pollution. Since 1906 Pennsylvania's death rate from typhoid has dropped from 54.8 per hundred thousand to 10.1, a reduction of 81 per cent.

### SYMPOSIUM ON PNEUMONIA AND EMPYEMA

#### Diagnosis of Pneumonia

DR. THOMAS G. SIMONTON, Pittsburgh: Attention is drawn to the nerves in relation to the lung and to their position in the mediastinum. In a beginning pneumonia or septic peritonitis with irritation of the phrenic nerve, pain may be referred to the tip of the acromion by reason of the fact that the phrenic is the fourth cervical nerve and sends communicating branches to the brachial plexus which, in turn, supplies cutaneous branches to the tip of the acromion. Patients with pneumonia during the influenza epidemic complained of pain, and a sense of constriction in the throat. They exhibited hoarseness, croupy cough, partial or complete aphonia, and in some cases inspiratory dyspnea. These symptoms are attributed to the fact that the free fluid or swollen glands in the mediastinum, or the peribronchial inflammation, caused a recurrent laryngeal or vagus paralysis. Intubation or tracheotomy should be considered early.

#### Management of Pneumonia, Its Complications and Sequelae

DR. LAWRENCE LITCHFIELD, Pittsburgh: The immediate determination of the invading micro-organism is made necessary by the success of early serum treatment. Pleuritic exudate is to be drained only after aspiration is found to be insufficient; then rib resection is not advisable. Follow-up treatment should be carried out with Carrel's method and chloric feeding. It is important to maintain the water supply

of the body by intravenous injection of glucose solution, if other means are inadequate. Attention is called to the efficacy of atropin in beginning pulmonary edema,  $\frac{1}{50}$  grain every twelve hours, to the danger of feeding during the first days and of using opiates as a routine. Alarming distention of the abdomen may be due to acute gastric dilatation. It may be relieved promptly by the stomach tube. If the distention is in the intestine, pitted extract is a valuable adjunct to the usual enemas. An almost exhausted organism in pneumonia may be tided over by the free use of caffeine and ephedrin. During an epidemic, Dunham's nasopharyngeal disinfection is more dependable than vaccines as thus far established.

#### Surgical Complications

DR. EVAN W. MEREDITH, Pittsburgh: Empyema occurred in several base hospitals in from 7 to 15 per cent. of all types of cases of pneumonia. Pneumonia secondary to measles, and streptococcal bronchopneumonia gave the highest percentage. The incidence of peritonitis is difficult to determine, but at the necropsy a rather high percentage of bronchopneumonia cases will show involvement of the peritoneum. Suppurative perichondritis of the thyroid cartilage was observed in three patients. Abscesses in the abdominal wall in the suprapubic region were seen in two patients. Arthritis with effusion is a frequent complication. Two patients with encapsulated empyema in the upper part of the pleural cavity were for many weeks suspected of having tuberculosis. Drainage and resection resulted in prompt cure.

#### Acute Alveolar and Interstitial Emphysema in Influenzal Bronchopneumonia

DR. FRANK F. D. RECKORD, Harrisburg: Of 45,000 men, 14,000 became sufficiently ill with influenza to require hospital treatment. Of these, 2,500 developed pneumonia with a mortality of 800, or 32 per cent. From the first it was evident that death from influenza meant death from lung complications, pneumonia in some form. Bronchiectasis and interstitial emphysema were of rapid development. A striking type of reaction recognized was a condition of acute alveolar emphysema with the deposit of a hyaline fibrous material on the alveolar walls. It is the one distinctive feature in the pathology of influenzal pneumonias. The patient is virtually blowing bubbles in his own lungs, into a medium of exudation relatively poor in fibrin. The bacteriology of the lungs was mixed in a significant number of cases, but the one organism occurring with greatest constancy was the influenza bacillus.

#### DISCUSSION

DR. GEORGE R. MOFFITT, Harrisburg: In a number of cases of measles and pneumonia that came to necropsy we did not find the extensive bronchopneumonia described by Lucke. In many of the cases in which death had been sudden we would find from 2 to 3 liters of seropurulent fluid in the pleural cavity, and the lungs were filled with a thick, plastic exudate. This could not be withdrawn by pipets, thus explaining why it was not discovered before death. The necropsies generally showed hemolytic involvement of the lung. In the influenzal pneumonias we found the influenza bacillus in slightly more than 4 per cent. of the cases.

DR. M. HOWARD FUSSELL, Philadelphia: In the matter of referred pain in pneumonia it is to be remembered that many abdomens have been opened with the thought of appendicitis or gallbladder disease. In no case of supposed abdominal disease should an operation be done until after careful examination of the lungs. I agree with Dr. Litchfield that large amounts of water should be given in the pneumonia cases; nothing so reduces the toxemia. Not only is moving air a necessity, but it must be literally fresh air. While I would condemn the routine use of opiates, I consider the giving of a small dose of opium in a selected case preferable to the exhaustion from two sleepless nights. The occurrence of acute gastric dilatation following the crisis in pneumonia is not as well known as it should be.

DR. A. T. LIVINGSTON, Jamestown, N. Y.: No mention has been made of the basic factor underlying pneumonia or

other inflammation, namely, disturbance of the circulation. Inflammation is the result of abnormal dilatation of the capillary system in the affected part. Rickets cause disease because of stasis in the circulation. Disease will not be present if the circulation is maintained in proper condition. Ergot is the only drug that acts on the abnormally dilated capillaries.

DR. GEORGE E. HOLTZAPFEL, York: To surround the patient with plain or medicated steam is an exceedingly valuable procedure in combating the cyanosis following the administration of opium in small dosage.

#### Diagnosis and Treatment of Congenital Pyloric Stenosis

DR. ALBERT F. HARDT, Williamsport, Pa.: The first symptom that attracts attention is vomiting, frequently beginning as a regurgitation which gradually becomes worse until it becomes distinctly projectile in character, the vomit often being projected several feet. It occurs after each feeding or after several retained feedings. There is nothing distinctive about the character of the vomitus. Of all the symptoms, the vomiting is the most alarming. A peristaltic wave appears after food is taken, and radiates from the cardia to the pylorus. A tumor may be felt to the right and above the level of the umbilicus, usually a small movable mass. There are scanty stools and urine and progressive loss of weight. It is now generally agreed that only in the mildest cases with partial retention and with no loss or little loss of weight should expectant treatment be tried. In all other cases, operation should be advised at once.

#### DISCUSSION

DR. LEVI J. HAMMOND, Philadelphia: At times the tumor can be felt in the region of the pylorus, though more often the liver, which is invariably enlarged, so covers it over as to prevent its being palpated. The other symptoms are those naturally to be expected and incident on persistent vomiting. As the condition is surgical from the onset medical treatment should not be employed longer than is necessary to establish the diagnosis. Surgical treatment should consist in either pyloroplasty or posterior gastro-enterostomy; the former is indicated when the pathology is demonstrably localized. As this is not in my experience often possible, I have always elected posterior gastro-enterostomy, which I believe will meet the greater number of indications.

DR. JOHN J. GILBRIDE, Philadelphia: Congenital stenosis of the pylorus has a fairly definite symptomatology. Having a child with persistent vomiting in the presence of constipation, one might well suspect the presence of a stenosis of the pylorus; and the mere fact that the practitioner suspects such a condition leads him a long way toward making a correct diagnosis. One should be reasonably certain about the diagnosis before recommending operation, as operation on these little patients demands a very careful and painstaking technic in order that their lives shall not be sacrificed needlessly.

#### Fracture of the Pelvis

DR. SAMUEL P. MENGEL, Wilkes-Barre: There is no doubt that if roentgen-ray examinations were made as a routine in all doubtful cases, there would be a greater number of fractures of the pelvis, and incidentally, fewer recorded deaths from internal injuries. Fractures involving the crest of the ilium are very rarely complicated. Fractures of the pubes and ischium occur more frequently, are often multiple and complicated, and have a high mortality. Owing to the intensity of the fracturing force, the pelvis is crushed in many cases, with extensive damage to the soft parts. The necessary time requisite for a complete cure in these cases is directly proportionate to the extent of injury and the displacement of the bones. In suspected cases of ruptured bladder, an exploratory laparotomy should be performed as early after the injury as possible.

#### DISCUSSION

DR. WILLIAM L. ESTES, South Bethlehem: Fractures of the pelvis occur much oftener than one would suppose. They

occur very frequently in industrial establishments. Roentgen-ray examination is very essential to making the diagnosis.

DR. JOHN B. ROBERTS, Philadelphia: I was recently called to see a woman, aged 78, who had been knocked down by an automobile. She had a fracture of the face and was violently shocked. She had fracture of both bones of one leg. There was a good deal of confusion showing a blow about the hips. The roentgenogram disclosed a fracture of the pubis on one side.

#### Pulse Pressure in Traumatic Cerebral Compression

DR. HARRY M. ARMITAGE, Chester: In severe fractures of the base with widespread hemorrhage, the blood pressure symptoms are valueless. In traumatic cerebral compression when the local symptoms suggest a blood clot or a depressed fracture pressing on the brain, as evidenced by the roentgen ray, palpation or paralysis, the general symptoms, such as slowed pulse and blood pressure findings, may be of little value if the medulla is not involved by pressure. Operation is the only rational treatment in these cases. In cases with major symptoms of choked disk, headache, disturbed sensorium, coma, increased pressure of the cerebrospinal fluid and slow pulse, there is also invariably a high pulse pressure. The systolic pressure is too uncertain a factor to be of any value in diagnosing the amount of pressure. Our decision as to whether or not a patient should be trephined should be determined after grave reflection and consideration of the entire group of symptoms; but in all cases of head injury, frequent estimations of the pulse pressure and pulse rate should be made.

#### DISCUSSION

DR. LYNDON H. LANDON, Pittsburgh: In at least 80 per cent. of cranial cases the surgeon sees there is increased intracranial pressure. I rely very largely on the direct estimation of intracranial pressure by the spinal mercurial manometer. By lumbar puncture the presence or absence of blood is determined. It is important not to postpone decompression until the intracranial pressure reaches 40 or 59 mm. of mercury, until the pulse pressure far exceeds the pulse rate, and all the symptoms of Kocher's third stage have appeared. The time to consider operation is when signs of beginning compression appear.

DR. CHARLES H. FRAZIER, Philadelphia: Decision as to trephining should be determined after grave reflection and consideration of the entire group of symptoms; but in all cases of head injury, frequent estimations of pulse pressure should be made. If one were to rely on rise of blood pressure and choked disk as giving the indications for or against operation, it would be done in many instances in which it should not have been done and would not be done in many instances in which it should have been done. In determining the indications for or against operation, the whole clinical picture must be taken into consideration.

#### Pennsylvania's Campaign Against Venereal Diseases

DR. S. LEON GANS, Philadelphia: All means must be utilized to prevent infection. Methods must be employed to locate and detect infected persons. When infection is detected, treatment must be carried out until a cure is accomplished. Under prevention is classed the educational campaign, conducted by organizations which are being formed in every town in the state. These organizations will be composed of responsible men and women, their purpose being to carry education to the individual in his or her town. The block system has been successfully carried out, which brings comprehensive education into each home and deals with broad public health work. These organizations will supervise a system of talks to assemblies of men and women which will be graded as to sex and age and followed by the distribution of carefully prepared pamphlets. It is recommended that a selected course in sex instruction be introduced into schools, and that the parents, the clergy and the family physician be urged to discuss this problem so that the growing child will have a sane sexual education rather than a morbid sensual smattering. All inmates of penal institutions or reformatories are being examined and treated when infected. They will be given instructions concerning

prophylactic measures and the dangers of infection and the spread of venereal diseases. Framed posters will be distributed throughout the state giving information on venereal infection, advising the proper method of securing relief, and warning against quacks.

(To be continued)

## KENTUCKY STATE MEDICAL ASSOCIATION

Sixty-Ninth Annual Meeting, held at Ashland, Sept. 22-25, 1919

The President, DR. JOHN G. SOUTH, Frankfort, in the Chair

### Surgery of Thyrotoxicosis

DR. L. WALLACE FRANK, Louisville: The operation of thyroidectomy is not without danger, and should be undertaken only by those familiar with the anatomy of this region. Close to the gland lie the great vessels of the neck and also the recurrent laryngeal nerve. It is extremely easy to tear the thin walls or blood vessels of the gland. I saw a case in which even the inferior thyroid was torn close to the jugular. While the toxic thyroid may be a secondary condition, nevertheless, it is the seat of pathology and its removal produces cure or marked improvement.

### Epidemiology of Communicable Diseases

DR. IRVIN LINDENBERGER, Louisville: From results obtained thus far with the Rosenow vaccine in influenza, it appears possible to afford protection by prophylactic inoculation of persons against the more serious respiratory complications. The duration of the immunity is not known, but indications are that it is relatively short. As regards vaccine treatment, since the severer complications of influenza, such as pneumonia, do not usually begin until the fourth day or later, the vaccine, if given at the onset of the disease, might reasonably be expected to afford some protection. The initial prophylactic dose daily for one, two or three days, is recommended, provided no unfavorable symptoms occur. The vaccine is harmless, and a certain degree of protection is afforded. Prophylactic inoculation against the respiratory infections, so fatal during the epidemic, should be studied on a large scale by many according to the principles laid down. This endeavor is being made by the Kentucky State Board of Health at the present time. Reports on about 3,000 cases indicate that the vaccine decreases influenza, almost entirely prevents pneumonia and in practically no case in which it was used has death occurred. Inoculations were begun by the health department in Louisville, Dec. 4, 1918, and were continued until Jan. 10, 1919. Investigations made ninety days after the last inoculation show that 750 inoculations were given. One hundred and eighty persons could not be located; four persons contracted influenza after the third inoculation; no cases of pneumonia developed after the third inoculation.

### Tendency Toward State Medicine

DR. W. W. ANDERSON, Newport: The state function in medicine began with quarantine in a few diseases. We now have twenty-seven reportable diseases under the Kentucky law. Many of the states provide laboratory tests, antitoxins and vaccines free or at low cost. State care for defectives has advanced to meet the needs of the insane, feebleminded, idiotic, epileptic, blind, deaf, mute and incurable, and to sterilization of the unfit. Hospital service has greatly increased and extended outside in health stations, milk stations, fresh air, farms, community nursing and clinics. Clinics which originated for medical teaching alone have gone into public service, and we have baby clinics, maternity clinics, tuberculosis and venereal clinics. Our national government is greatly extending its activities in public health service and army medical supervision outside the army itself. State medicine is coming and we must prepare for it by, first, emphasizing to ourselves and to the public the high ideal of medicine, secondly, by excellence in present forms of medical work; thirdly, by better average quality of private practice.

### Roentgenography in Diagnosis of Tuberculosis

DR. J. H. BROWN, Winchester: Roentgenography affords opportunity for exact diagnosis of pulmonary tuberculosis in its incipency. Investigation has established beyond any doubt that in the great majority of cases the initial focus is in the hilum which is diagnosed only by means of the roentgen ray.

### War Surgery of Bones and Joints as Applied to Civil Practice

DR. ISAAC ARNOLD, Louisville: The factors which contribute to success are: (1) a competent surgeon, who is especially educated in mechanical surgery; (2) asepsis; (3) proper instruments and appliances to do good work; (4) proper equipment; (5) specially trained nurses and assistants; (6) cooperation on the part of the nurses and assistants; (7) absolute control of the patient. All the surgery done on bones and joints in military practice is applicable to civil life, except that the methods may have to be made slightly less radical.

### Diagnostic Significance of Vertigo to the General Practitioner

DR. J. D. HEITGER, Louisville: Vertigo may be caused by (1) a lesion in the ear or of the eighth nerve, such as hemorrhage, effusion, labyrinthitis, inflammation of the middle ear producing congestion and irritation of the labyrinth, leukemic infiltrations, trauma, neuritis, low grade specific meningitis, etc.; (2) lesions affecting the intracranial pathways, such as hemorrhage, trauma, tumor, abscess, thrombosis, infarction, tubercle and gumma, multiple sclerosis, syringomyelia, meningitis of various types, poliomyelitis; (3) involvement of the ear mechanism by toxemia from any organ or part of the body, chemical poisoning from alcohol, lead, salicylates, quinin, infectious fevers and local infections; (4) involvement of the ear mechanism by ocular disturbances or by circulatory disturbances, cardiorenal and cardiovascular conditions. Vertigo involves essentially a study of the vestibular apparatus. It signifies a disturbance of that apparatus.

### Early Diagnosis in Diseases of Rectum

DR. BERNARD ASMAN, Louisville: In no part of the body is disease more frequent than in the rectum and anorectal regions, and in no other part of the body is disease more frequently overlooked or longer neglected. The apathy or failure on the part of many physicians to care for rectal diseases properly is not attributable to incompetence, but to negligence and to following blindly a long-established but vicious custom. The great importance of more frequent rectal examinations should be emphasized and urged on each individual member of the medical profession.

### Diagnosis of Peripheral Nerve Injuries

DR. B. F. ZIMMERMAN, Louisville: Peripheral nerve lesions are differentiated from lesions of the central nervous system by the history; location of the injury; by the fact that a paralysis of central origin is spastic and not flaccid; that the reflexes are increased, and that the paralysis does not coincide with the distribution of the peripheral nerve. In paralysis of central origin more frequently the entire limb is paralyzed; but if the lesion is in the cord and is small, paralysis may be limited to certain muscles of the extremity. In such a case the paralysis is segmental or of the root type, and does not correspond to any given nerve.

### An All-Time Health Officer

DR. J. A. PHELPS, Hickman: The aim of the health officer is the prevention of disease, and to this end he owes it to himself, to the public and to his profession to be the possessor of an intimate knowledge of every community under his supervision. He should be advised promptly of every outbreak of infectious or communicable disease in the county, and when he is so advised he can then make a personal inspection of the surroundings and conditions and remove the cause.

### Prostatectomy

DR. J. HENNER PEAK, Louisville: Prostatectomy is indicated when from any cause the prostate gland becomes suffi-

cally enlarged to interfere markedly with micturition and endanger the life of the individual from infection of the urinary tract which almost invariably supervenes sooner or later. The only exception to this rule is where prostatic enlargement is due to acute infection which usually subsides under appropriate medical treatment. I have performed about 800 prostatectomies, with only three fatalities, and these followed the suprapubic operation. One patient, 84 years of age, died from the anesthetic and shock. The second patient contracted pneumonia just as he was to be discharged from the hospital. The third patient had a rapidly growing fibrosarcoma. Death occurred eight weeks after the operation from extension of the malignant process.

#### The Obstructing Prostate

DR. CARL LEWIS WHEELER, Lexington: I suggest the term "obstructing prostate" to supplant the terms "prostatic hypertrophy," "enlarged prostate" and "prostatism." Too many prostates are being removed which are suspiciously malignant, suspicion only being aroused by the postoperative report of the pathologist. It is a well-known fact that carcinomatous areas can be detected in the midst of an adenomatous prostate. In this type of prostate, why should we operate? These patients should be subjected only to radium. I prefer the suprapubic route, and strongly advocate the two-stage operation, the first stage being done under local anesthesia, when it is possible, the second stage under gas and oxygen with as short an anesthesia as will suffice. The interval between first and second stages varies between two and six weeks. Forced feeding is begun at the same time drainage is instituted. In several instances, patients have gained as much as 30 pounds before the time for the second stage has been reached.

#### Tuberculous Peritonitis

DR. CHARLES A. VANCE, Lexington: Tuberculous peritonitis is most common between the ages of 20 and 40, and females are affected more than males, owing to the occurrence of tuberculous salpingitis. Tuberculous peritonitis predisposes to abdominal catastrophes by causing adhesions which bind down the intestinal coils. Tuberculous mesenteric glands produce adhesions between the glands and the adjacent coils of intestine, or, by breaking down into abscesses, produce suppurative peritonitis. Tuberculous peritonitis demands internal treatment. Only under special conditions does it require surgical treatment. The treatment is, in general, the same as that for tuberculosis in other parts of the body and consists mainly in rest, proper food, fresh air and general hygienic measures. Tuberculin may be used in selected cases. The disappearance of the effusion, when it is present, may be hastened by moderate purgation, by restriction of the diet, and by the use of ordinary diuretics. Treatment by the roentgen ray has benefited some patients. Laparotomy is indicated in the cases of serous effusion, if after several weeks of conservative treatment, satisfactory progress has not been made. Other indications for laparotomy are the presence of well-defined and probable primary foci in the tubes or appendix, a localized suppurative process, or the presence of some condition causing partial or complete intestinal obstruction. At operation, the primary focus must be removed, if possible. The abdomen is closed without drainage. The ulcerative types and those without effusion are unsuitable for operation and should not be operated on, except in the presence of definite indications. In the purely adhesive type, operation is almost hopeless. Nitrous oxid-oxygen anesthesia should be used in all tuberculous cases as a precaution against lighting up or aggravating pulmonary lesions, which is a real danger if ether is used.

#### Fractures of Cervical Vertebrae

DR. F. P. STRICKLER, JR., Louisville: Fractures of the cervical vertebrae constitute from 25 to 36 per cent. of all spinal fractures, and occur most frequently in the male of middle age. Several vertebrae may be fractured and dislocated at one time, but the parts most frequently involved are the body. When this is the case the fracture is usually accompanied by dislocation and compression which produce a

rather sharp kyphosis. The spinous and transverse processes are also frequently the site of fracture, but in fractures of this nature there may not be much deformity. The site of these fractures, fracture dislocations and compression fractures is in the larger number of cases found in the lower cervical vertebrae. The nerve symptoms found in fracture and dislocation of the cervical vertebrae are produced by contusion or crushing of the cord at the time of injury, or by persistent compression of the cord by fragments of bone, effusions, blood clots, and later on by callus or the products of inflammatory changes.

If few or no cord symptoms are manifested, either the conservative or operative treatment may be employed, depending on which form of treatment will give the best results in the individual case. The conservative treatment is carried out by immobilizing the spine in plaster-of-Paris jackets, the Calot jacket being the type most frequently used in fractures of the cervical region. If the operative treatment is decided on, one of two operations may be used—the Albee or the Hibbs. The prognosis is guarded. In those cases in which there are marked cord lesions it is very grave, for few, if any, of these patients show improvement. The case usually terminates in death.

#### Diagnosis and Treatment of Cerebrospinal Meningitis

DR. E. B. BRADLEY, Lexington: It is highly desirable to recognize the disease early—if possible before meningitis develops. This may be done by a combination of clinical and laboratory findings. If the spinal fluid is negative at first, a second puncture two hours later may show organisms. Repeated punctures should be made, if necessary, and every method used to cultivate the organism from the blood. Treatment with large doses of antimeningitis serum intravenously should be used as early as possible, combined, when meningitis is present, with intraspinal injection. This treatment lowers the mortality of the severe cases from about 66 to 17 per cent., and in those cases in which the diagnosis is made late the mortality is reduced from 42 to 19 per cent. Complications are also greatly reduced.

#### Early Diagnosis of Valvular Heart Disease

DR. C. W. DOWDEN, Louisville: For the diagnosis of mitral stenosis, a presystolic or diastolic murmur must be present, and this can be intensified and detected much earlier by the use of the amyl nitrite test. Disease of the aortic valve can best be detected with the patient in a bent forward position, after exercise, and with the examiner's ear over the chest. For the diagnosis of mitral regurgitation, in addition to the murmur, cardiac hypertrophy, or a history of rheumatism, is necessary.

### INDIANA STATE MEDICAL ASSOCIATION

Annual Meeting, held in Indianapolis, Sept. 26-27, 1919  
(Concluded from p. 1309)

#### Blood Sugar in Cancer

DR. SCOTT EDWARDS, Indianapolis: Normal blood sugar varies from 0.07 to 0.14 per cent., with an average of 0.10 per cent. The curve in a normal individual generally reaches its peak near the forty-five minute interval and is well back to normal or entirely so at the end of two hours. In contrast to the normal curve, the cancer curve reaches approximately 200 gm. per hundred c.c., and at the two hour interval, after the glucose is ingested, the blood sugar is approximately the same figure or it may be considerably higher. The normal is reached in from three to four hours. The curve in all other diseases examined, except one, followed the general contour of the normal curve. In one case, which was later diagnosed as pernicious anemia, the curve was typically that encountered in cancer. I feel, therefore, that while blood sugar tolerance determination offers some diagnostic evidence, it is of greater value as a method of eliminating cancer than in proving its existence. A failure to establish such a curve is strong evidence against malignancy.

### Lipovaccines

DR. A. PARKER HITCHENS, Indianapolis: In the military emergency the lipovaccines were valuable because of the difference between a single dose vaccine and one which required ten days to administer; but in civil practice, especially in the prophylaxis against the complicating infections of influenza, I would prefer at the present time to use saline vaccines. I do, however, prefer typhoid lipovaccine because I believe its value has been demonstrated thoroughly.

#### DISCUSSION ON PAPERS OF DRs. EDWARDS AND HITCHENS

DR. H. K. LANGDON, Indianapolis: The question of sugar tolerance must not be a question of theory, but of fact; and if this curve proves constant and is demonstrable in the early stages of malignancy it will be of untold value. The true value of lipovaccine will be determined only by the test of time.

DR. THOMAS C. KENNEDY, Indianapolis: What we need most of all in cancer is early diagnosis, and I hope that Dr. Edwards will continue his work and report if he finds anything of value.

### Some Fractures of the Pelvis

DR. CHARLES HAYWOOD, Elkhart: In the treatment of fracture of the pelvis, the first thought is reduction of the fragments and means for holding them in apposition. Violent manipulations must be avoided because of their tendency to increase shock as well as the extent of the visceral injury. Careful manipulation of the limb is often necessary to assist in digital manipulations through the rectum or vagina. In fractures of the crest of the ilium, supporting sand bags are all that is necessary, and are preferable to bandaging. In fracture of the pubes and rami of the ischium a cast is sometimes employed, but the same result can be accomplished better by adhesive strips. In wide separation of the fragments, resort may be had to wiring. Fracture of the acetabulum and penetration by the head of the femur will require traction laterally and probably the Beck extension. In all these cases the ingenuity of the surgeon is called into play in order to employ the proper means of immobilization and to make the patient comfortable.

### Relative Merits of Surgery, Radium and Roentgen Ray in the Treatment of Uterine Fibroids

DR. E. E. PADGETT, Indianapolis: The cases of uterine fibroid to be treated by means other than surgery are a very small minority, being only those cases that are unfit for surgery.

### Chronic Uterine Infections

DR. WALTER H. BAKER, South Bend: Surgery of the female pelvis could be undertaken in these cases with much more confidence, and would ultimately be much more successful, if we knew better all of the physiology and pathology of the internal secretions of the ovary and the relation they bear to other internal secretions. A few observers have argued that the tubes and uterus play a part in the internal secretion of the ovary, that without them the ovarian secretion did not functionate properly and a vasomotor complex would arise. Undoubtedly the internal secretion from the ovary persists for many years after the reproductive function has subsided.

#### DISCUSSION ON PAPERS OF DRs. HAYWOOD, PADGETT AND BAKER

DR. THOMAS C. KENNEDY, Indianapolis: Workers with radium have been convinced of its efficacy in the treatment of fibroids, and I believe that it will only be a short time until the most skeptical will be convinced that it is the treatment of choice in a large number of cases of uterine fibroids. Of course, it must be used with care, but it is readily controllable in skilled hands.

DR. EDMUND D. CLARK, Indianapolis: I believe there is a middle ground in this question. I do not by any means believe that all fibroids should be treated by radium or the roentgen ray, nor do I believe that they should all be treated by surgery. Of course, pyosalpinx, appendicitis and gallbladder disease should be eliminated; we should simply treat fibroids by radium or roentgen ray, and the treatment should be limited to small fibroids. Large tumors should

be removed. The conservative surgeon is the man who operates quickly when his diagnosis convinces him that surgical work is necessary.

DR. J. R. EASTMAN, Indianapolis: I am sure we conserve life when we take out an infected appendix promptly on making the diagnosis.

DR. H. K. BONN, Indianapolis: We must beware of a false conservatism. In the surgery of the female pelvic organs we should have less so-called "conservative" surgery and more complete work.

DR. A. M. COLE, Indianapolis: The treatment of uterine fibroids by the roentgen ray has passed the experimental stage, and this method must take its place as a legitimate and highly efficient therapeutic agent in these cases.

DR. O. G. PRAFF, Indianapolis: Small fibroids (the class in which the use of roentgen ray or radium is recommended) can be removed surgically at one sitting under gas anesthesia with very little discomfort and almost without mortality. Large tumors should not be subjected to roentgen ray or radium treatment. As to the appendix, we shall save the greatest number of lives if we operate in every case as soon as the diagnosis is made if the patient can stand an anesthetic. The earlier the better.

DR. H. O. PANTZER, Indianapolis: These divergent views emphasize the fact that we have not yet such scientific data as will enable us to do in every instance what is satisfactory for the patient in making differential diagnoses and seeking or finding the proper remedy. I myself feel that we have reason to antagonize the free, invariable use of radium and the roentgen ray for fibroids, considering the extremely low mortality of surgery in these cases.

DR. W. D. GATCH, Indianapolis: In regard to the mortality of the operation for fibroid, it seems to me there are two factors beyond our control which are bound to cause a considerable mortality. These are possible sepsis in degenerated submucous fibroids, and embolism. Under the best of conditions the mortality from embolism will be from 2 to 5 per cent. We can cure most of these patients by roentgen ray or radium.

### Hour-Glass Bladder

DR. JI. K. BONN, Indianapolis: This case was an apparently true "hour-glass" bladder, the two compartments connecting with one another by means of a ringlike opening which admitted only the index finger. The anterior septum of this ring was divided in one plane and then resutured in the plane opposite to that of division. Four fingers could now be passed from one vesical cavity into the other. The patient, a man aged 62, made an uneventful recovery and remains free from symptoms.

### Renal Tuberculosis

DR. P. E. McCOWN, Indianapolis: Early diagnosis is most important in renal tuberculosis, and early nephrectomy is indicated. A large incision will be of great help in exposing the kidney and getting to its pedicle; it will save time and save maceration of the kidney and wound contamination. It seems best to divide the ureter first, permitting greater access to renal vessels. The vessels should be well cleaned of adhesions to insure secure ligation. Single thread ligatures, repeated if desired, are less likely to slip than double threads.

### Prostatectomy

DRs. W. N. WISLARD AND H. G. HAMER, Indianapolis: Of 120 patients, the oldest was 84 and the youngest 45 years of age. Symptoms at time of consultation were frequency and difficulty of urination in fifty-five cases; frequency, difficulty and pain in thirty-seven cases; marked hematuria in three cases, and complete retention in fourteen cases. Forty-eight of these patients had used a catheter prior to consultation. All patients were operated on by the suprapubic method; eighty-seven by the two stage method; the average interval between the preliminary cystostomy and the enucleation was two or three weeks.

Post-operative results were: There was residual urine, from  $\frac{1}{2}$  ounce to  $3\frac{1}{2}$  ounces, in ten cases. One patient had 6 or 7 ounces and a recurrence of hypertrophy in the subcervical

prostatic glands which are being destroyed by fulguration. The other patients have good emptying power and good control, except one who has some incontinence, probably resulting from a spinal lesion. The mortality from the operation was 1.66% per cent.

DISCUSSION ON PAPERS OF DRS. BONN, McCOWN,  
WISHARD AND HAMER

DR. WILLIAM S. ERICH, Evansville: Thorough preparation is a very important, if not the most important, element for the success of prostatic surgery.

DR. FRANK H. JETT, Terre Haute: The reason appendicitis patients do better than gallbladder or prostatic patients is that they have been taught that they need operation and need it at once.

DR. J. C. FLEMING, Elkhart: The fatalities following prostatectomy may be divided into three classes: cases of malignancy, cases in which there is excessive hemorrhage, and cases that are not allowed to clear up entirely after their preliminary drainage.

**Cardiac Phase of War Neuroses.**—The special purpose of Cohn's paper is to point out milestones in the history of this subject. Da Costa first defined it in 1871. On the basis of his work the study continued in this war. In his view the disorder arose most often as the result of infectious diseases, was most likely a functional disorder, going on to organic change in the heart, and was certainly affected beneficially by drugs. The symptoms which he described, and which are now recognized are alike. At present it is believed that the matter was the predisposing cause, whether it be infectious disease, malfunctioning glands of internal secretion or gas poisoning, the disorder is essentially a neurosis, depending on anxiety and fear; that it is removed by the disappearance of the exciting cause and that it is cured by measures designed to influence the neurotic state.

**Long Duration of Remission in Pernicious Anemia.**—Stockton saw his patient for the first time in 1899. It was in all respects a typical case of pernicious anemia. There was an irregular improvement for six years, at which time, although there was a moderate anemia, the blood lost all characteristics of the pernicious type. In 1907 no abnormal cells were found. The blood was in every way satisfactory. In 1918, there was a sharp recurrence which soon became

threatening. The patient failed to respond to the action of atoxyl and sodium cacodylate, which drugs formerly had appeared to be of benefit. A transfusion led to temporary improvement. Three weeks afterward the patient developed lobar pneumonia and died three days later, nearly twenty years after the recognition of her first attack of pernicious anemia. In this case there was disappearance of all evidence of the disease, except a continuance of achylia gastrica. Stockton says he had never found an exception to the rule of the presence, sooner or later, of achylia gastrica.

**Meningococcus Arthritis.**—A study of an epidemic of 321 cases of meningococcus infection impressed Herrick and Parkhurst with the frequency of arthritis, with the variety of its manifestations and with the clinical profit of a separation of these arthritides into different forms or types. The result of their studies has been the classification of these varieties of arthritis met with in meningococcus infections. The authors classify this arthritis in three forms. Type A is an acute polyarthritides that is frequently the initial symptom, more often one of a number of symptoms of onset, and that does not, except in rare cases, appear later than the third day of the disease. This type is a feature of many of the cases of severe infections and is usually a harbinger of a stormy course. Almost all these patients have profuse hemorrhagic rashes coincident with the polyarthritides. In many, but not in all instances, the arthritis is as transitory as the rash. It would seem that these early joint symptoms are due to hemorrhage into the articular and periarticular structures, especially the synovial membrane that they are identical with the hemorrhagic lesions of the skin and serous membranes. The clinical picture is not unlike that of acute rheumatic polyarthritides. In Type B the onset is late, usually about the fifth day. With few exceptions only one joint is affected, generally the knee, occasionally the ankle, hip, shoulder, wrist or elbow. Effusion is a prominent feature, so that aspiration of the synovial capsule is suggested in many cases. Swelling is great, but redness, pain, tenderness and limitation of motion are surprisingly slight. In no other acute arthritis is there this striking disproportion between the swelling and the other inflammatory signs. The duration of the process is usually from one to four weeks, recovery being gradual, but complete. Type C is the well known serum arthritis.

**Ascending Renal Tuberculosis.**—Buerger gives what he regards as clinical and pathologic proof of the occurrence of cases of ascending renal tuberculosis, ascending at least in the sense that the renal and ureteral lesions are secondary to the bladder involvement.

**Atropin in Effort Syndrome.**—In cases of "irritable heart" studied by Sturgis, Wearn and Tompkins and in normal men after injection of atropin sulphate there was generally a preliminary drop followed by an increase in pulse rate. This increase was greater on the average in the "irritable heart" cases than in the normal controls. There was also a drop in pulse pressure in the majority of the subjects, dependent on a rise in diastolic blood pressure in the majority of cases and on an additional drop in systolic blood pressure in some of the cases. There was no increase in basal metabolism after the subcutaneous injection of atropin sulphate. There was a slight fall in the basal metabolism in three of the six cases studied. There was always a slight drop in the respiratory quotient.

**Differentiation of Pulmonary Abscess, Bronchiectasis and Tuberculosis.**—Pottenger states that a history of persistent expectoration of moderate or large quantities of sputum, with a diminished respiratory excursion on one side of the chest and an absence or paucity of crepitations or mucous râles on auscultation over the side affected should make one think of pulmonary abscess or bronchiectasis. Ronchi are often present but they, too, may be absent.

**Imminent Psychology.**—Collins predicts a glorious future for psychology, in fact all transactions will be placed on a psychologic basis: work, occupation, recreation; the spiritual, physical, social, financial, hygienic betterment of mankind; admission to schools, colleges and universities; choice

of profession, occupation or career; promotion or advancement in any intellectual field will be determined by psychologic examination of the individual seeking position and preferment. Medicine will be quickened, revived and enriched by doing teamwork with the science of psychology.

**Diagnosis of Bronchiectasis.**—Stivelman emphasizes that a diagnosis of bronchiectasis may be arrived at only after a careful history of the case has been taken and painstaking repeated physical examinations have been made. Given a patient with a history of cough and profuse expectoration of many years' duration following pneumonia, yet well nourished, leading a moderately active life, especially when no history of such constitutional symptoms as tachycardia, chills, fever and sweats can be obtained, and the abundant sputum after repeated and careful examinations does not show the presence of tubercle bacilli, it is most probable that the disease in question is not tuberculous in character, although hemoptysis may have occurred. When this is supplemented by repeated physical explorations of the chest, which show that the lesion is to be found exclusively at either or both lower lobes and that the apices are free from disease, a diagnosis of bronchiectasis may be justifiable. Guinea-pig inoculation of the sputum in question may rule out tuberculosis. Roentgenoscopy and at times bronchoscopy may be of assistance. Tuberculosis complex fixation is not as yet reliable. Extensive basal tuberculosis is most frequently a terminal condition and is associated with bilateral upper lobe involvement and marked constitutional symptoms of toxemia.

**Leukocytosis in Chronic Appendicitis.**—Transitional leukocytosis or an increase in large mononuclears and in transitional leukocytes, or an increase in either of them was found by Friedman in the blood of 87 per cent. of patients in whom evidence of chronic appendicitis was obtained. There was no transitional leukocytosis in the blood of patients in whom evidence of chronic peptic ulcer was obtained or in the blood of those in whom cholecystitis, renal stones or other organic abdominal conditions were found at operation. A transitional leukocytosis was found in patients in whom appendicitis was present, with other organic abdominal conditions. A hyperleukocytosis and a polynuclear leukocytosis are not as frequently found in chronic appendicitis as is a transitional leukocytosis. A transitional leukocytosis as a diagnostic aid of chronic appendicitis, Friedman says, is superior to roentgen signs which are supposed directly or indirectly to point to a diseased appendix. Transitional leukocytosis often persists in the blood after an appendectomy is performed.

**Mediastinal Hodgkin's Granuloma.**—A case of neoplastic growth having the tissue characteristics of Hodgkin's granuloma situated primarily in the mediastinum is described by Lyon. It occurred in a young adult, white, male, of good previous and family histories. Its duration was sixteen months. The neoplastic mass caused pressure erosion of the chest wall; the right pleura became infected and a retropleural and retroperitoneal abscess developed, the patient dying of toxemia and exhaustion. The chief pathologic findings were extension of the mediastinal neoplastic growth into the right lung, involvement of the bronchial and mediastinal lymph nodes, of many abdominal lymph nodes and of the retroperitoneal and inguinal nodes. Metastatic growths were found in the unenlarged spleen, in the tail of the pancreas, in the right kidney and in the epicardium and of the pancreas, in the right kidney and in the epicardium and beginning to invade the myocardium. The liver and the cervical, maxillary and axillary lymph nodes were uninvolvement.

**Blood Volume in Wound Hemorrhage and Shock.**—The observations reported by Lee seem to indicate the importance of blood volume in wound hemorrhage and shock. Profound disturbances of blood volume are always serious, and if maintained for any considerable period are usually associated with death. Blood volume can be estimated easily and roughly by comparative readings of the hemoglobin percentage before and after the intravenous infusion of a known amount of fluid. The milder cases of wound hemorrhage and shock require only an increase in blood volume. The

severer cases require both an increase in blood volume and an increase in oxygen carrying constituent. This double requirement is met in part by transfusion. However, when transfusion is indicated it is usually desirable still further to increase the blood volume, which may be accomplished in various ways. Continued observations on blood volume give, furthermore, valuable information as to prognosis. A general study of blood volume strongly suggests certain procedures which may be utilized for the prevention and control of the associated symptom complex known as wound hemorrhage and shock.

**Exudates Complicating Influenza.**—The pleural fluids of seventeen cases of influenza pneumonia occurring in previously healthy individuals, were examined by Luke and Barker. The cells encountered were: polymorphonuclear leukocytes, large and small lymphocytes and so-called transitional cells slightly larger than the leukocytes and having a single indented nucleus. Besides these there occurred considerably larger, oval or round mononuclear cells measuring from 10 to 20 microns and possessing a large, usually deep staining nucleus, with several prominent nucleoli and pale staining cloudy protoplasm. Their cytoplasm frequently shows numerous small vacuoles, probably evidences of degeneration. In ten of the seventeen cases examined endothelial cells constituted over 40 per cent. of the total number. In five of these cases they even formed over 70 per cent. of the cells present. These endothelial cells are slightly phagocytic for erythrocytes and occasionally engulf bacteria.

Use of Very Small Dosages of Pituitary Extract in Inducing Labor at Term in Combination with Nitrous Oxid Anesthesia to Alleviate Labor Pains. A. Stein, New York.—p. 470.

**Carcinoma of Ovary.**—Spalding reports a case of carcinoma of the ovary arising from the epithelial lining of a cystic teratoma. The tumor was noted some days after operation following laboratory examination. The patient reports every six months for examination. Two years have elapsed since the teratoma was removed and there is no sign of recurrence.

**Sterility and Dysmenorrhea.**—After careful consideration of a series of cases, several of which are cited, Holden believes that further experience with endocrines will tend to clarify our present position in regard to the treatment of dysmenorrhea and sterility. Operative procedures alone give a small percentage of successes and sometimes add a troublesome pathologic condition of the genital organs to the symptoms of dysmenorrhea and sterility.

**Omaha Detention Home for Women.**—About one year ago this institution was opened and Findley makes a report on the work. Of a total of 275 women admitted to the institution all but eight were gonorrhoeic, 70 per cent., were also syphilitic though only one in ten showed any clinical evidence of syphilis. The complement fixation test for gonorrhoea was of no practical value. In only 30 per cent. of the cases, which ultimately revealed the gonococcus, was the organism found in the first examination and in isolated cases the gonococcus was not revealed until the eighth, tenth and in one instance the fifteenth successive daily examination. In

only 2 per cent did the tubes reveal any evidence of infection in the clinical examinations. More than half the women were drug addicts and all were social delinquents. As a moral problem, Findley says, the work was most discouraging. He doubts that the public is as yet ready for this reform movement. Public sentiment is as yet not crystallized, but much has been accomplished in educating the public and there is no doubt that the U. S. P. H. Service will perform an invaluable service in continuing the propaganda that has been so effectively pursued in the past year.

Loss of Sight from Retrobulbar Neuritis Due to Posterior Accessory Sinus Diseases. Report of Seventeen Cases. L. E. White, Boston.—p. 483.

**Treatment of Carcinoma of Skin with Radium.**—The statistics analyzed by Simmons show that in 72.5 per cent. of the cases of carcinoma of the skin suitable for radium treatment an immediate cure is to be expected, and of these 90 per cent. will remain free from the disease or if a recurrence does take place, it will yield readily to further light treatment. It is maintained, however, that in cases of epidermoid carcinoma in which the growth can be removed easily without marked resulting deformity, or cases in which metastases are likely to occur, operation is the treatment of choice. Of the twenty-eight patients treated by operation, twenty-six were alive and free from recurrence one or more years later. Ten of these cases were of carcinoma about the orbit so extensive that removal of the orbital contents, together with the lids, was considered advisable. Nine of these patients are still free from recurrence. Five were operated on as radium failed to destroy the disease.

### Colorado Medicine, Denver

October, 1919, 16, No. 10

Litter Learning—and the Rocky Mountain News. C. S. Blumel, Denver—p. 239.

Progress and Problems in Medicine. F. H. McNaught, Denver—p. 240.

Tuberculosis in Children. G. H. Cattermole, Boulder—p. 244.

\*Von Pirquet Test and Results of Its Use. E. Friedman, Denver.—p. 246.

**Results from Use of Von Pirquet Test.**—Friedman has performed the von Pirquet test 525 times on 464 unselected patients ranging in age from a few months to 18 years. Nearly all the children tested were of Jewish parentage, living under conditions comparable with those prevailing among the poorer working classes of the larger cities. Most of the children were of tuberculous parents, many of whom had been inmates of a sanatorium where they had had thoroughly inculcated rules of prophylaxis, which were observed scrupulously in many of the homes. Of the 465 children tested, 39.8 per cent. reacted positively, the number of positives among the males being 2 per cent. in excess of those in the females. Under 1 year, almost 12 per cent. reacted positively; from 10 to 14 years, 55 per cent., and from 14 to 18 years, only 51 per cent. reacted positively. The highest number of positive reactions was noted during the eleventh to thirteenth year period, with 66.7 per cent.; and the lowest at the fifth and the sixth year period, with only 13 per cent. positive. Of the 274 children having a tuberculous parent 53.6 per cent. reacted positively; of the 181 not exposed in this wise, only 23.2 per cent., or less than half reacted. Of the nonexposed, 135 were born in Colorado, and only 20.7 per cent. reacted positively, as compared with 25 per cent. of the boys. Of the 126 children born in Colorado and exposed to tuberculosis, 56.4 per cent. of the girls and 42.3 per cent. of the boys reacted positively. Of 189 children exposed to a parent with open tuberculosis, 58 per cent. reacted positively; of seventy-eight exposed to a closed case, 38.5 per cent. reacted; whereas, nonexposed children reacted only to the extent of 23.2 per cent. Of those children whose father harbored closed tuberculosis, only 27.6 per cent. reacted posi-

tively; and when exposed to a mother with closed tuberculosis almost double the number, or 48.4 per cent., showed positive reactions. An observation deserving recognition is, that of the female children exposed to a father with closed tuberculosis, 40.7 per cent. become infected; whereas of the male offspring similarly exposed, only 10 per cent. or less than one fourth react positively. On the other hand, boys and girls exposed to either parent with open tuberculosis react in about equal ratio; eight children had both parents tuberculous, and seven reacted positively. Tuberculous infection is said to exercise a retarding influence on the physical growth of the child. Friedman found that of children reacting positively, 61.8 per cent. are below normal in development, 20 per cent. are normal, and 19.5 per cent. are above normal. Of those with negative reactions, 56.1 per cent. are below normal, 31 per cent. are normal, and 12.6 per cent. are above normal. Infected children under 7 years of age show relatively less developmental impairment than do those above the age.

Endocrinopathic Constitutions and Pathology of War. N. Pende, Palermo, Italy—p. 329.

**Fetal and Maternal Athyrosis.**—Smith maintains that the occurrence of disorders of the teeth, nails and hair during pregnancy indicates that there is a very wide occurrence of a more or less severe form of maternal athyrosis. The increase of the proteolytic enzymes in the blood of the pregnant woman tends to produce a condition similar to that under which fetal and maternal athyrosis is produced among domestic animals—not an abnormal condition, but still one that requires an abundant supply of iodine. Lack of function of the thyroid is a probable cause of albuminuria and toxemia of pregnancy which may be overcome by an abundant supply of iodine. A milk diet for the elimination of toxemia of pregnancy will probably be very disastrous to the fetus unless it be supplemented with an abundant supply of iodine. When either of the parents is suffering from a disturbance of the thyroid it is imperative that the ordinary diet should be supplemented with an abundant supply of iodine throughout the gestation period and possibly also when they are suffering from a disturbance of the parathyroids. To insure the normal function of the thyroid the ordinary diet should be supplemented with from one-half to 1 gram of iodine approximately daily during pregnancy and menstruation and for a period of seven days each month during puberty, especially during the first three months of the year.

**Diabetes in Infancy and Childhood.**—Abt agrees with other observers that diabetes in children is infrequent as compared with its occurrence in adult life. The symptoms are almost identical with those in adults. Emuresis is not an infrequent symptom. Urticaria, pruritis and eczema occur as well as furunculosis. The teeth decay early, and stomatitis is not uncommon. Edema about the face and ankles has been observed in advanced cases. Headache, backache and radiating pains in the extremities are sometimes seen. Particularly characteristic are pains in the calf muscles. The urine contains sugar, at times acetone and diacetic acid, and not infrequently albumen and casts. An early and conspicuous symptom is irritation of the external genitals. Diabetes in children may begin in a mild or severe form, though it must be observed that the transition from the mild to the severe form occurs more rapidly than in adults. In some cases the disease has not been recognized until after this transition has

occurred. Some children seem to improve after the sugar tolerance has been regulated and the urinary sugar kept low. At times they gain in weight. The temperature is inclined to be subnormal. When the glycosuria has disappeared none of the children lose their tendency toward it. Sugar returns on the slightest provocation. It reappears following psychic disturbances, such as disappointment about a journey or a bad school report. Sugar also tends to return following coryza, parotitis, pharyngitis and diarrhea. In most cases the sugar tolerance can be restored, but an accumulation of insults, that is frequent recurrences, tends gradually to reduce permanently the level of tolerance. In consequence of this fact infections of the upper respiratory tract or other infections have an ominous significance and tend to produce complications in diabetic children. The younger the individual the more marked is the tendency for the disease to pass suddenly from the mild to the severe type. In Abt's experience such cases as he considered mild and amenable to dietetic treatment nearly always terminated fatally in the course of several months or a few years.

**Function of Thymus.**—The animals used by Uhlenhuth for his experiments were the larvae and adults of amphibians—water lizards, newts, mudpuppies or salamanders. His findings lead him to believe that the thymus does produce an internal secretion, but one which, so far as is known at present, has only a toxic effect in that it is the factor causing the "tetanic parathyreopriva." There are, however, Uhlenhuth says, no facts known at present to warrant the claim that the thymus gland does not produce an internal secretion which is required to maintain the normal physiologic condition of the organism.

**Effect of Splenectomy on Thymus.**—Observations were made by Mann on adult dogs, puppies, kittens, rabbits and goats from which the spleen had been removed as to the effect of this operation on the thymus. Decided variations were found, but there was no evidence that splenectomy produced any specific change. Most of the splenectomized animals died before the controls died, however, and under the same conditions that the controls were developing normally. While removal of the spleen in the young did not produce any noteworthy change in development, it seemed to make the animal less able to withstand the stress of life.

**Influence of Thyroid on Formation of Antibodies.**—Koopman claims that the injection of thyroid gland into rabbits causes the formation of an ambioceptor with a high titer.

**Action of Epinephrin on Kidney.**—The experiments made by Hartman and Lang prove that epinephrin frequently causes dilatation of the kidney. This dilatation can be caused by action on the semilunar ganglion, dorsal root ganglia, or, in some cases, on structures in the kidney itself.

**Nerve Injuries.**—Danforth's paper is based on a study of the patients suffering from nerve injuries who were treated in Stiles' service at the Edinburgh War Hospital. Single examinations were never accepted as sufficient to indicate operative measures, except possibly the correction of deformities. As a rule, one examiner made all the tests. In this way it was possible for him to note at once any apparent discrepancies between the results of the voluntary power tests and the electrical responses, or between changes in muscle power and changes in cutaneous sensibility. Complete loss of voluntary power with loss of faradic excitability and with slow galvanic response, associated with anesthesia and analgesia over the area supplied by the nerve, and absence of tingling distal to the site of injury, means physiologic loss of continuity in the nerve trunk. Only repeated examinations can indicate the probability of anatomic loss of continuity, or that recovery will not take place. The general working rule was to wait from six weeks to two months after complete wound healing before operating, and during that time the patient had two and usually three complete examinations. In addition, a voluntary power examination was made each week. If, at the end of six weeks or two months, it was found there was no change in the condition, and that the examination showed a complete loss of physiologic continuity, or incomplete but unchanged loss, operation was done, if the amount of disability warranted it. The interval of six weeks or two months between the time of wound healing and the possible operative treatment was employed in improving the nutrition of the muscles, correcting any deformities and restoring flexibility of the joints in the affected extremity. If no deformities were present, the muscles were protected from stretching by appropriate splinting. This was found to be a very important feature and its lack was often sufficient to retard or prevent restoration of power in the muscles, and further, it was found necessary to maintain this relaxation constantly. This was, perhaps, especially so in circumflex, musculospiral and external popliteal paralysis, but undoubtedly is nearly as necessary in all nerve injuries. In addition to the protection given by splinting, the muscles were treated by hot soaks, or whirlpool baths, followed by massage and either active or passive motions, and electrical stimulation. In cases in which deformity was present, the deformity was corrected. For restoration of flexibility of small joints various methods were tried. Massage and hydrotherapy were found successful in a few instances. Forceful manipulations with or without anesthesia were found helpful in only a very few instances, and much more often rendered the joints stiffer. Finally elastic traction was tried; at first pulling in direct flexion if the fingers were fixed in extension. This was helpful in a certain number of cases and never made the condition worse. Then elastic traction in the direction to first stretch the joint capsules was tried. This was found a great advance. The traction was applied by strips of adhesive on the sides of the fingers to which elastic bands were attached, and these in turn were attached to the splint. The pull was at first always in the line of the deformity and then gradually changed as the motion in the joints permitted. Sometimes metacarpophalangeal joints which had been fixed in hyperextension for months would be completely flexed in two or three weeks, but usually several months were required

**Drugs in Tuberculosis.**—Cohen is of the opinion that it is now generally recognized that drugs occupy a secondary place in the treatment of tuberculosis, but unfortunately, it has been forgotten that they also occupy a necessary place. Without proper dietetic and hygienic management, drugs are of small service. On the other hand, Cohen does not believe that recovery is often complete and maintained without them. The relative failure of sanatorium treatment is to be attributed to the neglect of their powerful aid. Two groups of remedies have "stood the test of time"; namely, certain iodine compounds, and creosote and its congeners. The use of calcium, introduced on the somewhat crude basis that calcification and fibrosis are the natural methods of healing of tubercles and tuberculous ulceration, is also commended. These drugs help tuberculous patients to recover and to stay "well." Iodine in the infiltrative stage; phenol, creosote or guaiacol for use in the more advanced stage, or in the presence of fever; and calcium for use throughout, are, in Cohen's judgment, although secondary, nevertheless necessary agents in the successful management of the great mass of cases of chronic pulmonary tuberculosis. They are to be used freely—with discretion to be sure, and with individualization—but also with persistence.

**Paresis.** Weeks emphasizes strongly that the parietic is a dangerous individual to be at large, especially during the early stage of the disease. Repeated blood and spinal fluid examinations should be made in all cases of syphilis long after active symptoms have disappeared. Observations should be made for neurologic symptoms and when they do appear the patient should be confined in a hospital immediately. No person showing a positive Wassermann on the blood and spinal fluid and any neurologic symptoms should be permitted to hold a position of trust and responsibility.

**Influenza.**—This report is based on an analysis of 900 cases of influenza admitted to the U. S. Naval Hospital, Philadelphia, during the recent epidemic of that disease. For purposes of critical study the cases are divided into four groups: Group 1, including those patients which were admitted to the hospital within twenty-four hours of the onset of their illness; Group 2, those admitted within forty-eight hours; Group 3, those admitted within seventy-two hours, and Group 4, all those admitted at a later period of their infection. In Group 1 the most frequently mentioned chief complaint was headache, which occurred in 52.2 per cent. of the cases. Next in order of frequency were chills, general muscular pains, cough, backache, sore throat, weakness and coryza. In Group 2, headache was again the most frequently mentioned chief complaint, occurring in 34 per cent. of the cases, and followed by general muscular pains, cough, chills, backache, coryza, sore throat and weakness. In Group 3, headache occurred in 32.7 per cent. of the cases, followed by chills, general muscular pains, cough, coryza, backache, sore throat, weakness and nausea. In Group 4, headache was again the most common chief complaint, occurring in 30.6 per cent., followed by cough, chills, general muscular pains, backache, weakness, coryza, sore throat, nausea and vomiting, and dyspnea. On examination the physical sign most frequently encountered in Group 1 was râles, which occurred in 51.9 per cent. of the cases. In Group 2 râles occurred in 55.8 per cent. of the cases. In Group 3 râles occurred in 74.4 per cent. of the cases. In Group 4 râles occurred in 74 per cent. of the cases, followed by toxemia, cyanosis, congestion of the throat, eyes and nose, delirium, pleuritic friction, herpes, enlargement of the superficial lymph glands, jaundice, erythema and hiccup, as was also the case in the first three groups. The complication most frequently encountered in Group 1 was bronchitis, which occurred in 43.3 per cent. of the cases, followed by pneumonia, which occurred in 8.5 per cent. In Group 2 bronchitis occurred in 40 per cent. of the cases, followed by pneumonia in 15.7 per cent. In Group 3 pneumonia was the most frequent complication, occurring in 42.2 per cent. of the cases. In Group 4 the most frequent complication also was pneumonia, which occurred in 42.8 per cent. of the cases, of which 40.4 per cent. were bronchial in type and 2.4 per cent. lobar. The pneumonia most often

was of the bronchial type. The next most frequent complication in Groups 3 and 4 was bronchitis, followed by myocarditis, nephritis, epistaxis, pleurisy, endocarditis, otitis media, abdominal distention, and two cases each of cholecystitis and retention of urine, and one case of typhoid. In Group 1, which included 352 cases, 82 per cent. of the patients recovered without stimulation and 0.3 per cent. died; of those requiring stimulation 13.9 per cent. recovered and 2.5 per cent. died. In Group 2, comprising 197 cases, 73 per cent. recovered without stimulation and 1 per cent. died. Of those requiring stimulation 17.2 per cent. recovered and 7 per cent. died. In Group 3, which included 116 cases, 47.5 per cent. recovered without stimulation with no deaths. Of those requiring stimulation, 21.5 per cent. recovered and 27.5 per cent. died. In Group 4, which included 235 cases, 48.1 per cent. recovered without stimulation and none died. Of those requiring stimulation, 20 per cent. recovered and 29.8 per cent. died. In summarizing all the cases, irrespective of their groups, it was found that the chief complaint was headache; the most common symptoms were headache and cough; and the most constant sign found on examination was râles, either as an expression of bronchitis or pneumonia. Of the complications, bronchitis was found in 37.8 per cent. of the cases and pneumonia in 23.3 per cent.; 21.9 per cent. were bronchopneumonia and 1.4 per cent. lobar pneumonia. Myocarditis occurred in 14.4 per cent. of the cases, epistaxis in 9.6 per cent., nephritis in 7.3 per cent., and pleurisy in 4.1 per cent. There were eight cases each of endocarditis and abdominal distention, two cases each of cholecystitis, sinusitis, retention of urine, and meningitis, and one case each of typhoid fever and epididymo-orchitis. The death rate for the cases of pneumonia was 63.3 per cent., and the total death rate, irrespective of the complications was 14.7 per cent.

**Study of an Epidemic of Mumps.**—Convalescent serum was injected by Gradwohl and others in a number of cases of mumps. Five c.c. serum was used for both subcutaneous and intravenous injections. Very little reaction was noted. The effect of these injections was a lessening of pain and an earlier subsidence of swelling, together with an earlier drop in temperature.

**Lack of Pulsation in Umbilical Cord with Living Child.**—

Ballard affirms on the basis of much clinical experience and experimental work that the lack of pulsation in the prolapsed umbilical cord does not inevitably imply that the child cannot survive. Auscultation may reveal life in the child, and even when the auscultation findings are negative the fetus may still be living. The lack of pulsation in the cord may be due solely to compression at some point reducing the caliber of the vessels. With prolapse of the still pulsating cord, he advises during the period of dilatation to push the cord back if possible; expectant treatment in any event if there is reason to anticipate resistance from the soft parts, giving chloroform or morphin to moderate the contractions of the uterus. On the other hand, if the period of expulsion is under way, he advises to proceed at once to artificial extraction of the child unless an extremely rapid spontaneous expulsion seems impending.

- Fracture of the Forearm. R. Darget.—p. 353.
- Ileus from Diverticulitis. H. L. Roher.—p. 355.
- \*Tardy Epilepsy and Senility of the Brain. Anglade.—p. 356; 1d. p. 358.

**Pseudo-Angina Pectoris.**—Analysis of the stethoscopic findings in the case reported by Moulinier demonstrated that the obstruction to the circulation was in the venous rather than in the arterial system. The patient was a man of 53 and the sudden agonizing pain back of the sternum came on only after effort, such as walking soon after a meal. The balance in the circulation is soon restored, so that this venous form of angina pectoris is never fatal although causing these attacks of intense pain as the years pass. The mechanical disturbance is like that with tricuspid stenosis. The minimal blood pressure keeps at the normal figure. When the arm is raised above the level of the heart, the flow of the venous blood out of the arm is facilitated by gravity, and the arterial wave finds readier access; if the arterial circulation is at fault, the maximal pressure instead of dropping keeps at the same figure as when the arm is held horizontal. In the case reported, the maximal arterial pressure at the wrist during an attack, the arm on a level with the heart was 17, with the arm raised 16, with the arm pendent 21. The corresponding minimal pressure figures were 10; 7; 12, and the pulse did not vary. The stethoscope revealed the upset of balance between the pulmonary and aortic systems (doubling of the second aorta period); a strong blood wave in the aorta, and increased pressure inside the right auricle (the sounds at the tricuspid more explosive), but this increased pressure does not affect the valves in the left side of the heart (the second mitral sound extinct) nor force the myocardium to the effort which the explosive aortic sounds seem to indicate (first mitral sound remote). The patient showed numerous varicose signs in the limbs with other signs of hampered return circulation, but the jugulars were not turgid and the venous pulse was normal. All the heart valves were sufficient.

**Diverticulitis and Ileus.**—Rocher gives an illustration of the way in which the inflamed diverticulum of Meckel in a boy of 13 had become inflamed and adherent to the mesentery, constricting two loops of the bowel.

**Tardy Epilepsy.**—Anglade has encountered in the last ten years four cases of epilepsy developing between the ages of 46 and 60. In one it was preceded by seven years of a tendency to melancholia with transient phases of agitation. Necropsy showed a strip of sclerosis, resembling shagreen leather, on each side of the brain, extending from the frontal to the occipital pole, apparently skipping the motor convolutions but the microscope showed that these also had been involved. He reiterates that these cases of epilepsy in the elderly will well repay study as they show transitional forms between the epilepsy of organic nature and the epilepsy still called essential and functional.

- \*Radium Treatment in Gynecology. R. Condamine and L. Nogier.—p. 372. (Cont'd.)
- Some Souvenirs of German Army Surgeons. A. Gonachon.—p. 413.

**Radium in Gynecology.**—Condamine and Nogier here conclude their long article on this subject. Their experience with radium treatment in 750 cases has confirmed, they say, the absolute necessity for radium treatment for all uterine cancers at the limit of operability as a preliminary to an operation, and also when the cancer is manifestly inoperable; also to relieve extensive cancers, hoping for nothing beyond arrest of hemorrhages and attenuation of the pains, and, finally, for postoperative recurrences in the vagina or lower parametrium. Besides the above absolute indications for radium therapy, they list as relative indications certain operable cancers, especially the infiltrating forms in young women which often give such deplorable results after an operation. A further relative indication is after hysterectomy,

to root out the last possible traces of the neoplasm. It seems to be established, therefore, that large doses are indispensable for uterine cancer, up to 250 mg. in a forty-eight hour application, never going below 100 or 125 mg. Striking hard once and for all seems to give a durable result more effectually than any succeeding applications can yield.

\*Surgical Insufficiency. A. Szary. p. 533.

\*Fluoridosis of the Urinary Apparatus After Fifty. C. Lepoutre. p. 535.

\*General Anesthesia by Pharyngeal Intubation with Delbet's "Pipe." I. Dufourmentel. p. 537.

**Suprarenal Insufficiency.**—Szary classifies suprarenal insufficiency under three headings: the fulminating, rapidly fatal form, the monosymptomatic form (myasthenia or amyotrophy), and the form inducing a whole set of symptoms, acute (syndrome of Sergent-Bernard); subacute and slow (Addison's disease and its varieties). Tuberculosis may induce any one of these "syndromic forms" of suprarenal insufficiency, and syphilitic processes often locate in the suprarenals, as also those of diphtheria, typhoid and other acute infections. Specific treatment should be given when such is possible, antitoxin with diphtheria, for example, or quinin with malaria. Rest and suprarenal treatment are useful whatever the infection, but he prefers the extract of the whole gland, and given by the subcutaneous route. He reserves epinephrin for acute disturbances with collapse of the heart, and recommends the subcutaneous route. He gauges the dose by the therapeutic results obtained with the first doses and by the signs of intolerance. A rise in the blood pressure is a good index of the efficacy of the opotherapy, but the fact that it does not rise does not prove that the treatment has been ineffectual. A still more instructive index is the finding with the dynamometer showing the variations in the strength of the muscles tested fifteen and thirty minutes, one hour, three hours and so on after the injection of the suprarenal extract. When these two tests show a favorable influence from the suprarenal treatment, he keeps up this dose, not increasing it until the effect grows less pronounced. The appearance of tremor calls for caution; glycosuria, albuminuria, circulatory disturbances require suspension of this treatment. In some cases the doses have to be high and kept up for several weeks or even months before a good result is obtained. Signs of intolerance should be watched for with special care in these circumstances. Sometimes addition of pituitary will give surprisingly fine results when the suprarenal treatment is a failure. With cheesy tuberculosis and cancer, the knife is still the ideal treatment, possibly resecting only the pathologic tissues and leaving the rest intact. But in order that this can be done the disease has to be diagnosed early, and it is to be hoped that the progress of medicine will soon render this possible.

**Tuberculosis of the Urinary Apparatus After Fifty.**—Lepoutre remarks that Kochet is the only writer he knows of who has called attention to tuberculosis of the urinary apparatus in elderly men. He describes a case of the kind in a man of 58 which proved fatal in little less than a year from the first symptoms. Analyzing some published statistics he shows that tuberculosis of the urinary apparatus is not exceptional after 50, and it occurs in about the same proportion in men and in women, but the number of operable cases in men after 50 is exceptionally small. It escapes diagnosis only because physicians do not think of it as a rule. In 1,530 cases he has compiled from the literature, 44 were in men over 50, and an operation was attempted only in 13 in this group. In the 13 operative cases 7 terminated fatally in an average day to five months, the outcome is not known in 4 cases; one died twenty months later, and only Verhoogen's one patient was still well after an interval of six months. These had results justify nonoperative treatment, he says in conclusion.

**General Anesthesia by Pharyngeal Intubation.**—Dufourmentel lauds the superiority of Delbet's pharyngeal tube for this purpose. It is much simpler, more effectual and less harmful than an intralaryngeal tube, for general anesthesia,

with operations on the neck and face, while it prevents blood running down into the esophagus or air passages. He gives an illustrated description of it.

Aug. 1, 1919, 29, No. 8

\*Trauma of the Chest and Pulmonary Tuberculosis. Tecon. p. 361. Psychotherapy and Its Indications. A. Kalinovich. p. 380.

Medical Certificate as Requisite for Marriage License. Lévy Du Pan. p. 394.

Influenza in the Insane. V. Demole and M. Alikan. p. 397.

**Trauma of the Chest and Pulmonary Tuberculosis.**—In this installment of his long article, Tecon gives the details of twenty-seven cases of war wounds of the chest among soldiers of the Allied armies interned in Switzerland. Tuberculosis had been assumed in all, but only 18.5 per cent. had tubercle bacilli in their sputum. In only 7.4 per cent. was there any evidence connecting the pulmonary lesion with the war wound. All the men had been long in captivity in Germany, and yet notwithstanding the depressing conditions of their imprisonment, tubercle bacilli only very rarely invaded the lungs and only exceptionally settled at the site of the war wound. This was the more remarkable as some of the men had old tuberculous glandular lesions. Tecon examined further 1,033 known tuberculous interned soldiers and found that only 1.1 per cent. had had a chest wound at any time, thus confirming his assertion of the rarity of pulmonary tuberculosis consecutive to penetrating wounds of the thorax.

### Revue Neurologique, Paris

June, 1919, 26, No. 6

\*Origin and Nature of Sclerosis in Patches. G. Marinesco. p. 481.

\*Pathogenesis of Tabes. O. Gallotti and S. Azevedo. p. 489.

Decompressive Trephining to Relieve Mènière's Vertigo. H. Aboulker. p. 493.

**Origin and Nature of Sclerosis in Patches.**—Marinesco insists that study of this disease should be on the basis that it is of inflammatory origin, and that some infectious agent is responsible for this inflammation. He injected six guinea-pigs with cerebrospinal fluid from two persons who had pronounced symptoms of sclerosis in patches. The injections were made into the brain, peritoneum and spinal cavity. The outcome demonstrates, he states, two new facts, namely, the transmissibility of the disease by means of a virus, and that this virus is represented by a special spirochete quite distinct from the pale spirochete. These assertions do not seem to harmonize with the isolated character of sclerosis in patches; it is not epidemic or endemic, and it seems to be exclusively limited to the central nervous system. The evolution of the disease, the successive waves, and especially the aspect of the fundus of the eye, which mirrors the different phases of the parasites, analogous to that in syphilis—all point to the spirochete found by Kühn and Steiner and by himself as the probable pathogenic agent of the disease. One thing is certain, he remarks in conclusion, sclerosis in patches is an actual entity and not a set of symptoms from diverse causes. The localizations of typhus in the central nervous system look entirely different.

**Pathogenesis of Tabes.**—Gallotti and Azevedo report inoculation of three dogs with trypanosomes. Degeneration of the nerve fibers of the spinal cord was pronounced the twenty-fifth day afterward (Weigert method) in one of the dogs; the others died soon after the inoculations. The findings confirm Spielmeier's findings in the dogs inoculated with *Trypanosoma brucei* and developing trypanosomic tabes. The symptoms in none of the dogs were very pronounced, but the posterior roots, the optic nerve and the trigeminal showed marked degeneration.

### Correspondenz-Blatt für Schweizer Aerzte, Basel

Sept. 4, 1919, 19, No. 36

\*Parenteral Injections of Milk in Therapeutics. Peter Rybiner. p. 1337.

\*Extravasal Coagulation of the Blood. A. Rodella. p. 1345.

\*Surgery of the Base of the Brain. Henschen and Nager. p. 1349. Cont'n.

**Parenteral Injections of Milk.**—In this communication from the university children's clinic at Zurich, Rybiner reports

that there were no therapeutic results from the subcutaneous injections of milk in any of a large number of diseases tested, in hemorrhagic nephritis, in diphtheria bacilli carriers, in erysipelas, in anemia, and in attempts to activate the protoplasm in the prematurely born and others. No reaction of any kind was observed with absolutely fresh milk, approximately sterile, nor with breast milk. The reaction seems to be due to bacterial toxins or decomposition products of the milk. The reaction in the blood-producing system is much less and is inconstant in infants in comparison to older children. The rarity of phenomena indicating anaphylaxis may be explained by assuming that milk by the mouth induces anergy. He tabulates the differential blood count before and at different intervals after the injection in eight children from 8 days to 12 years old, and also in two injected with perfectly fresh cow's milk, and three with breast milk. In this last group of five there was absolutely no modification in the blood picture. Although his experiences were thus negative, he does not denounce the protein therapy but warns not to neglect old and tried measures for it.

**Extravasal Coagulation of Blood.**—Rodella calls attention to the difference in the aspect of the crusta phlogistica whether there is or is not a serious pathologic modification in the coagulation of the blood. By crusta phlogistica he means the yellowish, shriveled, bacon-like appearance of the crust that forms on the blood clot. In uremia and in the pregnant this crust is more transparent than under other conditions, and there is no sharp demarcation between the crust and the blood clot below while the latter looks paler and less compact than usual. The crust with pneumonia differs completely from this nomenclologic type.

**Transethmoidal Access to Pituitary Tumors.**—Henschen and Nager conclude their discussion of surgery of the base of the brain in general with an illustrated description of a paranasal method of reaching a pituitary tumor through the ethmoidal sinus. The incision starts in the middle of the eyebrow, keeps in it and is carried in a broad curve down on the cheek and outward on the cheek to a point nearly directly below the starting point. The flap thus lifted up and turned back includes the whole of the contents of the anterior half of the orbit. This is Chiari's technic, and they have applied it recently in a case described. The subjective improvement was pronounced, the vertigo, asthenia, headache and vomiting subsided, as also in Kahler's, Chiari's and Schmieglow's experience. The visual disturbances retrogressed by sectors as they developed, and the retrogression may be complete or only partial, and even this depends on the operation coming in time. Even the acromegaly may retrogress. The menses return and erections, but the full sexual functions have never been completely regained. In the case of the man reported there was secretion of milk by the third year of the lesion; it disappeared after the operation. This experience confirms that the secretion of milk is not connected with specifically female endocrine organs, but can occur by the action of the pituitary alone. Roentgen treatment of pituitary tumors seems to be winning its way, but cannot apply to treatment of cysts, abscesses, hydrocephalus and similar lesions. Roentgen treatment is certainly advisable after removal of the pituitary to ward off recurrence. In conclusion they review the whole field of the pathology of the pituitary, classifying under seven headings the various pathologic conditions that have been encountered in the pituitary. The list includes aneurysm, spontaneous hemorrhage, echinococcus disease, tuberculous and syphilitic processes, etc., besides primary and metastatic tumors.

\*Transmission of Typhus by Lice. G. Mueller and L. Urizio.—p. 734.

\*Otorhinolaryngology and the Practitioner. G. Gradenigo, p. 735. Aortic Lesions of Thyroid or Neuritic Origin and Aortic Lesions in Persons with Hyperthyroidism or Neurases. D. Cantelli.—p. 738. Heart and Lung Changes in Malaria. Augusto Jona.—p. 743. Radical Treatment of Acute Empyema. S. Dalnazzoni.—p. 744. Appendicitis with Movable Kidney. D. Giordano.—p. 752.

**Transmission of Typhus by Lice Stools.**—Mueller and Urizio report the results of experimental research which confirm that the dejecta of lice are able to transmit typhus even without the bite of the insect. A laboratory accident confirmed this even more strikingly: the syringe filled with the emulsion of lice stools was being held by Urizio while Mueller was holding the guinea-pig ready for the injection, when the animal jerked and spilled the emulsion over the hands of both. Urizio was immune, having had typhus two years before, but Mueller, whose hands were irritated from other causes, developed seventeen days thereafter a classic form of typhus.

**Otorhinolaryngology and the General Practitioner.**—Gradenigo protests emphatically against the carelessness or ignorance of general practitioners in failing to diagnose mastoid disease, failing to treat properly acute otorrhea or disease of the upper air passages, or else going to the other extreme and mistaking impacted wax, for instance, for some serious condition. He cites two or three dozen cases typical of these blunders. The serious results from them in soldiers make a particularly striking impression, men dying from mastoiditis probably avoidable or curable, and, on the other hand, men wasting their time in hospitals merely on account of disturbance from impacted wax. One man had thus escaped military service, being at the front only fifty days in two years. The study of the ear, throat and nose is optional in the Italian medical schools, and few take advantage of the opportunities for this. Gradenigo asserts that the experiences here related, to which he could add many more, justify making compulsory some study of those organs and their pathology.

\*Eclampsia without Albuminuria. J. B. Silvestre González.—p. 115. Claustrics Producing Hypospadias. Sicilia.—p. 117. Case of Pernicious Cardialgic Malaria. M. S. Manzano.—p. 118.

**Spinal Anesthesia in Gynecology.**—Summarized when published elsewhere. See page 1021.

**Eclampsia Without Albuminuria.**—Silvestre remarks that the absence of albumin from the urine of the pregnant does not exclude peptonuria, but albuminuria very rarely occurs without peptonuria. The latter may be the expression of insufficiency of the liver, and he thinks it should warn of possible eclampsia even when no albumin can be found in the urine. If the experience of others confirms this assumption, we have thus a simple means at our disposal for the foretelling of eclampsia as the determination of peptonuria is easier than the quantitative tests for albumin, etc.

\*Chronic Serpiginous Venereal Ulcer Subsides under Tuberculin. M. F. Criado.—p. 136.

Tracheotomy as an Emergency Operation. C. Galleron.—p. 139.

**Venereal Ulcer of Long Standing Heals Under Tuberculin.**—Criado relates the further history of a case of serpiginous venereal ulcer published by Azua as a typical instance of the rebellious nature of these lesions. The condition four years later was practically the same as in Azua's description. Criado then gave eleven intravenous injections of tartar emetic to a total of 0.75 gm. No benefit was apparent from this and he then gave a series of eight injections of a tuber-

cult) in minute doses. Each one induced a local reaction but no local or general reaction. By the sixth injection the chancrous ulceration had entirely healed and the others were nearly healed over. There were no signs or symptoms of tuberculosis or syphilis, and the possibility of mycosis was suggested, but there was no growth in any of the various culture tests made. Whatever the explanation may be, the rapid cure under tuberculin of a lesion of ten years' standing is an established fact. Analogous experiences have been reported with rebellious eczemas. Criado suggests that possibly the preceding course of tartar emetic may have cooperated in the cure, and advises in similar cases to try tuberculin first. If this fails, give a course of tartar emetic and follow with the tuberculin anew.

\*Auricular Fibrillation. Luis Calandre.—p. 5.

\*Secondary Malaria. H. Salvador Clavijo.—p. 16.

\*Degeneration and Regeneration of the Deep Membranes of the Eye.

H. Muñoz Urra.—p. 28.

\*Lichen Eruption from Grain Dust during Threshing. F. García Pastor.

—p. 42.

**Auricular Fibrillation.**—Calandre reports a case of auricular fibrillation in which the complete arrhythmia occurred in paroxysms. The man was a morphin addict and, during a course of treatment for this, developed the auricular fibrillation when his system was clamoring for the morphin. It subsided regularly as soon as morphin was given him, and after the course of treatment was carried to a successful conclusion there was no return of the auricular fibrillation. As a rule, however, the prognosis of auricular fibrillation is extremely grave. Surprising benefit may be realized, however, from heart tonics in cases of rheumatic origin. Under digitalis the edema may subside and the whole condition become quite satisfactory, but the irregularity never entirely disappears. He advises to give digitalis when the heart beats above 100 during repose. Milk or vegetables should be the main reliance in food, without salt as long as there is edema. He keeps up the digitalis for four days, stopping when the pulse drops to 70. Other heart tonics may be preferable in certain cases. Fourteen typical pulse tracings are reproduced.

**Secondary Malaria.**—Clavijo discusses in this article the excessive functioning of the spleen, with or without its enlargement, as studied on a large number of patients. He discusses the localization of symptoms in the different organs, anemia and melanemia, the mechanism of the relapses, means to forestall the impending chill and fever, the treatment and prophylaxis. In speaking of the ravages of malaria in Spain and its possessions in Africa, he quotes statistics showing an average annual mortality from malaria of 301,260. He states that of the 9,261 towns in Spain, malaria is present in 1,818. He reiterates that the expense of reclaiming malarial regions by proper engineering, etc., would be more than offset by the increased productivity of the land, to say nothing of the saving in lives. In his own region malaria is increasing rapidly. In one regiment of 1,748 men, 208.35 per cent. were given treatment during 1916 while only 90.97 per cent. required it in 1913. He points to what Gorgas accomplished in Panama and what the Argentine Republic has accomplished since it made registration of malaria compulsory in 1907.

**Regeneration of the Retina.**—Muñoz gives ten colored views of the degeneration and regeneration of the deep membranes of the eye, and describes the mechanism of the repair of tissues as studied by his special method of silver staining. The reformation of the axis-cylinder processes of the nerve cells proceeds to an actually surprising extent but the cicatricial tissue forming in the choroid prevents the restoration of the nerve elements, the cicatricial tissue smothering the newly formed axones. He declares in conclusion that the regeneration of the retina is now an established fact, but it is impossible to restore the vitality of the membrane on account of its being hampered by the medium in which it has to develop.

**Eruption from Grain Dust.**—The symptoms in the woman whose case is described by García resemble those of hay-fever to some extent, but there is also a severe itching lichen eruption on the uncovered parts of the body. This eruption develops as soon as the grains begin to ripen, and it returns again and again until the harvest is entirely over. No treatment has proved effectual, but all symptoms subside as soon as she leaves the farming country for the city. The eruption has returned every year for eight years, to date, and no drug or local treatment of the nose with preparations of grains has proved effectual.

Decompressive Trephining for Brain Tumor. H. Lea Plaza.—p. 461.

The Scientific Work of Prof. R. Kraus.—p. 466.

**Protein Therapy in Typhus.**—Prado Tagle was impressed with the possibilities of Nolf's method of intravenous injections of peptone in treatment of infectious diseases, and he applied this technic in fifty-nine cases of typhus. Aside from one patient that died in less than forty-eight hours, the mortality was about 5 per cent. The absence of by-effects confirms the harmlessness of the method for all ages, he declares in conclusion. The general health improves, the duration of the disease is shortened, and convalescence sets in earlier. The benefit was more pronounced the earlier the injections had been begun. His report represents extensive research by the different physicians on the hospital staff, much experimental and laboratory work being carried on preliminary to and during the clinical experiences. Nolf's technic was closely followed, except that the acidity of the solution of peptone in physiologic serum was reduced to 4.3 per thousand, and the remedy was put up in 5 c.c. capsules. About 10 c.c. was given as the first dose, to robust adults, otherwise from 4 or 5 c.c. for older children, up to 6 or 8 c.c. giving afterward only about half of the initial dose, and allowing an interval of forty-eight hours to elapse. In almost all the cases a second injection was given and, exceptionally, a third, with only 1 or 2 c.c. A subcutaneous injection of 2 or 3 c.c. of 20 or 25 per cent. camphorated oil was given every six hours day and night, with 0.25 c.c. of 1 per thousand epinephrin in each syringe. The patient must be kept in repose. The blood pressure falls during and immediately after the intravenous injection of peptone, but if it is made slowly (1 c.c. per minute) and if epinephrin has been given, the drop is slight. The coagulation time of the blood is much retarded. Analysis of the blood showed that the urea content could be disregarded with this protein therapy as the latter only slightly augmented it, and it soon dropped to below its previous figure from the rapid reaction to the injection, while the dietetic restrictions in typhus aid in its being speedily cast off. Analysis of the urine likewise showed that the injections of peptone had no detrimental influence on the kidneys and hence there were no contraindications on the part of the kidneys, except of course with grave nephritis. There are no characteristic findings in the urine in typhus. The fever charts given show the attenuating and abbreviating influence of the protein therapy better than anything else. An interesting feature of the cases was that when the temperature had gone down under the injections, a further injection did not induce any appreciable reaction. The production of antitoxins can then be regarded as sufficient and the case as cured. In every case improvement in the general condition was unmistakable.

**Protein Therapy of Typhus.**—Opazo reports the application of Nolf's method in 27 cases of typhus, with 14 recoveries, 4 in convalescence and 7 still under treatment; 2 of the patients died, but the disease in their cases had reached a stage when reaction was no longer possible. He reiterates that the protein therapy induced a favorable reaction which modified the disease and all the symptoms. In his experience the reaction was prompter and more effectual in children than in adults. He is now applying this protein therapy as the routine treatment in all cases of typhus.

\*Projectile in Base of Brain. Rogelio Stincer.—p. 439.  
The Venereal Peril. José Arias Avellan.—p. 442.

**Bullet in Base of Brain.**—Stincer relates that the boy of 15 was bleeding profusely, the bullet having traversed the tongue, arch of the palate and nasal fossae on its way from the median suprahyoid point of entrance to its exit at the right nasal fossa. The blood came mostly from the tongue, tamponing not arresting it. Stincer threw a ligature around the external carotid artery in the carotid triangle and the bleeding stopped at once, and by the tenth day the boy was able to eat naturally. The eighteenth day remittent headache developed. Stincer had warned the father that headache might be a symptom of traumatic meningo-encephalitis or abscess. The boy was operated on later by others and died, and the family ascribe the fatality to Stincer's having "ligated the vein."

\*Congenital Blindness. Joaquin de Salterain.—p. 522.  
\*Epidemic Poliomyelitis. F. Figueroa and Others.—p. 560.

**Infantile Mortality in Uruguay.**—Bauzá urges that both national and municipal vital statistics should list the deaths separately, according to the causes, for each of the first four weeks of life and then month by month to the end of the first year, and then year by year up to the fifth year. He suggests further that the form of feeding used for two weeks before the death should also be recorded, as also whether the child is illegitimate or not. An annual summary should be published giving these particulars in detail. The statistics of the municipal registration area should be kept separate from those of the suburbs, which are beyond the jurisdiction of the municipality. Births and deaths in the public institutions, he adds, should be recorded in the statistics of the place of residence. He also urged the federation of all societies and organized efforts for welfare work for mothers and children, extolling the creation in all countries of an organization like that of the Children's Bureau at Washington to centralize and direct the efforts to reduce the infant death rate. He remarks parenthetically that 108 per thousand of living children born in Uruguay die before reaching their second year, while the rate in Southern Australia is only 62.

**The Biologic Significance of the Phenomena of Hysteria.**—Fontecilla argues that hysteria is an atavistic survival of the open manifestation of emotions which civilized man suppresses more or less completely but which primitive man and women and children still have found useful in the struggle for existence. Primitive man yelled and gesticulated to frighten away the enemy attacking him; children scream and throw themselves on the floor when they are angry, and women's tears are still their most decisive argument. These reactions to emotions have thus a useful purpose for the person making use of them. But they are forms of defensive reactions which man in civilized life is abandoning

more and more for other means better suited to the difficulties he has to overcome, that is, for more rational means. He does not merely yell and gesticulate to frighten off the attacking enemy, but the higher the civilization he has attained, the more he reflects, calculates and acts without wasting his energy in emotional manifestations. The emotional reactions are atavistic manifestations of the struggle for existence, but they are atavistic manifestations. They can be traced in primitive man and in certain animals, and analysis of the manifestations of hysteria shows that there is no essential difference between them and the ordinary reactions to emotions. The difference is merely in intensity and degree, not in quality. What is the difference between syncope in an apparently normal person at some sudden catastrophe or great misfortune and the syncope in a hysterical woman from some trivial cause? What is the biologic significance of the syncope? It is a defensive reaction that benumbs the appreciation of the great grief or catastrophe as chloroform abolishes pain. But the hysterical make excessive use to actual abuse of this means of defense. And they accomplish their purposes with it. But these triumphs with the aid of these abnormal means, he reiterates, all have one indelible stamp: "They are antisocial. The triumphs of hysteria are invariably of an egotistical and antisocial nature." Only the minutest proportion of cases of hysteria come to the knowledge of physicians; the majority of its manifestations in conjugal life, in the home and in society are recognized only by the experienced psychologist. The mental abnormality responsible for hysteria is at its maximum in the young, and with proper training and environment the milder forms subside so that it is very rare in the elderly."

**Health of Children in Relation to Income.**—Rossi presents in picturesque terms a plea for protection of children against poverty and against superabundance. Each of these is almost equally detrimental. The living cell, he says, is "the great rebel that dictates terms to emperors. We can apparently conquer it because we seem stronger than it, but from its hidden nook it strikes back and conquers in the end by dying. The living cell, besides being the great rebel—or perhaps on this account—is just and wise. It asks only for just what it needs (air, light, heat and nourishment) and does not want more or less than its actual needs, and does not recognize economic distinctions." . . . "The mentality, on the other hand, is simply the faithful and eloquent corollary of economic conditions."

**Treatment of Congenital Blindness.**—De Salterain gives a historical review of the operations on record for congenital cataracts in both eyes, from Cheselden's pioneer work in the eighteenth century to Moreau's case in which the child was kept in the hospital for fifteen months afterward (1913). Moreau emphasized that removal of the cataracts is merely the preliminary to the child's learning to see, as the mental perception is a plant of slow growth. De Salterain has operated in nineteen cases at one sitting for congenital blindness; one of the patients was 32 and has been capable of self-support during the twenty years since. The others were all children, and he describes two cases in detail to confirm the necessity for continuous intelligent training in the use of the eyes as indispensable for vision. His own and the experiences on record confirm that the development of the child's mind before the operation is the decisive factor in what can be accomplished later. One very backward boy of 6 was given training by the Montessori method about a year after the operation, and in nine months was mentally and visually the peer of normal children of his age. The other child whose case is described was not mentally backward, and she was soon able to attend school with other children.

**Epidemic Poliomyelitis.** The *Revista* gives the summaries of the official reports by the delegates to the Child Welfare Congress in regard to the prevalence of acute poliomyelitis in the different countries represented. Figueroa said that there had been two small epidemics at Rio in eight years, a total of 120 cases with a mortality of 1:30. He queried whether the cases of cephaloplegia with recovery in a few

days might not be a rudimentary form of epidemic poliomyelitis. Alvarez Alfaro stated that there had never been an actual epidemic spread of the disease in Argentina, but since 1910 there had been a few hundred cases, the proportion a little higher since 1916. In his own practice he has never been able to trace the infection to its source. In one family the three children developed the disease almost at once. The only treatment which displayed any efficacy was the intraspinal injection of convalescent serum. The early diagnosis and the systematic evacuation of the lumbar puncture fluid are particularly important as they permit serotherapy in time, before convalescent serum is installed. The Uruguay delegate reported three epidemic waves in 1909, 1912, and 1916, and mentioned that pain was an important element in the clinical picture in Uruguay. He asked the adoption of a resolution authorizing pediatricians to study and practice serotherapy in this disease. Fontecilla reported that in Chile there had been no epidemics, but the sporadic form is relatively frequent. He queried also whether acute poliomyelitis might not be responsible for cases in which mild gastrointestinal disturbances or slight fever were followed by symptoms of cerebral paralysis with epileptiform attacks and mental impairment, which may progress to idiocy. He urged serologic research into the origin and nature of infantile cerebral paralysis which is so common in America. The various speakers all mentioned that they had never seen cases of the cephaloplegia encountered at Rio (described in THE JOURNAL, Dec. 14, 1918, p. 2030). The classification of infants' gastro-intestinal disturbances, and tuberculous glandular disease were also discussed at special meetings, and the summaries are reproduced here.

### Semana Médica, Buenos Aires

July 10, 1919, 26, No. 28

- \*Tuberculin Treatment by Minute Doses. J. José Vitón.—p. 29.  
 \*Sterility in Men. F. A. Deluca and V. Widakowich.—p. 35.  
 \*Rheumatism. C. Gering, J. A. Sanchez.—p. 37.  
 \*Treatment of Tuberculosis by Liberty in Learning. L. Velasco Blanco.—p. 39.  
 \*Polymorphism of the Tubercle Bacillus. J. Santos Fernández.—p. 41.

**Broadening the Field of Tuberculin Treatment.**—Vitón's views in regard to the causal benefit from treatment with minute doses of tuberculin have been summarized repeatedly in these columns as, for instance, May 24, 1919, p. 1581. He stresses that only the minutest doses, long kept up, are effective; the ordinary large doses used by others do actual damage. His success with these minutest doses is not confined to pulmonary tuberculosis but Ponce's "chronic tuberculous rheumatism" subsides under it likewise, and a number of other lesions and morbid conditions which have never been connected with tuberculosis hitherto. Their disappearance under this method of treatment throws new light on their etiology, so that this "tuberculin diagnostic-therapeutic method" he calls it, is opening new fields for research and clinical treatment. It has proved exceptionally useful for the new recruits, discharging those who already are infected (see THE JOURNAL), and enabling them to throw off the infection, and to avoid the inconvenience and disappointments attending treatment on other bases. He has found the minute doses to be much useful further to stimulate the vital force in advanced pulmonary tuberculosis, as, for instance, when actual pneumothorax has ceased to prove effective.

He also points out as an indication that the dose has been too large, the occurrence of any kind follow. The "100 tuberculin dose" is less, i. e., of a 100,000,000 solution. The dose has been generally made with one part of this solution and nine parts distilled water acidulated with  $\frac{1}{4}$  per cent normal hydrochloric acid. The same is made in the same way with a 100,000,000 solution. The minimal dose is that required to free the patient from the morbid picture. The dose is repeated at regular intervals, and the reappearance of symptoms is the signal for a new injection. It should never be made before the benefit from the preceding injection begins to decline. As treatment continues, the benefit begins to be more and more lasting each time, demonstrating an actual cumulative beneficial action. There can thus be no irregularity in the dates of the injections. The intervals vary from even to case and at different periods in the same

patient. In this article he expatiates in particular on the surprising benefit from tuberculin treatment in these minute doses in many morbid conditions which have never been supposed before to have any connection with tuberculosis. Their complete subsidence under this method of treatment certainly suggests that tuberculosis is one factor if not the only one. This group includes not only apical cases, but cases of peritonitis, periocolitis, enteritis in members of tuberculous families, joint, glandular and gastro-intestinal lesions, endocrine disturbances, etc. The tuberculin treatment reveals the tuberculous nature of the morbid process and often proceeds to cure it. In a case of unilateral optic neuritis, for instance, this treatment induced marked improvement and the presumptive diagnosis was confirmed by discovery of a minute tubercle close to the entrance of the optic nerve into the eye. Continuing the tuberculin treatment resulted in the complete subsidence of the lesion and recovery of vision. Both clinical, operative and necropsy findings, he states, have confirmed the tuberculous nature of this great variety of morbid conditions which show such marked improvement under these courses of minute doses of tuberculin. As long as appreciable improvement is manifest the same dose must be repeated indefinitely, merely "marking time to keep step," as it were.

**Sterility in Men.**—Deluca and Widakowich found azoospermia in 10 per cent, of 100 men of different classes of society at Buenos Aires. This is about the same proportion as has been reported from Paris, Berlin, Scotland and Brazil. This demonstrates, they say, the preponderance of the male in the responsibility for childlessness. All of the men with azoospermia had had gonococcus orchitis or epididymitis. The writers query whether women should not be protected by legislation against wedding men with azoospermia.

- Vaccine Therapy of Influenza. Julio Méndez.—p. 53.  
 Subsidence of Tuberculous Skin Disease under Tuberculin Treatment. C. Lagones.—p. 59.  
 Colophematometra from Imperforate Hymen. H. Brignardello.—p. 63.  
 \*Polymorphism of the Tubercle Bacillus. F. Jáuregui.—p. 66.  
 \*Psychophysiology of Aviators. J. A. López.—p. 68.

**Polymorphism of the Tubercle Bacillus.**—Jáuregui is chief of the Instituto Maragliano at Buenos Aires, and he ascribes to Maragliano the announcement (1892) of the polymorphism of the tubercle bacillus within the single species. Ferrán followed him in 1897 with his announcement of the close connection between the tubercle bacillus and the colon bacillus. He explained that the acid-resistant tubercle bacillus sowed in a series of culture mediums containing constantly less and less glycogen, peptone and glycerin, the cultures agitated every twelve hours for a few months, finally lose their acid-resisting properties and acquire the properties of the colon bacillus in time. He describes further how it is possible to transform the colon bacillus in much the same way into the actual tubercle bacillus. Or the tubercle bacillus that has been transformed into the colon bacillus can be modified back into its pristine characteristics.

**The Psychophysiology of the Aviator.**—In this sixth article on the medical aspects of aviation, López discusses the prophylactic deductions from his research on the psychophysiology of aviators. He also discusses the influence of flights on the abdominal organs and kidneys. No personal experiences are described.

### Siglo Médico, Madrid

**Diathermy in Gastro-Intestinal Disease.**—Carro regards diathermy as one more weapon at our disposal in the treat-

ment of chronic torpid ulceration in the digestive tract, refractory to other measures. He has applied it in five cases of the kind, and the lesion seemed to retrogress completely in one case and to be materially benefited in some of the others. It seemed also to hasten the recovery in three other, acute cases. The only contraindication, he says, is a tendency to hemorrhage.

- \*Standardization of Antithyroid Serum. J. Sanchis Banús—p. 668.
- \*Etiology of Mucomembranous Enteritis. D. Ramón Alcón—p. 674.
- \*Traumatic Shock. José Segovia y Caballero—p. 676. Cont'n.

**Mixed Psychoneuroses.**—Fernández has encountered in his practice cases in which one psychoneurosis was evidently superposed on another. The prognosis is grave when psychasthenia breeds neurasthenia, as this indicates the seriousness of the former. When there are evidences of hysteria with a psychoneurosis, the prognosis is generally more favorable than without the hysteria so far as the other symptoms are concerned. The combination of psychasthenia with emotional depression has always proved a grave condition in his experience as it borders on actual insanity. This is also the case when a psychoneurosis of anxiety accompanies depression; constant vigilance may be necessary to prevent suicide if these symptoms are due to an actual psychosis. He emphasizes the necessity for the general practitioner to familiarize himself to a certain extent with these five great groups of psychoneuroses, as it is so important to distinguish between functional and organic disturbances of this nature, even in the simple cases.

**The Murillo Method for Standardizing Antithyroid Serum.**—Sanchis refers to Murillo's recent assertion that antithyroid serum enhances the susceptibility of guinea-pigs to diphtheria toxin to such a degree that they die from twelve to twenty-four hours earlier. Sanchis has been experimenting to learn whether the antithyroid serum had a similar activating action on the susceptibility of guinea-pigs and rabbits to cocain, but his experiments failed to show any action of the kind from the serum of thyroidectomized rabbits. The results were positive, however, with serum from hyperthyroid rabbits, the cocain proving fatal in half the time. He theorizes that the difference may be due to action on the vagus rather than on the sympathetic. Whether the Murillo phenomenon has anything to do with the therapeutic action of the serum is still undetermined.

**Mucomembranous Enteritis.**—Ramón Alcón relates some cases to illustrate the necessity for detecting and removing the cause of bowel disease instead of routine prescribing of drugs and dieting. In one case the enteritis had proved rebellious to five or six months of this treatment and the man was very thin and depressed. It was learned that the onset of the enteritis had followed a severe accident to his wife, and that a brother had epilepsy. He was then treated as for a neurosis and a prompt and permanent cure was soon realized. Another group of patients presented signs of the gouty diathesis, and the enteritis subsided under correct treatment of the arthritis. The stools in these cases often show oxalate and urate crystals and these are liable to set up irritation. By varying the diet to induce an acid reaction in the stools, the putrefactive bacteria are crowded out and the bowel is given a chance to heal. Enteritis of this kind is rare among the poor. Fifty enteritis cases are encountered among the well-to-do for one among the poor. The enteritis following typhoid, influenza, etc., generally subsides as strength is regained.

**Intraspinal Treatment of General Paralysis.**—Juarros supplements the intraspinal mercurialized arsenotherapy with intravenous injections of mercury and neo-arsphenamin. He remarks that in some of his patients the improvement might be called a cure, if he were inclined to be optimistic. In other cases no benefit was apparent, and in a few instances

the intraspinal treatment coincided with an aggravation of the condition. The physical symptoms showed greater improvement than the mental.

- Case of Lethargic Encephalitis. J. E. Beman—p. 186.

**Specimens of Blood Corpuscles Showing Ameoboid Movements.**—Van Herwerden insists that the ordinary methods of fixation of blood specimens fail to show the corpuscles in their natural state. This can be accomplished by the simple technic he uses as he demonstrates by a photomicrograph showing the most extreme ameoboid movements in the leukocytes and thrombocytes. While the red corpuscles have the natural smooth, round outline, one mononuclear leukocyte is seen forming an L-shaped figure with nine fringe-like processes at one end, and three long arms at the other; a leukocyte shows over fifty ameoboid processes. To seize the corpuscles in this ameoboid phase, all that is necessary is to kill them rapidly while these movements are at their height. For this a watch-glass is placed in the incubator at 38 C, covered with a second watch-glass which is fitted inside with a piece of filter paper moistened with water. A drop of Ringer's fluid or of van Deetjen's fluid at body temperature is placed on a cover-glass, and a very small droplet of blood from the finger is dropped on it. The cover-glass is then placed between the two watch-glasses and left in this warm moist chamber for fifteen minutes. Then the upper watch-glass is rapidly changed for another containing a piece of filter paper impregnated with 40 per cent. formaldehyd. This is left for about half an hour, and then the cover-glass is taken out and the droplet of fluid on it is cautiously poured off, leaving the formed elements adhering to the cover-glass. The resulting preparations are remarkably fine. The blood platelets in particular show up instructively, sometimes larger than the erythrocytes, especially with the Heidenhain staining technic. He relates further that preliminary exposure to 31 mg. of radium bromid before applying the formaldehyd did not arrest the ameoboid movements of the leukocytes even when the exposure was kept up for eight hours, that is, for a longer time than it takes to arrest completely the development of the ova of a small crustacean, *Daphnia pulex*. The thrombocytes, however, did not show any ameoboid movements after this long period, either in the radium treated or untreated specimens.

**Fat Embolism and Convulsions After Nonoperative Orthopedic Intervention.**—Timmer describes the case of a girl of 7 who developed epileptiform convulsions forty-six hours after reduction of bilateral congenital dislocation of the hip joint. The convulsions kept up for two and a half hours and then subsided completely. Aberle and O'Leary ascribe such disturbances to fat embolism in the vessels of the brain, but C. Divilla is among those who explain them as a kind of reflex epilepsy. In three of the cases on record there had been sudden asphyxia, dyspnea and cyanosis before the convulsions developed, and necropsy revealed fat embolism. In one of Aberle's three similar cases, with recovery, osteotomy had been done above the knee to correct contracture from a tuberculous process. Dyspnea and cyanosis developed suddenly as the leg was being straightened, and the child stopped breathing. Under massage of the heart and artificial respiration the child began to breathe again, but the narcosis passed into deep coma. Half an hour after the breathing had stopped there were clonic spasms in both arms. By the end of three quarters of an hour the child reacted to stimuli to the skin and was soon completely roused. It seems evident here that in straightening the limb fat was forced into the blood vessels and it obstructed the capillaries in the lung. Later, the fat reached the vessels in the brain and induced the clonic spasms.

Epileptiform convulsions apparently develop only in the protracted, in neur. path., and in children with cerebral paralysis or Little's disease. There is usually an interval of from two to six days after the intervention, which is always one that required considerable wrenching of soft parts, such as correction of contracting or congenital dislocation of the hip joint. The disturbances are transient, subsiding completely in a few hours. Analysis of fifty fatal cases of fat embolism on record shows that the first includes only six children, although operations such as are liable to induce fat embolism are done commonly on children. There are no fat cells in the long bones before the age of 6 or 7; after the age of 14 the fat cells may be numerous. Atrophy of the bone is peculiarly liable to be accompanied by production of fat. We can thus assume that fat embolism need not be feared with young children unless there has been protracted inactivity and there is much atrophy of the bone, such as is likely with paralysis. Under these conditions it is wisest to refrain from osteoclasis and similar procedure. With a predisposition to nervous disturbance, with Little's disease or cerebral paralysis, extreme caution is necessary. Bilateral correction of hip joint disease should be done at two sittings, and rough force should not be applied. Timmer adds that fat in the soft parts is more compact and is not so readily taken up by the blood vessels as fat from the bone marrow.

**Heredity as a Factor in Bacterial Disease.**—Hagedoorn reports what he thinks is the first instance in which has been demonstrated the part played by heredity in modifying the susceptibility to bacterial disease. A number of Japanese breeding mice were crossed with ordinary white mice, and when an epidemic broke out in the 700 cages in three different rooms, the Japanese mice all died, but not the white mice, and lack of susceptibility proved a dominant among the offspring, as also among the offspring of the bastards paired with the white mice. These data throw light on the incidence of tuberculosis; why some escape and others develop the disease. Analysis of the heredity may well repay the trouble.

**Torsion of the Spleen.**—Nijhoff's patient was a woman of 72, previously healthy, until sudden abdominal pain and nausea developed, with other symptoms accepted as indicating torsion of an ovarian tumor. Splenectomy is easier and simpler in these cases than with a normally located spleen.

 \*Cerebral Hemorrhage. Van Braam Honckgeest.—p. 343.  
 \*Cyst of the Ovary. Jar Panter's Cyst. C. Orban, Jr.—p. 345.

**Fracture of the Neck of the Femur.**—Wassink devotes thirteen and Schiemaker ten pages to description of the recent findings in ten and in twelve cases of fracture of the neck of the femur, with eleven and three illustrations, respectively. These experiences demonstrate, Wassink declares, that fractures of this kind seldom heal, that the lack of apposition of the fracture surfaces prevents the formation of periosteal callus and hence the parts cannot grow together. He found also that the stumps were not in contact even when the roentgenograms seemed to demonstrate good coaptation. Some of his cases demonstrated further that a good position at first became defective later from traction of the muscles. The effect of weight bearing also contributes to this. The circulation in the parts is also seriously compromised, especially in the proximal portion, by the trauma and the distention. This may prevent consolidation even when the parts are in a good position. Some of his cases show that with the old defective methods of treatment, a good result may occasionally be secured, or even without any treatment. To ensure good results, the coaptation must be satisfactory and the parts must be held in the proper position long enough for them to grow solidly together. This takes an unusually long time for this special fracture on account of the exceptional strain on this bone.

Schiemaker remarks that the more innocent the fracture looks, the graver it actually is, as a rule. The swelling and

other phenomena are much less pronounced with fracture of the neck than with trochanter or basal fracture. Fracture of the neck can heal with a growth of callus around it although the neck itself may not take direct part in this reconstruction. In one case illustrated a voluminous callus developed in this way in six weeks in a woman of 81. To favor healing of basal fracture in a good position he turns the leg far inward until the axis of the foot lies in the frontal plane. This brings the neck approximately into its normal position and stretches the muscles so that they exert pressure on the trochanter mass and on the base of the neck, and promote the locking of the neck in the mass of the trochanter. The neck slants a little more than usual. Then slight abduction follows which brings the neck almost into its normal position while conditions favor its retaining this position, and healing proceeds exceptionally rapidly. In 107 cases thus treated, only once was there insufficient callus production. The foot must be held in this extreme inward rotation for six weeks; a plaster dressing is usually the best means to accomplish this, but it is not absolutely necessary if the patient is in bed.

With fracture of the neck in the middle or close to the head, treatment must be quite different. No callus forms with fracture of the neck itself. The aim here is to utilize the weight of the body to force the head down on the neck. By rotating the leg inward, with maximal abduction we can bring the neck up under the head. The plaster cast is applied to half way up the thigh, the assistant forcing the foot up to ward off equinus. Then both legs are rotated inward to the extreme limit. If only the diseased leg is rotated, the pelvis moves with it. The toes thus point toward each other, and a third assistant twists the knee and its plaster cast—all forcibly but very slowly. The leg is placed in abduction at the same time, and when the inward rotation is concluded, the abduction is continued to the extreme limit, abducting the sound leg at the same time but less forcibly. Now the operator takes hold himself, pressing the thigh outward with one hand while with the other hand he pushes the trochanter inward and down. When this has been done to the extreme possible without violence, the plaster dressing is completed, enclosing the whole of the pelvis and on the sound side high up on the ribs, to maintain the abduction. It would be still better if the sound leg could be encased in the plaster, but this would prevent walking. Abduction is about 45 degrees, and the knee is turned almost completely inward. His roentgenograms show the almost perfect results realized with this technic in 23 cases. In 8 others the outcome was a total failure; in 3 the patients can walk but not well; 8 are still in treatment, and 10 have died since, of the 52 cases of subcapital fracture treated in this way. In the cases of failure, operative intervention may be required. The latter is not advisable for the aged, and the above non-operative technic is almost certain to succeed in the young. The field for operative interference is thus restricted to the middle aged, and Noordenbos's method of fixation with a peg from the fibula driven into the head seems to be most promising.

**Mode of Action of General Light Baths.**—The results of Sonne's experiments apparently demonstrate that the chemical rays have very little to do with the therapeutic action of heliotherapy or general light baths. The light from the sun, the special arc electric lights, and the mercury vapor light all have the property, he says, of heating the blood to a remarkable degree without at the same time heating the body tissues. It seems plausible to assume that to this action, common to these three sources of radiant energy, their unmistakable therapeutic effect is due.

## THE EFFICACY OF EXISTING MEASURES FOR THE PREVENTION OF DISEASE \*

GEORGE A. SOPER, PH.D.

Major, Sanitary Corps, U. S. Army

NEW YORK

### I. THE CONTROL OF DISEASE

These remarks relate to an inquiry into the different procedures for the prevention of the ordinary epidemic diseases of civil life, the object being to determine the spheres wherein substantial progress has been made and the trend in which future efforts should be directed.

It is proper to state that the scope of an inquiry of this kind is necessarily limited by the fact that less than 1 per cent. of the world's population enjoys the benefits of systematic health work, and, of this small part, only a fraction compiles such records as will permit the efficacy of the work being known. It may be asked how we shall measure the efficacy of procedures for the prevention of disease if vital statistics do not afford the means? The answer is that we must do the best we can with the statistics that are available, and for the rest rely on personal observation. To a considerable extent we must use our judgment. We must note where success or failure has occurred and try to find the reasons.

When we turn our attention to the list of great epidemic diseases, we find that definite and effective procedures are available to combat most of them. The list includes plague, cholera, typhoid and dysentery, typhus, malaria and yellow fever. Such difficulty as exists in controlling these diseases lies in the practical application of the procedures rather than in the procedures themselves. The crux of the difficulty lies in the fact that the diseases in question often need to be combated among people to whom habits of ordinary cleanliness and decency are unknown. It is in consequence of this that when occasional cases of cholera, typhus and plague are brought to western countries there is no fear of them, and when they occur in some other countries it is impossible to stamp them out.

We have spoken of the control that can be exercised over occasional cases. How far an epidemic disease may spread in a sanitary environment if a sudden and extensive outbreak of it occurs is another matter. Sometimes it gains great headway and becomes ungovernable. It is one thing to deal with an infection in its retail aspect and another to manage it in wholesale proportions. This is true of all epidemic diseases.

Disease is like fire; only certain amounts of it can be controlled. We can do nothing with a conflagration.

If a disease visits only a house, or barrack or ship, it can be restricted to that place. If it attacks an extensive locality or a group of localities, whether it shows a tendency to spread from one to another or affects all simultaneously, it is more difficult to deal with it. If the epidemic visits large tracts of country at once or in succession, it is practically impossible to stop it. And a disease that breaks out over vast areas of the world's surface at long intervals is entirely beyond human control. It is, therefore, only in their more restricted, not to say attenuated forms, that most epidemic diseases are controllable. Applying the illustration of fire again, we must seek out the sparks and quench them before they kindle a blaze.

So far as the greatest of all epidemic diseases is concerned, we know nothing. We do not know what influenza is nor how it can be prevented. We are as powerless against it as were our ancestors against smallpox before vaccination was discovered. It is to be hoped that the many intensive studies that have been made of the recent influenza pandemic will result in effective preventive procedures being devised, but so far nothing that is practical seems to have been brought to light.

### CAUSE OF THE DECLINING DEATH RATES FROM EPIDEMIC DISEASE

In the opinion of some persons we are as helpless against many other diseases as we are against influenza. The assertion is made that it is due to their peculiarities rather than to any control that we are able to exercise that the infections which are commonly with us are not more prevalent than they are. Reference is here made particularly to meningitis, poliomyelitis, measles, scarlet fever, mumps, whooping cough and diphtheria.

Some diseases that exhibited alarming epidemic proportions fifty years ago no longer occupy a prominent place in mortality statistics. Scarlet fever, which formerly showed marked fluctuations and a high rate, taking annually, in some years, 125 lives per thousand of population, has become steady in prevalence and seldom claims more than one life in 10,000 in a single year.

Diphtheria, which sometimes ran an epidemic course for years, and in one state, at least, caused an average mortality of 410 per hundred thousand of population, has subsided nearly everywhere to a steady, low death rate of about 10. Measles, whooping cough, and other so-called contagious diseases, have shown as distinct, if a less marked reduction.

It is a curious fact that the diseases mentioned, although differing markedly in prevalence among themselves many years ago, have in recent years come down

\* Read before the Seventieth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

to a low and uniform prevalence. One is only a little more common than another. The rate in one part of the country seems to be about the same as the rate elsewhere. Undoubtedly the epidemic diseases have become less and less epidemic. Why is this? Are we to conclude that it is owing to our better knowledge of the causes and to the greater efficacy of our measures of prevention that these infections have been disappearing? If so, we must assume that our knowledge has increased over that which we possessed in former times and that our measures for combating disease are superior to those which were formerly employed. This supposition is incorrect in both of its parts. We know nothing more as to the cause of some of these diseases than was known twenty years ago. Nobody can maintain that the procedures followed in combating scarlet fever or measles are more effective than those which were used then. It is true that the cause of diphtheria is known and that there has been an intelligent and well directed fight made against it. But the decline began before this knowledge appeared. The means of prevention of scarlet fever and measles and whooping cough and various other contagious diseases are as difficult today as they ever were and there are no more vigorous measures taken against them now than formerly.

The epidemic diseases are disappearing, probably not so much because of the fight that is made directly against them, as on account of indirect influences that bear on them. It is impossible to state with scientific accuracy what all of these are or exactly how they operate, but it is possible that they have to do with the higher standards of living which prevail.

Disease is an ally of ignorance, dirt and disorder, and it everywhere tends to disappear on the improvement of knowledge and of social conditions. Standards of personal, domestic and municipal living are ever advancing and sweeping away the opportunities that formerly existed for the spread of infection.

Glancing over the range of common infections, it appears that, aside from smallpox, the kinds of disease that have proved most amenable to direct control are of the enteric type. The part of the world with which we are familiar has seen an immense reduction in the prevalence of these diseases. Devastating epidemics, formerly a constant menace, rarely occur now. Typhoid, diarrhea and dysentery have yielded their greatest terrors to the fight that has been made against them.

It is in the management of the respiratory infections, which terminate so often in pneumonia, that the least progress has been made. This group constitutes the leading cause of death in most civilized countries.

When the data representing the death rates from pneumonia in our cities and states from year to year are plotted, the curve forms a very different figure from the curve of any other infection. First, it lacks uniformity to a marked degree. Second, it is always high; it is about ten times as high as the curves of the exanthems. Third, it is, as a whole, not declining. These are criteria of epidemicity: fluctuating high and not receding rates. Pneumonia is unquestionably an epidemic disease which is manifesting a characteristic epidemic behavior. It is not under control and up to the present no way has been discovered to control it. These facts ought to be recognized at once. We shall see them clearly in a few years. It is our nearness to the conditions that causes us to be so indifferent to them.

#### THE THREE GREAT FIELDS OF EFFORT

Passing to a consideration of the ways in which disease of different types has been combated, we note that there have been three general fields of effort:

1. *Sanitation.*—By sanitation is here meant systematic health work of the type that generally requires a plant and a force of men to maintain it. Examples are works for the procurement of wholesome drinking water, the collection and disposal of liquid sewage and the gathering and final disposition of kitchen waste, ashes and other discarded material.

Sanitary works possess a number of advantages as compared with other measures for the prevention of disease. First, they have a wholesale application. A water supply that is made pure is wholesome for every person who has occasion to drink it. Although there is a considerable investment of capital in these enterprises, the maintenance charges are not excessive and the results are satisfactory. Yielding to works of sanitation are not only typhoid, dysentery and other diarrheal diseases, but some other forms of sickness that cannot conceivably be conveyed by drinking water. This phenomenon has been described in papers that are so easily accessible as to need no repetition here.

It is impossible to pass this point without suggesting that the introduction of any measure that materially contributes to the cleanness, convenience and order of a community helps to eliminate disease, even though its exact manner of doing so may not be apparent. Simple cleanness is one of the most healthful as well as one of the most educative measures known. Contributing, therefore, to the efficacy of existing measures for the prevention of disease in a community must be included such betterments as good street pavements, adequate lighting systems, suitable police regulations and agreeable parks.

Among the disadvantages of sanitary works is the fact that they are not available for communities of small size. A town must be rather large and compactly built before it can afford to have its houses served with a common water supply, a common sewerage system and a common scheme for the collection and disposition of ashes and garbage. Up to a certain point the relative cost is in inverse proportion to the size of the place.

2. *Administration, or Board of Health, Work.*—The scope covered by administrative action is large. It is essentially twofold. The primary intention is to keep disease from entering a community. When this effort fails, the next purpose is to detect the presence of the infection and to take appropriate action to suppress it.

The essence of this kind of work lies in three procedures: (a) the collection of data which, when properly interpreted, point to the existence of conditions that need attention; (b) the investigation of conditions to which attention is drawn, and (c) the application of the detailed measures of suppression that are necessary.

Under the head of administration are to be considered such useful activities of boards of health as the collection of statistical facts in relation to population, sickness and death; the supervision of foods and drugs; the regulation of quarantine; the performance of vaccination and inoculation; the distribution of serums and the education of the public through bulletins, lectures, reports and other methods of publicity.

In controlling disease, boards of health have the advantage of a broad range of action and an authority

that is granted to few departments of government. The powers of boards of health are equal to those of the police, of which they are, in fact, a part. No lack of authority exists, therefore, for the enforcement of any measures that may be necessary.

The chief disadvantage of board of health work lies in the fact that to be effective it must be skilful. It seems difficult for the public to understand this fact. Of all the departments of a city or state, the board of health should be the most free from corrupt or incompetent management. Too often a board of health is looked on as a quasipolitical organization in which persons of less than first class ability are considered fit for even the highest offices.

Boards of health are often embarrassed by a multiplicity of duties that could as well be attended to by other departments of government. Some boards of health are actually loaded down with work of this kind. In view of the fact that boards of health have so much difficulty in securing proper support for the work that they really should attend to, they should confine their efforts as far as practicable to what is essential and within their province. By doing well the things that they must do they can accomplish far more for the public welfare than by attempting so much.

It must not be supposed that boards of health are everywhere of equal efficiency or have the same problems to deal with. Boards of health should everywhere combat disease, but they must do this in different ways in different places. There is a vast amount of difference between the duties of a rural health board in an out-of-the-way district and the work of a city board in a highly congested region. The object to be accomplished in conducting board of health work is to fit the effort to the local circumstances. To do this in the most direct and effective manner possible should be the aim.

The communicable diseases that are usually considered especially amenable to administrative control are the exanthems, malaria and the enteric diseases, and such respiratory affections as tuberculosis and diphtheria.

An important field for administrative health regulation, and one that has only recently been fully appreciated, lies in the prevention of disease connected with industrial occupations. These are of various types and are preventable, whether they are infectious or not, by the employment of the general principles of avoidance, detection and investigation and by application of special procedures suitable to the particular circumstances in which they occur.

3. *Personal Precautions.*—Theoretically, the scope of personal effort for the prevention of disease is very large; as now practiced it is limited. It might be regarded as a branch of administrative work appropriate to boards of health except that its proper development by the ordinary administrative agencies that exist is almost wholly neglected. It would seem better to handle this subject on a bigger, broader and better plan. A suggestion along this line will presently be offered.

Personal precautions are unique in the field of disease prevention in that they possess a double function and a double responsibility. This lies in the circumstance that many diseases cannot be prevented by the exercise of precautions solely on the part of the persons who are in danger of them. In many instances the person who constitutes the danger must himself take the steps that will protect others.

As now practiced, personal precautions are restricted and uncoordinated. Every one exercises certain precautions, consciously or unconsciously. It is instinctive to avoid things that smell bad, that look revolting and that suggest pain or discomfort in any form. Other precautions are a part of the elementary education which every person gets in the school of experience. The efficacy of all of these efforts suffers for want of direction. Things are constantly being done by most persons which expose them unnecessarily to disease, and aggravate their illness when attacked.

#### THE SPECIFIC MEASURES FOR COMBATING DISEASE

The specific measures that are employed for the prevention of disease may be grouped for consideration under the three heads of sanitation, board of health work and personal precautions which we have used in discussing the three great fields of preventive effort. The relative efficacy of each under its appropriate head is indicated by the order in which it is placed in the subjoined list:

##### SANITATION

1. Public water supplies, water purification and the conservation of the sources from which drinking water is derived.
2. Sewerage and sewage disposal.
3. Land drainage for the elimination of stagnant water and mosquitoes.
4. Street cleaning and garbage and waste collection and disposition.

##### BOARD OF HEALTH WORK

1. Isolation of the infectious sick, including quarantine, and the maintenance of special hospitals for contagious diseases.
2. The collection of vital statistics.
3. The preparation and employment of vaccines and serums.
4. The supervision of food and dairy products.
5. The sanitary inspection of dwelling places, industrial works and recreation.
6. The regulation of plumbing.
7. The supervision of dangerous trades and occupations.

##### PERSONAL PRECAUTIONS

1. The avoidance of the presence of the infectious sick.
2. The proper disposal of bodily wastes.
3. Vaccination and inoculation.
4. Discrimination against obviously dangerous foods, drugs and beverages.
5. Avoidance of chill, excessive fatigue and other conditions believed to predispose to, or aggravate, disease.
6. Cleanliness.

When all these procedures are examined critically, we are startled by the fact that so few of them seem indispensable. Of the seventeen specifications there is hardly one which could not be dispensed with, in any city or town, without the least danger of precipitating an epidemic. Many could be omitted indefinitely without producing any visible effect on the death rate.

This leads us to perceive that in cities the effectiveness of measures for the prevention of disease depends not on one thing, or a few things, but on many things. The comparatively low death rates of urban as compared with rural communities is largely the result of circumstances that directly and indirectly make it difficult for infectious matter to pass from person to person.

When we come to consider our seventeen specifications in relation to rural conditions we are likely to be still further surprised. We find that most of them are not applied. There are millions of people living in rural communities in America to whom all these procedures are unknown. Surprising as it may seem, they

know not sanitation or board of health work or personal precautions nor any of the technical procedures included under these heads. With them infectious diseases run a natural and unrestricted course. It may or may not be due to this fact that, in spite of the crowding, there is less infectious disease of some kinds in the city than there is in the rural districts.

It is worth while to look over the mortality statistics issued by the Bureau of the Census to see what the death rates are in the city and in the rural districts of the United States. About 70 per cent. of the population of this nation is represented in the returns; for the rest the figures are too inaccurate to warrant the government in publishing them. The latest data relate to the year 1916.

For some time the general death rate from all causes has been slightly higher in the cities than in the rural districts. The rate for the cities has varied from about 14.5 to about 15 per thousand population. The rural rate has ranged from 14.0 to 14.6.

Faking ten of the most common infections for comparison, we find that typhoid, influenza and whooping cough are more prevalent in the country than in the city and that pneumonia, tuberculosis, diphtheria, scarlet fever and measles are more common in the city than in the country.

The measles and scarlet fever that have occurred in the American army camps in the war have been explained on the ground that a large proportion of the men were from the country districts and had never had those diseases so that they were consequently susceptible to them. In passing it is rather curious to note that whooping cough, which ordinarily causes as high a death rate as measles or scarlet fever, and is often associated in point of time and place with those diseases, did not gain footing in the army. The age of the men seems to have protected them against it.

It must, therefore, be confessed that the efficacy of the best preventive measures is not great. Excluding water and sewerage works, the collection of statistics, the use of vaccines and serums, and such personal precautions as the proper disposal of bodily wastes and the isolation of patients ill of contagious diseases, there are no technical procedures that are known to have much specific value in preventing disease in civil life. It is curious to see how useless many of them are. It is still more curious to see how we cling to measures whose uselessness is perfectly apparent.

#### II. LESSONS TAUGHT BY THE WAR AS TO THE CONTROL OF DISEASE

Curiosity will naturally be felt as to the lessons taught by the war. In some quarters it is supposed that the experience that the mobilization of our army has offered has thrown much new light on the possibilities of controlling disease. This is not the fact. The light that this experience has thrown has not so much resolved new facts as it has made some old facts more plain. The war has proved most useful as a teacher of the fundamental principles of disease control.

It has shown more clearly than ever that it is persons and not things that are to be feared; that danger lies in short, direct and often obvious channels of infection rather than in long, roundabout and mysterious ones.

The importance of early and accurate diagnoses for the purpose of detecting the sources of the infective

virus has received much attention. The war has demonstrated the need of searching out these sources rather than waiting for them to come to light later on. Formerly, in civil life, if a child was sick it was kept at home, more or less separated from its fellows, until its disease unmistakably manifested itself. In the army the men, whether apparently sick or well, were stripped and inspected periodically for the earliest possible evidence of infection. If they had knowingly been exposed to certain diseases and did not acknowledge it, they were subjected to court martial. By this procedure, many cases were detected in their incipency and others of a mild character that would have escaped detection through their whole course were discovered. The prevention of infection thus accomplished was probably considerable.

The value of isolation was abundantly proved. This, of course, is the most perfect means of keeping disease from spreading that has ever been invented. It is the basis of a great variety of practical procedures such as quarantine. The use of masks and cubicles afford applications of the same principle. The difficulty with isolation always has been in making it effective without too greatly interfering with the person's normal activities. Nowhere have better opportunities to observe the advantages and disadvantages of isolation been afforded than in this war.

Nothing new of importance has come to light in regard to disinfection as applied to the environment. Disinfection, except in special circumstances, had been practically given up in the army before America went into the war, and nothing that has been found out since has led to a return of this old-fashioned procedure. It is to be understood, of course, that the disinfection of water supplies does not come within the scope of this remark. Oiling of floors to keep down dust and the wiping of walls, the airing and sunning of bedding and similar measures are not disinfection, as that term is ordinarily employed.

Great emphasis has rightly been placed on indirect measures of prevention. Such simple and well tried measures as ventilation and cleanliness were among the most valuable steps taken to prevent disease in the American army. The American soldier stood for cleanliness. It is probably not too much to say that an army was never mobilized in more clean and orderly camps and never took the field with higher standards of personal cleanness than did the American troops in this war.

The war has demonstrated the great value that attaches to focused attacks on disease. This was illustrated in two entirely different groups of infections, the typhoid group and the venereal group. The lines of attack on typhoid were sanitation and preventive inoculation. The result was that typhoid, notoriously a disease of camps, was practically unknown in the American cantonments where these procedures were carried out. Every city and community should learn the lesson that this experience teaches. In seeking to eliminate typhoid fever, the last of the filth diseases, sanitation, inoculation and personal precautions should all be insisted on.

Nothing that the army did was more profitable than its efforts to teach the soldier how to take care of himself. The war taught no greater lesson in any direction. It was found that the men could learn and did learn. The increasing resistance of the individual was not simply the result of a hardening process. It was partly

the result of the shrewd application of a thousand small precautions that the experienced soldier knows.

We have spoken of the useful lessons that the war has taught. Let us look on the failures. The war has shown the hopelessness of efforts conducted along ordinary lines in the fight against respiratory infections. Little was done successfully in handling this group of diseases in the camps. A great lesson has been learned as to what it is useless to do. The war has taught us the need of attacking this subject in a manner different from anything heretofore undertaken—in a manner commensurate with its vast importance. It is time civilization stopped temporizing with the respiratory infections and undertook to put their management on a satisfactory basis.

The army has done a great work in combating epidemic diseases even if this work has not always been as successful as idealists would have had it. Briefly, it has taught that the time to study the management of infections is before the pressing necessity for this knowledge occurs. It has taught that disease must be looked for and not waited for; that the existence of infection is usually proof of neglect in some direction or other; that disease is really a reflection on common sense; that responsibility for it is not only a matter for communities to give attention to, but it is for the individual person to learn about and to avoid. In teaching personal responsibility, ground has been prepared for substantial improvement throughout the whole range of preventive effort. It is a part of the large significance which attaches to this subject that the lessons of the army are not only to be useful to armies in the future, but rightly they are the property of, and will be appropriated by, the world in times of peace.

#### THE GREATEST NEED IN HEALTH WORK

There is a great field, quite uncultivated as yet, for the competent instruction of the public in measures for the prevention of disease. Everybody should know how to do his part in avoiding infection. Infectious diseases do not monopolize the list; other forms of illness that are within the range of personal control are comprised in the category. When illness is disposed of, the promotion of an ever greater share of health affords a goal toward which every one should be taught to strive intelligently.

How to live and work and enjoy the greatest share of health should be taken out of the realm of uninformed guesswork where now it exists and set before the public on a substantial basis of scientific fact and authoritative opinion. This cannot be done at once. It cannot be done with the agencies or resources now available. There is much to be learned in respect to the laws of health and collective and individual precautions. The course to pursue is clear. There should be study, enunciation, and propaganda of sound principles.

Who is to teach this doctrine and put disease control on a sound basis of efficiency? The national government can help, if it is properly equipped and can secure the necessary support; schools of hygiene and the insurance companies can help; and great associations like the American Medical Association; and humanitarian foundations; and industrial physicians; and individual persons. But what is needed above all is leadership. This should come from competent professors in our medical schools and universities. The university should be the fountain head of knowledge

From here, as from a focus, competent instruction should radiate.

Reviewing the whole subject of the efficacy of existing measures for the prevention of disease, we may say, without fear of successful contradiction, that the respiratory infections which terminate in pneumonia are the ones that need most attention, and that need and opportunity both joint to well instructed, individual effort as the means most likely to prove effective against them.

There should be a well organized, nation-wide effort to develop the field of personal precautions. There should be a campaign to teach men and women and children what they should do to protect themselves and their neighbors against infection. The interest in personal precautions that has been aroused by the campaign against venereal disease has well prepared the public to take up further health instruction.

Responsibility for the teaching that is required belongs primarily to our professional educators. The administrative authorities in our educational institutions whose business it is to select and support capable teachers should see to it that well trained and experienced persons are placed where their efforts will count. Every university and medical school in the United States should have a chair of hygiene.

#### A CLINICAL STUDY ON THE USE OF CALOMEL INUNCTIONS\*

H. N. COLE, M.D.

AND

SIDNEY LITTMAN, M.D.

CLEVELAND

Since the earliest times, mercury inunction has been used for the treatment of syphilis. The drug, however, has always been employed in the form of an ointment of the metallic mercury. Recently Wile and Elliott<sup>1</sup> and Schanberg, Kolmer, Raiziss and Gavron<sup>2</sup> have suggested the use of an ointment made of calomel; this, for several reasons: The blue ointment is very uncleanly; it leads to discovery, and it frequently sets up an irritation of the skin. As calomel is more cleanly, and as the latter four authors felt that it is fully as well absorbed through the skin as the ordinary blue ointment, they suggested that it be used for inunction purposes in a formula consisting of:

	Gm.	
Hydrargyri chloridi mitis . . . . .	3	gr. xlv
Lanolini . . . . .	1	gr. xv
Adipis benzomati . . . . .	2	gr. xxx

The arguments of these writers seemed convincing, and we commenced using calomel inunctions, especially in private practice, in the spring of 1917. Since then the use of the calomel rubs has become so extensive that a manufacturing drug house has brought out an ointment of calomel which is a little more pleasant in form than the ordinary preparation, though probably no more efficient.

\* Read before the Section on Dermatology at the Seventeenth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

<sup>1</sup> From the Department of Dermatology and Syphilis of the Western Reserve University, School of Medicine and of the Cleveland City Hospital.

1. Wile, U. J., and Elliott, J. A.: Mode of Absorption of Mercury in the Inunction Treatment of Syphilis, *J. A. M. A.* **68**: 1024 (April) 1917.

2. Schanberg, J. I.; Kolmer, I. A.; Raiziss, G. W., and Gavron, J. I.: Experimental Study of the Mode of Absorption of Mercury When Applied by Inunction, *J. A. M. A.* **70**: 142 (Jan. 19) 1918.

It was only after we had used this for some time that we began to feel more and more that it was not doing what was required of it. In the first place, we noticed, as was later called to our attention by Dr. Forald Sollmann of the Pharmacology Department of the Western Reserve University, that the patients did not get salivated. Moreover, it seemed that many times the patients did not react to treatment as they had formerly, when we were using inunctions of blue ointment instead of calomel, or when using injections of mercury. Therefore, in order to test out the efficacy of the inunction of calomel thoroughly, we commenced a series of experiments, using the fresh, clinical syphilis in our wards in the venereal disease department of the Cleveland City Hospital. We shall report the results of tests carried out in the past year or so in fifty-four cases. This investigation was undertaken at the suggestion of the Therapeutic Research Committee of the Council on Pharmacy and Chemistry of the American Medical Association.

Before describing these individual cases, we would say that we have tried to be as unprejudiced as is possible. The cases have been carefully followed; routine Wassermann tests on the blood, *Spirochaeta pallida* examinations and spinal fluid examinations were made in every instance. Moreover, in using the ointments, the patients have always been under the observation of an orderly or of a nurse to see that the inunction was carried out through a space of at least thirty minutes for six nights in each week, with a hot bath on the seventh night, and without other medication. Each patient has used an ordinary potassium chlorate mouth wash, but otherwise the run of teeth has been simply that of the teeth that one finds in any free hospital practice, which is to say, usually very poor.

In nearly all cases we used the 50 per cent. calomel ointment described above and made up by the hospital pharmacist. In the few cases which are noted in the clinical histories we employed a proprietary calomel preparation.

It has often been difficult to keep the patient under the calomel rubs for as long a time as we would desire, especially if the patient did not seem to improve in his own estimation. Again, we have found that frequently the patients would get together and talk over the therapy and advise each other as to their estimation of the therapy being used. To overcome this, and to make the experiments still more objective, we finally gave the patients saline injections into the arm during the course of the calomel rubs, so that they would not know that they were not receiving arsphenamin injections. In this manner we did our best to carry on the inunction treatment as long as possible, with practically every patient.

#### REPORT OF CASES

CASE 1.—G. M., a woman, aged 19, had marked mucous patches on the tonsil and the pillar, condylomas of the vulva and anus and a mixed macular papulosquamous eruption. After thirty-two rubs the patches were still present on the tonsils, though the skin showed some improvement. Rapid improvement followed the use of arsphenamin at this time.

CASE 2.—A. A., a woman, aged 25, had marked condyloma of the anus and a generalized macular eruption. There was no change after eighteen rubs, and the patient demanded arsphenamin.

CASE 3.—G. H., a man, aged 40, had marked patches on the tonsils, an annular syphilid on the forehead and extensive condylomas. There was no change after eighteen rubs, and because of the patient's insistence he was given treat-

ment with arsphenamin, especially as the spinal fluid cell count had increased from 3 to 50. The patient had very bad pyorrhea, yet showed no gingivitis after thirty rubs.

CASE 4.—E. F., a man, aged 28, had mucous patches on the left pillar and a generalized macular eruption. After eighteen rubs the patches were still present on the pillar, and there was no change in the eruption. Rapid improvement followed treatment with arsphenamin.

CASE 5.—G. L., a woman, aged 21, complaining of headache and rheumatism, had a spinal fluid cell count of 25 and patches on the right soft palate. After twenty-four rubs the patches were much worse in the throat, and the patient was given arsphenamin therapy. Rapid improvement followed.

CASE 6.—W. G., a man, aged 31, had a "veneric" chancre the size of a dime, of three weeks' duration, on the foreskin. During the course of twenty-two rubs, a secondary eruption developed, and large patches appeared on the left tonsil. Rapid improvement followed treatment with arsphenamin.

CASE 7.—N. C., a man, aged 27, had a follicular syphilid. After twenty rubs, patches appeared on the left tonsil. He rapidly improved after treatment with arsphenamin.

CASE 8.—N. W., a woman, aged 20, colored, had an extensive annular syphilid over the entire body. The condition became worse after eighteen rubs, and a deep, syphilitic ulcer began on the right tonsil after twenty rubs. Rapid improvement resulted from treatment with arsphenamin. The rubs were continued up to forty with no evidence of stomatitis or gingivitis.

CASE 9.—J. S., a man, aged 28, had a symmetrical papulosquamous syphilid. There was no change after thirty-one rubs. A rapid improvement followed treatment with arsphenamin.

CASE 10.—D. A., a man, aged 45, had a large gumma in the right inguinal region. A history of syphilis was denied. The spinal fluid count was 108 cells. After thirty rubs the gummatous mass showed no change, but the spinal fluid count dropped to 35 cells. We continued the calomel rubs to forty-three with no stomatitis or gingivitis. The gumma healed quickly on one injection of arsphenamin, showing improvement almost within twenty-four hours.

CASE 11.—E. R., a woman, aged 52, had papulocrustaceous and serpiginous lesions on the right arm. They all disappeared after twenty rubs with calomel. She received thirty rubs with no effect on the teeth.

CASE 12.—E. B., a man, aged 18, had a papulosquamous syphilid and areas of lichen syphiliticus. After twenty-five rubs, the eruption on the body was fairly well cleared up, but patches in the throat and on the lips were much more severe. Rapid improvement followed treatment with arsphenamin.

CASE 13.—J. B., a man, aged 29, had marked patches on the tonsils, and macular syphilis. After nineteen rubs the patches entirely covered the tonsils, though the skin was clear. There was a rapid improvement under arsphenamin treatment. No stomatitis was present after twenty-three rubs.

CASE 14.—A. K., a girl, aged 16, had a chancre on the upper lip and a macular eruption and patches in the throat. There was no change after twelve rubs, and the patient demanded different treatment.

CASE 15.—J. N., a woman, aged 20, had condylomas and also patches on the left anterior pillar, uvula and soft palate. There was no change after twelve rubs, when the patient escaped from the hospital.

CASE 16.—W. E., a girl, aged 16, had condylomas of the vulva and patches on the left tonsil. After twenty-one rubs the tonsils were still covered with patches, when the patient escaped from the hospital.

CASE 17.—J. H., a man, aged 25, had patches in the mouth and the throat, condylomas of the anus, and fissures at the corners of the mouth. After nineteen rubs the oral fissures became condylomatous, with no evidence of gingivitis. There was a rapid improvement after arsphenamin treatment.

CASE 18.—T. S., a man, aged 28, had mucous patches on both tonsils, the soft palate, and inside of the left cheek; and a faint, macular syphilis. After twenty-four rubs the

patches were worse, though there was no gingivitis in the mouth. The patient complained severely of rheumatic pains, and of the joints. There was a rapid improvement under treatment with arsphenamin.

CASE 19.—C. B., a man, aged 25, had a faint macular eruption and primary lesion in the balanopreputial sulcus. After eighteen rubs the primary lesion showed no change, and the patient had very severe rheumatic pains. The eruption became more marked. There followed a rapid improvement under arsphenamin treatment, with the teeth showing no gingivitis after twenty-five rubs.

CASE 20.—J. S., a man, aged 42, had a large ulcerocrustaceous syphilitic covering the entire abdominal wall. There was a moderate improvement after forty-one rubs, with a miraculous change within forty-eight hours after arsphenamin was given. The teeth showed no gingivitis.

CASE 21.—W. W., a man, aged 21, colored, had patches on both tonsils and an annular syphilitic on the neck, right elbow and buttock. After thirty rubs the lesions in the throat showed no change, and several circinate lesions had appeared on the right elbow. The patient escaped from the hospital at this point.

CASE 22.—A. W., a woman, aged 29, colored, had an annular syphilitic of the face and lips, and around the nose. After eight rubs she developed a marked edema of the skin, followed by desquamation and tenderness. A faint trace of albumin and a few casts appeared in the urine. The condition was diagnosed as calomel dermatitis, and it all cleared up quickly after the calomel rubs were stopped.

CASE 23.—C. S., a woman, aged 24, had patches on the lower lip and lesions on the labia majora. After twenty-six rubs papulosquamous lesions, syphilitic in character, appeared on the arms and neck. There was no change in the patches. Instantaneous results followed the use of arsphenamin.

CASE 24.—R. H., a man, aged 28, had a macular syphilitic on the chest, abdomen and back. After twelve rubs the macular eruption was gone, and the mucous membranes cleared. The patient felt fine after fourteen rubs. After thirty-two rubs an extensive mucous patch began to develop on the right posterior pillar. There was no evidence of gingivitis. The spinal fluid count, on the patient's admission, was 43 cells. After thirty-two rubs there were 38 cells. Bloody fluid was found after the patient had received three injections of arsphenamin. He reacted immediately to treatment with arsphenamin and showed no evidence of hydrargyria after forty-three rubs.

CASE 25.—J. A., a woman, aged 17, had condylomas of the vulva and anus, a faint, macular syphilitic, and patches on both tonsils and pillars. After twenty-four rubs the condylomas were markedly improved, but the patches in the throat were much worse, though they had showed some improvement after twelve rubs. The patient was given arsphenamin, and results were rapid. She took thirty-six rubs, with no evidence of stomatitis.

CASE 26.—R. H., a woman, aged 18, had mucous patches on both tonsils; a flat, papular syphilitic on the face, chin and neck, and a general macular eruption. After eighteen rubs the lesions had all disappeared. The patient developed marked stomatitis and gingivitis after twenty-one rubs. She was then given arsphenamin.

CASE 27.—H. P., a man, aged 28, had mucous patches on the lips, tongue, tonsils, pillars and uvula, and a faint macular eruption. After eighteen rubs the lesions on the lip and tonsils were practically gone, the skin showing a slight desquamation. The patient was then treated with arsphenamin.

CASE 28.—J. D., a man, aged 18, had mucous patches inside the upper lip and over the tonsils, pillars and uvula. After twenty-two rubs the patches on the left corner of the mouth had become almost condyломatous in character; those in the throat remained the same. There was a rapid improvement under treatment with arsphenamin. The patient took thirty-eight rubs, with no evidence of stomatitis or gingivitis.

CASE 29.—W. M., a man, aged 24, had maculopapular syphilitic and condylomas along the sulcus and around the anus. After thirty-four rubs there was no change in the condition. It cleared up rapidly under treatment with arsphenamin. The

patient took fifty-one rubs with no evidence of gingivitis or stomatitis.

CASE 30.—R. M., a man, aged 22, had phimosis with a papular chancre of four weeks' duration. Under treatment with rubs, a papulosquamous syphilitic appeared, and after twenty-three rubs the patient had severe patches in the throat and one on the upper lip. After thirty rubs he began to complain of loss of hearing, which was explained as an extension of the mucous patches and inflammation up the eustachian tubes. After thirty-six rubs the patient was given arsphenamin and rapid improvement followed. No evidence of stomatitis or gingivitis appeared after forty-two rubs.

CASE 31.—A. D., a woman, aged 33, had mucous patches on the tonsil along the edge of the tongue, flat, papular lesions over the labia and general papular syphilitic. The patient immediately salivated after twelve rubs. Patches were still present in the mouth after eighteen rubs, though the lesions on the vulva were somewhat better. She was given arsphenamin at this time because of the teeth.

CASE 32.—J. C., a man, aged 32, had marked phimosis with condylomas in the sulcus back of the glans. Spirochetes were present in the lesions. The patient was much worse after fifteen rubs, and was given treatment with arsphenamin. The lesions showed a marked improvement twenty-four hours later.

CASE 33.—J. L., a woman, aged 26, had mucous patches on both tonsils, the pillars and uvula. After seventeen rubs the lesions in the throat were more extensive, and the patient was given arsphenamin. She took thirty-two of the rubs with no evidence of stomatitis or gingivitis.

CASE 34.—J. C., a man, aged 51, had macular syphilitic. After ten rubs his eruption was fainter. After twenty rubs definite patches began to appear in both tonsils, and he was given arsphenamin. He had thirty rubs with no evidence of gingivitis. The spinal fluid count, on the patient's admission, was 11 cells. After twenty rubs, there were 22 cells in the spinal fluid.

CASE 35.—J. U., a man, aged 55, had extensive mucous patches on the right anterior pillar, on the shaft of the penis, and on the scrotum. Condylomas of the anus were present, and macular syphilitic. After twenty-two rubs, the patches in the throat extended high up on the soft palate, and arsphenamin was ordered. Rapid improvement followed. The patient took thirty-six rubs with no evidence of stomatitis or gingivitis.

CASE 36.—J. R., a man, aged 29, had a macular eruption, extensive mucous patches on both tonsils and on the pillars, and large patches on the under surface of the right side of the tongue. After twenty-one rubs of the proprietary, the lesions on the tongue had become an ulcer, and the patient developed severe headache. He was given arsphenamin, and all symptoms cleared up rapidly. He received twenty-six rubs with no evidence of stomatitis or gingivitis. On the patient's admission, the spinal fluid cell count was 1. After twenty-one rubs, the fluid was bloody.

CASE 37.—J. J., a woman, aged 25, had a fine military syphilitic. After twenty-four rubs, the rash was fading. After thirty-seven rubs, a follicular syphilitic appeared on the face and forehead, and a definite mucous patch on the tonsil. The patient was given arsphenamin, and there was a rapid improvement. She took fifty rubs with no evidence of gingivitis or stomatitis. The spinal fluid cell count, on her admission, was 3. After thirty-seven rubs, there were 27 cells in the spinal fluid. The count dropped to 3 after four injections of arsphenamin. In this case the proprietary preparation was not used.

CASE 38.—L. G., a man, aged 45, had an extensive ulcerocrustaceous syphilitic on both legs. After twenty-three rubs of the proprietary preparation, the lesions on the thigh had improved 50 per cent., and the patient had a slight gingivitis in conjunction with an old, extensive pyorrhea. At this time he developed gangrene on his leg. Operation was refused and the patient died.

CASE 39.—Peter H., a man, aged 26, had a generalized maculopapular eruption, with patches in the mouth and on the genitalia. After ten rubs with the calomel, the lesions on

the genitalia had disappeared, and the eruption was entirely gone after the patient had taken eighteen rubs. The tonsils were still large and swollen, however, and a new mucous patch appeared on the right tonsil. There was no salivation. The patient was given the diarsenol brand of arsphenamin.

CASE 40.—M. S., a woman, aged 32, had a chancre of the lip, a generalized maculopapular and pustular eruption, iritis of the right eye, patches on the soft palate, and enlarged and indolent tonsils. After ten rubs, there was a slight fading of the eruption. After eighteen rubs, the eruption of the face was clearing up, and there was some fading of the eruption on the body. After thirty five rubs of the proprietary, the patient developed some new lesions on the right side of the lower lip. There was no improvement in the eye condition until she was given arsphenamin and mercury injections.

CASE 41.—M. P., a woman, aged 26, had a chancre of the lip and mucous patches inside of the left cheek and over the soft palate. After twelve rubs, the lesions cleared up. This patient was not observed further, but was given arsphenamin at once.

CASE 42.—M. M., a woman, aged 32, had a primary lesion of the left labium majus, with marked edema of the parts, and headache and rheumatism. There was practically no reaction to thirty rubs with calomel ointment, but a rapid improvement under arsphenamin treatment.

CASE 43.—C. G., a man, aged 28, had extensive patches in the mouth and over the scrotum. The spinal fluid count was 20 cells. After nineteen rubs, the lesions in the throat and over the scrotum were practically gone. The patient had a slight salivation. He was given the diarsenol brand of arsphenamin and discharged.

CASE 44.—J. F., a man, aged 28, had a history of chancre given months before. There were no physical signs of syphilis except headaches and a +++ Wassermann reaction. After seven rubs with calomel, the patient was severely salivated.

CASE 45.—J. P., a man, aged 22, had a lesion of the glans of two weeks' duration. Spirochetes were present in large numbers with dark field illumination. The lesion was unchanged after twenty-three rubs, and the patient was given arsphenamin.

CASE 46.—Grace M., a woman, aged 21, had a maculopapular eruption and extensive patches in the mouth. After fifteen rubs the eruption had practically disappeared, but the mucous patches in the throat showed no change, and the patient complained of dizziness and severe headaches. She received a buccal puncture. Rubs of 50 per cent. unguentum hydrargyri were given and, after ten of them, all symptoms and lesions disappeared. She was then given arsphenamin and discharged.

CASE 47.—R. C., a woman, aged 21, colored, had condylomas of the vulva and an annular syphilitic of the face and neck. The lesions had practically cleared up after sixteen of the proprietary rubs, but, beginning with the twenty-third daily rub, some mucous patches appeared in the throat which lasted until she had had forty-one rubs. The patient then received the diarsenol brand of arsphenamin, and the patches cleared up rapidly. There was no salivation.

CASE 48.—N. B., a woman, aged 23, had a diffuse maculopapular eruption which entirely disappeared after twenty-five rubs. After thirty-two of them, a heavy trace of albumin and casts appeared in the urine. The skin was entirely clear.

CASE 49.—A. G., a woman, aged 24, had a generalized maculopapular eruption, and patches in the mouth. After twenty-three rubs, the mucous membranes and skin were clear, and the treatment was continued until thirty-two rubs had been given. There were no further symptoms.

CASE 50.—L. W., a man, aged 28, had a lesion of the glans of two weeks' duration. There was no reaction to twenty-eight of the calomel inunctions. The lesion cleared up quickly under treatment with arsphenamin. A Wassermann reaction was ++++.

CASE 51.—S. S., a man, aged 31, had a lesion of the glans and prepuce of three weeks' duration, occurring four weeks

after intercourse. Spirochetes were present in large numbers. The patient took thirty-eight rubs of calomel with no change in the lesion. It cleared up immediately after the use of arsphenamin.

CASE 52.—M. S., a man, aged 23, had a marked papulopustular syphilitic on the head, face, neck, trunk and arms, and patches on the left tonsil. After thirteen rubs with calomel ointment, the patient demanded arsphenamin. All the lesions cleared quickly.

CASE 53.—N. N., a man, aged 36, had a periurethral chancre of two weeks' duration, and spirochetes were present in large numbers. After ten rubs with 50 per cent. calomel ointment the patient showed no improvement and demanded arsphenamin. The lesion healed at once.

CASE 54.—F. N., a man, aged 33, had a generalized maculopapular eruption, with a patch on the left tonsil and a mucous patch on the genitalia. There was no change after thirteen rubs with 50 per cent. calomel ointment, and the patient refused further therapy and was given arsphenamin.

#### ANALYSIS OF RESULTS

An analysis of the foregoing results shows several things: In the first place, we note among these fifty-four cases that nineteen times (35 per cent.) the lesions, especially those on the mucous membranes, became much worse; five times (9 per cent.) they grew worse; sixteen times (29.5 per cent.) there was no change; five times (9 per cent.) there was a slight improvement; three times (5 per cent.) they were quite markedly improved, and three times (5 per cent.) the patients' symptoms disappeared entirely. In other words, there is a great preponderance of instances in which the patients got much worse under therapy, and this despite the fact that over forty rubs to a patient were used eight times (15 per cent.), that twelve times (22 per cent.) between thirty and forty rubs were used, and that thirteen times (24 per cent.) between twenty and thirty were used.

We had hoped to keep all the patients under treatment by calomel inunctions until from forty to fifty rubs had been given. This was impossible, however, as we have explained, for many times the patients refused further therapy, and in many instances they kept getting so much worse that strenuous measures had to be used to check the course of the disease. It will be noted from the reports that there was practically never any improvement in primary lesions when inunctions were used.

It is interesting to note that in one of the cases, after six rubs, a generalized exfoliating dermatitis developed as a result of the calomel inunctions, with a complicating acute nephritis and edema of the entire skin. These lesions all disappeared rapidly after discontinuing the use of the drug.

The lack of salivation is in striking contrast to results after the use of unguentum hydrargyri. It is difficult, if the patient is using unguentum hydrargyri properly, to give him more than eighteen or twenty rubs without marked symptoms of gingivitis and salivation. But in our fifty-four cases in which calomel inunctions were used, this was present in only three (1.5 per cent.) cases. In one patient there was a slight salivation after eighteen inunctions. In another there was a moderate salivation after nineteen inunctions, and one patient with a bad pyorrhea had a marked salivation after seven inunctions. Salivation was entirely absent in twenty-nine patients (53.5 per cent.) who used from twenty to forty rubs. We wish to call attention particularly to this point, and we agree with Dr. Sollmann that this striking lack of sali-

vation after the use of calomel inunctions means a very low grade of mercury absorption.

We are quite sure that if any one will carefully follow a series of cases such as our own, checking them up carefully from day to day, he will come to the same conclusions. Calomel inunctions, though cleanly and pleasant for the patient, do not compare in efficacy with inunctions of unguentum hydrargyri.

CONCLUSIONS

Observations on a series of fifty-four patients treated intensively with calomel rubs show that:

1. Calomel inunctions are almost totally inefficient against primary and secondary syphilis.
2. Calomel inunctions very rarely produce salivation or gingivitis. This means poor absorption of the mercury and explains this clinical inefficiency.
3. Calomel rubs may occasionally produce a dermatitis.

These results have led us to abandon calomel inunctions, and we would strongly advise against their further use in the treatment of syphilis.

ABSTRACT OF DISCUSSION

DR. JAY FRANK SCHAMBERG, Philadelphia: I have been greatly interested in this valuable and practical contribution to the therapy of syphilis with particular reference to inunctions. It is obvious that the patients who received the calomel inunctions did not absorb enough mercury in the blood. There is no essential difference in the effect of different mercurial preparations. With the mercurials now in use it makes little difference whether an inorganic or an organic compound is used, the question is how much mercury reaches the blood stream. Gray oil has been used for years for intramuscular injections. The French preferred calomel. If syphilitic manifestations failed to yield to calomel injections, it was felt that no mercurial treatment would accomplish the result. Before the days of arsphenamin, calomel injections constituted the "dernier ressort." From the therapeutic failures narrated by Dr. Cole, it is evident that not sufficient calomel reached the blood. It is therefore pertinent to inquire the reason for this. A certain school of physicians in Europe has long held the belief that the effect of mercurial inunctions was largely due to volatilization of the mercury and absorption through the lungs. In order to determine the truth of this thesis, Drs. Kolmer, Raiziss and myself carried out a very thorough series of experiments on rabbits in a specially contrived box apparatus. We caused one series of rabbits to be rubbed, and another to breathe a mercury laden atmosphere. While some mercury was absorbed into the lungs, the evidence in favor of cutaneous absorption as the dominant channel of entrance was convincing. In this article we called attention to the fact that blue ointment was more volatile than calomel. In order to administer calomel ointment and blue ointment in parallel doses, a larger amount of the former would have to be used, inasmuch as calomel contains only 85 per cent. of mercury. Furthermore, the lesser volatility would also require a further increase of the calomel content as compared with an ointment of metallic mercury. Dr. Cole's conclusion as to the therapeutic superiority of mercurial ointment over calomel ointment appears to be thoroughly justified by his careful observations. In view of this and of the fact that his patients were not salivated by the calomel ointment, it is evident that not enough calomel reached the circulating lymph and blood stream. In view of the disadvantage of the dirty blue ointment as compared with the cleanly calomel ointment, it would be worth while trying calomel ointment in considerably larger dosage, say (A) grains of calomel to an inunction.

DR. JOSEPH ZEISLER, Chicago: I consider this paper of value because it will help to destroy a fad that has come into use, for I consider the use of calomel rubs nothing but

a fad. The remarks of Dr. Schamberg might be misleading when it comes to the question of intramuscular injections. There, of course, we deal with an entirely different proposition. There is no question that intramuscular injections properly done are very valuable, but in the case of inunctions we deal with an entirely different proposition. The value of inunctions with blue ointment need not be discussed. That is a historical fact that amounts to absolute knowledge but in the case of calomel inunctions the technical conditions are entirely different. I would remind you of the old calomel vaporizations, where efficiency on localized lesions was quite manifest, but in that case it was vaporized by heat. In the ordinary calomel inunction there is no chance for vaporization. While I have never used calomel rubs Dr. Cole's experience will only confirm my previous belief.

DR. HARRY G. IRVINE, Minneapolis: Dr. Cole's observations are very timely. Many of us hoped that this would give us something clean that could be used in place of the blue ointment. I should like to comment about one particular point, however. I think that every man who has treated a large amount of syphilis will remember back in the old days quite a large number of cases such as Dr. Cole mentioned. Many of his patients had mucous membrane lesions. In the old days, before arsphenamin came into use, there was great difficulty in clearing up these mucous membrane cases with any form of mercury. I would suggest that in order to come to a conclusion Dr. Cole should change to some other form of mercury rather than change to arsphenamin. It would have been very interesting if he had tried the blue ointment in some of these cases to see if there was any difference in the agents rather than change to the arsphenamin injections. This would have given us an idea of the relative values of the two preparations.

DR. RICHARD L. SUTTON, Kansas City, Mo.: We frequently experience considerable difficulty in clearing up lesions of the mucous membranes with mercury. With regard to the relative value of ointments, and particularly blue ointment and preparations containing calomel, I have had a good deal of experience with the mixtures recommended by Schamberg and his associates and suggested by Wise and Elliott, and I do not believe that Dr. Cole has run up his dosage high enough. Another point to bear in mind is that the application should be placed on a moist, warm surface, such as the soles of the feet or the axillae. By doing this, the vaporized mercury gets into the circulation almost as quickly as when administered hypodermically. I believe the amount of calomel ointment should be increased until the physiologic action is secured, even though four or five drams of the ointment are required each day.

DR. HENRY H. HAZEN, Washington, D. C.: I do not see why we should make such a furor about inunctions. In the dispensary cases none of the patients will rub in the mercury satisfactorily. In private practice, certainly among the men, no proportion of them can be trusted to rub in inunctions. The women will sometimes use them because they do not like to have injections. In a large percentage of cases in private practice and in all the dispensary cases we cannot trust to inunctions. The patients will not so do it, no matter what drug is used, as to get any real value out of it.

DR. HAROLD N. COLE, Cleveland: I write to Dr. Schamberg and received a letter suggesting that we use larger amounts and we had started that. We have used 4 gm. of calomel in the inunctions in quite a large number of cases where we are still continuing the experiments. One patient has had sixty rubs of 4 gm. each and another has had thirty-six rubs of 4 gm. each and they developed an acute syphilitic iritis within thirty-six hours. It was the most striking thing I ever saw in the way of an acute syphilitic iritis. In my experience any amount of the calomel is useless as an inunction. In a few cases there seemed to be a certain amount of absorption and that explained why they seemed to get better results. In two or three cases we carried them on to a certain point and then changed over to unguentum hydrargyri and then saw results within a very few days. I think there is no comparison whatever between calomel and mercury rubs.

FIELD EXPERIMENTS IN MALARIA CONTROL\*

WICKLIFFE ROSE, I.L.D.  
General Director, International Health Board  
NEW YORK

Malaria is recognized as one of the most serious of the disabling diseases of man. It is estimated that in India alone it causes on the average each year about 1,130,000 deaths and more than 100,000,000 cases of illness. The economic losses resulting from it are incalculable. The failure of the early Panama Canal project and the difficulties encountered in building the Madeira Railroad are only spectacular examples of what it is doing continuously and on an enormous scale to hinder industrial enterprise. On farming populations its burden falls with peculiar emphasis. Many of the richest agricultural lands in warm climates cannot be developed until the infection in these regions has been brought under control. The direct annual cost of the sickness and death that it produces in India alone is estimated at about \$284,000,000; and this does not take into consideration the vastly greater losses due to the impaired productive power of labor.

More serious still are its effects in retarding the development of individuals and communities. Like hookworm, the malaria plasmodium is an anemia-producing parasite. It saps the life of its victims by destroying their blood. The disease is most prevalent among children under 15 years of age, and therefore preys on the vitality of the race during the important period of physical and mental growth. Its effects, moreover, are cumulative. They are handed on from one generation to the next, and

become to the community an increasing handicap in all things that make for social development. And these results are widespread. Malaria in mild form is almost world-wide in distribution, and in its malignant form belts the globe in a broad zone including tropical and semitropical regions. Of the 1,600,000,000 inhabitants of the earth, more than half live in countries in which the infection is prevalent and constitutes a serious menace to life and health and working efficiency.

And these conditions prevail in spite of the fact that malaria is a controllable disease. It is twenty years since the discovery by Ross, confirmed and extended by the Italian scientists and others, definitely established the life cycle of the malaria parasite and thus gave us the facts on which to base an intelligent program of control. It is well understood, not only by scientists but also by intelligent laymen, that the spread of the infection may be prevented by mosquito control, by protecting people from being bitten by mosquitoes, or by destroying the parasite in the blood of the human carrier. It has been shown, moreover, by repeated demonstrations that by application of any one of these measures or of any combination of them the amount of malaria in a community may be reduced indefinitely. There are few diseases that present so many vulnerable points of attack and none perhaps the control of which may be made more definite or certain. Still the infection persists. And still we refer to it as the chief obstacle to the development of civilization in the tropics. Comparatively little has been done during these twenty years to bring into general operation the practical measures for which the scientific basis has been so well laid.

Fig. 2. Record of malaria control by antimosquito measures, Crosssett, Ark., 1916-1918.

\* The field tests here reported under the head of malaria control by mosquito control measures, by screening, and by immunizing quinin were carried out in cooperation with the U. S. Public Health Service and the Arkansas Department of Health, Dr. H. A. Taylor having in charge the antimosquito work and Dr. T. D. Haas of the University of Arkansas in charge of the quinin tests. The experiment in malaria control by sterilizing the human carriers was conducted under the general supervision of the Mississippi Department of Health and under the scientific direction of Dr. C. C. Bass of Tulane Medical School. In the preparation of this paper, earlier reports, particularly the Fourth Annual Report of the International Health Board and Bulletin No. 83 of the U. S. Public Health Service, have been drawn on freely.

\* Owing to lack of space, this article is abbreviated in THE JOURNAL by the omission of certain maps. It will appear in full in the author's reprints.

THE ITEM OF COST AS A DISCOURAGING FACTOR

Nothing has done more to discourage the general application of antimalaria measures than the item of cost. Many of the early demonstrations that attracted wide attention were relatively expensive. Watson's brilliant results in the Federated Malay States, 1901 to 1905, were accomplished at a cost of \$50 per acre treated at Klang and \$250 per acre at Port Swettenham. More recently, large areas have been treated on rubber estates near Klang at a cost of from \$25 to \$30 per acre. The cost of operations in the Canal Zone—our most conspicuous demonstration in malaria control—was on the average for a period of five years about

\$365,000 annually. With an average population of about 100,000 for the area treated, this represents an annual per capita cost of \$3.65. Controlling mosquitoes at from \$25 to \$30 per acre is a sound business investment on rubber estates that pay more than 100 per cent. in annual dividends and in a region in which the death rate among the coolies on unprotected estates runs as high at times as 176 per thousand. Such expenditures, however, are practical only under exceptional conditions. As a necessary part of digging the canal, the cost of sanitary operations on the Zone is negligible; but as a part of normal public health work such measures are feasible only in limited areas in which there is a dense population to support them.

More recent demonstrations indicate that malaria control may be brought within reach of the average community. It was with a view to contributing, if possible, to this end that the series of field experiments here to be reported were undertaken. In these experiments it has been assumed that if communities are to be induced to undertake the work they must be shown that the investment pays, and that it can be carried out within limits of expenditure that they can afford. It has been assumed also that no single measure can be made universally applicable; that the effective program in malaria control will comprehend the free employment of all means that are known to be serviceable, and will place emphasis at any particular time and place on that measure or combination of measures that under the given conditions will accomplish the result with least expenditure. It is assumed, furthermore, that the successful operation of a program of this character will presuppose, on the part of the person administering it, definite understanding of the conditions under which the work is to be done and of the possibilities and limitations of each of the measures that he is to employ. No attempt has been made, therefore, in these first experiments to put into operation a full program of malaria control, but rather to try out the possibilities of some of the more important elements that would enter into such a program. Thus far, four types of field experiments have been undertaken for the purpose of ascertaining as far as practicable the degree of efficiency under given conditions and the cost of malaria control by antimosquito measures, by the screening of houses, by administration of immunizing quinin and by direct attack on the parasite in the blood of the human carrier.

I. CONTROL BY ANTIMOSQUITO MEASURES

That malaria may be successfully controlled by antimosquito measures alone, and that this procedure is economically feasible for cities and large towns, is well understood. The early demonstrations at Ismailia in Egypt, a town of 10,000 inhabitants, where complete control was effected at a cost of \$1 per capita initial expenditure and about 40 cents per capita for annual upkeep, and at Port Saïd, a city of 100,000 population, where satisfactory control was maintained at a cost of about 10 cents per capita, are examples of what has been done and is being repeated in many localities representing a great variety of conditions. In the experiments here reported, effort has been made to test the feasibility of malaria control in small communities by resort to such simple antimosquito measures as would fall within the limits of expenditure that such communities might well afford. The habits of the three mosquitoes—*A. quadrimaculatus* Say, *A. punctipennis* Say, and *A. cruzians* Wiedermann—which are responsible for the infection in these communities have been made the subject of constant study with a view to eliminating all unnecessary effort and thereby reducing cost.

*Experiment at Crossett, 1916.*—The first of these tests was undertaken at Crossett, a lumber town of 2,129 inhabitants, situated in Ashley County in southeastern Arkansas, about 12 miles north of the Louisiana line. Crossett lies at the edge of the so-called "uplands," in a level, low-lying region (elevation 165 feet), with sufficient undulation to provide reasonably good natural drainage. Climatic conditions and abundant breeding places favor the propagation of anophel.

Malaria in its severe form is widely prevalent as an endemic infection, and according to the estimate of local physicians is the cause of about 60 per cent. of all illness throughout the region. Within the town itself the malaria rate was high and was recognized by the lumber corporation and the people as a serious menace to health and working efficiency.

The initial step in the experiment was a survey of the community to determine the malaria incidence, to ascertain the species of mosquitoes responsible for the spread of the infection, and to locate the breeding places of these mosquitoes. Breeding places were exhibited on a community map (Fig. 1), and organized effort was centered on their destruction or control. The program of simple measures excluded all major

Fig. 4. Record of malaria control by antimosquito measures, Hamburg, Ark., 1917-1918.

drainage. Borrow pits and shallow ponds were filled or drained; streams were cleared of undergrowth when necessary to let the sunlight in; their margins and belts were cleared of vegetation and obstructions; and they were trained to a narrow channel, thus providing an unobstructed off-flow. Artificial containers were removed from premises; water barrels on bridges were treated with niter cake. All remaining breeding places were regularly treated by removing vegetation, opening up shallow margins to give free access to small fish, and spraying once a week with road oil by means of automatic drips or a knapsack sprayer. All operations were under the supervision of a trained lay inspector. Care was exercised to eliminate all unnecessary effort and to secure, not the elimination of the last mosquito, but a reasonably high degree of control at a minimum cost.

The first conspicuous result apparent to every person living in the community was the practical elimination of the mosquito as a pest. The reduction in malaria, as shown by a parasite index taken in May, 1916, and again in December of the same year, was 72.33 per cent. The reduction in physicians' calls for malaria in 1916, as compared with the number of calls for the previous year (company's records), was 70.36 per cent. The per capita cost of the work—omitting overhead—was \$1.24 (Fig. 2). During the year the Crossett Lumber Company had repeated these measures at two of its large logging camps with results that were convincing as to the soundness of the investment.

At the end of 1916 the community took over the work, and for two years has maintained it at its own expense and under its own direction. The measures have been continued under the supervision of a trained native lay inspector.

*Results Confirmed at Hamburg (1917).*—After the work at Crossett had been turned over to the community, operations were transferred to the neighboring town of Hamburg with a view to putting the practicability of antimosquito measures to test under somewhat more difficult conditions. Hamburg was not governed and financed by a wealthy corporation. It had no hospital. It depended for medical service on private practitioners who were deriving about 60 per cent. of their income from malaria. The town was less compact, and with only 1,285 inhabitants had a higher malaria rate and more abundant breeding places for mosquitoes (Fig. 3) than had Crossett.

The measures that had stood the test of the previous year at Crossett, with the introduction of certain economies that experience had suggested, were repeated here. Physicians' calls were reduced from 2,312 in 1916 to 259 in 1917, a reduction of 88.8 per cent. For the latter half of the year—July to December, inclusive—there were only forty-three calls for malaria in 1917, as compared with 1,995 calls for the same period the previous year, a reduction of 97.8 per cent. The per capita cost—omitting overhead expenses—was \$1.45.<sup>1</sup>

At the end of the year again the community took over the work, assuming entire responsibility for its continued maintenance and direction. Figure 4 exhibits graphically the results for the two years. As a result of community effort during 1918, the total calls for malaria fell to fifty-nine, and the work was maintained at a per capita cost of 44 cents.

*Demonstration in Four Communities (1918).*—

Taking as a basis the plan of operation that had been tried at Crossett and further developed and confirmed at Hamburg, effort was made during 1918 to carry out a demonstration on a somewhat larger scale and under a variety of conditions. For this purpose four small Arkansas towns were selected. They are rural towns ranging in population from 975 to 3,023. Lake Village, county seat of Chicot County, presented the problem of a level, low-lying area of buckshot soil with 2 miles of lake frontage and an extensive area of shallow swamp in the rear. Dermott, about 20 miles away, also in the flat lands of the Mississippi, presented the peculiarity of having abundant anopheles breeding places throughout the municipal area, owing chiefly to

Fig. 9.—Record of malaria control by antimosquito measures, Lake Village, Ark., 1918.

is a typical hill town for which a number of clear streams with adequate fall over a stiff clay soil furnished an abundant supply of anopheles. Bauxite, a rambling mining community of about 2,500 inhabitants, presented the difficulties of a large area to be treated, a heavy sand flow in the beds of its numerous small streams, and extensive hillside seepage areas offering ideal breeding conditions. Figures 5, 6, 7 and 8 exhibit for these communities the breeding places to be treated.

A preliminary survey of each community at different seasons during the previous year made it possible to omit from the working plans much that otherwise would have been waste effort. Each community was presented in advance with an estimate of its malaria prevalence, a chart exhibiting its breeding places, a working plan with budget, and an estimate of what might be expected as a result in degree of malaria control. The community in each case provided the funds required except for general supervision, and agreed to assume entire responsibility for the work after the first year.

The plan of operation followed at Crossett and Hamburg, with improvements suggested by experience

and adaptations to local conditions, was repeated in each of these towns. For the four communities combined, physicians' calls for malaria were reduced from

5,065 (the average for the two previous years) to 554, a reduction of 89.1 per cent. The per capita cost of the entire work, omitting general overhead expenses, was 74 cents. Results and costs by communities are graphically exhibited in Figures 9, 10, 11 and 12.

Comparison of cost of operations with results accomplished in these six towns tends to show that malaria control in such communities, considered merely as a business proposition, pays. At two dollars per physician's call, Crossett has been paying annually more than four and one-half times as much in doctors' bills alone for the privilege of having malaria as it expended in 1918 for the upkeep of the work that kept it practically free from malaria and from the mosquito as a pest. Hamburg's annual doctors' bill for malaria had been eight times the cost of protection in 1918. In the four new communities the annual payment for physicians' calls would cover even the relatively heavy cost of first year operations, almost one-and-a-half times over. And the doctors' bills are but an insignificant fraction of malaria's total cost to the community.

II. CONTROL BY SCREENING

For communities situated above there seems to be little need of resort to other procedures than those directed against mosquitoes. The control of malaria in towns, however—even in small towns—does not reach the heart of the matter. Malaria is essentially a rural disease, bearing most heavily on the people and the industries of the farm. There are large rural areas, moreover, in which, in the light of our present knowledge, the control of mosquito breeding is not practicable. Malaria in these localities, if it is to be controlled at all during the pioneer period of settlement, must be attacked from another angle. It has been shown by demonstration that under conditions that make the cost of mosquito control prohibitive, it is still possible to reduce the malaria rate by the screening of houses, by the systematic administration of immunizing quinin, and by detecting the human carriers and destroying the parasites in their blood.

In order to test the efficiency and the cost of screening as a control measure, a field experiment was conducted in 1916 on a group of cotton plantations near Lake Village, Ark. The community, which lay along the shore of Checot Lake, had an abundant supply of anopheles and a high malaria incidence. The houses on these plantations were typical negro cabins, many of them loosely constructed and therefore difficult to protect against entrance by mosquitoes. All selected

Fig. 13.—Record of malaria control by antimosquito measures, Dermott, Ark., 1918.

houses were screened with galvanized wire cloth, 10 mesh, the work being carefully done by carpenters and without cost to the owners. The people were taught to house-to-house visits the importance of keeping the screens in good condition and the dangers of exposure to mosquitoes on the outside after dark. Each home was inspected at regular intervals throughout the season. No other measure was employed.

The estimate of result was based on parasite index. An index taken in May, 1916, when the work began, showed an infection of 11.97 per cent, a second index taken in the same month of the same year showed an infection of 3.52 per cent, a reduction of 70.9 per cent. Unfortunately the index for May, 1917, which would have afforded a more instructive comparison, is wanting.

On a visit during the season of the following year it was found that the screens were still in good repair and that the people—mainly typical plantation negroes—were convinced of their value. The average cost of screening for the community was \$14.59 per house. Estimating the life of the screens at two years, the average annual cost would be \$7.29. On this basis the annual per capita cost of the screening alone was \$1.75.

#### IX. CONTROL BY ADMINISTERING QUININ

In another plantation community, immunizing quinine was put to similar test. This second community lay along the bank of a sluggish bayou from which it derived its supply of amphipods. Under the direct supervision of the physician in charge, quinine was administered to all persons in the community in doses of 5 grains morning and evening—making 10 grains a day—for two successive days each week. For children under 15 years of age the dosage was reduced to 1 grain for each three years and was administered in the same way. A parasite index taken in May, 1916, at the beginning of the work, and again in the same month of the same year, showed a reduction of 14.47 per cent. Against the same index for May, 1917, none is reported. The per capita cost of the work, counting the overhead expense, was \$7.00.

These tests of malaria control by screening and by the administration of immunizing quinine are to be regarded as preliminary and their results as suggestive only. Generalization may be attempted only when they have been carried out on a much larger scale under a variety of conditions and with a more reliable measure of results.

#### IX. CONTROL BY TREATING THE CARRIERS

Since all infected mosquitoes have derived their infection from the blood of infected persons, it is theoretically possible to prevent the infection of mosquitoes and thereby prevent the spread of malaria in a community by destroying the parasites in the blood of the human carrier. Robert Koch first suggested the possibility of controlling malaria by the treatment of carriers during a visit to Italy in 1878, and in 1900 he demonstrated his theory by a definite reduction of the malarial rate in a small community of 734 persons at Stephansort, German New Guinea. The measure has been rather widely employed in German colonies and with varying degrees of success. Malaria has been reduced, but in no community does the method seem to have been put to an adequate test and with sufficient attention to measure of results and to counting of costs.

*Initial Experiment in Bolivar County, Miss. (1916-1917).*—As a preliminary study, a two-year field experiment, in which more than 30,000 persons were registered, was conducted in Bolivar County, Miss., during 1916 and 1917. The large number of blood examinations confirmed with emphasis the importance of the malaria carrier. Persons who have had clinical attacks are likely to carry the parasites in the blood for months after the clinical symptoms have disappeared. The examinations revealed also that the usual doctor's treatment of malaria, although breaking the chill and sending the patient back to his work, does not, in most cases, sterilize his blood. The results of chill tonics, on which so many people depend, are still less satisfactory. A very large percentage of malaria patients treated by physicians, or by the use of chill tonics, continue for months, after apparent cure, to carry the parasites and to be therefore subject to relapse and a possible source of infection to others. These tests, furthermore, established the fact that 10 grains of quinine a day for eight weeks sterilized the blood of about 90 per cent. of the carriers to whom it was administered.<sup>2</sup>

With this standard course of treatment established, effort was made during 1918 to carry out a test demonstration in malaria control by treating the carriers.

*Test Demonstration in Sunflower County, Miss. (1918).*—For purposes of the demonstration, a typical rural area was selected in Sunflower County, Miss. This area, like the delta region in the heart of which it

FIG. 10.—Cases of malaria control by antimosquito measures, Bolivar County, Miss., 1916-1918.

<sup>2</sup> There is reason to believe that this result does not hold for all cases. It seems to be much more difficult, for example, to sterilize the blood of carriers in certain tropical regions.

lies, is level, low-lying, and covered at frequent intervals with a net-and-patchwork of sluggish streams, bayous and swamps. Mosquito breeding is abundant throughout the season, and the cost of its control under present conditions is prohibitive. The area contains about 100 square miles and a population of about 9,000, about 1,000 living in the town of Ruleville and about 8,000 on cotton plantations under typical delta conditions. The blacks outnumber the whites by about four to one. Most of the negroes can read, but as compared with a white population living under similar conditions the grade of intelligence is relatively low. The dominant industry of the region is the growing of cotton, and the life of the community centers in and revolves about the cotton plantation. There are relatively few small farms operated by their owners, the prevailing type being a large plantation operated with negro tenant labor under the supervision of a resident manager.

The disabling disease of the region is malaria. At cotton cultivating and picking time, when labor is in greatest demand and when delay means direct money loss, malaria is most severe. It is estimated that from one third to three fourths of the people on these plantations have one or more attacks of malaria each year, and that 70 per cent. or more of all sickness disability in the community is due to this cause. On one plantation, for example, having a tenant population of about 600, the average annual doctor's bill for the last ten years has been approximately \$4,000. Of this sum about \$3,000, or \$5 per capita, is attributed by the manager to malaria. The loss to the tenant and the landlord in crop returns is much larger. And since the landlord must look to the tenant's crop both for return on his capital investment in land and equipment and for reimbursement for his large current advances to his tenant families, he is most deeply concerned in any condition that impairs the health and efficiency of the workers on his plantation.

The first step in the demonstration was to map the area, locating roads, streams and homes; to take a census of the population, and to make a survey involving a record of each person on the census roll. This survey showed that of the rural population 40 per cent. had had clinical malaria within twelve months, and that of the remaining 60 per cent. who had not had a clinical attack, 22 per cent. had the parasites in their blood. All persons giving a history of clinical malaria within twelve months and those who were found by blood examination to be carrying the parasites were given sterilizing treatment, namely, 10 grains a day for eight

weeks. Effort was made by personal instruction and by repeated house-to-house visits to have the prescribed course of treatment followed to the end. Irregularities occurred and are under such conditions inevitable; but, in general, instructions were followed. In the rural area no other measures were employed.

In the town of Ruleville, malaria control was based in the main on antimosquito measures. Here inspection disclosed the fact that mosquito breeding, which was abundant, was due almost exclusively to running hydrants and leaking pipes supplied by flowing artesian wells. The problem was extremely simple. The enactment of an ordinance followed by the imposition of a number of fines resulted in the destruction of breeding places and the consequent extermination of mosquitoes in the town.

*Results.*—Unfortunately no reliable record of the number of physicians' calls within the area before the work began is available, and the second parasite index will not be taken until next season. The results of the test, so far as they may be estimated in advance of the final report, may be thus summarized:

1. There has been no transmission of malaria within the town of Ruleville during the year, and the town has been free from the mosquito as a pest.

2. The degree of malaria control resulting from the measures carried out in the rural area is estimated by the director in charge at approximately 80 per cent. This estimate is based on the record of malaria histories, intimate observation during the season, informal reports by tenants and plantation managers, and regular monthly reports submitted by physicians.

3. Physicians practicing within the area report a marked decline in malaria cases.

4. Plantation owners and managers operating within the area are of one accord in reporting an obvious decrease in malaria as compared with previous years. One manager, for example, operates a large plantation within the demonstration area and a smaller one outside the area. The plantation under control has a tenant population of about 600, the one not under control about 180. The doctor's bill for the year on the smaller plantation has been greater than on the large one. This difference he attributes altogether to the malaria control on the larger plantation.

5. These reports and estimates were checked by personal inspection on a recent house-to-house visit among tenant families on plantations, and families in a community of small landed proprietors. Of the first ten families visited (Table 4) within the month

Fig. 12.—Record of malaria control by anti-mosquito measures. Parham, Ark., 1918.

Neighboring counties in Mississippi have asked that the work be extended to them and have indicated a willingness to provide the funds. The demonstration, however, is only begun. It is suggestive, but far from complete. No conclusion will be attempted until the test has been continued over a period of years within the same area, has been tried under a variety of con-

ditions, and has been submitted to a more definite measure of results.

#### SUMMARY AND CONCLUSIONS

1. For the average town in our Southern states having a thousand or more inhabitants and a reasonably high infection rate, malaria control by antimosquito measures is economically feasible; it is, in fact, a sound business investment.

2. In heavily infected regions, in which the cost of mosquito control would be prohibitive, the amount of malaria may be greatly reduced by resort to screening, to immunizing quinin, or to destroying the parasites in the blood of the human carriers. The indications would seem, in fact, to justify the hope that by the systematic application of these measures the malaria in a community may be held within reasonable bounds, and that this result may be accomplished within limits of cost that the average community may well afford.

3. The people in these communities are prepared to provide the funds by public taxation for malaria control when they have been shown by demonstration that the program proposed will accomplish definite results that justify the expenditure.

4. The results thus far accomplished would seem to justify continuing these field experiments until the

principal procedures that have been found useful in controlling malaria have been pretty thoroughly tested separately and thus evaluated. It will then be possible to operate intelligently a combination program in which each control measure will be given its place and will receive varying emphasis from time to time according to the local conditions that have to be met. This freedom in the use of our tools will in turn contribute toward the object that we have in view, namely, the highest degree of malaria control consistent with a reasonably low per capita cost.

## FACTORS INFLUENCING RECOVERY AND RESOLUTION IN LOBAR PNEUMONIA

WITH SPECIAL REFERENCE TO THE CHEMISTRY OF THE PNEUMONIC EXUDATE\*

FREDERICK T. LORD, M.D.

BOSTON

Various factors may be operative in the recovery from lobar pneumonia and in the resolution of the fibrinous exudate:

### I. PREVIOUS OBSERVATIONS WITH A BEARING ON RECOVERY AND RESOLUTION

Recovery from lobar pneumonia is at present thought to be due to the elaboration of protective substances during the course of the disease. Through the work of G. and F. Klemperer,<sup>1</sup> Neufeld and Haendel,<sup>2</sup> Dochez<sup>3</sup> and Clough<sup>4</sup> the blood serum from patients at about the time of or after the crisis has been shown by animal experiments to possess protective power against otherwise fatal doses of pneumococci. These protective substances in small amounts are usually present, but at times are not demonstrable at all. The use of both pneumococci and serum from the same patient is important in their recognition.

An advance in the study of the mechanism of recovery is the demonstration by Bull<sup>5</sup> of the importance of agglutinins in the disappearance of pneumococci from the blood, and by Cole<sup>6</sup> of soluble inhibiting substances in the blood with the property of neutralizing pneumococcus antibodies.

It is, of course, possible that the methods at present available for the demonstration of humoral immunity are inadequate and that it is a more potent factor than animal tests indicate. The inconstant presence and small amount of the protective substances, however, suggest that the humoral factors, while important, are, by themselves alone, an insufficient explanation of so striking an incident as the crisis in pneumonia.

In explanation of resolution, it has long been clear that enzymatic action must account for the solution of the exudate. Sørensen<sup>7</sup> called attention to the important relation between H-ion concentration and enzymatic processes in general. Deribys<sup>8</sup> work on the autolysis of animal tissue has been of assistance in suggesting methods applicable to the investigation of enzymatic processes in the pneumonic exudate.

### II. OTHER FACTORS INFLUENCING RECOVERY

The following data suggest that local biochemical changes as well as humoral factors may be of importance in recovery from pneumonia. These may be grouped under these headings:

1. *Acidosis in Pneumonia*.—Various observations have shown that in the metabolism in pneumonia a considerable amount of acid is produced. This is indicated by a diminished carbon dioxide content of

the blood, an increased ammonia output in the urine, an increased titrable acidity, and an increased alkali tolerance. In his study of thirty cases of pneumonia, Palmer<sup>9</sup> found that in many, usually the more severe cases, the urine contained a large amount of an organic acid which is free at a H-ion concentration of 5.0.

2. *Partial Isolation of the Pneumonic Lung.*—The exudate fills the alveolar spaces and is separated from the general circulation by the limiting alveolar wall. Kline and Winternitz<sup>10</sup> have shown that the pneumonic lung in experimental pneumonia communicates imperfectly with the circulation. This partial isolation suggests that within the involved region biochemical changes may occur which are reflected only to a limited degree in the body as a whole. An increase in H-ion concentration of the exudate may thus occur without a change in H-ion concentration of the blood.

3. *Acid Death Point of the Pneumococcus.*—Experiments with the pneumococcus<sup>11</sup> indicate that it is susceptible to varying H-ion concentrations. The production of acid is the most important bactericidal factor in the short viability of the pneumococcus in glucose bouillon cultures. Such cultures, allowed to grow and die out, usually reach a final H-ion concentration of about 5.1. The exposure of living pneumococci to 5.1 or a higher H-ion concentration shows that the organism does not survive longer than a few hours in a H-ion concentration of about 5.1, and that it may live for at least many days at 7.4 to 6.8. In the intervening H-ion concentrations, between 6.8 and 5.1, the pneumococcus is killed with a rapidity which bears a direct relation to the H-ion concentration, that is, the greater the acidity, the more rapid the death. The following observations suggest that some other factor, also influenced by the degree of acidity, may be responsible for destruction of pneumococci:

4. *Dissolution of Pneumococci.*—As shown by Lord and Nye,<sup>12</sup> a critical degree of H-ion concentration has a bearing on dissolution of pneumococci. Cloudy suspensions of washed pneumococci in H-ion concentrations varying from 8.0 to 4.0 show, after incubation, disappearance of organisms apparently due to their dissolution in lower H-ion concentrations than about 5.0. This dissolution is most marked at about 5.0 to 6.0; some also takes place toward the more alkaline end of the scale. An enzyme set free from the bacteria themselves may be the explanation. Dissolution of pneumococci under the favoring influence of a change in H-ion concentration may be a factor in the disintegration of organisms observed in the pneumonic exudate in the more advanced stages.

5. *H-Ion Concentration of the Pneumonic Lung.*<sup>13</sup>—The H-ion concentration of the press juice from the pneumonic lung at necropsy in fatal cases is higher than that of other tissues of the body, and reaches a  $p_{H}$  of about 6.0. The pneumonic exudate in experimental Friedländer and pneumococcus pneumonia in dogs may likewise be more acid than the press juice of other organs and the blood. In one dog with experimental pneumococcus pneumonia killed on the third day, the H-ion concentration of one involved lobe, taken immediately from the body, was 6.0, and that of

another 5.4. From the former, pneumococci were grown in pure culture, but from the latter no growth of pneumococci was obtained.

The pneumococcus can usually be cultivated from the pneumonic lung after death, even when the H-ion concentration is about 6.0. To judge from the observations on the acid death point of the pneumococcus, however, slightly higher H-ion concentrations than this, as in the dog's lung with a  $p_{H}$  of 5.4, would probably have resulted in death of the organisms.

These observations were made, using the colorimetric method after dialysis through a celloidin membrane. It is desirable that the H-ion concentration of the pneumonic lung and its influence on the pneumococcus in the tissue itself be determined during the course of pneumonia in the living subject by the electrometric method.

### III. FACTORS INFLUENCING RESOLUTION

As has been shown elsewhere,<sup>14</sup> cellular material obtained from the pneumonic lung in the stage of gray or red-gray hepatization contains a proteolytic enzyme capable of digesting coagulated blood serum at an H-ion concentration of 7.3 to 6.7 inclusive and inactive in more acid concentrations. Such cellular material also contains a proteolytic, peptone-splitting enzyme operative at H-ion concentrations of 8.0 to 4.8 inclusive and most active at 6.3 or 5.2. A digestive action on coagulated blood serum probably indicates a similar action on fibrin, the split product of which is then acted on by a second enzyme and reduced to amino-acid. The products of protein digestion may thus be converted into a form in which they can be absorbed.

The finding of two enzymes in the pneumonic exudate, one digesting coagulated blood serum in weakly alkaline and weakly acid mediums and the other splitting peptone to amino-acid nitrogen with an optimum activity in still more acid mediums, may serve to suggest, independently of the previous observations, that the pneumonic exudate undergoes an increase in H-ion concentration, according to the principle Michaelis<sup>14</sup> established for enzymes in general, that the H-ion concentration of tissue fluid, containing specific enzymes, is the same as that at which the enzymes work best.

### IV. LOCAL BIOCHEMICAL CHANGES AS AN EXPLANATION OF RECOVERY AND RESOLUTION

The findings suggest a theory in explanation of recovery from pneumonia in the course of which humoral immunity is assisted by local biochemical changes. Acidosis in pneumonia may be due to partial isolation of the pneumonic lung, permitting a local increase in H-ion concentration, the excess of acid formed in the exudate gaining entrance to the circulation. Dissolution of the pneumococcus may proceed at first slowly and later more rapidly as the local acidity increases. When the local H-ion concentration reaches the acid death point of the pneumococcus, crisis and recovery follow.

The findings also suggest an explanation of resolution in the course of which the fibrinous exudate is locally split to a form in which it may be readily and harmlessly absorbed. With the breaking down of the cellular exudate, an enzyme digesting protein (fibrin) in weakly alkaline and weakly acid mediums is liber-

ated. As the acidity increases, the action of this enzyme ceases. An enzyme capable of splitting peptone to amino acid nitrogen, also active during the proteolysis of the fibrin, is still further activated at an H-ion concentration of 6.3 or 5.2. The exudate may then be dissolved, and resolution takes place.

## TECHNIC OF NERVE SUTURE AND NERVE GRAFTING\*

CHARLES A. ELSBERG, M.D.  
NEW YORK

From the beginning of a peripheral nerve operation to its end a very perfect technic is necessary. The freeing of the ends of a divided nerve and the excision

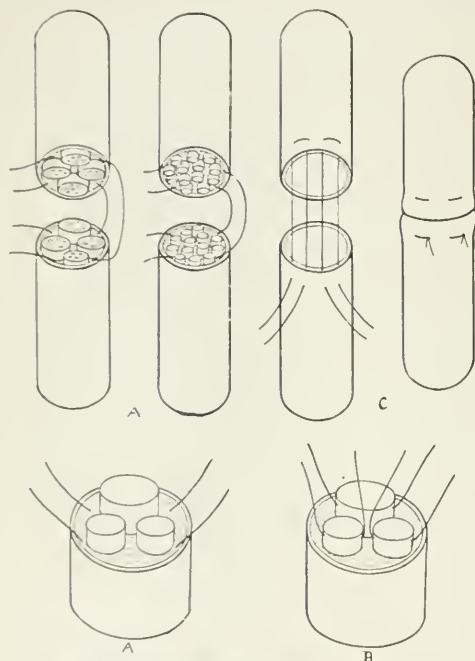

FIG. 1.—A, traction is made, the perineurial sutures are passed; B, the epineurial suture should never be used; C, epineurial mattress suture.

of the surrounding scar tissue with the least injury to the delicate nerve structure, the perfect control of bleeding, the accurate sectioning of nerve bulbs until good nerve fibers are exposed, the proper approximation and suture of the nerve ends without tension—all these and many other details are of great importance. One minute fault in technic—whether it be the failure to obtain a dry wound, too rough handling of the nerve trunk, insufficient excision of scar tissue from the bulb or from around the nerve, improper application of the sutures, etc.—and the chances for a good nerve regeneration are much diminished, no

matter how skillfully all other manipulations have been accomplished.

On account of lack of time and space, nothing will be said, in this paper, concerning the proper incisions for exposing injured nerve trunks—incisions so planned as to cause the minimum amount of injury to the muscles. Nor shall I touch on the manner in which nerves should be handled, the methods by which they are to be freed from the surrounding scar tissue—neurolysis—and the means by which the formation of adhesions between the nerves and the surrounding tissues can be prevented. On account of its great importance, I shall limit myself to an account of the technic of nerve suture and nerve transplantation which we have followed, and shall only mention in an abbreviated form certain guiding principles in the surgery of the peripheral nerves.

### PRINCIPLES IN SURGERY OF PERIPHERAL NERVES

1. *Identification of the Injured Nerves.*—Identification may appear difficult when many of the ordinary landmarks have been destroyed. According to my experience, care and patience and a good knowledge of anatomy are all that are required. If the surgeon will first expose a normal part of the nerve, or nerves, below and above the lesions, and will work from normal to scar tissue, the identification of injured nerves and their branches—even in complicated plexus injuries—is always possible.

2. *Exposure.*—The lower end of a divided nerve should always be exposed and freed first, because it is the degenerated end. The upper end should be exposed for as short a time as possible, and should be handled with special care. Strong traction should never be made on it, and it should not be stretched in the effort to approximate the ends of a divided nerve.

3. *Examination for Nerve Bundles.*—If there is no gross separation of the ends of the nerve, but only a bulbous thickening, the bulb should be minutely examined before being sectioned transversely. No matter whether the patient presents the symptoms and signs of a complete interruption or not, the bulb should be carefully incised in a longitudinal direction in the search for nerve bundles which can be saved. In a considerable number of patients, some perfectly good nerve bundles are preserved on the surface of or in the deep parts of the bulb, and such nerve bundles may be freed from the scar tissue and not divided. When these nerve bundles run on the surface of the bulb, they can be isolated without much difficulty. When they run through the center of the bulb their isolation and preservation may require much patience.

4. *Excision of the Bulbous Enlargement or of End Bulbs.*—When the operator has demonstrated that there is a complete anatomic discontinuity of the nerve, the bulb or end bulbs should be divided transversely, with a sharp scalpel, in successive sections until normal funiculi can be readily recognized by their characteristic appearance. As the upper end of an injured nerve is often swollen, perfectly good funiculi may present an edematous or glairy appearance. Usually—and this was especially noted in the sciatic nerve and its branches, and in the median nerve—there is fairly active bleeding from the intraneurial blood vessels when normal funiculi are reached. This bleeding can usually be controlled by gentle pressure with a sponge wrung out in hot saline solution. Occa-

\* Read before the Section on Orthopedic Surgery at the Seventieth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

sionally, the bleeding from the central end of the sciatic nerve is so active that the isolated vessel must be grasped with fine mosquito forceps and must be

and should remain in place until part of the end to end suture has been completed. By this means the handling of the nerve in the succeeding manipulations can be reduced to the minimum, and rotation of the one or other end prevented.

Fig. 2.—Suture of posterior intersosseous nerve, showing the perineurial sutures passed.

ligated with very fine catgut or silk. While the vessel is being exposed, the bleeding can be controlled by gentle compression of the nerve with the fingers cephalad to the bleeding point.

There is an interesting and easily understandable difference between the central and the peripheral end bulbs. When the peripheral end bulb is being sectioned, the successive cross sections present the appearance of smooth, shiny scar tissue, until one section is reached which contains the ends of many normal funiculi without any scar tissue. When the sections of the central bulb are made, the transition from scar to normal is much more gradual. In successive sections there is an increasing number of good funiculi until an altogether normal transverse section is exposed. When end bulbs are sectioned outside of the body, this difference between the central and peripheral bulbs will identify which of the bulbs was the central and which was the peripheral one.

5. *The Prevention of Rotation of the Nerve Ends and Distortion of the Nerve Pattern.*—Before the sections of the bulb or bulbs are made, the epineurium on the outer and inner aspects of the nerve is grasped with mosquito forceps a little cephalad (in the central end) and a little caudad (on the peripheral end) to the points at which, it is estimated, the final sections will have to be made. These forceps grasp only scar tissue and epineurium,

The ideal apposition of the ends of the nerve would be one in which the cut end of each funiculus is placed exactly opposite to its corresponding end, but in practice this is impossible. For the best apposition of the nerve ends with the least distortion of the nerve "pattern" a good understanding of the arrangement of funiculi in the different nerves, and in the different parts of each nerve, is indispensable. The investigations of Stoffel, Compton, Langley and Hashimoto, and others have shown that there is probably a definite nerve pattern and that within each nerve trunk there is a definite arrangement of the nerve funiculi and even the nerve fibers. Langley and Hashimoto, and Compton have demonstrated that there is a complicated arrangement of the funiculi and fibers within a nerve trunk, as "nerve plexuses" occur within the nerve trunks because of the frequent rearrangement of the fibers within the nerve.

I have made a large number of observations in my peripheral nerve operations, and Dr. H. A. Riley and I are investigating this subject on human cadavers. In the large majority of nerves, there are, at different levels, definite groupings of the funiculi, easily recognizable with the naked eye. In very many instances these groupings are so regular that by the proper suture the end of each divided funiculus can be brought into approxi-

Fig. 3.—Suture of the outer head of the median nerve, and the ulnar and the internal cutaneous nerves, showing epineurial mattress sutures.

mate apposition to the corresponding end, and rotation of the ends of a divided nerve and distortion of the nerve pattern can be prevented.

In the majority of instances in which I have resected bulbs in gross continuity, or end bulbs in complete separation, the nerve patterns in the central and peripheral ends visible to the eye were either identical or very similar. An entirely different pattern was observed in a surprisingly small number of the patients.

It is certain, I believe, that ideal peripheral nerve surgery will be possible only when we have learned a great deal more of the minute structure of the peripheral nerves, and of the arrangement of fibers and bundles of fibers (funiculi) to form the nerve "pattern," and have developed a finesse and delicacy of technique which an ideal nerve suture demands.

without tension by relaxing the nerve by flexion of adjoining joints (flexion at the wrist for injury of ulnar and median nerves in the forearm; flexion at the elbow for median and musculospiral nerves in the arm and forearm; extension at the elbow and adduction of the arm for the ulnar nerve in the arm and forearm, plantar flexion of the ankle, flexion at the knee, etc., for nerves in the lower extremity). Transplantation of the ulnar nerve to the front of the internal epicondyle is often necessary for the approximation of the ends of an ulnar nerve injured above or below the elbow. When this is done, especial care must be taken that the branch of the ulnar nerve to the flexor carpi ulnaris is not injured. If all of these procedures have

FIG. 4.—The cable graft. *A*, bulb resected and ends of nerves exposed; *B*, sutures passed through the cutaneous nerve used from cable graft; *C*, cable graft ready for transplantation; *D*, cable graft ready for transplantation; *E*, sutures passed through ends of cable graft and ends of nerve; *F*, sutures tied; *G*, perineurial sutures tied. (Diagrammatic.)

We can obtain additional knowledge of nerve pattern by the electrical stimulation of the ends of a recently divided nerve. I have been investigating this aspect of the subject in the nerves of freshly amputated limbs. My investigations are far from complete, but a number of definite observations have been made, which will be reported at a later date.

#### *G. Approximation of the Divided Ends of a Nerve.*

The approximation should always be made without tension. In the majority of instances, this can be accomplished by freeing the nerve ends—especially the peripheral part—for a considerable distance. In this procedure, however, due consideration should be given to the location of branches, and care should be taken that important sensory and motor branches are not injured. The nerve ends can often be approximated

been used and the nerve ends cannot be approximated, a nerve grafting operation must be performed.

#### TECHNIC OF NERVE SUTURE

The suture of the divided ends of a nerve is a very delicate procedure. For suture material I use fine Carrel needles with very fine silk. For the actual union perineurial and epineurial sutures are used. I do not believe that epineurial sutures, alone, will bring the ends of the nerve into the best approximation. If a little bleeding occurs into the nerve, the blood is apt to collect between the ends of the funiculi, and the resulting scar tissue is apt to interfere with the down growth of the neuraxons. After the proper relation of the nerve ends has been determined, so that the minimum amount of distortion of the nerve pattern will

occur (effected by the attachment of mosquito clamps to the sides of the nerve so that the arrangement of the funiculi in both ends is made visible) one, two or three fine perineurial stitches are passed, the number

beautifully how nerve fibers will pass around such a fine perineurial suture.<sup>1</sup>

All of the perineurial sutures should be passed before they are tied, and, when they are tied, care should be taken that the sutures just bring the funiculi into apposition. If the sutures are tied too tightly, the funiculi are bent at their ends with a resulting poor approximation.

After the perineurial sutures have been tied, the mosquito forceps can be removed. The epineurial stitches should be placed with exactness, so as to approximate the free borders of the epineurial sheath. I believe that the best approximation can be obtained by mattress sutures (Figs. 1 and 3); they are much less apt to tear out than are simple sutures. From four to five mattress stitches suffice, each suture being left long for traction while the succeeding one is being passed. In some sutures of the sciatic nerve, I have made a continuous running suture of the epineurium, as in the Carrel technic for blood vessel suture.

Fig. 5.—Median and ulnar end bulbs.

depending on the arrangement and number of the funiculi. The epineurium will usually have retracted, and no special difficulty should be encountered in passing the stitches through the perineurial tissue between the funiculi if the needle and the suture material are sufficiently fine. I have found it practical to hold the needles in fine mosquito forceps rather than in the fingers, and to grasp the needle with the forceps about 0.5 cm. from its point. When the nerve consists of a number of small funiculi (as in the ulnar, median and sciatic nerves) two or three of these perineurial stitches are necessary. When the nerve consists of from two to four large funiculi, two of these stitches are usually sufficient to approximate the funiculi. If the sutures are well placed, with due regard to the nerve pattern, a fairly accurate apposition of the ends of the funiculi is possible (Figs. 1 and 2). This apposition would be more perfect if the sutures were passed through each one of the large funiculi, but such a suture is inadvisable on account of the interference with a certain number of nerve fibers which such an "end to end funicular suture" would entail. Professor Huber, to whom we are indebted for very remarkable experimental and histologic studies, has shown me microscopic sections which demonstrate

NERVE TRANSPLANTATION

Transplantations of the nerve to a more superficial level are sometimes necessary. To separate the line

Fig. 6.—Bulbs resected. The defect has to be filled in by a graft.

of union from the bone, muscle or fascia, plastic operations must often be performed, to surround the line

1. All those who have had the good fortune to be present at Professor Huber's lectures and demonstrations at the sessions of the New Surgical School of New York for Medical Officers of the U. S. Army have derived not only much information, but also a great stimulus from his as yet unpublished work.

of union with a cuff of tissue and thus to protect it from the surrounding scar tissue. Fat transplantation is sometimes of value, and Cargile membrane may sometimes be useful for a similar purpose.

#### TECHNIC OF NERVE GRAFTING

As all experience in human surgery and all animal experiments have shown, a direct end to end suture is far preferable to a nerve grafting. If, however, the ends of a divided nerve cannot be approximated by all the methods above described, a graft must be inserted between the ends of the nerve. I shall not enter into a discussion of the comparative value of autografts, homografts and heterografts, and of homografts preserved in cold storage, or in alcohol (Nageotte). The results of animal experiments and experiences in human surgery have shown that the autograft is to be preferred. We have limited ourselves to the use of autografts obtained from the patient himself, and have used cutaneous nerves—the external cutaneous of the thigh, the internal saphenous in the leg, the anterior and posterior cutaneous branches of the musculo-cutaneous, and the internal cutaneous in the upper extremities.

The grafts were obtained by the method later described, and we made use almost exclusively of the "cable grafts"—that is, grafts consisting of a number of strands of a cutaneous nerve. I believe that wherever possible the cable grafts should be made up of as many strands as there are funiculi of the same size in the nerve ends. The nerve strands which are to be united into a cable should be handled as little as possible with instruments or the hands, and for this reason, I have devised the following method (Fig. 4):

After having determined the length of the defect which is to be bridged over by the graft, and the number of strands that will be required, one or several cutaneous nerves are exposed and carefully dissected out until they remain attached only at their upper and lower ends. Two sutures are then passed in and out of the nerve at measured distances. For the sake of description, let us say that the graft is to be 7 cm. long and is to consist of three strands. The one suture (*A*) is passed through near the attached upper end of the freed nerve, from the inner to the outer side of the nerve; a loop is left loose, and the needle is then passed through the nerve from the outer to the inner side a little more than 7 cm. from the first point; again a loop is left, and the needle passed through the nerve, from its inner to its outer side, at the same distance

from the last point. The needle is then laid aside and a second needle and suture taken. This needle (*B*) is passed through the lower end of the nerve, from its outer to its inner side, a little more than 7 cm. from the point of emergence of needle *A*. A loop of the suture is left and the needle passed through the nerve, from the inner to the outer side, at a point 3 mm. above the point of emergence of suture *A*; finally, the needle is passed through the nerve, from its outer to its inner side, 3 mm. proximal to the next point above. The points at which the suture *A* has passed through the nerve correspond to the upper ends of the graft; and the points through which needle and suture *B* have been passed correspond to what are to be the lower ends of the strands. After the loops have been carefully arranged, the nerve is cut with fine scissors or a fine scalpel (1) 1 mm. above the beginning of *A*, (2) 1 mm. below the beginning of *B* and (3) between each two points through which sutures *A* and *B* are passed, apart in the nerve. An assistant then grasps

the two ends of suture *A* and the operator the two ends of suture *B*. When traction is made, the strands are drawn together. Then each suture is loosely tied. *A* brings all of the upper ends of the strands together; *B* brings all the lower ends together.

After the cable graft has thus been made, it is transferred to its place between the divided ends of the main nerve and sutured in position, according to the method shown in Figures 4, 5, 6 and 7.

I have performed fourteen cable grafts by this method, and have found it a very

satisfactory procedure, in which the handling of the strands of the nerve to be used for the graft is reduced to a minimum. The method is a very simple one when its technic has been mastered.

There are a number of questions in grafting to which we have not yet any definite answer. How do these grafts act? Is it advisable to expose the graft eight or more weeks after the first operation, at a time when regeneration through the graft, down to its lower end, has occurred, in order secondarily to resect the lower union and freshly unite the end of the graft to the peripheral end of the nerve? These and other questions cannot be considered here. I have exposed the lower end of one graft ten weeks after the first operation, and have found it in such a good condition, without scar tissue, that the wound was closed without interfering with the lower end suture. It is possible that in some cases, at least, the resection and the resuture may be necessary. This will depend on whether or not the regenerating neuraxes will pene-

Fig. 7.—Cable grafts in place, bridging over defects in median and ulnar nerves. Epineurial stitches have been tied.

trate a recent suture line more easily than they will an older one.

If the condition of a nerve permits it, a neurolysis is always better than a resection and suture, and a resection and suture far better than a resection and grafting. The results of neurolysis, in cases in which it may properly be employed, are very satisfactory, and we have seen the improvement begin almost immediately after the operation. Insufficient time has elapsed to permit me to speak of the results of our nerve sutures and nerve grafts. Although nerve grafting has been very successful in animal experiments, the question of what results can be obtained in grafts in the human being has still to be answered. We believe that the era of perfect peripheral nerve surgery is still to come, when we have learned much more about the minute internal anatomy of the peripheral nerves. The wide and varied experience gained from the war is surely of great value, and has greatly enriched our knowledge. The points of view in this paper are taken in an effort to develop new points of view in the surgery of the peripheral nerves.

### THE INDICATIONS FOR SURGICAL INTERVENTION IN PERIPHERAL NERVE INJURIES\*

KARL WINFIELD NEY, M.D.

Major, M. C., U. S. Army; Chief of Neurosurgical Service, U. S. Army General Hospital No. 3, Colonia, N. J., and U. S. Army General Hospital No. 41, Fox Hills, Staten Island, N. Y.

NEW ORLEANS

Lesions of peripheral nerves have proved to be a rather common complication of gun-shot injuries of the extremities. This is especially true of shell wounds, in which the rough, serrated fragments produce extensive laceration of the soft parts and comminution of the bone.

The nerve trauma may result in a complete division of the nerve trunk, or only a portion of its fibers may be injured. It may be crushed against a bone and its fibers interrupted without rupture of the nerve sheath. Frequently it is only bruised, producing swelling and hemorrhage in the nerve substance. In all these conditions, function is usually lost immediately, and if the nerve fibers have been divided, it is not regained until the axis-cylinders have completely regenerated and connected up with the end-plates which subserve the function of motion, sensation, etc. This regeneration of the axis-cylinder consists of a complete outgrowth from the point of division to its terminal end-plate, along the distal segment of the divided nerve which acts only as a conducting structure for the direction of their course. When scar or other interposed tissue prevents the downgrowing axis-cylinders from reaching the divided end of the distal segment, they stray in all directions in their futile efforts, and meeting only the antagonistic reception of a foreign tissue, continually change the direction of their search, until the result of these never-ceasing contortions is the production of a bulky mass of nerve tissue which constitutes the neuroma frequently found on the proximal end of the divided nerve. With the contraction of scar tissue about a divided nerve or within a nerve trunk, the axis-

cylinders gradually lose their regenerative activity, and with their complete strangulation, all growth ceases. A nerve may even escape injury at the time of the wound and subsequently become caught in bone callus or scar tissue and compressed until it can no longer convey impulses, producing a physiologic interruption. If this compression is severe enough to interfere with the blood supply of the nerve trunk, degeneration of the axis-cylinders is the result. Such lesions do not develop a neuroma, and at operation, if it is possible to dissect the nerve out from the scar tissue it often appears as a flattened cord. When sectioned, the ends do not show nerve bundles but present rather a gelatinous appearance. This condition may extend some distance up and down the nerve trunk; and often after making many sections to find normal nerve bundles, we have been compelled to make a suture in nerve tissue having this appearance, believing it preferable to grafts; in all such cases, however, regeneration seems to be progressing favorably. Frequently nerves which have been compressed only to the extent of impulse interruption will regain their function in a few weeks after the scar tissue is removed, as there has not been anatomic interruption of the axis-cylinders.

The majority of patients with peripheral nerve injuries recover without operation; but it is always a question of considerable time before positive evidence of regeneration is to be seen in the return of voluntary motor power or the clearing up of areas of anesthesia. During the period of regeneration or the time required for the downgrowth of the divided axis-cylinder, there are months of patient waiting during which time it is difficult to determine positively whether or not regeneration is progressing satisfactorily. We believe the rate of growth of an axis-cylinder, in the process of regeneration, is from 1.5 to 2 mm. a day, provided its growth is not inhibited by scar tissue, sepsis, etc.

Practically all war wounds are infected and suppurate for some time, and it would be folly to attempt nerve suture during this period. Our experience has taught us that it is not safe to operate on wounds recently healed, especially those which have suppurred for some time. Many bacteria lie dormant in these tissues, and it requires only some slight traumatism to produce a recrudescence of the infection. As a rule we do not consider it advisable to operate in the vicinity of wounds which have suppurred until they have been completely healed three months or longer.

Most of the patients we now see in military hospitals are those who have waited a number of months for the clearing up of infections; and when the time has arrived after which operative procedures are justifiable from the standpoint of sepsis, the proposition has then to be confronted as to just how much progress the nerve has made toward regeneration.

When a diagnosis of peripheral nerve lesion has been made, the vital question as to the extent of regeneration immediately presents itself; and frequently this can be answered only after a comparison of notes made at several consecutive examinations. Only when it is possible to determine the progress or fixity of symptoms by the comparison of several accurately recorded examinations is it possible to determine with any considerable degree of certainty whether regeneration is progressing satisfactorily or not. It will be readily understood that if examinations are not accurate and the record of findings not complete, they may be responsible for entirely false conclusions. In the

\* Read before the Section in Orthopedic Surgery at the Seventieth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

examination of muscles supplied by an injured nerve it is not sufficient to note simply that a certain group is paralyzed or that all muscles supplied by a given nerve are involved. Each muscle, as far as possible, should be examined individually to determine the slightest function as seen in the movement of its tendon or its influence on the position of a given joint. If some slight movement is overlooked at one examination and recorded at a subsequent observation, it might be considered as evidence of regeneration. Attention should here be directed to mistakes often made in the observation of muscular action as seen in false or substitution movements. Many patients will learn to simulate to a greater or lesser degree certain movements which are suggestive of function in paralyzed muscle; and unless examinations are made to determine individual muscular function, error is almost certain.

The examination and recording of sensory disturbance are of great value in determining the progress of regeneration, for one of the earlier signs of regeneration is the contraction of fields of anesthesia. Here definite charts should be made at each examination to show the exact area of sensory disturbance. This must not only show the definite area of sensation involved but must also state the nature of the sensation examined, whether it be by light touch, by cotton or camel's hair brush, pin prick, pressure or other means. The examination for the more delicate sensations of degrees of temperature, etc., are of great interest, but at this stage give no information which we may consider of any great value in determining regeneration. The recording of sensory findings in terms of epieritic and protopathic is to be discouraged, as a much more reliable chart may be had by recording the findings of the individual sensations.

The electrical examination of paralyzed muscles is of great value in questions of diagnosis, and very often the differentiations of functional and organic lesions is impossible without its use. But after the diagnosis of division is definitely made it is of little value in determining the presence or absence of regenerative changes. The reaction to faradism is always slow to return, and as a rule does not appear until after definite voluntary motion is evident. The galvanic current gives definite signs of degeneration by its slow contractions, and in neglected cases suggests the fibrous character of the muscular tissue by the complete loss of all response to such stimulation; but outside of giving us such information, which is indispensable from a standpoint of diagnosis, it gives us very little regarding regeneration until a late stage. The quickening of the galvanic response and the return of normal polar reactions are suggestive of regeneration; but we frequently see all of these changes brought about in completely non-regenerating nerves by proper physiotherapeutic treatment.

Muscular tone is lost from the time of injury and does not return until the motor fibers are connected with their end-plates. It is a valuable indication of regeneration, but it is manifest only a short time before actual voluntary movement are noticed. After a careful study of our comparative findings with regard to voluntary motion, areas of anesthesia, electrical findings, tone, trophic changes, etc., it may readily be seen that while it is possible to make a diagnosis of complete division of a nerve, the question of determining its regeneration is difficult, even in the hands of those who have had considerable experience in this class of

work. It is often only after months of close observation that one may make a diagnosis of satisfactory regeneration on the foregoing clinical findings. In fact, many operators of experience consider that at the end of six months, if there is no decided evidence of regeneration as seen in the return of voluntary motion, the nerve should be exposed, and at that time a decision should be made as to the operative procedure which should be adopted—whether resection with suture or simply freeing the nerve of scar tissue.

We do not believe that a properly conducted aseptic exposure of a nerve and the freeing of it from scar tissue can in any great degree be productive of harm; in fact, many cases have shown the value of such a procedure. But it has been our experience that, as a rule, it is not possible to determine completely the condition of a nerve after exposure, and the tendency is too often to resort to resection and suture. This, of course, is indicated when the ends are definitely separated and a neuroma is present; but this is very often not the case, the nerve being found simply incorporated in a mass of scar tissue. From the microscopic appearance alone the operator is unable to say whether or not axis-cylinders have been able to penetrate through the scar tissue, and should he perform a resection and suture it would mean interruption, and all the regenerative efforts and progress attained in these months would be lost.

When a nerve is partially or completely divided, the divided portion has a tendency to retract, and the formation of a neuroma is the rule. When this neuroma is absent, it is almost impossible to differentiate between anatomic division or a strangulation of the nerve trunk. When there is no definite neuroma, it is probably a case of strangulation. Whether or not it is a complete anatomic division or strangulation with degeneration of the axis-cylinders, the process of regeneration must proceed the same. The question immediately asked is, Why not perform a resection of the part involved in scar tissue, and make a suture where the section shows normal appearing nerve bundles? There would be no objection to this procedure if it were possible to make nerve sutures perfect in respect to the physiologic topography of the nerve trunk. This we are unable to do at the present time with any degree of certainty in spite of all precautions directed toward the prevention of axial rotation of the nerve trunk. In nerve suture, the impossibility of correct approximation of the individual physiologic fascicular elements, makes it an imperfect operation; motor fibers most certainly will be connected with sensory pathways in the lower segment, and sensory fibers with motor pathways, so that in this way many fibers are physiologically lost. Motor fibers of the upper segment, accustomed to the control of a given muscle may be directed to another muscle and there will be a question of reeducation involved. A realization of our limitations in nerve surgery should compel us to pay the greatest respect to the physiology of nerve structure in individual nerves and we should be on our guard against assuming a too radical attitude with reference to nerve suture.

When the proximal end of a divided nerve is subjected to mechanical irritation, the patient complains of a tingling sensation resembling an electric shock in the area of the sensory distribution of that nerve. For instance, after a division of the musculospiral nerve,

pressure on or tapping over the nerve at the level of the lesion gives this peculiar tingling sensation, which the patient immediately localizes on the dorsum of the thumb, index finger and the adjacent portion of the dorsum of the hand. The sensory distribution of all other nerves, when divided, will be just as accurately located. Tinel, who called attention to this phenomenon, has demonstrated that when axis-cylinders are not protected by their normal coverings they are very easily stimulated by the slightest mechanical irritation.

The progress of the downward growth of the sensory axis-cylinders can be followed very accurately along their course by this method, and from month to month their progress may be judged by the persistently lower level at which this tingling may be elicited by gentle tapping along the course of the distal segment of the nerve. At first, it is possible to elicit the sign only at the level of the lesion; at the end of six weeks, if regeneration is progressing favorably, it may be found an inch or an inch and a half below the level of the lesion. At the end of three months it may be found 4 or 5 inches lower, and so on until it is present at the distal extremity of the nerve. This indicates that certainly some sensory fibers have been able to bridge the nerve gap, that they have found the separated end of the distal segment, and that they are progressing down. It gives us no information regarding motor fibers, but we consider it a valuable sign of at least some regeneration; and if sensory fibers can find the distal end of the nerve, there is certainly reason to expect a certain proportion of motor fibers to do the same. It is true that not all the fibers may get through the scar tissue; but when this formication or tingling on percussion progresses steadily down the course of a nerve, that is, with maximum intensity as compared with that found at the level of the lesion, and at a rate equivalent to the growth of a millimeter and a half a day, we may conclude that scar tissue is not seriously influencing the regenerative process. Though there are no other signs of regeneration present, the finding of formication advancing steadily downward should be considered a favorable indication of spontaneous regeneration. When it is present at the level of the lesion and does not progress below, we have always considered it to be a positive indication for operation, and our operative findings have always borne this out. When formication is not intensive by percussion below the lesion, or when it only extends a short distance, stops, and shows no further progress, the indications are for surgical intervention.

I have several times heard surgeons say that formication was present along the course of a nerve and at operation they had found the nerve completely divided. It is quite possible for just a few sensory fibers to get through what appears to be a complete division; but I am quite sure that immediately after the operation these surgeons found the formication absent. The sign of formication has a very definite prognostic value, the favorableness of which depends on its intensity and rate of progress, and, like most other diagnostic signs, requires experience for its interpretation. We are constantly seeing patients with nerve lesions of from eight to ten months' duration completely recover motor and sensory function. If we had depended on other signs of regeneration alone and ignored Tinel's sign, many of these patients would have been operated on, and much valuable time would have been lost. We have on many occasions seen complete

motor and sensory function regained after more than twelve months had elapsed, during which time the only evidence of regeneration seen was the progressively downward course over the nerve trunk, at which formication could be strongly elicited.

#### ABSTRACT OF DISCUSSION

ON PAPERS OF DRs. ELSBERG AND NEY

DR. FREDERICK C. KIDNER, Detroit: I want to say one word in substantiation of what Dr. Ney has said in regard to the probable recovery of very large numbers of injured nerves. I disagree with him, however, regarding the necessity for operation. A very large percentage of nerve injuries should be explored; because there are numbers of cases that will be greatly hastened in recovery by an early freeing from dense scar tissue. The objection he has raised to operation, based on the probable recurrence of sepsis, is, I believe, to be largely avoided by the use of the two stage operation. That is, as soon as a wound is healed, where there is a severe nerve injury, it is possible to do an exploratory operation that does not in any way involve the nerve itself, but makes a pathway to the nerve, so that if sepsis does recur, it is easy to throw the wound wide open and drain it. If sepsis does not recur, it is possible, in a week or ten days, to go in again, explore the nerve itself and suture it, if necessary. What he says about leaving nerves alone when they seem to be badly scarred, but are not actually cut across, is very wise. The nerves that look almost impossible at the time of exploration, if dissected free, will many times recover of themselves. The matter of nerve suture is an encouraging one. The trouble with the people who have made such discouraging prognoses on nerve suture, it seems to me, is the fact that they have not been content to wait long enough. In my service in England, I began to do nerve sutures in July, 1917; but in few cases did I begin to see results before July, 1918, when I left the British service. My total results are just beginning to come to me now, in July, 1919. They are not yet put together, but they are very encouraging and are so good that I am convinced that we should give nerve suture every chance, rather than to resort to early tendon transplantation and other destructive operations. I think that in nerve injuries, tendon transplantation has a very limited place, and should not be resorted to until three or four years after the receipt of the injury to the nerve.

DR. SAMUEL W. BOORSTEIN, New York: It was worth while to attend a meeting of this kind and learn of the cooperation necessary in these cases between the neurologist, neurologic surgeon and orthopedic surgeon. This is possible, even in a small hospital. I have had the good fortune of working with Dr. A. S. Taylor and Dr. Byrne at Fordham Hospital, N. Y., in many of these cases, and the best results were secured because the preoperative and the postoperative orthopedic treatments were not neglected. If this cooperative work were generally carried out, the results would be more encouraging than they have been. The orthopedic surgeon should, however, always assist at the operation. I really cannot add much to the details of the technic. Dr. Taylor follows the same technic as Dr. Elsberg. The only thing I would emphasize is the importance of support for a long time. If massage is used, we do not get much atrophy. We have kept one case on a support for a long time; and on leaving it off for three weeks, we had to resort to it again.

DR. DEAN D. LEWIS, Chicago: One of the first things that comes to the consideration of the nerve specialist is whether peripheral nerve suture should be done. From experience in the evacuation hospital, it seems to me that every nerve injury that comes into the evacuation hospital should be explored. In some cases, end to end suturing should be done. I agree with Dr. Ney that the majority of these patients recover. We are operating in 30 per cent. of peripheral nerve lesions, and the majority of patients are recovering slowly. If the diagnosis of anatomic division is

made, end to end suture should be done, with an autograft inserted. The only surgery that is reliable is end to end suture without tension. If the case goes two or three weeks without recovery and remains stationary, it should be explored. Muscle neurolysis is much superior to any other neurolysis that I have tried. I have seen many cases that have gone on for six months with complete physiologic interruption. Dr. Danforth's statement that the cards giving the history of the cases should be sent through with the patients is timely. This is one of the most essential things in war surgery. How it happened that the field medical cards were taken away at the port of embarkation, so that when they arrived we had no idea of what had been done, is hard to understand. We had to take the patient's word until we could verify it from the adjutant general's office.

DR. MARTIN B. TINKER, Ithaca, N. Y.: I hesitate to prolong discussion, but on the basis of experience with 600 peripheral nerve injuries at Base Hospital No. 26, I wish to confirm what Major Ney has said about the number of spontaneous recoveries. In the second place, I wish to call attention to the unreliability of the so-called Tinel's sign, deep tingling on percussion. Dr. Ney has emphasized its value. It is a subjective sign. The patient tells you whether he feels or not; and he is often so anxious for recovery that he feels as if he were getting it, when he really is not. In many instances patients would tell us that they felt it, when, at operation, we found complete severance of the nerve with several millimeters gap between the divided ends. I feel, therefore, that this sign is unreliable. A third point was brought out by several of the speakers: the desirability of delay in operation. Dr. Porter will confirm this experience that we had, that mild manipulation only, and no operation whatever, lighted up serious streptococcal infection in several cases that had been healed for months, leading us to believe that we should act with great caution in handling these cases.

DR. TOM A. WILLIAMS, Washington, D. C.: A diagnostic feature that has not been mentioned is ascertaining whether or not there has been regeneration by means of the periodic or augmentative current, a sign that is not subjective but objective. Suppose that there is a partial division of the ransculospiral nerve and the nerve does regenerate partially. Let us suppose, also, that some of the fibers that have not regenerated are motor fibers. In what way do we ascertain whether all the fibers have not regenerated and that a suture is therefore necessary? The way it is done is to ascertain the response of the muscles to stimulation by what is known as a periodic current. That current stimulates only muscles in which the nerve fibers have undergone degeneration. If the response of any of the muscles that have been stimulated by the periodic current alone disappears when this current is applied, you may assume that that nerve has regenerated. If one of the proximal branches of the musculospiral, the radial, ulnar or even the sciatic, which goes to a muscle near the room of a limb, has been damaged and we find within a certain length of time that there is no regeneration of the axons to these muscles, that is to say, that their stimulation by a periodic current does not disappear, we know that there is no regeneration in these fasciculi, even though there is ulnar or distal motor regeneration. Hence, in that case we must join that portion of the nerve. Even when Tinel's sign is readily present and is not merely in the suggestion of the doctor, that does not mean that there is a true reconnection of the nerve. It is common to find a partial division in the nerve. What we want to know is whether there are any fibers that have not regenerated. When they are there, only in that way can we arrive at a conclusion regarding the point. It is a method that has not been utilized in this country but has been in France. One should wait for years before one can record a hopeless prognosis and resort to limb transplantation, which at best gives only a minimal efficiency of the limb. Now that we have so much better methods of grafting with grafts from other animals, we should never resort to limb transplantation until the methods of approximation and interposition of autografts have been employed.

DR. W. WAYNE BARCOCK, Philadelphia: I should like to refer to a phase of reasoning in Dr. Ney's paper regarding recoveries after these important wounds of war; that is, the assumption that nerve injury inflicted by gunshot is more prone to recovery than that from a surgeon's knife. The argument apparently is, do not operate except in very limited number of nerve injuries, for nerves mangled by bullet or shell usually do better when uncorrected by surgical art. To carry out this idea to its final conclusion, one should advocate shooting through nerves as the best method of preparing them for regeneration. This logic recalls the old statistics of cesarean section, showing that these operations when performed by the horns of enraged bulls actually gave better results than when performed by the hands of surgeons. To claim that nerves that have been badly mangled and have had no operative attention will make a better recovery than those that have had a skilled operation correction under aseptic conditions seems rather curious. Yet a number of neurosurgeons apparently believe this. In more than 500 nerve injuries treated in U. S. Army General Hospital No. 6, Fort McPherson, Ga., 142 of these cases were mild, showing evidence of spontaneous recovery and were treated only by massage and electricity without operation. Up to May 1, 33 per cent. of these unoperated cases remained the same, and 67 per cent. have improved. In contrast; out of 148, much more severe cases subjected to herbage or neurolysis, 80 per cent. now show improvement. A number have shown improvement in the first few weeks after operation. As to cures: 17 per cent. of the unoperated; 20 per cent. of the neurolyzed and 10 per cent. of the hergaged cases show practically complete sensory and motor restoration; in other words, in our operated cases, progress is better and more rapid than in the milder unoperated patients.

Of about 170 cases of nerve sutures, 25 per cent. already show improvement and progress viewed in relation to the periods of time that have elapsed since operation; that gives us much confidence as to the final satisfactory outcome of these cases. A large percentage of gunshot injuries of nerves should be operated on because, first it is best for the nerve, and, secondly, it enables the associated correction of important orthopedic conditions. Because a man has a nerve injury, should he be deprived of the benefit of a needed orthopedic operation? Practically all these patients have large deforming scars with muscles bound together as a result of infection. Many have retained foreign bodies or joint or bone involvement. For unhealed wounds of soft tissues, we have found wound excision after the zinc chlorid and ethereal methylene blue sterilization with immediate operation on the nerve both safe and time saving. A nerve that has been damaged will recover in a progressively decreasing ratio the longer the delay after the injury. An early operation, if safe, is the desirable operation. Granted an aseptic field it is much better, in nerve injuries to look and see, than to wait and see. In operating, it is not enough to isolate a trunk that looks like a nerve. It may be only a mass of connective tissue. If you cannot demonstrate fasciculi the nerve sheath should be split. If that is not enough you should open the nerve along the normal line of fibers until you determine accurately the amount of nerve substance present. If only a few fasciculi remain undestroyed it is often better to resect freely the damaged area and do an accurate suture so that the man will have a chance to get from 90 to 100 per cent. return of function, rather than 10 to 20 per cent.

DR. KARL W. NEY, New Orleans: I did not wish to leave with you the impression that it is a discouraging procedure, but there are refinements in nerve surgery which should receive more attention, and the fascicular topography that Dr. Elmerg showed you in the slides is important. It is perfectly safe to remove scar tissue, but the great tendency is to do a resection when one finds a nerve that looks bad. In the suturing of nerve trunks there is always the probability of connecting up sensory fibers with motor and motor with sensory, also fasciculi which have had control of one muscle will be connected up with another muscle whose functions are different; for this reason nerve suture is not

a perfect operation from a physiologic standpoint. If it is possible not to do a resection of a nerve but simply free it from scar tissue I think we are doing the proper thing. However, the last word in nerve surgery has not been said.

## SYPHILIS OF THE EPIDIDYMISS\*

H. E. MICHELSON, M.D.

Instructor in Dermatology, University of Minnesota Medical School  
MINNEAPOLIS

Syphilitic involvement of the epididymis or cord, independent of disease of the testicles, is rare, and, if present, is overlooked in the examination of patients when one is searching for signs of syphilitic infection.

The discovery of several cases of infiltrated epididymides and thickened cords, due to syphilis, led to a search for more minute descriptions of these conditions, but little could be found.

Dr. Benjamin Bell, surgeon to the Royal Infirmary at Edinburgh in 1793, first called attention to syphilitic diseases of the testicles. Ricord denied the existence of syphilitic epididymitis, while Nélaton, Fournier, Dron (1863), Balme, Gosselin, Pinner, Shadek and others gave accurate descriptions and classified types. Very little has been written in late years on the subject. In 1916, Franklin R. Wright<sup>1</sup> gave descriptions of two cases, and, in 1918, Hinman and Lisser<sup>2</sup> described a single classical case. These two articles are the only ones recently published on the subject. The following notes are gathered from various sources, and are an effort to give a clinical description of syphilitic diseases of the epididymis and to bring the subject to the attention of this section, with the hope that the scrotal contents will be examined more often in the routine survey of syphilitics, and that patients presenting symptoms of disease of the scrotal contents will be examined for syphilis.

Three forms of syphilitic epididymitis have been described: (1) acute diffuse interstitial; (2) chronic diffuse interstitial, and (3) gummatous (circumscribed).

### THE ACUTE DIFFUSE INTERSTITIAL TYPE

The diffuse type is the more acute type, and may occur after the second month of infection. Gosselin, however, states that it does not occur before three and one-half months. Very few cases have been reported which occurred before the third year, and the majority of cases occur after the fifth year. Zeissl<sup>3</sup> reports a case which occurred in the second month of the disease, and was accompanied by grouped, papular syphilids in other parts of the body. Shadek has more minutely described the early type. He states that in the early, diffuse variety of syphilitic epididymitis there is a partial or total swelling of the entire epididymis. The swelling at first feels uniform, elastic and smooth, and does not attain a large diameter. As the process continues, distinct indurations arise, which are of variable size—from that of a bean to that of a hazelnut. Pinner states that these nodules are more often found

in the upper pole; more seldom, in the body, and rarely, if ever, in the lower pole. The enlargement is rather acute, somewhat painful, and is accompanied by some degree of hydrocele. After a few days, the acute, inflammatory symptoms subside, the swelling of the epididymis diminishes to some extent, and, as the hydrocele is partially absorbed, the condition of the epididymis can be detected by palpation as a painless, irregular, elastic, rather hard thickening of the entire organ. After a few months, the induration may become absorbed and the epididymis return to its normal size, but more often it remains very solid and somewhat sensitive. In some cases, the epididymis becomes atrophic, occluding the lumen. In the early type, the process seldom passes on to the testicle; while in the gummatous stage, on the contrary, the testicle is first attacked. The two epididymides rarely get diseased at the same time.

### THE CHRONIC, DIFFUSE INTERSTITIAL TYPE

The chronic, diffuse interstitial type is a connective tissue change which may follow the more acute variety, or it may come on independently of an acute attack. It is then a slow, insidious, chronic, diffuse process, or may consist of a series of distinct cartilaginous indurations. The condition is painless until the attention of the patient has been called to the enlargements, when he may complain of dragging sensations and tingling pains. Examination reveals indurations, usually confined to the upper pole of the epididymis; in most cases, we have found the entire epididymis to be involved. The indurations feel very solid; each may feel as though it were made up of several smaller ones, bound intimately together with a thick covering. They are only slightly tender to pressure. The entire epididymis makes a firm, resistant, solid, uneven, indented tumor in apposition with the testicle, without overlapping it (Lancereaux<sup>4</sup>). The induration ends abruptly and does not taper into normal tissue. The vas deferens is rarely involved.

Effusion, which is usually present at some stage, may perhaps be caused directly by the thickening of the tunica vaginalis, and subsequent disturbances of circulation (Finger<sup>5</sup>), or may be due to a chronic, passive congestion, with resulting transudate (Wright<sup>1</sup>). This fluid collects in the tunica vaginalis testes, leading to the mistaken diagnosis of hydrocele. The fluctuation may be very indistinct because of the much thickened tunica, or because of tension, so that it is difficult to isolate the testicle or the tumor mass. When the hydrocele sac is opened, the layers of the tunica are found to be closely adherent and lined with a thick, organized membrane, while numerous areas of slate-colored deposit are noted in quite a few instances. The fluid is not so great in amount as would be expected, and is thick (Joseph<sup>6</sup>). Wright's experience, however, is that the fluid has nothing characteristic about it and may be as much as 1,000 c.c. The Wassermann reaction on this fluid is negative.

### THE GUMMATOUS TYPE

The gummatous type of syphilitic epididymitis begins in the late periods of the disease, but earlier than tes-

ticular gummas (Pinner). Several small nodules, varying in size from that of a bean to that of a hazelnut, develop independently of each other, more often in the body or head of the epididymis. These nodules may be closely grouped, or dispersed at various points. The process is chronic and develops insidiously, but may be preceded by the history of an injury. The masses are smooth, quite hard and painless. They rarely break down to the extent that they rupture externally. When this is the case, the discharge is scanty and thick, and the subsequent ulceration has a decidedly indurated periphery, the entire mass and ulcer making a tumor with fungoid ulceration. The tumor has a connective tissue origin, either from the external coats of a blood vessel or from connective tissue membrane. It is made up largely of fibrous tissue, and goes through the various phases which are characteristic of all gummas. Gummas of the epididymis may be secondary to gummatous involvement of the testicle. Langhans reported a gross section of a syphilitic epididymis discovered postmortem. He described it as a solid, caseous knot of angular, ramified shape, about 1 cm. in diameter, with a small transparent zone along the edges. The vas deferens was not invaded, which fact, he said, differentiated the process from a tuberculous one.<sup>7</sup>

#### REPORT OF CASES

The following case reports are taken from the files of Dr. Franklin R. Wright, with whom I am associated.

**Case 1 (1440).—Syphilitic Funiculitis and Hydrocele.**—A man, aged 30, a taxicab driver, had had a chancre in 1911. He was married, had no children, and his wife had had no miscarriages. The early history was not important. The patient had received only local treatment for the chancre and had noticed no subsequent signs of syphilis. In September, 1918, the right side of scrotum began to enlarge. The enlargement proceeded rapidly until, at presentation, the scrotum measured 9½ inches in circumference. It was painless and rather hard. No distinct tumor could be felt, nor could the testicle be made out except at the lower, posterior end. The cord could be felt as thick as a thumb at the ring. The patient was seen by Dr. Wright and the condition diagnosed as syphilitic hydrocele and funiculitis from the history and thickened cord. A Wassermann reaction was positive. After two injections of mercuric salicylate, the circumference of the scrotum diminished 2 inches. The patient was given twelve injections of mercuric salicylate and four 0.6 gm. doses of the neosalvarsan brand of neo-arsphenamin, followed by twelve injections of mercuric salicylate, from Nov. 4, 1918, to March 26, 1919, when both sides of the scrotum were of equal size, and no indurations could be felt, except a slightly enlarged cord on the right side. The patient gained 10 pounds and continued routine treatment.

**Case 2 (1489).—Subacute Syphilitic Epididymitis.**—A married salesman, who had no children, had persistent shreds of the urine and a pain, with some swelling of the right epididymis. He denied ever having had gonorrhea, but a year previously he had had a small sore on the prepuce, followed by a "boiling" of the skin. He had taken no treatment. A Wassermann reaction was negative. A prophylactic dose of arsphenamin was given one 0.6 gm. dose of the neosalvarsan brand of neo-arsphenamin. The test was then strongly positive. He reported that he felt better after the administration. The course of treatment was

continued. The slight induration of the entire right epididymis entirely vanished. He gained 9 pounds. Twelve injections of mercuric salicylate were given and the patient continued the treatment. This case, although the diagnosis was not definitely made, proved to be one of a diffuse, syphilitic epididymitis, as discoverable by the rapid response to antisyphilitic treatment. The wife's blood gave a positive reaction to a Wassermann test.

**Case 3.—Syphilitic Interstitial Epididymitis and Hydrocele.**—A colored porter, aged 25, referred to Dr. Wright for hydrocele, had had a chancre five years before. Three months before coming to Dr. Wright he had noticed an enlargement of the right side of the scrotum. It had filled rapidly. The enlarged, hardened, elastic epididymis could be felt back of the testicle. The circumference of the scrotum was 11¾ inches. The diagnosis was syphilitic epididymitis and hydrocele. The treatment consisted of mercuric salicylate injections, and large doses of potassium iodid. After three treatments the circumference was reduced by 2¾ inches. The patient then lapsed in taking treatments, and it was not possible to follow the case farther.

**Case 4.—Gummatous Epididymitis.**—An unmarried plumber, aged 27, who had been infected with syphilis four years before he was seen by Dr. Wright and who took pills on and off for two years, noticed a small lump in the left scrotum three months previous to coming to Dr. Wright. This enlarged for a few weeks—was not painful; then subsided. A month before his first visit he received a blow in the scrotum. The swelling again appeared and the enlargement became painful. The skin became red and finally burst through, discharging a small amount of gelatinous pus. An ulceration followed, the size of a nickel, on the posterior surface of the left scrotum. The edges became much indurated, and the discharge scanty. The testicle could be palpated, and seemed to be matted in a mass the size of a walnut. The patient lost 18 pounds. The diagnosis was gumma of the left epididymis. Three injections of the neosalvarsan brand of neo-arsphenamin and potassium iodid were given. The healing was prompt. The patient gained weight, but refused to continue the treatment. He was married a year later, and his wife gave birth to a healthy (?) baby. No further report is available.

**Case 5 (1418).—A trainman, aged 45, with no history of chancre, had had gonorrhea, which lasted one month one year before he was seen. No complications followed. Eight months later the left epididymis began to swell. There was no pain. A large hydrocele appeared and was opened. The epididymis was indurated; the sac was semielastic and thickened, and the entire cord was thickened. The Wassermann reaction was negative. Iodids were given and the thickening began to disappear. The patient was then given four injections of the neosalvarsan brand of neo-arsphenamin, which resulted in a decided softening of the epididymis. The patient has not subsequently been seen.**

**Case 6.—Diffuse Syphilitic Epididymitis and Funiculitis.**—A brakeman, married, with no children, had a thickening of the left epididymis, which a physician had been treating as gonorrheal. He had never had gonorrhea, and his wife was reported well by a gynecologist (Dr. Condit). The left epididymis was hard and knotted, being made of numerous distinct indurations. The entire cord was thicker and harder than the right. The patient admitted having had syphilis seven years previously. He had had some pills, but no arsphenamin. The patient was called out of town before the examinations were completed. There was no Wassermann report and no therapeutic test.

**Case 7.—Gummatous Epididymitis.**—A boy, aged 2 years, a first child and of foreign parentage, concerning whom little history was obtainable, had an illness beginning with a lump in the left scrotum, which enlarged and finally ruptured externally. There was a mass the size of an olive in the upper portion of the epididymis. The ulceration showed a decidedly indurated border. Internal antisyphilitic treatment brought the lesion under control, with complete healing in two months' time.

<sup>7</sup> In addition to the references already given, the following will be found of interest:

Wassermann, A., *Die Syphilis*, 1908, p. 100. Lrk ankungen, Vienna, M. Henschel, 1914, p. 109.  
Hennrich, J., *Journal of Syphilis*, Philadelphia, Lea Brothers & Co., 1914, p. 7.

Two other cases observed were reported by Dr. Wright.

COMMENT

1. Syphilitic involvement of the epididymis is not an extremely rare occurrence, and will be more frequently found, if looked for.
2. Bilateral involvement is unusual.
3. The more common type is the chronic diffuse interstitial type.
4. Some cases of hydrocele are due to syphilis.
5. All patients presenting themselves for disease of the scrotal contents should be examined for syphilis.
6. The diseased portion is not necessarily confined to the upper pole, the entire epididymis being frequently involved.

RAGWEED DERMATITIS\*

RICHARD L. SUTTON, M.D.  
KANSAS CITY, MO.

The important part played by anaphylaxis in the causation of various eruptions has long been recognized. In a paper dealing with drug exanthems in relation to anaphylaxis, Cole<sup>1</sup> includes a brief but comprehensive review of the literature of the subject, and defines anaphylaxis as "a state of hypersusceptibility of the organism to foreign substances, which is brought about by the introduction of certain foreign proteins and their cleavage products."

The incubation period of sensitization varies in different species of animals from six to twenty-one days; and is shorter after intravenous than after subcutaneous injection. After an animal has once become sensitized, the hypersusceptibility persists almost indefinitely, and as Rosenau and Anderson<sup>2</sup> have demonstrated, may be transmitted from a mother to her offspring.

CAUSE OF ANAPHYLAXIS

Cooke<sup>3</sup> summarizes as follows: A foreign protein, not in itself toxic, gains entrance into the circulation for the first time. It stimulates the production of specific antibodies which previously did not exist. More antibodies, which may or may not be enzymes, are produced by certain cells of the body and seem to be intimately associated with the cells which produce them. If enough time is allowed for a sufficient number of antibodies to accumulate, and a second dose of the same protein is then introduced, the antibodies react with the protein, splitting it into toxic fragments, which in turn injure the body cells, and give rise to anaphylaxis. If, on the other hand, an excess of antibodies has been produced and these are free in the blood stream, they combine with the foreign protein and prevent it from reacting with the body cells, just as antitoxin neutralizes toxin. In other words:

When antibodies are absent or few in number, we have the nonsensitive state; when numerous and attached to body cells, we have the sensitive or anaphylactic state; and when in excess, with many unattached to body cells, we have the immune state. Anaphylaxis and immunity are the same in principle, differing only quantitatively.

Danysz<sup>4</sup> calls attention to the fact that certain symptoms are a result of anaphylaxis induced by microbes, living or dead, or their products, a fact which has also been emphasized by Duke,<sup>5</sup> Major<sup>6</sup> and others. Sensitization may be single or multiple. Cooke found multiple sensitization in more than 50 per cent. of his cases.

Moschowitz<sup>7</sup> calls attention to conditions that must exist in order to bring about a state of hypersensitization:

1. There must be previous susceptibility, which may be congenital or acquired.
2. The reaction is specific.
3. The reaction can be obtained by mouth, as well as by injection; also by cutaneous inoculation, such as rubbing the offending substance into an abraded surface.
4. Acquired susceptibility can be transferred by heredity to posterity.

The constitutional symptoms are respiratory disturbance, dyspnea, hyperemic and urticarial skin eruptions, and similar toxic phenomena.

Many if not all skin conditions thus far considered as anaphylactic are associated with eosinophilia.

Immediately following anaphylactic shock and repeated injections of antigen in small doses, there is a state of immunity to anaphylactic shock from further injections of the same antigen. This is called anti-anaphylaxis; it is absolute, though only temporary; thus differing from immunity (Strickler<sup>8</sup>). This method of desensitization is at times employed as a therapeutic measure and, occasionally, with a certain degree of success.

Chandler Walker,<sup>9</sup> in an extremely valuable paper on the causation of eczema, urticaria and angioneurotic edema, concludes that the proteins of horse dandruff, ragweed, and timothy pollens, may cause eczema in predisposed persons, both from external exposure and from internal injection.

Eczematous patients tolerate very small doses of the offending protein, and the eczema seems to improve; but a slight increase above this small amount makes the eczema worse. Therefore, desensitization for eczema, if such is possible, must be a very slow and cautious process, even more than in asthma.

Charles J. White<sup>10</sup> of Boston was one of the first, if not the first, to call attention to anaphylaxis as a factor in the causation of some cases of infantile eczema; and his efforts to popularize cutaneous tests for the detection of the various offending proteins have been of great educational value.

Ayres<sup>11</sup> has recently published an instructive paper on the value of cutaneous tests in unearthing the causative factors in various disorders probably developing as a result of anaphylaxis.

SKIN REACTIONS

Kolmer<sup>12</sup> thus summarizes the various skin reactions:

1. The true, or specific, anaphylactic reaction, due to the interaction in the skin of specific protein antigen and specific antibody.

3. Cooke: *Med. Clin. of N. America*, **1**: 721, 1917.

2. The pseudo-specific or nonspecific protein reaction, due to the interaction in the skin of general protein substances and nonspecific proteolysis.

3. The traumatic reaction consequent on the operation, or the irritant qualities of such substances as preformed bacterial toxins and various preservatives, as phenol and cresol contained in the injected material.

The intradermal method, which is the most delicate, but also more likely to yield traumatic and nonspecific reactions.

Strickler,<sup>13</sup> and Strickler and Goldberg<sup>14</sup> have adopted these standards as to what constitutes a positive cutaneous reaction:

1. Persistence of the lesions for more than twenty-four hours after the injection. (They fix the standard at forty-eight hours.)
2. The presence of a distinct papule.
3. The presence of a distinct erythema.
4. The presence of tenderness at the point of injection.

Blackfan<sup>15</sup> thinks there is no justification for the forty-eight hour standard, and believes that less time would suffice. Judging from my own experience, I believe a twenty-four hour period practicable.

In a final review of the subject of anaphylactic eruptions in general, Strickler and Goldberg conclude that:

Just as a syphilitic subject with a positive Wassermann reaction may develop a skin eruption that is unrelated to his systemic infection, so a patient with a positive food anaphylactic reaction may develop a cutaneous affection due to other factors than his food.

As Ayres has said:

The exact mechanism by which the multiple local edema characteristic of anaphylaxis is produced is not positively known. Heidenreich has suggested local anuria with increased permeability of the vessel walls; Vertz has deficiency of calcium salts in the blood; and Martin Fischer, a localized increase of acid products.

All three of the foregoing explanations are open to criticism, although each is supported by well recognized facts.

While all of us are familiar with the eruptions which develop occasionally as a result of anaphylaxis following the ingestion of various articles of food, and many of us recognize the part played by bacterial products in the causation of certain diseases of the skin, such as infectious eczematoid dermatitis and kindred disorders, I do not believe that the cutaneous phenomena which occur as a result of the absorption of foreign proteins through the respiratory tract and possibly

through the skin itself have received the attention and study that they deserve.

About seven years ago, I had an opportunity to study a case of goldenrod dermatitis, with an associated asthmatic disorder, due to the same agent. The patient was a little girl, and direct exposure to even small amounts of goldenrod pollen invariably and promptly produced a severe dermatitis, which quickly became generalized, and an asthma of varying degree, which persisted for twenty-four hours or more and then gradually subsided. Examples of dermatitis from this source are rare, however, probably owing to the fact that the flower is insect pollinated, and direct inhalation or direct contact must necessarily precede absorption.

#### REPORT OF CASES

CASE 1.—My first case of ragweed dermatitis was seen in a Kansas stockman, aged 48, referred to me by Dr. W. C. Labrop of Norton.

The patient's hypersusceptibility to ragweed pollen had existed about eight years; and, during an attack, the manifestations were almost wholly confined to the integument. Unlike some victims of the disorder, he had never suffered from hay-fever; and, so far as he knew, pollens other than those of ragweed did not affect his skin. The disease recurred annually, during August and September, and each time persisted for two or three months.

The face, chest, hands and forearms were the parts principally affected, although the trunk and the lower limbs occasionally were involved. Exposure to the dried weeds, in hay mows and stacks, during the winter and spring months, invariably brought on an attack.

The cutaneous eruption which developed as a result of these brief periods of exposure was comparatively mild, however, and generally subsided quite promptly under the influence of soothing, astringent lotions, as aqueous solutions of aluminum acetate.

The seasonal exacerbations were more serious, however, and practically incapacitated the patient for many kinds of farm work.

The cutaneous lesions varied in form from macules to bullae, the majority being macular, maculopapular and vesicular in character. Itching was invariably present, together with more or less burning and stinging. Free exposure to pollen would invariably precipitate an attack in from one to three hours, and twelve hours later the patient's face would be so badly swollen that he could hardly see. In this instance, no specific vaccines were employed.

CASE 2.—My second patient, also a farmer, referred to me by Dr. Frank McDermald, of Kansas City, had a clinical history which almost duplicated the one recorded above. In order that the affection might be the more easily investigated, I asked my friend, Dr. W. W. Duke, to make an exhaustive laboratory study of the case. This was done, and it was found that the patient possessed a marked hypersusceptibility to the pollen of common ragweed (*Ambrosia elatior*), and a slight susceptibility to the pollen of giant ragweed (*Ambrosia*

Fig. 1.—Common ragweed (*Ambrosia elatior*), principal cause of hay-fever in the Eastern and Southern states. (From "Illustrated Flora of North America," by Britton and Brown—after Scheppegrell.)

13. Strickler, J. N. *New York M. J.* 101:198 (July 29) 1916.  
14. Strickler, A., and Goldberg, J. M. *Anaphylaxis*, J. A. M. A. 69:249 (Jan. 22) 1916.  
15. Blackfan, K. D. *Am. J. Dis. Child.* 11:441 (June 16) 1916.

*trifida*). There was no reaction to timothy, goldenrod or cottonwood.

The use of ragweed pollen vaccine, in gradually increased dosage, afforded much relief; and at this time, after almost two years of interrupted treatment, the attacks are so infrequent in number and so mild in character that the patient is inconvenienced but little by them.

CASE 3.—In my third case, which occurred in a farmer, aged 43, referred to me by Dr. Edward Ashell, of Kansas City, there was a history of mild annual attacks of "rose fever," extending over a period of eight or ten years; but during the six years that immediately preceded the date of my examination, the patient had been entirely free from the nasal disturbance. The cutaneous disorder, which was characterized by the presence of irregularly distributed but roughly symmetrical collections of macules, papules and vesicles, involved the face, chest, trunk and forearms, and had at first appeared only during the late summer months. For the past two years, however, the patient had at no time been entirely free from it.

In view of the histories of the two preceding cases, it was a comparatively easy matter to discover, and prove, the nature of the offending agent. The hypersusceptibility in this instance was very great, so much so that the simple inhalation of a small amount of ragweed dust, contained in a wide-mouthed bottle, was sufficient to bring on a severe exacerbation of the cutaneous disorder. The ingestion of capsules containing pollen and particles of leaves had no appreciable effect on the patient's skin. As in Case 2, *Ambrosia elatior* was the offender.

Treatment with pollen vaccine was instituted, but it was not possible for the patient to report regularly for the injections, and they were discontinued altogether before any material benefit was derived from their use.

CASE 4.—In my fourth case, which also occurred in a farmer, referred to me through the courtesy of Dr. William J. Frick of Kansas City, the disorder was of five years' duration, and the patient, who was a very observant individual, had already discovered its cause.

Unfortunately, it was not practical for him to adopt so radical a prophylactic measure as the abandonment of his occupation, and he had tried a large number of local and internal remedies without securing relief.

Owing to the ease with which the remedy could be procured, Mulford's fall pollen extract was tried in this case. The result of the treatment was very satisfactory, relief from the burning and itching being almost immediate. After a series of twelve injections, in gradually increasing doses, the patient temporarily discontinued treatment. At that time, he could safely handle hay containing considerable amounts of ragweed, and, at present, he believes that he is cured. He has promised to report again later in the year, however, after the "ragweed season" is over, and the permanence of the cure can then be ascertained.

OFFENDING PLANTS

The plants that cause so-called "ragweed dermatitis" are probably the same as those causing hay-fever. The

principal offenders, as Lowdermilk,<sup>16</sup> Scheppegrell<sup>17</sup> and others have demonstrated, are the common ragweed, and the giant ragweed, with mugwort (*Artemisia heterophylla*), western ragweed (*Ambrosia psilostachya*) and bur marsh elder (*Iva xanthifolia*) in the lesser rôles.

As Scheppegrell has said, the responsibility of the noxious plants for hay-fever is dependent, first, on the proximity of the plants, and secondly, on the size of the pollen, which has a marked effect on its buoyancy. The pollen of the common ragweed is only 15 microns in diameter, and its buoyancy is so great that a wind velocity of 20 miles will carry it over large areas of territory.

PREPARATION OF POLLEN

The preparation of the pollen for dermal tests is a comparatively simple matter. Duke advises that a known amount of pollen be placed in a small, sterile mortar, together with a drop or two of sterile water. The pollen is then thoroughly triturated, being ground repeatedly until, when examined under a microscope, it is found that the grains are completely broken up. The mixture is then diluted with tenth normal salt solution, to which 10 per cent. of glycerin and 0.5 per cent. of phenol (carbolic acid) have been added, so that 1 c.c. of the mixture contains 10 mg. of pollen.

The same preparation may be used for treatment purposes; but if this is done, the solution should again be diluted serially, in order to guard against possible overdosage.

The initial dose should be small, not over from 0.0001 to 0.0003 mg. of pollen protein. Afterward, the dose may be increased in size, depending on the reaction secured. A safe plan is to inject the vaccine every third or fifth day, increasing the amount injected from 10 to 30 per cent. each time. Occasionally, the ensuing reaction is very severe and even violent; and it is wise always to have conveniently at hand atropin and epinephrin solutions, in case they are needed. The local treatment is that of an eczema.

Since this paper was written, Hannah<sup>18</sup> of Sander-ville, Ga., has published a report of a very interesting case of ragweed dermatitis of five years' duration, in a woman, aged 49. A specific diagnosis was made by means of intradermic tests, and prompt relief followed the hypodermic use of pollen extract.

## ABSTRACT OF DISCUSSION

Dr. C. A. SIMSON, Washington, D. C.: I enjoyed Dr. Sutton's case report very much. It is unfortunate that he has not endeavored to make a serious study of the subject of anaphylaxis, which would have prevented his confusing the term with skin sensitization. The two terms while superficially similar, in reality are quite different. The reaction of anaphylaxis is better understood, and its production requires certain definite specific factors. It must be produced by a protein in an animal or man who has become previously sensitized to that specific protein. The authorities, serologists and pathologists, not dermatologists, claim that so far no substance other than a protein can produce the anaphylactic phenomena. Ford, the only serious contender of this general opinion, was unable to duplicate his results with his so-called glucosid, von Audlung later showing that he was not working with a pure glucosid, but a compound. For Dr. Sutton to get a skin reaction with ragweed ground up in the menstruum he employed may mean almost anything. The requirements of true anaphylaxis are far from complied with, in fact, the reaction is simply an example of skin sensitization such as we see following the injection of arsenphenam or the ingestion of pure chemicals (not proteins), such as quinin and iodine. In my work with the primrose plant I at least made an effort to discover the irritating elements of the plant. I isolated a protein with which I sought to (1) produce a skin reaction in a susceptible patient, (2) actively sensitize a guinea pig, (3) produce an anaphylactic shock in two sets of pigs, one previously sensitized (?) by the patient's serum, the other sensitized (?) by a previous injection of the same primrose protein. All of these protein tests were negative. When an alcoholic extract of the plant (which had precipitated all proteins) gave an intense skin reaction, I was doubly sure that protein had nothing to do with the skin irritability. In a further analysis of the plant I obtained two compounds, both without a protein content, one an oleo-resinous mixture probably containing an acid, the other a crude glucosid, both of which produced the characteristic skin reaction where the protein failed. It is unfortunate that Dr. Sutton, at this late day, should confuse the two entirely different reactions. A casual investigation of the literature in *THE JOURNAL of the American Medical Association* might right his rather hasty and entirely incorrect conclusions.

Dr. J. H. BLAISDELL, Boston: I recently had a patient, a boy, 6 years of age, who reacted to ragweed in the usual way and in addition was very sensitive to the external application of dog dandruff. Every time he played with a neighbor's dog he suffered from an acute attack of asthmatic eczema of the parts that had come in contact with the animal. Another case was that of a lawyer who was susceptible to horse dandruff. He was so sensitive that if any one came into his office in the winter time and shook a fur overcoat after they had been driving a horse he would have an acute attack of asthma. Harnessing or carrying a horse could produce asthma and a dermatitis of the parts exposed to the dandruff.

Dr. LARRY S. LAM, Oklahoma City: I have looked up the subject for several years and have noticed a dermatitis which I had thought was produced by ragweed. I have however, attributed these cases more to the direct contact or friction, irritation by the hairs of the plant itself, than I have to the pollen. I do not doubt the possibility of plant pollen also producing a dermatitis when it comes in contact with a susceptible portion of the skin. I have noted several cases of ragweed dermatitis on the legs of children wading through the weeds on the way to and from school. If there is an abrasion on the skin they develop a dermatitis very easily. The subject of plant dermatitis is growing larger all the time and I think we should take careful notice of the various plants that produce it because the farmers and the city people who take their vacations in the rural districts are anxious to know about these plants and how to avoid them. Poisonous plants are classified by many botanists, though they classify them more especially as regards internal toxicity, produced accidentally or otherwise.

Of their poisonous substances very little is known or written. Take, for instance, the large nightshade group—nearly all members of this family are toxic when administered internally and a large number will produce a dermatitis when applied externally. I believe Dr. Sutton will find that not only is the ragweed toxic by means of the pollen which floats, but also by means of the fine plant hairs which perhaps prick the skin and deposit a poisonous glucosid.

Dr. WILLIAM ALLEN PUSEY, Chicago: I wish to defend Dr. Sutton's use of the term anaphylaxis. We all know that the term anaphylaxis was applied primarily to reactions from protein sensitization. We also know now that other reactions of the same character as these protein reactions occur from other substances. It is all very well to be purists in the use of language, but you cannot readily confine the use of a word to a phenomenon which is produced by one substance and deny its use to exactly the same phenomenon produced by another substance. For example, if a man has a reaction which we call anaphylactic to an infinitesimal amount of egg white, how are we going to prevent the application of this term to a clinically identical reaction to an infinitesimal dose of quinin in a quinin-sensitized person? Etymologically there is no objection to this broadening of its meaning; in fact, I believe there are many reasons for it.

Dr. HAROLD N. COLE, Cleveland: I would like to raise the same question as Dr. Pusey did in regard to anaphylaxis. They used the term first in relation to proteins. It has been shown by Ford that the same thing can be obtained from glucosids and I think the same thing may apply to asthma. When you get these symptoms I do not see why it should not be spoken of as anaphylaxis.

Dr. FRED WISE, New York: There is one point which I think will interest the section. Yesterday Dr. Schanberg told us that he produced desensitization to the reaction from poison ivy by the internal administration of rhus toxicodendron.

Dr. JAY FRANK SCHAMBERG, Philadelphia: For several years I have been using the tincture of rhus toxicodendron to desensitize patients susceptible to ivy poisoning, and so far I have never had a failure. It is perfectly possible to keep the patients free from ivy dermatitis. I use 1 c.c. of the rhus toxicodendron with 10 c.c. of alcohol with some fluid vehicle sufficient to make 100 c.c. I begin the treatment with one drop well diluted after the first meal, two drops after the second meal, and so on, until 20 drops are reached, and then for the purpose of simplifying the treatment I give one teaspoonful, well diluted, once a day through the ivy season. The immunity seems to last for about one month after the last dose has been taken. It is very simple, does not disturb the digestion and patients are able to keep themselves free from ivy poisoning in this way. I made brief mention of this at the session of the American Medical Association in Detroit, 1916, and since then I have had many cases and not one that was not protected. One patient was a young girl who was usually confined to bed for about three months of each year because she could not walk down a lane where ivy grew without becoming attacked. I have no doubt that other forms of dermatitis from poisonous plants could be prevented in the same way. I believe that Dr. Pusey will, on recollection, agree with me that patients who are susceptible to ivy poisoning do, as a matter of fact, have certain periods of immunity. Patients do not have recurring attacks without a number of weeks of relative or complete freedom. I think it is quite well established that persons susceptible to ivy poisoning may be attacked with ivy dermatitis without actual contact with the plant. The effect of the treatment to which I have referred is; after all, not to be prejudged by theoretical conditions, but by actual results obtained.

Dr. WILLIAM ALLEN PUSEY, Chicago: The proposition to produce immunity to poison ivy by the administration of tincture of rhus arouses in my mind the question why we do not see acquired immunity to poison ivy from previous attacks. Patients who are sensitive to the plant have attacks so readily on exposure that the duration of immunity produced by an attack must be very short, if it exists at all. If the attacks themselves do not produce immunity, how

much success are we going to have in producing immunity by the ingestion of a tincture of the drug?

DR. H. J. PERRY, Boston: I wonder if the members of the section have heard of immunizing patients by feeding them the leaves of the poison ivy. Some one called my attention to this method of feeding a leaf to an exposed or already poisoned patient every day, and said he had been able to protect them by this method and bring about a rapid cure of all symptoms.

DR. J. FRANK SCHAMBERG, Philadelphia: I believe that Dr. Pusey infers that patients do not have a period of immunity; but they do at times have a period of immunity; otherwise, they would be having successive attacks of ivy poisoning, but within two or three months they will again become susceptible. As regards the question of having an attack of ivy poisoning without coming in contact with the ivy, that has been substantiated. After all, it is not a matter of theory but of practice.

DR. RICHARD L. SUTTON, Kansas City, Mo.: I might follow out Dr. Simpson's argument "to its ultimate termination," but a rose by any other name smells just as sweet, and if he does not care to call it anaphylaxis, he can call it anything he pleases. With reference to Dr. Blaisdell's case of sensitization to horse dandruff, several well authenticated instances of anaphylaxis due to this substance are now on record. Dr. Duke has reported a very unusual example in which the patient, a young woman, was sensitized to the protein thrown off by cat fur. A friend of the patient once thought he would play a joke on her, and brought near her a small kitten, concealed in the pocket of his coat. The ensuing attack was so severe that a physician had to be summoned and an injection of epinephrin given to relieve the attack. So far as ragweed pollen in particular is concerned, I think the cutaneous reaction following the intradermal injection of even very minute amounts of the substance is amply sufficient to establish the relationship. When a severe attack of asthma, with an associated and clinically typical, dermatitis, invariably develops in certain individuals as a result of the injection of even so small an amount as 0.001 mg. of ragweed pollen, then if we are not dealing with anaphylaxis the condition is an utter stranger to me.

## THE FUNDAMENTAL PHYSIOLOGIC REACTION IN ANAPHYLACTIC AND PEPTONE SHOCK

PRELIMINARY REPORT \*

J. P. SIMONDS, M.D.  
CHICAGO

The causes of the remarkable differences in the manifestations of anaphylactic and peptone shock in different animals has been the subject of no little speculation. In the dog, anaphylactic and peptone shock are characterized by a marked immediate fall in arterial blood pressure, a simultaneous fall in venous (external jugular-superior vena cava) pressure, a rise in portal pressure, an increase in the volume of the liver, and, at least in peptone shock, an increased flow of lymph from the thoracic duct. It is evident, therefore, that in the dog, the flow of blood through the liver is greatly impeded in these conditions. The exact location of the obstruction has not heretofore been determined.

In reasoning from these facts it appeared that the only possible location for an obstruction that would explain all of them was not the extrahepatic splanchnic area, nor the portal vein and its intrahepatic

branches, nor the intralobular capillaries, but the hepatic vein and its branches. It has been shown that a fall in blood pressure such as is seen in the dog is not characteristic of anaphylactic shock in the guinea-pig (Auer and Lewis) or in the rabbit (Auer) or in peptone shock in the guinea-pig (Hirschfelder). In searching for a reason for this difference, a study has been made of the comparative anatomy of the hepatic vein in different animals. It has been found that the hepatic vein in dogs differs from that of the guinea-pig, rabbit and other herbivorous animals examined, in the relatively enormous amount of smooth muscle which is present in its walls. A report of the results of this study, made in collaboration with Dr. L. B. Arey, will be published later.

It appears, therefore, that the fundamental physiologic reaction in anaphylactic and peptone shock in dogs is a spasm of the smooth muscle in the walls of the hepatic vein and its branches. Experiments which make this evident will be reported later.

This interpretation of the physiologic mechanism of anaphylactic and peptone shock has certain practical bearings which will also be made the subjects of forthcoming publications:

1. It is known that in the guinea-pig the finer bronchioles are "practically nothing but muscular tubes" (Oppel, cited by Auer and Lewis). The characteristic clinical manifestation of these conditions in this animal is a violent dyspnea in which it can get air into its lungs but is unable to get it out. The dog and certain other animals have hepatic veins supplied with exceptionally large amounts of smooth muscle. The manifestations of anaphylactic and peptone shock in dogs have just been described. It seems possible, therefore, that the basis for these differences in the reaction of different animals in shock of this kind is an anatomic difference in the distribution of smooth muscle in the body. A similar anatomic anomaly may also account for certain types of asthma and serum reactions in human beings.

2. This observation may also bring peptone shock into relation with surgical and wound shock. It is only necessary to recall that among the theories advanced by various authors who have studied shock under war conditions is one which makes the absorption of the soluble products of damaged muscle in wounds responsible for the condition. Furthermore, it is obvious that any prolonged spasm of the hepatic vein and its branches, such as occurs in peptone shock in the dog, will lead to the same condition in the general circulation, or at least in the splanchnic area, of sequestration of blood in the venules and capillaries as was observed by Jackson and Janeway in the shock produced by them by the mechanical obstruction of the vena cava for limited periods of time.

3. It is evident, also, that in interpreting the results of experiments on dogs, especially those which have to do with blood pressures, this peculiarity of the hepatic vein must be taken into consideration. This will be discussed more fully in a paper on the interpretation of the blood pressure curve following injections of epinephrin (adrenalin).

**Cancer Mortality.**—During the great war the United States lost about 80,000 soldiers. During the same two years 180,000 people died of cancer in this country. Cancer is now killing one out of every ten persons over forty years of age.—American Society for Control of Cancer.

THE METABOLIC GRADIENT UNDER-  
LYING PERISTALSIS \*

WALTER C. ALVAREZ, M.D.

SAN FRANCISCO

Why does food normally go in one direction down the intestine? Why sometimes does it go slowly and haltingly, giving rise to symptoms of indigestion? Why sometimes does it turn around and come back through the mouth? These questions are fundamental; and the future of gastro-enterology as an exact science depends on the fulness with which they are answered. Until we obtain such physiologic knowledge we must face the fact that in practice we are trying to repair a machine, the normal structure and workings of which are largely unknown to us. Naturally the results are often unsatisfactory, just as they would be if we were trying to repair broken-down adding machines or wireless telephones.

What could the heart specialist learn about the arrhythmias until Gaskell, McWilliam, His, Keith, Lewis and others showed him where the beat normally arises and how it is transmitted from sinus to ventricle? Given that information, the student of heart pathology became inspired and rejuvenated; his knowledge advanced by leaps and bounds; and his textbooks had to be rewritten and remodeled. We should take hope from this good fortune which has come to our confrères and should seize on the methods of study which have been so productive in their hands. With these I believe we can advance to similar triumphs over the baffling problems in our own chosen field. We should study the gastro-intestinal tract in embryos and in lower and simpler forms of life; we should look for structural and metabolic differences in the neuromuscular apparatus in different parts of the tract, and we should study minutely the reactions of the muscular coat—its rhythmicity, irritability, conductivity, reaction to drugs, etc.—in different regions. As clinicians, we must get over the habit of thinking in terms of plumbing and rigid tubes held in one position. We must think instead of a muscular tube which has to contract in a coordinated way if material within it is to be pushed for many feet in one direction or the other.

Six years ago I showed that there is a very definite gradient of rhythmicity in the muscle of the small intestine from duodenum to ileum<sup>1</sup>. It seemed to me then that this gradient of rhythmicity or perhaps some underlying gradient of tone might be the essential factor in determining the direction of peristalsis. This gradient might conceivably be reversed by any distention, irritation or inflammation which would increase the tone and activity of the lower parts of the tract to a level above that maintained by the upper parts. In two papers<sup>2</sup> I reviewed much of the literature and showed how easily a great many clinical and roentgenologic observations can be explained on the basis of such a theory.

I cannot see now why there should be any great difficulty in accepting this idea of a gradient of

forces as a working hypothesis in the study of peristalsis. Wherever we find movement in this world we find a gradation of forces. Thus, water flowing in a ditch follows a gradient of gravity, i. e., the pressure on any one drop is greater on the upstream than on the downstream side. Electricity in a wire follows a gradient of potential or voltage; in a battery it follows a gradient of chemical activity, flowing from regions in which oxidation predominates to regions in which reduction predominates. The impulse in the heart follows a gradient of rhythmicity; and according to Tashiro<sup>3</sup> the impulses in nerves follow gradients of oxidation. In the stomach and intestine the contents move from regions of high rhythmicity, high irritability and high tone to regions of low rhythmicity, low irritability and low tone.

During the last two years I have been able to show that there is a definite gradient of oxidation and carbon dioxide production in the intestinal wall, underlying and probably giving rise to the other gradients of rhythmicity, tone, etc.<sup>4</sup>. In other words, the chemical processes of life go on at a faster rate in the duodenum than in the ileum or colon. Theoretically, if we should speed up these processes in the duodenum we might steepen the gradient and cause the food to go faster through the bowel; if we should speed them up in the ileum so that they would be faster than those in the duodenum, we might reverse the gradient and stop the downward progress of food. Recent study has shown that the local life processes are greatly speeded up by inflammation<sup>5</sup>, so it may be that the hypermotility actually seen in many cases of duodenal ulcer and cholecystitis and the hypomotility with appendicitis are due to changes in the metabolic gradient brought about by these lesions.

Galvanometric studies of bruised tissues suggest strongly that their metabolic rates are increased by the trauma<sup>6</sup>. If this be true in the intestine we can easily explain the fact that its contents cannot approach or pass through segments which have recently been pinched in hernial rings or maltreated at operations<sup>7</sup>. A local increase in the metabolic rate would make the gradient uphill in the section of bowel just oral to the lesion.

There is yet another and perhaps an even more important way in which the gradient may be reversed. Child<sup>8</sup> has shown repeatedly that tissues with a fast rate of oxidation are more susceptible to the effects of low concentrations of certain poisons, such as potassium cyanid, than are tissues with slow rates. If two lots of small planarian worms of different ages are put into a weak solution of potassium cyanid, the younger ones, with the faster metabolic rate, die first. Similarly, if children and old men were to be put into a room full of ether vapor, the children would probably all go to sleep first. Child showed that in some of the lower forms of life which have rows of swimming plates along their sides, the direction of the beat can be reversed by potassium cyanid because the pace-making region suffers most from the effects of the drug. Using excised segments from different parts

of the bowel, all beating rhythmically together in the same beaker of Locke's solution. I had no difficulty in showing that the duodenum is much more sensitive to potassium cyanid and to the lack of oxygen than is the ileum. Time and again while working in the laboratory I have been impressed by the great sensitiveness of the duodenum and of the pace-making region in the stomach to trauma of all kinds<sup>9</sup>. Compared with them, the ileum and the pyloric antrum are tough and hardy. I have also been impressed with the fact that the gradients of rhythmicity, latent period and metabolism are abnormal in sick animals. Just as we should expect, the duodenum and jejunum seem to suffer more from the effects of the toxins than do the ileum and colon. The distempered dogs and snuffling cats generally refused food. When it was put in their stomachs it remained there until it was vomited. Cannon has commented on the remarkable gastric stasis seen in distempered dogs. Similarly, food may remain for hours in the stomachs of people with tuberculosis and other intoxications. There I feel sure the stagnation is not always due to a failure in peristalsis; the waves may be seen traveling regularly over the stomach, but they do not force the contents through the pylorus. Something must be wrong with the gradient. I believe it has been altered by an unequal effect of the toxins on the muscle at the two ends of the organ. How simple this explanation is as compared with those which drag in a cumbersome and so far quite undemonstrated mechanism of nerves and internal secretions!

#### AN ILLUSTRATIVE SIMILE

Perhaps I can best express my ideas of what goes on in the intestine by means of the following simile: Let us imagine a game of push-ball played by a long line of men who have been graded according to their metabolic rates. At one end they are young, wide-awake and active; at the other end they are old and lethargic. These men represent the muscle fibers along the intestine. The ball is started by the first young man, who tries to force it past the second. The second resists but is soon overcome, owing to the greater activity and aggressiveness of number one. As soon as the ball passes number two, he joins with number one in trying to push it past three and four. Once past them, one and two rest while three and four push it past five and six, and so it goes. The men in the first third of the line (jejunum) play incessantly so long as the ball is near them, and they soon force it down among the old men. These play only occasionally, often letting the ball lie quiet while they sit down about it to rest. New balls are started down the line from time to time, and sometimes the old men will have three or four on their hands at once. Ordinarily they are roused to get rid of one or two of these when they see that a new one has started down (ileocolic reflex and defecation).

Usually the ball moves in one direction and there is small likelihood that the old men with their intermittent efforts will ever overcome the youths. But one day some of the old men get drunk, and under the influence of liquor they fight so fast and furiously that the others cannot push the ball anywhere near the lower goal. On another occasion some of the old men are injured and beg their comrades to relieve

them for a while from the trouble of handling the ball. Again these old men are stimulated to fight back so desperately that some of the balls are even thrown out the way they entered. On still another occasion a cloud of poison gas is liberated over them. All are weakened and made ill, but the young men who breathe the faster are more susceptible to the poison and suffer more from the lack of proper air than do the old men. Until they recover, the game is slower; the old men are more active than the young ones and the ball is sometimes sent back to the original starting place.

A change in the play might be brought about also by making the balls unpleasant or painful to handle. Let us suppose that they have been filled with pepper or stuffed full of sharp spikes. The first one or two to start down the line would probably be rushed through so that the players could get rid of them as rapidly as possible. The men would then be so irritated by this annoyance that they would probably throw back the next few balls that were offered them (diarrhea and vomiting).

If the game was being played on the side of a hill it would not make much difference whether the young men were above or below the old. The position of the line would not be the important thing. The essential factor determining the movements of the ball would be the gradient of activity in the line of players. If the men were to play in a lane between two board fences, a slowing of the progress of the ball would not mean necessarily that the lane had been narrowed or closed. As likely as not some of the players might be fighting back too hard, or those above might not be pushing down as they should.

I think most of my readers will recognize the bearings of this simile on the problems of gastro-enterology. Some may be surprised at the idea of one part of the bowel resisting the propulsive efforts of another part above, so I will say that I have watched this conflict take place so often, particularly in the rabbit's bowel, that I feel sure that it is a big factor in the regulation of diastalsis.<sup>10</sup> It is well known that it is this type of bowel action that keeps the food from pouring out of the stomach after pyloroplastics and gastrojejunostomies<sup>11</sup>.

#### CONCLUSION

I wish to point out briefly some of the ways in which these studies may throw light on the pharmacology of the heart and on the functional disturbances of that organ seen in asthenic states and during convalescence from acute infections. Since the heart beat follows a gradient of rhythmicity and almost undoubtedly one of metabolism, we should expect to find certain drugs and disease toxins reversing it just as they reverse other metabolic gradients. A review of the literature shows considerable evidence in favor of such a view. Thus chloroform will paralyze the auricle in concentrations which will only slightly inhibit the ventricle<sup>12</sup>; digitalis has a similar tendency, and I believe we must begin to ask ourselves whether this action may not flatten or reverse the gradient. Such changes might account for some of the retarding in conduction and also for the tendency to heart block and a reversal of the beat. Similar

upsets, with palpitation, nodal rhythm and even transitory blocks may arise through the activity of disease toxins. The disordered heart action and the digestive disturbances seen side by side in people recovering from infections such as influenza may easily be due to the fluttering effect of the one poison on the two gradients. I feel hopeful, therefore, that further study of the digestive gradients and of their modification in disease will not only bring rich rewards to those of us interested in gastro-entology, but will also enable us to repay the heart physiologists and biologists with interest for the loan of their methods and working hypotheses.

#### ABSTRACT OF DISCUSSION

DR. FRANKLIN W. WHITE, Boston: We are under great obligation to Dr. Alvarez and to other physiologists who develop these new ideas which are likely to be of so much service later. Alvarez has compared the gastro-intestinal canal to a railroad under the control of a "block system," where delay low down the line regularly holds up the passage of material for several blocks above. My clinical and roentgen-ray observations have shown that delay in emptying the stomach is the exception, not the rule, in lesions of the lower bowel, and that a strong stimulus is needed from the lower bowel to slow the stomach. We made a few simple experiments a year or two ago to test the correctness of this theory. We irritated the cecum in cats with a few drops of mustard oil, injected through a rectal catheter, and we found that one of several things happened: moderate irritation had no effect on the emptying of the stomach; marked irritation caused either (a) delay in emptying the stomach up to about twice the normal time or (b) hyperperistalsis and rapid emptying of the stomach and whole digestive tract. Intense irritation caused prompt reverse peristalsis in the stomach with vomiting of its whole contents. Similar experiments were made in human beings by giving them a large enema and allowing them to retain it as long as it could be comfortably done, for twenty minutes or one half hour, and watching to see if that would slow the down hill progress of things, that is, the emptying of the stomach. We found, as a matter of fact, that their stomachs continued to empty. We could see the pylorus passing things on at very much the normal rate. Obviously, the effect of this gradient, which is undoubtedly present is not a perfectly simple affair. Its results depend largely on the grade of irritation at the lower end of the canal, and the action of the mechanism is complicated by the contrary results of spasm and hyperperistalsis.

DR. JAMES T. CASE, Battle Creek, Mich.: I am very pleased to hear the interesting and instructive theory advanced by the author of this paper. To the support of this theory I am bringing a large series of clinical observations which I have made during the last ten years, especially regarding the point to which an ingested meal will penetrate in the alimentary tract in cases of intestinal obstruction. In the early days of the roentgen-ray examination, when I treated cases of colonic obstruction by means of the barium meal, I found that in my estimate of the exact site of the obstruction I was usually off a foot or more too far up the canal. I judged the point of obstruction by the farthest point to which, as far as I could observe, the ingested meal penetrated. I did not realize at that time that there is a state of peristaltic unrest in these cases so that the meal may at one hour be advanced or withdrawn alternately.

Checking these estimations by means of the opaque enema cases showed us exactly the point of obstruction. These phenomena could be explained very easily by the theory of peristaltic gradient to which we have just listened. About ten years ago, I called attention to the fact that in colonic obstruction, for instance, the larum ingested by mouth would after entering the colon be found, as a rule, not just proximal to the obstruction, but on the contrary as far away from the

obstruction as it was possible to get it. In other words, in obstruction of the sigmoid we would usually find the collection of barium to occur in the cecum, only rarely in the distal colon. I have even known of cases of gangrene of the cecum in sigmoidal carcinomas. We have observed the same thing in the small intestine. The administration of the opaque meal is a valuable means of determining the fact of obstruction, but the farthestmost point attained by the barium is usually some feet short of the actual point of obstruction in the bowel. While the essayist's theory seems abundantly confirmed by our barium meal studies, it does not seem to be true regarding gas accumulations occurring throughout the bowel for these are apparently just as marked immediately proximal to the obstruction as in more remote segments of the bowel.

DR. NATHAN ROSEWATER, Cleveland: Rectal fissures produce a tendency toward constipation, sometimes alternating with diarrhea, because nature finally asserts itself and a forced movement takes place. I found that by giving individuals inclined to seasickness (antiperistalsis) a cathartic, and continuing it for two or three days before embarking, antiperistalsis would not occur. Patients who before that were so inclined to seasickness that they could not stand being on the water could be on it in spite of the greatest storm, while others were sick, even the sailors. By giving them something which would overcome antiperistalsis by hyperperistalsis, if the gradient is sufficiently strong outward or downward, you have no tendency toward antiperistalsis. We have all tried it in numerous ways, with cathartics in cases of nausea, but the treatment must be guided by that principle of overcoming antiperistalsis. Twenty years ago I maintained that headaches, colds, etc., are often due to fecal obstruction, the effect of such stasis on the vasomotor mechanism, demanding greater heart action to overcome the narrowed caliber of the vessels from stasis and drag; it is forced to greater effort and pressure than the vessels of the upper tracts are adapted for, therefore, some headaches are relieved by enemas or cathartics long before the bowels are emptied. After feces have passed downward enough so that the place of obstruction is relieved, together with the resultant vascular pressure, which causes the headache, the headache disappears. These headaches cannot be toxic; relief is too quick. They are obstructional. At that time I stated that enlarged thyroid glands or any vascular engorgement or enlargement in the thoracic or cranial cavities may be from cardiac overaction. In these locations there is too much blood sent to the upper tract relative to the quantity sent into the abdomen. If the greatest amount of blood reaches the thyroid, it slowly enlarges and begins to overfunctionate in quantity and quality; the tonsils enlarge the same way. So much free space in the oral cavity causes a greater tendency for engorgement there, also in the nose and throat, the wedged-shaped nasal spaces are engorged the soonest and occluded with oozing of serous fluid or mucus. Obstruction of the narrow nasal passages is the logical result; coughs, colds, congestions and inflammations of the nasopharyngeal and respiratory apparatus soon follow.

DR. WALTER C. ALVAREZ, San Francisco: As I remember Dr. White's paper, when he stimulated the lower bowel mildly, he was unable to see any change; but when he stimulated it powerfully, he could see stasis above and signs of reversal. This is what we should expect. I believe, however, that mild stimuli will produce disturbances which a man can feel but which we cannot demonstrate in an animal. For instance, an enema, particularly one made irritating by the addition of much salt and soap, will produce nausea. This, I believe, is a sign of mild reversed peristalsis. Similarly, a constipated man will stop regurgitating his food the minute the rectal plug is removed. With such mild stimuli I do not believe we could see any changes in an animal's peristalsis. What I would emphasize is that the gradient is there in normal animals; there is no difficulty in demonstrating it; moreover, it is found reversed or flattened in diseased animals. These things must have some significance and it is up to us to face the problem and carry it to a solution.

## Clinical Notes, Suggestions, and New Instruments

### A JUVENILE PARETIC AND HIS FAMILY

EDWARD LIVINGSTON HUNT, M.D., NEW YORK

P. A. came to my service in the City Hospital, an emaciated and crippled boy of 12. Physically, he showed pupils that were unequal, irregular and immobile, a coated and tremulous tongue, and a coarse tremor involving the entire body. The speech was hesitating and distinctly ataxic. He was paralyzed from the waist down.

The physical signs showed a spastic paraplegia with the reflexes all exaggerated, and loss of control of both sphincters. There were contractures of both legs so that he lay in bed a helpless paralytic.

Mentally, he showed marked dementia. If touched he would scream, and if given orders he would obey them only after considerable repetition and explanation.

The story that the family gave was that up to about 9 years of age he had been able to attend school. After that he was unable to keep up in his lessons; the teachers found him almost impossible to manage, and his schoolmates considered him irritable and uncompanionable. He was taken out of school, but the family found him too great a care at home, and he was sent to the hospital.

The laboratory reported a markedly positive Wassermann reaction in both the blood and the spinal fluid. In the latter the cells numbered twenty. The butyric acid test was positive, and the colloidal gold test revealed a typical parietic curve.

The case was diagnosed as one of juvenile paresis. The young patient is still in the hospital, slowly losing both physically and mentally.

The intern staff took considerable interest in a 14-year-old brother of the patient who came to see him. They induced him to allow them to take some blood for a Wassermann test. The laboratory reported this as being markedly positive.

It then developed that there was still a third boy, aged 10. After a time we succeeded in getting a specimen of his blood. The Wassermann test on this boy was like that of his brother, markedly positive.

The boys were sometimes accompanied by a little sister of 8. Her blood was then examined. The report showed a strong positive Wassermann reaction.

The parents of the children were next approached with a view to obtaining a blood test. The father absolutely declined; the mother consented. The Wassermann report in her case was positive.

Here, then, is a family of six, in five of whom the Wassermann blood test was markedly positive, and one of whom presented a typical case of juvenile paresis.

41 East Sixty-Third Street.

### CASE OF FOREIGN BODY IN THE NOSE

BRYED WILSON, M.D., CHICAGO

A foreign body in the nose of a child is a matter of comparatively common occurrence, but not common, I believe, in adults who are sane and of ordinary intelligence; therefore, I am prompted to report this case:

Mr. A. B., aged 33, a student of mechanical engineering, came to my office, Dec. 28, 1918, saying that during the past three years, breathing on the right side of the nose had been almost completely obstructed. At times he could inhale a little air through that side of the nose, but he could not exhale. He also complained of a very foul discharge dropping back into the throat which sometimes even produced nausea.

On examination, the nasal septum appeared moderately deflected toward the right. The left nasal chamber showed no particular abnormality, but it was possible to obtain a view of only about the anterior one third of the right nasal cham-

ber. The application of a little 4 per cent. cocain solution brought about enough shrinkage of the membranes to disclose a grayish brown mass of irregularly flat form lying against the septum and occluding inspection farther back; on examination with a probe this proved to be of a hard mineral or stony-like character and extended well back where the probe met definite resistance by what seemed to be a larger mass of like substance. Considerable thick, foul secretion was present in this side of the nose.

With a pair of Hartmann forceps I gently grasped what could be seen of this mass, and two small pieces were removed. This was followed by quite free bleeding which subsided shortly and the patient was directed to return two days later, at which time the two larger pieces were removed with some small fragments. The large and more flat piece was removed anteriorly, but the irregularly spherical piece had to be pushed backward and expectorated by the patient; rather free hemorrhage followed, which subsided shortly. The nasal chamber was irrigated and sprayed with an iodized oil and the patient directed to return the following day, when further examination of the nose did not reveal the presence of any more foreign substance. The nose was treated by mildly antiseptic oil sprays daily for about ten days, at the end of which time the foul smelling discharge had ceased and the patient was breathing freely through both sides of the nose. The large spherical specimen was found to contain in its center a cherry pit, which, it is quite evident, became lodged in the posterior part of the nasal chamber, and gradually the mineral-like substance became deposited around it. But the patient was at a loss to explain how the cherry pit became lodged there. The only explanation seemed to be that he had sneezed or coughed at some time when eating cherries and the pit had then been forced up through the nasopharynx and into the posterior part of the nasal chamber. No evidence of sinus infection was found.

7 West Madison Street.

## Therapeutics

A DEPARTMENT DEVOTED TO THE IMPROVEMENT OF THERAPY,  
A FORUM FOR THE DISCUSSION OF THE USE OF DRUGS  
AND OTHER REMEDIES IN THE TREATMENT OF DISEASE.

### USE AND ABUSE OF CATHARTICS\*

(Continued from page 1363)

#### OLIVE OIL AS A LAXATIVE

Olive oil, cottonseed oil and other food oils and fats can do all that liquid petrolatum can do—and one thing more: they can nourish the body.

That digestible oils may act as laxatives, it is necessary to give more than can be digested and absorbed. This, in the case of an infant, may be one or more teaspoonfuls daily. To obtain laxative effects from olive oil in an infant, it is well to commence with one-quarter teaspoonful once or twice a day after feeding, and to add one dose a day until a dose is given after each feeding. It may then be increased to half a teaspoonful at a dose, if required and if it is well borne. It is inadvisable, however, to use more than 10 or 15 c.c. in a day in case of a young infant; even less than this would be the limit, if the character of the stools becomes abnormal.

The adult must take considerably more of digestible oil than of petrolatum to obtain the same laxative action. The exact dose will differ, of course, chiefly with the amount of other fat ingested and with the

\* This is the fourth of a series of articles on the pharmacology, physiology and practical application of the common purgatives and cathartics. The first article appeared October 1.

digestive capacity of the individual. One or two tablespoonfuls may have to be given three times daily either an hour before meals, or, if this interferes with appetite, two hours after meals. Or else, if the patient prefers it, a single dose of from one-half to one wine-glassful may be administered on rising, or two hours after breakfast. If this dosage is insufficient, it must be increased, until the desired effect is produced or the limit of tolerance is reached.

When digestible oil is thus administered until laxative action follows, the physician makes certain that the patient is kept at the highest point of fat digestion and assimilation possible for him. Hence, in view of the high caloric value of fat, gain in weight may be expected, unless the patient's previous use of fat was up to the limit of his digestive capacity, or unless the increased fat ingestion impairs appetite or digestion.

#### CONTRAINDICATIONS

In view of the fattening quality of olive oil thus used, it is obviously contraindicated in obesity, while it is especially indicated in malnutrition. In other words, in an obese person, liquid petrolatum would be the superior laxative; in an emaciated individual, digestible oil ought to be preferred.

In further drawing special indications and contraindications for the laxative use of oil, we should take cognizance of its action on gastric secretion and movement. That oil decidedly lessens the amount of free as well as of total acid, and that it delays the emptying of the stomach, is the verdict of all authorities on this subject. That the diminution in acidity of gastric juice also occurs in conditions of pathologic excess has been shown as well. Hence, while hyperchlorhydria, pylorospasm and peptic ulcer furnish special indications for the use of olive oil, gastric atony or subacidity would contraindicate the prolonged medicinal use of this or of other oils, including liquid petrolatum.

#### METHOD OF TAKING OLIVE OIL

In the administration of large quantities of oil, such as are contemplated for therapeutic effect, the natural repugnance of many persons against the drinking of fat must be reckoned with. While considerable quantities of oil may be taken with relish in the form of mayonnaise or of French salad dressing, still the amount that can be introduced in cookery is limited. The method advocated by Rutherford<sup>1</sup> is of interest. He advises mixing cold olive oil with about an equal quantity of hot milk. As these are of about the same specific gravity, they will mix perfectly in the form of an emulsion and remain in this condition for a short time (half a minute). Those who dislike milk might prefer to take the oil floating in fruit juice, such as orange, or grape juice. In course of time, people almost without exception acquire a taste for oil, and thereafter use it with relish in any reasonable amount. There is reason to believe that the capacity for taking large amounts of fats may be increased by gradual increase in the amount ingested. It is well, therefore, to commence with small amounts, and to have the patient increase the dose as tolerance is developed.

With some persons the taking of considerable amounts of fat leads to attacks of indigestion, with coated tongue, offensive breath, loss of appetite, abdominal distress and unusually offensive stools as the most

prominent symptoms; the condition known as "biliousness." In such, of course, the use of olive oil as a laxative would be ill advised. Whether liquid petrolatum is better borne by such individuals is not known at present.

#### OLIVE OIL NOT ADVISABLE IN DIABETES

It is now fairly well established that in a person suffering from diabetes, the digestion of excess of fat carries with it the danger of acidosis, owing to incomplete combustion of fatty acids in this condition. Liquid petrolatum should, therefore, be used as an oil laxative in a diabetic, even though the patient's emaciation would make the use of olive oil seem desirable.

#### SUMMARY

To summarize: Olive oil might be particularly serviceable as a laxative in spastic constipation in an emaciated individual, provided a sufficient quantity to produce this effect can be ingested without causing loss of appetite or other digestive disturbance. The use of olive oil as a laxative would be contraindicated in obesity, in diabetes, in gastric atony and in hyperchlorhydria, as well as in those inclined to "biliousness."

(To be continued)

## New and Nonofficial Remedies

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

W. A. PUCKNER, SECRETARY.

**ACETANNIN.**—Acidum Tannicum Diacetylicum.—Di-Acetyl-Tannin.—Tannyl Acetate.—The acetic acid ester of tannin.

**Actions and Uses.**—Acetanin is claimed to be practically nonirritant to the stomach, and to pass unchanged into the intestine, there to become effective as an astringent in contact with the alkaline juice.

It is employed in diarrheal affections, such as intestinal catarrhs, cholera morbus, cholera infantum and dysentery.

**Dosage.**—From 0.2 to 0.7 Gm. (3 to 10 grains) four times per day, dry on the tongue followed by a swallow of water, or mixed with food, avoiding warm or alkaline liquids.

Acetanin is prepared by heating tannin and acetic anhydride, in molecular proportions, in the presence of glacial acetic acid in a flask under a reflux condenser, pouring the product of the reaction into water, washing the precipitate produced with warm water, drying and powdering.

It is a light creamy white, odorless or almost odorless, and tasteless powder, which melts at about 160 C. It is practically insoluble in cold water, scarcely soluble in hot water, but soluble in alcohol, and also in solutions of borax, sodium phosphate, sodium carbonate, etc., being precipitated from these solutions by acids. It is rapidly saponified by boiling sodium or potassium hydroxide solutions, or gradually in the cold, into acetic and gallic acids, while ammonium hydroxide produces acetic and tannic acids.

Its aqueous solutions produce with ferric salts a green color, instead of the blue-violet color characteristic of tannic acid. A slightly alkaline solution in sodium phosphate exhibits all the characteristics of an astringent and precipitates albumin, but these properties are destroyed by borax or more alkali.

Acetanin is incompatible with alkalis and with salts of iron; it should not be exposed to heat or moisture.

**Acetanin-Calco.**—A nonproprietary brand complying with the standards for acetannin.

Manufactured by The Calco Chemical Company, New York. No U. S. patent or trademark.

**ANTIPNEUMOCOCCUS SERUM** (see N. N. R., 1919, p. 271).

The Gilliland Laboratories, Ambler, Pa.

*Antipneumococcus Serum, Combined Types I, II, and III (Gilliland).* Prepared by immunizing horses with dead and living pneumococci of the three fixed types (Types I, II and III) and standardized against

<sup>1</sup> Rutherford, H. H. Pure Olive Oil and Its Use in the Treatment of Chronic Dysentery and Allied Conditions. *Am. Med.* 7: 432, 1904.

Type I culture, so that 0.2 Cc. of the serum will protect a mouse against five hundred thousand fatal doses of virulent Type I pneumococci; in addition it contains antibodies for Types II and III.

Marketed in 30 Cc. gravity injecting packages ready for use and also in 50 Cc. and 100 Cc. vial packages.

**Cinchophen-Abbott** (see New and Nonofficial Remedies, 1919, p. 227).

The following dosage form has been accepted:

Tablets Cinchophen-Abbott 7½ grains.—Each tablet contains 7½ grains cinchophen-Abbott.

**ACRIFLAVINE AND PROFLAVINE**

The acridine dyes are derivatives of acridine, a base found in coal-tar. Most of the acridine derivatives have no bactericidal properties, but there are some marked exceptions. One of these (diamino-methyl acridine chloride) was found by Ehrlich to possess notable therapeutic effects in trypanosome infections and, on this account, he called it *trypanflavine*. Most of the studies, both bacteriologic and clinical, have been conducted by English investigators, who call it *acriflavine*. A closely related substance having similar properties is proflavine. Acriflavine and proflavine are claimed by some to have high antiseptic power, together with comparative freedom from toxic or irritant action and without inhibiting effects on the phagocytic action of the leukocytes or on the healing processes.

Acriflavine is believed to have greater antiseptic power than proflavine, but its action appears to be slower. Acriflavine and proflavine have been extensively used in the treatment of wounds, and acriflavine has been highly praised in the treatment of gonorrhoea. A great deal of literature on the properties of the flavines has appeared, but the reports are contradictory and the clinical evidence is so conflicting that judgment as to the therapeutic value of the substances must be withheld for the present.

**Actions and Uses.**—Solutions of the acridine dyes may be boiled, or they may be heated in an autoclave to 130 C. without decomposition. The solution most commonly recommended in the treatment of wounds is 1:1,000 in physiologic sodium chloride solution, although weaker solutions have been used. In suppurating wounds this solution is used for syringing and swabbing the wound after free incision, for irrigation after providing adequate drainage, and for soaking the gauze with which the wound is finally covered. Evaporation should be prevented by protective dressing. In cavities, gauze may be soaked in the solution (without wringing) and used as a light packing. Small quantities of the solution (100 Cc. or more) may be left enclosed in cavities or deep wounds. In fresh wounds the parts are cleansed thoroughly with the solution, as much of the solution as possible being left in contact with the injured surfaces. Such wounds may be closed by suture and may be expected to heal by first intention.

In gonorrhoea a strength of 1:1,000 in physiologic sodium chloride solution may be used for injection into the urethra. For lavation, when relatively large quantities are to be used, a 1:4,000 solution is preferable because it is less irritating. Solutions of from 1:6,000 to 1:8,000 strength have been used.

An ointment has been used containing 1 per cent. of proflavine oleate (prepared from proflavine base) in an ointment base composed of equal parts of petrolatum and calcium carbonate. A thick layer of the ointment may be spread on gauze and applied on the surface of the cleansed wound, or the ointment may be spread on the wound directly. The primary dressing need not be changed for several days.

**ACRIFLAVINE.**—3:6 diamino-10 methylacridine chloride (C<sub>13</sub>H<sub>9</sub>N<sub>2</sub>Cl<sub>2</sub>H<sub>2</sub>O).

**Actions and Uses.**—See preceding general article, Acriflavine and Proflavine.

**Dosage.**—See preceding general article, Acriflavine and Proflavine.

Acriflavine is a brownish-red, odorless, crystalline powder. It is soluble in less than 2 parts of water and in alcohol, forming dark red solutions which fluoresce on dilution and which have a bitter taste. Slightly soluble in ether, chloroform, liquid petrolatum, fixed oils and volatile oils.

An aqueous solution of acriflavine (1:250) is neutral to litmus paper (it dyes the litmus paper yellow).

Add a few drops of hydrochloric acid to an aqueous solution of acriflavine which is sufficiently dilute to be fluorescent. The fluorescence disappears, but partially reappears on further dilution with water.

Add 2 drops of sulphuric acid to about 1 Cc. of an aqueous solution of acriflavine (1:250) and agitate the mixture. An orange-red, crystalline precipitate is produced. Under the microscope the crystals are seen to be mostly long needles or prisms arranged in sheaflike or brushlike forms.

An aqueous solution of acriflavine (1:250) gives a precipitate with silver nitrate solution (*distinction from proflavine*).

An aqueous solution of acriflavine (1:250) does not give a precipitate with barium chloride solution (*distinction from proflavine*).

An aqueous solution of acriflavine (1:250) does not give a precipitate with formaldehyde solution (*distinction from proflavine which gives a brown precipitate*).

Add 2 drops of diluted hydrochloric acid to 5 c.c. of an aqueous solution of acriflavine (1:250) and immediately add 2 drops of sodium nitrite solution (1:10). A violet color is produced. By the further addition of an excess of sodium nitrite solution, a violet precipitate is formed and, after a few minutes, the color of the solution becomes cherry red. This may be best observed after filtration (*distinction from proflavine, the filtrate from which is colorless*).

An aqueous solution of acriflavine (1:250) gives an orange precipitate with sodium hydroxide test solution (*distinction from proflavine, which gives a yellow precipitate*).

Inverenate about 1 Gm. of acriflavine, accurately weighed. The ash amounts to not more than 1 per cent.

Dissolve about 1 Gm. of acriflavine, accurately weighed, in 250 Cc. of warm water, collect the insoluble matter, if any, in a weighed Gooch crucible, wash the insoluble matter with hot water, dry and weigh the residue. The insoluble matter amounts to not more than 1 per cent.

Dry about 1 Gm. of acriflavine, accurately weighed, to constant weight at 100 C. The substance loses not more than 10 per cent. of its weight.

**Acriflavine (Boots).**—A brand of acriflavine complying with the N. N. R. standards for acriflavine.

Manufactured by Boots Pure Drug Co., Ltd., Nottingham, England (Hynson, Westcott & Dunning, Baltimore). No U. S. patent or trade mark.

**PROFLAVINE.**—3:6 diamino acridine sulphate = C<sub>13</sub>H<sub>9</sub>N<sub>2</sub>.H<sub>2</sub>SO<sub>4</sub>.H<sub>2</sub>O.

**Actions and Uses.**—See preceding general article, Acriflavine and Proflavine.

**Dosage.**—See preceding general article, Acriflavine and Proflavine.

Proflavine is a reddish-brown, odorless, crystalline powder.

Proflavine is soluble in water and in alcohol, forming brownish solutions which fluoresce on dilution. Nearly insoluble in ether, chloroform, liquid petrolatum, fixed oils and volatile oils.

An aqueous solution of proflavine is neutral to litmus paper (the solution dyes the litmus paper yellow).

Add a few drops of hydrochloric acid to an aqueous solution of proflavine which is sufficiently dilute to be fluorescent. The fluorescence disappears, but partially reappears on further dilution with water.

Add 2 drops of sulphuric acid to about 1 Cc. of an aqueous solution of proflavine (1:250), and agitate the mixture. A brown, crystalline precipitate is produced. Under the microscope the crystals are seen to be mostly prismatic needles.

An aqueous solution of proflavine (1:250) gives a precipitate with barium chloride solution (*distinction from acriflavine*).

An aqueous solution of proflavine (1:250) gives no precipitate with silver nitrate solution (*distinction from acriflavine*).

Add a few drops of formaldehyde solution to 5 c.c. of an aqueous solution of proflavine (1:250). A brown precipitate is given (*distinction from acriflavine, which remains clear*).

Add 2 drops of diluted hydrochloric acid to 5 c.c. of aqueous solution of proflavine (1:250), and immediately add 2 drops of sodium nitrite solution (1:10). A violet color is produced. On the further addition of sodium nitrite solution a brownish violet precipitate is formed and, after a few minutes, the color of the solution becomes cherry red. This may be best observed after filtration (*distinction from acriflavine, the filtrate from which becomes cherry red*).

An aqueous solution of proflavine (1:250) gives a brown yellow color with sodium hydroxide solution (*distinction from acriflavine which gives an orange precipitate*).

Inverenate about 1 Gm. of proflavine, accurately weighed. The ash amounts to not more than 1 per cent.

Dissolve about 1 Gm. of proflavine, accurately weighed, in 250 Cc. of warm water, collect the insoluble matter, if any, in a weighed Gooch crucible, wash the insoluble matter with hot water, dry and weigh the residue. The insoluble matter amounts to not more than 1 per cent.

Dry about 1 Gm. of proflavine, accurately weighed, to constant weight at 100 C. The substance loses not more than 10 per cent. of its weight.

**Proflavine (Boots).**—A brand of proflavine complying with the N. N. R. standards for proflavine.

Manufactured by Boots Pure Drug Co., Ltd., Nottingham, England (Hynson, Westcott & Dunning, Baltimore). No U. S. patent or trade mark.

1. The Chemical Preparation Tablets that a certain patent was granted for the manufacture of acriflavine and proflavine, and the inventor claims that the manufacture of a crystalline product in the manner described in this patent is one of the foregoing. H. W. D. 111,111. Dunning will discount the sale of this product after Dec. 1, 1919.

## DEATHS INCIDENT TO AVIATION

The shocking losses of human life that attended the recent cross-continent aeroplane flights bring the reminder that aviation has created new problems, not only for the physiologist concerned with life at high altitudes and bodily adjustments in unusual environments, but also for the clinician and pathologist who are expected to deal with abnormalities of behavior and function on the part of organisms subjected to the unusual exigencies of aviation. The art of flying is, furthermore, still attended with grave dangers from accidents which in turn occasion death under circumstances rarely duplicated during the usual course of other fatalities of every-day life. In this country the special features of accidental death during aviation have not yet been critically discussed, presumably because the subject is still so new. During the war, however, the deaths of aviators were so common that the statistics of the injuries which they received in action have assumed considerable proportions.

A fall from a great height such as is frequently attained by an aeroplane at the moment of catastrophe is in itself an unusual experience, involving forces that are potent with harm for the person concerned. Added sources of danger and bodily damage are presented by the simultaneously falling machine with its heavy, moving masses of wood and metal. To crushing factors are joined the possibilities of severe laceration by revolving propellers and of burns by ignited fuel or heated parts. It is not surprising, therefore, that the injuries are manifold, complex and severe.

Certain recurring features have been summarized by Jaffé and Sternberg.<sup>1</sup> Fractures of the bones are almost invariably observed, the skull rarely remaining uninjured. Ruptures and injuries to the internal organs of the abdomen are liable to occur even though the walls of the latter remain intact; for owing to the varying weights of these organs they are subject to unlike movements and strains during the fall of the body through the air, often with attending irregularities of descent. Ruptured lungs have been observed

and, together with the extreme intra-abdominal distortions just referred to, they illustrate types of traumatism not often encountered in the usual run of accidents on terra firma. Almost every variety of crushing and bruising may be noted, as might be expected. Surprisingly numerous, however, are the accounts of the rupture of the aorta in those killed through aeroplane accidents. How the rupture of this strong vessel is so readily brought about has been debated. Its elasticity might be expected to afford protection against sudden stress in the form of pressure from within. When, however, the blood pressure is enormously increased in the upper region of the aorta, just beyond the heart valves, owing to compression of the vessel at some point farther removed from the blood pump, the walls evidently may be burst open. This is particularly possible when stretching of the aorta lengthwise to the limit of its elasticity decreases its effective resistance to blood pressure. Inward compression of the bony structures of the thorax may furnish the occluding factor; whereas the stretching may follow the displacement of the heart from its normal position. In any event, rupture of the aorta, however produced, may probably be regarded as an exceptionally frequent necropsy finding as a result of that complex group of maiming forces conspiring to produce death in aerial accidents.

## THE COLOR OF THE IRIS DURING INFANCY

The fact that the eyes of infants are almost invariably deep blue during the earliest weeks of life was recorded centuries ago. Modern investigations have furnished a clue to the explanation of the color changes in the iris during early infancy. The blue color is alleged to be due to the paucity of pigment in the stroma of the iris. This tissue is still very thin in early life, so that the posterior layer of pigment in the eye is plainly apparent through it. With increasing age, the stroma thickens. If no further pigmentation takes place in it, the iris tends to manifest a light blue or a gray shade; but when pigment is deposited in the iris layers, this organ becomes brown. Even in negro infants the iris may be blue in early life.

The progress of the changes of color shows some uniformity when large numbers of infants are observed. Doubtless they vary for different localities and races, which are well known to exhibit characteristic eye colors that show a hereditary constancy. The blond complexion of the Scandinavians is associated with the light blue, or less pigmented, iris. In a group of persons examined in Munich, only 32 per cent. of the adults retained the blue iris. Among the children of these persons the rate of alteration in iris color varied considerably. In the first three months of life three quarters of them still retained the blue color; in six months it was still characteristic of 70 per cent. of the infants; at the ages of 9 months and 1 year the

<sup>1</sup> Jaffé, R. H. and Sternberg, H. Der Fliegertod: ein Beitrag zur Frage der traumatischen Aortenrupturen, *Vrtljschr. f. gerichtl. Med.* 58:74, 1919.

blue-eyed infant population represented 63 per cent. and 53 per cent., respectively. These data thus indicate the slow progressive pigmentation of the eyes leading to darker iris colors in the Bavarian groups examined.

Schindler<sup>1</sup> has called attention in this connection to observations made in Pfaunder's clinic at Munich on a possible correlation between the rate of pigmentation, with corresponding change in the color of the iris, and the nutrition of the infant. According to her, the iris of many malnourished young, particularly among those suffering from somewhat chronic disturbances of digestion or metabolism leading to atrophic manifestations, may exhibit a change of shade at an age when healthy infants as a rule still retain the blue color. The appearance has been described as a dirty gray shade, sometimes fusing into a brownish tint.

If the premature pigmentation of the iris in early infancy is, in fact, a symptom of severe metabolic disorder—a suggestion which further careful clinical observation should help to establish or refute—its cause becomes an immediate occasion for speculation. In the absence of further experimental investigations on the subject, the Munich pediatricians conjecture that the darker color of the iris of malnourished infants is due to a deposition of pigment arising from augmented disintegration of blood pigment. Hemosiderosis has been described in the liver and spleen of atrophic infants. By analogy, a deposition of pigment elsewhere might be expected. At best, however, this is theorizing, for it is not even known whether the pigment of the iris is actually derived from that of the blood.

---

#### THE RELATIONSHIP BETWEEN HERPES ZOSTER, SYPHILIS AND CHICKENPOX

The significance of herpes zoster is still a matter for speculation. While technically a disease of the skin, the condition is one that has always been of interest to the neurologist and to the general practitioner. Originally regarded as occurring along the distribution of peripheral nerves, it has been recognized, since the epoch-marking discoveries of Henry Head, as having a segmental distribution. Certain aspects of the disease, particularly its relationship to syphilis, have recently been discussed by Brown and Dujardin.<sup>2</sup> These observers noted that herpes zoster was distinctly more prevalent among a group of soldiers under observation for syphilis than it was among an unselected group of patients from the civilian population of the district. Among the syphilitics, zoster occurred in a proportion of four cases per thousand, while among

the general population the disease occurred only in the proportion of one case per thousand. It was noted, too, that in the syphilitics the herpes had a predilection for the lumbar and sacral ganglions corresponding to the well known observation that spinal syphilis is more likely to attack the lower segments. In connection with these cases of zoster, the authors studied the changes in the spinal fluid and found that there was frequently a lymphocytosis occasionally accompanied by an increase in globulin, and in the case of the syphilitics sometimes accompanied by a positive Wassermann reaction. The authors assume that zoster is an infectious process, and that syphilis acts simply by producing local conditions which predispose the ganglions of the spinal cord to infection with the agent producing the disease.

This paper raises several interesting points. It is pertinent to inquire whether zoster is really a disease per se or whether it is a syndrome which may result from any condition causing inflammation of the spinal ganglions. It is well known that syphilis is frequently latent in the spinal meninges without clinical manifestations of spinal disease. Is it not possible, then, that the unusual frequency of zoster among syphilitics is due simply to the frequency of inflammatory conditions of the spinal meninges in this disease?

There is, however, some evidence which suggests that zoster is a specific infection due to the virus that causes chickenpox. Scattered through the literature for a number of years are observations, such as those compiled by LeFeuvre and more recently those by Low, which indicate a curious relationship between zoster and chickenpox. Instances are recorded of one member of a family developing herpes zoster, to be followed later by the appearance of chickenpox in other members of the family. Instances of the opposite order, namely, the development of herpes zoster in a family after chickenpox, have also been recorded, and there are a few instances of herpes zoster and chickenpox in the same person. There are so many of these cases now on record that it would seem that there was here more than mere coincidence. Many observers are convinced, therefore, that herpes zoster is simply an atypical manifestation of the chickenpox virus.

Interesting though these observations are, they do not seem to warrant the conclusion that herpes zoster is invariably an evidence of infection with the chickenpox virus. Chickenpox is a disease that is usually so insignificant and so lacking in symptoms suggesting involvement of the central nervous system that it is doubtful whether anybody has investigated the spinal fluid in a large number of cases. It is quite possible that investigation may prove that a low grade spinal meningitis is a common accompaniment of chickenpox just as it is of the large pox. A careful study of the cerebrospinal fluid in this disease, as well as a more thoroughgoing investigation of the spinal fluid in all

2. Brown and Dujardin: *Brain*, **42**, Part 1, 1919.

cases of herpes zoster, might reveal illuminating information on this point. Incidentally, it is difficult to see how Brown and Dujardin could be sure that the spinal lymphocytosis in their cases was not due to the underlying syphilis rather than the zoster.

#### THE COMPOSITION OF THE BLOOD IN SUNLIGHT AND DARKNESS

The belief that sunlight is indispensable to human welfare has become strongly entrenched in modern hygienic propaganda. The scientific study of the possible basis for such views has lagged far behind the claims that have been advanced for the beneficent effects of light. Fresh air and sunshine are advocated the world over as desiderata in the campaign against disease; yet those who proclaim their virtues might often find it difficult to explain precisely how these climatic factors affect the human organism. Bacteriology has demonstrated the action of light in destroying various micro-organisms. In specific cases the effects of light rays of different sorts on the skin and the functions of the body as a whole are admitted; but at best the phenomena of heliotherapy are inadequately understood, and the influence of light is far from being clearly demonstrated in relation to the ordinary physiologic manifestations.

The marked contrast between the pale complexions of most urban residents and the more ruddy color of the rural population has doubtless given rise to the assumption, once somewhat prevalent, that the relative exposure to light in city and country, respectively, is responsible not only for differences in the pigmentation of the skin, but perhaps also for the composition of the blood. Statements have been published to the effect that the long months of darkness during the absence of sunlight in the polar regions are productive of a pallor that might be charged to anemia. Actual reports regarding the health of members of various polar expeditions seem to negative this explanation. Blessing, who acted as physician during Nansen's expedition on the *Fram*, made blood examinations from time to time and testifies to an absence of anemia in the persons examined by him.<sup>1</sup>

An interesting test of the possible effects of prolonged lack of sunlight on the composition of the blood was made just prior to the war by Grober and Semjoff in Jena. They examined a considerable number of horses in use in the coal mines. Many of these animals had been kept at work for years in the absence of sunlight below the surface. Anemia was not discovered in any case in which a satisfactory nutritive condition existed. It is therefore improbable that

sunlight is in any sense directly concerned with the hematopoietic functions. At any rate, if it is, compensatory processes render the lack of sunlight negligible so far as the number of red corpuscles and their content of hemoglobin is concerned.

#### THE BODY TISSUES IN INDICANEMIA

The occurrence of indicanuria and its relation to putrefactive changes in the alimentary tract are well known. At one time there was considerable speculation in scientific circles regarding the origin of indican, some investigators being inclined to ascribe a part of the excreted product to abnormal changes in the tissues. The preponderance of evidence, however, points to indol, formed by bacterial decomposition of protein in the intestine, as the chief, if not the exclusive, precursor of urinary indican. The output of the latter appears to depend quite as much on the quantity and chemical character of the protein components of the diet as on the opportunities for bacterial changes in the alimentary tract.

One of the significant features of insufficiency of kidney function is the accumulation of catabolites in the blood. For example, the content of urea, uric acid and creatinin may be markedly augmented in the circulating medium of the body when the production of urine is interfered with through some damage to the renal tissues. Under such conditions, indican likewise may accumulate in the blood, instead of being excreted promptly. Indicanemia thus becomes one of the symptoms of uremia, although there is no conclusive indication that it represents a toxic factor.<sup>1</sup> From the standpoint of harmful dosage, the toxicity of the quantities of indican and its precursors that are formed and circulated is apparently too slight to account for any untoward manifestations. The consensus of evidence leads one to doubt the production of noticeable intoxication from either indol or indican under ordinary conditions.<sup>2</sup>

In the case of various excretory products and notably urea, it is now well known that they accumulate in the tissues proper in a concentration quite comparable to that which they reach in the blood whenever the renal functions are inadequate to remove them in normal measure from the body. Whether this bathing of the cells with solutions unduly rich in catabolites is a cause of irritation or damage cannot be definitely stated. Experiments by Becher<sup>3</sup> in the medical clinic at Giessen have shown that indican is an exception in contrast with the compounds familiarly classed under the nonprotein nitrogenous components of the blood. Even under conditions exhibiting severe indicanemia,

3. Becher, E.: *Ueber Indikanretention in den Geweben*, *Deutsch. Arch. f. klin. Med.*, 129: 8 (April) 1919.

indican is recoverable in very small quantities, if any, from the tissues. Indican is not found in the spinal fluid even during intense indicanemia.<sup>4</sup> Whatever the significance of indican may be in the genesis of harmful conditions in the body, it cannot be regarded as a direct cause of local detriment in the body tissues.

### Current Comment

#### THE MENACE OF THE PLAGUE

We are reminded by two recent events in widely separated parts of the United States what a serious menace is held over us by the smoldering of the plague in various places. October 29, while the American Public Health Association was meeting in New Orleans, a death from plague occurred in that city, and more cases have been reported since. This was the first human case reported in that city for several years, and plague-infected rats have not been found for some time. A still more ominous occurrence is the recent epidemic of plague in Oakland, Calif. The first case appeared, August 18, in a squirrel hunter, and was followed by thirteen cases of the pneumonic type, twelve of them fatal. Three of the patients, including the original squirrel hunter, were treated at home throughout their illness, with no precautions. The others in whom the identity of the infection was recognized were either hospitalized or completely isolated. The last death in this epidemic occurred on September 11, since which time no further cases have developed. It is inevitable that a certain sense of insecurity will be caused by these events, and that redoubled effort will be made to minimize the danger of squirrel plague infection. The Oakland epidemic suggests the unpleasant possibility of a more widespread outbreak of pneumonic plague where climatic conditions are favorable. It does not seem to be outside the range of possibilities that sooner or later the plague may win a foothold among the rats in the slums of some of our large Northern cities. If this happens, human pneumonic plague must evidently be looked on as a possible sequel.

#### THE ALLEGED FOOD VALUE OF SACCHARIN

Not long ago attention was directed in THE JOURNAL<sup>5</sup> to the subject of physiologic oxidation and its alleged relation to certain catalytic properties of the tissues. The latter, and particularly the blood, are capable of liberating oxygen from hydrogen peroxid by an enzyme-like reaction which has been ascribed to "catalase." It has been assumed by a few investigators, notably Burge, that a measure of this catalytic power of the tissues is an index of their metabolic activity. We need not reiterate here the criticisms of this view<sup>7</sup> which have already been advanced, notably by Becht.<sup>8</sup> He remarks that since the catalytic power of the blood

varies between enormously wide limits under the same conditions, it is unlikely that the catalases are important and that the measurement of them can explain "the mysteries of the processes of oxidation." One of the factors particularly advanced by Burge in support of his theory was the asserted increase in catalase noted as the accompaniment of features known to promote metabolism. Stehle<sup>7</sup> has repeated the studies at the University of Pennsylvania School of Medicine without finding the parallelism on which the catalase theory of metabolism is based. He observed that the fluctuations in the catalase content of the blood are due to variations in the number of red cells. Consequently, Stehle notes, it is simpler to regard the catalase content as dependent on the number of erythrocytes than to assume any direct relation between catalase and biologic oxidations. Among other compounds, Burge has ascribed to saccharin the property of increasing the catalase content of the blood.<sup>9</sup> Correlating this with an increase in metabolism, he concluded that saccharin exhibits advantages characteristic of foods that are known to augment metabolism. Despite the fact that the doses used by Burge in his experiments amounted to 5 gm. per kilogram of body weight and thus far exceeded any dietetically significant quantities, his seeming approval of the effect of these enormous doses of saccharin was promptly made use of by certain advertisers to promote the use of this chemical substance in the diet. Stehle<sup>7</sup> has disposed of the assumed basis for this undesirable propaganda by what amounts essentially to a denial of the claims made. The advocacy of saccharin as a food can no longer pose in the garb of scientific proof.

#### EXPERIMENTAL PARATYPHOID AND TYPHOID FEVERS

In view of the fact that paratyphoid and typhoid fevers have not been produced in animals experimentally by feeding, except in the chimpanzee, certain recent work by Besredka<sup>9</sup> is of considerable interest. He has found that when paratyphoid bacilli are introduced by mouth in the rabbit, they may be recovered in greater or less numbers in the pyloric part of the stomach, but the gastro-intestinal mucosa offers a definite barrier to their localization and dissemination in the organism. Massive doses of bacilli may be given by mouth with very little effect on the animal. In an attempt to overcome this resistance, ox bile was given by mouth, and then feeding of bacilli produced intestinal lesions corresponding exactly to those produced by feeding in the chimpanzee. The bile thus administered has not only a direct effect on the mucosa but also stimulates the secretion of bile, which causes an intense desquamation of intestinal epithelium, and this in turn opens an entrance for paratyphoid bacilli when introduced a little later. An animal treated in this manner develops recognizable symptoms of disease in from one to four days; diarrhea comes on and becomes

7. Stehle, R. L.: Some Data Concerning the Alleged Relation of Catalase for Animal Oxidations, J. Biol. Chem., 33: 163 (Sept.) 1919.

8. Burge, W. E.: Saccharin for Sugar, Science, New York, 48: 543, 1918.

9. Besredka: Ann. de l'Inst. Pasteur 33: 57, 1919.

progressively worse; there is rapid loss of weight; the temperature falls, and the animal usually dies within two or three days. After death, the changes in the intestine and gallbladder are found to be quite typical of paratyphoid infection. When the disease is not of long duration, pure cultures of the bacilli are obtained from the blood and bile. The stomach contents are sterile, but there is an abundance of bacilli in the intestinal contents. When paratyphoid bacilli are introduced intravenously in a rabbit, a generalized infection occurs, and the animal may die very quickly of septicemia or it may live for some time. In the latter case only a few colonies may develop in cultures of the blood, but bacilli may be present in large numbers in the bile and intestinal contents, and macroscopically the lesions are typical of paratyphoid infection. Besredka obtained corresponding results from feeding when typhoid bacilli were used in the experiments. In view of the ease with which bile renders the rabbit susceptible to typhoid and paratyphoid infections, the natural immunity of this animal to these infections seems to be largely of intestinal origin. Experimentally it seems possible to cause both paratyphoid and typhoid infection either by introducing the bacilli by the mouth in rabbits to which bile has been previously given or in some cases by intravenous injection of bacilli in rabbits without any preliminary treatment.

#### POLITICS PLAYS WITH PUBLIC HEALTH

The dictum of Disraeli that the care of the public health is of primary importance to the state seems frequently to have been taken by the politician to mean that positions in the public health department are primarily for his disposal. Newspapers coming from Hawaii indicate that the game has been played in that territory with all the old angles. About a year ago a new governor was appointed. At the time of his appointment the executive head of the public health department was a man who had been in public health work in Hawaii for some twenty-five years. During the time of his incumbency an organization was established that prominent public health authorities regarded as probably equal to any health department in the United States and better than the majority. The new governor removed the incumbent and appointed as head a business man—to be specific, a salesman of automobiles. According to the newspapers, the qualifications of the new health official soon were taxed to the utmost and he found himself somewhat in the position of a driver who holds the wheel of a car after the steering knuckle has broken. In an attempt to get out from under he involved himself with a local health officer, and according to the Honolulu papers the governor is now looking for a new head for the health department. One of the requirements is that he shall not be a business man—a knowledge of automobiles will not be considered necessary.

**Human Credulity.**—There is something in humanity that always leaps up and believes again at the bidding of spells and charms and incantations; and this is a true instinct, for the incantation is an attempt to sing in tune with the vaster rhythms and the tidal moods of the creating universe.—D. Marquis.

## Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

### ALABAMA

**Hospital Buys Land.**—The Alabama-Bryce Hospital, Tuscaloosa, has purchased 87 acres of land on the Huntsville Road, 3 miles from the city, for \$212 an acre. The land was needed as a location for the new institution for the feeble-minded of Alabama, for which the legislature has authorized the expenditure of \$250,000.

**Personal.**—Dr. Frank W. McCorkle, Uniontown, has been appointed assistant health officer of Huntsville and Madison counties.—Dr. Percy O. Claudron, Dothan, has been discharged as lieutenant-colonel, M. C., U. S. Army, and will resume practice.—Dr. Henry B. Wilkinsen, health officer of Montgomery and Montgomery County, has resigned and will resume practice in Montgomery.

### CALIFORNIA

**Personal.**—As the result of a competitive examination, Dr. Neal Naramore Wood, Lieut.-Col., M. C., U. S. Army, has been made first assistant superintendent of charities and medical director for the department of charities of the Los Angeles County Hospital, succeeding Dr. J. Mark Lacy, Los Angeles, who has resigned to enter private practice.

**Sanatorium at San Diego.**—Plans for the establishment of a large sanatorium at Alpine are well under way. The sanatorium will, it is announced, be the largest in southern California, and will include the Los Robles Hotel and 280 acres of ground facing the state highway. The institution will be under the medical direction of Dr. Hyman Lischner, San Diego, at present head of the Lischner Sanitarium for Children.

### COLORADO

**Graduate Teaching Arranged by State Association.**—The Colorado State Medical Society has announced that a course of graduate teaching is being arranged for county societies which desire it. About fifty members of the state association will probably be apportioned into groups of four. Each team will lecture to different county societies each two weeks for six consecutive months. These talks will be made by practitioners of medicine to physicians in active practice, and it is promised that the lectures will be made intensely useful in daily work.

### DISTRICT OF COLUMBIA

**Monument to General Sternberg Unveiled.**—A monument erected in memory of Surg.-Gen. George Miller Sternberg, at the National Cemetery, was unveiled, November 5, and remarks were made by Surg.-Gen. Merritte W. Ireland, U. S. Army, Brig.-Gen. Walter D. McCaw, Col. Edward L. Munson, and Col. Frederick F. Russell, Army Medical Corps, and Dr. George M. Kober, Washington, D. C.

### ILLINOIS

**Canton Physicians Organize.**—At the meeting of the physicians of Canton, October 9, the Canton Physicians' Club was reorganized, with Dr. Harvey H. Rogers, president, Dr. Charles N. Allison, vice president, and Dr. Everett P. Coleman, secretary.

**Health Report.**—During the week ended October 20, there were reported to the state department of health 306 cases of diphtheria of which Chicago had 188; 79 cases of influenza of which 16 were in Hannah City; 213 of scarlet fever, of which 30 were in Chicago; 35 cases of smallpox, of which 11 were in Roodhouse, and 12 in Crook Township, Hamilton County, and 33 cases of typhoid fever, and 7 cases of poliomyelitis.—An outbreak of typhoid fever is reported in Wood River Township, near East Alton, and Dr. Samuel S. Wimmer, Chicago, has been sent to take charge of the situation.

### Chicago

**Hahnemann Home-Coming Day.**—November 4 was celebrated as home-coming day for the Hahnemann Medical College and Hospital of Chicago. In the evening an informal

reception and dinner was given in honor of the newly elected president of the Hahnemann institution, Prof. Daniel Russell Hodgdon, and of Mrs. Hodgdon.

**English Surgeons in Chicago.**—Major-Gen. Sir Anthony Bowlby and Major-Gen. Sir Robert Jones, R. A. M. C., were in Chicago, November 1 and 2, and addressed a joint meeting of the Chicago Surgical Society and Chicago Orthopedic Society and were entertained by the members of these societies at dinner at the University Club.

**Personal.**—Dr. Anthony Bivankini was tendered a farewell dinner by the Czecho-Slovak citizens of Chicago, October 28. He left for Europe the following day.—Dr. Peter C. Clemensen has resigned as a member of the board of education.—Dr. George G. Davis has been appointed chief surgeon of the Illinois Steel Company, succeeding Dr. James Barry, deceased.

**Gynecologists Elect Officers.**—At the annual meeting of the Chicago Gynecological Society, held October 17, the following officers were elected: president, Dr. Arthur H. Curtis; vice presidents, Drs. Henry F. Lewis and Philip S. Doane; secretary, Dr. Joseph L. Baer; treasurer, Dr. Charles B. Reed; editor, W. C. Danforth, and pathologist, Dr. Carey Culbertson. The attention of the members of the profession was called to the fact that there is an annual prize of \$100 offered to the best inaugural thesis of the year, the subject matter representing original research or investigation. The active membership of the society is limited to fifty and there are at present twelve vacancies.

**Hospital Items.**—In the drive for \$250,000 to erect a new building for the Evangelical Deaconess Hospital, \$72,000 was received.—It is proposed to erect a new building for the Ravenswood Hospital at a cost of \$900,000, utilizing the old building for a training school and nurses' home. The new building will be on the southeast corner of Wilson and Winchester Avenues, 207 by 41 feet and seven stories and basement in height.—Announcement is made that the Lutherans of Chicago plan to build a hospital in the neighborhood of Humboldt Park, at a cost of \$350,000.—Members of the Gold Star Mothers' Association have subscribed several hundred dollars toward a bed in the new Paris-Chicago Hospital.

## INDIANA

**Personal.**—Dr. Edmund M. Van Buskirk, Fort Wayne, has been appointed assistant collaterater epidemiologist, and will cooperate with the United States Public Health Service and the state in fighting epidemics.—Dr. George F. Beasley, Lafayette, is reported to be seriously ill with pneumonia.

**Hoosier Health Herald.**—The first issue of this magazine, edited by E. Q. Laudeman, and published in Rochester, appeared, September 22. All of the articles pertain to tuberculosis and its prevention. The leading article is contributed by Dr. John N. Hurty, Indianapolis, secretary of the state board of health.

**Nurses' Home.**—The Methodist Hospital, Indianapolis, is to have a new home for nurses to cost \$300,000. The building will be in brick and stone, similar in design to the main building, will be five stories in height, and will have a frontage of 176 feet in Capital Avenue and a depth of 158 feet. The home will be completed next year.

**Resignation Accepted.**—At a dinner given by the Tippecanoe County Medical Society at Lafayette, September 23, the resignation from membership of Dr. Charles J. Brockway was unanimously accepted. It was also stated that Dr. Brockway's resignation from the staff of the Home Hospital and St. Elizabeth's Hospital, has been accepted by unanimous consent.

**New District Officers.**—At the annual meeting of the Eighth District Medical Society, held in Muncie, October 16, under the presidency of Dr. Leonard F. Schmauss, Alexandria, the following officers were elected: president, Dr. Milton T. Jay, Portland; vice president, Dr. Charles L. Botkin, Farmland, and secretary-treasurer, Dr. Clay A. Ball, Muncie.—At the annual meeting of the Eleventh Council District Medical Association, held in Wabash, October 16, Dr. Maurice H. Krebs, Huntington, was reelected president, and Dr. John H. Reed, Logansport, was reelected secretary and treasurer. The next meeting will be held in Peru.—The Union District Medical Association held its 104th semiannual meeting in Richmond, October 23. Connersville was selected as the place for the April meeting. Dr. Joseph N. Study, Cambridge City, was elected president, and Dr. James E. King, Richmond, secretary-treasurer.

## IOWA

**Smallpox in Lost Nation.**—It is reported that all schools and churches have been closed and all public gatherings prohibited at Lost Nation, where ten families have been quarantined.

**Southeastern Physicians Meet.**—The Southeastern Iowa Medical Society held its annual meeting at Washington, October 16. Dr. Edward T. Edgerly, Ottumwa, was elected president; Dr. Henry C. Hull, Washington, vice president, and Dr. E. Francis La Force, Burlington, secretary-treasurer.

**Personal.**—Drs. William H. Heller, Remsen, and James M. Fettes, Lemars, have been added to the staff of the Lemars Clinic.—Dr. Harley L. Saylor, Des Moines, reappointed as health commissioner, resumed his duties, October 1.—The meeting of the Jackson County Medical Society, September 19, was devoted to an appreciation of Dr. Asa B. Bowen, Maquoketa, who has practiced medicine in Jackson County for half a century.

## KENTUCKY

**Vital Statistics Registrar Moves.**—Dr. W. Edward Grant, registrar of vital statistics, has moved his office from the City Hall, Louisville, to the headquarters of the state board of health at Sixth and Main streets.

**Personal.**—Ellis Duncan, Lieut.-Col., M. C. U. S. Army, one of the first Louisville surgeons to enter war service, was discharged at Camp Zachary Taylor, September 30.—Dr. Tilden H. Singleton, Bowling Green, was operated on for appendicitis, October 14, at St. Thomas Hospital, Nashville, Tenn.

**Negro Antituberculosis Sanatorium.**—Articles of incorporation were filed, October 10, at Louisville, by the National Anti-Tubercular Sanatorium for Colored People, the object being to establish a sanatorium for treatment of negroes where climatic conditions are best suited. The corporation has no capital stock and is authorized to incur liabilities not to exceed \$20,000. The promoters are: Dr. William H. Perry, A. E. Meyezek, G. M. McClellan and W. H. Wright.

**Clinic Holding Company Incorporates.**—The Clinic Holding Company, composed of physicians associated with Dr. David Barrow, Lexington, filed articles of incorporation with the Fayette County clerk, recently. The corporation is capitalized at \$100,000 and is empowered to own real estate and personal property for the purpose of holding clinics and to carry on general practice.

**Praise Physicians for War Service.**—October 5, 180 physicians who served in the war were the guests of honor at a banquet given by the medical profession of Louisville at the Pendennis Club. Dr. Isadore N. Bloom, Louisville, officiated as toastmaster and responses were made by Major-Gen. Charles P. Summerall, commanding the First Division, Hon. Alexander P. Humphrey, E. R. Mullins and Hon. Albert Peter. A smoker was given, September 15, by the Jefferson County Medical Society at Louisville for 200 of its members who had been either with the American Expeditionary Forces in France or had in other ways given their services to the country during the world war. The address of welcome was made by Dr. Lewis S. McMurry.

## LOUISIANA

**Bubonic Plague.**—Up to November 3, four cases of bubonic plague were said to have been reported in New Orleans, with two deaths.

**Extension of Drug Addict Work.**—Extension of the clinic of the state board of health for the cure of drug addicts over the whole state is being considered by Dr. Merrick W. Swords, New Orleans, secretary of the board.

**Physician Pardoned.**—E. D. Roberts, Baton Rouge, convicted of attempted assault four years ago, has been pardoned by the governor, on recommendation of the board of pardons. During the influenza epidemic Dr. Roberts did excellent work among the convicts.

**Personal.**—Dr. Benjamin A. Ledbetter, New Orleans, fell into an open elevator shaft at the Charity Hospital, October 13, fracturing three ribs and sustaining other severe injuries.—Dr. Isadore Dyer, dean of the School of Medicine of Tulane University, New Orleans, has been appointed colonel on the staff of the Surgeon-General.—Dr. Edmund Moss, chief medical inspector of the public schools of New Orleans, has returned after serving in the Army.—Dr. James A. Henderson, chief surgeon of the Louisiana Naval Militia,

New Orleans, at the outbreak of the war, has been promoted to commander, M. C. U. S. Navy.

**Smallpox in Louisiana.**—The Louisiana records of deaths for the first six months of 1919 show 147 deaths from smallpox. Eighty-one of these deaths occurred in three of the southwestern parishes, two of which border on Texas. The fourth parish, in which there occurred twenty-five deaths, is among the south central parishes. One hundred and six of the 147, therefore, occurred in four parishes. The records of the bureau of epidemiology show 988 cases reported. One hundred and fifty-three physicians reported from forty-seven parishes. It is reported that smallpox was introduced into Calcasieu and Lake out simultaneously in December, 1918, in two places in Lake Charles, one the jail, and at West Lake, practically a suburb of Lake Charles. It is stated by the health officer of Calcasieu that all three cases came from Braunton, Texas. Unofficially it was reported to the board that the smallpox was spread to southwestern Louisiana from a child brought by a negro woman in her arms from a point in Texas to a Louisiana town. The type of smallpox is that which is characterized as "Mexican." It was diagnosed as ebullient and hemorrhagic. During the outbreak in Calcasieu, in January, 1919, vaccine was very hard to obtain.

### MAINE

**Hospital Incorporated.**—The hospital founded by the late Harrison B. Webster, Major, M. C. U. S. Army, at Castine, has been incorporated and will be known as the Castine General Hospital. The institution will be supported by an appropriation from the state and from private funds as well as from its own earnings. Dr. Harold S. Babcock is director of the institution.

**Anti-tuberculosis Association Elects Officers.**—At the annual meeting of the Maine Anti-Tuberculosis Association, held in Portland, September 25, Dr. Elmer D. Merrill, Foxcroft, was elected president; Dr. Sylvester J. Beach, Augusta, vice president, and Drs. Frederick C. Thayer, Waterville; Nelson E. Nichols, Portland; Theodore E. Hardy, Waterville, and Edwin W. Gehring, Portland, directors.

### MISSOURI

**Veneral Clinic at St. Joseph.**—At a meeting of the city council of St. Joseph, October 13, \$5,000 was appropriated for the establishment of a venereal disease clinic. Other persons interested will guarantee the remaining \$5,000 which will be required to conduct the clinic until the end of the fiscal year.

**Clinic to Be Opened Twelve Hours.**—The free clinic for the treatment of venereal disease which opened in Kansas City, October 16, will be open from 9 in the morning until 9 at night. The extension of these hours has been arranged so that people who work during the day may obtain the benefit of the treatment. Dr. Edward H. Clark is in charge of the clinic.

**Former Service Men to Meet.**—The temporary association of former medical service men of southwest Missouri will meet in Joplin, November 11, when a permanent organization will be effected. The territory includes twenty-eight counties of southwestern Missouri and in this territory there are about 75 physicians who served during the world war. Dr. William A. Delzell, Springfield, is temporary president of the organization.

**Chiropractors Licensed.**—The bill passed at the last session of the legislature to license chiropractors went into effect, October 1. All chiropractors will be required to obtain a license from the state board of health. Those who have practiced more than one year may obtain the license on the payment of the fee of \$25, while those who have practiced less than a year will be required to pass an examination. The law defines chiropraxy as follows: "The treatment by force or reward of abnormal nails, superficial excrescences of the skin not involving the subdermal tissues occurring in the feet, including corns, warts, callosities and bunions, but not including the treatment of injuries to or congenital or acquired deformities of the feet or conditions requiring the use of anesthetics or incisions involving the structure below the level of the true skin."

### NEW YORK

**Personal.**—Dr. William G. Bissell, Buffalo, director of laboratories in the Buffalo Health Department, has been reappointed president of the state board of medical examiners, and Dr. Aaron E. Miller, Syracuse, vice president. —Harold W. Lyall, Ph.D., formerly with the New York

State Research and Antitoxin Laboratory, Otisville, has been appointed bacteriologist in the division of laboratories and research of the New York Department of Health, Albany.

**Typhoid at Tonawanda.**—About 200 cases of typhoid fever have occurred at Tonawanda, coincidental with the lowering of the intake of the public water supply system. Extended investigation made by the division of communicable diseases and the engineering division in an effort to aid the city authorities in the suppression of the epidemic and the improvement of water supply conditions, disclosed that a break had occurred in the intake pipe, allowing contaminated Niagara river water to enter the mains.

**District Society Meeting.**—At the recent meeting of the Seventh District Branch of the Medical Society of the State of New York, held in Rochester, October 2, Dr. Owen E. Jones, Rochester, was elected president; Dr. I. Harris Levy, Syracuse, vice president; Dr. George K. Collier, Sonyea, secretary, and Dr. Alfred W. Armstrong, Canandaigua, treasurer.—At the annual meeting of Fifth District Branch of the Medical Society of the State of New York, held in Rome, October 3, Dr. William D. Aveyer, Syracuse, was elected president; Dr. Charles Berntsen, Rome, vice president, and Dr. George W. Miles, Oneida, secretary-treasurer.

### New York City

**Habit-Forming Drugs Found.** A package wrapped in newspaper found accidentally near Fort Lee, contained \$35,000 worth of habit-forming drugs, including heroin and codain.

**Academy Anniversary.**—The anniversary discourse was delivered at the New York Academy of Medicine, November 6, by Rev. Charles Oubrey Eaton, D.D., on "New Men for a New Age."

**Harvey Society Lectures.**—The third lecture of the Harvey Society series by Dr. Alonzo F. Taylor of the University of Pennsylvania, on "The Food Supply of Europe During the Coming Year," will be delivered, November 15, at 8:30.

**Acquitted of Furnishing Drugs to Addicts.**—Dr. Louis A. Falk and Julius Nelson, a druggist, have been acquitted in the Federal District Court of charges of violating the Harrison Narcotic Law by furnishing opium and other drugs to addicts.

**Red Cross Opens Health Flat.**—The New York branch of the American Red Cross has opened a "health flat" at 418 West Twenty-Ninth Street, where women of the Chelsea district, chiefly wives of dockmen and factory operatives, will receive instruction in home nursing and a general course in cooking. The school is a part of the peace program of the organization.

**New Society for Relief of Soldiers and Sailors of the Allies** has been incorporated in this state. The objects of the organization, as set forth in the petition, are: to raise and receive moneys, funds, securities and other properties by voluntary contribution and disburse the same for the relief of soldiers and sailors of the United States and of the nations associated with it in the war, who have been blinded in the war or as a result thereof. Sir Arthur Pearson is one of the patrons of the newly incorporated society.

**Health Department Assists in Diagnosis of Meningitis.**—A recent *Weekly Bulletin* of the New York City Health Department calls the attention of the physicians of New York City to the fact that the meningitis division of the health department is prepared to send one of its members to consult with them on cases of suspected meningitis or other meningeal involvement. Cases are not seen without the physician in charge being in attendance. Lumbar puncture will be performed if it is advisable, and serum will be administered if it is indicated. Physicians are urged to take advantage of this aid.

### PENNSYLVANIA

**Personal.**—Dr. Thompson McD. Baird, Tunkhannock, has been commissioned lieutenant-colonel, M. R. C., U. S. Army. —Dr. T. Lyle Hazlett, Pittsburgh, has been appointed medical director at the Mont Alto Sanatorium, succeeding Dr. Frederick C. Johnson, who has been granted leave of absence.

### Philadelphia

**Convict Osteopath.**—Prosecuted by the state board of medical education and licensure, Phillip Sheridan Daily, an osteopath, is said to have been convicted before Judge Martin in Quarter Sessions Court No. 2, October 30, on a charge of prescribing medicine without a license.

**Weir Mitchell Oration.**—The Weir Mitchell oration will be delivered by Dr. Charles W. Burr at the College of Physicians of Philadelphia, November 19, at 8:30 p. m. The subject of the oration will be "Dr. S. Weir Mitchell as a Physician, a Man of Science, a Man of Affairs, and a Man of Letters."

**Meeting of College of Physicians.**—At the stated meeting of the College of Physicians in Philadelphia, November 5, Dr. Francis X. Dercum read a memoir on the late Dr. Henry, and presented the college with a portrait of Dr. Frederick P. Henry in behalf of his family. The scientific papers of the meeting were by Major D. H. Gillies, R. A. M. C., surgeon in chief of the Queens Hospital for Facial Reconstruction at Sidcup, England, on "Plastic Operations on the Nose and Eyelid," and by James B. Wennell, civilian medical officer in charge of the massage department, Military Orthopedic Hospital, Shepherd's Bush, London, on "The After-Treatment of Fractures by Massage."

**Uniform Administration of Laws on Mental Diseases.**—Plans for a wider and more uniform administration of the law relating to mental hygiene were formulated at the first fall meeting of the mental hygiene committee of the Public Charities Association, October 29. The aim is to combat scientifically the future spread of mental diseases in Pennsylvania. The program contemplates the management of institutions for the treatment of the insane and epileptics, together with other classes of mental deficiencies under the control of a single board. The strict enforcement of the Lanus bill, passed at the recent session of the legislature, for regulating conditions relating to mental hygiene, is urged. Establishment of psychopathic hospitals and the broadening of their scope of usefulness through the employment of the vast knowledge on the subject gained as a result of the treatment of mental diseases during the war, also is planned. Dr. Owen Kopp of the Pennsylvania Hospital for the Insane was chosen chairman of the mental hygiene committee. Addresses were made by Dr. E. Stanley Abbott who has accepted the post of medical adviser of the committee, Dr. Theodore Diller, Pittsburgh, and Dr. Thomas W. Salmon, New York City.

#### TENNESSEE

**Sanatorium Burns.**—Fire originated in the negro male ward in the Memphis Tuberculosis Sanatorium, October 17, consuming the white and negro male wards and damaging other portions of the building. All inmates were removed from the structure without casualty.

**Personal.**—Dr. Eugene A. Gilbert, St. Elmo, has been appointed associate director of health for the city of Chattanooga, and Dr. Edward B. Wise, city physician and director of the municipal clinic.—Dr. William W. Core, superintendent of the Davidson County Hospital, Nashville, underwent an operation at St. Thomas Hospital, recently, and is reported to be doing well.

**Hospital Items.**—A hospital drive was initiated at Memphis, October 13, to obtain \$350,000 for the Tri-State Non-Sectarian Jewish Hospital. Only Jewish residents of Tennessee, Arkansas, and Mississippi are being solicited, but voluntary subscriptions will be welcome.—A hospital properly equipped for the employment of first aid and the performance of minor operations has been installed at the plant of the Harvey Steel Products Company, Jackson, under the charge of Dr. Stanford M. Herron, who has a trained nurse to assist him.—The U. S. Public Health Service announced, October 7, that pending improvements to enlarge the facilities of the hospital and to install additional beds, the Marine Hospital at Memphis will be closed.

#### TEXAS

**Surgeons Elect Officers.**—At the semiannual convention of the Texas Surgical Association, held in Temple, October 13 and 14, San Antonio was selected as the next place of meeting. Dr. Frank Paschal, San Antonio, was elected president, and Dr. Frank L. Barnes, Houston, was elected secretary.

**Rural Health Drive Organized.**—The counties of Tarrant, Wichita, Bell, Williamson and Jackson have organized for a health drive to begin January 1. The state and international health boards will give \$5,000 to each of the counties, and each will be expected to furnish a similar amount. The work will be under the charge of a whole-time county health officer with the necessary assistants.

**District Society Meeting.**—At the forty-sixth annual meeting of the South Texas District Medical Association held

in Galveston, October 9 and 10, the following officers were elected: president, Dr. William B. Thorning, Houston; vice president, Dr. Moses Thompson, Beaumont, and secretary, Dr. Jared E. Clarke, Jr., Houston. The next meeting of the association will be held in April, 1920, at Beaumont.

**Personal.**—Dr. Clute E. Rayburn, Waco, who served overseas during the World War, has been commissioned Major, M. R. C., U. S. Army.—Dr. Ira C. Garst has been appointed a member of the staff of the bureau of rural sanitation of the state board of health. Dr. H. L. Capps has been appointed county director in the same bureau and has been assigned to duty at Beaumont where he will have charge of the rural sanitation of Jefferson County.—Dr. Alexander P. Harrison, Austin, has been appointed director of the bureau of rural sanitation of the state board of health, succeeding Dr. Platt W. Covington, Austin, who has been transferred to Kentucky.—Miss Elizabeth Murford has been appointed assistant city pathologist of Houston, succeeding Dr. L. R. Hilliar, resigned.—Dr. L. E. Parker, Laredo, has been appointed state registrar of vital statistics with headquarters at Austin.

#### VERMONT

**State Association Meeting.**—At the annual meeting of the Vermont State Medical Society, held in Burlington, October 9 and 10, the following officers were elected: president, Dr. Michael F. McGuire, Montpelier; vice president, Dr. Alan Davidson, St. Albans; secretary, Dr. William G. Ricker, St. Johnsbury; treasurer, Dr. David Marvin, Essex Junction; councilors, first district, Dr. James N. Jenné, Burlington, second district, Dr. Schuyler W. Hammond, Rutland, third district, Dr. Frank E. Farmer, St. Johnsbury, fourth district, Dr. Alanson C. Bailey, Randolph; anniversary chairman, Dr. Charles A. Cramton, St. Johnsbury, and delegate to the American Medical Association, Dr. Frederick T. Kidder, Woodstock.

**Program of Tuberculosis Association.**—The Vermont Tuberculosis Association has announced an ambitious program for 1920. It is proposed to place a public health nurse in each of the ten health districts of the state, to open and equip a number of health stations, and to secure part time of a tuberculosis expert to consult with the physicians on diagnosis. The association also approves the open window schoolroom and will supply a cook, dishes, food, clothing, etc., to schools that will furnish a room where the children will go to school with open windows. The children will be warmly clothed, and will receive two warm lunches and a dinner at the school. The homes of these children will be visited to secure the cooperation of the parents so that they will receive practically the preventorium care at home. The association desires three of these rooms, each accommodating fifteen patients. To do the work outlined, \$40,000 will be required.

#### WASHINGTON

**Medical Building in Seattle.**—A medical building company plans to construct a ten-story office building in Seattle for the exclusive use of physicians and dentists.

**Traveling Tuberculosis Clinic.**—The Washington Tuberculosis Association is visiting different cities with a clinic and moving picture outfit for the exhibition of tuberculous conditions. Local physicians supplement the visits of the traveling clinic with health talks.

**Hospital Notes.**—Drs. James T. Mason, John M. Blackford and Maurice F. Dwyer, Seattle, have purchased a lot on which they will construct a modern hospital. It will be a concrete building, five stories high, and will cost \$150,000.—Construction has been begun on the new St. Joseph's Hospital, Aberdeen. The building will contain fifty rooms for patients, besides wards and three operating rooms.—As the present site of St. Peter's Hospital is desired for an addition to the new capital site, the Sisters of Providence of Olympia have purchased land on which it is proposed to build a new hospital.

#### CANADA

**Personal.**—Col. Wallace A. Scott, C. M. G., Officer Commanding, Moore Barracks Hospital, Folkestone, England, has arrived in Toronto from overseas.—Dr. John Harris McPhedran has returned to Toronto from overseas and has resumed practice.—Dr. Oswald J. C. Withrow, Toronto, will lecture in the United States on sex hygiene. He was recently elected secretary of the Ontario Association for the Care of the Feeble-minded.

**University News.**—Dean James C. Connell of the medical department of Queen's University, Kingston, Ont., denies the statement that the clinical work of Queen's Medical College will eventually be transferred to Ottawa. The hospitals of Kingston serve a large district of eastern Ontario, and plans are far advanced for the rebuilding and enlargement of the General Hospital, \$100,000 being in hand for the purpose. For some time past there has been more clinical material than is being used.

### GENERAL

**Röntgenologists to Meet.**—The twentieth annual meeting of the Western Röntgen Society will be held in Chicago, December 10 and 12, with headquarters at the Hotel Sherman.

**Ohio Valley Physicians to Meet.**—The annual meeting of the Ohio Valley Medical Association will be held in Evansville, N. November 11 and 12, under the presidency of Dr. J. K. Wills—Farrington, Chicago.

**County Health Conference.**—The second National Country Health Conference meets at the LaSalle Hotel, Chicago, November 8 to 11. The object of this conference is to arouse the interests of all rural institutions and agencies and their responsibility for better health in the country.

**Physicians Victimized.**—A physician of Jersey City notifies THE JOURNAL that a man has been victimizing members of the profession by taking orders for the Cameron light diagnostic outfit, and requiring a deposit in the name of the Dental and Surgical Company, 1807 Franklin Avenue, Philadelphia. A letter sent to the company has been returned with the notation "Not known." The man is about 5 feet 6 inches tall, fair, smooth face and smooth tongue.

**Red Cross Activities in Public Health Service Hospitals.**—Red Cross Hospital material valued at \$700,000 has been transferred to U. S. Public Health Service Hospital warehouses, and will be issued on order from the officials of the hospitals and of the Red Cross hospital personnel for the comfort of ex-service men under treatment in these hospitals. The supplies include gauze, pajamas, comfort kits, towels, laundry bags, fracture socks, bedroom slippers, underwear and bathrobes.

**New York and New England Surgeons Elect Officers.**—At the twenty-ninth annual meeting of the New York and New England Railway Surgeons' Association, held in New York City, October 20, under the presidency of Dr. James S. Hill, Bellows Falls, Vt., the following officers were elected: president, Dr. William B. Coley, New York City; vice-presidents, Drs. John F. J. Black, White Plains, N. Y., and Donald Guthrie, Sayre, Pa.; treasurer, Dr. James M. Hamilton, Rutland, Vt.; corresponding secretary, Dr. George H. Chaffee, Birmingham, N. Y., and recording secretary, Dr. John H. Reid, Troy, N. Y.

**Public Health Scholarships Granted.**—The American Red Cross has granted scholarships to 247 American nurses, 109 of whom have been released recently from military service in this country and overseas, to enable them to take training in public health service. Of these scholarships, 123 have been for \$50 each, permitting each recipient a four months' course of training, while the remainder have been for six, eight and nine months' courses, each nurse choosing the length of course she desires to receive her instruction.

**Appeal for Louvain University Library.**—The librarian of Louvain University, Belgium, October 25, setting forth the request made by the authorities of the University of Louvain for the re-constitution of their library. The publications of the learned societies of the United States are especially desired, and the Smithsonian Institution has undertaken to provide the material contributed through the International Committee on Scientific Cooperation. Any contributions should be strongly marked or labeled and plainly marked "The Smithsonian Institution, Washington, D. C., for the University of Louvain." The annual list of contributions should be sent directly to the Smithsonian Institution.

**Public Health Officers Meet.**—At the annual meeting of the American Public Health Association, held in New Orleans, October 27 to 30, under the presidency of Dr. Lee K. Frankel, H. D., New York, the following officers were elected: president, Dr. Watson S. Rankin, Raleigh, N. C.; vice-presidents, John Armyott, Ottawa, Ont., and Dr. William H. Kamm, New Orleans, and Guilford H. Sumner, Des Moines, Iowa; secretary, W. H. Hedrick, Boston; treasurer, Lee K. Frankel, Ph.D., New York, and directors, Drs. John Dill Robertson, Chicago, Henry F. Vaughan, Detroit, Mazyck F. Ravenel, Columbia, Mo., James Emerson, New York, John A. Kappelman, Canton,

Ohio, and Eugene R. Kelley, Boston. San Francisco was chosen as the place of meeting for 1920.

**Bequests and Donations.**—The following bequests and donations have recently been announced:

Women's Hospital, New York City, \$1,578,172; Presbyterian Hospital, State Charities Aid Association, and Infirmary for Women and Children, each \$776,586. Charity Organization Society of New York \$1,573,173; Mt. Sinai Hospital, \$100,000; New York Institute for the Deaf and Dumb, and Servants for the Relief of Incurable Cancer, each \$20,000, by the will of Mrs. Margaret Olivia Sage.

Kenosha, Wis., Hospital, Kenosha Service League and St. Catherine's Hospital, Kenosha, each one third of \$2,500 taken from four bandits who held up and robbed a gambling house in Kenosha recently.

Hartford, Conn., Hospital, a donation of \$50,000 from J. Pierpont Morgan, New York City.

Rockefeller Institute, New York City, an addition of \$100,000 to the endowment for additional research in biology, chemistry, physics, and medicine and general enlargement of the scope of activity of the institution.

St. Anthony's Hospital, Rock Island, Ill., a donation of \$1,000 from the Rock Island Plow Company.

Abington, Pa., Memorial Hospital, and Hahnemann Hospital, Philadelphia, each \$500,000, by the will of George W. Elkins.

Jewish Hospital, \$7,500 for a free room, and \$2,500 to be used by the hospital in any way it sees fit, \$2,500 for the Jewish Foster Home and Orphan Asylum, and \$1,000 for the Eaglesville, Pa., home for consumptives, by the will of Jacob MEYER.

### FOREIGN

**Dundalk Physicians Strike.**—In a recent cablegram it is stated that the physicians of Dundalk, Ireland, have gone on strike to enforce demands for a minimum weekly salary of \$35 for all public services. They claim that their present salaries average \$1,375 a year.

**Control of Venereal Disease in Spain.**—The King of Spain has issued a decree establishing a permanent board for the control of venereal disease, which is to make a study of the proposed measures and report back to the government the recommendations necessary to put the measures into effect.

**Field Hospital Finally Stationed.**—An American field hospital which traveled from Hoboken to France, from Bordeaux to Germany, from Trier to Constantinople, and from Constantinople to Ekaterinburg, Russia, has finally been placed with the southern division of General Kolchak's army. The hospital has 500 beds and two operating rooms, and includes all equipment needed for immediate operation.

**Sanitary Measures on Spain-Portugal Frontier.**—A French exchange states that an agreement has been signed between Spain and Portugal which provides for the compulsory declaration in the frontier zones of plague, cholera and yellow fever. Also, temporarily, for smallpox, typhus, typhoid, cerebrospinal meningitis and diphtheria whenever these diseases are assuming an epidemic character. Sanitary stations are to be organized along the frontier.

**Interallied Typhus Commission in Poland.**—The medical commission sent by the Interallied League of Red Cross Societies to study the typhus situation in Poland has begun its investigation in Warsaw. The commission is composed of Col. Hugh S. Cumming, Washington, D. C., Assistant Surgeon-General, U. S. P. H. Service, chairman; Lieut.-Col. Aldo Castellani, Royal Italian Navy Medical Service; Lieut.-Col. George S. Buchanan, Medical Officer of Health, Ministry of Health of Great Britain; and Lieut.-Col. Visbeck, French Army Medical Service.

**Typhus Exterminated from Serbia.**—The five-year campaign which American Red Cross physicians and nurses have been waging against typhus fever in Serbia has ended victoriously. The recent report of the Serbian Commission states that there are now only about sixty-five cases in the country, two thirds of these being in Belgrade. During 1915, 150,000 persons died from the disease out of a population of 3,000,000 and 150 physicians died, so that there was only one physician to 75,000 persons. The commission has now turned its efforts toward instilling the principles of hygiene, sanitation and nutrition into the minds of the people.

**Institute of Social Physiology.**—This is the title to be given to a new institute soon to be organized at Milan in connection with the other institutes for graduate work. The scope of this *istituto di fisiologia sociale* is to conduct research on problems relating to food, to industrial efficiency, to growth and the school, the manufacture of foods, professional and industrial safeguards for the health, applying functional methods of examination and psychic tests, etc.—aiming in short to control and assist the elementary, professional and industrial schools from the standpoints both of physiology and

pathology. Dr. L. Veratti is said to be the sponsor for this new institution.

**Some Missing Foreign Weeklies.**—After an absence of weeks or months three weeklies, the *Bulletin de l'Académie de Médecine*, the *Bulletin de la Société des Hôpitaux de Paris* and the *Policlinico* of Rome are again appearing. The latter has been suspended on account of a printers' strike, the issue for July 20 not appearing until September 10, and the publishers are unable to guarantee its regular appearance even now. The *Bulletin de l'Académie de Médecine* was not issued during the several weeks of the vacation of the Académie. This is the first time the Académie has taken a recess since the war began. The *Bulletin des Hôpitaux* was also suspended for the same reason. The Société des Hôpitaux opened its new year with a gala meeting to which were invited all the physicians, surgeons, accoucheurs and specialists of all the hospitals.

#### LATIN AMERICA

**Plague in Argentina.**—According to a cablegram from Argentina, bubonic plague has assumed a serious character in the territory of Formosa, in the northeastern part of Argentina.

**Influenza in Bolivia.**—It is reported from Chile that the influenza epidemic is spreading throughout Bolivia and the government is taking active measures to combat it. It is stated that several thousands of cases have occurred at Santa Cruz and its vicinity.

**Retirement of Prof. Decoud.**—Dr. Diogenes Decoud, professor of surgery at the University of Buenos Aires, having reached the age limit, has retired from his chair. Prof. A. F. Celsia has been given charge of the work until a new incumbent can be appointed.

**Smallpox in Havana.**—It is reported from Havana that smallpox cases are decreasing in number rapidly through the effectual work of the sanitary authorities. So far, the committee on infectious diseases has considered positive only one case which shows the low infectivity of the disease. The authorities expect, however, that new cases may occur in from eight to ten days.

**Milk Stations Conference in Chile.**—There was recently held in Chile the Congreso Nacional de Gota de Leche. A number of papers were presented by several physicians. The conclusions adopted included the extension of the Gouttes de Lait; visits to the children in their homes; medical assistance; improvement of milk supply; treatment of parents with infectious diseases, etc.

**New Methods for Teaching Hygiene in Buenos Aires.**—The National Council of Education has authorized the trial in three schools of Buenos Aires of a system of teaching hygiene suggested by Dr. José F. Montellano. This system contemplates teaching in concrete form only those fundamental principles of practical usefulness the truth of which has been demonstrated, and to furnish this in as objective a form as practicable. The purpose is to give the children some practical knowledge that may be necessary for the preservation of their health, and in such a form that they will understand it thoroughly and it will be impressed on them for life. Dr. Montellano has already furnished the first chart he is going to use which shows the progress of phagocytosis, including the composition of the blood, the red and white corpuscles, the introduction of microbes, their destruction, etc. Similar charts will be employed to show the progress of the different diseases and approved prophylactic methods.

**Deaths in the Profession.**—Dr. Juan B. Fuentes, formerly physician in chief of the Clínica de Partos at Havana, and since then connected with the public health service.—Dr. I. Rezende, formerly professor at the Rio de Janeiro medical faculty, but for many years practicing medicine at S. Paulo, aged 59.—Dr. C. M. de Novaes, a well-known surgeon and urologist at S. Paulo. Also from S. Paulo is reported the death of Dr. G. Ellis, physician to two of the hospitals and president of the Sociedade de Medicina e Cirurgia de S. Paulo, aged 72, and of Dr. J. Valeriano de Souza, surgeon to the Beneficência Portuguesa and professor in the pharmacy school.—Dr. Alfredo Porto, professor of skin and venereal diseases at the University of Rio de Janeiro since 1907 and a frequent writer on subjects connected with this specialty. He succumbed in the midst of robust health to the effects of scratch infection from a patient with cruris.—Mr. L. Cianci, an official radiologist for the Buenos Aires medical faculty, recently died at the age of 40 from injuries received during the performance of his duties.

## Government Services

### Personnel of the Medical Corps

Up to Oct. 31, 1919, there had been 1,564 men discharged from the Medical Corps 28,093 officers, which taken from a maximum of 30,591 leaves 2,498 in the service. The Reserve Corps contains 3,697 officers, including, 1 brigadier-general; 63 colonels, 208 lieutenant-colonels, 900 majors, 1,551 captains and 954 lieutenants.

### British Medical Officers Decorated

In recognition of their services during the late war, the President has conferred the Distinguished Service Medal on Major-Gen. Sir Anthony Bowlby and Major-Gen. Sir Robert Jones, R. A. M. C. The Secretary of War designated Major-Gen. Merritte W. Ireland to represent the President in conferring these decorations, which were presented in New York City.

Major General Bowlby, while serving with the British Expeditionary Force in France, placed his knowledge and experience at the disposal of the American Expeditionary Forces.

Major General Jones, who is an eminent orthopedic surgeon and chief of the division of orthopedic surgery in the British Army, gave most valuable advice and personal assistance in standardizing methods of the sick and wounded of the American Expeditionary Forces and also in the instruction of American Army surgeons in the branch of surgery for which he is noted.

### Distinguished Service Medal

The Distinguished Service Medal has been awarded to the following medical officers:

Charles Lynch, Colonel, M. C. U. S. Army. "As port surgeon, Port of Embarkation, Newport News, Va., his services at governing and controlling agencies for caring for sick and wounded soldiers, protecting them against disease, and safeguarding them prior to and during transport overseas, were conspicuous."

James M. Kennedy, Colonel, Medical Corps, U. S. Army. "As port surgeon, Port of Embarkation, Hoboken, N. J., organized, provided and administered with conspicuous efficiency all hospitals required for accommodation of transports going overseas for that port, as well as for the large number of sick and wounded soldiers returning home."

### Other Awards

Gray G. Holladay, Lieut., U. S. Navy, R. F., Portsmouth Va., surgeon of the U. S. S. *George Washington*, was honored by receiving a decoration from King Albert of Belgium.

Dr. Mary Hughes Elliott, Blue Mountain, Miss., who went to the Balkans last winter as a member of the American Commission to Serbia, has been awarded the Serbian Decoration of the Order of the Sava.

Alfred E. Lemon, Major, U. S. Army, Douglas, Ariz., has been awarded the Croix de Guerre, with citation by the Tenth French Army Corps, order No. 143821.

Captain Alfred E. Lemon, Medical Corps, 1,2th American Infantry. The 29th of August, 1918, near the farm of Vanomez, north of Seissons, being all day with the wind cut at the trenches and frequent aerial attacks, although under constant fire his behavior in danger and his "sang froid" served as an example to other doctors and men under his orders, causing the saving of the lives of many wounded. Signet Petain (by Caillemant).

### Educational Service Report

Educational service reports for August submitted by seventeen army hospitals show that ninety of the 3,494 who received certificates of disability for the month were designated as unfit for their old occupation, the balance being able to resume their old occupation, and are not in need of assistance. The enrollment of war handicapped decreased from 14,010 in July to 10,719 in August. Most of these patients were engaged in making and weaving textiles, reed, cane and fiber work, wood working and occupations in which leather, cardboard and binding materials are used. During August, 15,944, or 53 per cent. of the total number of patients in hospitals, were enrolled at the educational stage, as compared with 55 per cent. in July, 47 per cent. in June, 48 per cent. in May, and 43 per cent. in April.

### Recognition to Surgeon-General

A reception was given, October 9 by the members of the Officers' Club, District Circle, Washington, D. C., in honor of

Major-Gen. Merritte W. Ireland, Surgeon-General, U. S. Army, and Mrs. Ireland, and officers and ladies of the Surgeon-General's Department stationed in Washington and vicinity.

### MEDICAL OFFICERS, U. S. NAVY, RELIEVED FROM ACTIVE DUTY

CONNECTICUT	MASSACHUSETTS
New Haven—Dennehy, W. J.	Boston—Sise, L. F.
DISTRICT OF COLUMBIA	MICHIGAN
Washington—Stanley, A. C.	Ewen—Alden, S. J.
IOHIA	PENNSYLVANIA
Leamans—Gehlen, J. N.	Philadelphia—Edgar, J. M.
	Spout—F. M.

## Foreign Correspondence

### BUENOS AIRES LETTER

BUENOS AIRES, Sept. 21, 1919.

#### Public Assistance Difficulties

The progressive increase in the prices of drugs and foods has aggravated the constant economic difficulties with which the public assistance department of this capital is always struggling. This is in part due to the fact that we have constantly with us an enormous number of patients from all over the country, half of whom do not properly belong here. The surgical and medical equipment is deficient and the surgical service is maintained only through the public spirit of the physicians in charge. These difficulties have caused the authorities to make attempts to increase the hospital funds. Those in charge of the public assistance have requested the cooperation of the people, in order to provide clothing, shoes, orthopedic apparatus, transportation, etc., for the indigent patients. The commission appointed to this effect has obtained quite a large number of contributions, but on account of its expenses and the little success that attended some of the public sales, the funds obtained have not been by far as large as expected.

#### Influenza Epidemic

The epidemic of influenza has spread all over the country and has even reached the neighboring city of Montevideo. In this city the increase of cases of influenza as well as pneumonia has continued, although so far it has not assumed an epidemic character. The investigations carried out by the national department of public health showed the presence of the pneumococcus, streptococcus and the Pfeiffer bacillus. Dr. Méndez has stated, although without presenting any experimental data, that the only etiologic agent of the influenza affections is the pneumococcus, and holds that the streptococcus and Pfeiffer bacillus are only varieties of this micro-organism. On this theory he has prepared a special pneumococcal vaccine which has been employed as a preventive and curative agent on a very large scale throughout the country and which is very popular among the masses. It has also been used subsequently for the equine meningo-encephalitis, foot and mouth disease, puppy diseases, etc. There has also been an increase of the mortality caused by pulmonary tuberculosis. The national department of public health has been compelled to mobilize its forces on different occasions. Several commissions have been sent to different provinces, and some are now visiting Santiago del Estero and Tucumán. The secretary, Dr. Teófilo Lecour, has visited several places and made a tour of inspection of all the coast towns, to supervise the permanent sanitary organizations as well as those organized temporarily to combat influenza.

#### Creation of Public Health Stations

The national government has under consideration the creation of permanent public health offices at Jujuy, La Rioja and Salta.

#### Rat Eradication

The national congress has under consideration a bill for the compulsory destruction of rats, in order to prevent the possible spread of bubonic plague, isolated cases of which occur occasionally in different regions of this country.

#### University Exchange

The Spanish Culture Association of Buenos Aires gives annually at its expense a university course which is given by some prominent Spanish professor. This year the man

in charge is Dr. Augusto Pi y Suñer, the professor of physiology of the Medical School of Barcelona. The first lecture, given July 26, was a marked success. The complete course will consist of from eighteen to twenty-five lessons, in this city, and in addition some lectures in Rosario, Cordoba, Montevideo and other cities. In the first lecture he emphasized the existence of a tropic sensitiveness through which the nervous elements maintain their balance. This sensitiveness acts through the nerves and humoral chemical agents. Montevideo professors, including Drs. Pau Orfila, Pratt and Morelli, have also given some lectures in the School of Medicine of Buenos Aires. Dr. Pedro Chuto, who recently arrived from the United States, has also given a series on the surgical lessons learned during the war.

#### Malaria

As a result of the floods of the River Paraguay there have been observed a number of malaria foci in the district of Formosa, and a sanitary campaign has been arranged to control the spread of the disease.

#### Second Tuberculosis Conference

The second national tuberculosis conference was held at the city of Rosario, September 6. There was in connection with it a public exposition devoted to illustrate the prophylaxis of tuberculosis. The secretary of foreign affairs and public assistance delivered an address expressing the interest of the government in having tuberculosis prophylaxis and treatment placed on a sound basis, for which purpose a bill has already been introduced in congress. The discussions were somewhat heated, some of the participants having shown too much feeling in their remarks. While no papers of any special importance were presented, a certain uniformity was observed in the plans submitted. It was decided to advise the creation of dispensaries which will act as centers for assistance, selection of hospital cases and preventive education, this being supplemented by visits to the homes and assistance whenever required. The establishment of a sanatorium for each hundred thousand inhabitants was also advocated, as well as the creation of special tuberculosis hospitals and seaside or mountain sanatoriums when needed. The strict application of measures of sanitary supervision on foodstuffs, servants, public offices and public places was also recommended. In addition, the recommendations included the construction on a larger scale than heretofore of low-priced houses, the improvement of the measures for infant welfare, extension of the anti-tuberculosis and antialcoholic propaganda, especially in the schools, and the enforcement of a system of compulsory reporting of the disease and assistance to indigent families. In order to carry out these purposes, there was advocated the creation of a special independent commission with its own appropriations which would appoint special commissions under its jurisdiction. The pending governmental bill was indorsed, although it was considered necessary to have some system of compulsory health insurance.

#### New Tuberculosis Dispensary

The Argentina association for the prevention of tuberculosis has opened a new dispensary called Eduardo Wilde in one of the most populous sections of the city. The dispensary is provided with modern equipment, the funds for this purpose having been obtained through popular contributions.

#### Narcotic Legislation

The campaign against the use of habit-forming drugs has recently been given new impulse, and the existing laws are being enforced rigidly.

### MEXICO LETTER

Mexico, Oct. 26, 1919.

#### The Opium Case

The large quantity of opium which was found by the police in a private house, and which was believed to be intended to be smuggled into the United States, has been confiscated by the authorities, who have placed it at the disposal of the board of public health. The value of the confiscated opium is estimated as about \$22,000.

#### The Mexican Medical Association

The Mexican Medical Association has decided to address a petition to the House of Representatives, explaining the advantages that will accrue to the people in general, and the professional classes in particular, from the adoption of a law that will restrict the practice of medicine and allied professions to duly licensed persons. This law would put an end

to the serious harm that the quacks are doing at present in this country.—The association has decided to grant annually two prizes of 250 pesos (\$125) each, which will be granted to medical students who have completed the third year and are poor, honest and studious. The prizes will be granted by a jury consisting of two of the professors (the dean and one of the third-year professors), two of the officers of the Mexican Medical Association, and one third-year medical student who will not be eligible to the prize on account of his pecuniary position.—It has been decided to adopt an emblem for the members, which will consist of an enamel button on which will appear engraved the traditional staff and serpent of Esculapius.

#### The Field Nurses

The war department has ordered that hereafter the nurses belonging to the sanitary corps of the army will serve only in the hospitals, and that on no account will they be assigned to the troops on the field as done heretofore. This is due to the fact that some of them have complained of abuses. The services previously rendered by female nurses will hereafter be rendered by male nurses.

#### New Bacteriologic Department

There has been begun the construction of a pavilion for the National Bacteriologic Institute, which will be devoted to the study and growth of the most dangerous germs, such as the Yersin plague bacillus and the cholera vibrio. Some of the cultures of these bacteria, which the laboratory had previously, have been lost, and new ones have been imported from American laboratories. It is expected that the new building will give the necessary protection to prevent the so-called laboratory epidemics, and will permit at the same time the preparation of large quantities of anticholera serum and antiplague vaccine for use as required.

#### Sanitary Conditions

The federal sanitary authorities, as well as those of the state of Colima, have denied the occurrence of yellow fever cases in that state; but the newspaper correspondents continue to assert that cases of that disease have occurred there.

Malaria has presented itself in epidemic form in Iguala in the state of Guerrero, a great number of deaths having been reported. The same thing is happening in Tuxpan and its vicinity, in the oil region of the state of Veracruz, where there have occurred a number of cases of hemoglobinuric fever and several deaths.

The port of Tampico has established a quarantine against ships from Havana on account of the smallpox epidemic reported from that city.

Yellow fever continues to be present in Yucatan.

### LONDON LETTER

LONDON, Oct. 8, 1919.

#### Rabies in England

Sir Stewart Stockman, chief veterinary officer of the board of agriculture and fisheries, has reviewed the position of rabies in this country in recent years in his annual report. The disease was eradicated in 1902 by the muzzling of dogs, and stringent measures were taken against its introduction by a period of quarantine covering the usual latent period of the disease. For sixteen years these measures have been effective, but conditions arising out of the war have allowed the disease to be introduced from the continent. It first appeared in Devonshire in September, 1918. A veterinary inspector was sent down to report on the mysterious deaths of dogs; laboratory investigation showed that they were due to rabies. An order was issued prohibiting movement of dogs out of Cornwall and Devon and enforcing muzzling in an area round Plymouth, which was afterward extended to certain districts in the counties mentioned. Up to the end of the year, 112 cases were observed. Immediate muzzling was effectively applied, and a decrease began in the number of cases that appeared monthly in the congested district of Plymouth. Fortunately, most of the cases were of the paralytic form, which curtailed the wanderings of the animals and their ability to bite. Another favorable factor was that for some unexplained reason the majority of the dogs took a westerly course and came up against the barrier of the sea. Arrangements were made for seeking out and treating human beings who were bitten. So far there has been no death from hydrophobia among twenty-one persons treated. Some of the distances covered by rabid dogs during their run are given. In one case it was 20 miles; but because it had bitten a man, the dog was shot, while still going strong. In another

case the distance was 30 miles, when the animal was shot while still going strong.

#### The Mortality of the Tuberculous After Sanatorium Treatment

The Medical Research Committee has issued a report on the after-histories of patients discharged from the King Edward VII Sanatorium, which is important because of the large proportion of patients it was possible to trace. Of those discharged from the sanatorium since its foundation in 1914, only 3.5 per cent. were not traced. The present study is based on a record of seven years, covering 1,053 men and 1,064 women. Patients admitted in the incipient stage showed a mortality five or six times as great as that of the general population; moderately advanced cases between fifteen and twenty times as great; advanced cases nearly forty times as great. The smallest excess mortality was among patients discharged when the disease appeared to be arrested. The conclusion is drawn that residence in a sanatorium should be prolonged as long as possible. In the treatment, tuberculin proved disappointing. The method of administration was that advocated by Handelier and Roepke, which approximates the "reactionless" method of Sahli and Trudeau. No appreciable effect, good or bad, could be traced.

#### The Ministry of Health: Consultative Councils

When the ministry of health bill was before Parliament, it was made clear that the ministry when established would seek advice on a variety of subjects within its province from advisory bodies chosen so as to include men and women with full practical knowledge of the questions on which they would be asked to advise. In the act, these bodies are called consultative councils. In the case of England they will consist of the consultative council on medical and allied services, the consultative council on local health administration, and the consultative council on general health questions. The councils will consist of twenty members each, including a chairman and vice chairman, but they may for special purposes appoint committees in order that they may have the cooperation of other persons so that particular problems will be considered with the help of those who have made them a special study. The membership of the consultative council on general health questions, which will also be twenty in number, is not yet completely settled, but at least half of its members will be women.

To the consultative council on medical and allied services will be referred such problems as the national development and extension of medical, nursing and midwifery work, and it is proposed that for some purposes it should, in accordance with the arrangement outlined above, act through committees more specialized than the council itself. Its members have been chosen from the fields of specialist medicine and surgery, general practice, both private and insurance, the public health services, the work of women in medicine (particularly the care of mothers and infants), hospital administration, and the application of other branches of science to medicine. It is intended that when questions are under consideration that specially affect the nursing and midwifery services of the country, the council should be assisted by the appointment of a committee consisting partly of its own members but also including practicing nurses and midwives and other persons, not members of the council, who have devoted themselves specially to the study of nursing and midwifery questions.

The consultative council on national health insurance will, as its name indicates, consider problems of the work of approved societies arising in the administration of the cash benefits (sickness, disablement and maternity) by approved societies under the insurance acts. Its membership includes persons familiar with the work of all the principal types of approved societies.

The consultative council on local health administration will consider the administrative problems arising out of proposals for the development and extension of health services, and its membership includes persons familiar with the work of local authorities of various types, insurance committees and poor law guardians.

#### A New Journal

The first number of a journal entitled *Medical Science, Abstracts and Reviews* has appeared. It is produced by the Medical Research Committee and may, therefore, be regarded as a government publication. It is the successor of the *Medical Supplement to the Daily Review of the Foreign Press* issued by the general staff of the war office, which made its appearance privately during the war in 1918 with the object

of informing our army medical staff of the inventions and discoveries of the enemy, though it soon became something wider, a review of foreign literature in general. After the war it ceased with the review. The present periodical will be published monthly, and its annual subscription price is \$5. The first number, which appeared during the present month, contains 130 pages in good-sized type. Two thirds is occupied with reviews, and the remainder with abstracts. There are five departments which have been allotted to editors; surgery, Mr. W. G. Spencer; medicine, Dr. J. D. Rolleston; pathology, and bacteriology, Dr. W. Bulloch; neurology, Dr. F. M. K. Walshe; radiology, Dr. W. S. Lazarus-Barlow and Dr. Sydney Russ. The subjects of the reviews are: "Spina Bifida"; "Habitual or Recurrent Dislocation of the Shoulder"; "Repair of Tissues Destroyed by Injury and Disease"; "Cecostomy—Appendicostomy"; "Typhoid and Paratyphoid Fevers"; "Typhus"; "Influenza"; "Malaria"; "Dysentery"; "Cardiovascular Diseases"; "Alimentary Diseases"; and "Lethargic Encephalitis." The reviews are all written by the editors and take the usual form of critical summaries of the recent literature of a subject. In some cases the writer has gone farther and brought old classical papers into the review, which thus tends to become an essay. The abstracts are in most cases also written by the editors. As the names would indicate, the work has been well done, but by no means covers the field of medical literature, most of the specialties being excluded. The periodical should prove most useful to those engaged in research or interested in particular subjects, but, like most publications of the kind, very little of it is palatable for the general reader.

#### PARIS LETTER

PARIS, Oct. 16, 1919.

##### Provisions Made for War Orphans

The general federation of departmental associations of public school children has gained widespread recognition lately in view of the great work it is doing for the war orphans. The federation is composed of eighty-seven associations, which contribute to the support of 200,000 war orphans. During the year 1918 it has distributed to these orphans the total sum of 15 million francs.

The federation has also taken the initiative in founding the first sanatorium for heliotherapy *en altitude*, in France. This sanatorium will be for the treatment of patients suffering from surgical tuberculosis. Mme. L. Stern has already promised a million francs toward the project, but a much larger sum is needed before the plan can be realized. It is proposed to locate the sanatorium in the department of Pyrene-Orientales (Southern France), in the vicinity of Font-Romeu.

##### The University of Strasbourg

Alsace having again become French, university circles are busily engaged in working out plans in order to make sure that the old University of Strasbourg shall not fall behind the standard to which it is entitled. The University of Strasbourg is, in fact, three hundred years old. While its official foundation dates from 1621, its earliest beginnings really extend back into the sixteenth century. Moreover, the authorities had not waited for the end of the war before considering this subject. As early as two months after the entrance of the French (Nov. 22, 1918), a course conducted in French was inaugurated. The other courses were soon organized, the Alsatian professors remaining at their posts, while certain professors were sent in temporarily; officers who were university instructors in civil life were also placed by the military authorities at the disposal of the faculties. In spite of difficulties, all the courses were soon conducted in French. From the beginning of hostilities, French had been absolutely prohibited by the German authorities and violation of this edict were subject to severe penalties. It required, therefore, a real effort on the part of all the instructors, even of young men who formerly had had a sufficient knowledge of French, in order to adapt themselves to instruction in this language.

If, however, that is not the most delicate question. The most difficult point to solve is, how the University of Strasbourg is to be assured the prosperous condition of affairs that it merits. Before the war it had more than 2,000 students, half of whom were from Alsace-Lorraine. Half the students were German; these it will, of course, lose. It will also lose, through the natural course of events and by force of natural attraction, the students from Lorraine who heretofore attended the University of Strasbourg, for these will doubtless be drawn toward Nancy. The result has been that

this year Strasbourg has matriculated only 800 students, which seems to be the maximum that the local field is able to furnish. This number is too small to constitute a great university. We have in France half a dozen universities that have a larger attendance than this. The necessity therefore arises of providing the university with as many good courses and as many attractive features as possible, in order to induce a large contingent of students from outside of Alsace to take up their studies here.

Whatever may be done in the future, one may gain some idea of the present status of the medical faculty of this institution from the following:

There are twenty professorial chairs. The theoretical and practical instruction is given, then, by twenty full professors and twenty-four assistants (*chargés de cours*). This instruction is open to students who have completed their premedical studies, including physics, chemistry and the natural sciences, and to those who are preparing, according to the German system, for their state examination (*Staats-examen*).

A special course of instruction will be established for students who are too far advanced in their medical studies according to the mode of instruction of the German faculties to continue according to the French plan without considerable loss of time. These students will be attached, in the capacity of licentiates (*stagiaires*), to some service of general medicine or to a service of general surgery. Furthermore, special courses in clinical medicine (Professors Bard and Blum), in clinical surgery (Professors Sencert and Stolz), in pathologic anatomy and in general pathology have been provided for these advanced students.

##### Medical Fees in Industrial Accidents

The schedule of medical fees provided by the law pertaining to industrial accidents dates back to 1905. Living conditions having completely changed, especially since the war, this schedule was no longer in harmony with the high cost of living. In view of this fact, the insurance companies, acting in accord with the delegates of the *Syndicats médicaux de France*, requested that Senator Bienvenu-Martin should serve as arbitrator in establishing a new schedule of medical fees in industrial accidents. The arbitrator so chosen has decided that the schedule in force at the present time shall be provisionally increased 100 per cent.

##### Exchange of Professors Between France and Italy

The plan for the exchange of professors between France and Italy has been definitely worked out. This project, which has been under advisement for several years, is based on the desirability of each of the two countries possessing an exact knowledge of the other, and on the thought that in this manner a sort of common intellectual atmosphere might be created between the two nations. Such a plan of exchange will give the French and Italian professors of all ranks definite missions outside of their native country, which will afford an opportunity for an extended sojourn during which a friendly nation can be studied at first hand. It is also thought that scientific research will be facilitated by this innovation.

##### French Society of Medical History

The Société française d'histoire et de médecine has resumed its custom of holding monthly meetings. At a recent meeting, the president, Dr. Jeanselme, professor of cutaneous and syphilitic diseases at the Faculté de médecine de Paris, presented a very interesting communication, illustrated by photographs, on the medical manuscripts preserved in the National Library. Professor Roger, dean of the Faculté de médecine de Paris, announced a plan for the creation of a historical medical museum, designed to serve as a depository of gifts received from the members of the society.

##### Wounds Received by Physicians at the Hands of Insane Patients

Among the risks connected with the medical profession there is one to which alienists are particularly exposed. Within the space of a few days, two physicians of Paris have had to suffer on this account. Dr. Rogues de Fursac, physician-in-chief of the asylum of Ville-Evrard, was seriously wounded by an insane patient who struck him in the region of the heart with a saw-file. The attendant who accompanied the physician on his rounds was able partially to parry the weapon, which inflicted, however, a deep lung wound, causing copious hemoptysis. A few days previously, Dr. Ducosté, physician-in-chief of the sanatorium of Ville-Evrard, had been severely wounded in the head by an insane patient who had leaped at him with the intention of cutting

his face with a broken bottle. In spite of the severity of their wounds, these two alienists do not appear to have suffered a mortal injury.

#### Meeting of Gynecologists and Obstetricians

The first meeting of the Association des gynécologues et obstétriciens de langue française was held recently. Among the six subjects discussed at the meeting (*THE JOURNAL*, Aug. 23, 1919, p. 622), three are of especial interest: (1) the serodiagnosis of pregnancy; (2) rising early from childbed, and (3) operative treatment of cancer of the cervix of the uterus.

#### The Serodiagnosis of Pregnancy

Dr. Bar, professor of clinical obstetrics at the Faculté de médecine de Paris, and Dr. Ecalle presented a report on the subject of serodiagnosis of pregnancy, in which they discussed the advantages derivable at the present time from recent discoveries in regard to biologic reactions produced when substances of fetal origin are allowed to penetrate the maternal organism. The complement fixation method possesses very slight practical value, they find. The dialytic method (the Abderhalden test) is deserving of greater attention. The blood serum of pregnant women when brought in contact with placenta always doubles the amount of placental albumin; the reaction is always positive. The reaction seems to be little influenced by the stage of the pregnancy. It appears first during the second month of gestation and disappears generally during the three weeks following accouchement. In extra-uterine pregnancies the reaction is always positive if the embryo is living; it may become negative if the fetus is dead. The intensity of the reaction is generally diminished if some form of intoxication is present. Besides, it is important to note that the blood serum of nonpregnant women gives a positive reaction in 33 per cent. of the cases. The diagnostic value of this method is therefore subject to important restrictions.

Furthermore, the attempt has been made to base the diagnosis of pregnancy on the increase of antitryptic power, but Bar and Ecalle do not think that this increase would be of any aid in the diagnosis of doubtful pregnancy, especially in view of the fact that the increase is definite and constant during the last months of pregnancy. The clinical advantages of these biologic reactions, difficult and delicate of control, as they are, seem rather slight and are not at all commensurate with the labor that they necessitate. All the obstetricians who took part in the discussion were virtually of the same opinion. All emphasized the fact that the researches in question, and particularly the Abderhalden test, were of an extremely delicate nature and subject to numerous sources of error.

#### Rising Early from Childbed

In his report on the subject of rising early from childbed, Dr. Bourcart of Geneva called attention to the disadvantages connected with patients keeping their beds too long after accouchement; they grow anemic, their abdominal muscles atrophy, the lochial discharge is hampered, the chances of infection are increased, uterine involution is retarded, intestinal function is arrested, and, finally, the secretion of milk is diminished. Early rising from childbed makes it possible to avoid all these disadvantages, since muscle action is better and the blood circulation is more active. It is understood that it is necessary that normal abdominal conditions be re-established before a patient is authorized to get up. It is a very good practice to institute massage of the abdominal muscles before allowing the patient to leave the bed, as this promotes the return of normal intra-abdominal conditions.

## Marriages

CAREY F. McCafferty, Columbus, Ohio, to Miss Hazel Jacquelin Holcome of Portsmouth, Ohio, at Dayton, Ohio, October 17.

MARK ALEXANDER GRIFFIN, Morganton, N. C., to Miss Neppie Clary Brothers, at Raleigh, N. C., October 8.

HORACE PALMER BECK to Miss Dorothy Bateman, both of Newport, R. I., at New York City, October 15.

HOMER P. MACNAMARA, Springfield, Ill., to Miss Mabel Palmer Cowdin of Chapin, Ill., October 27.

ARTHUR HALE PARCHER, Ellsworth, Me., to Miss Winifred Ethel Hassall, October 8.

## Deaths

Robert Taylor Wilson \* Baltimore; University of Maryland, Baltimore, 1881; aged 59; gynecologist to the Union Protestant Infirmary, Baltimore; consulting physician and director of the Hospital for Consumptives; surgeon to the Hospital for Women of Maryland; president of the Hospital Relief Association of Maryland; formerly assistant recording secretary to the Medical and Chirurgical Faculty of Maryland; died at his home, October 6, from heart disease.

Horace Perkins Mackechnie, Somerville, Mass.; Bellevue Hospital Medical College, 1879; aged 78; a member of the Massachusetts Medical Society; formerly principal of the Green Mountain Institute, and later of the Lincoln School, Somerville; once president of the Somerville Medical Society and a member of the staff of the Somerville Hospital since its organization; died at his home, October 17, from heart disease.

John Müller, Chicago; College of Physicians and Surgeons, Keokuk, Iowa, 1876; aged 78, for four years professor of languages at the University of Upsala, Sweden; interpreter at the Oriental Congress in Stockholm; lecturer at the Università Popolari, Milan, Italy; once lecturer and demonstrator of anatomy at St. Louis Medical College; died in Alexian Brothers Hospital, Chicago, October 24.

Junius Merwin Hall \* Chicago; College of Physicians and Surgeons in the City of New York, 1874; aged 68; for fourteen years a medical inspector under the health commissioner of Chicago, and on duty during the smallpox epidemic of 1880 and 1881; for many years a member of the attending staff of the Passavant Memorial Hospital; died at his home, October 30, from cirrhosis of the liver.

Albert C. H. Barge \* Astoria, N. Y.; Long Island College Hospital, Brooklyn, 1911; aged 32; assistant gynecologist to the German Dispensary, New York City, and attending gynecologist to Lenox Hill Dispensary; died at his home, October 23, from diphtheria.

Orlando T. Maynard \* Elyria, Ohio; Eclectic Medical Institute, Cincinnati, 1875; Western Reserve University, Cleveland, 1884; aged 69; a member of the staff of the Elyria Memorial Hospital; died at his home, October 24, from heart disease.

Wellington Clark Ellis, Swiss, W. Va.; Barnes Medical College, St. Louis, 1910; aged 36; who was injured in an automobile wreck near Charleston, S. C., October 5, in which his wife was instantly killed, died from his injuries, October 9.

Edward Tracy Robinson, Chicago; Bennett Medical College, Chicago, 1906; aged 40; while motoring from Casper to Sheridan, Wyo., was instantly killed, July 25, when the car ran off a bridge, crushing Dr. Robinson beneath it.

Isidor Perlstein, Streeter, N. D.; Harvard University Medical School, 1912; aged 37; assistant physician to the Colonial Sanitarium, Rochester, Minn.; died at the Mayo Clinic, Rochester, September 23, from brain tumor.

Charles Edward Berkeley Duncombe, St. Thomas, Ont.; Trinity Medical College, Toronto, Ont., I.R.C.P. (Edin.), 1883; aged 55; was killed instantly in a collision between automobiles at Brantford, Ont., September 14.

Franklin Levi Hope, Tunica, Miss.; Vanderbilt University, Nashville, Tenn., 1882; aged 62; for one term sheriff and chancery court clerk of Tunica County; died at his home, August 28, from acute dilatation of the heart.

Albert Christian Amundson, Cambridge, Wis.; New York University, New York City, 1882; aged 64; author of many articles in Norwegian on quackery; died at his home, October 20, from carcinoma of the liver.

John F. Mulholland, Jordan, Minn.; Northwestern University Medical School, Chicago, 1879; aged 70; a member of the Minnesota State Medical Association; died at his home, August 24, from pernicious anemia.

Christian Kachelmacher \* Fargo, N. D.; University of Christiania, Norway, 1897; aged 48, shot himself in his room at a hotel in Chicago, October 29, and died a few hours later in the Alexian Brothers Hospital.

Thomas F. Leech, Downers Grove, Ill.; Jefferson Medical College, 1860; aged 78, a veteran of the Civil War in which he served as surgeon, U. S. Navy; died at his home, October 30.

Francis Brennan Fletcher \* Capt., M. R. C., U. S. Army, Springfield, Ill.; Rush Medical College, 1902; aged 39; died in Liverpool, England, July 30, five days after an operation for perforating gastric ulcer.

Joseph Dozier Bancroft, Birmingham, Ala.; Vanderbilt University, Nashville, Tenn., 1894; aged 47; a member of the Medical Association of the State of Alabama; died, October 10.

Fletcher J. Farwell \* Friend, Neb.; Ensworth-Central Medical College, St. Joseph, Mo., 1909; aged 49; a member of the local school board; died at his home, October 10, from erysipelas.

Arthur M. Smith, Los Angeles, Calif.; University of Southern California, Los Angeles, 1888, aged 44; died in the Receiving Hospital, Los Angeles, August 19, from cerebral hemorrhage.

Elmer Barwis, Trenton, N. J.; University of Pennsylvania, Philadelphia, 1873; aged 69; a member of the Medical Society of New Jersey; died at his home, September 9, from angina pectoris.

Luther Holt, Iuka, Ill.; Washington University, St. Louis, 1887; aged 57; a member of the Illinois State Medical Society; died at his home, August 23, from valvular heart disease.

Angus MacDonald, St. Paul; McGill University, Montreal, 1863; aged 76; once president of the Ramsey County Medical Society; died at his home, October 11, from cerebral hemorrhage.

Roy Clyde Pynn, Delaware, Wis.; University of Illinois, Chicago, 1907; aged 35; died in St. Joseph's Hospital, Milwaukee, October 14, from valvular heart disease.

William W. Sanders, DeKalb, Texas; University of Tennessee, Nashville, 1868; aged 80; president of a bank in DeKalb; dropped dead in his bank, October 2.

J. F. Ullman, Simpson, Kan. (license, Kansas, 1901); aged 66; a practitioner for forty-four years; died in the Beloit (Kan.) Hospital, October 7, from nephritis.

Emmett H. Robertson, Dalles, Ga.; Memphis (Tenn.) Hospital Medical College, 1895; aged 49; died at his home, October 11, from an accidental poisoning.

Robert Green Holloway, Port Royal, Va.; University of Pennsylvania, Philadelphia, 1856; aged 86; a Confederate veteran; died at his home, October 14.

Willett Wells Brown \* Montclair, N. J.; New York Homeopathic Medical College, 1910; aged 36; died at his home, October 18, from pneumonia.

Harry F. Walsh, Crawfordville, Ind.; Northwestern University Medical School, Chicago, 1898; aged 46; died at his home, September 14, from paresis.

J. D. Sasser \* Middleton, Tenn.; University of Louisville, Ky., 1871; aged 72; died in the Baptist Hospital, Memphis, Tenn., August 17, from nephritis.

Charles E. Paul, Litchfield, Neb.; St. Louis College of Physicians and Surgeons, 1902; aged 49; died at his home, October 8, from heart disease.

Martin Franklin VanBuren, Tacoma, Wash.; University of Medicine, Ann Arbor, 1871; aged 65; died at his home, October 11, from heart disease.

Carl Addison Allen \* Holyoke, Mass.; Long Island College Hospital, Brooklyn, 1874; aged 72; died at his home, September 11, from tuberculosis.

Simon M. Dubin, Philadelphia; University of Berne, Switzerland, 1896; aged 52; died at his home, October 15, from valvular heart disease.

August J. Beyer, Carmine, Texas; Memphis (Tenn.) Hospital Medical College, 1906; aged 37; died in a hospital in Austin, Texas, October 7.

William S. Mundhenk, Brookville, Ohio; Medical College of Ohio, Cincinnati, 1876; aged 68; died at his home, October 8, from heart disease.

Riley B. Womack, Prendergast, Tenn. (license, Tennessee, 1889); aged 75; was shot and killed in an affray near Patten, Tenn., September 26.

Louis Joseph Roy, Indian Orchard, Mass.; University of Victoria College, Celanorg, Ont., 1880; aged 61; died at his home, September 30.

Adolph Ludwig Barcus \* Philadelphia; Jefferson Medical College, 1891; aged 55; died at his home, October 12.

## The Propaganda for Reform

IN THIS DEPARTMENT APPEAR REPORTS OF THE JOURNAL'S BUREAU OF INVESTIGATION, OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORY, TOGETHER WITH OTHER MATTER TENDING TO AID INTELLIGENT PRESCRIBING AND TO OPPOSE FRAUD ON THE PUBLIC AND ON THE PROFESSION

### SOME MORE MISBRANDED NOSTRUMS

**Tubbs' Bilious Man's Friend.**—The Tubbs Medicine Company, River Falls, Wis., shipped a quantity of "Tubbs' Bilious Man's Friend" in August, 1916. In March, 1918, an information was filed against the concern charging that the product was misbranded. The Bureau of Chemistry reported that analysis showed the preparation to be a water-alcohol solution of sugar and plant extractives (rhubarb) with a very small amount of aromatics. The preparation was falsely and fraudulently advertised as a remedy for liver and kidney troubles, rheumatism, backache, indigestion, scurvy, worms, piles, malaria, and as a preventive of appendicitis and rheumatism. It was further misbranded in that the label declared the presence of 20 per cent. alcohol when, as a matter of fact, the product contained only 13.2 per cent. of alcohol. In July, 1918, the company pleaded guilty and was fined \$100. [Notice of Judgment No. 6461; issued Oct 18, 1919.]

**Fruitatives.**—In June, September and October, 1918, some 266 large packages and 388 small packages of "Fruitatives" were shipped from Fruitatives, Ltd., Ogdensburg, N. Y., into the state of Maine. The federal authorities declared the product misbranded, first, because the claims and pictorial devices on the label were false and misleading in that they conveyed the impression that the laxative properties of the product were due to the fruit or fruit extracts, "when in fact they were not"; second, that the nostrum was labeled as "antiseptic" which it was not; third, the "patent medicine"

bore the inscription "harmless" which "was false and misleading in that it was not harmless but contained an active poison nux vomica (strychnin)." The stuff was further declared misbranded because of the false and misleading claims of curative effect, such as:

- "Strengthens the stomach and liver."
- "Stimulates the kidneys."
- "Tends to purify the blood; tones up the nervous system."
- "Relieves . . . Recurring Headaches, Dizziness, Backache."

The government's cases came on for hearing in December, 1918, and February, 1919. The products were condemned and the court ordered that they should be destroyed by the United States marshal. [Notices of Judgment No. 6459 and 6477; issued Oct. 18, 1919.]

**Deerfield Water.**—In August, 1916, the Deerfield Mineral Springs Company, Deerfield, Ohio, shipped a quantity of "Triple Bi-Carbonate, Deerfield Water" which was adulterated and misbranded. In March, 1918, an information was filed against the concern. The water was declared adul-

terated "for the reason that it consisted in part of a filthy, decomposed and putrid animal and vegetable substance." It was declared misbranded because the labels "falsely and fraudulently represented it as a cure for stomach trouble, kidney disease, uric acid poisoning and liver troubles when in truth and in fact it was not." It was further alleged to be misbranded because the quantity of the contents was not plainly and conspicuously marked on the package. In February, 1919, the company pleaded guilty and was fined \$50 and costs.—[*Notice of Judgment No. 6482; issued Oct. 18, 1919.*]

**Robinson Spring Water.**—This product has been the subject of previous seizures on the part of the federal authorities because of false claims made for it. In December, 1917, C. L. Bradley of Pocahontas, Miss., shipped twenty-five crates each containing one 5-gallon bottle of Robinson Spring

Water from Mississippi to Louisiana. In January, 1918, a libel for the seizure of this water was filed on the ground that it was misbranded. It was charged that the claims that this water was effective in Bright's disease, diabetes, gout, rheumatism, indigestion, etc., were false and fraudulent. In February, 1918, the court entered a judgment of condemnation and forfeiture and ordered that the product should be released on the payment of the cost of the proceedings and the execution of a bond.—[*Notice of Judgment No. 6467; issued Oct. 18, 1919.*]

**Mederine.**—In May, 1917, the Northern Drug Company of Duluth, Minn., shipped in interstate commerce a quantity of "Mederine" which was misbranded. In July, 1918, an information was filed against the company. The Bureau of Chemistry analyzed the product and reported it to be essentially a water-alcohol solution containing sugar, potassium iodid, methyl salicylate, salicylic acid, glycerin and laxative plant extractives. It was declared misbranded because it was falsely and fraudulently represented to be a cure for chronic constipation, indigestion, liver complaint, "catarrh," rheumatism, eczema, all blood and skin diseases, kidney trouble, scrofula, pimples, gout, "blood taint," etc., "whereas in truth and in fact it was not." In July, 1918, the company pleaded guilty and was fined \$5.—[*Notice of Judgment No. 6483; issued Oct. 18, 1919.*]

## Correspondence

### "THE INFLUENCE OF DESICCATION ON HUMAN NORMAL ISOHEMAGGLUTININS"

*To the Editor.*—In THE JOURNAL, October 18, Karsner and Koeckert described the deterioration of normal human isoagglutinins within from two to three weeks and loss of group specificity within from three to five weeks, after drying of serums. Owing to the practical importance of this subject in view of the wide adoption of Sanford's method of using serum dried on cover glasses (THE JOURNAL, April 27, 1918, p. 1221), I believe that the results of additional investigations in this subject may be of some interest.

For several years, I have been under the impression not only that drying rabbit antihuman serum in filter paper after

the method of Noguehi results in affording a good method for preserving and handling antihuman hemolysin, but also that the use of these papers yields less agglutination of the corpuscles in the conduct of complement fixation tests than serums preserved in the fluid state. During the past year, two of my students, Sands and West (Experiments on the Removal of Hemagglutinins from Rabbit Antihuman Sera, *J. Immunol.*, to be published), have found that drying these immune serums at room temperature usually results in some deterioration of the hemagglutinins, affording an explanation of the better results sometimes observed in the conduct of complement fixation tests with dried antihuman serum, owing to a reduction or removal of the very bothersome hemagglutinins.

Studies were then made on the influence on hemagglutinins and hemolysins in normal human serums for the corpuscles of persons and certain of the lower animals, of drying the serums at room temperatures on cover glasses as described by Sanford and in filter paper, as described by Hartman (THE JOURNAL, Nov. 16, 1918, p. 1658). The general results of this investigation (Kolmer, J. A.: The Influence of Desiccation on Natural Hemolysins and Hemagglutinins in Human Sera, *J. Immunol.*, to be published), were to show that both hemagglutinins and hemolysins in normal human serums frequently undergo considerable deterioration within the first to the fourth day after drying. However, when human serums containing large amounts of these hemagglutinins were chosen for drying on cover glasses and properly preserved in a refrigerator as described by Sanford, satisfactory agglutination tests were observed over a period of two to three weeks at least. Unfortunately, I did not test the specificity of the agglutinins in dried serums, as have Karsner and Koeckert, and their observations along this line are unique and of considerable interest and worthy of further study. I am quite sure that it is unwise to rely on the results of negative hemagglutination reactions with dried serums in the typing of bloods unless preliminary tests have shown that specific agglutinins remain in the serum for at least a week after drying. The natural hemolysins in human serums for the corpuscles of persons and certain of the lower animals were found even slightly more susceptible to deterioration by desiccation.

While immune hemagglutinin, as that for human corpuscles, produced in rabbits as a result of immunization with human blood also undergo deterioration when the serums are dried, yet the amount present in the serum of a well immunized rabbit is so large that after the serum has been dried on cover glasses and the latter have been kept in a refrigerator, sufficient agglutinin escapes destruction to yield strong and very satisfactory results. The problem at hand is the production of these immune agglutinins specific for the four types of human corpuscles. I hope to be able to report my experiments in this field in the near future, but may state at present that multiple injections of any one type of corpuscles in rabbits results in the production of most agglutinin for these cells, and that the group agglutinins for the other types of corpuscles also produced may be removed by methods of absorption. These experiments offer considerable hope that it may be possible to produce specific agglutinating serums for all types of human corpuscles and thereby greatly facilitate the typing of bloods.

I may also state in this connection that the practice of relying on agglutination tests alone for the matching of bloods prior to transfusion is open to criticism. In the course of an investigation on hemolysins and agglutinins in normal human serums for the corpuscles of persons and the lower animals, conducted by M. E. Trist, A. M. Flicke and myself (A Study of the Natural Thermolabile and Thermostable Hemolysins and Hemagglutinins in Human Sera in Relation to the Wassermann Reaction, *Am. J. Syphilis*, to be published), it was found that hemolysins may be present in serums free of agglutinin for the same corpuscles, and it is possible that these isohemolysins may be responsible for some of the reactions following the transfusion of bloods free of agglutinins. For this reason I believe that tests preliminary to blood transfusion should include an examination for hemolysins as well as agglutinins, and dried serums are not suitable in tests for the latter. For these reasons, I agree

## Book Notices

### COMING EXAMINATIONS

- ARKANSAS: Little Rock, Nov. 11-12. Sec. Regular Board, Dr. T. J. S. Orr, Brickley, Sec. Elective Board, Dr. Claude E. Laws, 803 1/2 Garrison Ave., Fort Smith.
- CONNECTICUT: New Haven, Nov. 11-12. Sec. Regular Board, Dr. Charles A. Tuttle, 196 York St., New Haven. Sec. Homeopathic Board, Dr. Edwin C. M. Hall, 82 Grand Ave., New Haven. Sec. Elective Board, Dr. James E. Hair, 730 State St., Bridgeport.
- DELAWARE: Dover, Dec. 9-11. Sec. Regular Board, Dr. P. S. Downs, Dover. Sec. Homeopathic Board, Dr. H. W. Howell, 824 Washington St., Wilmington. Pres. Medical Council, Dr. Henry W. Briggs, 1026 Jackson St., Wilmington.
- FLORIDA: Tampa, Dec. 1-2. Sec., Regular Board, Dr. Wm. M. Rowlett, Citizens' Bank Building, Tampa.
- ILLINOIS: Chicago, Dec. 1-3. Mr. F. C. Dodds, Supt. of Registration, Springfield.
- IOWA: Des Moines, Dec. 16-18. Sec., Dr. Guilford H. Sumner, Capitol Bldg., Des Moines.
- KENTUCKY: Louisville, Dec. 2. Sec., Dr. A. F. McCormack, 532 W. Main St., Louisville.
- LOUISIANA: New Orleans, Dec. 1-3. Sec., Regular Board, Dr. E. W. Malher, 141 Elk Place, New Orleans.
- MAINE: Portland, Nov. 12-13. Sec., Dr. Frank W. Searle, 776 Congress St., Portland.
- MARYLAND: Baltimore, Dec. 9-12. Sec., Dr. J. McP. Scott, 137 W. Washington St.,agerstown.
- MASSACHUSETTS: Boston, Nov. 11-13. Sec., Dr. Walter P. Bowers, Room 501, No. 1 Beacon St., Boston.
- NEBRASKA: Lincoln, Nov. 12-14. Sec., Dr. H. J. Lehnhoff, 514 First Nat'l Bank Bldg., Lincoln.
- NEBRASKA: Columbus, Dec. 2-4. Sec., Dr. H. M. Platter, State House, Columbus.
- SOUTH CAROLINA: Columbia, Nov. 10. Sec., Dr. A. Earle Boozar, 1806 Hampton St., Columbia.
- TEXAS: Galveston, Nov. 18-20. Sec., Dr. M. F. Bettencourt, Mart Texas.
- VIRGINIA: Richmond, Dec. 9-12. Sec., Dr. J. W. Preston, 511 McHain Bldg., Roanoke.

### Virginia June Examination

Dr. J. W. Preston, secretary of the Virginia State Board of Medical Examiners, reports the written examination held at Richmond, June 17-20, 1919. The examination covered 9 subjects and included 90 questions. An average of 75 per cent. was required to pass. Of the 49 candidates examined, 44 passed and 5 failed. Twenty-three candidates were licensed through reciprocity. Eleven candidates were licensed on Army and Navy credentials. One candidate was granted an osteopathic reciprocity license. The following colleges were represented:

THE AMERICAN ILLUSTRATED MEDICAL DICTIONARY. A New and Complete Dictionary of the Terms Used in Medicine, Surgery, Dentistry, Pharmacy, Chemistry, Nursing, Veterinary Science, Biology, Medical Geography, Etc., with the Pronunciation, Derivation, and Definition, including much Collateral Information of an Encyclopedic Character; Together with New and Elaborate Tables of Arteries, Muscles, Nerves, Veins, Etc.; of Bacilli, Bacteria, Diplococci, Micrococci, Streptococci, Ptomaines and Leukomains, Weights and Measures, Eponymic Tables of Diseases, Operations, Signs and Symptoms, Stains, Tests, Methods of Treatment, Etc. By W. A. Newman Dorland, A.M., M.D. F.A.C.S. Tenth Edition. Leather. Price, \$5.50. Pp. 1201. Philadelphia: W. B. Saunders Company, 1919.

This new edition contains several hundred new words. Aside from this important fact, the dictionary remains much as usual—a complete and valuable work containing many convenient tables and charts, and a complete historical reference, for which the editor of the dictionary is indebted to Dr. Fielding H. Garrison. Unfortunately, a dictionary cannot discriminate but must define. At the very beginning of the book we learn that capital "A" is a symbol for *argon*; also abbreviation for *accommodation, acetum, anode and anterior*; and that little "a" is (1) an abbreviation for *accommodation, ampere, anode, anterior, aqua, water, and arteria*; (2) symbol for *total acidity*. This unfortunate condition deserves some remedy but, unfortunately, the dictionary can only point out the evil, not remedy it. In the same way other linguistic novelties may be noted until the final "Z. Z. Z." which concludes the book. However, this review might well conclude with a statement especially true concerning the book under discussion, but not always so true in many book reviews in which it frequently appears, namely, "This is an exceedingly instructive and interesting reference work."

CHRONIC TRAUMATIC OSTEOMYELITIS: ITS PATHOLOGY AND TREATMENT. By J. Renfew White, M.B., F.R.C.S. Cloth. Price, \$3. Pp. 144, with 37 illustrations. New York: Paul B. Hoeber, 1919.

This deals with the many difficult problems involved in the management of chronic traumatic osteomyelitis. The keynote of the book is thoroughness: a complete preoperative diagnosis, a thoroughgoing operation, and painstaking after-treatment. Every phase of the disease, from beginning to end, is carefully considered, and the logic of each step in treatment is made clear by exposition of the pathologic condition it is intended to correct. We might desire a more critical discussion of the subject of bone regeneration, and much of value has been left unsaid concerning the classification, pathogenesis and roentgenologic diagnosis of bone sequestrums. As an example, it may be pointed out that a bone sequestrum, being dead, is avascular and does not undergo absorption; the surrounding living bone becomes atrophic from disuse and as a result of the inflammatory reaction; in addition, the sequestrum either lies in a lake of pus or is embedded in granulations; therefore, sequestrums tend to cast denser shadows in roentgenograms than adjacent living bone, and are surrounded by a zone which casts a light shadow in contrast to living bone and sequestrum. These very important characteristics are illustrated in the frontispiece, but apparently have escaped the author's attention. The book is, nevertheless, an excellent work and a practical contribution to medical literature.

APPLIED ANATOMY AND KINESIOLOGY. The Mechanism of Muscular Movement. By Wilbur Parlon Bowen, M.S., Professor of Physical Education, Michigan State Normal College. Second Edition. Cloth. Price, \$3.50. Pp. 334 with 197 illustrations. Philadelphia: Lea & Febiger, 1919.

This book discusses the mechanism of bodily movement, and describes the principal types of muscular exercise, stating how they are performed, how they react on the body, and how they may be utilized in the prevention and cure of certain defects and deformities. It is a description of the mechanics of the most intricate and perfect machine ever devised—the human body. The book forms an excellent basis for work on physical training, especially for those interested in the orthopedic cure of physical defects.

of the end against the skin was plainly visible. Thereafter the plaintiff's injured limbs were exhibited to the jury that the latter might see the exact appearance of the ends of amputated limbs. The court has no hesitancy in saying that the exhibition of the injured limbs to the jury did not constitute error. The general rule is that evidence of this kind is admissible, when material to the issue, subject, however, to the right of the trial court in the exercise of a sound discretion to prevent unnecessary abuses in the offering of such evidence.

**Charges Filed in Time for Revocation of License**

*(Lewis v. State Board of Medical Examiners (Ga.), 99 S. E. R. 147)*

The Court of Appeals of Georgia, Division 1, in this case wherein defendant Lewis appealed to the superior court from an order of the state board of medical examiners that his license to practice medicine be revoked, holds that the evidence in the case demanded the verdict directed by the court against the defendant, and affirms the judgment of the superior court ordering that the license of defendant Lewis, authorizing him to practice medicine in Georgia, be revoked and his name removed from the record of all and any clerk of the superior court of the state. The court of appeals says that the defendant had been convicted of a misdemeanor, larceny after trust, in that when he had been intrusted with \$5 by a woman to purchase a railway ticket for her, which cost \$1.30, he failed and refused to return the balance. This was the only charge that the board relied on in the superior court, and it was on this charge that the verdict against the defendant was directed.

Acting under the Act of 1913, the state board of medical examiners, June 12, 1916, after hearing evidence on certain charges against the defendant, one of them being that he had been convicted of a crime involving moral turpitude, found the charges to be true, and ordered that his license be revoked and his name removed from the records of the clerk of the superior court. The defendant, on the same day, entered his appeal, which was duly certified by the secretary of the board and filed in the office of the clerk of the superior court, June 16, 1916. So far as the record showed, there was nothing to indicate that the case was ever called until it "came on regularly for trial at the October term, 1918," of the superior court, at which time the board presented certain written charges against the defendant, which bore an entry of filing by the clerk of the court, dated April 8, 1918. The defendant contended that this did not meet the requirements of the law; but the court of appeals holds that there was no error in refusing to dismiss the written charges preferred by the board against the defendant, on the ground that they were not filed at the proper time. No time is fixed by the statute when the board shall prefer written charges after an appeal has been entered by the defendant. It was argued that the same rule should apply here as in cases of an award by arbitrators; but there would appear to be a clear distinction between the effect of such an award and the decision of the state board of medical examiners. The award by arbitrators is binding on no one, and is of no legal effect whatever, until properly returned and entered on the minutes of the proper court, while the decision by the state board of medical examiners is a judgment within itself, and is final unless set aside on appeal.

Nor did the court err, there being no insistence that the judgment in the criminal case was void, in refusing to permit the defendant to introduce evidence for the purpose of showing that he was not in point of fact guilty of an offense involving moral turpitude, of which he had been convicted, since the judgment of a court of competent jurisdiction cannot be impeached collaterally, but is to be taken and held as a valid judgment until it is reversed or set aside by the court rendering it.

The writ of error in this case was originally filed in the supreme court, and that court having by formal order transferred it to this court, the transfer of the case was equivalent to a holding by the supreme court that the constitutional questions which the defendant attempted to raise by the writ were not properly made.

**MINNESOTA STATE MEDICAL ASSOCIATION**

*Fifty-First Annual Meeting, held in Minneapolis, Oct. 1-3, 1919*

The President, DR. GEORGE DOUGLAS HEAD, Minneapolis, in the Chair

**Protein Sensitization in Asthma and Hay-Fever**

DR. A. H. SANFORD, Rochester: A group of protein sensitized persons consisted, first, of those who were sensitive to animal emanations, in which group there were twenty-eight persons, the largest number of reactions being to horse dander; and secondly, of a small group sensitive to chicken feathers. Three of these were likewise sensitive to egg white, egg yolk and whole egg, and also to the meat of chicken. The food asthmatics, numbering 100 persons, were subdivided on the type of reaction, although many persons had little in their history to indicate that the particular reaction had much to do with their asthmatic condition. The most important group, comprising exactly one fourth of the members of the food group, were those who reacted to grain. Ten of these twenty-five were placed in a doubtful group, three because of their age, as asthma coming on after 40 is not usually due to protein sensitization, and the other seven because of repeated evidence of bronchitis which made it seem that infection was the chief factor, although food cannot be excluded entirely. Fifteen of the twenty-five were definitely sensitized to the cereals named. Wheat protease is the most common offender of this group, although rye occasionally gives reactions. The attempt to use "war bread" was mentioned as bringing to light the fact that there were many food asthmatics. While quite a number of patients were sensitive to vegetables, there were really very few foods of this sort that seemed to have much influence on the asthma. Potato is probably one of the worst offenders among the vegetable group, and some patients are relieved of their symptoms by omitting this vegetable from the diet. Fruits have very little to do with asthma, although banana occasionally gives marked reactions, and one case was undoubtedly due to this fruit. One of the most important groups contains the persons who develop asthma after hay-fever. These persons are classed among the seasonal asthmatics, as the pollens of certain weeds, notably ragweed, and occasionally timothy, are responsible for their hay-fever. Food asthmatics are best handled by eliminating particular foods from the diet. Those sensitive to animal emanations may be desensitized with doses of the offending proteins, and the hay-fever patients are treated with a series of injections of extracts of the particular pollen, starting twelve weeks before the onset of their hay-fever. Asthma should not be treated without first considering the patient's history and whether he may be sensitive to some particular protein.

**Treatment of Dermatologic and Syphilitic Cases in the University of Minnesota Dispensary**

DRS. S. E. SWETZER, JOHN BUTLER and H. G. IRVINE, Minneapolis: The scheme of treatment of syphilitics admitted to the University of Minnesota dispensary is determined by the stage or duration of the disease. We recognize (1) early primary syphilis with the chancre as the only symptom and a negative Wassermann reaction; (2) early syphilis with a chancre and glandular adenopathy and a positive Wassermann reaction; (3) evidence of secondary or tertiary stage of syphilis; (4) congenital syphilis; (5) early or late nerve involvement; (6) tabes and paresis, and (7) visceral syphilis. In cases of established secondary syphilis or the tertiary stage of the disease, three years' treatment followed by from one to two years' observation is recommended. During the

last year, from twelve to eighteen doses of arsphenamin are given in courses of from four to six injections given at intervals of from three days to a week. Between the courses of arsphenamin are given three courses of injections of mercuric salicylate. These injections are given twice weekly. In cases of hereditary syphilis, the arsphenamin and mercury treatment is used as in the acquired cases, but the arsenic dosage is necessarily smaller, from 0.2 to 0.4 gm. being used. The mercuric salicylate intramuscular injections or internal medication is not considered practicable in these cases. Mercurial injections are used almost exclusively. Cases of early or late nerve involvement, syphilis of the special sense organs, tares, paresis and visceral syphilis are treated individually. Most of these patients require intensive treatment over a long period of time. The diagnosis and energetic treatment of the early case of syphilis should be emphasized, the proper interpretation of the Wassermann test should not be forgotten, and the need of a lot of both arsphenamin and mercury for the established case is imperative.

#### Treatment of Tuberculosis of the Spine

DR. H. W. MEYERLING, Rochester: Of 100 patients operated by a bone graft operation, 48 per cent. had had symptoms from one to four years; 22 per cent. gave a history of trauma; 27 per cent. had tuberculosis in other organs, the lungs, joints, testicles, peritoneum, etc., before symptoms were manifest in the spine. Following operation, patients are kept in bed on an average of six weeks on a Bradford frame or a plaster-of-Paris cast, followed by a Taylor brace to be worn for from six months to one year. However, no definite rule can be laid down as to the period of recumbency. This must be left to the judgment of the attending surgeon. General hygienic care and the Rollier sunshine treatment are advisable. Children under 5 years of age, and adults with complications such as pulmonary lesions, sinuses, etc., are poor surgical risks. Eighty-six per cent. of the patients were relieved of clinical symptoms; 8 per cent. died; 3 per cent. have not been heard from, and 3 per cent. are unimproved.

#### Surgery of the Kidney

DR. E. S. JENN, Rochester: Of nineteen cases of pelvic kidney, nine patients required operations because of a pathologic condition of the kidney. In the other ten cases, the kidney was apparently functioning normally. The position of the kidney is usually not an indication for operative treatment. In a few cases in which intermittent hydronephrosis is suspected, surgical treatment may offer some aid, but the results may be none of the best. In cases of injury to the kidney in the presence of severe hematuria, early exploration is advisable, as infection may result if prostration is allowed. Repair of torn tissues or nephrectomy may be the operation of choice. In considering hydronephrosis, the complete ligation of the ureter causes ultimate atrophy of the kidney, and in no case has a hydronephrosis followed this method in my experience. Kidney tissue will recover and function normally after release of a ureter that has been ligated for fourteen days. The usual cause of hydronephrosis is a bladder to flow of urine over a long period. This may be due to the altered position of the kidney or to the pressure of an aortal vessel. Surgery should be advised with reserve in these cases; if there is mechanical deformity of the ureter, however, a plastic operation may be indicated, although the results are not always satisfactory. The hematuria is relieved if the kidney usually demand surgical treatment. Pyelitis and pyelonephritis are usually bilateral. Drainage or prosectomy may be indicated. Pyonephrosis may result from infection of a hydronephrosis or in association with stone; it also occurs bilaterally in prostatic enlargement and bladder stone. If it is unilateral, nephrectomy is indicated; if it is bilateral, drainage and removal of the stone from one kidney at a time appears to offer the best results. In tuberculosis of the kidney, if the disease is confined to one kidney, nephrectomy should be done. In bilateral cases, if one kidney is only slightly involved, the more diseased kidney should be removed. If active tuberculosis exists in the kidney, a healed or fairly active lesion

in the lung is not a contraindication to removal. Benign tumors are rare. Polycystic disease is more frequent, but is not essentially surgical. Experience with the Rovsing operation has not been satisfactory. Early removal of hypernephroma offers a fair prognosis. In advanced cases, radium should be employed. The carcinomas and sarcomas in children will generally recur if removed. Nephrectomy was performed on 239 patients, with a mortality of 2.9 per cent. Three of the deaths were in cases of tuberculosis, one of chronic nephritis and bilateral pleuritis, two of pyonephrosis, and one each of hemorrhage, thrombophlebitis, infection and metastasis and acute nephritis.

#### Hypertension in Its Clinical Aspects

DR. F. J. HIRSCHBOECK, Duluth: The diagnosis between essential hypertension and renal hypertension is often very difficult, particularly in the ambulant cases usually encountered in private practice. The factors of special importance in designating a case as renal are the higher values in the pressure readings, the degree of anemia, the frequent occurrence of gastric and respiratory symptoms, and lastly, the positive evidence of one or more of the renal functional tests, or the test for nitrogen retention products and more typical objective signs, such as albuminuric retinitis and albuminuria hyposthenia. Moderate hypertension usually occurs in hyperthyroidism and in pituitary disease. It is characterized also by increase in the pulse pressure. It is difficult to say whether cases at the menopause are due to disorders of the glands of internal secretion or whether the time of occurrence is merely coincidental, and that it may be due to other causes. We are certain, however, that there is nothing uniform about the elevation of blood pressure in women at the menopause. In mitral and aortic insufficiency there is usually an increase in the blood pressure, and the increase in the pulse pressure of aortic insufficiency is strikingly demonstrated when these cases are studied. Asthma, in our experience, has not shown any cases of hypertension. Diabetes per se is probably not a cause of hypertension. In lead poisoning we find a uniform elevation in our readings. In the decreescent type of arteriosclerosis there is an elevation of blood pressure in a small percentage of cases, but renal complications are the rule. In syphilis, although there are certain features, such as intracranial disease, aortic insufficiency and nephritis, which make for high pressures; yet there is a certain percentage of cases in which there is an elevation of blood pressure, moderate in degree, and not ascribable to one of these lesions. We cannot say dogmatically to what this is due; nevertheless, certain cases of syphilis show a hypertension aside from the causes mentioned.

#### Tuberculosis of the Thyroid

DRS. W. A. PLUMMER and A. C. BRODERS, Rochester: In seven cases of tuberculosis of the thyroid, the diagnoses were made following thyroidectomy. Three of the patients had symptoms, physical findings, thyroid signs, and basal metabolic rates typical of high grade exophthalmic goiter. Microscopic sections showed much parenchymatous hypertrophy, as is usual in exophthalmic goiter. Two patients had mild but definite hyperthyroidism, one probably had hyperthyroidism, and one had no symptoms or findings indicative of exophthalmic goiter. The latter four patients had small, hard, nodular glands suggesting carcinoma of the thyroid. Microscopic examination of three of these disclosed a great deal of gland destruction with a slight amount of parenchymatous hypertrophy. The last patient had no symptoms of hyperthyroidism owing to the very extensive destruction of the parenchyma of the gland. The striking point in these cases is that in six of them signs of hyperthyroidism were definite. The greater the tuberculous involvement, the less severe the toxic symptoms. There was nothing decisive to indicate that tuberculosis preceded the hyperthyroidism. No other foci were found on examination. One patient had myxedema following operation.

#### Treatment of Empyema by a Closed Method

DR. FRANK M. MANSON, Worthington: A 7 mm. trocar with cannula is introduced into the pleural cavity. The

trocar is withdrawn, leaving the cannula in place until a 24 F. catheter, with one terminal and two lateral openings, has been introduced. The pus is withdrawn with a 30 c.c. Luer syringe. Then, from 20 to 30 c.c. of surgical solution of chlorinated soda are injected into the cavity and sucked in and out to dissolve the fibrous masses. The cavity is then nearly filled with this solution, which remains for from ten to thirty-one minutes. The treatment is repeated from four to six times in the twenty-four hours, the frequency depending on the condition of the patient and the rapidity with which the pus accumulates. The tube remains clamped except when aspirating or injecting. All cases are controlled by laboratory count. When the discharge becomes sterile to culture and the cavity has diminished to a capacity of 15 or 20 c.c., the tube is withdrawn and the opening allowed to heal. Of forty-three patients treated by this method, all were cured; none had to have secondary operations.

**Palliative Treatment Versus the Radical Treatment of Trifacial Neuralgia**

DR. A. W. ANSON, Rochester: The average duration of the trouble in 310 patients was seven years. There were fifty-two ophthalmic division involvements; 237 supramaxillary division involvements, and 228 mandibular division involvements; 805 alcohol injections were administered, and seventy-one extractions of teeth, ninety-three avulsions or resections of peripheral branches, eleven nasal operations, and eleven mandible operations were done. Ninety-five patients submitted to radical operations; nine of these were ganglionectomies; four were removals of gasserian tumors; forty-nine were avulsions or resections of the posterior root, and thirty-three were incisions of the posterior root. Five of the radical operations were secondary, being due to incomplete division of the posterior root at the primary operation. Of the four deaths, two were due to hemorrhage, one to meningitis and one to senility. In making a summary of the results, it is found that in this group of 318 patients there was a total of 1,008 palliative surgical treatments, including 805 alcohol injections and 203 other palliative procedures. Since only ninety patients have had the radical operation with a consequent relief from pain, the remaining 228 are still seeking relief by temporary methods. I am convinced, after dividing the posterior root in seventy-four cases, that, after one or two alcohol injections, the radical operation is indicated in all operable cases in preference to the continuation of palliative procedures.

(To be continued)

**DELAWARE STATE MEDICAL SOCIETY**

Annual Meeting, held in Dover, Oct. 13 and 14, 1919

The President, DR. L. S. CONWELL, Camden, in the Chair

**Diseases of the Bile Ducts and Gallbladder**

DR. I. J. MACCOLLUM, Wyoming: Micro-organisms are not found in normal bile; and when bile contains bacteria, a state of disease exists. This diseased state may not give rise to active symptoms and lead to immediate deleterious influences, but is a constant source of danger should there develop an intercurrent disease or should the person's vitality become lowered by overwork, nervous or mental exhaustion, or some gastro-intestinal disturbance. All inflammatory processes of the gallbladder predispose to gallstones. Bacteria, bile salts that have been thrown out of solution and crystallized, a mass of desiccated epithelial cells, a plug of mucus and inflammatory debris may serve as a foundation on which gallstones are formed. A gallstone may lie dormant in the gallbladder for years and never give rise to any perceptible symptoms unless there is an associated inflammation; or unless the duct becomes occluded and stagnation occurs; or unless, for various reasons, a stone enters or starts to enter a duct. The diagnosis of cholelithiasis is not difficult in some cases; but in those cases in which the symptoms are vague and ill defined, the physician is taxed to the limit. The treatment consists of a well regulated diet with

absence of rich and fat foods, outdoor exercise, vegetables, large quantities of water, cold baths, and alkalis internally. The bowels should be kept regular, and systematic habits encouraged. Operation should be performed for repeated attacks of colic even if there is no jaundice present.

DISCUSSION

DR. JAMES A. DRAPER, Wilmington: In the majority of cases of gallbladder diseases, a careful examination will give evidence of previous inflammation of the appendix. Frequently it follows typhoid. In all cases of hydrops, the gallbladder should be removed. These cases are practically always caused by a stone impacted in the cystic duct. Drainage, as a rule, is unsatisfactory. The stone remains impacted, and chronic signs follow the drainage operation. The only satisfactory treatment in these cases is cholecystectomy and complete removal of the gallbladder.

**Tuberculosis**

DR. ALBERT ROBIN, Wilmington: Patients with tuberculosis may be classified into two groups: those having tuberculous infection without symptoms, and those who have tuberculous disease with certain definite manifestations. In other words, undoubtedly many persons are infected with tuberculosis whose immunity is sufficient to keep the pathologic process in abeyance. Such individuals are not aware of their infection, which is at times discovered in the course of an examination for some other disease. The group that interests us is that in which the patient presents a symptom with or without physical signs. It is in this group that a careful study of the symptoms will greatly minimize error. Of the symptoms that are most suggestive are: functional atonic dyspepsia; hyperchlorhydria; nausea with or without vomiting, or intestinal indigestion with diarrhea; persistent tachycardia; loss of weight and, generally, a slight elevation of temperature. In my experience, the majority of patients with early tuberculosis present these symptoms long before the development of cough, night sweats and localized physical signs. Tuberculosis is essentially a toxemia. Almost at any stage, the physical signs denoting the underlying pathologic lesions may be present and should be looked for. Frequent examinations of the sputum should be made, the discovery of tubercle bacilli being conclusive evidence of the existence of tuberculosis. Failure to find tubercle bacilli, however, does not exclude tuberculosis, and one should not rest content on negative findings. In the vast majority of cases the roentgen ray will furnish definite evidence. The diagnosis of tuberculosis in children offers few difficulties. When a child is suffering from malnutrition, has a slight fever and is otherwise below par, the chances are 6 to 4 that the case is one of tuberculosis. There is no specific treatment of this disease, and any physician who employs a supposed specific treatment with a promise of cure is obtaining money under false pretenses. What is new and of paramount value in the treatment of tuberculosis is the growing conviction that absolute rest is the only "specific" treatment. As one author puts it, "Rest in proportion to the severity and duration of the symptoms." Rest, either absolute or relative, depending on the degree of activity, should be carried out for weeks or months.

DISCUSSION

DR. JOSEPH W. BASTIAN, Wilmington: A few simple things in the early diagnosis of tuberculosis are the slight rise of temperature in the evening, the increased pulse rate and the stomach disturbances. Many people will go along for months complaining of being in a "run down" condition, but practically not manifesting a detectable lesion. In regard to the roentgen ray, there are many other conditions that will make shadows that will look so much like a tuberculous area that, even with an expert reading the picture, we can take that only as a link in our chain of evidence.

DR. J. C. COOPER, Dover: The army reports show that out of nearly 3,000,000 men subjected to examination, 69,000 were pronounced tuberculous. Men who are physicians in the real sense of the word, and not politicians, should be put on the boards, and then Delaware will know something regarding what tuberculosis really demands. The North American

Jews may practically be blotted out by tuberculosis. The white man will share the same fate if he sits down, as he is now sitting, and lets a lot of ignorant politicians run him and run him.

**Dr. ALGER KOEN, Wilmington:** If one puts the patient with fever and rapid pulse to bed for six weeks and if at the end of six weeks the temperature does not become normal and the pulse does become normal he will never improve. That is a practical point in prognosis.

**Dr. L. S. CONWELL, Camden:** It is as impossible for the state board of health to look after the sanitary conditions in every part of this state as it would be for one lamp to light in a twelve room house. If the physicians of the various towns will put into effect co-operation with their local boards of health, they can do a great deal more toward correcting sanitary conditions and curbing the streams of infection than they can by mixing it up as having anything to do with politics.

#### Roentgen-Ray Treatment of Hyperthyroidism

**Dr. GEORGE C. McFETRICK, Wilmington:** Of all the measures employed in the treatment of goiter, none have been so successful as carefully applied doses of the roentgen ray. I give large doses but am careful not to get a dermatitis. The advantages of the treatment are: There are no fatalities. There is no scar as after operation. It does not interfere with the patient's occupation. It is painless and causes very little inconvenience to the patient. If unsuccessful, an operation may still be performed with less risk because of the favorable action of the roentgen rays on the thymus glands.

#### Autointoxication

**Dr. CECIL DE J. HARBORDT, Dover:** A vast majority of the diseases found in childhood, outside of the eruptive fevers, are caused wholly by the retention of toxic material in the stomach or bowels. Chronic liver troubles are more often than not due to autotoxins, as are many of the more serious renal affections. The numerous forms of dyspepsia and indigestion are all caused more or less by autotoxemia. Even in cases of so-called nervous indigestion, were it not for the absorption of toxins the nerves would not be affected sufficiently to produce the nervous phenomena causing all of the distressing symptoms of this troublesome condition. Treatment in all intestinal and stomach diseases is to clean out the entire tract thoroughly and to place the patient on a proper diet in order to avoid a recurrence of the trouble. It is something to clean out the alimentary canal and quite another to keep it clean and free from putrefactive material. Many manufacturers claim to have a "cure all" for digestive and fermentative troubles, but the fact remains that there is no single drug or combination of drugs that is suitable for every case, for each case is a law unto itself, and calls for some special drug. It is often a most difficult matter to find the cause, the exact poisons that are producing the autointoxication. It may take a long study of the case and symptoms before the seat of the trouble is found; but until one finds it and removes it one cannot expect to effect a cure.

#### Dermoid Cyst in a Child

**Dr. SAMUEL C. BROWN, Wilmington:** M. D., a girl, aged six years, frail looking but always well, except for the distressing attacks of the disease of childhood, came under my observation through the complaint that at times during the past three months she had suffered from cramps and vague pains in the lower abdomen. These increased in frequency and severity. Physical examination in her mother's lap revealed a mass in the abdomen. On palpation I found an irregular shaped tumor the size of an orange above the symphysis and to the left, freely movable, with areas of fluctuation and hardness, and only slightly tender. Vaginal examination was impossible, and by the rectum no information of value was obtainable. At operation I found the tumor to be a dermoid cyst of the left ovary shaped like a potato and measuring  $2\frac{1}{2}$  by 3 inches at its greatest diameters. It was freely movable and without adhesions, but the pedicle showed one-twist to the left. In the growth of this cyst and its gradual rise out of the pelvis into the abdomen, it had pulled on the left broad ligament

until the uterus was only a thin band of muscle, while the cervix was the size of a lead pencil and 2 inches long. The right broad ligament was only slightly stretched, and that tube and ovary normal. After ligating the pedicle, I removed a long appendix. The child made an uninterrupted recovery. Inside this cyst we found the usual oily liquid, and growing into it one of the so-called "dermoid fluids," containing a lump of matted hair and a small fragment of bone.

### MEDICAL SOCIETY OF THE STATE OF PENNSYLVANIA

*Six Ninth Annual Meeting, held in Harrisburg, Sept. 22-25, 1919*

*(Continued from page 1389)*

#### Impressions Resulting from Experience in the Pennsylvania Legislative Session of 1919

**Dr. FREDERICK L. VAN SICKLE, Olyphant:** Every legally qualified practitioner of medicine must become interested in organized medicine. There is needed a united and strong organization of the medical profession which shall have an influence on constructive legislation. It would seem desirable that the pulse of the medical profession be noted prior to the passage of certain acts relative to the department of health and of education, that their application with less friction be possible. Of the important subject of publicity regarding legislative opinion, such publicity should come from our own ranks; we should maintain a bureau to furnish the press with properly prepared items. It seems not unreasonable that the attitude of organized medicine toward the legislative problem should be a preparedness to defend its rights and to advise on measures affecting the welfare and health of the public.

#### SYMPOSIUM ON GOITER

##### Thyroid Disease

**Dr. HENRY S. PLUMMER, Rochester, Minn.:** The exophthalmic goiter is seldom missed by relatively good men. Adenomas and hyperthyroid are constantly missed by the best men because many circulatory troubles attributed to myocardial degeneration do not suggest hyperthyroidism. When we are dealing with goiter we are dealing with a person who is burning food too fast or too slow. That people who have had exophthalmic goiter operations are not well is due to the fact that they still have exophthalmic goiter.

##### Epinephrin Hypersensitiveness Test in the Diagnosis of Hyperthyroidism

**Dr. EMIL GOETSCH, Baltimore:** In clinical states of hyperthyroidism there is an increased constitutional sensitiveness to epinephrin (adrenalin), and in states of hypothyroidism there is an increased tolerance for epinephrin hypodermically administered. I myself have carried out or supervised the carrying out of the test in 300 cases of thyroid disease and in approximately 100 conditions simulating in many respects hyperthyroidism. In a so-called positive reaction there is usually an early rise in systolic blood pressure and a fall in diastolic blood pressures. In a very mild reaction the fall in diastolic pressure may occur alone. There is a rise in pulse rate of at least 10 and sometimes as much as 50 or more millimeters of mercury. In the course of thirty or thirty five minutes there is a moderate fall of the pulse and blood pressure, then a characteristic secondary rise, and then a second fall to the normal in about one and a half hours. Together with these changes one sees an exaggeration of the clinical picture, especially the nervous manifestations.

##### Principles Underlying the Treatment of Toxic Goiter

**Dr. CHARLES H. FRAZIER, Philadelphia:** Patients with toxic goiter from the standpoint of treatment fall into one of five groups: 1. The mildly toxic goiter of the adolescent group. The enlargement of the gland is compensatory in nature, the toxic symptoms are not constant, and when present are of mild degree. Proper supervision of the girl's

life, as to hours of work and sleep, and restriction of studies for the schoolgirl, with a trial of iodine internally, will tide the patient over a period of thyroid disturbance from which, on entering womanhood, she may be entirely free. 2. The mildly toxic of the adenoma group. If under proper supervision there is no tendency to progression, the determination for or against operation will depend in large measure on how much the patient is handicapped either in work or in recreation. Operation is a choice and not a necessity. As a subdivision of this group may be entered the patient of definite neurasthenic type with a small adenoma. These are puzzling cases, and I know of no criterion, when the basal metabolism is not above normal, by which the surgeon is to determine whether or not the neurasthenia is dependent on the thyroid disorder. 3. The grave toxicosis of the adenomas, not the true exophthalmic type, always, but its equivalent so far as the gravity of the prognosis is concerned. If the condition is not already inoperable, as it sometimes is, no time should be lost in inaugurating a course of treatment leading up to an eventual resection. 4. The initial hyperplastic goiter, without the precedence of an adenoma, appearing most often in the early years of the third decade. The prognosis without operation is grave. The operative risks in the early stages are trivial, the period of convalescence is short and the end-results satisfactory. The possibility of a complete recovery in the late stage is appreciably reduced. 5. The degenerative or atrophic or the terminal stage of a more or less prolonged hyperplasia. There comes a time in certain cases when, should the patient survive the hyperplastic stage, definite signs of hypoplasia are apparent. Manifestly here, then, is no justification for the removal of gland tissue.

## DISCUSSION

DR. HAROLD L. FOSS, Danville: Goetsch's test is going to find its greatest value in the hands of the general practitioner. Every patient with goiter who comes to the surgeon has been treated with every sort of drug and chemical one can conceive of until, in the vast majority of these cases, particularly in the exophthalmic forms, the degenerative changes in the heart and nervous system and kidneys are so advanced that these patients are a profound risk. It is due to the fact that the general practitioner has not had at his command a means by which an accurate diagnosis can be made. He will now be able to submit his patients to this test and make positive diagnosis, and a larger number will be referred in time so that the surgeon can bring about a cure. If there is anything pernicious in medicine it is the haphazard treatment of these patients. Unquestionably, surgery is the treatment of goiter in all cases, except the diffuse goiters of young girls and the adenomatous goiters with advanced degenerative changes in the heart.

DR. GEORGE P. MÜLLER, Philadelphia: Toxic adenoma can be cured by operation. In cases of diffuse hypertrophy, one must be cautious as to the prognosis because of the large percentage of recurrence and a certain percentage of failures and mortality. Mortality practically never occurs in an adenomatous case, and does occur in the other type.

DR. ALBERT F. HART, Williamsport: The indiscriminate use of various glandular preparations, and especially the use of electricity, should be condemned. Patients that had been treated by electricity claim their thyroid had been reduced in size. We all know that the size of the thyroid has nothing to do with its toxicity. The small thyroids, scarcely palpable, may be intensely toxic.

DR. ADELAIDE ELLSWORTH, Warren: I wish to attest to the value of the epinephrin (adrenalin) test. I have used it as a routine for months in differentiating the nervous and circulatory disturbances that arise in cases of neurasthenia, hysteria and the psychoneuroses from subacute hyperthyroidism. Many women are called neurasthenics when they are in reality suffering from hyperthyroidism.

DR. EMIL GOETSCH, Baltimore: I have never yet seen a patient who had a had postoperative course if it had had a mild reaction before operation. In those cases in which there was a sharp reaction before operation there was generally a stormy postoperative course. So forewarned, you

get operation through in a hurry, whereas otherwise you are likely to delay a little, and it may be those fifteen minutes that will give you a bad result. If you make the test in this early stage and find it positive, you have a great deal of evidence on your side that you can help the patient by operation. I know that my best results have come from this class of cases. I have not seen a test yet that is infallible; but if it is 95 per cent. good, it is valuable. In regard to cases in which syphilis is present, I do not want to discourage the point of view that there might be a connection between intoxication of syphilis and hyperthyroidism. I think there must be an association between definite syphilis and an expression of hyperthyroidism.

SYMPOSIUM ON DISEASES OF THE  
GASTRO-INTESTINAL TRACT

## Value of the High Rectal Enema

DR. HENRY D. JUMP, Philadelphia: We made persistent efforts with men and women patients in various postures to run the tube into the sigmoid flexure. While this may be done under certain conditions, it is difficult, uncertain and in most instances impossible.

## DISCUSSION

DR. ROBERT A. KELTY, Danville: We have tried on several occasions at a necropsy to pass a tube high, and have found that only under exceptional circumstances will the tube pass the sigmoid flexure at the brim of the pelvis.

DR. THOMAS McCRAE, Philadelphia: The idea is so firmly fixed that there is a difference between giving fluid low down and supposedly high up that it is going to take many years and a great many papers before that idea will get into the minds of more than a comparative few. It is important for nurses in training schools to know this. Much time is lost in teaching nurses how to give this and that sort of enema.

DR. J. J. GILBRIDE, Philadelphia: I do not know that we miss a great deal by being unable to pass a tube high up. Of course, this paper will serve a purpose in emphasizing to others the needlessness of trying to do something that cannot be done.

DR. DAVID J. HETRICK, Harrisburg: Some time ago I had a nurse discharged from a little patient because she persisted in using a catheter high up. She gave the child intense pain. She said it was her teaching.

DR. HENRY K. PANCOAST, Philadelphia: There is one danger in the attempt to give a high enema. When the tube is kinked, considerably more force has to be used to get the fluid into the rectum. It must be given slowly; if given too fast, there is sure to be spasm of the descending colon which will prevent the fluid going very far. The ileocecal valve serves its purpose well when taking care of fecal contents; but when it tries to stop enemas, it has no power to do this and it opens almost invariably. Our time to stop barium enemas is when we see the ileocecal valve give way. One case is on record in which a barium enema has been vomited. I believe that in one instance the tube has been introduced as far as the splenic flexure.

DR. ALFRED T. LIVINGSTON, Jamestown, N. Y.: The only thing that has not been mentioned is the most important of all, and that is the technic of the enema. There is a tendency to spasm if the fluid is introduced rapidly, which causes great pain and obstruction of the flow of fluid. I found that approaching a pint this spasm would occur. When approaching a pint I stop the flow, wait a few seconds, and then slowly begin again. If it passed a pint and a half, I was sure that the sigmoid had relaxed, and then I was sure there was a free passage. As a rule, I give from 4 to 6 pints or even as high as 9 pints.

DR. ALFRED C. WOOD, Philadelphia: It may be worth while to call attention to the danger of making an effort to pass the so-called high rectal tube; but in spite of that, as Dr. McCrae has said, certain individuals still insist on trying. I have known of instances in which not only was the rectum perforated, but the nurse went on with the administration of the enema, all of which was received into the peritoneal

cavity. Therefore, it seems to me that Dr. McCrae's hint should be taken to heart, and all of us who have anything to do with the teaching of nurses should impress on them that it is only in the rarest occasions to pass the tube more than 2 or at most 3 inches, but also if they have a rather rigid tube there is very positive danger in it. In regard to the quantity of fluid that may be administered, I have been at the operating table in a case of severe hemorrhage in which the efforts of the physicians present to sustain the patient until the operation might be concluded were so persistent and aggressive that the physiologic sodium chloride solution put into the patient's bowel finally ran out of the mouth while I was operating. In another case the emema came out of the mouth from the constant desire to overcome, as supposed, fecal impaction, which did not exist.

#### Present Status of Therapeutic Pneumothorax in Pulmonary Tuberculosis

DR. ALEXANDER ARMSTRONG, White Haven: I am convinced that therapeutic pneumothorax is the only new plan of treatment for pulmonary tuberculosis discovered in recent years which has positive value. Selection of the suitable case for the operation requires careful physical diagnosis and usually several weeks of close observation of the patient. Progressive softening is still the indication which most often calls for compression of the lung. Remembering that pleurisy is usually a forerunner of tuberculosis, this treatment should be employed early. I would urge that in every town of more than 10,000 inhabitants one physician familiarize himself with the plan of treatment. If it is used at the right time there will be fewer cases of the advanced type of pulmonary tuberculosis.

#### DISCUSSION

DR. ISADORE KAUFMAN, Philadelphia: We should be very cautious in recommending this procedure to the general practitioner. The suitable case must be selected with much care, and the procedure carried out under strictly aseptic technic. The man who uses the method must be a surgeon working under the direction of a man familiar with tuberculosis, or the injection can be carried out by a man thoroughly conversant with the disease, performing the operation himself.

DR. ALEXANDER ARMSTRONG, White Haven: Regarding the time of giving the treatment, to wait under the expectant treatment longer than six weeks is almost criminal negligence. Admitting that the treatment is on trial, I believe every patient should be given the chance it offers.

#### Medical Treatment of Diseases of the Gastro- Intestinal Tract

DR. JOHN A. LEITCH, Pittsburgh: The points of difference between medical and surgical treatment of diseases of the gastro-intestinal tract center usually about diseases of the appendix, gallbladder, stomach, especially ulcerations, and pancreas. An acute appendicitis is plainly a surgical condition, a chronic appendicitis, which is always difficult to cure, is not receiving the same enthusiasm from the general side as it did formerly, and is receiving more serious attention from the medical man. With reference to peptic ulcer there are still those who feel that it is a surgical condition, and only that. Evidently, the difference of opinion has largely disappeared due to the fact that the surgeon speaks of a chronic ulcer, a chronic, indurated, incurable, peptic ulcer, whereas the physician speaks of an acute ulcer which may heal spontaneously if left alone, or in which the healing may be hastened about more promptly by attention to diet and by the use of well known remedies and procedures. In diseases of the gallbladder, matters are reversed. The acute condition requires medical attention; the chronic condition is usually all cases the surgical condition. In diseases of the pancreas, conditions are very much as with the appendix. The acute condition demands prompt surgical procedure; the chronic condition demands most deliberate study and possibly largely medical and dietetic treatment.

#### Attitude of the General Practitioner

DR. WILLIAM EGBERT ROBERTSON, Philadelphia: The conviction is soon borne in on the general practicing physician

that it is to him that the ailing individual first comes for advice, and that it is his privilege and duty so to study the patient's condition that relief may follow on an exact diagnosis, or that the thorough preliminary study may result in the selection of other counsel most suited to the particular need of the case. It is necessary, not alone to permit the patient to narrate his complaints, but to take a history and make a complete physical examination in every instance. I fear that the tendency on the part of the busy family physician to accept a patient's diagnosis is somewhat frequent. It leads to errors of subsequent judgment, and in consequence, to errors in handling the patient, and it may lead to operation unnecessarily, and because of this fact may jeopardize or even sacrifice the life of an individual, or may postpone till too late an operation that might have promised cure. These are the reasons which make imperative the more careful study of any patient who presents apparent gastro-intestinal symptoms. How often is the physician the advance agent of some drug concern? Thoughtlessly handing out a sample, he may invite the development of a habit of self medication, or may aid in confirming a tendency already in existence. If notes are not kept, and no record of the progress of the patient's condition is made, he is not able to recall the details either of the patient's condition or the treatment, and hence he is forced to rely on the patient's statement for these, as he was for the diagnosis, and the patient is not slow to grasp the situation.

(To be continued)

**Roentgenography of Brain After Injection of Air into Spinal Canal.**—As has been shown by Dandy, one or more of the cerebral ventricles can be outlined sharply in a roentgenogram if the ventricular fluid be withdrawn and replaced by an equal quantity of air. In the course of this work he also noted that in many cases some of the air had passed out of the ventricular system and could be seen in filaments on the surface of the brain, that is, in the sulci. These observations, Dandy believes, point to new possibilities in intracranial diagnostic study. Many lesions of the brain affect part of the subarachnoid space directly or indirectly. These, and no doubt many other conditions, should be demonstrable by the

absence or by the presence of air over the cerebral hemispheres. This air is injected into the spinal canal. By this method the influence of the ventricular system is eliminated entirely; the air passes directly into the cisterna magna and thence into the ultimate ramifications of the subarachnoid space. Dandy cautions that this procedure is not devoid of danger. Medullary distress, even fatal results, might follow from increased intracranial pressure if the amount of air injected were even slightly in excess of the fluid withdrawn. He has injected air intrapneumously into four children and four adults without any bad effect. In this series of eight cases, the location of the lesion was determined accurately in three. In the remaining five, the subarachnoid space was normal. In the three patients in whom the lesion was located by means of intraspinal air, other methods had failed entirely. The findings in these cases are stated briefly.

**Fracture of Skull.**—Wilensky analyzes in detail seventy-two cases of fracture of the skull in which the mortality was 31 per cent. He points out that conservative and expectant methods of treatment, whenever they can be employed safely, yield the best results. He is unalterably opposed to operating indiscriminately in every case of fracture of the skull. Operation is imperative in every case showing the signs of an advancing intracranial pressure. Operation should be done in the early stages before there is evidence of medullary involvement. Irritative or paralytic focal symptoms pointing to pressure on or disorganization of definite cortical areas are the next most important indications of operative interference. Isolated or irregular disturbances of neurologic function can be discarded and in these cases conservative forms of treatment will yield superior results; seemingly these abnormalities have no important therapeutic bearing in the total clinical picture.

**Treatment of Gunshot Fracture of Humerus.**—Smith favors suspension and traction in the treatment of gunshot fractures of the humerus because it gives a favorable posture for treatment of the wound, favors the maintenance of reduction for any type of fracture, and promotes early recovery function.

**Fracture of Lower Third of Femur.**—Van de Velde divides open fractures by missiles into three different types—fractures with: (1) no comminution; (2) slight comminution, and (3) much comminution. For each of those types three different methods of treatment were used at La Panne. Those methods are: (1) wiring; (2) traction on the femoral condyles by ice tongs, Steinman pins, or Willems screws, and (3) Depage's vertical suspension of lower fragment combined with horizontal traction on the leg.

**Barrel Stave Splint in Fracture of Clavicle.**—Royster disclaims originality for this treatment which, it is said, was devised by Dr. Spohn of Corpus Christi, Texas. To apply this barrel stave splint to a fractured clavicle, the center of the stave is found, and this should be placed over the center of the patient's manubrium, at the suprasternal notch. The stave is then sawed off at each end to fit just inside the head of each humerus while the shoulders are drawn backward. One inch from each end a nail is driven into, but not through, the splint. The splint is then padded with cotton, retained by a bandage, and placed in the position as first measured, the concave surface being next to the chest. While the splint is held in place and the shoulders kept firmly back, bandages are tied to the nails, carried under each axilla, and crossed on the back in the figure-of-eight fashion; many turns are made and the stave is drawn as tightly as necessary. If there is a tendency of the splint to turn or to slip, adhesive plaster may be applied to reinforce the bandage, but it is rarely needed. If the patient is a heavy, muscular subject, the arm is put into a sling. The appealing quality of this dressing is its comfort. The patient may use his hands and forearms at will without disturbing the fragments, and he is relieved of the distress which the older dressings give.

**Foreign Bodies Arrested in Duodenum.**—Fisher reports three cases. In the first case a hair pin was fixed in the third portion of the duodenum, one end of the sharp point having become bent at an angle and penetrating the mucous

coat of the duodenum. In the second case, a basting thread remover was fixed in the third portion of the duodenum, the sharp point having penetrated its posterior wall. In the third case, a beauty pin was fixed along the inner edge of the vertical portion of the duodenum, the sharp point having penetrated the bowel. In each case the foreign body was removed successfully by means of a duodenotomy.

**Enuresis of Adults.**—Six cases are cited by Brahdly. He claims that there is a clinical syndrome characterized by occurrence in families, congenital onset, frequent voiding of small amounts of urine with marked urgency, easy fatigue and drowsiness, tenderness to percussion of lower lumbar and upper sacral vertebrae and trabeculated bladder. These cases illustrate a type of bladder disturbance probably due to a congenital hypertonicity of the bladder. The difference between the amount of urine usually voided and the amount of fluid which can be injected, the trabeculated bladder and the powerful urinary stream indicate increased tonus. The lumbar pain, the tenderness of the vertebral column, the frequency and urgency in the absence of any unusual stimulus, the occasional spasm of the abdominal and leg muscles on filling the bladder, indicate hypersensitive as well as hyperactive cord centers. The cases are characterized by an urgent desire to urinate when the bladder contains from 100 c.c. to 150 c.c. of urine. If this desire is not acted on involuntary urination takes place. The physical bladder capacity is only occasionally markedly diminished. The "physiologic capacity," that is, the amount the bladder will hold before the bladder contraction reflex takes place, is always less than half the normal. Remissions occur but are rare, of short duration and not complete. The treatment thus far given in these cases has been very unsatisfactory.

**Cardiac Disease with Extensive Venous and Cardiac Thrombosis.**—Finley reports a case of cardiac hypertrophy and dilatation accompanied by extensive venous and cardiac thrombi. The patient, a woman, 39 years of age, complained of pain in the chest, cough and paralysis of the right arm and leg. Then the left side became paralyzed. Fullness in the supraclavicular region was noticeable, with tenderness along the course of the axillary veins and of the veins at the bend of the elbow, with some enlargement of the veins of the forearm and front of the chest. The hand was slightly swollen and there was marked edema about the elbow. A rounded and tender cord was present in the supraclavicular region and along the line of the brachial vessels. This condition was regarded as a thrombosis of the brachial, subclavian and probably the innominate veins. Then she complained of considerable pain in the right side of the neck and forearm, followed next day by fullness in the supraclavicular region with tenderness extending down to the axilla. A cord was felt along the posterior border of the sternomastoid muscle and along the course of the brachial vessels, the veins of the forearm and front of the chest were slightly swollen and prominent. Swelling of the right arm was present for a few days. During her illness there was considerable dyspnea, often orthopnea, with a moderate grade of cyanosis. The heart almost constantly presented the presystolic gallop rhythm and there was heard only an occasional systolic murmur at the apex. A diastolic murmur heard on admission passed off soon after admission, being only heard on two occasions. The case was regarded during life as probably being one of infective endocarditis. In favor of this view was a heart with failing compensation, fever without other apparent cause, and the presence of emboli. The necropsy findings revealed a hypertrophied and dilated heart, corresponding to the signs found during life. The only trace of endocarditis consisted of an antemortem grayish yellow clot in three chambers of the heart, the ventricles and the right auricle. The largest of these was situated near the apex of the left ventricle where the wall of the heart was thinned and fibrous and its center was broken down and fluid and contained a growth of *Staphylococcus aureus*. Several clots in the right ventricle also contained softened centers.

**Treatment of Burns by Tincture of Iodine.**—The use of a 10 per cent tincture of iodine is endorsed by Mercer as a treatment for burns of all kinds and degrees. The treatment is painful during its application and for a few minutes (four or five) following it, but as soon as the pain is caused is over, the pain that always accompanies the burn is completely suppressed and the patient feels a complete relief. No untoward effects have been noted. The tincture is applied with a piece of absorbent cotton, soaked heavily in the tincture of iodine. Only one application is made. Mercer's experience with this treatment has been very gratifying.

- \*Tetanus Tetraletia with Very High Temperature. G. C. Johnson, Evansville, Ind.—p. 266.

**High Temperature in Tuberculosis.**—Following an attack of measles and whooping cough, Johnson's patient, then 10 years of age, developed pulmonary tuberculosis. She was treated in a camp and was finally discharged with the disease arrested. Three years later her temperature ran an irregular course for which no explanation could be given. She had no cough or physical signs of activity in her chest.

The temperature began to reach 109 and 110 F., going up quickly though never remaining up for more than one or three hours. She did not complain much during these periods, except of headache. The sputum and urine were negative, also the blood, except for moderate leukocytosis. A roentgenogram of the chest showed considerable involvement of the right apex with a small cavity. A number of miliary tubercles were found on the left choroid (examination two years later failed to find any evidence of these). A diagnosis of acute miliary tuberculosis was made on the eye findings. At this time she was suffering with toothache, and an examination disclosed an abscess at the root of one of her teeth. The trouble was corrected, following which her temperature promptly dropped to normal.

**Action of Radium on Yeast.**—Growth promoting factors in yeast may be inactivated partially by means of exposure to radium emanation. It is suggested by Sugiura and Benedict that it is possible that the therapeutic effect of radium on neoplasms may be due in part, at least, to this destruction of growth promoting substance.

**Nitrogenous Extractives and Protein Metabolism.**—The presence in the body of a mechanism regulating the concentration of amino nitrogen in the fluid of the tissues is indicated by Green's work. The importance of this observation and its significance relative to the theories of protein metabolism are discussed.

**Nonamino Nitrogen in Proteins.**—Hiller and Van Slyke found that in the mono-acid fraction of the products of protein hydrolysis, as analyzed by the method of Van Slyke, the nonamino nitrogen, comprising the nitrogen of proline, exo-proline, and one-half that of the tryptophane, can be determined directly by a single Kjeldahl determination. The amino nitrogen is removed by warming with sodium nitrite and hydrochloric acid, the excess of nitrous acid is reduced with a zinc copper couple by Seales' method, and the non-amino nitrogen in the residue determined by Kjeldahl. The results by this method agreed closely, in analyses of casein and gelatin, with the results obtained indirectly by Van Slyke's original procedure, in which the nonamino nitrogen is calculated as the difference between total nitrogen and amino nitrogen.

**Colorimetric Determination of Hemoglobin.**—A method for the colorimetric determination of hemoglobin in blood is described by Cohen and Smith which combines the methods of Sahli and of Palmer. The hemoglobin of whole blood is changed to acid hematin with hydrochloric acid and compared with a standard in a colorimeter. When the Autenrieth-Hellige colorimeter is used, this method is admirably adapted for field use and yields accurate results.

- \*Icthen Plasmus. E. G. Little, London, England—p. 639.
- \*Icthen Plasmus. C. J. White, Boston—p. 671.

\*Hitherto Undescribed Generalized Pigmentation of Skin Appearing in Infancy in Brother and Sister. G. W. Wende and H. H. Bancus, Buffalo.—p. 685.  
Recent Progress with Syphilis. H. G. Irvine, Minneapolis.—p. 702.

**Treatment of Lichen Planus.**—In the treatment of lichen planus, Little places most reliance on a combination of arsenic and mercury. It has been very successful in his hands in all stages of the disease, the acute and intensive cases as well as the chronic cases, especially in controlling itching, which usually yields within a week of treatment. In acute cases it is well to restrict the diet to bread and butter, rice and water for several days at the outset of treatment.

**Treatment of Lichen Planus.**—In White's opinion no internal remedy is worthy of the name in this disease. Menthol in ointment form will temporarily relieve the pruritus. Detergents will tend to reduce the hyperkeratosis. Stimulants will possibly decrease the infiltration. Roentgen rays, in White's experience, have proved a broken reed to lean on.

**Pigmentation of Skin.**—In the two cases cited by Wende and Bancus the pigmentation began when the children were less than 1 year of age, making its appearance first on the scalp and face and then on the trunk until the process involved the entire body. Finally, the skin, especially of the face and trunk, became almost black. No causative factor could be found, either in the parents or in the children. The process suggests abnormal physiologic function rather than pathologic disturbance. The histologic findings were limited to abnormal cells corresponding to chromatophores in the corium and epidermis. The pigment apparently was derived from nuclear material.

\*Dementia Praecox in Twins. M. H. Frantz, New York.—p. 325.  
Nervous and Mental Diseases in the War. J. F. W. Meagher, Brooklyn.—p. 331.

**Bilateral Frontal Hemorrhage.**—Farnell reports the case of a woman, 49 years of age, whose make-up apparently was normal, with a clear history of no previous attacks or upsets. She develops a mental state not unlike the manic form of manic depressive insanity which settled after several months in a hypomaniacal condition. Physically, there was hypertension, blood pressure, 210; albumin in the urine. Approximately twelve months after the onset of this so-called functional psychosis, she had a cerebral hemorrhage with the clinical signs suggesting the intraventricular type. This was followed by a complete change in the mental picture; irregular functional psychosis with thought disorder, which settled into an organic psychosis with obstructive disorders or an intellectual loss. Her physical condition improved, but not her mental state. Within five or six weeks cerebral compression developed and ultimately contributed toward her death. At the necropsy the brain showed bilateral mid-frontal hemorrhage with organization, secondary necrosis and softening of the brain tissue itself. The vascular sclerosis was localized to the cerebral vessel system.

**Menstrual Disturbances in Feeble-minded.**—Seven hundred women, inmates of an institution for the feeble-minded, were examined by Swanberg and Haynes for the purpose of ascertaining those suffering from pathologic menstrual disturbances. Of this number, 425 were menstruating normally; 177 had a physiologic amenorrhea and 108 were suffering from pathologic menstrual disturbances. The most common disorders were irregularity, amenorrhea and dysmenorrhea. The percentage of menstrual disorders was in proportion to the degree of mental deficiency; the lower the mental state, the greater the number of pathologic cases. Amenorrhea and

possibly oligomenorrhea were far more frequent among the lower types—imbeciles and idiots, while the vast majority of cases of dysmenorrhea were among the higher class—the morons.

**Acute Prison Neurosis.**—Yawger describes a prison anxiety neurosis which develops in individuals of constitutional inferiority. The subjective evidence presents in the form of restlessness, decreased power of mental concentration, irritability, hypochondriacal and introspective manifestations, dreams of a disturbing nature often broken by a distressing insomnia, digestive and genito-urinary manifestations, cardiac irregularity or respiratory disturbances. Usually there is appreciable loss of weight and sometimes an increased use of tobacco. Objectively, a tremor may be encountered and generally an increased activity of the skin and tendon reflexes.

**Dementia Praecox in Twins.**—Frantz' patients were twin brothers, 20 years of age. Both had dementia praecox of the catatonic type. One was an inmate of an institution; the other was not in need of any restraint. The family history was fairly good although the father had been very nervous.

**Stomach Spirochete.**—Aside from the fact that this organism was found by Kobayashi and Kasai in the stomachs of a large number of dogs, cats, rats, monkeys and other animals, a point of interest is the belief held by the authors, that the cases of hemorrhagic gastro-enteritis described by Balfour and Luetet are in all probability due to the secondary pathogenicity of this spirochete.

**Human Lung Distome.**—The human lung distome was found by Nakagawa in the crab. He claims that its identity with the larvae of *Paragonimus westermani* is a matter beyond dispute.

Pages of Philippine Islands. O. Bianchi, Florence, Italy.—p. 295.

**Pelvimetry on Filipino Women.**—The data given by Acosta-Sison and Calderon are the result of an examination of 1,237 women. It is evident that the Filipino pelvis is of a type different from either the white American or the negro pelvis, and its average normal measurements are similar to those of the generally contracted pelvis of the white American. The index of the posterior pelvic plane in cases of contracted intertubular diameter is important in the determination of the probable outcome of labor. Contracted pelvis, except in cases of osteomalacia, is rarely an indication for cesarean section among Filipino women. There is practically no difference in the measurements of the pelvic diameters of multiparas and primiparas. The new-born babies of multiparas are longer and heavier than those of the primiparas. The babies of mothers who stayed in the hospital for one or more weeks before delivery are heavier than those whose mothers entered the hospital at the time of labor. The male babies are in greater number and are longer and heavier than the female babies. Labor is longer in primiparas than in multiparas.

Roentgen-Ray Examination of Liver, Gallbladder, and Bile Ducts. R. Klein.—p. 119.

**Biocular Vision and Roentgenography.**—Burdon reports the results of an investigation undertaken to account for the various anomalies that occur in the use of roentgen rays stereoscopically, and to find a means of overcoming them.

**Distortion of Stereoscopic Images.**—While attempting to devise a method of calibration directly applicable to stereoscopic images, the authors of this paper were struck with peculiar discrepancies in the proportions of the image when projected under ordinary working conditions. They were thereby led to a mathematical investigation of the laws governing stereoscopic effects as applied to roentgenography. The investigation brought to light the remarkable fact that only under specially debated conditions is the stereoscopic to be relied on to portray an accurate representation of reality, and that if these conditions are not fulfilled, the resulting effects are distorted in a curious manner. A study of this question was made by the authors and their results show that, in order to obtain stereoscopic images giving a true representation of reality, the tube shift must always be made equal to the distance between the eyes, and also the plates

must, in every case, be viewed at a virtual distance equal to that at which the roentgenograms were taken.

**Distortion of Cardiac Shadows Produced by Varying Distances of Anticathode from Plate or Film.**—The experiments made by Salmon show that to avoid gross distortion of the size of the heart and its great vessels, if an orthodiagraph cannot be used, the distance between the anticathode and the plate should be at least 3 feet, and more if it can be arranged conveniently.

Combined Sclerosis with Heterotopia of Spinal Cord. G. E. Rennie, and O. Latham.—p. 410.  
Diaphragmatic Hernia of Entire Stomach and Great Omentum. J. G. Andrew.—p. 412.

**Materials Used for Nerve Suture.**—An investigation was undertaken by Sargent and Greenfield with a view to ascertaining which of the many materials in general use as nerve sutures was least likely to produce harmful reaction in the delicate tissue of a nerve. They found that while plain thread or silk sutures give rise to no irritation, they are relatively unabsorbable. "Plain sterilized" or "plain iodized gut" are of value by reason of their rapid absorbability, but their low degree of tensile strength and their slightly irritating nature counteract these advantages. "Japanese silk-worm gut" has great tensile strength and in rate of absorbability and the reaction which it causes holds a place midway between thread and silk sutures and catgut sutures. The authors advise that chemical antiseptics should be avoided in all suture materials.

\*Two Cases of Pneumococcus Meningitis of Bacteriologic Interest. H. A. Haig.—p. 431.

**Symptoms of D. A. H. in Neurasthenic Patients.**—Of 100 patients admitted to the hospital for "neurasthenia," thirteen showed well marked symptoms of D. A. H., and fifty-seven had the same condition in lesser degree. The evidence available does not show the same causal relation between previous infection or gassing and "neurasthenia" as holds in the case of D. A. H. No definite relation could be traced by Davies and Priestly between the abnormal Hering-Breuer reflex of D. A. H. patients and the altered tendon reflexes of neurasthenic patients. Attempts to control the Hering-Breuer mechanism by hypnotic suggestion were only partially successful. The respiration could be slowed for a short time while the patient was relaxed, but no permanent effect could be obtained.

**Pneumococcus Meningitis.**—The organism isolated by Haig from one case closely resembled *B. pestis*, and in the second case the clinical aspects were so closely allied to those seen in cerebrospinal meningitis that until the *B. pneumoniae* was isolated from the cerebrospinal fluid the case was considered to be one of meningococcal infection.

**Heterosotherapy in Pulmonary Tuberculosis.**—Perkins and his associates employed the method of heterosotherapy first suggested by Jousset in, 1912 in the treatment of eight cases of pulmonary tuberculosis. In three cases the administration of the pleural fluid was without any apparent effect on the symptoms or course of the disease. In two cases, where improvement coincided with treatment, it is admitted that these two patients had shown signs of improvement before it was commenced. Two were going steadily downhill in spite of other measures of treatment; in both the use of pleural fluid was followed by rapid and marked improvement, in both the cessation of the injections was followed by a tendency to relapse, and in both renewed improvement followed their resumption. Both these patients received injections of the same pleural fluid (from a case of "primary" tuberculous pleurisy) used within a few weeks of its preparation. In the remaining case, though the patient's general condition was good throughout, troublesome symptoms which had persisted for months disappeared within a few weeks of the administration of the pleural fluid. The authors are of opinion that the use of "heterosotherapy" in this disease is worthy of further investigation.

**Hyperkeratosis of Hair Follicles in Scurvy.**—In dealing with about 3,000 cases of scurvy which occurred among Serbian troops, Wiltshire noticed that a condition of hyperkeratosis of the hair follicles was commonly present, in addition to those skin changes which are generally described as proper to this disease. The proportion of cases showing follicular hyperkeratosis amounted to no less than 87 per cent. The follicles which showed this change were usually limited to the lower extremities, the favorite sites being the front and inner aspects of the thighs and the upper parts of the legs. When they were numerous in these regions—and in some instances nearly every follicle was affected—those of the public hairs were often affected as well (20 per cent. of the cases), and sometimes those of the backs of the wrists and forearms (2.5 per cent.). Each affected follicle presented a hard conical swelling about the size of a pin's head, owing to a collection of horny epithelial debris which had accumulated at the follicle mouth. In some cases a thin atrophic hair, or a broken hair stump, projected from the summit of this cone; in others, the hair was wanting, having been shed or broken off flush with the surface. When dirt was present it tended to be incorporated with the material forming the cone, which then, on superficial examination, resembled an ordinary sebaceous comedo. By degrees the conical projection flattened down into a scale, under which, on examination with a lens, a new developing hair could be seen coiled up like a watch spring. At this stage, also, the appearance on casual examination resembled that of a comedo. Later the flattened scale was shed, the new hair erupted and was seen to be growing from a pink recovering follicle. These changes were not simultaneous in all the follicles. When a patient was admitted to hospital it was the rule to find some follicles in the stage of conical swelling with the hair still present, some in the stage of flattened scale covering a new developing hair, and others in intervening stages of broken or shed hairs. The whole process took place gradually and was spread over many weeks. Under treatment recovery was gradual.

**Wheat Culture Medium.**—Experimental results obtained by Otabe show that there is no more value in meat extract cul-

ture mediums than in wheat extract culture mediums. Otabe roasts the wheat (with or without husk) in an iron pan until it becomes brown. One pound of the roasted wheat without washing is placed into 1,600 c.c. of distilled water. This is boiled in Koch's boiler for half an hour, strained through a clean cloth, and made up to 1,000 c.c. with distilled water, if under this quantity. To this is added 0.5 gm. of taka-diastase or ordinary diastase and the flask well shaken. The temperature of the contents at this time should be maintained at from 30 to 40 C. for one-half hour. Then the contents are filtered. The resultant fluid ought to be quite transparent with yellowish color, almost the same as ordinary meat broth. The fluid has a sweet smell, the reaction being slightly alkaline. Five gm. of sodium chlorid and 10 gm. of peptone albumin are added, the mixture boiled and filtered. To make wheat agar, 15 gm. (in winter) or 20 gm. (in summer) of agar are added to the above quantity. For the rest the preparation is almost the same as that of meat agar as usually prepared. Many special culture mediums can be made of the wheat broth and agar medium.

- \* Retrograde Intussusception of Jejunum through Stoma of Gastrojejunostomy. R. Warren.—p. 615.

**Cardiac Massage and Resuscitation.**—Cardiac massage is regarded by Norbury as a very important adjunct to the methods of resuscitation, applicable in cases of heart failure during surgical operations, as also in certain other conditions mentioned. With stoppage of the heart during the performance of an abdominal operation no time should be lost before starting subdiaphragmatic massage, and valuable time should not be wasted in the administration of drugs. Artificial respiration and cardiac massage should be carried out simultaneously. In such circumstances a very few compressions will usually reestablish the heart beat. If heart massage be contemplated, it should be commenced certainly within five minutes of cardiac arrest. Norbury resorts to massage after giving other methods a trial of only two minutes. It may be necessary to continue rhythmical compression of the heart for several minutes before spontaneous contractions occur. In temporarily successful case, the heart was massaged for thirty minutes before it could be made to beat; previous to this ordinary measures had been tried ineffectively for forty-five minutes. Norbury is convinced that the subdiaphragmatic route is undoubtedly the most satisfactory of the various methods of access to the heart for purposes of massage. Artificial respiration should be commenced as soon as normal breathing has ceased, and should be persevered with until spontaneous breathing is reestablished. In obstinate cases, Norbury says, means should be adopted for raising the blood pressure, either by pressure on the abdominal aorta, bandaging the extremities, or the application of Crile's pneumatic suit, if this be at hand. Intravenous infusion of weak solutions of epinephrin in physiologic sodium chlorid solution is also very efficacious, and this is especially applicable in cases where intravenous infusion with physiologic sodium chlorid solution has already been started before the heart stopped, when epinephrin can be added to the solution quickly. In cases where an intravenous infusion is not being already carried out this may be done by using the internal saphenous vein, since the arms will be wanted for performing artificial respiration, or, as an alternative, the common carotid artery may be exposed in the neck, and a weak solution of epinephrin in physiologic sodium chlorid solution be injected forcibly toward the heart by means of a syringe with a fine needle attached. Injection of epinephrin solution into the heart cavities or wall is liable to set up fibrillary twitchings, and is of no use as a means of restoring normal cardiac contractions.

**Antimony in Filariasis.**—Rogers reports on the use of sodium antimonyl tartrate, 1:50 solution, in cases of filariasis. So far as his observations have gone all that can be said at present is that repeated intravenous injections of safe doses of sodium antimonyl tartrate appears to produce a definite diminution of the number of filarial embryos in the peripheral blood, which is probably due to a direct toxic effect on the embryos in view of the great decrease in the activity of their movements observed just prior to a rapid diminution in their numbers. Whether the treatment has any effect on the adult worms in the lymphatics or on the symptoms of the disease remains undecided, but the data so far obtained are sufficiently encouraging to make it advisable to continue the observations.

**Conjugal Tuberculosis.**—Out of 156 cases in which the mate of a tuberculous husband or wife was examined by Ward,<sup>99</sup> persons were found to be tuberculous, 16 suspect and 19 negative. Considering solely wives whose husbands were first notified, out of 120 cases 66 were tuberculous, 12 suspect and 42 negative. While among husbands of tuberculous wives, in 36 cases, 25 were tuberculous, 4 suspect and 7 negative. These figures have been collected over a period of five years. In 15 cases the tuberculous mate first notified has died, and in 7 cases both husband and wife have died of tuberculosis. After following up cases of conjugal tuberculosis for some years Ward takes the view that the great majority of the mates of tuberculous husbands or wives do sooner or later show signs or develop symptoms of tuberculosis; but that the great majority of those infected recover, and make a speedier recovery than most tuberculous patients. This may reasonably be attributed to an enhanced immunity conferred by the graduated doses of bacilli which they usually receive.

**Pfeiffer's Bacillus in Influenza.**—The investigation made by Wilson comprises the examination of forty-three separate specimens of blood. Ten of the specimens were from cases that were definitely not influenza, but included such conditions as vaccinia, mumps, bronchitis, etc. In all of these no agglutinins for the *B. Influenzae* were found. The remaining thirty-three cases were typical examples of influenza of a severe type and all of the patients were suffering from or were convalescing from bronchopneumonia at the date of the examination. Of the thirty-three the blood serum of eleven showed distinctly the presence of agglutinins for Pfeiffer's bacillus. The important point was that the positive cases still manifested elevation of temperature, while those that were negative had been afebrile for periods varying from six to thirty-two days. The study of three cases showed that the agglutinins very rapidly disappear from the blood when the patient becomes convalescent.

**Bronchopneumococcosis in Egypt.**—Of twenty-two persons who spat bloody expectoration, Farah found the condition in six due to bronchial pneumococci, in twelve to tubercle bacilli in two to *B. Pfeiffer*, and in two to bronchomoniliasis. The majority were more or less chronic coughers. In one case the disease was of four years' standing. Practically all the cases of bronchopneumococcosis were taken for phthisis. Examination of the sputum revealed total absence of tubercle bacilli but the specimens were swarming with bronchial pneumococci of varying shapes. In no one case was the tubercle bacillus found in association. Besides hygienic and other measures in the treatment of these patients, arsenic was used with satisfactory results.

**Foreign Bodies in Esophagus.**—Of thirty-seven cases of coins in the air passage collected by Moore during a period of nearly a century (from 1819 to 1915), twenty-two were impacted in the larynx, three were in the trachea, nine in the right bronchus, one in the left bronchus, while the remaining two were stated to be in a bronchus (in which lung was not stated). Seventeen were coughed up (eight assisted by suction), and two were coughed up into the mouth, swallowed, and later evacuated per anum. Death occurred in only four cases—from pulmonary tuberculosis, in three cases and apoplexy in one case. Thyrotomy was performed in one case, laryngotomy in two cases and laryngotracheotomy in three cases (in one of these cases the coin was coughed

up, swallowed, and later evacuated per anum). Laryngeal forceps were used in six cases, no attempts at removal were made in two cases; peroral endoscopy was employed with success in three cases. The longest sojourn of a coin in the larynx was six years and in the bronchi ten years. The remote effects of the sojourn of coins in the respiratory tract were rarely associated with death. Only four deaths in thirty-seven cases is a small number compared with the deaths reported as resulting from the impaction of coins in the food passages. The inaccessibility of the respiratory passages to the coincatcher, bougie and probang, and their consequent safety from the rough treatment generally meted out to the esophagus, in Moore's opinion, appear to be the chief reason of these happy results.

**Retrograde Intussusception of Jejunum Through Stoma of Gastrojejunostomy.**—For thirteen years after gastrojejunostomy Warren's patient remained well. One year ago he began to have abdominal pain after meals and vomiting, which relieved the pain. There were intervals of remission of these symptoms of as much as a month. Two days before Warren saw him he had a worse attack of pain, associated with hematemesis, which continued. An emergency laparotomy was done. A few adhesions of the transverse colon to the abdominal wall were separated, the stomach and pylorus appeared normal in front. Turning up the stomach to examine the stoma, the distal loop of the jejunum coming from the stoma was found to be turgid and purple for 8 inches, at which point the entrance of a retrograde intussusception was found. The intussusception passed up the turgid distal jejunal limb, its apex projecting about 3 inches into the stomach through the stoma. The intussusception was reduced without great difficulty, and had started apparently about a foot below the stoma. The reduced gut was very edematous and purple, but at no point could any thickening suggestive of ulceration be felt. The gut appeared to be viable. The abdomen was closed. The duration of the operation was twenty minutes. After a slight brown vomit the next day the patient improved till the seventh day, when respiration became rapid, and he began to bring up offensive sputum, and finally died on the tenth day. The lungs were in a condition of severe bronchopneumonia with many abscesses; the abdomen, except for slight plastic peritonitis about the site of intussusception and remains of bruising of the intestine, was normal. The gastro-enterostomy as seen at operation proved to be in excellent order, of good size, and well planned. The reason of the retrograde intussusception and its relation to the late dyspepsia and vomiting does not appear certain.

**Paroxysmal Tachycardia.**—Galli relates that in taking several hundred tracings of the heart action he has several times happened on the very instant when a paroxysm of tachycardia began and when it stopped. He analyzes the mechanism as he has thus caught it at work, and compares his findings with the various theories in vogue. They seem to confirm the assumption that the cause may be in some cases merely a functional nervous disturbance traceable to endocrine influences. The prognosis is naturally more favorable than in the cases of intracardiac origin.

- Case of Periodical Vomiting with Acetonemia. M. A. Vassiliou.—p. 543.
- Aplastic Anemia in Children. J. Comby.—p. 545.

**Plastic Peritonitis.**—Morquio has encountered at Montevideo four cases in which a child developed acute peritonitis, and a certain region in the abdomen swelled and became painful. Instead of the anticipated suppuration, however, the hard tumor and the pain subsided, and another patch developed at some other point. The disease progresses by waves in this way, but spontaneously subsides at last by the end of the third month, and the children seemed to be healthy when examined up to ten years later. The ages ranged from 3 to 13. In one case an operation was done for the assumed appendicitis but the appendix seemed to be normal. In another child, infection from the genitals seemed probable; in another the process started in the sigmoid region. But in all the peritoneal picture was the same. The complete and permanent recovery excludes tuberculosis.

**Serotherapy of Purulent Pleurisy in Infants.**—The three cases reported by Nobécourt and Paraf, in infants 2, 4 and 5 months old, testify to the excellent results from antipneumococcus serum in bronchopneumonia complicated with purulent pleurisy. The pneumococcus of type II was cultivated from the pleural effusion and from the nose and throat secretions. The treatment included also hot baths, cool moist packs of the thorax, injections of camphorated oil and inhalation of medicated oxygen. The antiserum was injected into the pleura after evacuation of the purulent fluid, and into the lung, in doses of 5 or 10 c.c. and 3 c.c. respectively. One of the children was injected with it also by the vein. The injections were kept up for three to five days, and a total of 30 c.c. in two and of 60 c.c. in the third case was thus used. Unmistakable improvement followed the serotherapy, and the infants all recovered from their pneumococcus infection.

- \*Twin Tubal Pregnancy in One Tube. Hardouin.—p. 331.
- \*Painless Delivery. Metzger.—p. 342.
- \*The Puericulture School.—p. 359.

**Unitubal Twin Pregnancy.**—Hardouin adds another to the thirty-six cases he has found on record in which two fetuses were found in the ruptured tube. He gives summaries of the entire number, and remarks that as only two fatal operative cases have been reported the total is probably larger, other unfavorable cases not having been published.

**Painless Delivery.**—Metzger gives nearly four pages of bibliography, set solid, dealing with painless delivery, and states that every one of the technics described for the purpose still represent some risk for the mother and for the child. Whatever the procedure or the substance, all agree that the parturient should be under the constant surveillance of a specialist. This being so, he adds, it is not to be wondered at that the more recent publications still extol ether or chloroform which, under good supervision, are no more dangerous perhaps than the newer methods.

**The Puericulture School.**—This new institution is a French-American foundation connected with the Paris Medical Faculty, but it is independent and autonomous. Its statutes are reproduced here with other details of the work. It is designed to develop and coordinate the teaching of puericulture to physicians, students, midwives and nurses; to create a permanent movement for the propaganda of child welfare work of all kinds; and to make appropriations for every form of scientific research tending to improve the hygiene for mothers and for children. The foundation is managed by a council of from fifty to seventy members appointed by the general assembly of the Association. To be a member of the Association one's name must be pre-

sent by two members, and be accepted by the council, and an annual subscription of \$4 paid. The "benefactor" members pay \$20, and the charter members \$100, at least.

- \*Medical Impressions of the United States. Béguin and Piqué.—p. 390. Cont'n.

**Scapulalgia.**—Rocher here reports two new cases of osteoarthritis of the humerus inducing severe pain in the scapula region. He remarks that certain environments and certain seasons of the year render nonsurgical measures practically impossible, while local injections to modify the tuberculous process sometimes actually whip up the process. In these and in his five other cases of scapulalgia a complete cure was finally realized by resection and immobilization. In all, the tuberculous lesion was in the head of the humerus. Some were of the white swelling type and others were dry caries.

**Impressions of the United States.**—Drs. Béguin and Piqué were the official delegates, with Dr. Lemaitre, from France at the Victory Meeting of the A. M. A. and they here review their impressions of this meeting and of their trip afterwards through the country. They express regret that France was represented by only three delegates when even Belgium sent five and Great Britain thirty. They add that they tried to make up in activity for their small numbers, "we multiplied ourselves, taking part in all the ceremonies and meetings and presenting, each, one or more communications." They describe the Victory Meeting and also the university system here in general and in detail, the research institutes, etc., and relate that they were shown a piece of connective tissue which has been kept alive in an artificial medium for seven years in Carrel's laboratory. Every second day the edges are resected. They mention that at the Johns Hopkins "a reading knowledge of French and German is one of the requirements for admission, and the examinations are severe. Farther along the examining boards are more lenient!" . . . "Each of the forty-eight states of the Union mistrusts its neighbor, and a physician admitted to practice in one state cannot practice in a neighbor state until he has passed a new examination. . . . In the United States—so modern from so many points of view—there are still custom house barriers for science."

- Radiosurgical Table. Rechou.—p. 370.

**Radiologic Findings at the Base of Tuberculous Lung.**—Barjon and Longy analyze the findings at the base as a guide for the production of artificial pneumothorax. The research on eleven patients with chronic tuberculosis was confirmed by necropsy, and the details of each case are given. They demonstrate that any modification of the shape and of the shadow cast by a costophrenic sinus must be accepted as testifying to symphysis. There may also be adhesion without any appreciable abnormal findings in the sinus. The existence of symphysis does not necessarily hamper materially the play of the diaphragm. It may modify the amplitude of the excursions of the diaphragm, but the respiratory amplitude of the diaphragm is determined almost entirely by the respiratory capacity of the tuberculous lung. The radiologic examination of the sinus on each side disclosed abnormal findings in only six of the total twenty-two,

but necropsy showed symphysis in seven others also. In every case of symphysis the amplitude was reduced somewhat on that side but the adhesions were responsible for this only secondarily.

**Fluoroscopy Simultaneously in Two Planes.**—Gage is the consulting radiologist at an American Red Cross hospital at Paris. The method he describes, with illustrations, by which the part can be inspected in the screen from two sides at once, is particularly useful in the reduction of fractures.

- Nonpenetrating Toothed Forceps. Id.—p. 192.

**Hydronephrosis of Movable Kidney.**—The kidney had sagged into the pelvis and had developed hydronephrosis which had become infected after a war wound of the knee. A catheter had been introduced into the sagging kidney and water introduced through it into the kidney induced the pain of distention of the kidney pelvis while water introduced into the bladder induced merely a desire for micturition. Recovery was soon complete after the nephrectomy although the latter had been complicated by a threatening hemorrhage. This and Kumpel's case, Rafin adds, are the only ones in which the correct diagnosis had been made before the operation.

**Papillomas in the Ureters.**—Marion is enthusiastic over his success in destroying with the electric current a polyp in the ureter in two cases. The electrode is a little narrower than that used for polyps in the bladder, but otherwise the technic is the same after the lesion has been located with the ureter catheter. A papilloma in the ureter should be suspected when a polyp is found in the bladder near the ureter mouth, in case of hematuria. Also when the ureter catheter releases suddenly a gush of bloody urine, or the catheter is arrested at some unusual point. His two patients were 64 and 76, and both had polyps in the bladder. The hematuria continued after they had been destroyed with the electric current, and the bleeding polyp was located by the arrest of the catheter when introduced to a depth of 5 cm. With a not very strong current he applied the *étincelage* for some time, moving the electrode about all the time but keeping it in the lower portion of the ureter. The pain was no more severe than during destruction of bladder polyps. In the younger woman the success was compromised by polyps in the kidney pelvis which compelled nephrectomy later.

**Calculated Cyst in Epididymis.**—Marsan reviews the history of epididymis cysts, and describes the case of a man who from childhood had had a bilateral tumor of the epididymis. It had never caused any trouble until at 52 sudden pain developed in the right hard tumor, and malignant disease seemed probable. The operation revealed calcification of the entire wall of the old cyst. The location and features of the cysts suggest that they had developed from embryonal relics of the wolffian body.

**Microscopic Study of Urologic Cases.**—Vivier gives two colored plates and nine photomicrographs in the text to illustrate the typical findings and their interpretation with disease of the urinary apparatus. Some of the photomicrographs show the findings in the same patient during the course of treatment.

- \*Phlorizin in Therapeutics. A. Leclercq.—p. 248.
- Old Fracture of the Semilunar Bone. P. Japiot.—p. 250.

**Indications for Prostatectomy.**—Michon remarks that the renal filter is almost invariably more or less impaired by the time a *prostatique* reaches the surgeon. It is therefore extremely important to determine the extent of this impairment before the prostatectomy, as otherwise the postoperative azotemia common to all operations, superposed on a preceding high azotemia, may have disastrous effects. On the other hand, if the azotemia is induced or aggravated only by causes which the prostatectomy in itself will do away with, then even a high azotemia figure indicates merely that the prostatectomy had better be done at two sittings. Much graver is high azotemia when there is no retention or fever to explain it. Ambard's formula is instructive here, especially in the intermediate cases with the urea content of the blood between 0.70 or 0.90. The Ambard coefficient then will reveal whether the outlook is grave or not, and will enable us to seize the least unfavorable moment for the intervention.

**Partial Paralysis of the Abdominal Wall.**—Roger gives an illustration of a case of war wound of lumbar nerves which had entailed paralysis of part of the abdominal wall. The wall in this region had lost its elasticity and stretched, protruding like a woman's breast. No benefit has been realized in such cases from muscular exercise or electric treatment, and an abdominal band has to be worn, or the skin drawn up with quilted silk sutures.

**Debility of the Bronchi.**—Flurin ascribes to a local lack of vitality the inadequate resistance of the bronchi to infection in some persons. Ordinary saprophytes are able to set up infectious processes with this dystrophy of the respiratory "tree," and this opens the portals for disease in nose and throat. The *syndrome de débilité bronchique* is characterized by signs revealing the hyperesthesia of the mucosa, the unstable circulation and the special secretory response to any causes liable to stimulate secretion in the mucus glands. These signs may be detected even before the bronchial process has developed, so that it can be warded off by proper treatment.

**Meningeal Complications of Influenza.**—Schreiber comments on the fact that no one has published cases of purulent pneumococcus meningitis in the course of influenza, to his knowledge. Capitan has reported the discovery of pneumococci in the false membranes in the space around the optic chiasm, but the cerebrospinal fluid even in these cases was clear and sterile. In Rosenthal's two cases of alleged influenza meningitis the fluid was opaline rather than purulent. Netter found a distinct cellular reaction in the spinal fluid in his three cases of influenza serous meningitis, with recovery of two of the three patients. In his own experience, Schreiber encountered only one case of serous meningitis and the young soldier recovered after lumbar puncture. There were 20 or 30 lymphocytes in each field. From 8 to 10 is said by some to be a common finding in influenza as a transient meningeal reaction, but he saw it in only three cases. Influenza meningitis occurs more frequently. The symptoms suggest meningitis but the fluid keeps normal. Lumbar puncture thus clears up all these cases, and it is interesting to recall the "pseudo-meningitis" of the pandemic of influenza in 1890, which was before the days of lumbar puncture.

**Phlorizin in Therapeutics.**—Leclercq calls attention to the excellent results he has obtained with phlorizin in treatment of dyspnea, cardiorenal disease and the acidosis of diabetes. It acts where other diuretics fail. He used ampules of 0.005 or 0.01 gm. of the phlorizin dissolved in a 2.5 per cent. solution of sodium carbonate; 1 c.c. of this solution dissolves 0.005 gm. of the phlorizin. Intervals of four or five days between the injections seem the preferable technic. Two hours after the injection there is an output of sugar which keeps at about 8 gm. for four hours at most. He never found any sugar by the twelfth hour. The diuresis increases during the first few days up to the eighth day, then remains stationary, and begins to go down the ninth and the tenth days. There is no freshet, as after theobromin and digitalis, but it aids in the throwing off of the substances from which

urea is derived, and thus seems to act effectually in combating nitrogen intoxication. Dietetic restrictions, repose, sodium bicarbonate and four injections of phlorizin in the course of seven days banished the acidosis in a case of lean diabetes with the Gerhard reaction intense. Under this treatment 4 liters of urine were voided daily as the acidosis subsided, with 58 gm. of sugar.

### Presse Médicale, Paris

Sept. 18, 1919, 27, No. 52

- \*Etiology of Appendicitis. A. Riff.—p. 512.  
The Albumin Reaction in the Sputum. M. Salomon.—p. 523  
Oct. 1, 1919, 27, No. 55
- \*Serotherapy of Hemorrhage. II. Dufour and V. Le Hello.—p. 553.

Abscess in Breast with Inverted Nipple. J. Duverger.—p. 555.  
Pleural Spirochosis in Traumatic Hemothorax. E. Lancereaux.—p. 556.

**Etiology of Appendicitis.**—Riff declares that no evidence has been presented yet that disproves Letulle's assertion that appendicitis is always of intestinal and never of blood-borne origin, or the assumption that the primary lesion is some breach in the epithelial lining of the appendix. The oxyuris has been incriminated in the making of these primary breaches in the epithelium, as we know that this helminth finds a snug lurking place in the appendix. Riff found the oxyuris in the appendix in 48 per cent. of 152 operative cases at Strasbourg. In one appendix he counted 147 males and 50 females; in another 58 males and 201 females, and in a third there were over 400. In a recent series of 63 cases in children under 15, at Paris, the oxyuris was found in the appendix in 80 per cent. These findings convinced him of the causal role of the oxyuris, and this explains the immunity of young infants, the prevalence of the disease among the young, and its frequent familial occurrence. The discovery of the oxyuris may turn the scale in diagnosis in dubious cases, and if we finally learn how to expel the oxyuris we may hope to reduce the prevalence of appendicitis.

**Seric-Serum for Controlling Hemorrhage.**—Dufour and Le Hello noted that an anaphylactic reaction in a patient with hemorrhagic purpura seemed to modify the blood in such a way that the tendency to hemorrhage was arrested. This suggested that a therapeutic anaphylaxis might be induced which would arrest hemorrhages impossible to control by other means. They selected for this the method of passive anaphylaxis induced by injection of a small amount of serum from a rabbit in a state of anaphylaxis. They injected the rabbits several times at regular intervals with small doses of diphtheria antitoxin by the vein. They are bled the twenty-first day after the first injection, and their serum injected into guinea-pigs sensitizes the latter immediately, and induces manifest hypercoagulability. Injected subcutaneously in human beings, it almost immediately induces hypercoagulability and has thus arrested hemorrhage in numerous cases. Normal rabbit serum does not seem to modify the coagulation of the blood in man. A number of cases are described in which this seric-serum against hemorrhage, as they call it, arrested grave hemophilic and other postoperative hemorrhages, severe recurring uterine hemorrhage in a young woman, and fulminating epistaxis. They declare that nothing to compare with this prompt arrest of the tendency to hemorrhage has ever been realized with other measures. The seric-serum was injected in the dose of 10 c.c. and the effect was evident in about four hours, one hour or two hours in the different cases. In none of the cases were more than two injections needed.

### Revue Mens. de Gynécologie et d'Obstétrique, Paris

July, 1919, 14, No. 7

- \*Radium Treatment in Gynecology. E. Rouffart.—p. 241.  
\*Diagnosis of Impending Phlebitis. S. Remy.—p. 255.  
\*Embryotomy. J. Duque de Estrada.—p. 260.

**Radium Treatment in Gynecology.**—Rouffart here reviews the ultimate outcome in cases of gynecologic disease in which radium treatment had been applied five years ago. He mentions parenthetically the ever increasing numbers of uterine cancers encountered during the years of war. He says that

operative measures are preferable to radium treatment, but the latter is a useful adjuvant and in inoperable cases may induce long survival, as also after a palliative operation. The cancer heals over and the patient seems reborn, but after an interval of from one to four years the malignant disease reappears and radium then does not modify it. The postoperative exposures to radium do not cause any complications, but he reports a case of rapidly developing cancer in a woman of 27 which was treated with radium in three exposures and then the uterus was removed. The woman returned a month later with a gangrenous patch in the floor of the bladder, and she is still wearing a urinal, but there has been no return of the cancer during the five and a half years since. This is the only grave accident that has occurred from radium in his practice. The case teaches the necessity for extreme caution when radium is applied preliminary to an operation. This has the further disadvantage that it toughens the tissues and renders the operation harder. A palliative operation followed by radium exposures is much better.

In conclusion he expatiates on the efficacy of radium in arresting hemorrhages from uterine fibromas. In his fifty cases of the kind the promptest results were obtained when the tumor in the small pelvis did not reach higher than two or three fingerbreaths above the pubis, but equally good results were obtained with tumors extending to or beyond the umbilicus, only this took more time. By gauging the doses, the hemorrhages can be arrested without bringing on the artificial menopause, but the hemorrhages may recur eight or ten months later, requiring renewed radium treatment. Then the menopause sets in and the fibroma becomes reduced in size as a rule.

**Menace of Phlebitis.**—Remy advises absolute bed rest with measures to soothe the inflammation and reduce congestion when a pregnant woman or a parturient develops symptoms suggesting impending phlebitis. This proved all that was necessary in a case reported in which there was a history of phlegmatia alba dolens after the second of the five pregnancies. Remy denounces the idea of interrupting the pregnancy from fear of impending phlebitis.

**Embryotomy.**—Duque de Estrada writes from Mexico to extol the advantages of the embryotomy of which he gives an illustrated description. The metal conductor is 37 cm. long and curves. An elastic steel spring with a ball at the tip passes through the conductor and coils in concentric circles when forced out of the tip of the conductor. To the other end of the steel spring is fastened the strong chain to do the cutting; no saw is necessary. The ball-tipped spring glides along the body of the fetus from axilla to axilla or at the neck, and appears in the vagina. Pulling on the spring draws the Chassaignac chain into its place and the embryotomy can be completed without the slightest injury of the uterus.

### Revue Neurologique, Paris

July, 1919, 26, No. 7

- (Congenital Intraosseous Cyst. K. H. Kredde (Copenhagen).—p. 561.  
\*The Strümpell Phenomenon. Noxa (Bucharest).—p. 567.  
\*Case of Gitanism with Acromegaly and Marie Depressive Psychosis. C. I. Parhon and A. Stocker (Jassy).—p. 573.

**The Strümpell Phenomenon.**—Noxa remarks that in normal subjects, and especially in the young, there are movements in the other leg, when one leg is flexed on the thigh, which resemble the movements in Strümpell's phenomenon. In healthy persons the movements are not elicited unless some effort has to be made to overcome resistance, as when a hand is placed lightly on the subject's knee. He explains how this and other facts observed confirm the assumption that the Strümpell phenomenon is a normal associated movement but modified by the loss of the motility of the paralyzed extensors, while the motility of the tibialis anticus has been retained. The infant learns to make associated movements before it can make isolated movements. A man recovering from motor aphasia may be able to pronounce a certain word which he is unable to pronounce the letters separately that form the word. A lesion in the pyramidal tract partially suppresses voluntary control of movements and especially of isolated

movements, carrying us back as it were, to that early stage of our evolution in which only associated movements were possible.

**Practical Training in Surgery.** Hotz has discarded the old system of giving lectures on surgery over the cadaver, and has introduced the system of teaching the students from the patient as the operation is being done. This throws a great burden of responsibility on the teacher, but the gain for the students is immeasurable. The students are separated into small groups and one serves as first and one as second assistant, while others have charge of the anesthetic and the instruments. Early in the term they are taught about anesthesia, dressings, surgical technic and all that will be called on for the operations. Just before the operation each group is instructed in the theoretical data and in the anatomy of the region, and pictures of it are inspected. Each group gathers around an operating table with the professor, the adjunct professor or an experienced assistant. These do the operation but in mild cases they may give the knife to a student and take his place as assistant. The rule is that from the first washing of the patient until he is put back to bed, the medical students do everything that is done, all of course under strict and constant supervision by the surgeon and the nurse.

**Subcutaneous or Retroperitoneal Drainage for Ascites.**—Schärmer reports the later outcome in the case of ascites in which Tavel drained the fluid into the subcutaneous tissue in 1910, using a glass spool to hold the communication open. No other case is on record of long permanent success. These operations have been done otherwise only to relieve ascites from cirrhosis of the liver. In Tavel's case the ascites was of the premenstrual type in a young girl. The fluid thus artificially drained into the subcutaneous tissue formed large cysts in the groins which sagged down on the thighs. These water bags were finally resected in 1918. The diversion of the ascitic fluid had remarkably improved the general health, but the symptomatic benefit was counterbalanced by the deformity resulting from the passive edema of the subcutaneous tissue and the proliferation of connective tissue in the interstices, this proliferation further impeding absorption. Conditions in the retroperitoneal and lumbar tissues are more or less favorable for absorption, as he explains, pointing out further that the fluid might work its way from here down over the leg, thus obtaining a very large area for absorption. The glass device for draining was cast off as a former drain in Tavel's case. Fish bladders and rubber tubes are liable to this same drawback, but calf aorta treated with formaldehyd seems to answer the purpose perfectly. The coils in place and become organized without becoming contracted. Possibly, merely a large hole in the retroperitoneum might answer the purpose without an actual drain. He notes the conditions on annt drainage of ascites, and gives the distribution of Tavel's case before and after the removal of the ascitic water rubricus eight years after the retroperitoneal drainage.

**The Swallowing Reflex from the Cornea.**—Schnyder was the first to demonstrate that a swallowing reflex could be induced by irritation of the cornea, or that if induced it indicated deep-seated conditions in the cornea.

### Annali d'Igiene, Rome

May 11, 1919, 29, No. 5

- \*The Venereal Peril after the War. V. Montesano, p. 302.
- \*Average Weights of Italian Soldiers and the Diet. G. M. Belli, p. 327.
- \*Synthesis of Influenza Bacilli in Pathologic Products and in Cultures. M. Carpani, p. 349.
- \*Dermatogenous Diseases. II. A. Sals, p. 366. Contin.

**Food in Wartime.**—Both Rho's and Belli's articles were read at the Inter-Allied Sanitary Conference held at Paris last March. Belli's statistics include 4,418 sailors weighed after their sixth and eighteenth months in the service. The average weight was below 60 kg., and they all except 7.9 per cent had gained in weight. This is accepted as evidence that the diet represented adequate amounts of calories although the ration averaged only 2,800 or 2,900 calories.

**Vitality of the Influenza Bacillus.**—Carpano's experiments show that the influenza bacillus may long survive in a moist medium, even up to three months. When desiccated it dies in about four days. In sputum, effusions, and blood in the test tube it dies in about twenty days. Horse serum and hemoglobin-serum-agar offer the most favorable conditions for its survival of all the mediums tested. The most favorable temperature for its conservation is between 32 and 37 C.

**Deficiency Diseases.**—Scala presents the present status of our knowledge of the probable causes of beriberi, pellagra and other of the so-called deficiency diseases, and emphasizes the importance from this standpoint of the mineral elements in the food. Deductions from experiments in this line have not been conclusive to date as they have not reproduced natural conditions.

### Gazzetta degli Ospedali e delle Cliniche, Milan

Aug. 14, 1919, 10, No. 65

- \*Effect of Paracresol and Indol on the Circulation. B. Vasoini, p. 673.
- Aug. 24, 1919, 10, No. 68
- Clinical Notes on 10,921 Native Patients at Dispensary in Northern Africa. F. Mazzone, p. 710.
- Aug. 28, 1919, 40, No. 69

- Aug. 31, 1919, 10, No. 70
- Principles for Treatment of Bone and Joint Lesions as Learned from War Surgery. M. Passano, p. 731.

**Effect of Paracresol and Indol on the Circulation.**—Vasoini's experiments on cats and rabbits have apparently established that indol and paracresol have a vasoconstricting action. Paracresol induced in the animals an abrupt and pronounced drop in the blood pressure, and both this and indol reduce both the systolic and the diastolic excursions of the isolated heart.

Sept. 11, 1919, 10, No. 73

- \*Case of Chorea of Esophagus and Stomach. G. Ceresole, p. 770.

**Chorea of Esophagus and Stomach.**—The young man whose case is described by Ceresole was of a weakly, nervous constitution and the contrast meal showed that the esophagus was the site of irregular choric movements changing about from point to point, peristalsis and antiperistalsis occurring irregularly and even together. The stomach showed similar irregular movements, with spastic closure and relaxation of the pylorus and the cardia. While these motor convulsions were going on in the esophagus and stomach, the abdomen seemed to be entirely at peace and the movements of the diaphragm were regular and normal. This localized chorea dated from childhood, and did not cause pain or vomiting or materially impair the general health.

### Riforma Medica, Naples

Sept. 13, 1919, 33, No. 37

- \*Multiple Endocrine Disturbances. V. Livi, p. 778.
- \*Agglutination Test in Diagnosis of Typhus. A. Montefusco, p. 782.
- \*Colon Bacillus Infection of the Eye. I. Betti, p. 784.
- \*Mammectomy for Cancer. N. Federici, p. 786.
- \*Varicos on the Legs. E. Avevoli, p. 786.

**Multiple Endocrine Disturbances.**—Livi entitles his article "Sindrome pluriglandular," as the woman of 33 presented unmistakable evidences of deficient functioning of the suprarenals, pituitary body and ovary, along with status lymphaticus, and the spleen was much enlarged. None of the symptoms was pronounced enough to classify the case as one of Addison's disease, etc., but the combination of the

whole was grave and proved fatal in about seven years. She ascribed the beginning of her disturbances to sorrow over the loss of her child. The severe headaches and the rebellious eczema of the legs were evidently traceable to the pituitary and the endocrine anomalies. There was no reaction to injections of pituitary, ovary or thyroid, and only slight to epinephrin, but there was a good reaction to atropin and also a partial reaction to pilocarpin (no sweating); none to tuberculin. The tendency to vomiting, diarrhea and chronic bronchitis of the asthma type suggested vagotomy.

**Agglutination in Typhus.**—Montefusco remarks that during the present small epidemic of typhus at Naples, many physicians recognized the disease who had never seen typhus before, but the differential diagnosis is difficult in the first sporadic cases—the most important for prophylaxis. Agglutination of *Proteus X* occurred constantly—1:50 to 1:800—in the 100 cases of typhus in his experience, with a single exception. The reaction disappears completely during convalescence. The test was constantly negative in a large number of patients with acute diseases other than typhus except in one patient with smallpox. The agglutination does not become manifest until the eruption has appeared and by that time the clinical diagnosis is practically certain, but it may be important for a retrospective diagnosis and to detect atypical cases.

**Colon Bacillus Eye Disease.**—Betti reports two cases of panophthalmitis in men of 56 and 38, following a contusion of the eye. In four and two days the anterior chamber was full of pus, the vitreous all pus, and the eyeball had to be removed. Cultivation of the germs in the eye and inoculation of rabbit eyes demonstrated that a highly virulent colon bacillus was responsible. In a third case phlegmonous dacryocystitis developed three years after a contusion of the region which had been followed by recurring catarrhal conditions in the conjunctiva after the first stormy inflammation. The dacryocystitis perforated spontaneously and recovery was soon complete after dacryocystectomy. He cites a few other authors who have reported similar colon bacillus dacryocystitis. The colon bacillus is thus able to induce acute processes in the eye and its annexes, with a destructive course.

**Exenteration Mammectomy.**—Federici applies this term to the technic he has applied in two cases of cancer in its early stages. He cuts a pear-shaped flap encircling the breast, except that the incision skips the distance along the median line. The small end is at the axilla and he turns this flap of skin upward and inward. After excising all morbid tissue, he returns the flap to place and sutures without drainage. The outcome during the few months to date in his cases has been excellent.

**Treatment of Varicose Veins.**—Aievoli calls attention anew to Schiassi's method of injecting an iodine-iodid solution into the vein as a simple and effectual means of combating varices in the legs. He describes it in detail but without illustrations.

\*Epileptic Gastric Crises. S. Martínez Gómez.—p. 453.  
\*Rebellious Gastric Ulcer with Epigastric Hernia. C. Ordoñez.—p. 458.

**Epileptic Gastric Crises.**—Martínez describes the case of a man of 39, a gardener, apparently robust, who for three years had had attacks of pain in the stomach accompanied by great depression and sometimes by loss of consciousness and convulsions. During the intervals he felt well but said he had always had "a delicate stomach." The pain during the attacks was agonizing at times, and it reappeared each day for three days; then followed a free interval of about three months on an average. By exclusion, the only diagnosis possible seemed that the attacks were a manifestation of tardy epilepsy. In time the gastric symptoms grew less pronounced while the epileptic character of the seizures became unmistakable. No treatment addressed to the stomach had the slightest effect and the ordinary bromids were not borne well by the stomach, but considerable relief was obtained with strontium bromid which seemed to be well tolerated. The intervals grew longer and the seizures less severe. The fetid breath and large amounts of indican in the urine just before the seizures were combated with dieting, laxatives, hexamethylenamin and sodium benzoate by the mouth.

June, 1919, 32, No. 6

\*Puerperal Psittis. J. Gorostegui.—p. 11.  
\*Placenta Praevia plus Eclampsia after Induced Delivery at Eighth Month; Recovery. J. Peláez Brihuega.—p. 178.  
\*Case of Intra-Uterine Ichthyosis. Fraets.—p. 122.

**Puerperal Psittis.**—Gorostegui gives an illustration of the peculiar attitude of the woman with febrile psittis after a twin pregnancy with great autointoxication and premature delivery at the seventh month. The fever persisted after the uterus had been cleared of putrefying scraps, and there was much pain in the left iliac fossa, with tympanism. The woman held the left leg flexed and in abduction and outward rotation all the time as she lay in bed. An incision above Poupart's ligament where the tumor and the tenderness were most pronounced released a large amount of fetid pus and recovery was soon complete.

\*Clinical Forms of Granulomatosis. Alfredo da Matta.—p. 249.

**Artificial Eyes.**—De Gouvya reproduces the photograph of a man showing ideal conditions in the orbit with an artificial eye mounted on a rabbit's eye which had been implanted in the orbit about twelve years ago. Since he learned in 1908 that rabbits were very subject to contamination with syphilis, he has not ventured to apply this technic, notwithstanding its advantages. In another case he introduced a ball of paraffin and the illustration shows good results with this also, perfect when the eyes are quiet, but there is some asymmetry with conjugated movements of the eyes.

Physiotherapy. A. Goardía Albal.—p. 153.  
Vaginal Gauze Holders. Victor C. Hill.—p. 156.  
Differential Diagnosis of Pterion Tumors. W. López Albo.—p. 158.

**Vaginal Gauze Holders.**—Covill applies the term "conductor" to an instrument shaped like a very long needle, slightly curved and with the tip cleft like forceps with a ring below to tighten the grip. He uses these to pass gauze from the abdomen down into and out of the vagina in abdominal hysterectomy operations, instead of groping blindly for the gauze from below. An illustration is given of these vaginal conductors, also of a special forceps for grasping the uterus without injuring the surface, and also of an angiotome which allows the sutures to be taken while it is in place. It can then be removed without interfering with the sutures.

**Prefrontal Tumors.**—López Albo reports two cases of tumor of the frontal lobe originating in the dura and sparing the brain proper. The tumor was a sarcoma in both cases and there has been no recurrence during the three years to date since its removal in the first case. The psychoparalytic changes in the other case were intense, and the woman succumbed to postoperative infection. The symptoms in the first case included hemiparesis and paraparesis, rigidity of the muscles of neck and thorax without convulsions, tremor or sensory disturbances, and mental impairment of the depression and dementia type. In the other case, changes in speech and dementia were accompanied by a fine tremor of the arms and exaggeration of the reflexes. The tumor in this case was as large as a mandarin orange but, as with prefrontal tumors in general, it was easily enucleated.

Chronic Myeloid Leukemia. J. L. Yague.—p. 253. (Hearl Disease—Blood Diseases—p. 268, 270.)

**Dynamics of the Heart.** Misael Bañuelos reports the results of experimental research on arrhythmias, on the stimulation of the vagus, on the arrhythmia induced by rephing, etc. He warns that the effect on the heart from stimulation of the vagus may differ widely according as the

ventricles are or are not distended at the time. It is necessary therefore in all such tests to note whether the ventricle is full or empty.

**Fascia Plastic Fixation of Sagging Kidney.**—Scrés gives eight illustrations of the technic for utilizing a broad rectangular strip of aponeurosis cut from the fascia lata to suspend the kidney in its proper place. The strip is slit half way its length to fit around the pedicle, and the ends are then drawn up and sutured to form an outer capsule around the kidney. Three double threads are then passed through this outer capsule at the center and near the poles, as with Guyon's procedure, and these threads are then used to suspend the kidney in its proper place, passing them through or over muscles or ribs as indicated. With this technic the kidney tissue proper is left intact. Another procedure which he calls *renoplastura* he uses to reduce the size of the kidney after hydropnephrosis. Seven fine catgut threads were quilted back and forth over the inferior pole of the kidney, without perforating the wall. The ends were drawn up and tied and the normal outline of the kidney was thus restored.

**Meningitis.** Palanera's photomicrographs reproduce the findings in three interesting cases of meningitis. The meningococcus was found in one, the pyocyanus in the second, and the third was of influenzal origin.

**Pathologic Biology.**—Suñer discusses anergy and the predisposition to infections and anaphylaxis as their manifestations are encountered in children. Among the practical points emphasized is the importance of secondary infections and the imperative necessity for warding them off. He remarks in regard to anaphylaxis that it is in epidemic cerebrospinal meningitis that anaphylactic states are most to be dreaded. To avoid them he advises injecting 10 or 20 c.c. of the antiserum subcutaneously the first day; the analysis of the spinal fluid once made, then 30 or 40 c.c. can be injected intraspinally without inconvenience. If haste is necessary, he advises intraspinal injection of 2 c.c. and after waiting an hour or two, injecting the full amount 20 or 30 c.c. Or else, 1 c.c. of a dilution of 5 c.c. in 10 c.c. of saline could be injected by the vein. If there is no reaction to this in three or five minutes, then 3 c.c. of the same dilution can be injected, and if no disturbance follows, then 10 c.c. can be injected, and after waiting another two minutes, the final injection of 25 c.c. of the same dilution can be made. From this moment the patient is vaccinated against anaphylactic disturbance, and in ten minutes can be given by the vein or spinal canal up to 30 c.c. of the undiluted antiserum. He quotes extensively from Besredka's recent work on anti-anaphylaxis which throws more light on the biologic principles involved.

**The Art of Medical Writings.**—Santos Rubiano holds up as a model of probity and precision in medical writings the oldest one known, found on a votive tablet in the temple of Esculapius. It states: "The god told an old soldier, named Valerú Aper, to take the blood of the white cock, mix it with honey and anoint his eyes with this for three days; the Soldier did so." Santos deplors the frequent "kleptomania of ideas," and says of the conclusions of an article that they should be the necropsy of the body of the article, and should distinguish between what is postulated and what is asserted, and the deductions therefrom.

**Transformation of Chronic Myeloid Leukemia Into the Fulminating Type.**—This occurred in two cases described in full; in one under the influence of intercurrent influenza when the general condition had been so much improved under cautious roentgen treatment that long remission of symptoms was anticipated. In the other case chronic leukemia in a person with a history of tuberculosis had flared up several times, and the last time this occurred the streptococcus was cultivated from the blood. In this case also there had been marked improvement under roentgen treatment. It seems plausible to assume that the transformation of chronic into acute leukemia after roentgen treatment is due to toxic infectious agencies, and that the action of roentgen treatment needs to be revised. The toxic-infectious agencies may be those responsible for the disease in the first place, or they may be from intercurrent disease.

- Treatment of Syphilis. M. Antonio Rueda.—p. 592. Concn.

**Sarcomas in Long Bones.**—Martínez gives illustrations of several of his 13 cases of extensive sarcoma of the long bones, and states that 80 per cent. were in males and that the age ranged from 20 to 40, with two cases in persons over 50. In almost every instance there was a history of contusion of the region. In his latest series the sarcoma was in the upper end of the femur in 5; of the humerus in 3; the lower end of the femur in 3; the lower end of the humerus in one, and in one case in the middle of the tibia. In some of his cases the sarcoma had grown to enormous size. His experience has confirmed that amputation or disarticulation is necessary in the rapidly developing sarcomas involving the soft parts, but under other conditions resections into sound tissue seem to give as durable results as amputation.

- \*Treatment of Morphin Addiction. Cesar Juarros.—p. 739.
- Treatment of Helminthiasis in 1750. R. Hernández Briz.—p. 740.

**Treatment of Morphin Addiction.**—Juarros comments on the constantly increasing numbers of morphin addicts, and emphasizes that treatment must be individualized, using the abrupt or the gradual method of suppressing the drug according as the patient is young, with the habit acquired within three years, the doses not over 2 gm. at most, and the viscera sound, or as the habit is of long standing and large amounts of morphin have been regularly taken. In this latter group, abrupt suspension is dangerous, especially if the patient is over 40, and has organic disease of any kind, particularly of the cardiovascular system. Strict individualization is necessary, even for the purges ordered. The lack of this is responsible for the many addicts whose cases are considered beyond redemption because two or three courses of treatment have failed. Juarros reiterates that 99 per cent. can be cured without fail if the physician can refrain from imposing his favorite method of treatment on all alike, and will remember that psychotherapy is an indispensable adjuvant. He prefers Sollier's technic for rapid suspension and Jennings' for the slow method.

**Ferrán's Vaccination Against Tuberculosis.**—See Madrid Letter, Oct. 4, 1919, p. 1074.

**Induced Pneumothorax.**—Gutiérrez-Gamero and Cerdeiras trace the history of therapeutic artificial pneumothorax back to Baglivi's communication in 1609 on the frequent healing of pulmonary tuberculosis after a wound opening up the pleural cavity. Stokes in 1838 called attention to the way in which pulmonary lesions began to heal after spontaneous pneumothorax, but Forlanini in 1882 suggested artificial pneumothorax and in 1892 began to apply it systematically in treatment. This article pleads for its application early in pulmonary tuberculosis, not waiting until it is the last resource. This delay has materially hampered the progress of this valuable method of treatment and brought undeserved discredit on it, as more has been asked of it than it is capable of accomplishing. The technic is described in detail and it is emphasized that this "collapse therapy" does not conflict with any other therapeutic measures. In fact, it may smooth the path for them to be effectual. Fully 60 per cent. of the patients whose condition indicates artificial pneumothorax can be restored to normal life by this treatment they reiterate in conclusion.

**The Psychology of the Insane.**—Delgado explains that "deep in the soul of every one the lost Paradise lies buried, out of sight but alive, still inducing its magic seduction."

"Conduct is the result of the interaction between our response to the world of reality and to this inner seduction of the lost Paradise, and what we call sanity and insanity depends on which of these two forces elicits the predominating response."

**Indirect Surgical Treatment of Gastric Ulcer.**—Alvarez explains certain cases of gastric ulcer as the result of the excessive action of the sympathetic nerve innervating the stomach. This nerve has both a sensory and secretion-promoting function, and likewise a vasoconstricting action. When functioning to excess, there inevitably follow hyperchlorhydria and hypersecretion at the same time as anemia of the mucosa. The vasoconstricting influence deprives the mucosa of its proper nourishment and leaves it defenseless against the extra corroding action of the hyperchlorhydria which acts on the mucosa abnormally long on account of the hypersecretion. A further factor is the spastic closure of the pylorus from the irritation induced by the hyperchlorhydria. The whole train of phenomena can thus be traced to the excessive functioning of the sympathetic, and this he attacks by stretching the nerve involved to induce, as he says, *connoción á distancia del gran simpático torácico*. He has thus treated 53 patients and reports 25 completely cured and 8 improved. The outcome is not known in 10 cases and no benefit followed in 10 others. In the cases of failure, organic stenosis of the pylorus was evidently a factor, and this contraindicates this method, he says. He describes the technic and gives the details of a number of typical cases. Lately he has been restricting the intervention to stretching the fifth intercostal nerve on both sides. At first he acted on the sixth, seventh, eighth and ninth. The nerves are severed and each is stretched with forceps aiming to act on the great sympathetic and the semilunar ganglia and through them on the nerve fibers passing directly to the stomach. The consequence is an immediate vasodilation with hyperemia of the gastric mucosa, suppression of the hyperesthesia and hypersecretion, and as the consequence of this, arrest of the tendency to spastic contracture of the pylorus, and hence normal evacuation of the stomach contents.

"Typhoid Cholecystitis in Boy of Fourteen. *G. J. J. van Berckel*—p. 415.

**Paralysis of Tibialis Anticus.**—Laan has already published several comprehensive articles on the sequelae of poliomyelitis, seeking to determine the best technique for orthopedic treatment in the individual case. He here discusses what is to be done for isolated paralysis of the tibialis anticus, reporting 75 cases, including 4 with bilateral paralysis, thus a total of 79 cases. There was paralysis in the thigh or in the other leg besides in 46 cases, bilateral in 17. The literature has dealt mainly hitherto with paralysis of the tibialis posterior, but none of the 79 anticus paralysis cases was any improvement in the paralysis observed, the paralysis or the weakness persisted unmodified. In 70 cases the paralysis dated from before the fourth year and in 48 there had been no attempt at orthopedic treatment although the paralysis was of six years' standing in 30 and from seven to eighteen years in 18. All kinds of treatment had been applied except operative and orthopedic measures. Some of the patients could only crawl, and some others could not do even this. After the operation the patients have to be left in others' hands, and it is important to make the after-treatment as simple as possible. Massage and electricity have to be resorted to in this account and the main reliance placed on keeping the foot in a good position and getting the patient to walk. In 10 of the cases only special shoes were found necessary to accomplish this, in 32 a walking stirrup was worn. A walk was worn at night also; in 38 special shoes were worn during the day and a correcting apparatus at night. Only 2 of the total number were unable finally to walk unassisted. The war has compelled revision of the course of treatment of infantile paralysis. This has emphasized the necessity for classifying cases for treatment by age and also the possible necessity for resection of the distal apparatus and of the skeleton of the feet. Two cases were resorted to be placed on tendon transplantations, etc. In the series the outcome is not known in 11 and 3 have recurred. The outcome was poor in 12, but in all the 44 other cases the treatment may be considered a success. The most favorable results were obtained when the extensor digitorum was utilized in place of the tibialis anticus. Only two out of 100 when treated along the anticus without using any of the other cases it seemed to answer the purpose excellently, and it was resorted to a strong traction. In the few cases in which the muscle was utilized, its normal function is not found in the children affected and the two prominent muscles remaining in function. He reiterates that if it is possible to obtain somewhat better results than first-class, it is hardly attainable. He gives the typical cases of the various different forms in which infantile paralysis may present itself, and the orthopedic treatment in each group. The primary remedy is in paralysis of other muscles which rarely, except in a few cases, is the exception. But it is in ties of the distal part that the greatest benefit may be realized,

comparatively speaking, freeing the children from apparatus and reducing the crippling to the minimum.

**Asphyxia of the Newly Born.**—Mik explains that no air can get into the lungs of the new-born child so long as the entrance to the trachea is closed, and there is nothing to impel the air to enter the trachea if the vocal cords are impacted together. But a brisk downward movement of the diaphragm induces a vacuum and the air rushing in forces the cords open. The change from the uterus to the air of the room is such a sharp stimulus to the skin that by the resulting reflex action the diaphragm is usually forced downward and respiration is inaugurated. Schultze's swinging of the infant, he thinks, is merely another form of stimulating the skin, as even this is unable to force air into the trachea so long as its opening is obstructed. He recalls that stimulation of the nasal mucosa is a more potent source of reflex action on the diaphragm than can be realized from the skin. Ticking the nasal mucosa at its most sensitive point—perhaps with a feather—is an old measure. Its action might be promoted by ammonia or irritating gases. Clearing out the nose might facilitate matters; this is easily accomplished by blowing air from a rubber bulb into first one nostril and then the other. This forces out the mucus, etc., through the second nostril. From the theoretical standpoint, stimulation of the nasal mucosa should rank above all other measures for combating asphyxia neonatorum.

**Cancer in the Married.**—Sanders tabulates the statistics of cancer of the uterus and breast at Rotterdam 1902-1914. They show that cancer of the uterus is more prevalent in the married than in the unmarried. Cancer of the breast is also more common among the married up to the age of 40.

**Typhoid Cholecystitis.**—Van Berckel relates that the thirty-six gallstones found in the gallbladder of the boy of 14 had probably developed since the typhoid which had induced the cholecystitis. Typhoid bacilli were still found in the stools two and four months after the cholecystectomy.

Aug. 30, 1919, 2, No. 9

"Mammary Cancer. *H. T. Deelman*, p. 573.  
"Hyperthermia. *J. R. Kollwijn*—p. 584.

**Mammary Cancer.**—Deelman reviews the outcome in 582 operative cases of mammary cancer at the Amsterdam public hospital from 1885 to 1915. Among the points thus brought out is that there is at least an 8 per cent. difference in the mortality between the figures for a three year interval and a five year interval. Only 30.6 per cent. were still living five years after the operation of the 245 patients operated on 1885-1911. Only one third of the total operated on were living at the fourth year, and of those that had died in the interim five out of every six had succumbed to cancer or its consequences. A marked change for the better appears in the statistics from 1900 onward, and systematic postoperative raying seems to be improving conditions lately even more. Of the women operated on in 1900-1914, over 42 per cent. are still living. The figures show further that the age between 40 and 50 offers the best chances for survival.

**Hyperthermia.**—Kollwijn states that there were signs of exophthalmic goiter in two of the eight cases of protracted slight fever he reports, and syphilis was evident in another case. The temperature was persistently above normal, at least during the latter part of the day. Nothing could be found to explain this unless possibly nervousness or hysteria could be incriminated. He thinks that "nervous fever" might be found oftener if it were regularly sought for. At the same time he thinks that this can scarcely be accepted as the explanation for cases in which the temperature keeps above 38 C. (100.4 F.) for a long time. With men, syphilis should be suspected, with women impending exophthalmic goiter. If the temperature keeps below 38 C. there is scarcely need to interfere with the patient's occupation, but if it keeps above 38 the rest is safer.

## A NEW GERMICIDE FOR USE IN THE GENITO-URINARY TRACT: "MERCUROCHROME-220"

PRELIMINARY REPORT OF EXPERIMENTAL AND  
CLINICAL STUDIES\*

HUGH H. YOUNG, M.D.

EDWIN C. WHITE, Ph.D.

AND

ERNEST O. SWARTZ, M.D.

BALTIMORE

During the past two years the research work in the laboratories of the James Buchanan Brady Urological Institute has been given over largely to the study of antiseptics with a view particularly to the development of drugs applicable to the genito-urinary tract. Attention was first directed to internal antiseptics, since Hinman<sup>1</sup> had previously shown in our laboratories the questionable value of hexamethylenamin. Starting with the remarkable selective activity of the kidneys on phenolsulphonephthalein, as shown by the work of Abel and Rowntree<sup>2</sup> and developed as a functional test in our clinic, we tried to attach other chemical agents to phenolsulphonephthalein and thus produce an effective internal urinary antiseptic. Some interesting drugs were produced and studied by Davis and one of us (E. C. W.<sup>3</sup>). The war interrupted these studies, but the urgent need of really effective antiseptics for local use in the genito-urinary tract induced us later to concentrate on this problem. Browning was visited in London by one of us, and sufficient quantities of his flavines were obtained and sent to Baltimore. As a result of experiments and clinical use in this clinic, Davis and Harrell<sup>4</sup> recommended the use of acriflavine in the treatment of acute gonorrhoea, and this form of therapy was then used with good results in certain venereal clinics of the American Expeditionary Forces.

Impressed with the possibilities of using dyes as a basis for the development of therapeutic compounds, we have concentrated our efforts on the production of new drugs possessing the penetrating qualities of dyes while at the same time being germicidal and relatively nontoxic and nonirritating. The number of compounds that have been and are being produced in the pursuit of this research is considerable. From among them

the substance reported on in this paper has been selected for extended study. In mercurochrome-220 we have a drug of demonstrated germicidal value. The speed with which some old infections of the bladder and kidney pelvis have disappeared after its use is striking, and the absence of irritating and toxic qualities, together with the ability of the patient to retain a 1 per cent. solution for hours without discomfort, are sufficiently proved to establish the possibilities of the drug in these conditions. For the first time, we have a drug of great germicidal strength that can be tolerated in the human bladder for several hours, which establishes an ideal condition from the standpoint of its sterilizing effects.

Its value in colon and staphylococcus infections has led us to apply mercurochrome-220 to gonorrhoea and chancroidal ulcerations, our investigations having been carried on under the grant recently made us by the Interdepartmental Social Hygiene Board for research in the prevention and treatment of venereal diseases. Our series of cases so far is limited, but the demonstration of the sterilizing value of the drug in the urethra, bladder and kidney pelvis is promising enough to warrant this early publication.

### CONSIDERATIONS GOVERNING SYNTHESIS OF A NEW URINARY GERMICIDE

In synthesizing a drug for local use as a urinary antiseptic, it was sought to combine the following properties: (1) ready penetration of the tissues in which the infection exists; (2) lack of irritation of the drug to tissues; (3) high germicidal activity; (4) ready solubility in water and stability of the solution; (5) freedom from precipitation in urine, and (6) sufficiently low toxicity to avoid systemic effects from the small amount of the drug that may be absorbed.

In order to meet the first requirement it was decided to make use of a penetrating dye, not necessarily a germicide of itself, but serving merely as a carrier in which a germicidal chemical group could be substituted. The clinical experience that the basic dyes such as fuchsin, brilliant green, crystal violet, and, in some cases, the flavines, are too irritating to the mucosa of the urinary tract for general use suggested the use of acid dyes. This class of colors, which includes as its commoner representatives the phthaleins and most of the azo dyes, offers a wide range of choice. From purely chemical considerations it might be predicted that the basic dyes would be more irritating than the acid dyes. The former are salts of weak bases, and therefore their solution must have an acid reaction. The acid dyes, on the other hand, are used as sodium salts, and solutions of them necessarily have a neutral or slightly alkaline reaction, depending on whether the free dye is a strong acid, such as a sulphonic acid, or

weak acid, such as a phthalein. Since the tissues are generally more sensitive to acidity than to alkalinity, this reasoning led to the choice of an acid dye as the basis of the synthetic germicide.

The extensive use of eosin as a cytoplasmic stain at once suggested its use as a suitable dye of this class. However, it does not lend itself to chemical modification, because those positions in its molecule susceptible to substitution by other chemical groups are already occupied by bromin. On the other hand, it was found that the closely related substance dibromofluorescein could undergo substitution by the germicidal group we chose and still retain practically the same tinctorial properties that eosin itself possesses.

Mercury was chosen as the active germicidal principle to be substituted in the dye molecule. Virtually the only form in which this metal has heretofore been used in the urinary tract has been that of the chlorid or cyanid salts. The chlorid is so extremely irritating that only very dilute solutions (1:30,000) are tolerated, and it is extremely doubtful whether such solutions, especially in the presence of urine, exert much effect on the infection. Concerning the use of the cyanid there is little available information. In the case of either salt, however, the degree of penetrability is uncertain and in all probability is slight.

The irritating effect of solutions of mercuric chlorid is due to the mercury ion. If, however, the metal is substituted in an organic compound, such as an acid dye, the mercury no longer yields ions, but exists as a firmly bound part of the dye molecule itself. In this form of combination the properties of the metal as manifested by mercury salts are more or less completely masked. The new substance gives a negative reaction with the usual reagents for mercury, such as alkalis, iodids and alkali sulphids. The organic combinations of mercury also generally exhibit lower toxicity than do corresponding amounts of mercury in salt form, and frequently, but not always, their germicidal action is milder than that shown by the salts. With the great variety of possible combinations offered, depending on the nature of the organic substance used, it is not very difficult to find products whose advantages of nonirritability, lower toxicity and high penetrating power more than offset their somewhat decreased germicidal power as compared with that of the mercury salts.

Although a large amount of investigation of the therapeutics of the organic mercury compounds has been carried out in Europe, the study of these compounds in this country has, as far as we know, been limited to that of Davis, White and Rosen<sup>7</sup> and of Schenberg, Kelmer and Raiziss.<sup>8</sup> Most of the work reported has dealt with the use of these substances in treating acute infections. The principles we employ in the use of organic mercury compounds in the urinary tract we believe are new.

#### DISTRIBUTION OF MERCUROCHROME 220

To the substance obtained by substituting one atom of mercury in the molecule of dibromofluorescein we have given the name "mercurochrome-220."<sup>9</sup> Chem-

ically it is dibrom-oxymercurifluorescein, or its sodium salt. The latter contains about 26 per cent. of mercury, and is represented by the formula:

The free acid is a red powder insoluble in water but readily soluble in sodium hydroxid solution, with the formation of a deep cherry red color, showing fluorescence on dilution. The dry salt forms iridescent green scales, slightly hygroscopic and readily soluble in water. The solution is stable and is not affected by moderate heat or exposure to the air. Strongly acid urine ( $p_H=5.0$ ) gives a slight precipitate of the free dye; but if the acidity is  $p_H=6.4$  or less, no precipitation occurs. There is entire freedom from precipitation when a 1 per cent. solution of the drug is mixed with an equal volume of medium rich in protein, such as hydrocele fluid. The solution stains the skin a bright red color, but the stain is readily removed by rubbing first with 2 per cent. potassium permanganate solution, and then with 2 per cent. oxalic acid solution.

It was found that under proper conditions a second atom of mercury could be introduced into the dye molecule. However, the substance thus formed showed no greater germicidal action than the simpler compound, and was consequently discarded.

It should be mentioned that a "mercury dibromofluorescein" has been experimented with by Hahn and Kostenbader.<sup>7</sup> These authors give no description of their drug, but its mercury content (35 per cent.) indicates that it differs from our substance and that it is not a homogeneous chemical compound.

#### PENETRATION

Attention must be paid to the penetrating power of any germicide for use in the urinary tract. Fenger<sup>8</sup> has shown that "in thirty-eight hours after inoculation the gonococci have only just begun to effect entrance between the epithelial cells. The inflammation extends until the gonococci have penetrated deep into the layers of the mucous membrane, which has become acutely congested, the epithelium undergoing mucous degeneration, and exfoliating in patches." MacCallum<sup>9</sup> states that "the gonococcus penetrates among the epithelial cells and extends even into the subepithelial tissues of the urethra." Sections made from cases of papillary cystitis and from pyelitis show the organisms to have penetrated to the deeper layers of the epithelial cells.

Attention was called by Davis and Harrell<sup>1</sup> to the rapid diffusibility of acriflavine in the tissues. During the administration of mercurochrome-220 by injection of solutions into a rabbit's ear vein to determine toxicity, the same phenomenon was observed. This compound spread rapidly from the vein into which it was being injected, and in a few seconds the entire ear

<sup>2</sup> Schenberg, Kelmer, Raiziss, and Truitt, *J. Infect. Dis.* 24:537 (June) 1917.

<sup>3</sup> The name "mercurochrome" will be applied generically in all the mercury bearing dyes that we are investigating, the individual being designated by the letter following the name. We have made a number of such compounds, including phthaleins, azo dyes, basic dyes, thiazins, etc., on which we shall report in due time.

<sup>7</sup> Hahn and Kostenbader: *Ztschr. f. Chemotherap.*, Orig., 2:71, 1914.

<sup>8</sup> Fenger, quoted by Keyes: *Modern Urology*, 1:59.

<sup>9</sup> MacCallum: *Textbook of Pathology*, p. 530.

was colored a reddish pink. This color persisted with varying intensity for from twenty-four to forty-eight hours.

With a view to determining the penetrability of this mercury-bearing dye, when used in the urinary tract, a series of direct experiments was carried out. A rabbit was catheterized, a soft rubber catheter being used. Through this catheter an ounce of 1 per cent. solution of the drug was slowly injected into the bladder, and the catheter was slowly withdrawn, allowing some of the fluid to escape through the urethra. At the end of five minutes the catheter was again introduced, and the bladder was emptied. The rabbit was quickly killed, and the bladder and urethra were dissected out intact. The bladder was then opened, and excess of solution was removed by washing with water. Frozen sections of the urethra and bladder were made immediately and were examined without the use of any other stain. In other instances the bladder and urethra were opened and immediately transferred to formaldehyd solution and hardened. Paraffin blocks were made and sections were cut without the use of any other stain. This experiment was carried out several times, the catheter being used in one instance, and in the other instances the bladder being filled through the urethra by means of a small syringe. The latter method was used to avoid any possible trauma to the urethral mucosa. In other rabbits under ether anesthesia, the abdomen was opened, the ureters were exposed, and by means of a small record syringe the ureter and kidney pelvis were gently filled with a 1 per cent. dye solution, care being taken to prevent overdistention of the kidney pelvis, and the ureter was ligated. After five minutes the rabbit was killed, the ligature was removed from the ureter, the kidney and the ureter were taken out intact, and frozen sections were made and promptly examined. In other instances, paraffin sections were made.

Examination of the frozen sections as well as of the paraffin sections shows that the epithelial cells of the urethra are stained a deep red. This staining is most intense in the superficial layers, and becomes less intense toward the submucosa; but the submucosa was stained in places, though not so uniformly as the epithelial layers. In some places the stain penetrated the submucosa into the muscularis. This mercury-bearing dye stains the epithelium of the anterior and posterior urethra uniformly, and to a less extent penetrates to the submucous layers. Sections of the bladder and the ureter show the same uniform penetration and staining of the cytoplasm of the epithelial cells, and the submucosa is less deeply stained. Sections of the kidney pelvis showed penetration and staining of the epithelium. The dye had also been taken up by the cells of the collecting tubules, and they were stained for a short distance up the tubules from the papillae. In the urethra, the epithelium of the glands opening into the urethra was stained for some distance from the mouths of the ducts.

#### TOXICITY

In determining the toxicity of the drug, various solutions were administered intravenously. The urine was examined and the phenolsulphonephthalein excretion was determined, and in dogs blood urea was determined before injection. We noticed a variation in the amount of the drug that rabbits and dogs could tolerate. Ten mg. per kilogram invariably killed rabbits in

twenty-four hours, and no gross lesions were found at necropsy. Rabbits receiving 5 mg. per kilogram showed a decrease in phenolsulphonephthalein output and an albuminuria that lasted about a week. Dogs tolerated 10 mg. per kilogram very well with no evidence of discomfort or illness. In each instance there was produced an albuminuria without casts and a temporary reduction in phenolsulphonephthalein output but no rise in blood urea. The albuminuria persisted about five days. At no time were casts found. The phenolsulphonephthalein output returned to normal with the disappearance of the albuminuria. No evidence of kidney damage was found at necropsy on animals killed at the end of the experiments. With this toxic limit established no harm is to be expected from the small amount of the drug that may be absorbed when used locally in the genito-urinary tract.

#### IRRITATION

One per cent. solutions of mercurochrome-220 gave no evidence of irritating qualities when used in the conjunctival sac of rabbits. Solutions of this drug in strength from 0.1 to 5 per cent. have been used in the human genito-urinary tract as a local antiseptic. In the kidney pelvis a 1 per cent. solution was used. This was slowly injected through the ureteral catheter, the catheter was plugged, and the solution was retained for five minutes. There has been no sign of irritation or reaction following its use. This procedure has been carried out three times in one week in some instances. In the urethra a 5 per cent. solution caused only temporary burning when retained five minutes, and a number of cases of acute urethritis have been treated by the use of 1 per cent. solution injected four times a day, the solution being retained five minutes at each injection. There has been no irritation beyond occasional temporary smarting. No cases of retention have been seen, and no stricture formation has resulted from its use in our series of cases, as will be seen from the case reports.

In only two instances was there any complaint of burning or irritation. These were both chronic cystitis cases in old men with residual urine. One of them had extensive carcinoma of the prostate involving the bladder, with a residual urine of 200 c.c. He was on interval catheterization, and about 1 ounce of 1 per cent. mercurochrome was placed in the bladder and retained until the next catheterization, about six hours later. This man complained of severe burning in the bladder and had a reaction, which persisted for several days, after which his urine became much clearer but his infection persisted. The other case was similar, that of an old man with an enlarged prostate, his general condition being such as to make prostatectomy out of the question. There were several hundred cubic centimeters of residual urine. After several hours he complained of severe burning in the bladder, which persisted several days.

With the exception of the two cases noted, we have seen no irritation beyond occasional temporary smarting at the time of injection. The solution has been used in a number of bladder infections with small amounts of residual urine without irritation. The fact that irritation has been seen so rarely indicates that its occurrence in these cases is due to some individual hypersensitiveness rather than to any inherent property of the drug. Some observers who have been using

it have reported not only absence of irritation but also a prompt cessation of pain following the use of the drug in infected bladders and kidney pelves.

#### BACTERIOLOGIC TECHNIC

The medium chosen in which to test the germicidal action of drugs intended for use in the urinary tract was urine. We are aware that the objection may be raised that many infections have their seat in an environment more closely related to serum than to urine, and that serum therefore represents the most rational medium for test tube experiments. How far this contention really applies to infection of the urinary tract may well be questioned, especially in such infections as may be located not much deeper than the epithelial layers. Moreover, no set of test-tube experiments can be relied on for much more than a rough comparative evaluation of various germicides, which will bear no necessary relation to relative efficiency in clinical tests. For this reason urine seemed a medium fairly well representing clinical conditions. It had the further advantage that the results obtained with it take into account any precipitation or other chemical change that the drug may undergo under conditions of actual clinical application in the urinary tract.

The tests were carried out after this manner: Urine was voided aseptically into sterile flasks, and adjusted to the reaction of 6.4 on the hydrogen-ion scale. Blank tests were made to insure sterility. Nine c.c. of this urine were inoculated with a 3 mm. loopful of a twenty-four hour broth culture of the organism. To the inoculated urine was added 1 c.c. of an aqueous solution of the drug ten times as strong as was desired in urine dilution. Thus, 9 c.c. of urine plus 1 c.c. of the 1:100 drug solution gave a final dilution of 1:1,000 in urine. The mixture was at once well shaken, and at the end of the desired time period 0.1 c.c. of the mixture was transferred with a sterile capillary pipet to 10 c.c. of agar, and this mixture was immediately plated. The advantage of adding the drug to inoculated medium rather than to inoculate medium already containing the drug has been forcibly pointed out by Dakin and Dunham.<sup>10</sup> The former procedure simulates that carried out in an actual disinfection, and has the advantage that, in case the drug is altered in any way by the medium, it at least gets an equal chance to act on the organisms as well as be acted on by the medium.

In making tests with final dilutions that are low (for example, 1:100), it must be remembered that a considerable concentration of the drug may be present in the agar plate. Thus, if 0.1 c.c. of a 1:100 solution in urine be transferred to 10 c.c. of agar, we shall have a new hundredfold dilution; that is, the dilution in agar will be 1:10,000. Since the agar plate is inoculated at least twenty-four hours, we have in effect a dilution of a 1:10,000 solution on the organism for twenty-four hours rather than action of a 1:100 solution for whatever time period we may choose in our test. The results thus obtained are obviously erroneous, and in order to avoid them, this expedient was adopted: After the low dilution (1:100) had acted on the inoculated urine for the stipulated time, 0.1 c.c. was mixed with 2 c.c. of sterile water, and 0.1 c.c. of this new dilution was plated with 10 c.c. of agar. The dilution in agar was then 1:200,000, a dilution which separate experiments showed was without action on

the organisms even in twenty-four hours. Blank experiments with this double dilution showed that when no drug was present, enough organisms were left to give a good growth in agar plates.

The composition of urine from the same individual varies considerably, and of course variable results were obtained. In every case three or more tests were made, and the figures given in the tables represent the highest dilution that always gave a sterile plate. In all cases an average of results would be more favorable to the drug, but we feel that the method of report we have adopted is safer and less open to criticism than an average would be.

In testing the germicidal value of the flavines, the precaution must be taken to read the plates after forty-eight hours as well as after twenty-four hours. We have frequently found that a flavine plate would apparently be sterile at the end of the first period and would show a growth of many colonies at the end of the second period. No such delayed growth was observed in tests with mercurochrome-220. This emphasizes the fact that the value of the flavines lies in their antiseptic action rather than in their germicidal action.

It should be mentioned that the notable difference between the action in acid and in alkaline urine shown by acriflavine is not shown by mercurochrome-220. The action shown by this compound in alkaline urine was slightly inferior to that shown in slightly acid urine.

#### COMMENT ON BACTERIOLOGIC TESTS

The outstanding fact observed on comparing the germicidal values of mercurochrome-220, acriflavine, protargol and argyrol (Tables 1, 2, 3, 4 and 5) is the rapidity of action of the mercury compound in fairly high dilutions. In one minute it kills *B. coli* or *Staphylococcus aureus* in a dilution of about 1:1,000, a result obtained with none of the other drugs even in one hour. In fifteen minutes its effect is nearly as great as in twenty-four hours, killing *B. coli* in this short time at 1:5,000, and *Staphylococcus aureus* at 1:10,000. A few tests were made to learn the minimal time in which a 1:100 solution would sterilize. *Staphylococcus aureus* was killed almost instantaneously; that is, as rapidly as we could introduce the drug, withdraw a sample, dilute in water (to dilute the drug out of action in the agar) and plate. This procedure took no longer than ten seconds. The same test on *B. coli* revealed that a few organisms remained after ten seconds' exposure to the drug. Since a 1:800 solution kills this organism in one minute, the time necessary for a 1:100 solution to kill is possibly no more than thirty seconds.

Acriflavine is shown to be much less potent as a germicide in even the most concentrated solutions, if allowed to act on the organisms for one hour or less. It surpasses mercurochrome-220 in the twenty-four hour test, at this time period appearing to be about four times as effective as the mercury compound. It is hardly logical to judge a local urinary germicide by its action on organisms during such a long period of time; a short period of exposure in the test, on the other hand, approximates clinical conditions. If rapid disinfection is a desideratum, as it appears to be, mercurochrome-220 is superior to acriflavine.

Comparison of mercurochrome-220 with the silver protein compounds is open to two interpretations. If we consider the action in the test tube of those solu-

10. Dakin and Dunham: Brit. M. J. 2: 641 (Nov. 17) 1917.

tions used clinically—10 per cent. argyrol and 1 per cent. protargol—the silver compounds compare favorably with the mercury dye except in the action of

TABLE 1.—THE GERMICIDAL STRENGTH OF MERCUROCHROME-220 IN URINE\*

Medium	Organism	Time Exposed to Drug	Highest Dilution Killing Uniformly
Urine (pu = 6.4)	B. coli	1 minute	1: 800
	S. aureus	1 minute	1: 1,000
	B. coli	5 minutes	1: 1,000
	S. aureus	5 minutes	1: 5,000
	B. coli	15 minutes	1: 5,000
	S. aureus	15 minutes	1: 10,000
	B. coli	1 hour	1: 5,000
	S. aureus	1 hour	1: 10,000
	B. coli	24 hours	1: 20,000
	S. aureus	24 hours	1: 20,000
Hydrocol fluid	B. coli	1 hour	1: 1,000
	S. aureus	1 hour	1: 1,000
	B. coli	24 hours	1: 4,000
	S. aureus	24 hours	1: 4,000

\* The test consisted in treating 9 c.c. of sterile urine with 1 c.c. of drug solution ten times as strong as desired in final urine dilution. One-tenth c.c. portions were placed in agar at the end of stipulated periods.

protargol on *Staphylococcus aureus*. If, on the other hand, we consider the action of solutions of the same concentration of these three substances, we find that the silver compounds are in no wise comparable with mercurochrome-220. Since most of the urinary infections penetrate more or less deeply into the mucosa, therapeutic results will probably be controlled by the concentration of the germicide that finds its way into the tissues. It therefore appears that our comparison should take into account the effective concentration of the various drugs, rather than the concentrations applied to the surface of the infected area. The latter concentrations may not, and in the case of a nonpenetrating substance, like argyrol or protargol, probably do not, represent the relative concentrations of the germicide actually reaching the seat of the infection.

TABLE 2.—THE GERMICIDAL STRENGTH OF ACRIPLAVIN IN URINE\*

Medium	Organism	Time Exposed to Drug Action	Highest Dilution Killing Uniformly
Urine pu = 6.4	B. coli	1 hour	1: 100
	Staph. aureus	1 hour	1: 200
Urine pu = 7.6	B. coli	1 hour	1: 200
	Staph. aureus	1 hour	1: 400
Urine pu = 6.4	B. coli	24 hours	1: 10,000
	Staph. aureus	24 hours	1: 10,000
Urine pu = 7.6	B. coli	24 hours	1: 20,000
	Staph. aureus	24 hours	1: 20,000

\* No exposure for less than one hour was made because of the weak germicidal action for the one hour period.

For this reason a comparison of absolute concentrations (Table 5) seems a reasonable one, in view of the superior penetrating power of mercurochrome-220, and such a comparison shows a superiority of the mercury dye over the silver proteins. Thus, whereas both argyrol and protargol at 1:1,000 fail to kill either *B. coli* or *Staphylococcus aureus* in one hour, the same concentration of the mercury dye kills both organisms in about one minute.

METHODS EMPLOYED IN THE CLINICAL USE OF MERCUROCHROME 220

In the treatment of infections of the kidney pelvis, the following procedure was employed: Ureteral catheterization was done and a separate collection was made from each kidney. This was centrifuged, and a stained smear was made and examined microscopically. After the collection was completed, the kidney pelvis was gently filled, the gravity method being used in

some instances and the syringe in others, with a 1 per cent. solution of mercurochrome-220, the catheter being plugged and the fluid retained in the pelvis for five minutes. There has been no complaint of pain and no severe reaction in any of our cases. This procedure was repeated twice a week, and when the urine from each kidney was free from pus and organisms for a week, the patient was discharged to return for further observation in a month.

In treatment of bladder conditions, the urethra was first irrigated with sterile water, a coudé catheter was passed, and the bladder was washed clean. One ounce of 1 per cent. mercurochrome-220 was then injected into the bladder through the catheter by pressure from a bulb syringe, or by a Keyes syringe. The patient was instructed to retain this solution for at least one hour, and longer if possible. Some patients have been able to retain the solution for more than three hours. This procedure was carried out twice a day, as a rule, and in some instances three times a day. There was

15 minutes	S. aureus	Growth
1 hour	B. coli	No growth
1 hour	S. aureus	Growth

occasionally some slight burning and smarting, which lasted only a short time. Several complained of smarting of short duration after three or four treatments, but not at first. The urine voided by the patient on arising in the morning was centrifuged. A stained smear was made and examined. After three or four treatments, the urine usually began to clear up, and as soon as it was free from organisms, the number of treatments per day was gradually reduced. It was noticed that as long as mercurochrome-220 was used in the bladder, the urine remained hazy owing to the

presence of exfoliated epithelial cells, and not of pus and organisms.

An abstract of ten cases treated in this clinic is included herewith.

REPORT OF CASES

CASE 1 (F 32830, J. H. H. D., Dr. Wesson).—Urethral stricture, perurethral abscess, cystitis and posterior urethritis.

A white man, aged 54, came in complaining of inability to void urine. The family history was negative. The patient denied previous venereal disease. Four years before, the patient was admitted to the Johns Hopkins Hospital with a diagnosis of perineal abscess and urethral stricture. During his stay of one month in the hospital, the abscess was opened and the stricture was thoroughly dilated. During the interval the patient had no trouble. On his return there was a large swelling in the perineum, and the patient voided with great difficulty. Filiforms and fall-wipers up to 24 F. were passed, and a caude catheter was then introduced, through which 500 c.c. of foul-smelling, sanguinolent urine was withdrawn. The patient was placed on daily bladder irrigations of a potassium permanganate solution (1:1,000) and at the end of five days the urine was still cloudy and infected with both bacilli and cocci. Irrigation of a warm solution of mercurochrome-220 (1:1,000) were then given daily. Following the irrigation, 1 ounce of 1 per cent. mercurochrome-220 was placed in the bladder and the patient was instructed to retain this for at least one hour. The infection immediately began to clear up, and at the end of five days the urine was clear and entirely free from pus and organisms, and remained so until his discharge from the clinic four weeks later. The patient is still under observation, returning for weekly dilations of the stricture. The patient was able to retain the 1 per cent. mercurochrome-220 solution for more than two hours in the bladder without any discomfort.

CASE 2 (7298, B. U. 1).—*Subacute cystitis with chronic terminal vesiculitis*.—A white man, aged 20, came in complaining of the presence of pus in the urine. The family and venereal histories were negative. The patient stated that for the past three years he had had intervals of bladder irritability associated with the passage of cloudy urine. The past history was otherwise negative. Examination of the urine disclosed the presence of a bacillus infection and a large amount of pus. Urethral catheterization repeated several times revealed that the kidneys were free from infection, and no acid-fast organisms were ever found. The patient received treatment at irregular intervals at the Brady Clinic for six months, receiving prostatic massage, seminal vesicle stripping, irrigations with potassium permanganate solutions (1:1,000), and instillations of solutions of acriflavine (1:1,000). Flavine solutions were used twice a week for two months without clearing up the infection. Instillations of from one-half to 1 ounce of 1 per cent. solution of mercurochrome-220 were then begun, given on alternate days. The urine began to clear immediately, and after the sixth treatment was found to be free from pus and organisms. The urine was examined at weekly intervals for a month, and no infection was found at any time. The patient had no difficulty in retaining the solutions in the bladder for from one to three hours. The patient returned, after a month's absence, with cloudy urine, which was found to be due to phosphates and was free from infection and pus.

CASE 3 (7775, B. U. 1).—*Cystitis*.—A white man, aged 54, came in complaining of kidney trouble. The family and venereal history were negative. He gave a history of a severe bilateral renal colic twenty years previously. He had had no recurrence or symptoms until six months before, but had had about a dozen attacks in the past six months. On admission his bladder urine was cloudy, owing to a small amount of pus and a bacillus infection. The duration of this infection was indefinite. On cystoscopy there was no residual urine, and the bladder capacity was 250 c.c. The bladder was traumatized, and a small median bar with a pouch behind it existed. The kidneys were negative and no stone was found either to the ureter or the kidney by wax tip, plain roentgen ray or pyelogram. The treatment consisted of daily instillations of one-half ounce of 1 per cent. mercurochrome-220 through a posterior urethral instillator into the empty bladder, the patient retaining the solution for at least an hour and for longer periods if possible. After the first injection, the urine became clearer, but pus cells and organisms persisted until the fourth treatment. After this the urine contained a few desquamated epithelial cells, but no organisms were found at any time. The urine was studied twice during the

week following the discontinuance of treatments and was found free from infection both times, and also on discharge at the end of this time.

CASE 4 (6007, B. U. 1).—*Bilateral pyelitis and cystitis*.—A white man, aged 58, came in complaining of soreness in the left kidney region. This was the patient's third admission to the hospital. On his first admission he had a perineal prostaticectomy, convalescence from which was satisfactory except for a complicating epididymitis, and a febrile reaction associated with a pain in the lumbar region, probably due to a pyelitis. The patient improved markedly after leaving the hospital, and was well up to five weeks previous to his second admission. At this time he noticed that the urine was cloudy and highly colored. Three weeks previous to this he had had a second febrile reaction associated with pains in the kidneys. Urethral catheterization disclosed a bacillary infection of both kidney pelvis. The patient was treated by pelvic lavage, silver nitrate solutions being used and his infection entirely cleared up, so that on his discharge he had no pus or organisms in the urine. At this time he developed an acute epididymitis, which prolonged his convalescence. Four months later he returned to the hospital the third time, and a diagnosis of bilateral pyelitis and papillary cystitis due to a bacillus was made. The pyelitis was treated by pelvic lavage, 1 per cent. mercurochrome-220 solutions being used. The pelvis was gently filled with the solution until the patient became conscious of a sense of distention; the catheter was then withdrawn, leaving the pelvis filled. This was done once a week, and on alternate days the bladder was treated. From one-half to 1 ounce of a 1 per cent. mercurochrome-220 solution was used, being injected into the empty bladder and retained for an hour or more. It required ten treatments to render the urine pus-free and organism-free. The patient's urine was free from pus and infection on discharge after one month's treatment.

CASE 5 (7498, B. U. 1).—*Prostatic bar obstruction; Cystitis and bilateral pyelitis*.—A white man complained of pain across the pubic region on admission. The family history was negative except for the death of one brother from tuberculosis. He admitted a gonorrhoeal infection twenty years previously with no complications or recurrences. He dated his trouble to a severe attack of influenza about one year before. On his first admission to the hospital, studies made then led to the diagnosis of cystitis, median bar obstruction, bilateral pyelitis due to a bacillus infection, and a right-sided hydronephrosis of moderate grade. Previous to his admission the patient had been treated in another hospital for seven weeks by pelvic lavages, autogenous vaccines and bladder irrigations, but the infection persisted.

On his second admission a punch operation was done. When convalescent, urethral catheterization was performed, and the urine from both kidneys was found infected with bacilli, there being only a few pus cells present. Each pelvis was filled by gravity with a 1 per cent. mercurochrome-220 solution, and the catheter was withdrawn. Examination of the urine obtained by urethral catheterization on the first and third days following this one treatment failed to reveal any pus or organism. The patient left the city immediately after this last examination, but at a later date is to report for observation.

CASE 6 (E, outside case).—*Cystitis*.—A white man, aged 35, came in for an examination because of cloudy urine. The family and personal history were negative. The patient's urine was found to contain a small amount of pus and many bacilli. No definite history as to the length of time the infection had existed could be obtained. The kidneys were negative on urethral catheterization. No pathologic condition was found in the bladder except signs of a chronic cystitis due to long-standing infection. Daily instillations of one-half ounce of 1 per cent. mercurochrome-220 were carried out, and on the fourth day the urine was found to be free from infection and pus, and remained clear until the patient left the clinic.

CASE 7 (7728, B. U. 1).—*Prostatic bar; cystitis*.—A white man, aged 53, came in complaining of prostate trouble. The family and personal histories were negative except for two

gonorrhoeal infections without complications. On admission the patient had a few cocci in his bladder urine but no pus cells. Cystoscopy revealed a prostatic bar, and a punch operation was done and a retention catheter was left in place for forty-eight hours. On the removal of the catheter the urine was found to contain a large amount of pus, many bacilli and no cocci. The patient was treated by instillations of from one-half to 1 ounce of 1 per cent. mercurochrome-220. These treatments were preceded by irrigation of the anterior urethra; a coudé catheter was then passed, and the bladder was irrigated with sterile water. Instillations were given twice a day, and the solution was retained for at least an hour without any pain or burning. After the first day the urine became clearer, and after seven instillations (the morning of the fourth day) the urine was found to be free from organisms. Daily examination of the first urine voided in the morning failed to detect any infection during his subsequent stay of one week at the clinic.

CASE 8 (4364, B. U. I.).—*Chronic cystitis*.—A white man, aged 68, came back for observation. The patient had had a perineal prostatectomy four years previously, and had secured an excellent result; but a bladder infection persisted. Examination of the urine revealed a large amount of pus and many bacilli. The urethra was thoroughly irrigated with sterile water; a coudé catheter was passed; the bladder was washed clean with sterile water, and 1 ounce of 1 per cent. mercurochrome-220 was injected through the catheter into the bladder. This was done twice a day. Daily examination of the urine was made. The morning urine the third day (after five treatments) was found to be free from organisms, but contained many epithelial cells. The urine was examined each day during the rest of his stay at the clinic (three days), and no organisms were found at any time. There was no irritation or burning when the solution was retained in the bladder from two to three hours.

CASE 9 (7732, B. U. I.).—*Chronic cystitis*.—A white man, aged 53, complained of kidney trouble. The family and personal histories were negative. For the past three years the patient had had a pain in the right lumbar region at times. This was never severe, but rather of the dull aching character. Five months before admission, the patient began to have hematuria and renal colic on the right side. Urethral catheterization revealed a coccus infection on the right side and no infection on the left side. A pyelogram was made and a diagnosis of right hypernephroma made. Nephrectomy was performed. Following this the bladder infection persisted. The patient was then given bladder instillations of one-half ounce of 1 per cent. mercurochrome-220 on alternate days to be retained for one hour. There was an immediate reduction in the number of pus cells and organisms. After the seventh treatment the urine was found to be free from infection and remained so for two weeks. In this time the urine was carefully examined four times, but no infection was found.

CASE 10 (7857, B. U. I.).—*Cystitis*.—A white man, aged 50, had complained of urinary difficulty for the past six years. The family and personal histories were negative except for two gonorrhoeal infections, the last one being six years previously, from which time the patient dated his urinary trouble. Examination detected a tight stricture in the membranous urethra and a contracted vesical orifice. A punch operation was done under local anesthesia, and a retention catheter was left in the bladder for drainage for forty-eight hours. The patient developed a mixed infection of the bladder, both bacilli and cocci together with a large amount of pus being found in the urine. After the removal of the tube, daily instillations of 1 per cent. mercurochrome-220, preceded by irrigations of sterile water, were begun. The urine was examined daily. There was a gradual diminution in the number of organisms and the amount of pus. There were no organisms found on the fifth day, a very few on the sixth and none afterward up to the twelfth day of the treatment.

#### RESULTS IN URETHRITIS

The bacteriologic tests of the action of mercurochrome-220 on the gonococcus have not been completed as yet and will be published later.

In fifty-one cases of acute specific urethritis, treatment has been given by intra-urethral injections of 1 per cent. solutions of this drug. These were all public dispensary cases, and a large number of the patients were negroes, many of whom failed to cooperate, while others failed to continue their treatment after the discharge began to diminish, especially if they had no complication to cause them pain or annoyance. In none of these cases have we seen any irritation beyond a temporary burning or smarting, whether the drug was used in the anterior or in the posterior urethra.

The method used in these cases has been: microscopic diagnosis as to the presence or absence of gonococcus; the three glass test to determine the part of the urethra involved and the extent of involvement, and an examination of the prostate and the vesicles on the first visit. We did not examine the urethra with a bougie à boule, owing to the presence of an acute discharge. An anterior urethral irrigation of warm sterile water or dilute (1:10,000) potassium permanganate solution was then given. This was followed by the careful injection into the anterior urethra of sufficient 1 per cent. mercurochrome-220 solution to fill completely the anterior urethra, the patient compressing the lips of the meatus and retaining the solution for five minutes. If the posterior urethra was involved, the solution was gently forced into the posterior urethra by means of a bulb syringe, and was retained in the bladder for an hour or more. A small quantity of the drug solution and a blunt nosed urethral syringe were dispensed, and the patient was instructed to inject the solution four times a day immediately after urinating, retaining it for five minutes. On return to the clinic, smears were examined microscopically, and as the organisms lessened in number, the number of injections was reduced to three and then to two and later to one per day. The reduction should be gradual. As long as the drug is used the urine will remain cloudy owing to exfoliated epithelial cells, which will be found stained pink, while the polymorphonuclear cells will not be stained by this drug.

We were able to follow thirty cases until an apparent cure was effected. This involved in some cases the treatment of preexisting or consequent prostatitis, vesiculitis or stricture. In such cases a cure was considered accomplished when the urethral discharge had disappeared and the urine remained free from shreds for two weeks. It was found very difficult to secure the cooperation of this class of patients, in the treatment of residual prostatitis, when all urethral and urinary signs had disappeared.

Twenty-one other patients were improved and discontinued treatment. The average length of time required to render the discharge free from gonococci was ten days. The shortest time required to accomplish this was three days. These were acute cases, two of which remained free from further infection, but in one case there was a recurrence of organisms after nineteen days, due to a reinfection from the prostate. The longest time required to render any case gonococcus-free was seventeen days. This was an acute exacerbation of a chronic infection, with involvement of the posterior urethra and the prostate.

Recurrence of organisms took place in six cases, or 20 per cent. of our total. Two of these six were cases in which the anterior urethra alone was involved, and the recurrence was probably due to stopping the injections before the entire canal had been sterilized.

CHANCROIDAL ULCERATIONS

As a result of the laboratory tests demonstrating the penetrability and germicidal activity of mercurochrome-220, it was decided to use it as a local application in the treatment of nonsyphilitic venereal ulcerations. Fourteen dispensary patients were treated with the local application of mercurochrome solutions. We were able to follow ten of these patients until healed. In four cases an initial treatment was administered and some of the solution was given for local use, but the patients failed to return for further treatment and observation. All these cases were negative on repeated dark field examination for *Spirochaeta pallida*, and gave negative Wassermann reactions. No cases are included in which the patients were found to be syphilitic or were receiving intravenous arsenical medication. The type of sore was that of the old sore with undermined edges and dirty gray necrotic base which showed no tendency to heal.

These sores were thoroughly cleaned with soap and water, and all the necrotic tissue was removed. A moist dressing of 1 per cent. mercurochrome-220 was then applied, and some of the solution was given the patient with instructions to moisten the dressings twice a day with the solution. Later it was found more convenient to use a starch paste containing 5 per cent. mercurochrome-220 by weight, instead of the solution, the sore being dressed only once a day. No irritation or burning was complained of by any of our patients.

TABLE 7.—SYNOPSIS OF RESULTS DETAILED IN TABLE 6

Number of cases studied.....	51
Number of cases observed until an apparent cure was effected.....	30
Number failing to improve.....	0
Minimum time required to render discharge gonococcus-free.....	2 days
Maximum time required to render discharge gonococcus-free.....	17 days
Average time required to render discharge gonococcus-free.....	10 days
Number of cases in which complications developed after treatment was begun.....	3

In all of the cases, the sores cleaned off in from one to four days and presented a healthy healing surface. The prompt change in the appearance of the lesions when treated with mercurochrome was very striking. After the sore was clean and healing over, a simple ointment of boric acid was used as a protective dressing, silver nitrate being used on the granulations as needed. Whenever indicated, a dorsal slit was made and buboes were opened and drained. Tables giving the length of time required for complete healing are not included, as many of the patients left the clinic after the sore was partly healed.

CONCLUSIONS

1. Mercurochrome-220 is experimentally a drug of great germicidal value, a solution of about 1:1,000 killing *B. coli* and *Staphylococcus aureus* in urine in one minute. It has practically fifty times the germicidal strength of acriflavine in urine medium for exposures of one hour.

2. In a strength of 1 per cent. the new drug is tolerated by the human bladder for from one to three hours without irritation. Injections of 1 per cent solution into the renal pelvis are likewise free from pain, even when held in situ by plugging the catheter.

3. That mercurochrome-220 has a remarkable germicidal value is shown by the rapid sterilization accomplished in a series of cases of cystitis and pyelitis of long standing and refractory to other treatments. Now for the first time we feel that we have a method of quickly curing certain chronic infections of the bladder.

The rapidity with which a few cases of old purulent cystitis disappeared was surprising, becoming free of pus and bacteria in a few days.

4. Studies of the comparative value of acriflavine and mercurochrome-220 in gonorrhoea are not yet complete, but it has been demonstrated that with both drugs, methods of great value in the treatment of the disease have been produced.

5. Mercurochrome-220 has proved to be eminently satisfactory in the treatment of chancroids and as a dressing for buboes after incision.

Other drugs developed along the same lines have been produced and are being experimented with by us.<sup>11</sup>

ROENTGEN-RAY TREATMENT OF WIDE-SPREAD AND GENERALIZED DISEASES OF THE SKIN\*

FRED WISE, M.D.

Instructor in Dermatology and Syphilology, Columbia University  
College of Physicians and Surgeons  
NEW YORK

In the early days of the roentgen-ray therapy of skin diseases, those who resorted to this mode of treatment employed it chiefly in certain cutaneous affections which, as a rule, were restricted in area, or were limited to certain well defined regions of the body, or occurred only as circumscribed or isolated lesions. For example, such affections as epithelioma and sarcoma, the various granulomas, keloid, ringworm of the hairy surfaces, and other diseases which did not readily respond to the older methods of treatment in common use at the time, would be, so to speak, consigned to the mercies of the roentgen ray, to reap the benefits of, or to suffer the evils from a subtle and powerful therapeutic agent, the precise nature and action of which is to this day unknown. Even in such relatively small and well defined lesions as basal cell epitheliomas, keloids, warts and circumscribed granulomas, the administration of the roentgen ray was at one time, not far gone, a more or less haphazard, indeterminate process, the outcome of which, if it resulted favorably, was often at best only "the happy combination of fortuitous circumstances."

EXACTNESS IN THE ADMINISTRATION OF DOSAGE OF RAYS

As is well known, the last few years have witnessed great strides in the science and art of roentgenotherapy as applied to cutaneous affections. Improvements in the manufacture of the various types of exciting apparatus, and in devices for measuring the quality and quantity of the rays, have done much toward the introduction of many refinements in technic, so that we are enabled today to measure the exact quality and to determine the exact quantity of a given roentgen-ray

11. In treating acute anterior gonorrhoea, we are at present using a 1 per cent. solution of mercurochrome instead of 1 per cent. This may be used every three hours, and should be preceded by a vigorous irrigation of sterile water. It is now a three hours burning that is 1 per cent. solution, which, however, is temporary. On one subject, it is seen that the time necessary for the bacteria to be rendered unfavorable complications have been observed. At present a series of cases is being treated by the use of a 1 per cent. solution of mercurochrome and potassium cupric periodate of the same strength. The above results indicate that the former treatment is an efficient one, the latter being even more easily prepared.

\* Read before the Section on Dermatology at the Twenty-fifth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

emanation, without the least difficulty; in other words, we can easily administer an exact dose of roentgen rays. These improvements in apparatus and advances in technic have culminated in the production of the Coolidge tube with its remarkable flexibility and its steady delivery of rays of uniform quality.

The present-day degree of perfection attained in this method of treatment of skin diseases may therefore be measured by the facility and the simplicity with which a given dose may be safely and accurately administered, within a specified and reasonable length of time. This degree of perfection was not arrived at without much laborious experimentation and investigation; and the modern dermatologist owes a large debt of gratitude to such diligent workers and scientists as Sabouraud and Noire, Benoist, Holzknecht, Kienböck, Pusey and Caldwell, MacKee and Remer, Withelbee, Shearer, Corbett, Hampson and many others, too numerous to mention here.

#### TECHNIC

For the benefit of those who have not yet taken up this method of dermatotherapy and who contemplate doing so, I will briefly describe the technic which I employ with the best results in my practice and the effects of which I have constantly the opportunity to observe in the roentgen-ray service of the Vanderbilt Clinic, under the direction of Dr. John Remer. This technic has been elaborated and standardized by Drs. MacKee and Remer, and it is to them that I am indebted for my acquaintance with the more recent refinements of roentgen-ray administration.

Heretofore it had been necessary to employ a Holzknecht radiometer and a Benoist penetrometer or other similar devices designed for the purpose of ascertaining the quality and quantity of roentgen-ray doses. With the advent of the Coolidge tube, however, these measuring instruments are no longer essential to practical and accurate dosing. The vacuum of the Coolidge tube being stable and constant, the dosage may be determined by the observance of other important factors: namely, the length of the parallel spark gap, the distance between the anode of the tube and the skin, the amount of current passing through the tube during a given exposure, and the length of time of the exposure.

*Apparatus.*—Many excellent types of apparatus are on the market. That which I use consists of a two kilowatt, sixty cycle transformer unit, with a rotary converter to convert the direct current of 220 volts to an alternating current, and with a so-called rectifying disk, mounted on the same shaft. Attached to the cabinet are an amperemeter, a rheostat, a millimeter for the exciting current, and a meter for the Coolidge tube filament. The filament is heated by a current from a small, separate rotary converter, fed by a 110 volt main, the current from which is passed through a step-down transformer. An apparatus of this type appears to be sufficient for all purposes which the dermatologist is likely to require in his daily practice. It is capable of backing up an 8-inch parallel spark gap, and may therefore be employed also for deep therapy, a filter of 3mm. of aluminum being used.

*Standardization of Apparatus.*—This apparatus was standardized according to the method suggested by MacKee and Remer. To obtain one Holzknecht unit at "skin distance," that is, with the exposed pastil of barium platinoeyanid resting on the skin, the following

factors were found to be serviceable as convenient working constants: length of parallel spark gap, 6 inches; amount of current passing through the tube, 2 milliamperes; distance from the anode to the skin, 8 inches; time of exposure, three minutes.

With the Coolidge tube backing up a 6-inch parallel spark gap, the Benoist penetrometer reading is approximately No. 8, that is, a "hard" ray. Experience has taught that a No. 8 to 9 B ray is to be preferred in dermatologic practice, to much softer or much harder emanations.

*Accessories.*—A stout wooden table, 6½ feet long, 2 feet wide and of the height of an ordinary dining room table, fitted with heavy roller casters, is most useful. It should be fitted with an adjustable head rest and leg and arm rests, preferably made of wood, and so constructed that they may be folded and put out of the way when not in use. A heavy tube stand, constructed with a well-balanced counterweight and a stout lead glass bowl for the Coolidge tube is to be preferred to the lighter wooden stands, the risk of accident to tube and patient being lessened with the use of a heavy apparatus. An overhead trolley system for conducting the leads to the tube, and a lead screen to protect the operator, complete the outfit.

*Method of Administration.*—In a general way, it may be said that the treatment of widespread and generalized skin diseases consists in the administration of repeated fractional doses to the entire affected integument. In the majority of eruptions a dose of one-eighth to one-quarter Holzknecht units at "skin distance," administered once or twice a week, over periods varying from two to eight weeks, is sufficient to bring about involution of many of the dermatoses amenable to the treatment, so that the skin is exposed to a total dosage varying from three-quarters to one and a half Holzknecht units (skin distance) in from three to eight or nine weeks. These figures are, of course, only approximate, being subject to considerable variation. For example, a superficial, thin-scaled generalized psoriasis may involute under a half or even a quarter the amount of radiation that would be required to heal a chronic, infiltrated and thick-scaled eruption of the same disease. Again, certain eruptions as a whole require different amounts of roentgen ray and different intervals between the exposures: for example, the smooth plaques and the elevated tumors of mycosis fungoides, which may occur simultaneously in one patient.

*Exposures of Large Areas of the Skin.*—When large areas, such as the anterior surface of the trunk, or the entire back, are to be treated, the rays are so administered as to permit of an approximately equal distribution of the dose over the flat and convex surfaces of the body. This is accomplished by allowing the rays to overlap from different focal points of the tube, on the same principle as the Kienböck-Adamson method of treating ringworm of the scalp, although the accuracy of the latter method cannot be duplicated in treating the trunk, nor is such exact dosage strictly necessary for practical purposes. The usual procedure is to expose certain regions of the skin in succession, as both sides of the upper chest, both sides of the mid-thoracic region, both sides of the abdominal region, etc., each area receiving the required one-eighth to one-quarter unit of radiation. Investigations bearing on this technic were carried out, about a year ago, by

W. H. Guy,<sup>1</sup> under the direction of MacKee and Remer. Guy found that a uniform dosage of roentgen rays striking a flat surface is not circular in outline as was thought to be the case, but is elliptical, with the long axis of the ellipse at right angles to the long axis of the tube. Employing a standard treating distance of 8 inches from the anode, the ellipse measured 8 by 4 or 5 inches. To quote from Guy's paper:

Thus at 8 inches the selected points for treatment should be not more than 5 inches apart in the long axis of the tube if the method of multiple application be followed. On the other hand, if one uses the open tube and allows for overlapping of rays, then in the long axis of the tube, treatments should be applied about 10 inches apart; at right angles to the long axis of the tube, about 15 to 20 inches apart. This of course applies only to a flat surface, concavities and convexities being allowed for, according to the law that intensity varies inversely as the square of the distance, excepting when using filtered rays, when the rule of direct proportion applies, as recently established by Remer and Witherbee. In treating large or convex surfaces, the law relative to the intensity being in direct proportion to the sine of the angle of incidence, must be considered. By increasing the distance from the anode we found that the size of the elliptical field increased proportionately, but was not as well defined as at the shorter distance. On the other hand, when the tube was moved nearer, the field was narrowed. Thus, if one desires to treat a comparatively large area by a single application, approximately accurate dosage may be obtained by placing the tube farther away.

*Subdivision of Doses.*—It is unwise, and may even prove to be dangerous, to expose more than one third or even one fourth of the body surface at the same sitting, or on the same day. It is best to allow several days to intervene between the treatments, so that approximately two exposures a week are administered, when the entire skin requires radiation, the different regions of the body being treated at different times. For example, the arms and thighs may be exposed to the rays at one sitting, to be followed, after a lapse of three or four days, by roentgenization of the skin of the back or of the chest. This is done to obviate all risk of toxemia from absorption products or ill effects brought about by changes in the blood, resulting from exposure of large surfaces of the integument to roentgen rays.

When treating extensive surfaces, such as the chest and abdomen or the back, cognizance must be taken of the law that the intensity<sup>2</sup> varies inversely as the square of the distance. That is, the quantity of roentgen rays striking a given area of integument varies inversely as the square of the distance between the anode and the skin. In the application of this rule in practice—for example, in exposing the entire chest of a man—the anode may be focused at a given distance above each nipple, to which areas a certain dose is administered, say  $\frac{1}{4}$  H unit over each breast. In this procedure, calculations based on the law of intensity determine the quantity of rays striking the area of skin between the two focal points, in this case, each nipple; that is to say, the sternal portion of the chest receives overlapping rays from each lateral exposure, approximately equivalent to  $\frac{1}{8}$  H unit from each side, resulting in a  $\frac{1}{4}$  H dose to the intermammary region.

*Two Groups of Skin Diseases.*—Broadly speaking, the extensive dermatoses that most favorably respond to roentgenotherapy may be placed in two groups. The

first group comprises those in which a lasting amelioration of the symptoms or a permanent cure is to be expected; the second group comprises those in which only a temporary subsidence or removal of the lesions can be hoped for. The first group includes such diseases as lichen planus, seborrheic dermatitis, various forms of eczema, extensive eruptions of pityriasis rosea and of acne, generalized prurigo, and various forms of lichenification. The second group embraces psoriasis, dermatitis exfoliativa, pityriasis rubra, mycosis fungoides, leukemia cutis, the various forms of sarcomatosis and lymphogranulomatosis, Darier's disease, acanthosis nigricans, and other dermatoses having a tendency to implicate extensive surfaces of the body.

#### THERAPEUTIC RESULTS

I do not intend, in this paper, to go into details with regard to the therapeutic results obtained in these various dermatoses. It will suffice to say that extensive outbreaks of eczema, seborrheic dermatitis, lichen planus, widespread lichenifications, psoriasis, dermatitis exfoliativa, infectious eczematoid dermatitis and similar obstinate diseases respond to the treatment much more readily, and exhibit involution of the lesions much more rapidly, than they do under any other form of therapeutic procedure. Very few cases of this kind fail to show distinct improvement after a series of exposures amounting to three quarters to one and a quarter units of roentgen rays, administered over a period of from three to eight weeks.

The advantages of roentgenotherapy over the older methods of treatment with ointments, lotions, plasters, etc., need not be enumerated. In the pruritic eruptions, the itching, smarting and burning sensations usually are relieved after the second or third exposure. The annoyances and inconveniences attending the use of external applications are eliminated. Patients with extensive eruptions of psoriasis are freed of their trouble, if only for a time, within from three to six weeks, without resorting to mercury, tar or chrysarobinunctions, although they are advised to use petrolatum or cold cream to hasten the elimination of scale formation. In my experience, seborrheic dermatitis and psoriasis respond to the treatment more rapidly than the other affections above mentioned, the various lichenifications of the skin and lichen planus of the diffuse variety being next in order. In some patients, a well marked pigmentation of the skin remains at the sites of the lesions for several weeks after involution has taken place, especially after psoriasis and lichen planus.

With regard to the graver dermatoses, such as Darier's disease, mycosis fungoides, leukemia cutis, disseminated sarcoma of the skin and related maladies, we have in roentgenotherapy practically the only remedy which may be said to be of the slightest practical value in the treatment of extensive diseased surfaces. The most striking results are obtained in mycosis fungoides and Kaposi's sarcoma. In cases in which the lesions are not too far advanced, and sometimes even in the most advanced instances, the individual plaques, tumors and ulcerations are often healed without difficulty and in a remarkably short time. Not only does roentgenotherapy keep alive the patients with these diseases, but, if they submit to persistent and judicious treatment, they live in comparative comfort and retain a fair state of general health. In mycosis fungoides the ordinary unfiltered applications suffice

1. Guy, W. H.: Experiments with Roentgen Rays and Radium, *J. Cutan. Dis.* 30:332 (June) 1918.  
2. Amount or quantity of roentgen rays.

to bring about involution of most of the lesions; but in the various forms of disseminated sarcoma it has been found necessary to employ the deep, filtered ray to restore the tissues to their normal state (Remer). It is quite true that roentgen rays do not cure patients with these grave maladies; the lesions recur sooner or later, and the victim dies of metastases or intercurrent disease. But it is equally true that no other form of treatment can compare with roentgenotherapy in effectiveness with regard to the relief of subjective symptoms and objective signs, and with regard to checking the progress of the disease and retarding the fatal outcome. To permit this class of patients to spend the few remaining months or years of their lives in constant agony, when relief and perhaps even cure may result from roentgen treatment, seems to me to be nothing short of heartless negligence.

#### OTHER DISEASES AMENABLE TO ROENTGENOTHERAPY

I<sup>3</sup> recently reported an instance of acanthosis nigricans of the juvenile type, occurring in a young woman under my care. She presented typical and well pronounced lesions implicating practically the entire body, with rugose and papillary growths in the axillae and the groins. A series of roentgen-ray treatments, extending over a period of five months, has resulted in complete involution of the lesions, so that her skin today is normal in appearance and texture. Cognizance is taken of the fact that the juvenile variety of this disease occasionally heals spontaneously; but the fact remains that until the rays were administered, no definite signs of healing were manifested in this patient's eruption.

In the treatment of pityriasis rubra pilaris, dermatitis herpetiformis and the various bullous and desquamative diseases grouped under the head of pemphigus, I have had too little personal experience to venture an opinion as to the efficacy of roentgenotherapy. But I feel that we are justified in giving this form of treatment a very thorough trial in such affections, knowing, as we do, that in most instances our efforts to cure the patients or even to ameliorate their symptoms with the older remedies usually prove to be fruitless.

#### CONCLUSION

The carefully computed fractional dose administration of roentgen rays may be used with impunity in the great majority of extensive dermatoses, which do not readily respond to the usual older remedies; and though it is true that certain maladies seem to be not susceptible to the healing properties of the rays, roentgenotherapy should nevertheless be given a chance to prove its worth, in the knowledge that no harm, and possibly a great deal of good, may result from its judicious administration in many of the widespread dermatoses.

24 West Fifty Ninth Street.

#### ABSTRACT OF DISCUSSION

DR. EBERETT S. LAIN, Oklahoma City: I was pleased to hear this very concise and interesting résumé of Dr. Wise's experience with the roentgen ray. He has gone into the details so explicitly as regards the technic that it seems that almost any one might follow his technic and do successful work. There are a few things, however, on which he was not so explicit and which might lead to error on the part of some one attempting to treat diseases. Of course,

it was only lack of time that Dr. Wise did not mention these things. He considers the advantage of treating psoriasis by roentgen ray though he certainly should have mentioned the misfortune one might have in treating the scalp with this agent, also over the eyebrows and eyelashes. However, in my experience, and that of others too, a first depilatory ray is usually not permanent. Dermatitis herpetiformis, I believe, belongs in the second group, as mentioned by Dr. Wise. It is more benefited by this method than by the use of medicine, but, like psoriasis, it is sure to return unless some etiologic factor is sought and removed. He mentions the use of only one radiometer, the Holzkecht. If I am not mistaken that is not obtainable at present. I was unable to obtain the pastilles soon after the war began and so had to invest in another, a Hampson, and I believe it is more convenient for the inexperienced man than the Holzkecht is. No one should attempt treatment at all without first measuring his machine carefully. Every machine varies. No two machines will give exactly the same output under the same conditions, for many reasons; first, because of the different windings in the various coils, also because of the different output conditions in the various cities. Again, the same type of machine from the same manufacturer, in my experience will not always give the same amount of ray which a former machine may have measured. Machines should always be carefully tested before attempting roentgen therapy.

DR. GEORGE M. MACKEE, New York: I believe that a technic has been developed that stands all the requirements of practical work, a technic that is very versatile and that can be handed from one individual to another and used on any apparatus in any part of the country. Dr. Remer and Dr. Witherbee, among others, have tested this technic very accurately in every way on every transformer we have been able to find in the different cities, and the results are absolutely the same. What Dr. Lain says one must take cognizance of, of course. The technic, although accurate, is by no means fool proof, and one must not only be acquainted with the technic but with all possible errors. The technic cannot be made fool proof. It is no longer necessary, I am glad to say, to depend on any form of radiometer whatever. It is possible to estimate the dose with arithmetical accuracy, provided a man has had any experience. Any technic that can be used on the scalp by a number of different individuals, some of them necessarily in different cities, certainly stands all the tests, and that has been accomplished. Listening to Dr. Wise's paper has made me a little reminiscent and I cannot help but recall the difficulties we had ten or fifteen years ago. Those of you who are undertaking the work now do not realize the difficulties the earlier workers encountered and overcame, some of them dying in the attempt. There was at first a wave of enthusiasm and confidence and everybody was going to treat everything with the roentgen ray. That wave did not last long and was followed by a wave of pessimism and it was difficult to get permission to apply the roentgen ray, either from the patient or the patient's doctor. Within the last few years, thanks to the efforts of a few scientifically inclined dermatologists and roentgenologists, we have roentgen-ray therapy placed on a scientific basis and there is again a feeling of confidence. I would urge that those who write on roentgen rays and use them pay particular attention to technic and the avoidance of statements that are not conservative. Otherwise we will have history repeated and in claiming results we cannot get, together with untoward results associated with overconfidence and carelessness, we may have another wave of pessimism. Thanks to modern technic, the day of the acute roentgen-ray burn has passed, but the day of sequels has not passed, and that has not so much to do with the roentgen ray as with judgment. That depends on the judgment of the person using it and that requires a certain amount of experience which is within any one's reach. Sequels such as telangiectases, atrophy, roentgen warts and epithelioma can be avoided. We make it a rule in the clinic never to produce an erythema, except in some cases where we are justified in doing so, such as in epithelioma. We never produce an erythema in any disease where it is not absolutely necessary,

<sup>3</sup> Wise, Fred: Acanthosis Nigricans Foliwig Decapsulation of the Kidneys: Report of a Case, *J. Cutan. Dis.* **34**: 35 (Jan.) 1913.

because an erythema may lead to telangiectasia and atrophy years afterward. It is not only a question of technic but also of judgment.

DR. J. D. GIBSON, Denver: Unfortunately, many of us got our burns before the technic was produced, and I was one of them. We must watch the treatment and know what we are trying to accomplish. In skin treatments we must never lose sight of the fact of whether we want to get a reaction or not. In the deep conditions we usually want a reaction, but in many of the others, like psoriasis, it is not necessary to produce a profound reaction.

DR. WALKER J. HIGHMAN, New York: In substantiation of Dr. MacKee's experiences, I wish to state that the latter were confined on the skin service at the Walter Reed General Hospital, Washington, D. C. The scheme of dosage suggested by MacKee was followed.

DR. JOSEPH ZEISLER, Chicago: It is with a great deal of hesitancy that I get up to say a few words, not at all in criticism of what has been presented and with admiration of the modern progress in roentgen-ray therapy. But after all, we should hold to this maxim; we employ roentgen rays for the purpose of accomplishing a certain result and in doing so we should avoid harm. If these two conditions are fulfilled the technic becomes of minor importance. I think I am expressing not only my own view but also that of Dr. Pusey when I say that with fractional doses these conditions can be fulfilled. I do not deprecate massive doses. I have employed fractional doses for eighteen years and have never had a sleepless night or any worry whatever on their account. In using the roentgen ray for generalized dermatoses I have always held that it should serve merely as an adjuvant, and that the more important consideration is the underlying cause.

DR. GEORGE M. MACKEE, New York: We have not been talking about massive doses. These are used only in a very few conditions, like plantar warts, epithelioma, etc. What we have been talking about is not a massive dose but a carefully measured dose, so that we know exactly how much is given. If so much treatment is given per week, we know how much per month. The technic is so simple in that respect that in Dr. Fordyce's clinic I simply write out a prescription for the dose. We advocate carefully measured doses, fractional or intensive, and with a technic that can be made universal so that results may be duplicated by the same operator and by other operators.

DR. HENRY H. HAZEN, Washington, D. C.: I would like to agree with everything Dr. Wise and Dr. MacKee have said. I have had several years' experience and in the last four years have been using the measured dose. If there is anything I dislike to get it is a patient coming from a man who does not measure his dose and does not know what the patient has received. You have no idea where the patient is going to get off or where you are going to get off. You cannot possibly send the patient from one man to another unless you can tell absolutely what has been done. So far as personal results are concerned, in the case of my own patients who have not been referred I can see no more comparison than between daylight and darkness and I would not think of going back to the old methods of unmeasured dosage. One thing I think we should be careful about at present. In view of the fact that we are using the Coolidge tube and much larger doses, it seems to me that the safety of the operator should be looked after. We are using a very powerful ray and we should protect the operator. For that purpose I have a telephone booth with lead on four sides and a switchboard inside, with holes for ventilation. It seems to me we should not neglect to protect ourselves and I do not think that a lead screen in front is sufficient. I thought that with the various Coolidge tubes I had I could estimate my dose in the manner mentioned. Then something happened and I had to use an old tube with a heavy metal deposit on it. I apparently found that with this tube we did not get quite the radiation with the same technic as we had before. It seems to me possible that with an old tube with an extremely heavy deposit there might be some slight difference in the result.

DR. R. A. McDONNELL, New Haven, Conn.: In the employment of roentgen rays and radium we sometimes neglect adjuvants to their use. I have not heard anything said about the advantages of curetting such lesions as epitheliomas and other deep growths before using the roentgen ray. In the last few years I have made it a rule to use the curet on the lesion before using the roentgen ray, and when that is done it is possible to get results with a much smaller dose, and consequently greater safety.

DR. GEORGE M. MACKEE, New York: In regard to using an old Coolidge tube: We have naturally tried out a large variety of tubes, old and new, and we now have one old tube that is absolutely black, but there is no difference in the results obtained. No two tubes have exactly the same resistance in the filament but that makes no difference. We pay no attention to the filament meter for we are guided entirely by the milliamperage and spark gap.

DR. FRED WISE, New York: Dr. McDonnell evidently misunderstood me. I was speaking not of epithelioma but of widespread skin diseases, in which the curet is not used. Dr. Lain's remarks were apropos; I failed to state that seborrheic dermatitis and other scalp diseases should not be treated in the scalp and eyebrow region with large doses of roentgen rays. One thing should be emphasized for those who are not acquainted with roentgen-ray technic and that was one point that I brought out. It is no longer essential to employ the various radiometers and penetrometers to obtain exact dosage, so that we are not dependent on various European devices as we were heretofore, but are enabled to measure accurately a dose of roentgen rays by means of the various factors which were elucidated in my paper.

## SPECIAL SPLINTS FOR CERTAIN INJURIES AND DISABILITIES OF THE EXTREMITIES\*

E. W. CLEARY, M.D.

SAN FRANCISCO

War and the accidents of civil industry produce large numbers of injuries to the extremities, the care of which involves the problem of splinting active ambulatory patients. Satisfactory appliances must be light, secure of adjustment and so contrived as to disturb the statics and dynamics of the wearer to the minimum degree consistent with the performance of the function for which the splint is prescribed. It is my purpose here to describe three appliances developed in caring for several hundreds of war wounds of the extremities. These appliances are (1) a shoulder abduction splint; (2) an elbow and knee traction splint, and (3) a forearm supination splint. Three models of the shoulder splint and two of the elbow splint are to be presented.

### SHOULDER ABDUCTION SPLINT

The framework of the simplest model of the shoulder abduction splint is shown in Figure 1, and the complete appliance in Figure 2. This splint is remarkably comfortable because (1) it disturbs the statics of the wearer hardly at all; (2) the weight of the disabled arm is supported by a broad leather saddle on the well shoulder, and (3) though no metal part presses against the body, yet no ordinary activity can disturb the adjustment. With a pair of brace wrenches the frame can be bent and shaped to carry the arm at almost any angle within the normal range of motion. Patients wearing this splint bear themselves with a relaxed and easy carriage which is in marked contrast to the strained posture of those wearing any type of splint

\* Observations made and work done while the author was chief of the orthopedic section, U. S. Army General Hospital, N. Y.

which throws the weight of the abducted arm and of the appliance all, or nearly all, on the side of the injury, thus throwing to that side the center of gravity of the body.

The construction is so simple that one shopworker, without special machinery, turns out a complete frame (Fig. 1) in twenty minutes. We use the detachable diagonal brace only when an extra heavy patient is fitted, or when lighter rods are used for the frame. We have found it expedient to have a stock of splints made up in a standard size. By adjusting with wrenches we are able to make this standard size serve for the average man weighing from

Fig. 1—Arm abduction splint with detachable brace. For left arm (frame only, rear view).

130 to 185 pounds. We make special sizes for very small and very large patients.

In order that the reader may clearly visualize the appliance, I will describe the making of a standard size abduction splint as if it were being shaped about the body of the patient:

A soft iron rod 12 feet long and five-sixteenths inch in diameter is bent into the shape of a double pointed carpet tack with legs of equal length and a middle segment 12 inches long. The middle segment is curved to fit the waist on the uninjured side at the level of the iliac crest, the two ends pointed upward. Each end is bent laterad through a right angle at a point 2 inches above the middle segment. Another right angle bend in the reverse direction is made in each end of the rod one-half inch higher. These bends form offsets which will keep the belt of the finished splint from slipping upward. The end sections of the rod now stand upright, one in front of, and the other behind, the well shoulder. The next step is to bend each horizontally across the body, 1 inch above the level of the axilla. Both hori-

Fig. 2—Arm abduction splint complete.

zontal segments are given a slight curvature, with the convexity toward the body. The injured arm is brought to a position of 90 degrees abduction, with the elbow in right angled flexion in the horizontal plane. The rear rod lies behind the arm and projects beyond the elbow. It is now bent forward through a right angle, 26½ inches from the last bend, so that it lies along the forearm. In the same way, the front rod is bent at a point 21½ inches from its last bend, so that it extends forward inside the forearm. Eleven inches from the bend at the elbow this inside rod is

now bent through a right angle across the hand. The outside rod is bent inward through a right angle where the inside rod crosses it, and the surplus ends of the two rods are cut off so that when the ends of the frame are brazed together the space between the inside and the outside forearm rods is 5½ inches. A piece of five-sixteenths rod 13 inches long is bent into an arch and brazed to the front and rear rods so as to arch over the injured shoulder. Its purpose is to increase the rigidity of the frame. It should never rest on the shoulder when the splint is adjusted. The construction of the detachable diagonal brace is sufficiently well illustrated by Figure 1.

The splint is completed, as shown in Figure 2, by the addition of a waist belt of webbing 2 inches wide, and by leather axillary and shoulder saddles. The axillary saddle has a thick roll of felt under leather at the top edge, and its front and rear borders arch up to the angles of the frame and are sewed firmly to the acromial borders of the shoulder saddle. This is a very important detail, as it makes a firm armpit for the well shoulder and adds an essential factor to the stability of the splint. Both axillary and shoulder saddles should be of leather and 4 or 5 inches wide. The two flaps of the shoulder saddle are held firmly down by a strap and buckle, as illustrated. For additional sta-

Fig. 3—Arm abduction splint with shoulder and elbow hinges. For use on either arm—adjustable to breadth of shoulders. (Inset shows detail of hinge plate.)

bility, a webbing strap may be added to buckle over the injured shoulder (Fig. 2), but this should never be tightened so as to carry any considerable weight. A flap of canvas is sewed to the outside of the arm piece from the axilla to the hand. The inside edge of this flap is provided with eyelets and laced to the inside rod. Only in severe cases is it necessary to undo this lacing to put on the splint. Many of our patients whose condition necessitates their wearing the splint only during the day, put on and remove their own splints. When the No. 1 model is to be worn night and day, we sew a strip of thick leather, 3 inches wide and 14 inches long, so that it lies between the rear rod and the body. The leather is padded with felt. Patients sleep without special discomfort in a splint so padded. We are, however, coming to use almost exclusively for continuous wear the model shown in Figure 4.

A reversible abduction splint capable of a considerable degree of adjustment as to size, and applicable to either right or left arm injuries, is shown in Figure 3. The hinge plate is of sheet iron one-sixteenth inch thick. A sheet 6 by 5½ inches will cut for the hinge plate and the two locking plates. The holes in the locking plates are farther apart than the corresponding holes in the hinge plate. Each locking plate is curved

sufficiently to make the holes correspond to those in the hinge plate. When the locking plate is in place, tightening the bolt through its center effectually locks the rods which pass through the end holes, so that they cannot slip in the hinge plate. One locking plate is made with a lug instead of a hole at one end. This lug goes into the hole at the back of the hinge plate which receives the end of the diagonal brace when the splint is reversed. On account of the wide range of motion permitted to the abducted arm, this splint has to be fitted with a diagonal leather strap from the rear belt offset to the hinge plate at the rear. The axillary saddle used is made to unbuckle at one end for convenience in applying the splint; the strapping is otherwise the same as in Figure 2. Owing to the satisfactory way in which the other models meet the requirements of most patients, this model has not been much used.

The all-anterior model of the arm abduction splint shown in Figure 4 has two advantages: (1) it may be applied with ease to even the severest injuries, and (2) no metal crosses the back of the patient and interferes with his comfort when he is lying in bed. The frame is but little more difficult to make than that of the Figure 1 model. The distance between the axillary half loops (standard size) should be 14 inches. The vertical distance from the horizontal bar to the lower edge of the waist belt should be 15 inches. Other dimensions are the same as in the standard size of the Figure 1 model. In this model a broad leather strap crosses the back from the rear border of the axillary saddle and fastens by two flat buckles to the rear of the axillary half

Fig. 4.—Arm abduction splint (left). Frame with double anterior brace. No metal across the back.

loop on the injured side. A diagonal strap, extending up from the rear waist belt offset, buckles just below the broad horizontal strap. Thus, a leather triangle at the back corresponding to the metal triangle in front holds the splint firmly in place. Buckles must be close in the axilla so as not to come under the back of the recumbent patient. The axillary saddle is as described above and shown in Figure 2. It extends between the metal half loop and the body and should carry all the pressure of the axilla and the side. The metal loop should stand free and function only as a stay. It is a fundamental principle of every model of this type of abduction splint that all the weight and pressure of the body be sustained on fabric straps and leather saddles, and not on metal parts. In the all-anterior model, the rear of the shoulder saddle is sewed partly to the short horizontal segment of the frame at the rear of the axillary half loop and, for the rest of its width, to the broad strap crossing the shoulders. The buckle strap of the shoulder saddle should attach to the frame and not to the back strap.

The arm, supported on one of these abduction splints, lies relaxed on a comfortable platform. It may be subjected to traction, tied down firmly, or allowed any degree of motion consistent with the patient's welfare. I have seen a patient whose arm was being held in right-angled abduction using a small carpenter's plane with the abducted hand. If it is desired to hold the

arm directed forward at an angle of 45 degrees to the sagittal plane of the body, a position much favored by some eminent surgeons, the splint can easily be adjusted for this position by bending the rods. I have observed, however, that patients who are much of the

Fig. 5.—Elbow extension splint for increasing extension by elastic traction, the so-called "diamond splint."

time in an erect position prefer to have the arm abducted straight out from the side. This is specially true of those whose forearms may be left free for use of the wrist. A patient with the splint adjusted straight out can, without disturbing the abduction of his shoulder, swing his forearm inward free of the splint and do many sorts of things with his hand and wrist without having the splint so much in his way as if it were bent forward 45 degrees.

Very light frames made according to the all anterior model of this splint should be of much service in caring for the pitiful little dangle arms left by infantile paralysis. An appalling amount of disability and suffering is still occurring for the want of an ideal shoulder abduction splint. I believe that such a splint must provide for the carrying of the weight of the injured arm on the well shoulder and the axilla. I trust that the models presented will direct attention to this fundamental principle of successful shoulder abduction splinting.

Fig. 6.—Elbow splint, same as in Figure 5, adjusted to increase flexion.

#### ELBOW AND KNEE SPLINTS

Elastic traction as an agency for the correction of deformity has, through misuse and injudicious use, come somewhat into disfavor. I have found it of very great assistance in the treatment of a large number of elbow and knee injuries involving limitations in joint motion. When india rubber is used with sufficient patience and discrimination, I consider it one of the most potent of all agencies for the restoration of joint function. Extreme care must be taken not to apply

too great a force. The amount of a continuously acting force necessary to increase the range of motion in a joint tied up with scars and adhesions is often surprisingly small. It is usually best to begin with very light traction and gradually to increase it until careful measurements, taken at intervals of a few days, show definite improvement, or until the degree of force being exerted is causing marked discomfort. Definite acute pain or inflammatory reaction in the affected joint

Fig. 7.—Elbow splint, light model, made of "vulcanite" fiber.

indicates that too great force is being applied, or that the condition is unsuited for this treatment. When such a reaction occurs, traction should be discontinued at once and the joint immobilized until all signs of reaction have for some days been absent. Very light traction may then be again begun. A dull ache is usual after hours of efficient traction, and is not an indication for discontinuing the treatment. It is practicable to relieve deformities by the use of rubber traction only by imitating that slow, insidious, persistent march by which the forces of gravity, muscular pull and connective tissue contraction produce deformities. Stretching and pressure atrophy are accountable for the results obtained.

Figures 5, 6 and 7 illustrate the types of splint which we are using in elbow cases. For knee extension, I use a heavier, longer splint, built as shown in Figure 7, but with two pairs of traction levers. For exerting traction, I prefer loops cut from the end of new automobile inner tubing, varying the width of the cut according to the force required. Ordinary rubber bands of assorted widths may be used. For elbows, we have used the Figure 5 model most for extension, and the same splint, reversed and stripped of traction levers and olecranon strap, for flexion (Fig. 6). The cuffs of this splint are each made of a sheet of thin tin 8 inches square. A three-fourths inch strip is bent back and flattened along two opposite edges. The flat pattern is then cut roughly to the shape of a dress shield. The cuff is bent into a semicylinder, the doubled edges forming the sides. The two horns of each cuff are rounded and drilled. Each horn, bolted to the corresponding horn of the opposing cuff, forms half of the elbow hinge. Four iron straps, one-eighth by one-half by 6 inches, make the traction levers. These are drilled at each end and bolted together at one end in pairs. Each pair is bolted by its free ends through holes drilled midway in the corresponding edges of each cuff. Stove bolts, three-sixteenths by one-half inch, are used. Adjustable leather button straps, buckle straps and a felted

olecranon strap with a hole in the center are added as shown in Figure 5. The entire splint is lined with felt, which should extend one-half inch beyond the metal on all edges. The diamond shape formed by a pair of traction levers with the opposed edges of the cuff caused this splint to become known as the "diamond splint." Under this name, various models of the splint have been used in several of the army hospitals.

The light model shown in Figure 7 is made of vulcanite fiber. A still simpler model, the cuffs of which are attached to each side bar by one rivet only, is now being tried out. The cuffs of this model, being free to swing, adjust themselves perfectly to the surface of the limb. The model maintains its adjustment with one strap only, the olecranon strap. It is chiefly useful for extension. Long traction levers on any of these splints are unnecessary. Far more force than is therapeutically practicable may be exerted through short levers. Lightness, simplicity and slightness are significant factors in securing the results from appliances in ambulatory cases. It is in the effort to have all of these essentials in the highest practicable degree that the various models have been developed.

#### FOREARM SPLINT FOR SUPINATION OR PRONATION

For maintaining the forearm in any desired degree of rotation, we use the splint shown in Figure 8. A paddle-shaped sheet of tin, 6 inches wide at the palm, 4 inches wide at the elbow and 16 inches long, turned down along all edges, makes the forearm piece. A piece of strap iron, one-eighth by one-half by 17 inches, is riveted down the center so as to project  $2\frac{1}{2}$  inches at the elbow end. A  $5\frac{1}{2}$  by 7 inch sheet of tin, rounded at the corners and bent into a semicylinder  $5\frac{1}{2}$  inches long, forms the arm piece. Strap iron, one-eighth by one-half by 7 inches, is riveted down the center, projecting  $1\frac{1}{2}$  inches. The free ends of the two pieces of strap iron, joined by a rivet, make the elbow hinge. The arm cuff can swing from one side to the other of the forearm piece, so that the splint may be used for either arm. An adjustable strap prevents the applied splint from swinging to the point of full extension of

Fig. 8.—Forearm supination splint for use on either arm, adjusted for neutral rotation.

the arm, as in that position the splint no longer controls forearm rotation. The palm of the hand is next the forearm piece. The strap iron is twisted to get the desired degree of rotation. Any degree of wrist cock-up is secured by bending the hand piece. This splint is efficient but somewhat clumsy and unsightly. Effort is being made to perfect a better appliance.

**Feeble-mindedness.**—There is no panacea for feeble-mindedness. There will always be mentally defective persons in the population of every state and country. The program for meeting the needs of these persons must be as flexible and complex as the problem itself.—W. E. Fernald, *Mental Hygiene*, October, 1919.

THE MOULAGE AS A RECORD  
EMPLOYED AT THE ARMY  
MEDICAL MUSEUM\*J. FRANK WALLIS, M.D.  
WASHINGTON, D. C.

Medical institutions in Europe are famous for their wonderful collections of reproductions in wax of dermatologic lesions and pathologic conditions, and for their models of embryology, histology and anatomy.

The great educational value of these artistic records has long been appreciated by Americans who have taken graduate medical courses in these foreign clinics. All who have studied abroad remember the great assistance these models have afforded, and return with regret that their own country lacks this impressive manner of teaching.

America has awakened; she has gradually unfolded until she now stands equal with the world of nations. To hold this lofty position which she has acquired she must prove herself equal to teach the science of medicine as she has taught the world her prowess in war and industrial achievement.

To make her medical course complete, the art of illustration is essential. Max Brödel and his pupils have demonstrated the value of medical illustration to literature, and the realistic moulage is necessary to complete the teaching of the medical sciences.

The art of wax modeling should be taught in our universities. Every large medical clinic should have a modeler on its staff, to reproduce the usual and the unusual pathologic states. All large cities are rich in clinical material that can be recorded and made available to the medical student and the graduate.

A course in wax modeling should include a brief study of histology, pathology and anatomy as an aid in reproducing the various structures in their normal and abnormal conditions. The technic required in making the uncolored wax model is quickly learned, but accurate coloring will depend on the interpretation of the surface markings of the wax positive. This course should also include a study of the chemistry of pigment and its durability, the association of color with disease and its diagnostic value, the memory of color, the taking of color notes and sketches, and the application of color to the surface of the wax.

Many physicians have artistic ability and will rapidly acquire a knowledge of the various steps necessary in the production of a moulage. To them, it is hoped, this short paper may be of assistance, as it briefly outlines the method now in use in the Army Medical Museum in Washington, D. C.

A moulage or wax model of the skin and underlying structures must truthfully represent a map of the topographic structures of the normal tissues and their pathologic states. It must be a positive in wax, unaltered by tooling or handling.

The negative or plaster mold is the matrix from which the wax impression is obtained. The plaster negative bears the same truthful relations as does the negative film in photography.

The wax impression must possess all of the delicate tracings of the normal skin as well as those of the altering or destructive processes of disease. An uncol-

ored wax positive or impression is translatable to those who are familiar with the histology and pathology of the skin.

The formation of a wax model is divided into four steps: (1) negative plaster impression; (2) positive wax impression; (3) mounting, and (4) coloring.

The first step comprises the preparation of the patient and selection of the field from which may be reproduced the lesion or lesions, and in which there will be sufficient evidence of landmarks to indicate the location of the eruptions.

The preparation of the patient consists in placing the subject in the most comfortable position necessary to expose the field of operation. Papers are placed on the floor to collect particles of plaster; towels are spread to cover bedding or clothing; the part is shaved if it exhibits much hair, and the lesion is cleansed of exudate. A dam is now built around the area selected. The most satisfactory material for this purpose is made by saturating gauze or cheesecloth in a thin mixture of plaster of Paris and water. The dam should extend about 1½ inches above the surface of the skin. This method is very good, as it reinforces the edge of the cast and thus eliminates the possibility of breakage in the transport of molds. The method we now employ is to use wet towels as a dam. When the plaster is poured on the towel, it leaves an impression of the fabric which is reproduced in wax, affording reinforcement as well as an attractive border.

When the dam is formed, the surface of the skin and the lesions is oiled with a thin oil. This is done to prevent particles of plaster from adhering to the skin or hair on removal of the cast. When a distinctly hairy region is to be cast, such as the head, bearded face, axilla or the pubic region, petrolatum is a good medium to clump the hairs together. These are then smoothed down and a thin oil applied as on any other surface.

All is then ready for the mixing of the plaster of Paris. This is to be prepared after the dam is built and the parts oiled; otherwise, the mixture would harden before it could be used. The plaster of Paris is sifted into a basin half full of cold water until the saturated plaster fills the basin within an eighth of an inch from the surface of the water. The mixture is gently stirred to drive off the air, and this produces an even combination, free from lumps.

The plaster must be of a consistency approximating whipped cream in order to insure a fine impression. After the proper consistency is obtained by stirring or by adding plaster of Paris gradually and in small quantities, the mixture is applied with a scoop, large spoon or cup. The plaster is first poured around the edges, then on the surface, and last on the lesion or wound. A fine impression is obtained if the plaster is blown with the mouth as it is being distributed. This also eliminates the possibility of bubbles, which often spoil the impression.

The mold is now built up evenly to about the height of 1 inch, and strips of burlap dipped in plaster are placed over the cast. The burlap prevents the cast from breaking if the plaster should happen to crack while it is setting. The mold is now formed and allowed to set about fifteen minutes. The absorption of water by the plaster causes heat to be radiated. When the mold feels warm to the touch, it can be removed with safety, as the chemical action of the plaster and water has then taken place.

\* Read before the Section on Dermatology at the Seventieth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

Various areas of the body require special technic so that precautions are necessary to insure a good mold, free from cracks and imperfections.

The greatest difficulty comes in avoiding undercuts. These usually occur in casting angular, rounded or irregular surfaces when making a one piece mold. Two piece molds should be avoided unless the distribution of the eruption requires it; even then, two distinct models mounted on a single board would be more desirable, as for example, in instances of eruptions on the dorsal and palmar surfaces of the hand.

Casts of the face are best made in one piece molds. The dam is built the same as for any other part of the body. Eyebrows are well greased with petrolatum, and the hair well smoothed down in the natural direction of growth. The eyelashes should be treated in the same manner. It is often advisable to cover the eyelids with cigaret paper. Rubber tubing should be placed in the nostrils, and cotton plugs in the ears.

Molds of the chest and of the abdomen should not be taken at the same time on account of respiratory movements. Any slight movement on the part of the patient will crack the cast. Cracks are often unavoidable in molds of this kind; but unless very large, they will not be conspicuous in the finished model.

The procedure of taking a plaster cast is not painful, even in the most sensitive lesions. The only discomfort will be caused by the pulling of hair along with the cast.

When molds of deep wounds are taken, the plaster and all utensils should be sterilized with dry heat by being baked in an oven for an hour. The most important precaution necessary to insure a good mold is to use a good grade of plaster.

The wax impression or model is made by pouring melted wax into the plaster mold. After this is colored and mounted, we have the finished model, which should bear an exact resemblance to the original as regards shape, color and surface markings.

It must be remembered that before making a wax model from a mold the plaster cast should be soaked in water for from twelve to twenty-four hours, until it becomes entirely saturated and free from air. After being taken out of the water it should be thoroughly dried with absorbent cotton.

The wax material is composed of: white beeswax, 2 pounds; paraffin, 1½ pounds; starch, 1 pound; talcum powder, 1 pound, and yellow beeswax, 2 ounces.

The white beeswax and the paraffin are first heated on a water bath until entirely melted, when the starch and talcum powder are slowly added through a fine sieve. When the powders are entirely submerged, the mixture is stirred gently and allowed to remain over the fire for about an hour, with occasional stirring. The yellow beeswax is added to give the mixture the proper color.

This wax combination is now poured into the plaster cast and quickly shaken, so that it will cover rapidly the entire surface, without lines or streaks. The remaining wax is then poured back into the boiler, and the process is repeated until the proper thickness is obtained, usually about one-quarter inch. The wax is allowed to cool, from five to ten minutes generally being sufficient for this purpose, before being removed from the mold. The wax impression should be removed with great care and immersed in cold water.

Care must be taken during all of the processes from now on, so as not to mar the model with the warm

hands or to allow it to come in contact with anything but wet cotton. The impression, as now made, must be kept perfect, otherwise the model is of no value. As a precaution, it is advisable to wear wet cotton gloves while working with the model.

The method of mounting models at the Army Medical Museum has a distinct advantage over the old method used by some artists. The linen draping is eliminated, as it does not add attraction. The small tacks which were used to attach the model to the baseboard are responsible for the cracked models and offer frail support to the specimen.

To mount the model, bolts are screwed into blocks of wood, are embedded in the reverse side of the model, and are held by nuts to the baseboard. The baseboard is selected from well seasoned wood. To prevent the board from warping, cross strips are inserted at both ends of the board. This precaution is necessary, as the slightest warping might crack the model. After the model is safely mounted, it is ready for coloring.

Pure colors in oil, free from opaques, are absolutely necessary for wax. The surface of the wax impression after leaving the plaster cast is receptive to color. All good, permanent, transparent colors are satisfactory, and the accuracy of reproduction is dependent on the skill of the artist.

The wax model can be adapted to illustrate pathologic conditions in the deeper structures of the thorax and abdomen, lesions in the brain and spinal cord, and in various organs. The field for the pathologic moulage is unlimited and is of extreme value in recording unusual mortuary findings as well as in providing the usual teaching specimens for the student.

When we review the various lesions of tuberculosis and syphilis and their selected territorial invasions, we can appreciate the advantage of permanent records, accurate as to color and structure, over the transient specimen often imperfectly mounted in its preserving fluid in the museum jar. Reproductions in wax of the various types of pneumonia would be of great educational value. Models of surgical anatomy and stages of operations would be of much value to the surgeon, as well as to the medical student.

The Army Medical Museum is now building a collection that will surpass any ever produced in the foreign clinics. Every medical man in this country is going to be interested in the American collection, and many will contribute to its formation and receive honorable mention in our National Museum.

To establish this American collection it is necessary for physicians and clinicians in American cities to cooperate with the museum in obtaining material of interest. This material can be easily gathered if plaster molds of all interesting lesions, rare skin diseases or pathologic findings, with photographs, are sent to the curator of the Army Medical Museum. With the aid of Congress in appropriation of sufficient money to carry on our work, and with a staff of well trained artists, we would accumulate rapidly a fine collection of usual and unusual dermatologic and pathologic models.

The day will come when it will be possible to visit our Army Medical Museum in our national capital and study diseased conditions in its various phases, and leave with the conviction that medicine can be taught in America and can be learned without visiting the well known clinics in European cities.

## ABSTRACT OF DISCUSSION

DR. WILLIAM ALLEN PUSEY, Chicago: I would like to express my appreciation of the work which Dr. Wallis has undertaken. The only large collection of models that has ever been made is the collection in Paris made by Beretta. There is no doubt that good models are the best illustrations of the diseases of the skin which we can have, and I think the work that Dr. Wallis has initiated is one that we should support. Dr. Wallis is a trained dermatologist and he is self-sacrificing enough to take up this work. It has been started under the auspices of the army and it is to be hoped that the army will continue to support the work. If it does, it will in time have a collection that will be worthy of pilgrimages from all over the country, and that will be a source of reputation to the institution that possesses it. There is great room for such a thing in this country. Every medical school that undertakes to teach skin diseases should have a collection of the common diseases. If Dr. Wallis can only develop that work he will be doing a benefit to the dermatologists of the entire country.

DR. J. FRANK WALLIS, Washington, D. C.: I appreciate the interest you have taken in this work. It was largely accidental. I started to carry out the work and then we found that men who were interested in dermatology were expected to make models, but the work was very slow and was given up. I did very little with it until a year ago when I made a model, very quietly, of a case of pityriasis rosea that was developing into a psoriasis. Another dermatologist had also seen the case before I saw it. I made a model of it and it was seen by my commanding officer, but instead of being court-martialed I was sent to Washington and I have been there for a year having a good time. I enjoy it and if I can do anything to help others I shall be glad to do it. America has never had any modeling and I shall be very happy to help carry out the work.

## LATE RESULTS OF SUPPOSEDLY SUCCESSFUL ABDOMINAL OPERATIONS ON THE DIGESTIVE TRACT\*

THOMAS R. BROWN, M.D.  
BALTIMORE

When one contemplates the marvelous change in the past twenty years in our knowledge of the diseases of the digestive apparatus and honestly tries to analyze what has been the fundamental cause of this change—this metamorphosis from poverty of method and uncertainty of result to our present wealth of diagnostic data and successful therapy—I feel that we must admit that it is to the surgeon and to the physiologist that this great change is mainly due.

The use of the stomach tube has been an aid, and the more refined and newer methods of studying gastric and intestinal secretions have proved of interest; but an attempt to evolve a gastro-intestinal pathology fundamentally on the basis of secretory variations is to lean on a frail reed—and in the stomach the secretory findings must be regarded as but general indexes of the tendency of the functional digestive act rather than as exact expressions of discrete pathologic entities—one of the many clinical data which does not furnish the answer itself but which adds its little to the many other aids at our command at reaching a true conception of the underlying disease process.

From the physiologist we have learned a great deal. The work of Pawlow and his followers, of Baylis

and Starling and of Cannon has shown us that there is order, not chaos, in the physiology of digestion in both motor and secretory spheres, and has furnished us with normal standards of inestimable value in studying the changes in the various digestive functions due to disease.

But, after all, it is the development of modern surgical technic with its concomitant ability to explore safely and carefully—not disturbed by the factors of time or of pain or of possible infection—the abdominal cavity in its various diseased conditions that has been the fons et origo of our modern knowledge of the pathology of digestion, furnishing us a real comparison of clinical signs and symptoms with definite pathologic changes—both gross and microscopic—a true necropsy in vivo. There is no clinician who is not eager to render to the surgeon full credit for the marvelous increase in our knowledge of the diseases of the digestive tract.

So many of the organic lesions of the stomach and intestine are fundamentally surgical—the results, especially the early results of surgical treatment have been so brilliant—that there has arisen in the minds of most patients, many clinicians and more than a few surgeons the idea that the knife is the sole therapeutic agent of value in this field. Yet, especially within the past few years, there has been a growing feeling that although a condition may be fundamentally surgical, nevertheless, the limitations of surgical method may be such that sequelae may develop which nullify the good effects of the primary operation; and there has been a noticeable lessening of enthusiasm for the surgical treatment of organic gastro-intestinal lesions, notably, of course, those of a chronic nature, for obviously in the severe acute lesions such as acute appendicitis, perforated gastric ulcer, repeated attacks of gallstone colic, empyema of the gallbladder and acute intestinal obstruction, immediate surgery is the one and only safe mode of treatment.

Why is this? There can be but one answer, and that is, that notwithstanding the brilliant early results of surgery in most of the acute and many of the chronic digestive lesions there is a realization that the late results in these cases are often far from ideal, and that the second state of the patient may be no better and even worse than the first, owing to postoperative adhesions or partial obstruction with a recurrence of the same or the development of new symptoms or other causes.

In this short paper I wish to discuss very briefly some of the factors that play a part in this connection, to make certain suggestions as regards postoperative treatment from the point of view of the clinician, and to try to suggest certain principles in the treatment of the chronic abdominal lesions which may, if followed, be likely to produce the minimal percentage of failure.

## METHODS OF AVOIDING COMPLICATIONS

Let us then, in the first place, discuss methods by means of which the aftermath of inevitable abdominal operations may be as free from complications as possible—taking up, in turn, operations on the stomach, on the gallbladder, and on the intestine, these conclusions being based on the careful study of operative treatment and its sequelae in many hundreds of cases during the past ten years. After all, it is to the internist rather than to the surgeon that the patient returns if the results of operation are not so successful as

\* Read before the Section on Gastro-Enterology and Proctology at the Sixty-sixth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

expected—or often as promised. It is, in fact, the skilled clinician who should in the chronic—not the acute—conditions be the final judge as to whether treatment should be medical with its accessory dietetic and physical aids, or surgical; although even now the clinician's hand is often forced by the patient's insistence on the apparently quicker surgical route, although in our experience this enthusiasm for surgery on the part of the laity is very markedly less than it was five or even three years ago, obviously because there is a gradually dawning realization that, after all, surgery is a two edged sword, and is not omnipotent in the prevention of postoperative adhesions or a catarrhal intestinal condition which may nullify partly, or in whole, the success of the operation per se.

In deciding on the relative value of surgical and non-surgical treatment, we feel that the tendency has been far too great to rush into surgery without giving other means a fair and honest trial. Our feeling is that the more acute the need for immediate surgery, the more clean-cut the picture, the more likely the success, both immediate and later, of surgical treatment.

There are many conditions, as, for example, chronic appendicitis, various forms of abdominal adhesions, as those associated with chronic appendicitis, former attacks of gastric or duodenal ulcer, pericholecystitis, as well as that large and evergrowing group of postoperative adhesions in which the tendency has been to operate—especially on the part of the patient, and the clinician, and when the surgeon is often by far the most reluctant of the three, in which surgery should be resorted to only as a last resort—for in this group of cases we have the greatest chance, even with the best postoperative care, of the formation of new adhesions with the reappearance of the old or other symptoms. No one who has studied this group of cases thoroughly can have failed to note that there are certain individuals in whom adhesions are peculiarly likely to form, however rigorous the operative technic.

On the other hand, it is in this group of cases that the functional and organic are so exquisitely blended in the production of symptoms that it would take a veritable magician to determine beforehand the relative rôle played by each in the production of symptoms.

Rest—that most potent of all medicaments in gastrointestinal therapy; elimination of foci of infection; local heat or cold; posture; supports; an appropriate diet, sometimes soothing, sometimes stimulating; massage; exercises; medicines, antispasmodic, lubricating, tonic; oil instillations; irrigations—all of these should be tried conscientiously before one thinks of surgical treatment, for these are the cases that test the stuff of which the physician is made; if he realizes that, to get results by medical and physical means, time is essential, that the patient, while being encouraged, should be made to realize that improvement must, of necessity, be slow, possibly taking many weeks, oftener months; and if he can get a real appreciation on the part of the patient of the underlying principles of the treatment and his hearty cooperation in carrying it out, then he will, indeed, be able to get good and often brilliant results in this most difficult group of cases, and to realize that, after all, the organic, which is fundamentally surgical, we freely admit, was playing but a minor rôle, or possibly no part, in the causation

of symptoms, and that by correcting the functional disturbances associated with it the patient became so nearly well that he was unconscious, or almost so, that any organic lesion was present.

Again, operation is advised in many cases on a wrong conception of the underlying process—notably that enormous group of cases of so-called chronic appendicitis associated with high grades of visceroprosis in which the patient and physician both believe that removal of the appendix will be followed by a complete cessation of symptoms, when in reality such a belief is chimerical to say the least, as the chronically diseased appendix represents but one phase of a diffuse low grade peritonitis involving the terminal ileum, cecum and ascending colon, and frequently pelvic organs as well. These are the cases, extremely numerous, in which a realization of this fact and absence of surgical treatment will save the patient and the physician from disappointment and heartache.

Another point of great importance in cases in which surgery is obviously necessary as, notably, callous ulcer with true obstruction (although even here it is well to try first the effect of nonirritating diet, local heat, rest and antispasmodic and alkaline treatment to determine the relative rôle of functional spasm and true organic obstruction in the production of symptoms); ulcer with repeated hemorrhages or intractable to the ordinary therapeutic procedures; gallbladder disease, either obviously surgical from the first or in which conscientious treatment along other lines has proved unavailing—a point of fundamental importance is the choice of the proper operation. I feel very strongly, for instance, that a gastroenterostomy, whether with and even more so without pyloric resection, is fundamentally unphysiologic in that an acid, unchymified mass is projected without the benefit of true sphincter control into a portion of intestine designed only to receive alkaline semiliquid chyme, and that even with the utmost postoperative dietetic care it is almost impossible to avoid a certain amount of jejunal irritation, to which, of course, must be added the possibilities of the regurgitation of duodenal contents or even a true vicious circle in those cases in which the pylorus is left patent. We have followed the subsequent history of many of these cases, and we feel, as did Mathieu, from his series of more than thirty years, that in practically all cases there is to be found some form of digestive disturbance, usually intestinal.

Whenever possible I believe that a pyloroplasty or even a Polya operation should be performed in preference, as these, especially the former, far more closely approximate normal physiologic conditions.

In cases of gallbladder disease, my feeling has been that in the majority of cases, in my experience at least, a cholecystectomy, even with its slight possibility of refractory duodenitis and diarrhea, is more productive of good results than a cholecystotomy, while obviously far less likely to be followed by a return of gallbladder symptoms or by malignant changes.

In cases of gastric carcinoma I have always felt that far too many patients are operated on, when the abdomen is simply opened and closed, merely to confirm a palpably obvious diagnosis, but that if an operation is performed, far too few surgeons are willing to make extensive resections in the one hope of really pro-

ducing radical improvement. In fact, for many years my feeling has been that surgery of the chronic lesions of the upper right quadrant has been so likely to have an unsatisfactory aftermath that I have been delaying operation further and further and trying other forms of treatment longer and longer, sometimes with almost complete or partial success, oftener, I am free to admit, with final recourse to surgery after all.

As for extensive resection of the bowel, my feeling is that in the vast majority of these cases, absolute failure is the usual ultimate outcome; and in my experience, the only cases in which even partial success has been obtained are those in which the resection is only of a limited portion of intestine, notably from terminal ileum to beginning transverse colon which, after all, in the majority of cases is that portion most likely to show real pathologic changes.

#### POSTOPERATIVE TREATMENT

As regards postoperative treatment in abdominal surgery, I feel very strongly that a far closer association between surgeon and clinician is essential to get the best results for the patient. The surgeon is not trained in dietetics; he is singularly prone to follow a routine in the postoperative management of his cases, and this lack of individualization is often productive of deplorable results.

For instance, in cases of reflex hyperacidity and pylorospasm secondary to a diseased appendix, the gastric symptoms persist long after the appendix is removed, and a nonirritating diet with alkalis and antispasmodics may be necessary for many weeks. Yet, how often do we find our patients eating salads and acids on the fifth or sixth day because they were told by the surgeon that "the only trouble was with the appendix, and they could eat anything now that it had been removed."

Also, to my way of thinking, every case of major operation on the stomach—gastro-enterostomy, resection, pyloroplasty or Polya operation—should be treated *exactly* like an acute gastric ulcer. I am convinced by the study of a great many cases that by a carefully and slowly graded dietetic therapy, from a few days of absolute starvation, through many days of nonirritating liquid diet in small amounts, to many weeks of a bland, soft diet, a great many, if not all, of the discouraging sequelae of these operations could be avoided; for I am sure that the tendency of the vast majority of surgeons is to feed these patients too soon and too much.

A third point of great importance, I believe, is the advisability—I was almost going to say the necessity—of every clinician's attending every operation in his cases of digestive disease. In the first place, it is of incomparable value in demonstrating the correctness or incorrectness of his diagnosis, and, in the latter case, of suggesting to him the cause of his mistake; in the second place, it should make him realize the difficulties which confront the surgeon in so many of these cases, and, in the chronic group of which I have spoken so often, should accentuate the advisability of further treatment by medical, dietetic and physical means before having recourse to surgery; while in the third place his presence at the operation should suggest to the surgeon the wisdom of utilizing his clinical experience both at the operation and in the management of the postoperative period.

Of course, the most important of all is the installation of proper postoperative measures to minimize that bugbear of surgeon, clinician and patient, the formation of postoperative adhesions. I have followed this group of cases for many years and have made many hundreds of fluoroscopic studies of them, always, of course, studying the patients in both prone and upright positions, and I am convinced beyond peradventure that a great deal can be done by measures designed to prevent stasis of intestinal contents and of the intestine itself. Admitting perfect surgical technic with the closing in of all raw surfaces, as far as possible, the postoperative treatment should consist of frequent change of position in most cases, or sometimes with especially localized adhesions, a special position, such as elevated foot of bed or head of bed, or lying on one side or the other, with free purgation as early as possible, repeated very frequently, and, as soon as the incision warrants it, deep abdominal massage, to be kept up for several weeks.

I am absolutely convinced that by a persistence in these measures, adhesion formation, while not abolished, is reduced to a minimum, just as I am convinced that the leaving within the abdominal cavity of oil, salt solution or solution of sodium citrate or the hypodermic administration of fibrolysin is valueless in this connection.

If a perfect operation for diseases of the stomach and intestine had been devised there would be no need for a paper such as this; but there is no ideal abdominal operation. In all, even with perfect technic, adhesions are not only possible, but probable. In many cases, such as gastro-enterostomy or cholecystectomy, an unphysiologic condition is produced. In others, such as pyloroplasty, pyloric resection, Polya operation, especially if retrocolic but even with a long anterior loop, closure due to adhesions, or changes in the omental fat with partial or complete obstruction and the necessity of a secondary operation may occur, while the value of a gastro-enterostomy may be nullified by the development of a vicious circle, by the subsequent closure of the new orifice or by subsequent development of ulcer.

I realize that I have offered in this article thoughts which have occurred to many surgeons and clinicians, especially those interested chiefly in digestive diseases, and that most that I have said is but a series of truisms. But it has seemed to me that such a general presentation is more likely to do good than a careful statistical study, although my conclusions are based on a study of many hundreds of postoperative cases through a long series of years and on personal attendance at several thousand abdominal operations.

When we realize the cases of late failure, each of us has seen after surgical treatment, as, for example, jejunal ulcer or jejunitis; vicious circle, or recurrence of old ulcer symptoms after gastro-enterostomy; postoperative adhesions, here, as well as in pyloroplasty, Polya, or other operations for resection of the stomach with partial obstruction and sometimes need of a secondary operation; adhesions; duodenitis; return of calculi or infection after gallbladder operations; adhesions after appendix operations or persistence of symptoms notwithstanding the removal of the appendix, due to unrecognized trouble elsewhere; extensive adhesions after partial or complete resections of the bowel, or the formation of new adhesions after opera-

tion for old adhesions, I feel that I am, indeed, justified in calling attention to this group of cases in the hope that some means of lessening the failures may be formulated.

#### CONCLUSIONS

The conclusions that have come to me from these many years of intensive study of this peculiarly difficult yet wonderfully interesting field are, in summary:

1. The surgeon has been too prone to believe in the success of treatment of abdominal lesions because of the brilliant success of surgery for acute abdominal conditions and to the apparent early cure of many chronic conditions when, however, some of the improvement must be ascribed to rest, careful nursing, change of environment, diet, and the other adjuncts to successful hospital treatment. If, after a few months, there is a return of the same or the development of new symptoms, the surgeon is often not cognizant of them, for it is to the clinician and not to the surgeon that the patient is likely to return with his complaints.

2. Some failures are to be ascribed to a definitely wrong appreciation of the real underlying pathologic process, as notably in the case of the so-called chronic appendicitis met with in cases of visceroposis of marked degree and of long standing; and here the operation falls into the same category as that of many cases of fixation of the kidney, or suspension of the uterus, in which symptoms are ascribed to these abnormalities quite out of proportion to their true pathologic significance.

3. In many cases, partial or complete failure may be converted into partial or complete success by a clearer conception on the part of the surgeon of the underlying pathologic physiology, for in none of these abdominal lesions is it safe to rely on the correction of the morphologic changes done. Without a realization of the associated and often quite persistent functional disturbances, what should be a successful operation is often a failure. A proper diet determined in each case individually; the utilization of posture, purgation and massage to minimize adhesion formation; the choice of medication appropriate to the motor and secretory disturbances associated with the organic lesion—all these measures add immensely to the chance of a successful issue in this group of cases. While the clinician is unquestionably too prone to ascribe too much to functional disturbances, the surgeon, on the other hand, is far too likely to be guided by morphologic changes alone, and it is only by a proper balance between these two in our conception of the disease process and its consequent therapy—surgical and medical—that the optimum result can be obtained.

4. There is far too great a tendency to plunge too soon into surgery in the treatment of chronic and subtle abdominal conditions, and far too little enthusiasm for persistence in medical, dietetic and physical therapy in these cases before having recourse to surgery. Until methods have been devised absolutely to eliminate adhesion formation or operations evolved which can absolutely duplicate the normal physiology—if not the normal anatomy—of the various abdominal viscera, surgery should not be our first choice but should be the *dernier ressort*, only to be employed if skillfully directed therapy along nonsurgical lines has been tried conscientiously and over a sufficiently long period of time to prove that it is absolutely unavailing.

5. And this, after all, is really the motif of this paper: Real success in this most difficult field can only be obtained by a far closer rapprochement between surgeon and clinician: the internist should be present at every operation on his patients; the surgeon will be able to compare operative findings and preoperative clinical data, and the clinician's advice should be of help to the surgeon in the choice of the operative procedure. On the other hand, the visual demonstration of the pathology of the disease to the clinician should be of inestimable value to him in his future study of similar syndromes; the clinician with his knowledge of the previous functional digestive disturbances of his patient should cooperate with the surgeon in the management of the postoperative and convalescent period, and with his greater training along these lines, should direct the diet, medication and physical therapy, always, of course, in collaboration with his surgical confrère. The clinician, on the other hand, should keep the surgeon posted as to the subsequent history of the patient, and, if symptoms do recur, should not neglect, either through forgetfulness or tenderheartedness, to notify the surgeon of the fact. For, after all, the object of each is the same—to bring health to the patient—and it is only by far closer cooperation and a far greater appreciation on the part of each of the rôle that the other should play in the management of this group of cases that we shall be able to reduce to the irreducible minimum the failures—a really appalling number in toto—in cases which have been regarded as successful examples of the surgical treatment of abdominal diseases but whose subsequent histories—often altogether unknown to the surgeon—absolutely nullify this belief.

#### ABSTRACT OF DISCUSSION

Dr. JOHN A. LIGHTY, Pittsburgh: The physician has noticed the shortcomings of surgical procedure for a long time, and the surgeon himself is aware of his shortcomings. A few years ago a surgeon called attention to the unsatisfactory results from surgical procedure, in gastro-intestinal diseases particularly, and was recommending methods by which this could be overcome, such as regulation as to who should and who should not operate, etc. It will not be decided in that way. It will be decided in a coming together, as Dr. Brown suggests, of the physicians and the surgeons, and a more close cooperation. I noticed in my own work for a number of years a class of cases diagnosed secondarily as "postoperative cases." At first they were few in number, but about six years ago I began to collate and tabulate these cases. Of about 6,000 patients, 348 had the so-called postoperative symptoms. The patient was asked whether the symptoms were the same as they had been before the operation, and when the answer was affirmative, it was called a "postoperative" case. Among those 348 cases there were 150 cases of operations for appendicitis, gallbladder disease, peptic ulcer, etc. I was rather surprised at this. I thought there would be more cases of gastro-intestinal tract disease. Then I began to look over my own cases, because for some patients I had advised operation, and they came back with poor results. Most of these cases were very early gastro-enterotomies. A patient who was operated on for gastric ulcer alone, without any other indications, was worse after than before operation. We do not see very many of these cases any more because surgeons will not operate for a pure, simple, gastric or duodenal ulcer unless some other conditions are associated, such as intense, uncontrollable hemorrhage, perforation, or pyloric obstruction, or where it is decided that the patient cannot follow out his ordinary occupation under medical treatment. The other cases were

gallbladder cases. In those cases we usually found that the difficulty was that the pathology which had occurred in the biliary tract was of such a nature that surgery could not be expected to cure it. You could drain the gallbladder or remove it, and yet you did not cure the patient. The conclusion which I would like to present, together with Dr. Brown's conclusion, is that surgery is not a panacea. Some of these conditions cannot be cured by the best surgery. When the surgeon stops saying that he can cure all patients simply because he can operate, and will put himself on a plane with the clinician, who usually recognizes his limitations, I believe we will have fewer of these cases. The one class of cases which gave me the most trouble was that in which there was a button-hole incision for "chronic appendicitis," a small in the right lower abdomen, only about one inch long, with the evidence of only one suture having been inserted.

DR. ALFRED A. STRAUSS, Chicago: Medical men will turn their patients with appendicitis or a diseased gallbladder over to the surgeon for removal of the offending organ, but they will stand beside the operator and see him perform a simple gastroenterostomy for relief of a gastric or duodenal ulcer without an attempt to excise the ulcer. The same pathologic and surgical principles that hold good for the removal of the diseased gallbladder and appendix should hold good for removal of the ulcer. Many surgeons claim that gastroenterostomy alone cures the ulcer because less food passes over it and the regurgitation of bile into the stomach alkalizes the secretions, but no one has ever proved that bile cures the ulcers or that the regurgitation actually takes place to any extent, except in a vicious circle, and the idea is contrary to all information we have as to the physiology of the flow of bile from the liver into the duodenum. Realizing the ineffectiveness of simple gastroenterostomy for gastric and duodenal ulcers, I devised plastic operations both on the stomach and duodenum whereby those portions of the stomach may be reconstructed after excision of the ulcer by fascial transplants. If the ulcer is on the stomach side, as, for instance, in an ulcer of the lesser curvature, an additional plastic operation is performed on the pyloric sphincter by cutting a small portion of the ring sphincter away, without incising the mucosa. This allows the stomach to empty very rapidly, in from one and one-half to two hours, and is far more effective than a gastroenterostomy. It takes less time and requires less surgical skill and leaves the stomach and duodenum in their normal anatomical physical relationship. So far as the hyperacidity is concerned, we have learned by the fractional test meal in cases where the ulcer has been excised that these patients have a normal acidity within a short time after operation, although a marked hyperacidity was present before operation. This must be interpreted to mean that the hyperacidity is the result of the ulcer and not that the ulcer is caused by the hyperacidity. Duodenal ulcers that cannot be excised should be closed off by means of a fascial transplant plus gastroenterostomy. I agree with Dr. Brown that the patient should be guarded carefully by the medical man after operation, but one thing is positive: if the pathology, namely the ulcer, is excised, the patient will need far less medical treatment than if the ulcer is permitted to remain.

DR. JULIUS FRIEDENWALD, Baltimore: I am very interested in Dr. Brown's paper because I have been following the results of operation for many years. In 1915, Dr. Finney and I collected our pyloroplasty and gastro-enterostomy cases and compared the results of both operations. We found that in our gastro-enterostomy cases 82 per cent. were immediately satisfactory, while of the pyloroplastic cases 90 per cent. were immediately successful. Of the gastro-enterostomy cases followed during the first year after operation the results were satisfactory in 84 per cent. of the cases, while in the cases of pyloroplasty the results were entirely satisfactory in 93 per cent. The end results after five years in the gastro-enterostomy cases showed 77 per cent. satisfactory results, while the pyloroplasty cases presented 88 per cent. of satisfactory results. These figures demonstrate that while the immediate effect of an operation may be exceedingly

satisfactory, the final results may not be nearly as satisfactory.

DR. ROBERT H. ROSE, New York: The truth is we hoped for too much from surgery. We got to the point where we expected an operation to cure the patient absolutely. Sometimes it did, sometimes it could not. I believe surgery often does more than we have a right to expect. I had a case of appendicitis with a good deal of cecal stasis. Appendectomy was performed. The operation had no effect on the stasis. In a similar case appendectomy cured constipation and stasis. We really have no right to expect appendectomy to cure cecal stasis. Appendicitis has its effect on motility, and where there is intestinal inflammation it will always or practically always disturb motility. Now, in a case of a cecal stasis, appendectomy may help the stasis because it does away with a certain amount of interference with the normal motility. It is effective when dilatation is not extreme. But it is not going to reduce the caliber of that portion of the intestine to any great extent. It will improve motility and tone. It will help evacuation. Then if we continue to follow up the case, as we should, we may be able to reduce the stasis of the cecum still further. No one treatment will cure all cases, and when we talk as if surgery could, it shows that we have expected too much of it. What surgery does not do, the gastro-enterologists ought to be able to do in some other way, and I think we can nearly always accomplish it if we follow up our cases. When surgery is indicated, other methods fail. I know it is proverbially true that surgeons know very little about diet, and they are very much inclined to overfeed patients after operations.

DR. HARRIS WEINSTEIN, New York: The surgeon has come in for well deserved criticism for postoperative failures in operations on the digestive tract, but I would ask the medical man what he can accomplish by medical treatment in organic, or, for that matter, in functional gastro-intestinal diseases. I would like to hear any man indicate the treatment for gastric or duodenal ulcer, or for chronic appendicitis, that would be effective or permanent. While we relieve symptoms, the relief is but temporary, lasting from three months to one year. If we are very fortunate it might last a little longer, but the symptoms are bound to return. There is not a method of medical treatment in chronic appendicitis that is effective, and sooner or later the appendix will have to be removed. If you do not get it out sooner, you will regret it when compelled to remove it later. Recurrence of distressing gastric symptoms after appendectomy emphasizes the inefficiency of surgery in these cases, but we have nothing better to offer. In operations for gastric or duodenal ulcer, the tendency is either to operate without proper regard for indications, or to have recourse to a compromise operation, gastro-enterostomy, which disturbs the normal physiology of the stomach and does not remove the dangers from complications. Hence the many postoperative failures, which, in my estimation, are far above the accepted 15 or 20 per cent. Resections are generally shunned by the surgeon for good or bad reasons.

DR. G. A. FRIEDMAN, New York: Dr. Brown's paper is a very important one, but his suggestion that surgeons and medical men should get together and come to definite conclusions is of little value, because we do not know what the etiology of these conditions is, and that is the reason why the medical man does not succeed with medical treatment and the surgeon does succeed with the knife. I pointed out last year that gastric and duodenal ulcer is due to a constitutional disturbance, and no matter what the end results, the organic lesion is removed but the constitutional disturbance, which is the cause of the ulcer, remains with the patient. That is the reason why many of the patients return unimproved. In the first years of my practice I was very enthusiastic about surgery. I sent practically every patient for operation, and the majority of them returned unimproved. When I found hyperacidity before the operation, I found it later, and the roentgen-ray findings were identical with those found before operation. This shows that all the conditions are not due to the ulcer, but it is possible that the nervous element, the functional disturbance, leads to the

ulcer; and, therefore, assuming that the medical man does not succeed with treatment and sends some patients to the surgeon, it is not because he is sure the operation will cure the patient, but because there is a limit at the present time to medical treatment. There is a strict indication for operation only in those cases where there is obstruction. Operations for ulcers are somewhat discredited by the public. I do not agree with Dr. Strauss that the hyperacidity is the cause of ulcer. If that were so we would have hyperacidity only with ulcer. We have hyperacidity in so many other conditions that one cannot absolutely consider the hyperacidity as the cause of ulcer. Hyperacidity is only a coincidence in ulcer.

DR. HENRY LITOWAY, New York: This is the most remarkable surgical paper I have heard in a long time—remarkable in that it takes up the matter of the many post-operative recurrences, and seeks to find the reasons therefor. I believe it will do more for the advancement of gastro-intestinal surgery than many of the more elaborate papers on this subject that have been presented hitherto. He says that the after-treatment of the patient is of the utmost importance. This is certainly true, more especially so as far as the diet is concerned. After the patient has been operated on and has recovered, he is sent out with the information that he is entirely well now, and that all restrictions on his eating and drinking are removed. It is in these cases that we have the post-operative recurrences. It is not the fault of the surgeons. The operations have been made skillfully, but the same causes that brought on the trouble originally have brought it on again. I do not look on gastric diseases, cancer, tuberculosis, syphilis (the latter two of rarest occurrence) excepted, either as infections or as constitutional diseases. They all have a local origin. The stomach is neither a leather nor a rubber bag. It is a highly organized organ of flesh and blood. It has most important physiologic functions, and has certain capacities, and if these are overtaxed, trouble ensues. If the surgeon will tell the patient on whom he has operated, assuming that the operation was performed with the necessary skill, and the wound well healed, what he must do and what he must avoid to keep well, he will not have any post-operative recurrences. As to gastro-entrostomies, I have never opposed to them for a number of years. I have never seen any benefit from a gastro-entrostomy that could not have been obtained as well by other measures of treatment. In several cases that have come under my observation, the patients have been much worse than before the operation. Only in cases of cancer where the days of the patient are numbered and where the conditions are frequently such as to make any other operation extra-hazardous, do I advise a gastro-entrostomy. Otherwise, I hold that an excision of the pylorus after some fashion is the operation to be preferred. With regard to ulcer of the stomach, I believe that with proper treatment the patient can be cured without an operation. Ulcer is not a constitutional disturbance, but a local ailment produced by a local cause. The hyperacidity produces the ulcer. The acid secreted by the stomach is the strongest of acids, and if you will take into consideration the patient's habits of life you will find ample cause for the hyperacidity and for the ulcer. Correct what it is, and you will cure your patient.

DR. EDWIN C. DODDING, New York: I did not hear enough about the influence of infection as the cause of ulcers and some of the other conditions mentioned. Focal infection has taken a great deal of our attention in the last few years and if it is what it is said to be it must be considered in a routine way in the preparation and treatment of all these cases. Rosenow has done what seems to be very complete and thorough work and proved that the streptococcus originating from the oral abscesses either at the apices of the teeth, from root infection, or from the tonsils, is the cause of duodenal and gastric ulcers; and it is said by other men to be the cause of various functional disturbances. If this is true it should be brought into the routine treatment of the case, and I would like to ask Dr. Brown whether they have gone into this matter thoroughly, whether they have

had satisfactory results, and what he thinks of the matter in general.

THOMAS R. BROWN, Baltimore: I am not one of those who have yet been convinced of the efficiency of the streptococcus in the development of gastro-intestinal ulcers. This is really very much more than a surgical or medical paper. It is a plea in recognition of the fact that the more acute the thing and the more striking the symptoms, the more successful the surgery. That is the reason, entirely contrary to the consensus of medical opinion expressed here, my experience with gastro-entrostomy has not been bad in some cases. In cases of high obstruction, when other forms of exploration were impossible and gastro-entrostomy has been done to relieve it, the results have been very good, and I do fear that the condemnation of gastro-entrostomy is wrong. My plea is that it should only be done in cases where it is absolutely necessary. One, at least, of the good results of gastro-entrostomy is due to the regurgitation of acid contents in the stomach. I think that point has been made enough of, but I believe it is a specially fundamental point. Another point of great fundamental interest, in regard to Dr. Friedenwald's series, is perhaps that some percentage of the series depends on the choice of the surgeon. It is really a question of what not to do. I have been connected with Dr. Finney for many years, he has done a great many operations for me, and he has convinced me more and more that every year he does a little bit better, even though he has an enormous experience, because he knows what to leave undone. After all, the object of the paper is to call attention to the fact that where we have to do the operation in chronic conditions surgery is a two-edged saw. If we could help and bring back a normal physiology, if not a normal anatomy of the gastro-intestinal tract in the first place, and if we could devise means by which postoperative adhesions could be averted, surgery would be absolutely the treatment for every one of these cases. It is just because we cannot duplicate normal physiology that we do have a probability of adhesions and a probability of recurrence of these other symptoms. It is for this reason that the result is unsatisfactory in the chronic group. It is for this reason that it seems a timely moment to bring together in a very broad way the surgeons and the clinicians, not criticizing the surgeons, nor criticizing the clinicians, but criticizing the clinician much more than the surgeon, because it is very much more the surgeon's hand that is forced by the clinician in the chronic condition. It is just the broad general principle that two people, clinician and surgeon, one trained in one line and one in another, ought both to apply their best energies to the treatment of these chronic cases.

---

**Plague and the Rat.**—Some connection between plague and rats or mice has been repeatedly noted since the time mentioned in I Samuel, IV, and VI, when "the mice marred the land," and at the same time the people were smitten with "tumours." In the eighteenth century, in Yunnan, China, is the record that "in the day time, strange rats appeared in the house and lying down on the ground perished with blood spitting." There was not a man escaped the instantaneous death after being infected with the miasma." Probably one of the oldest references to plague in rats is that contained in the Bhāgavata Purana, one of the most important, and perhaps one of the most ancient of the sacred Hindu writings. The people are instructed to quit their houses and go elsewhere as soon as they observe that "rats fall from the roofs above, jump about and die." These instructions are followed in many parts of India to this day. When the plague prevailed in India, in 1611-1618, rats and mice seem to have been affected by the disease. During the great plague of London in 1665, it was feared that rats and mice might be the means of spreading the infection. DeFoe writes, "All possible endeavours were used to destroy the mice and rats, especially the latter . . . and a prodigious multitude of them were also destroyed." (He also says that they tried to kill off all the dogs and cats.)—Clemow, "The Geography of Disease."

THE PHYSICAL AND ECONOMIC BENEFITS OF TREATMENT FOR HOOKWORM DISEASE\*

LOUIS SCHAPIRO, M.D.

State Director of Campaign for the Relief and Control of Hookworm Disease in Costa Rica

SAN JOSÉ, COSTA RICA

A campaign for the relief and control of any disease, to be effective, must result not only in a reduction of morbidity, mortality and suffering, but likewise in a monetary saving to the individual and the community. For more than two years we wished to demonstrate to the government and people of Costa Rica the economic value of the campaign for the relief and control of hookworm disease that was being carried on in that republic. But it was impossible to do this because we had worked in but few areas in which accurate data as to wages were available, and in these few areas sufficient time had not elapsed after the people had been examined and treated for a satisfactory comparison to be made of their earning capacities before and after treatment.

Lately, however, we have had opportunity to make a detailed analysis of the earning capacities before and after treatment of 320 patients cured of hookworm disease on the estates of Rodeo (located in the canton of Mora, province of San Jose) and Aquiares (canton of Turrialba, province of Cartago). These are representative estates on which conditions are neither better nor worse than the average. They are situated, the first on the Atlantic, the second on the Pacific, slope of the country, in the midst of rich agricultural regions. The owners of these estates, always interested in the welfare of their people, insisted that they should be examined for hookworm disease, and be treated and cured if found infected.

Rodeo lies partly in the central tableland of Costa Rica, and partly on the Pacific slope, at an altitude of about 2,000 feet. The climate is tropical. Sugar cane is cultivated, corn and beans are grown, and cattle are raised. The people live in poorly constructed wooden houses. They take their water for domestic purposes from creeks.

Aquiares is situated on the southern slope of Turrialba volcano, at an altitude of about 3,000 feet. The climate is moderately warm. Coffee, corn and beans are cultivated for export. The people live in well constructed, though neglected, wooden houses. Water for the homes is supplied by creeks and by an open ditch.

SUMMARY OF CAMPAIGN AND SURVEY

In the campaign of relief and control, conducted on Rodeo from September to December, 1916, 243 of the 263 persons living on the estate were examined, and 237, or 97.5 per cent., of those examined were found to be infected with hookworm disease. Two hundred and twenty-eight of the infected persons were treated one or more times, and 191 of them were eventually shown by microscopic reexamination to have been cured. To learn what effects the relief from hookworm infection had had on the general health and earning capacity of the workers on this estate, we went back and reexamined, during the period from June 4

to June 8, 1918, ninety-seven (or approximately one half) of the 191 persons who had been cured eighteen months earlier. Fourteen of them were found to have been reinfected—a reinfection rate of only 14.4 per cent. Not one of the homes on this estate was provided with a latrine when the campaign of relief and control began, and only 25.6 per cent. were so provided when it ended. At the time of the resurvey in 1918, the percentage of homes with latrines was only 30.2. All of these figures are shown in Table 1.

The first campaign of control on Aquiares was carried out during two periods, from June 5 to Dec. 22, 1916, and from July 6 to Dec. 20, 1917. There were then 822 workers on the farm, and 745 of them were examined. Infection was found in 447, or 60 per cent., of those examined. All but eighteen of those found infected received one or more treatments, and 334 of them were eventually shown by microscopic reexamination to have been cured. When we went back for our resurvey, between May 7 and May 20, 1918, we reexamined 223 of these 334 cured persons, and found that only nine of them had been reinfected since the close of our first campaign five months previously.

TABLE 1.—STATISTICAL SUMMARY OF CAMPAIGN AND SURVEY OF RODEO AND AQUIARES ESTATES

	Rodeo Estate				Aquiares Estate			
	Campaign of Relief and Control		Resurvey		Campaign of Relief and Control		Resurvey	
	No.	%	No.	%	No.	%	No.	%
Census of estate.....	263	....	....	....	822	....	....	....
Examined for hookworm disease.....	243	92.4 <sup>1</sup>	97	....	745	90.6 <sup>2</sup>	223	....
Found infected with hookworm disease.....	237	97.5 <sup>1</sup>	14	14.1 <sup>3</sup>	417	60.0 <sup>2</sup>	9	4.03 <sup>4</sup>
Given treatment for hookworm disease.....	228	96.2 <sup>1</sup>	....	....	429	96.0 <sup>2</sup>	....	....
Cured of hookworm disease.....	191	83.8 <sup>1</sup>	....	....	334	77.9 <sup>2</sup>	....	....
Houses on estate.....	43	....	43	....	132	....	152	....
Houses with latrines:								
First inspection.....	0	0.0	13	30.2 <sup>5</sup>	7	4.6	76	50.0
Last inspection.....	11	25.6	15	30.2 <sup>5</sup>	76	50.0	76	50.0

\* Percentage based on census.  
<sup>1</sup> Percentage based on number examined.  
<sup>2</sup> Percentage based on number found infected.  
<sup>3</sup> Percentage based on number given first treatment.

This gave a lower reinfection rate than that for Rodeo, being only 4.0 per cent. In the resurveys on both estates, three negative 2 by 3 inch microscope slides were required before any person was pronounced free of infection. On Aquiares, 4.6 per cent. of the homes were provided with latrine accommodation at the beginning of the campaign of relief and control. One half of the homes, however, had latrines when this campaign ended. This situation remained unchanged when the resurvey was made in May, 1918. The resurvey on both estates showed that the latrines that had been erected during the progress of the campaign were being maintained in satisfactory condition.

INCREASE IN HEMOGLOBIN

In the campaign of relief and control on Rodeo estate, the average percentage of hemoglobin among 185 of the infected persons before they were treated was but 42.1. Among 169 of these persons after they had been cured of hookworm disease, the average hemoglobin was 63.3 per cent. This is an increase of 21.1 per cent. In the resurvey the fourteen persons found reinfected had an average hemoglobin of 71 per cent., as compared with an average of 76.8 per cent. among the fifty persons who remained uninfected. The

\* The studies described in this paper were made during the progress of a campaign for the relief and control of hookworm disease, conducted by the International Health Board of the Rockefeller Foundation and the government of Costa Rica.

resurvey figures for this estate suggest that the hemoglobin index continued to rise for a considerable period following the close of the regular campaign measures.

On AQUIARES the hemoglobin index among 280 infected persons before treatment was 70 per cent.

TABLE 2.—HEMOGLOBIN INDEX OF INFECTED PERSONS BEFORE AND AFTER TREATMENT FOR HOOKWORM DISEASE

	Rodeo Estate				Aquiars Estate			
	Campaign of Relief and Control		Resurvey		Campaign of Relief and Control		Resurvey	
	Infected Persons before Being Treated	Infected Persons after Being Cured	Persons Found Reinfected	Persons Remaining Cured	Infected Persons before Being Treated	Infected Persons after Being Cured	Persons Found Reinfected	Persons Remaining Cured
Average percentage hemoglobin	65.1	67.3	71.0	76.8	70.0	78.9	83.3	79.7
Total persons examined	185	109	14	50	280	100	0	94

Among 100 of these persons after they had been cured, the average was 78.9 per cent. The resurvey figures indicate that the cured persons who were reinfected sustained a slight decrease in hemoglobin between the close of the campaign of relief and control and the date of the resurvey. In the resurvey, the persons found reinfected had an average hemoglobin index of 73.3, and those who remained cured an average of 79.7 per cent.—the latter slightly higher than the average of 78.9 per cent. established immediately after cure. All of these figures are summarized in Table 2.

#### INCREASE IN EARNING CAPACITY

In an effort to arrive at an accurate estimate of the increased earnings of the workers on the two plantations, the records of all persons remaining cured in the resurvey were carefully checked and all were excluded from consideration except those for men more than 18 years of age who had worked on the estates at least one year before the campaign of relief and control began, and at least six months after it ended. The

TABLE 3.—DAILY AND MONTHLY WAGES OF ESTATE LABORERS BEFORE AND AFTER BEING CURED OF HOOKWORM DISEASE

	Average Monthly Earnings (Colones)	Monthly Gain (Colones)	Average Daily Earnings (Colones)	Daily Gain (Colones)	Percentage of Increase in Earnings
Rodeo Estate					
Before treatment	4.96	...	1.68	...	...
After treatment	5.66	0.70	1.92	0.24	14.6
Aquiars Estate					
Before treatment	1.76	...	0.59	...	...
After treatment	1.74	0.56	1.36	0.27	27.0

1 Colón = 86.00.

gross earnings of these men during three selected months of 1916 before the campaign had opened—were then compared with their gross earnings during the same three months of 1917 or 1918—after it had closed. On Rodeo, the months of June, July and August were chosen; on AQUIARES, those of February, March and April. In the case of the latter estate, the comparison was made between the wages for three months of 1916 and those for three months of 1918.

The data show that there was an increase in the earning capacity of the workers on Rodeo estate of 14.6

per cent., and on AQUIARES of 27 per cent. The wages on Rodeo remained the same, while those on AQUIARES were reduced 15 per cent. between the periods compared. On the latter estate there was, therefore, an increase of 42 per cent. in earning capacity if the 15 per cent. reduction in pay is taken into consideration. Detailed figures for wages during the periods before and after treatment for hookworm disease are given in Table 3.

#### INCREASE IN ACREAGE CULTIVATED

Larger areas have been cultivated and greater crops obtained since the workers were treated and cured of hookworm disease. On AQUIARES, as Table 4 indicates, the acreage under coffee cultivation was increased 33 per cent. This has been accomplished without additional labor, and with a lower unit cost for cultivation.

During 1916, ten colones were paid for each manzana (17½ acres) cultivated, while at present 8.5 colones are paid, yet the worker receives higher compensation.

The table indicates also a considerable increase in the acreage devoted to corn cultivation. The estate donates to its workers small plots of ground for raising corn, with the understanding that the corn produced thereon may either be used by the laborers themselves or be disposed of to their profit. The increase in the

TABLE 4.—AREA CULTIVATED ON ONE ESTATE BEFORE AND AFTER TREATMENT OF LABORERS FOR HOOKWORM DISEASE (NUMBER OF LABORERS THE SAME ON BOTH OCCASIONS)

Crop	Area Cultivated (Manzanas)		Percentage of Increase 1918 over 1916
	1916	1918	
Coffee	300	400	33.3
Corn	80	250	212.5
Beans	40	40	0.0
Pasture	182	200	9.9
Total	602	890	47.8

acreage devoted to corn cultivation therefore means that the workers are producing not only enough corn for their own consumption, but have some to export as well. The owners report that the net results of this, and of the higher wages the laborers are receiving, are a healthier, more contented, more permanent laboring force, earning more for themselves and producing more for their employers.

#### CONCLUSIONS

Although the life, labor and customs of the people living on these two estates do not differ from those that obtain generally throughout the country, and although every effort was exercised to guard against error in conducting the study, the number of cases considered is probably insufficient to justify the drawing of conclusions that will apply to whole territories. Nevertheless, the figures may be taken as pointing toward, if not as establishing, the following:

1. There is a permanent increase in hemoglobin as a result of treatment for hookworm disease.

2. On one farm, in spite of a 15 per cent. reduction in unit pay, the laborers earn 27 per cent. more. On another, where there has been no reduction in unit pay, they earn 14.6 per cent. more.

3. The owners of one farm are cultivating 33 per cent. more coffee with the same number of laborers, at a lower unit cost.

In addition to the benefits mentioned above, one estate reports a marked reduction in morbidity and in

infant mortality, and both estates report that the laborers spend less than formerly, or else spend nothing at all, for quack medicines and quack physicians to cure their infirmities.

## FURTHER EXPERIENCES WITH THE STRING TEST\*

MAX EINHORN, M.D.

Professor of Medicine, New York Post-Graduate Medical School  
NEW YORK

In several papers,<sup>1</sup> I have published numerous observations on the duodenal bucket and the value of the thread or string test. It is now about twelve years since my first paper on the duodenal bucket appeared. I thought it would be of interest to give you my experiences regarding the string test up to date.

Since the accuracy of the test will depend on the exactness of its performance I herewith give again a detailed description of this method.

### METHOD OF USE

The patient swallows the duodenal bucket in the evening, late after supper, with a glass of water. The end of the thread is attached to the nightgown in such a manner that a length of from 30 to 32 inches from the lips can enter the digestive tract, and the bucket is allowed to travel by itself over night while the patient is asleep. In the morning before breakfast, it is slowly and carefully withdrawn by the physician. When the larynx is reached a resistance will be felt. This must not be overcome by forcible pulling, but the patient must be told to swallow, and during the act of deglutition the bucket may be easily withdrawn.

Before the bucket is removed, a knot must be made at the teeth in order to determine the length of the thread in the digestive tract. It is important that the patient should take no substances at supper that might cause a stain on the white silk thread resembling blood (as coffee, jellies, claret, etc.). It is also essential that the entire length of 30 inches should be within the digestive tract before the patient goes to bed.

After withdrawal of the bucket, the thread is immediately and carefully examined (1) for blood spots and (2) bile stains. Then the contents of the bucket are aspirated by means of a small pipet and likewise examined.

### SIGNIFICANCE OF THE STRING TEST

The distance of the blood spots from the knot at the teeth will give the location of the ulcer. If the end, say the lower 4 to 8 inches, is stained a golden yellow, it will show that the bucket had passed the pylorus—provided the length of the thread in the digestive tract remaining white exceeds 22 inches—and that, therefore, the pylorus is permeable. (The distance from the teeth to the pylorus is on an average 22 inches.)

If the bucket has been in the duodenum, the contents are usually golden yellow, viscid and slightly alkaline. Sometimes, however, they may be acid and whitish, especially if the bucket has been only beyond the pylorus.

A blood stain in the neighborhood of 40 cm. (16 inches) points to an ulcer at the cardia; from 44 to 54 cm. (17½ to 21½ inches), ulcer of the lesser curvature; from 55 to 56 cm. (22 to 22½ inches), pylorus; 57 cm. (22½ inches) and more, ulcer in the duodenum. Two definite small blood stains near each other usually indicate the size of the ulcer, the spots being given by the margins of the ulcer.

If the string test is made several times, the results usually harmonize. Sometimes, however, there is a difference in the site of the brownish spot. This may be explained by the patient's involuntarily pulling the thread somewhat out of position during the process of washing and dressing. There is at times a very long brownish discoloration for a great distance. This need not correspond to the size of the ulcer, and can be easily explained by different parts of the thread coming into contact with the ulcer successively during the migration of the bucket through the pylorus and the duodenum. This is particularly noticed in malignant disease of the stomach, which as a rule presents fresh ulcerations.

The thread test appears to be of importance not only in the recognition of the position of the ulcer, but also as a criterion of the efficiency of our procedures, especially whether a cure has been accomplished or not. In those cases in which perfect healing of the ulcer has taken place, the test becomes negative.

In the diagnosis of cancer of the stomach, the thread test is of value in aiding us to recognize a suspected neoplasm before it is yet palpable. This is particularly the case in malignant affections of the cardia and the pylorus. In a case of cancer of the cardia, the bucket returned once filled with a piece of tissue of the tumor showing microscopically all the characteristics of a cancerous growth, while the thread above showed a blood stain. In several cases of neoplasm of the pylorus, the bucket did not pass beyond the pylorus and came back filled with a brownish fluid of a fetid odor, the thread being discolored brownish for quite a distance from the bucket.

The string showing no bile stain and having a length of 25 inches or more from the lips indicates the failure of the bucket to pass the pylorus. This may be due to either an organic stricture or a spasm of the pylorus. To decide this the test is repeated and atropin given. Absence of bile on the string in this second test seems to speak for a real pyloric stenosis.

### EXPERIENCES IN PRIVATE PRACTICE

In reporting my experiences with regard to the string test in peptic ulcers I select the material of my private practice, as the figures are more definite. Moreover, the strings of all my private patients were kept as a record and are to be found in my collection. By far the greater majority examined with the string test had some symptoms of peptic ulcer, or belonged to that group in which there was a possibility of its existence.

All in all, 1,044 patients with suspicion of peptic ulcer were examined, with the string test, during the last eleven or twelve years. Of these, 481 showed a positive blood stain, while 563 were negative with regard to blood.

The location of the ulcer (according to the string test) and its distribution according to sex are presented in Table I.

Cardiac ulcers show a greater percentage among the female sex (14 per cent.) than the male sex (6 per cent.). The reverse is found in duodenal ulcers,

\* Read before the Section on Gastro-Enterology and Proctology at the Seventieth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

1. Einhorn, Max: A New Method of Estimating the Permeability of the Pylorus. *New York M. J.* 87: 1179-1182 (June 20) 1908; A New Method of Recognizing Ulcers of the Upper Digestive Tract and Localizing Them. *M. Rec.* 75: 549-552 (April 3) 1909; The Importance of the Thread Impregnation Test for the Recognition of Ulcers of the Upper Digestive Tract. *M. Rec.* March 18, 1911.

namely, greater frequency among men (37 per cent.) than among women (22 per cent.).

TABLE 1.—LOCATION OF THE ULCER AND ITS DISTRIBUTION AMONG THE SEXES

	Curlin (36.1%)		Lesser Curvature (43.5%)		Pylorus (64.5%)		Duodenum (Beyond 53)	
	No.	%	No.	%	No.	%	No.	%
Males	20	6	13	40	58	17	120	37
Females	20	14	09	47	26	17	82	22

Among 399 patients whose gastric juice had been examined and analyzed and a classification made into hyperacidity (60 and above) and subacidity (below 60), we find the results given in Table 2.

TABLE 2.—RELATION OF GASTRIC ACIDITY TO ULCER (POSITIVE STRING TEST) AMONG THREE HUNDRED AND NINETY NINE PATIENTS WITH POSSIBLE ULCERS

	Hyperacidity String Test						Subacidity String Test					
	Total		Positive		Negative		Total		Positive		Negative	
	No.	%	No.	%	No.	%	No.	%	No.	%	No.	%
Males	181	153	76	46	24	80	40	50	40	50		
Females	81	64	77	17	23	63	33	62	20	38		

It is easily seen from this table that in both sexes among ulcer suspects with hyperacidity, the presence of ulcer is found more frequently than in those with subacidity.

What proofs have we that a positive string test indicates some form of ulceration?

From the figures given in the tables it is evident that among ulcer suspects we find the frequency and location of the blood stain harmonizing with the distribution of ulcer encountered in necropsies and in operations. The greater frequency of duodenal ulcer among men than women is, likewise, demonstrated by the string test. From a considerable experience I can say that, in the greatest majority of instances, patients with probable ulcer and a positive blood stain on the string do well when subjected to an ulcer cure. In a great many instances the roentgen-ray findings of a peptic ulcer tally almost exactly with the results of the string test. The same remark applies to operations on ulcer patients. To be sure, there are instances in which roentgen-ray signs are lacking, and in which, likewise, inspection and palpation of the stomach, at operation, from the outside fail to show anything definite with respect to an ulcer, in which the string test is distinctly positive. Here there are two possibilities: Either the blood stain is due to an extensive inflammatory process of the gastric mucosa, or—which is more probable—to a superficial ulcer.

I am aware of quite a few instances in which an operation failed to reveal any ulceration of the gastrointestinal tract. These patients continued to suffer after the laparotomy just as much as before. The string having been positive for peptic ulcer, they were given duodenal alimentation and were completely relieved of their troubles.

#### CONCLUSIONS

In addition to the foregoing, my experiences with the string test on ward patients in the Lenox Hill and Post-Graduate Hospitals—which will equal if not exceed those of my private patients—justify the following conclusions:

The string test has proved itself extremely useful in the diagnosis of peptic ulcers and their location, also

in demonstrating patency or stenosis of the pylorus. Frequently the existence of a gastroenterostomy opening and its proper functioning can, likewise, be made up by this method (the bile stain on the thread, then, usually beginning at 19 to 20 inches from the lips, instead of 23 to 24).

Of all the tests we employ in our routine examinations of patients afflicted with digestive disturbances the string is certainly of great, if not the greatest, importance. It frequently points the way to a correct diagnosis and a proper plan of treatment.

#### ABSTRACT OF DISCUSSION

DR. SIDNEY K. SIMON, New Orleans: Some years ago I made some tests on individuals in hospitals who had no gastric disturbance at all. I wanted to check up on digestively normal individuals the results that I had observed with the ulcer cases. With the kindness of my confrères I used for that purpose fifty individuals who happened to be in the hospital for some other disturbance, broken legs, and so forth. I made some very interesting observations with the string. Of those fifty individuals, twelve, or about 25 per cent., showed a distinct reaction on the string. The stain varied from a rather deep, blackish discoloration to mere streaks along the string, and the conclusions I came to in regard to these experiments were these: That the tautness of the string before pulling it out made quite a difference as to whether one would find a blood stain or not. If the string were allowed to pass into the intestinal tract, that is, the bucket more than thirty-three inches, it became so taut that on attempting to pull it out trauma was produced along the tract, either at the orifices of the stomach or in the esophagus, and we obtained a streaking of blood. The mere streaking of blood on the string amounts to nothing, practically. If one observes the restriction of not allowing the string to enter into the intestinal canal more than twenty-three inches from the incisor teeth, and will use ordinary precautions in pulling the bucket out with the string, I believe that the test has a great practical value. In another series of cases of demonstrable ulcers I found at least one half with blood stain. But the stain must be at a measured spot on the string that corresponds to the side of the ulcer; that is, with regard to the cardiac end or the pyloric end of the stomach. The stain must be a distinctly deep discoloration, not a mere streak of blood—but a deeply imprinted stain, and usually of a blackish color, and must measure some distance along the string which would correspond to the distance in the gastro-intestinal upper tract where the ulcer is suspected, either the esophagus or the pyloric end. Mere streaks of blood amount to nothing, and particularly if the bucket has been allowed to go into the intestinal tract farther than the thirty-three inches from the incisor teeth.

DR. CLEMENT R. JONES, Pittsburgh: I began to use the Einhorn test string quite a number of years ago, and I have used it routinely ever since that time. I have for a considerable time placed a great deal of confidence in the test. I think that the manner in which the test is used is very important, and I would like Dr. Einhorn, if he will, to tell us the exact character of the string he uses. I have experimented with different types of string and I believe that the character of the string has a good deal to do with some of the tests for blood in otherwise normal individuals. I also some time since ceased to use any weight on the string. The tension of the bucket, or whatever weight may be on the string, seemed to produce a sawing process in some cases which resulted in a stain that would not otherwise have been present, although that stain formed by the sawing is to the experienced observer not often mistaken for the larger stain of the ulcer. I believe that if this test is applied carefully with the string, with simply a knot on the end of the string, that knot being placed in a capsule and passed through the pylorus, we will get a more satisfactory result from the use of this test.

DR. I. O. PALEFSKI, New York: It is generally conceded that in a bleeding gastric or duodenal ulcer the thread may be positive. In many instances, however, the positive thread for ulcer cannot be corroborated by other clinical or roentgenographic evidence. Laparotomy in these cases, as a rule, reveals no ulcer. We observed two conditions which are particularly prone to show a positive thread although no ulcer is present: first, in periduodenal cholecystic adhesions, and, second in low stomachs with high pyloric limb. In the former, the mucosa at the point of the deviation or angulation of the duodenum, as a result of the periduodenal adhesions, is apt to become traumatized by the thread as a result of undue tension caused by the peristaltic waves of the duodenum. In the latter condition the capsule of the string in its passage into the duodenum must assume, first, an upward direction and, second, on reaching the duodenum, a downward course with the point of tension at the pylorus. The conclusions reached by Dr. Einhorn are generally recognized among roentgenologists, although in the experience of Dr. Carman 90 per cent. of duodenal ulcers show a six hour gastric residue. One often finds hypermotility in the course of roentgenographic examination in conditions other than duodenal ulcer or gallbladder disease and, therefore, the phenomenon of hypermotility by itself can hardly be of diagnostic consideration. This is particularly true in gallbladder disease which usually shows no other roentgenographic evidence. It is not usual to find hypermotility in chronic appendicitis. Clinically, however, the predominating features of chronic gallbladder disease and chronic appendicitis are those of gastro-intestinal stasis. I do not believe that motility of the gastro-intestinal tract can be studied accurately with inert salts, such as barium sulphate or bismuth. A mixed meal as a motor test meal is preferable, as it more likely stimulates peristalsis and the digestive secretions. I have had the opportunity to examine a number of patients and was surprised to note the discrepancies occurring between opaque and mixed meals as motor test meals. Our present knowledge of the rate of evacuation of the gastro-intestinal tract under normal and pathologic conditions is still incomplete. The solution of the problem requires team work between the gastro-enterologist and the roentgenologist. It is conceivable, therefore, that in such conditions, the blood-stained thread may be the result of traumatism. In my opinion, a positive thread when unsubstantiated by other definite evidence of ulcer should receive no serious consideration.

DR. JULIUS FRIEDENWALD, Baltimore: I have used the Einhorn string test in many instances in suspected ulcers, and have always found it of considerable aid in diagnosis. The principal fact that I have observed, however, regarding it is that one should not rely on a single examination. Two or three tests should be made, and when the blood stain is precisely at the same distance at every examination I am convinced that it then presents definite evidences of ulceration. This method is also very useful in those instances in which the results of the roentgen-ray examination are indefinite, and yet the symptoms are positive of ulceration; in these instances the string test gives very valuable information as to whether there is an ulcer at hand or not.

DR. WILLIAM VAN V. HAYES, New York: I wish to confirm what has been said. The string test has been under fire from various sources and all sorts of absurd things have been done and wrong interpretations made. For instance, one man condemned it. He said he had found it positive in one or two cases, had operated and had found no ulcer. In my opinion that is an entirely wrong way to use the string. The string should be used to secure one item of evidence, one bit of corroboration of our diagnosis. As Dr. Friedenwald said, we should confirm it by two or three tests. If we get a definite stain at a definite point persistently present it means something. It does not necessarily mean a big indurated ulcer; it may mean a slight erosion; and I am not sure but that in some cases we get a stain where there is simply marked pyloric spasm or a definitely congested state of the mucous membrane. But the stain on the thread does indicate something which is path-

ologic. It may be an ulcer or it may be something that is much milder, but it is something that needs treatment. Personally, I do not feel satisfied in the handling of a case showing a definite stain until I have got rid of that stain. It seems to me that is the way we ought to use the test. One other point: In using this string test I have regularly employed No. 15 surgeon's twisted silk, as being a little softer than the braided silk, and, consequently, a little less apt to produce irritation of the mucous membrane. Also, I have used a little bead about an eighth of an inch in diameter, not having any great weight, and have then taken pains in withdrawing the thread not to use any force. If the bead catches, I simply wait until the spasm relaxes, and then gently withdraw the thread. Under these conditions we will usually get reliable results.

DR. MAX EINHORN, New York: With regard to the string, I usually use English braided silk, No. 5. That is the best although you may use anything else. The string should not be much longer than thirty-three inches from the lips, entering. That is long enough to see whether there is anything or not. I use the bucket on the string. This is important in order to determine the permeability of the pylorus. If a certain length passes through (25 inches or more), and bile is seen on the end of the string, and then white above it, that bucket has entered the pylorus. The bucket is size 23, French, I think. You may use a larger or a smaller one, but it helps you to get an idea as to the permeability. In regard to the pulling: I have frequently seen cases where we encountered resistance. In such cases we should wait and not pull hard; wait a little and then pull again. But in some cases where there was a strong resistance I found that there was no stain at all, indicating that the pulling alone does not give a stain. If trauma were caused by the pulling of the string it would show a stain of fresh blood. But these stains are usually dark, as of something oozing out. There is a great difference between the two. With regard to the localization, I pay more attention to a small stain, especially two tiny little spots than to a big splashing stain. But a big stain does not indicate the size of the ulcer; it is caused by the movement of the string, coming in contact with different parts of that same area. We find that more frequently in malignant conditions than in benign conditions. On the whole, I can only repeat that the method is very useful in diagnosis.

#### CERTAIN LIMITATIONS OF ROENTGEN-RAY DIAGNOSIS OF GASTRO-INTESTINAL DISEASES\*

DUDLEY ROBERTS, M.D.

NEW YORK

The roentgenologic diagnosis of gastro-intestinal diseases has been developed with such marvellous rapidity that a great degree of caution should be observed in directing attention at the present time to its seeming limitations. It must be conceded that roentgenology has put gastro-intestinal diagnosis on a new and sounder basis, changing to a great degree the current conception of the meaning of abdominal complaints and demonstrating some abnormalities with unerring accuracy which on the operating and necropsy table had usually been overlooked. Nevertheless, there are definite limitations to which this method can be stretched, and the very fact that so much reliance is now placed on it makes it desirable that these limitations be admitted and generally understood. The duty are actually coming to believe that a roentgenogram is a diagnosis and not, as we know very well,

\*Read before the Section on Gastro-Enterology and Proctology at the Seventy-fifth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1913.

a source of data on which opinions may be expressed with the widest range of values.

The serious practical objection to the general use of the method in gastro-intestinal diagnosis is the expense it entails when properly carried out. Commercial roentgen-ray laboratories are springing up all over the country to meet the demand for work at moderate prices, but it is difficult to conceive how complete and satisfactory work can be offered to the charity patients except in highly endowed institutions. I myself am convinced that much of the time, incomplete and unsatisfactory technical work and inexperienced interpretation simply confuse the issue, and the patient would be far better off if reliance were placed on clinical and laboratory data and the results of exploratory laparotomy when apparently indicated.

It is not, however, to these limitations in the practical utility of the method to which we wish to direct attention, but rather to certain more fundamental limitations which depend on the difficulty or impossibility of demonstrating abdominal abnormalities by roentgenographic method.

By roentgenographic examination we can visualize the shape, size, contour and position of the various parts of the gastro-intestinal tract when it is properly filled with opaque substances, and we can with reasonable accuracy roentgenograph the outlines of the liver, kidneys and urinary tract. The development of soft part detail work has progressed rapidly, but it must be admitted that we cannot visualize the changes in the structure of the abdominal organs. In recent years, attention has been largely centered on the recognition and treatment of the gross lesions of the abdominal viscera. Comparatively little progress has been made in the study of those visceral changes of a structural nature which are so obvious on the post-mortem table and would seem to be of such great importance. The gastro-enterology of a decade or two ago has gone. We now appreciate the frequency and varied clinical pictures associated with gross organic lesions of the abdominal viscera. With the exclusion of these lesions made possible in the great majority of cases by systematic roentgenographic examination, we should be in a far better position to push the study of those disturbances of function and changes in structure on which this method can throw no direct light. *A negative roentgen-ray diagnosis of a gastro-intestinal lesion should never be regarded as final in the exclusion of gastro-intestinal disease.*

In the recognition of the gross abdominal lesions by roentgenographic methods there are also many difficulties and some impossibilities. In large part, it is true, these are failures or imperfections in technic and extensible fallibility in roentgenographic interpretation.

The study of the esophagus by the fluoroscopic and roentgenographic method has been an important step in the clinical study of its abnormalities, but we must admit that the passage of the meal through the unobstructed esophagus is rapid and the filling too incomplete to make for satisfactory examination. Unfortunately, clinical symptoms are seldom complained of until obstruction takes place; but it is just as well that we bear in mind the danger of a negative diagnosis of esophageal lesion by roentgenographic methods. A negative examination calls for the use of all other methods when any symptoms are present. The differentiation of spasm from annular growth in the

cardia is sometimes made with disastrous results. On the whole we should regard the roentgen ray as more distinctly an aid to other methods of diagnosis in esophageal work than in the diagnosis of disturbances in other parts of the gastro-intestinal tract, because it can be examined so directly with the esophagoscope.

The stomach is in many respects the most easily roentgenographed of all parts of the alimentary tube, and I believe that in only a small majority of cases will adequate fluoroscopic and plate studies fail to show a gross lesion. There are, however, certain stumbling blocks which must be reckoned with in every examination.

The cardiac end of the stomach with an ordinary opaque meal fills out poorly; and unless a suspicion is entertained of the infrequent lesion in this area, it will probably be overlooked. I feel that here is a definite place for the gastroscope in diagnosis when symptoms and findings suggest a lesion in this region.

Ulcer and cancer of the posterior wall of the stomach, unless large and encroaching on the curvatures, fail on the immediate plate to give definite filling defects. We have seen on two occasions symptoms of cancer which we later proved by operation to be of the posterior wall but which gave an absolutely normal series of plates taken immediately after the ingestion of the opaque meal. It is possible that the lesion might have shown on the two or four hour series.

Early annular growths in the pylorus are compatible with normal roentgenographic appearances, as has been demonstrated twice in my experience. Almost always by the time symptoms are present the presence of the growth is obvious on the plates.

There is a definite group of cases that resemble ulcer in history and laboratory findings while the roentgenographic examination is absolutely negative. While it is probable that some of these cases are not true gastric cases, there is a small number that I believe are unquestionably florid or mucosal ulcers of the stomach. Sometimes even these shallow superficial craters can be caught on the lesser curvature. We have seen such craters show at the first examination, then disappear with medical treatment, and later fail to show with a definite recurrence of symptoms. Positive roentgenographic evidence of ulcerative or indurative lesion of the stomach may contradict all other evidence, and negative evidence of a gastric lesion has some weight; but I feel that we should hesitate to accept a negative roentgenographic diagnosis of gastric lesion with a positive history and suggestive laboratory findings unless some other lesion is discovered as a possible cause of the clinical disability.

The roentgenographic determination as to whether a visualized lesion is active or healed is possible in many cases, particularly in the gastric side of the pylorus. Frequently we are left in much uncertainty as to the condition of the ulcer when the roentgenographic examination is repeated after the completion of the ulcer cure.

The differentiation between ulcer, cancer and syphilis may be made with a reasonable degree of certainty, particularly in the advanced case. Differentiation is by no means always easy, even on direct examination of the ulcer or mass. We have seen syphilis of the stomach cured by treatment give the same roentgenographic picture as cancer, and we do not believe it is ever safe to reach a differentiation solely on roentgenographic evidence.

With the development of technic, it is now possible to visualize gallstones in a large majority of cases; and frequently the chronic thickened gallbladder is definitely shown. All stones and all chronic gallbladders cannot at present be demonstrated. I cannot agree with those who contend that the gallbladder that can be visualized is a pathologic gallbladder, as we have seen such removed and found them normal. In view of the commonness of a pathologic condition of the gallbladder among those in middle life and beyond, a failure to show the condition even in 20 per cent. of cases is an important consideration, and shows the folly of making an absolutely negative diagnosis of a pathologic condition of the upper abdomen on roentgenographic examination.

The terminal ileum and cecum offer diagnostic difficulties of the most varied kinds. Persistent deformities are found to be of little consequence; anatomic peculiarities are mistaken for pathologic conditions. There are cases in which the evidence of a pathologic condition is too definite to be questioned; but, on the whole, I have come to regard the roentgenographic diagnosis of conditions in the right iliac fossa with considerable suspicion, insisting that a definite opinion should be expressed only when there is the most unmistakable, persistent evidence in support of the clinical picture.

The diagnosis of incompetency of the ileocecal valve can, of course, be made with certainty with the barium enema; but whether under such artificial conditions the phenomenon has clinical significance is extremely doubtful. The weak spot in the results from repair work on the valve is the fact that usually the chronic appendix is removed at the same time, and often definite constricting bands are freed.

The roentgenographic diagnosis of appendix has become popular in recent years, although it rests on a very insecure foundation of established fact. It may be made with reasonable certainty in the case showing definite evidence of deforming adhesions. The failure to fill or to empty when filled, even after several days, is entirely compatible with a normal appendix, as has been observed in my experience repeatedly. We have seen the appendix filled, curved, somewhat angulated and remain filled for ten days, and yet prove normal on removal. I cannot see that we are justified in accepting the statement so frequently heard that the appendix that fails to empty promptly or that is retrocecal is a dangerous appendix per se. As clinicians, we are not so much interested in whether the appendix is somewhat abnormal, but whether it is responsible for disability or is a source of danger from acute disease. The roentgenographic decision on these points is made difficult by the superficial opinions on the condition of the appendix expressed by the surgeon, and the failure to study after-results from the removal of the supposed chronic appendix. I am convinced that the after-results are very poor in those cases giving no history of definite acute attacks, and I believe that a positive or negative opinion of appendix disease on roentgenographic evidence should not to any great degree influence our judgment as to the desirability of appendectomy reached on clinical grounds.

The study of the colon is, on the whole, satisfactory, as it can so well be visualized by opaque meals in I enemas and stereoscoped so accurately. We cannot expect the visualization of mucosal changes or the

demonstration of growths projecting into the lumen without affecting the wall. The sigmoid and rectum are more difficult to study because of anatomic arrangements, the variations in the normal course and fixation. Small lesions can readily be missed, and a negative opinion of low ulcerative lesion should be guardedly made on roentgenographic examination.

The ideal form of roentgenographic examination of the gastro-intestinal tract resembles the complete necropsy which the pathologist approaches without bias in the effort to discover the exact condition of each part, and later perhaps correlate his findings with the disabilities observed during life. With a reasonable degree of positiveness, conclusions may be reached as to gross lesions of the abdominal organs by roentgenographic examination; but it must not be forgotten that the accuracy of these conclusions depends entirely on the pathologic knowledge, the experience and the scientific honesty of the interpreter, and due allowance must always be made for the limitations of the roentgenographic method of diagnosis.

270 Park Avenue.

#### THE OPERABILITY OF CANCER OF THE STOMACH AS DETERMINED BY THE ROENTGEN RAY\*

R. D. CARMAN, M.D.  
ROCHESTER, MINN.

An important diagnostic aid which can give much operative information with regard to operability of lesions of the stomach is the roentgen ray. It can demonstrate the size, the shape and the position of the stomach, important factors with which the surgeon has to reckon, as well as the size, the location and the extent of the lesion. It can show whether a stomach suspected of disease is normal, whether a tumor is present, and whether the tumor is intrinsic or extrinsic. The roentgenologist, by basing his judgment on the sum of knowledge gained from the roentgen ray, can point out whether a cancer or lesion of the stomach is operable or not, so far as the stomach is concerned; but it remains for the internist and the surgeon to advise operation and for the surgeon to decide on the kind of operation. The earlier the lesion is discovered, the less will be their quandary.

Without the use of the roentgen ray, a positive diagnosis of cancer of the stomach is often not made until cachexia, loss of weight, achlorhydria, obstruction, Oppler-Boas bacilli, and a palpable tumor are noted; these are all signs of advanced gastric cancer. The patient's fate depends too much on his physician's personal opinion and too little on the true but hidden conditions of the case. As many physicians have believed, and still believe, that the presence of a palpable tumor precludes operative relief, some patients whose lives might be prolonged by operation are not operated on. Others are subjected to useless exploratory laparotomies which roentgen-ray examination can prevent.

The roentgenologist does not look on this method of examination as independent or ultimate, as it is only one part of a thorough clinical examination, and the verdict of operability based on its findings is only of

\* From the Section of Roentgenology, Mayo Clinic.

\* Read before the Section on Gastro-Enterology and Proctology at the Seventeenth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

relative value except in cases that are indisputably inoperable. The syndrome of early cases of cancer of the stomach is not sufficiently characteristic to differentiate it from that of other gastric diseases. Nor can a cellular diagnosis be made by the roentgen ray; but a filling defect may be shown which enables the roentgenologist to make a gross pathologic diagnosis in the majority of cases. An indication for operation should be recognized in the location and extent of the filling defect in the gastric contour, especially when we consider that 95 per cent. of all tumors of the stomach are cancerous. As metastasis and an extended lesion prevent operation in many more cases than does the location of the primary lesion, early diagnosis seems the surest preventive of a high gastric cancer mortality; the roentgen ray has often proved to be a means of diagnosis and of forecasting the operability of carcinoma of the stomach at a time when clinical symptoms are so slight as merely to hint at malignancy.

The eliminative value of the roentgen ray in gastric diagnosis applies to the healthy as well as to the diseased stomach. A roentgen-ray examination of patients who complain of such symptoms as indigestion and dyspepsia, conditions which are often manifestations of other gastric and extragastric disorders, may result in negative findings. The outline, size, shape and position of the stomach prove that the stomach is normal and only the victim of reflex disturbances which the roentgen ray may aid in finding. If the roentgen-ray examination reveals a tumor of the stomach, however, screen and plate findings should be studied with one purpose in mind—possible cure by operation. The chances for cure which the particular case possesses place it, according to the roentgen-ray evidence of operability, in one of three groups: operable, borderline or inoperable. The limits of each group are roughly marked by the roentgen divisions of the stomach: Group 1, tumors of the pars pylorica, the operable zone; Group 2, tumors of the pars media, the questionable or borderline zone, and Group 3, tumors of the pars cardiaca, the definitely inoperable zone.

#### OPERABLE TUMORS

In Group 1 are those tumors which are located in the pyloric end of the stomach; these are shown by the roentgen ray to be operable so far as the stomach is concerned. In this type are included those cases in which the lesion has not spread far on the stomach wall to the danger zone, the pars media (Fig. 1). As approximately 70 per cent. of all gastric cancers occur in the pyloric end of the stomach, and as about 95 per cent. of all lesions which encroach on the gastric lumen are carcinomatous, a lesion in the pyloric end should always make one strongly suspicious of malignancy. The character and size of the filling defect may also give some hint as to malignancy; but the question of malignancy which is of importance in considering the advisability of operation is of no importance from the standpoint of the possibility of operation; that depends on the amount of healthy stomach wall remaining. Often cases which present such severe symptoms clinically as to seem inoperable prove operable on roentgen-ray examination, for even a very large palpable tumor may be resected if it is confined to the lower half of the stomach. While a palpable tumor does not, therefore, prevent surgical intervention, it does mean that the lesion has existed for some time and that metastasis may be present. Free motility of the cancerous stomach favors resectability, but the signs which point to

it may also be misleading. The filling defect may be atypical of cancer and the clinical symptoms alone may offer little explanation; but if the patient who has indefinite gastric symptoms has any filling defect in the contour of the stomach, whether typical or atypical of cancer, the chances are that a malignant growth is present (Fig. 2).

According to Deaver,<sup>1</sup> the importance of the roentgen ray rests on the demonstration of a surgical condition in the stomach, not on the power of differentiating the condition. It is true that it cannot in 100 per cent. of the cases differentiate between cancer and ulcer, and in the doubtful cases all other methods of differentiation must yield to exploratory incision and pathologic examination. This exploratory method of diagnosis was advocated by W. J. Mayo<sup>2</sup> twenty-one years ago. We know now, however, that the roentgen ray can detect the primary lesion in a very early stage, and if, as Deaver has stated in a recent article, almost half of the gastric cancers seem to have followed on ulcers, a lesion of the stomach cannot be too early discovered and looked on as potentially malignant. When the roentgen-ray examination shows a tumor in the pyloric third, the most accessible portion of the stomach, it is considered operable.

A lesion of the stomach can be pronounced operable, however, only with respect to the stomach, as perforation and metastasis almost invariably remain undiscovered until after incision. The clinician can prevent useless operations in some cases which are indicated as operable by the roentgen ray, as he can find metastasis to the rectal shelf, supraclavicular glands, umbilicus and the skin; ascites, when associated with a history of malignancy, is a fairly reliable index of inoperability. Gross metastasis to the lungs and bones is roentgenologically demonstrable, but it is so rare in cases of cancer of the stomach as to merit no more than mention in this brief discussion. Abdominal metastasis, the most frequent form, is a condition which neither the roentgen ray nor any other method of preoperative examination can discover and which the surgeon is unable to cope with, even when the tumor is in the most favorable location for resection (Fig. 3).

#### BORDERLINE TUMORS

The tumors of the second group are those which extend so far up on the stomach wall, into the questionable zone, that their resection becomes uncertain; they are classed as the borderline cases. These cases present the most puzzling problems of operability from a roentgenologic standpoint. Their removal depends, as in the cases of Group 1, on the possibility of metastasis, plus the judgment and skill of the surgeon. The position and size of the stomach may be a surgical drawback; the small high-lying stomach of the robust person offers much greater difficulty to the operator than does the relaxed stomach of the asthenic person. Therefore, if the roentgenologist is familiar with the surgeon's technic he can better form his decision as to the operability of the particular case than if he knows nothing of the operator's dexterity and willingness to attempt resection when the tumor lies in the borderline zone of the stomach. The nearer the lesion approaches the cardiac zone, the more adept must be the surgeon in order to work high up under the costal

arch and to remove just enough of the stomach as to leave it free from neoplasia (Fig. 4).

Tumors of the fundus which do not produce pyloric or cardiac obstruction, and which are not palpable

Fig. 1 (263349).—Filling defect and obstruction due to tumor of the pyloric end of the stomach. The irregularity corresponds to a palpable mass. The lesion is operable "so far as the stomach is concerned."

because of their high location, may exist for some time without causing much inconvenience; by the time clinical diagnosis is definite, they are usually inoperable. Also, when a tumor is in a questionable position with regard to operability, allowance must be made for the type of tumor and consequent type of invasion of the stomach wall. The fungoid carcinomas produce multiple irregular filling defects, and the real extent of the cancer is quite closely simulated by the roentgen shadow; while the scirrhus cancer produces a filling defect less gross which may gradually shade off and not picture the true limits of the disease. Even after allowing for an excess of involvement of a scirrhus cancer beyond that indicated, exploration may reveal inoperable conditions (Fig. 5). As free mobility of a cancerous stomach favors resectability, as fixation resulting from extension to adjacent organs makes successful intervention less probable, as cancer roentgenologically demonstrated as small may at operation be found to have invaded or become adherent to adjacent abdominal organs, and as metastasis may exist without detection by the roentgen ray, the roentgenologist is forced to make such a relative diagnosis of operability in the borderline group of cases that it might be called the exploratory group, for on the surgeon devolves the operative decision.

#### INOPERABLE TUMORS

In Group 3 are the cases of gastric tumors which are pointed out with finality by the roentgen ray as inoperable. The tumors of this group are located in the cardiac end of the stomach, or they have spread

from a pyloric or fundal carcinoma to within this inoperable zone. Surgery can bring no relief to the patient when the cardiac end of the stomach is cancerous. The tumors in this region of the stomach are easily recognized by the roentgen ray as inoperable (Figs. 6 and 7).

Statistics of cancer of the stomach show an appalling number of inoperable cases, especially when it is considered that surgery may bring cure early in the course of the disease. The high fatality rate of cancer of the stomach may be largely attributed to too-late diagnosis.

#### VALUE OF THE ROENTGEN RAY

Of recent methods which have so far been adapted to discover the cancerous growth and to prophesy the chances for its removal, the roentgen-ray signs when correlated with clinical findings seem to be the most promising means by which operability may be increased through earlier diagnosis. So many seemingly benign lesions of the stomach prove to be malignant that the advisability of medical treatment instead of operation seems very questionable or even homicidal. Periodic roentgen-ray examinations in a suspected case can, of course, be made; but if instead of retrograde changes a filling defect typical of carcinoma is noted in time, attempted operation may be too late because of metastasis; the watchful waiting policy often proves not to have averted operation and perhaps to have been the only cause of the patient's early death from a malignant gastric tumor. Even though a growth may be very extensive, if it has not invaded the cardiac end of the stomach the patient should be given the chance of its successful removal through exploratory laparotomy, as some cancers evidently metastasize later than others. The exploratory incision is of little danger and it may be the means of finding a growth which has not quite reached the dividing line between operability

Fig. 2 (134942).—A small filling defect immediately prepyloric, with obstruction. No corresponding palpable mass. Lesion favorable for operation.

and inoperability, that is, when the dividing line represents metastasis.

When the testimony in favor of the roentgen ray is collected, we find, then, that its only decisive value in predicting the operability of carcinoma of the stomach

is its prevention of operation in inoperable cases. Its value in the borderline cases is limited to preoperative information with regard to the location and extent of the growth, and their significance for malignancy. In the first group, which includes the highest percentage

of the symptoms, a roentgen-ray examination should be included. The roentgen ray can now discover 95 per cent. of all gastric tumors, of which only about 50 per cent. are still in the operable stage. When routine examinations of persons presenting gastric symptoms have become a reality, the roentgen ray should be able to raise that percentage encouragingly, for the inoperable tumors should be practically only those which cannot be resected because of cardiac location, and carcinomas of the cardia represent a small percentage of gastric cancers.

#### ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. ROBERTS AND CARMAN

DR. GEORGE E. PFÄHLER, Philadelphia: I wish to emphasize the point that we must not depend on the roentgen ray alone for these diagnoses. I do not think that any first class roentgenologist ever asks that or expects that. I want all the evidence I can get in making the interpretations and in making the investigations, because if I have the evidence presented from the clinical standpoint I will investigate more thoroughly the part of the gastro-intestinal tract that is under suspicion, so as either to prove it normal or abnormal, and I do not like to make any report merely "negative." When I say normal, that only means normal from my roentgenologic standpoint; it does not mean that the organ is absolutely normal. I do not wish to convey any such impression. The next point that I want to emphasize is that an incomplete or careless examination by the roentgen ray is worse than none at all. An examination made by an incompetent roentgenologist, technician or commercial employee is frequently worse than nothing, especially in gastro-intestinal diseases. A man may make an interpretation of a fracture in almost any position and may show the line of fracture in the obvious cases, but in gastro-intestinal diseases we have movable organs to deal with; we have varying conditions present continually, so that a wide experience in interpretation is necessary if we want to avoid mis-

Fig. 3 (147635).—Filling defect with obstruction in the operable zone. The lesion was operable so far as the stomach was concerned, but proved to be inoperable because of metastasis found at operation.

of operable cases, the roentgen-ray diagnosis of operable so far as the stomach is concerned can be almost 100 per cent. diagnostically correct, while operability determined by metastatic conditions dwindles to about 50 per cent. As the likelihood of metastasis and the spread of the disease seem to increase with the age of the disease, it is an obvious corollary that many more patients could be successfully operated on if a diagnosis were made early.

Until all medical men and laymen realize the necessity of early examinations of all persons with any gastric complaint, the death rate from gastric cancer will remain high while the successful operability rate of carcinoma remains discouragingly low. Propaganda which will direct the public's attention to the dangers of disregarding gastric symptoms seems as justifiable and perhaps as necessary as the campaigns which have decreased the death rate of tuberculosis. In 1900 the mortality statistics<sup>3</sup> for all forms of tuberculosis were 201.9 for 100,000 population; in 1916 they had dropped to 141.6, more than 60 per cent. The death rate from cancer, of which gastric cancer is the most common form, rose in that time from 63 to 81.8 for 100,000 population, more than 18 per cent. These statistics have only a relative value, of course, but they do surely mean that the death rate from tuberculosis is lower than eight years ago, while the death rate from cancer is no lower despite the advance in surgical technic. Publicity through national and state public health departments which will lead persons who are suffering from chronic indigestion or dyspepsia, which are not diseases but only symptoms, to consult a physician, who will conduct a thorough examination, should be one of the means of raising the operability of cancer. In every such routine examination, no matter how slight

Fig. 4 (106837).—Gross filling defect extending into the questionable zone. Operability of tumors of this extent can be determined accurately only by an exploratory incision. The tumor was found to be inoperable because of posterior attachment.

takes. We know that it is the most valuable method we have of studying the gastro-intestinal tract. That does not mean that we must discard other methods. We must make investigations roentgenographically and fluoroscopically and then by careful interpretation we will make few mistakes.

<sup>3</sup> United States Mortality Statistics, 1916, p. 20.

With regard to the diagnosis of carcinoma of the stomach, if those cases are studied thoroughly few carcinomas will be overlooked. The fact that some men will try to diagnose all these lesions as carcinoma does not condemn the method. We cannot differentiate in the early cases between indurated ulcer and carcinoma. The microscope can

want to commend Dr. Roberts for his note of conservatism and to assure him that roentgenologists who take pride in their work and who are doing successful work will most heartily agree with him that the roentgen method is only one method of diagnosis and should by no means be set up as a unique method to be depended on by itself alone. As to Dr. Carman's excellent paper, I want to suggest just one thing—that perhaps the use of the word "resectable" might be more appropriate than the use of the word "operable."

DR. R. WALTER MILLS, St. Louis: It is difficult to discuss the papers of Dr. Carman and of Dr. Roberts; they are in keeping with the views of those of us who have been interested in this work. I may call attention to the stabilizing of gastro-intestinal roentgenology and certain things that Dr. Carman mentioned that forecast the future. Roentgenologist and clinician are met now for the first time on a common basis of efficiency. There is no question of the value of the roentgen ray. The trend of the meeting is along the line of the limitations of the roentgen ray, our own psychologic reaction to the overwhelming value of the thing. I should like to ask how many cases of nonobstructive operable cancer of the stomach medical men have diagnosed by clinical means. The roentgen ray has its limitations. We make mistakes but these mistakes diminish in direct proportion to the skill of the examiner. Gastro-intestinal roentgenology is not easy. One must become sensitized to it. Dr. Carman hits a strong blow in his education of the public to the symptoms of gastric cancer, and of course with the obvious outcome of routine complete roentgen-ray examination in all suspicious gastro-intestinal pictures. The real keynote is the education of the public in the same way we educate them in the matter of tuberculosis and carcinoma of the uterus. There is one sinister note against the success of the curing of the cancer of the stomach surgically. Many persons do not have symptoms sufficient to drive them to the physician until it is too late, and this we can never control. The difference in surgical skill is a tremendous factor in the treatment of gastric cancer.

DR. LOUIS J. HIRSCHMAN, Detroit: Speaking as a clinician, I wish to offer this: We must remember we are calling on

Fig. 5 (123017).—Filling defect of greater curvature involving the operable and questionable zones. Operability questionable so far as the stomach is concerned. Operation: sleeve-resection.

scarcely do it. The surgeon cannot do it when he gets it out on the table.

DR. JAMES T. CASE, Battle Creek, Mich.: Dr. Roberts will not find fault with me for disagreeing with him in some small details. I do not quite agree with him regarding the negative value or uselessness of the roentgen method in the study of the esophagus. With the esophagoscope, it is impossible to see deeper than the mucosa, and many of the early malignant lesions in the lower end of the esophagus are not first seen from the mucosal side. I have often found a spasm of the cardiac orifice in what later proved to be a carcinoma of the cardia, where the early roentgen sign was cardiac spasm. I am convinced that spasm of the esophagus is often an early sign of carcinoma, a finding which can be determined by means of the roentgen rays long before the esophagoscope can see the lesion. In regard to incompetency of the ileocecal valve, I think one of the doctor's statements is susceptible of criticism. He mentioned that the enema test of ileocecal valve incompetency is made under very abnormal conditions. Incompetency of the ileocecal valve as such is a matter of minor consequence. Cases which are pathologically significant are those in which there is a retrograde movement of ingested food from the cecum back into the ileum. This has been demonstrated in many of the severe cases where there were clinical symptoms which might be ascribed to the condition. The mere fact of ileocecal valve incompetency is not significant. It is an end-result, not an entity, not a primary thing, and there is just about as little justification for operating on the ileocecal valve alone as there is in removing the appendix in so-called chronic appendicitis and expecting this operation to cure the patient. Both ileocecal valve incompetency and the so-called chronic appendix are end-results of more far-reaching causes. We cannot shut our eyes to the fact that there are a large number of cases characterized by distention and distress in the lower abdomen accompanied by occasional cramps, with clinical evidence of ileac stasis, with nausea and the rest of the symptoms which we have felt were indicative of ileac stasis. In my experience, the more marked these symptoms, the more marked the incompetency of the ileocecal valve. I

Fig. 6 (109449).—Tumor involving questionable and inoperable zones. A tumor in this location is indisputably inoperable.

the roentgenologist as a consultant, not as a man to take pictures, not as a man to give us a report as to examinations, but as a consultant, and we must consult with him in every sense of the word. The surgeon who does not spend a good part of his time in the roentgen laboratory with the roentgenologist, seeing, feeling and studying, is not going to be

of best service to his patient, no matter how much credence he places on the reports of the roentgenologist when he gets them. A man connected with a hospital or clinic who is fortunate to have a good roentgenologist associated with him does not need any advice along this line; but a great many

Fig. 7.—Tumor located in the inoperable zone. Operation is contra-indicated in cases of this type.

men who are treating cases solely on the report they receive on paper as given by the roentgenologist are often led astray. It is not fair to the roentgenologist to expect him to give advice as a consultant as to the desirability of operation in a given case, and as to the operability of a given case. But if more team work were indulged in you will be a better surgeon and you are going to be better able to interpret his reports when he does give them to you. The point Dr. Roberts brings out about not placing too much credence on roentgen-ray examination is all very well. There are some operative procedures, particularly in the intestinal tract, where by the use of the roentgen ray we are able not only to decide whether or not a case is operable, but in a large measure to plan the operation. We must correlate our own clinical findings from every point of view with the result of our consultation with the roentgenologist, and we will be better able to plan our operations than we could do before.

Dr. THOMAS R. BROWN, Baltimore: Quite a few years ago it was said that no one could expect to make an early diagnosis of carcinoma; that we should be satisfied to make a late correct diagnosis. I want to call attention to a point I think is of fundamental importance. There are three clinical types, the one that develops the type of ulcer which should be of great importance; the second group in which the picture is so thick and aggravated in the late chronic dyspeptic, so that it is almost impossible to tell the transition and where generally it is too late; third, the classical type, with absolutely no preventive symptom as far as we know, where suddenly without warning there is a development in the digestive system. This group I am firmly convinced should be suspected as carcinoma. Clinical study plus the most careful roentgenologic study should give us results in most cases. I remember a great European physician once said that the careful, well trained clinician should make his diagnosis from the history; that the rest of his examination should be simply confirmatory, and this is the type of cases in which it is peculiarly applicable.

Dr. ANTHONY BASSLER, New York: You cannot diagnose all abdominal conditions by the roentgen ray. So far as disturbances of sensation are concerned you cannot do anything with the roentgen ray, nor with catarrhal conditions, nor with toxic conditions. My experience has been this:

In esophageal conditions it is most helpful. As soon as one gets down in the stomach, depending on the roentgen ray alone, then there is an element of danger. This is increased in the small intestine and slightly only less so in the colon, and I think we should think of these as important in the matter of proportion of failures. In ethmoidal disease, and pretty nearly everything osseous the roentgen ray is of use. In soft tissue diagnosis it must be taken more in a confirmatory sense. But when it comes to early carcinoma of the stomach the only way you can diagnose it is with the roentgen ray.

Dr. BYRON C. DARLING, New York: The propaganda that Dr. Carman advocates brings up one sinister cloud, as suggested by Dr. Mills, and also by Dr. Roberts. The commercial laboratory is practicing medicine. Twenty-two different laboratories have opened up in New York City where you can get a written or oral diagnosis of stomach lesions and all sorts of other conditions. This is practicing medicine, because anybody who treats and diagnoses, and so forth, is practicing medicine. To take another point of view, the surgeons and physicians who are sending their patients to laymen are in a rather paradoxical position. The public appreciates the value of this method, and the physician submits a case to a layman for final, or at least, a help in his diagnosis. The patient presumably pays for those services either in a commercial laboratory or in a lay technician's office, or in a specialist's office; and if he pays for those services may he not be entitled to those services—to the judgment, to the experience of a trained medical man instead of a layman? Is it not compatible with fair and square dealing to submit your pertinent findings to the review of another medical man? Why not collaborate? Why not corroborate? This is a violation of the Medical Practice Act. This is a violation of caution and of safety.

## THE ORTHOPEDIC SURGEON AND INDUSTRIAL ACCIDENTS\*

LEO MAYER, M.D.  
NEW YORK

My work during the past two years has served to bring into marked contrast the unusually expert care given by our military authorities to the treatment of gunshot injuries and the comparative lack of care bestowed on similar injuries occurring in the ordinary course of industry. The Surgeon-General's Office took

Fig. 1.—Contracture of the fourth and the fifth fingers, due to paralysis of the ulnar nerve. This deformity could have been prevented by the use of the small splints holding the fingers extended.

pains to give special courses, training men in orthopedic and surgical principles applicable to war injuries; a special commission has devoted itself exclusively to the perfection of splints; pamphlets have been issued, and a special department of education by means of photographs and moving pictures has been efficiently organized. As a result, the American wounded soldier

\* Read before the Section on Orthopedic Surgery at the Seventieth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

has had far less to suffer than his comrade in arms, either of the allied or of the hostile armies.

Contrasted with this excellent organization, dealing with the complicated gunshot injuries, the treatment of which is peculiarly difficult owing to the suddenness with which military hospitals are inundated with huge numbers of injured, is the general lack of care and organization accorded the employee who suffers a comparatively simple type of injury. True, there are exceptional instances in which certain firms and insurance companies have organized their work in a systematic and effective way; but on the whole, and here I speak from my personal experience, I gain the impression that the care of those injured in industrial accidents, particularly in the early stages, is haphazard and is left to men of insufficient experience.

I shall confine my paper entirely to the orthopedic aspect of the situation. I shall deal, first, with the most usual mistakes in splinting; secondly, with some of the simpler types of appliance applicable to injuries of the upper extremity and thirdly, with some of the operations on nerve, tendon and bone, particularly useful in the operative treatment of industrial injuries.

#### COMMON MISTAKES IN SPLINTING

Ischemic gangrene following the application of a tight splint is a frequent source of trouble. The novice

Fig. 2.—Marked contracture of the thumb due to a wound of the thenar eminence. The contracture could have been prevented by splinting the thumb in the abducted position.

fails to realize that a plaster dressing, or in fact any firm dressing applied shortly after the accident, although a perfect fit at the time, rapidly becomes too tight, owing to the swelling of the extremity. Ischemia may occur within twenty-four hours, and when once present is extremely difficult to cure. A second mistake is the application of an unnecessarily large splint, which immobilizes joints unnecessarily. Patients with fractured clavicles are usually brought into the clinic with the entire extremity enveloped in the classical Velpeau dressing. Within two weeks, the metacarpophalangeal joints of a workman or workwoman over 50 are so stiffened by this unnecessary immobilization that weeks are required before they can be limbered up—a much longer time than it takes for the fractured bone to heal. The Colles fracture, too, is almost universally splinted with immobilization of the fingers. The surgeon seems oblivious of the fact that two short arm splints properly adjusted, with a little felt pad placed posteriorly over the inferior fragment and anteriorly over the proximal fragment, is amply sufficient to hold them in position.

A third group of mistakes includes even a larger number of cases; those in which no splint whatever is applied, although its use is more urgently indicated

than in a fracture. To this group belong the numerous nerve injuries. Musculospiral paralysis is frequently treated by applying a sling in such a way as to increase the wrist drop. No attempt whatever is made to hold the hand in the "cock-up" position. Figure 1 illustrates the deformity subsequent to an injury of the ulnar nerve. The contraction of the fourth and fifth fingers could easily have been avoided by the use of appropriate measures. Figure 2 illustrates another type of

Fig. 3.—Contracture of the fourth and the fifth fingers due to a wound of the flexor sublimis digitorum muscle. At the right is shown the result of three weeks' intensive treatment in overcoming the contracture. This treatment would have been unnecessary had the fingers been properly splinted from the outset.

injury, a marked contracture of the thumb, due to neglect to splint the finger in the abducted position, and Figure 3, contracture of the fourth and fifth fingers due to an injury of the forearm, involving the flexor sublimis digitorum muscle. In each case, deformity could have been avoided and weeks of extensive treatment saved the patient and the insurance company, if sensible orthopedic measures had been instituted from the outset.

I want also to emphasize the danger of retaining any splint too long a time. No matter how good the splint, it will do damage if the joints are immobilized over an excessive period. This is well illustrated in Figure 4, showing an injury received in a railroad accident (multiple compound fractures of the lower arm) in which complete functional disability ensued, because of immobilization extending over a period of four months.

Equally to be condemned is the use of injudicious early forced motion. This applies particularly to the fractures around the elbow joint. The lesson in this connection, taught by Sir Robert Jones, cannot be learned too thoroughly: Motion at this joint should

Fig. 4.—Complete functional disability due to excessively long immobilization. A useful hand could have been secured had the motion of the fingers been begun three weeks after the accident.

never be forced; after primary immobilization at an acute angle the arm should be allowed to extend from its own weight. Brisement forc e invariably produces excessive callus and increased stiffness.

#### SIMPLE TYPES OF APPLIANCES

Thus far I have dealt chiefly with mistakes in splinting. Now a few words as to simple methods of fixation applicable to injuries of the upper extremity:

For injuries of the musculospiral nerve, I use the little brace shown in Figure 5. It is better than any other I know, because in addition to holding the hand in the cock-up position, it holds the thumb abducted. For ulnar paralysis, a light splint should be made of two tongue depressors or of cigar box wood, and the fourth and fifth fingers held extended. For Colles' fracture, the rounded metal splints used by Sir Robert Jones are unquestionably the best. For any form of injury, in which there is danger of contracture, a little splint should be molded by running a plaster-of-Paris bandage backward and forward to form a layer sufficiently thick to hold the parts in the appropriate position. Injuries of the circumflex nerve or of the deltoid muscle, in which the abducted position of the arm is indicated, can be splinted by a corresponding plaster-of-Paris mold, reinforced by a small iron or steel band. This band is incorporated between the layers of the plaster-of-Paris, while these are setting, and should form an integral part of the splint. This plaster-of-Paris abduction splint I find lighter and very much cheaper than the aeroplane splint frequently used during the war.

In the after-treatment of contractures and stiff joints,

Fig. 5.—Light brace for musculospiral paralysis, holding the hand in the cock-up position and the thumb abducted.

the form of apparatus most generally used, the Zander pendulum devices, usually defeat their own purpose. A steady force constantly applied to the joint is far more efficacious than the sudden impacts produced by the pendulum apparatus. Of particular value are the splints shown in Figure 6. They are simply constructed, reasonable, and are so made that the same device can be used to extend as well as to flex the joint. Similar contrivances can readily be made out of plaster of Paris.

#### USEFUL OPERATIONS

In the operative treatment I wish to touch on three new phases in the treatment of tendon, nerve and bone injuries. The problem of the suture of tendons has been before the surgeon for many years, and numerous answers have been given. To my knowledge, there are at least fifteen different tendon sutures advocated by well known surgeons. Whenever there

is such a marked variety, one may be certain that there is no preeminently satisfactory method. During the last year, however, a technic for end-to-end suture of tendons has been devised by Dr. Bunnell of San Francisco which to my mind represents a radical surgical advance. Bunnell, basing his investigations on researches which Biesalski and I had conducted, applied the principles set forth by us for the transplantation of tendons in paralytic conditions to the suture of tendons divided by trauma. He showed that the usual method of tendon manipulation in these cases disrupts the tendon fibers and destroys those delicate gliding cells on the surface of the tendon whose significance my previous publications have emphasized. To overcome these difficulties he devised the tendon clamp, illustrated in Figure 7, so constructed as to hold the tendon fibers firmly together during the insertion of the suture, and at the same time to avoid traumatism to the gliding surface of the tendon. The

Fig. 6.—Schede-splints for the treatment of contractures and stiff joints. The same splint which is used to produce flexion of the knee can, by being inverted, cause extension. This also applies to the elbow, hand and finger splints.

method of inserting the suture is well illustrated and requires no further explanation. The results obtained by this method have, in my hands, been unusually good. It is applicable not only to the immediate suture of divided tendons, but also to the free transplantation of tendons to fill in the defect when the tendon ends have retracted excessively. Figure 8 illustrates a case in point: one of traumatic division of the flexor longus pollicis tendon, which came to operation two months after the accident. The gap of 2½ inches between the tendon ends was bridged by a free transplant of the flexor carpi radialis tendon. The resultant motion is shown in the illustration.

In nerve suture there is little question relative to the technic when an end-to-end suture of the neurilemma is feasible. When, however, loss of nerve substance has been so great that end-to-end apposition is impossible, then some form of bridging operation is required. I strongly favor the free transplantation

of a sensory nerve taken from the same individual to fill in the gap between the ends of the injured nerve. Since the sensory nerve at our disposal is invariably smaller in diameter than the injured, several segments must be used to construct a kind of nerve cable. For this purpose, a modification of the Bunnell clamp is of great service, as is seen by reference to the diagrammatic Figure 9. The results of this method of nerve bridging are shown in Figure 10.

In cases of loss of bone substance, the inlay graft method as developed by Dr. Fred Albee is of the utmost service. Figure 11 shows a case of injury to the radius with 2 inches of substance and consequent marked deformity of the hand. As the first stage of the operation, a wedge osteotomy of the ulna was performed, so as to permit correction of the deformity. The defect in the radius was then bridged by a solid graft taken from the tibia, wedged in

Fig. 7.—Bunnell clamp for end-to-end suture of tendons (courtesy of Tiemann & Co.); 1, side view of clamp applied to tendon; 2, cross section (end-on) view; 3, first insertion of needle; 4, second insertion of needle; 5, third insertion of needle—suture pulled tight in first interspace; 6, other end of Pagenstecher linen thread, armed with needle—first insertion of this second needle; 7, second insertion of second needle (third insertion is identical with that shown in 5, but is naturally in the opposite direction); 8, diagrammatic representation of sutures in place, indicating which threads are knotted together (tendon is relaxed so that both ends come together without tension, and knots are tied); 9, completed suture. Passive and active motion should begin on the fourteenth day.

between the fragments of the radius in such a way as to hold them apart. The functional result was excellent.

ABSTRACT OF DISCUSSION

DR. ARTHUR H. CILLEY, New York: There is one point to be considered in connection with the type of "cock-up" splint that Dr. Mayer described. One must be careful not to have the patient wear it too long, because it tends to flatten the metacarpophalangeal arch, and also to hyperextend these joints. We who served in the British hospitals saw many of these hands, and they were very hard ones to restore to usefulness. In order to grasp, one must be able to hollow the palm, and the metacarpophalangeal joints are the most necessary of all in this action. For this reason we gave up the full palm splint and have used the short palm splint, making this part somewhat like a ball. We also try not to have the splint interfere with adduction of the thumb,

Restoration of the function of the hand is frequently very difficult, and interference with the arches makes it just so much more so. With reference to the abduction shoulder splint, at U. S. Army General Hospital No. 9, at Lakewood, N. J., we used a splint which I had never seen before. Whether Dr. Cleary devised it or not I do not know. He

Fig. 8.—Traumatic division of the flexor longus pollicis tendon, with a gap of 2½ inches between the retracted tendon ends. The gap was filled in by a free transplant of the flexor carpi radialis tendon, the Bunnell clamp being used. The photographs illustrate the resultant range of motion three months after the operation.

was responsible for its use there, at any rate. Instead of having the entire splint on the affected side of the body, the bars along the body from the pelvis to the axilla were on the opposite side, the weight being carried by the webbing belt across the affected side of the pelvis instead of on the steel bar on this side. It has the added advantage of leaving the shoulder on the affected side entirely exposed, and also supported, instead of having the weight slung onto it. Through its use, also, I have not seen the deformities of the spine which I have seen when the weight was all on one side of the body, of course, only when the splint was required for a very long time. I hope some time to see a plaster-of-Paris splint that weighs as little as a steel or wire one. I have seen and made a good many, and one strong enough to be efficient has always been very heavy.

DR. JOHN RIBLON, Chicago: I should be glad to have the others who are to discuss the paper and Dr. Mayer say

Fig. 9.—The author's method of constructing a nerve cable of a sensory nerve, to be used as a graft, bridging the gap between the ends of the severed nerve; A, modified Bunnell clamp open; B, manner of doubling the sensory nerve backward and forward, so as to form a nerve cable; the clamps hold the nerve segments together; the dotted lines indicate the point at which the nerve is cut across by scissors or a razor; C, semidiagrammatic sketch illustrating the end of the nerve cable, a single stitch has been inserted holding the four nerve segments together; note that the neuromas present a sharp cross section, and can thus be brought into intimate contact with those of the injured nerve; D, semidiagrammatic sketch, illustrating the implantation of the nerve cable between the ends of the injured nerve. It is held in place by fine pericardial sutures, one at each end of each nerve segment.

whether it is better to splint with the rigid cock-up splint or with a spring cock-up splint which will, when the muscles are relaxed, cock the hand up, but by which, when the patient wishes, he can flex the hand. Is it an advantage, or

a disadvantage, in the treatment of these cases, where a nerve suture has been done?

DR. SAMUEL W. BOORSTEIN, New York: The principles of Dr. Mayer are commendable and should be emphasized at lectures before insurance companies. The insurance companies do not refer cases to the orthopedic surgeon till marked deformity has occurred. For instance they think that any one is qualified to treat a fracture or burn, the result being that even in the slight cases bad deformities are allowed to develop. I had recently under my observation a patient with marked flexion deformity of the knee and hip and dislocation of the tibia on the femur as a result of a burn. That patient was discharged as cured because the wound was healed. The companies forget that the cost of such neglect is more than the few dollars they save by not having a specialist attend to their fracture cases or any other injuries leading to deformity. As far as the difference between a solid or a spring splint for the cases of peripheral nerve injury, my experience, while working in cooperation with Drs. Byrne and Taylor, was that the solid one is better as it does not permit any stretching of the weakened muscles.

DR. LEO MAYER, New York: I thoroughly agree with what Dr. Boorstein said, and I hope that my remarks will come to the ears of the insurance companies and that they will profit by the opinion of this assembly. I certainly think it necessary that all cases should, from the outset, have the benefit of orthopedic advice; just as every single military accident and injury had the orthopedic advice of the army surgeon. Relative to the type of splint to be used, I think that the rigid type is better than the spring appliance;

of the external popliteal nerve, a splint to keep the foot dorsiflexed. As between the short and the long cock up splint, there is much difference of opinion. In some cases, it is easy to flex the metacarpophalangeal joints, even in the long splint. If it prevents this action, use the shorter splint.

Fig. 11.—Marked deformity due to a 2 inch loss of bone in the radius.

Fig. 12.—Same arm as in Figure 11, subsequent to osteotomy of the ulna and bone graft of the tibia. The graft is shown inserted between the fragments of the radius.

Fig. 13.—Hand with injury to the ulnar nerve, 5 inches above the wrist, one and a half years, subsequent to the implantation of the dorsal sensory branch of the ulnar nerve to bridge a 2-inch gap of the injured nerve. Note the absence of atrophy of the hypotenar muscles, the ability of the patient to spread his fingers apart and the comparatively slight atrophy of the interosseous muscles. This atrophy was distinctly more marked before the operation, and gradually diminished subsequent to it.

because I believe in the principle of Sir Robert Jones that we must have complete relaxation of the muscle fibers. If they are stretched, more or less damage is done. Therefore, I use a permanent cock-up splint; or, in the case of injury

It is important to drive the point of the proper treatment home to the minds of the medical profession at large, so that we shall not get these miserable drop wrists. So far as the airplane splint is concerned, I wish that Dr. Cilley would come and see the splint Dr. Ogilvy uses. He would find that it is lighter than any other. I saw an illustration of a splint used by Dr. Frazier that impressed me as being very efficacious, in which the bar started on the opposite shoulder and the longitudinal bar ran down the opposite side of the body. I think that this will be an improvement on anything we have seen thus far.

**The Plague Menace.**—The first case of pneumonic plague reported in Manchuria, occurred in Manchouli on Oct. 12, 1910. The last case was reported Dec. 25, 1910, two and one-half months after the outbreak. Owing to the energetic action of the Russian authorities only about 400 died. (Officially registered 392, p. 28.) In Harbin (or Fuchratein) the first cases were reported on Nov. 7, 1910. They were two tarbagan hunters, who had come from Manchouli. From both the Russian and Chinese records, small epidemics of pneumonic plague had occurred here before, but this time, within three months, over 5,000 persons in a population of 30,000 were killed by this disease. Harbin is closely packed and built on a low-lying swampy plain. It has narrow streets, and is inhabited principally by coolies. The majority of the houses are low, dark, dirty and overcrowded. On the other hand, Shuangchengiu, which is situated on the railroad line, 30 miles south of Harbin, is a finely planned city with wide streets and is famed for its large, well constructed houses. The population consists chiefly of families who have settled there. Half of the families are Manchus. There are wealthy land owners and leading Chinese merchants, people clean in their habits and homes. Yet, within seven weeks, there were 1,500 deaths in this city of 60,000 inhabitants.

RADIUM IN DERMATOLOGY\*

HOWARD MORROW, M.D.

AND

A. W. LEE, M.D.

SAN FRANCISCO

This is a summary of three years' experience with radium as one of the factors in the nonoperative treatment of certain forms of cutaneous pathologic processes.

The first amount of radium placed at our disposal was received in 1916. As this was small in quantity we were obliged to confine our use of it to minor lesions. Since 1916, radium has been given to the University of California Hospital in steadily increasing quantities, and the good resulting from its use has increased correspondingly.

At the present time, the total amount of radium available for our use is 250 mg. This is distributed in varying quantities and in different forms of containers, ranging from a 5 mg. disk container to a 50 mg. tube container.

Obviously the different types of container, along with their varying content of radium, have different uses. For example, a rodent nodule the size of a pea would call for the application of a container, the periphery of which should only slightly overlap that of the area being treated. More extensive lesions would require a greater surface contact of radium. The needle form of container has some special points of value, such as in treating diseased conditions of the nasal cavity, tumors and deep seated growths.

Excision is seldom employed in basal-cell growths, usually on account of the location, which is frequently on the nose or at or near one of the canthi. Curretting followed by cauterization is painful, the resulting crust is unsightly, and the scar is often rough and depressed. The application of arsenic paste is still more painful, and the scar following its use may be very pronounced. Roentgen-ray treatment for this type of growth is usually satisfactory, but we frequently find cases that resist this form of therapy and which clear under the

Fig. 2.—Basal-cell epithelioma (before).

Fig. 3.—Basal-cell epithelioma (after).

Fig. 1.—Basal-cell epithelioma before radium treatment.

RESULTS OF RADIUM TREATMENT

It has been our practice, up to the present time, to bring the radium more or less into direct juxtaposition to the lesions subject to its action, with intervening screens of several types. The method of employing radium at varying distances from the parts to be influenced by it has, as yet, not been practiced by us.

Radium has been employed by us in a variety of

skin diseases, but we feel that our best results have been in treating true basal-cell epitheliomas. In fact, radium therapy appears to be the ideal treatment for this class of slowly malignant neoplasm. There is very little if any pain attendant on the treatment, recurrences are rare, and the resultant scars are almost unnoticeable.

exhibition of radium. On the other hand, basal-cell carcinomas that do not improve under radium emanations are not affected by roentgen therapy. Furthermore, when such growths are located on the lids, or on or within the nose, they are more easily handled with radium plaques than with the Coolidge tube. In a former paper, before enough radium was at our disposal to be of sufficient value in treatment, we remarked that the so-called Bowen's type of epithelioma might be cured by its use. Since then we have had enough experience with radium to convince us that this view was correct. In all, we have treated five patients with the unmistakable signs of Bowen's form of epithelioma, and the condition, in each instance, has been cleared up.

*Basal-Cell Epithelioma.*—We have treated 112 cases of basal-cell epithelioma with radium. Of this group, the site of affection, in forty-four cases, was on the nose; in twenty-four, on the cheeks; in fourteen, at the canthi; in nine, on the temple; in seven, on the neck; in four, on the upper lip; in three, on the forehead; in one, on the abdomen; in one, on the chin, and in one, over the mastoid region. Of this number, three cases were so far advanced that treatment was futile, and they terminated fatally. In eighty-nine the condition cleared up, and so far has shown no recurrence. In fifteen instances there were recurrences, which cleared again with further radium treatment.

*Squamous-Cell Carcinoma.*—Our experience with this type of neoplasm has been quite limited, as we have advised the patients in nearly all such cases to consult a surgeon for treatment. We have assumed this attitude because of the uncertain action of radium on squamous-cell carcinomas, and on account of the early involvement of the neighboring lymph glands in this type of cancer. It therefore impresses itself on our minds that such cases should have the advantage of judicious surgery. Those cases of squamous-cell carcinoma which we have exposed to the action of radium

\* Read before the Section on Dermatology at the Seventieth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

have been instances of recurrence, inoperable on account of the age of the patient or the location of the growth. Of these, fourteen resisted treatment, but five were healed and possibly cured. We have had some good results with radium therapy in cases of carcinoma of the floor of the mouth; these were considered inoperable by consulting surgeons. We have had similar experience with extensive squamous-cell

Fig. 4.—Basal-cell epithelioma (before).

Fig. 5.—Basal-cell epithelioma (after).

carcinomas of the face and neck, in which operations were considered inadvisable because of the age of the patients.

**Sarcoma.**—The number of sarcomas subjected to radium emanation has been so small that any attempt to give a detailed statistical report would be of little value. Still, the results obtained in our small series were more satisfactory than in any other type of malignant disease, omitting the basal-cell epitheliomas. With the exception of melanotic sarcoma, all of the several varieties appear to be favorably influenced by radium treatment. These cases demand a heavy dosage, thick screening, and the burying of needle containers of radium in the tumor masses.

**Nevi.**—The large group of congenital cutaneous malformations should be spoken of in some detail, as radium has revolutionized the treatment of these conditions. The nevus which shows the most startling improvement after treatment with radium is the so-called strawberry mark, or cavernous angioma. In these cases the growths disappear entirely after a few applications, and the resulting scar is almost like the normal skin; this is particularly so if the radium has been sufficiently screened to cut off the superficial reaction, which so often leaves telangiectases. This variety of treatment is superior to that with carbon dioxide, as it is painless, and as the final results are generally more satisfactory. Horny or warty linear nevi are also successfully removed by radium. In previous years, we were in the habit of attacking such conditions with the galvanocautery or Paquelin cautery; but that practice necessitated the administration of an anesthetic, and was occasionally followed by keloid formation. Pigmentary nevi can be nicely removed by radium. Here, long exposures with heavy screening have given us the best results. The most unsatisfactory type of nevus for radium therapy is the angioma simplex, or port wine mark. Of the nevi handled by us in this manner, forty-two were of the strawberry mark type; seven, of the cavernous variety, consisting of large and hard vessels, and two, of the linear variety. All of the strawberry marks disap-

peared after from two to five treatments with radium, and the large cavernous growths were greatly improved. One linear nevus was quickly cured, and a very extensive one is now slowly yielding to treatment.

**Warts.**—All varieties of warts can be satisfactorily removed by subjecting them to the use of radium. But, as they are amenable to so many other and more available forms of treatment, it seems advisable to restrict radium therapy to certain types of verrucae. The most important are the warty growths which occur at the sides of, or under, the finger nail. If radium is employed in such conditions, and screened with proper precautions, the results will be satisfactory in most instances, both as regards the relief of pain and the large percentage of nonrecurrence. Second, perhaps, in importance come plantar warts. It is a common experience, however, that their identity is not recognized, because they are confounded with callosities and corns. In this type of case a chiropodist has usually been called on for relief, and all he does is to remove the horny covering, thus failing entirely to effect a permanent cure. On the other hand, the results of treatment of plantar warts with radium are all that can be desired.

**Keloid.**—In the majority of our cases of keloid, the application of radium gave excellent results. Considerable improvement can be predicted, especially when the keloid is of recent origin and appearing in young subjects. These forms are best treated by the tube or needle type of radium container, with 1 mm. of silver screening, and from four to six hours' exposure. This exposure should be repeated in at least six weeks. Additional treatments, of course, may be necessary.

Fig. 6.—Bowen's type of epithelioma.

**Lupus Erythematosus.**—This is probably one of the most harassing diseases with which the dermatologist is confronted. In consequence, anything added to our therapeutic armamentarium in this field should be given our most thorough consideration. For the discoid, and the red, scaly, thickened areas of erythematous lupus,

radium is of value. Many short exposures are indicated in these conditions. In all, we have treated ten cases of erythematous lupus, and in some of them we have obtained more satisfying results than any we have secured in the past with other methods. We have found that this type of the disease reacts more favor-

elaboration of details as to screens, but this is very frequently done. It is a source of confusion and the exact measurement of the thickness of screens is a matter of no practical importance. If you use a rubber finger cot, for example, you cut out the alpha rays. It does not make any difference whether this cot is one-fifth, one-half or one millimeter thick. The same is true of a thin aluminum screen, or a thin silver screen. Each cuts out the rays of a certain penetration, and the variation of a few tenths of a millimeter in thickness practically makes no difference.

Fig. 7.—Basal-cell epithelioma (before).

Fig. 8.—Cavernous hemangioma (before).

ably to radium treatment than to that with carbon dioxide snow or with the various types of heliotherapy.

*Myxomatous Cysts.*—Occasionally, we see small myxomatous cysts on the dorsal and lateral aspects of the distal phalanges. In our hands, radium seemed to have a beneficial effect on these growths when it was applied in small plaques for an hour at each period, and with 0.5 mm. of brass screening.

*Other Conditions.*—In addition to the conditions mentioned above, other varieties of cutaneous lesions have been treated by us with success by the use of radium, such as lupus vulgaris, leukoplakia and pruritus ani; but with each the number of cases has been so small that we do not feel like discussing them at this time.

#### ABSTRACT OF DISCUSSION

DR. WILLIAM ALLEN PUSEY, Chicago: In general I agree entirely with the experience of Dr. Morrow. A few points which he brings up are of interest to me; with some I agree and with some I disagree. First, as to the relative value of radium and roentgen rays. I have been using radium for many years and I have been using roentgen rays for many years. From my experience I am entirely convinced that there is no essential difference between the two in their effects on living tissues. We can do with one just what we can do with the other. It is a question of the amount of energy we have available with either agent, and a question of convenience of application. Sometimes we get results with roentgen rays and not with radium; on the other hand, sometimes we get good results with radium and not with roentgen rays. I am firmly of the opinion that these variations in results are due to variations in the amount of energy which we apply or to some other variation in technique. As to screens: Dr. Morrow did not set up any confusing

has not, in my opinion, changed much in fifteen years. Early in my experience with the use of roentgen rays I formulated from an analysis of their effects on tissues the indications for their therapeutic use. The generalizations then arrived at have guided me ever since and I have not seen any reason to change them. As an argument for the fact that roentgen rays and radium produce the same effects, Dr. Simpson, of Chicago, in an article on radium which he read two years ago, practically adopted verbatim my thera-

Fig. 9.—Squamous-cell carcinoma (before)

Fig. 10.—Linear nevus (before).

peutic indications for the use of roentgen rays as those to be followed in the use of radium.

DR. EVERETT S. LAIN, Oklahoma City: Dr. Morrow's experience has been very similar to that of most other men who have been using radium for several years. I have been using the roentgen rays for sixteen or seventeen years, having been a close follower of Dr. Pusey and other pioneer men in roentgen-ray therapy. Therefore, I was slow in tak-

ing up radium. But after visiting Dr. Sutton and Dr. Simpson about three years ago I was persuaded that I also needed radium. My experience has been similar to that of Dr. Pusey and Dr. Morrow. I was glad to hear Dr. Morrow say that radium was more effective than roentgen rays in sarcoma. I have found this especially true in cases of sarcoma of the antrum. Again, in cases involving the cartilages of the nose and ears, the roentgen ray had not been so satisfactory, nor had it been in cases of lesions on the surfaces with thin underlying tissues. There is a greater predilection to telangiectasis with roentgen rays than with radium, perhaps because we did not screen roentgen rays in the early days as we did radium. I am sure that radium

Fig. 11.—Linear nevus (before).

has come to stay and it is only a matter of time before all dermatologists will be using it. I have used it, as has Dr. Pusey, in the squamous cell types of epithelioma and have noted almost equally as good results as in the basal cell type. However, I still do not rely on radium alone in any of the malignancies in which there is a suspicion of metastases. I still use deep roentgen-ray therapy over all the adjacent glands. This routine in connection with radium has given me more successful results.

DR. WILLIAM H. GAY, Pittsburgh: I wish to bear testimony to the same results that Dr. Morrow reports and also speak of the relationship between roentgen rays and radium filtered and unfiltered. In the use of filters, particularly, it seems to me, it is important for us to understand that roentgen rays are heterogeneous gamma rays and that in filtered radium we again use the gamma ray, but of more homogeneous composition and also of greater penetration. I am inclined to disagree with Dr. Pusey. We do get some results in the chronic thickened patches of lupus erythematosus with unfiltered radium. One should produce a fairly sharp reaction, taking care to overlap thoroughly the edge of the lesion. I think that in vascular nevi of the port wine mark variety radium is of little service. The point made by Dr. Lain regarding telangiectasis as a result of radium depends to some extent on whether unfiltered rays are used or not. Quantity for quantity unfiltered rays will produce a good deal more reaction in the skin than filtered rays. When working with Dr. McKee I used an unfiltered plaque of radium on my forearm and later used the filtered plaque on a different spot. The place where the unfiltered ray was used is still on my arm, but where the beta ray was cut out by the filter the mark has practically disappeared and I have nothing to show as the result of it. So that I feel that we have a definite therapeutic indication for the use of radium and definite indications for the filtering or unfiltering. When it is filtered we use the gamma rays altogether and I agree with the previous speakers that the result will be almost the same where gamma rays of radium or roentgen rays are used, if they are used in the same quantity. Some results may be attributed to lack of penetration. Roentgen rays are the choice in many cases on account of the enormous output of energy and ease of application in extensive dermatoses. Radium is at times chosen on account of the difficulty in treating certain parts with roentgen rays, and in some cases because it gives therapeutic results when roentgen rays fail.

DR. HOWARD MORROW, San Francisco: I think Dr. Pusey will admit that the cases of erythematous lupus which are

localized and scaling and rather thickened will improve a great deal under radium therapy. Certainly, generalized cases or diffuse areas over the face should not be treated by radium or any other type of radical treatment. In regard to the screening, when we first used radium we screened very little. I remember treating a plantar wart in a nurse with about one-tenth mm. aluminum screen for two hours, as recommended by the people who sold the radium to us, and about a week afterward the patient developed a very severe reaction. There was erythema for a few days and then a deep, big blister; this was followed by sloughing and this lasted about two or three weeks. To be sure, it cured the wart. I think the longer we use radium the more screening we are inclined to use. If we can use radium and get the results without well marked reaction, it is our desire to do so, and the greater the amount of screening the less apt are we to get the reaction. Of course, this means a great increase in the time of exposure.

## Clinical Notes, Suggestions, and New Instruments

### REPORT OF CASE OF CONGENITAL ABSENCE OF BOTH CLAVICLES

WALTER G. STERN, M.D., CLEVELAND  
Orthopedic Surgeon, Mount Sinai Hospital

L. C., a boy, aged 6 years, was admitted to the wards of Mount Sinai Hospital for the purpose of having his tonsils removed on account of chronic infection.

In the course of the usual routine examination, the house officer noted the absence of both clavicles and the fact that the shoulders could passively be brought together to an even farther degree than that shown in the accompanying illustration. There were no other anomalies and no pathologic findings outside of the enlarged tonsils. Palpation showed both clavicles to be entirely absent, with the exception of small rudiments one-half inch in length, articulating with the sternum and bearing the origin of the clavicular portion of the sternocleidomastoid muscle. While these rudiments articulate with the sternum, they can be moved in all directions, except anteriorly, by hooking the finger under them. The absence of the clavicles does not seem to interfere materially with the use of the arms or to diminish the strength of the muscles in this region. The boy's deltoid muscles are as strong as those of other children of his age, and the pectoralis minor muscles stand out firmly when actively contracted.

On inquiry into the child's family history, it was found that the father is suffering from a similar condition. In the father's immediate family are three brothers, all of whom lack clavicles, and one sister, who is blessed with the usual and normal number. The boy has two brothers, both of whom have this anomaly, and three sisters, who are normal in every respect.

Thus, in this family there are seven males, all of whom present the condition of congenital absence of both clavicles, and four females, none of whom are afflicted.

Boy with congenital absence of clavicles.

GUNSHOT INJURY OF THORAX WITH EXTRUSION OF THE ENTIRE STOMACH AND LACERATION OF SPLEEN\*

CHESTER H. WATERS, M.D., OMAHA

The reports of many interesting and remarkable instances of thoracic and diaphragmatic war injuries will, no doubt, shortly appear in the literature; but the case to be reported will illustrate what can happen in ordinary civil existence. This fact alone offers my excuse for reporting it at this time.

REPORT OF CASE

**History.**—H. M., a boy, aged 15. Oct. 30, 1918, with several companions, was out hunting with a shotgun. The lad had climbed a steep embankment, and while he was on his knees, in the act of drawing up the gun, the muzzle toward him, with his left hand, it was discharged. A great hole was torn in the anterolateral aspect of the left side of the thorax. With assistance, the boy managed to walk about 600 feet to the nearest house, where he was seen by me about twenty minutes later.

**Examination.**—The lad was in considerable shock. The entire stomach, much distended, was found extruded through the enormous hole in the lower part of the left chest. It occupied much the same position as a football when properly carried in the angle of the elbow, and was about the size of an adult head. The stomach seemed to be intact and was covered with a varied debris—dirt, grass and fragments of clothing—and was prevented from retracting by the jagged ends of the ribs. The patient was at once given 0.5 grain of morphin and transported to the hospital, at which everything had been ordered to be in readiness.

**Operation.**—Only the upper clothing was removed, and, under light ether anesthesia, the stomach was thoroughly irrigated with saline solution; then, as no perforations or lacerations were found, it was replaced in the abdomen, its size having first been reduced by compression.

The laceration of the diaphragm was linear, 3 inches long, and involved only the muscular portion. Exploration of the thoracic cavity disclosed that there was complete retraction of the lung, a portion of the lower lobe margin shot away, and considerable clotted and fluid blood. The heart, readily palpated, had retracted to the right and was lying under the sternum. The inner extent of the thoracic wound, however, was probably not more than one-half inch below and to the outer side of the normal situation of the apex. The chest cavity was carefully cleared of clots, fragments of ribs and clothing, and attention was directed to the diaphragmatic rent.

Suture had been started at the inner angle, No. 2 chromic gut being used, when considerable blood was observed issuing from the abdominal cavity. Investigation revealed that the spleen was almost completely torn in two and its diaphragmatic surface extensively lacerated as well. An attempt to deliver the organ through the diaphragmatic opening failed to offer comfortable access to its pedicle, largely because the costal margin was intact. The suture of the diaphragm was hastily completed, and the abdomen opened through a left rectus incision. A liter (quart) or more of free blood was found in the peritoneal cavity. The spleen was rapidly removed, after double ligation of its pedicle *en masse*, and a yard roll of 3-inch gauze was packed firmly in the subdiaphragmatic space to control oozing and to serve

as drainage. No further injury was noted; the abdomen was then closed with through and through silk-worm-gut sutures.

Then arose the problem of closing the thoracic wounded, which was 8 inches long and 2 inches wide. The seventh, eighth and ninth ribs having been shot away, an inch or more of the fragmented ends was removed, thus permitting further collapse of the chest wall and facilitating closure. Interrupted silk-worm-gut sutures were used and the wound closed, but under considerable tension. Tube drainage was maintained for forty-eight hours.

The operation consumed about one hour, and the patient was in fair condition, with a pulse of 150. Proctoclysis and hypodermoclysis, with the usual stimulation, were given, and the patient rallied well. The gauze pack was removed at the end of thirty-six hours, under light anesthesia, and the thoracic drainage the day following.

**Postoperative Course.**—The course was satisfactory for ten days, and then the patient began to have a daily rise in temperature, which would reach 100 or 102. A suspicious area of dullness in the left chest was aspirated, and only old blood obtained. Several days later the attempt was made again, and a thick, mucopurulent exudate was found. Rib resection under local anesthesia resulted in the opening of a small pocket containing about 2 ounces of pus, in which one buck-shot was found. Dense adhesions of visceral and parietal pleura were separated as widely as possible. The visceral pleura was greatly thickened and almost cartilaginous in character over the lacerated area of the lower lobe of the lung. Tubes were inserted to drain the abscess cavity.

Considerable superficial sloughing of the chest wound prolonged its healing. In anticipation of a scoliosis which was already quite marked, the patient was early given appropriate exercises to correct this inevitable tendency. Deep breathing, while the patient was hanging with the left hand from a height which just permitted touching the toes to the floor, met the requirement perfectly. In a comparatively short time the left chest had filled out, the heart returned to its normal position, and the spine became perfectly straight. The patient gained rapidly in weight and strength and was back in school two and one-half months following the injury. He is now a robust boy and apparently no worse for his experience.

A roentgen-ray examination made at the end of two months revealed almost complete expansion of the lung, with free action of the diaphragm. Numerous shot, evidently in the chest wall, were also showing, but have caused no trouble.

In the hope of noting the blood changes resulting from splenectomy, daily blood counts were made for a period of two weeks. A persistent average of 16,000 white cells with a polymorphonuclear percentage of from 80 to 85 was noticed. In the interpretation of the blood changes in this instance, one should consider the probable influence of moderate infection, as the patient was slightly febrile during the observation. July 19, 1919, nine months later, a blood examination gave a count of 5,500,000 red cells; the white blood count was 12,500, and polymorphonuclears, 78 per cent.

COMMENT

The literature reveals a number of cases of hernia of the stomach in injuries of the abdominal wall and in diaphragmatic trauma, but I do not find record of an instance which parallels the one just reported. The surprising feature of this case, to my mind, is that with the nature of the injury even more damage was not sustained.

### USE AND ABUSE OF CATHARTICS\*

(Continued from page 1492)

#### THE OIL ENEMA

While the oral administration of oil is conditioned on the absence of certain contraindications, its rectal injection is almost free from these; and, provided it can be retained, a much more direct method of softening the feces and favoring their evacuation than having it pass all the way through mouth, stomach and small intestine. For, it must be remembered, the contents of the cecum and ascending colon are liquid; if we can get the oil to these parts, which can be done by proper technique, it will keep the feces soft because it cannot be absorbed. Furthermore, the softening of the feces is also due to interference with the absorption of water, probably in a purely physical manner, the oil preventing diffusion of water into the mucosa. Lipowski<sup>1</sup> considers this effect of the oil enema of special significance, as he believes that a common form of constipation is due to excessive absorption of fluid from the colon, which results in abnormally hard fecal masses. According to him, the excessive fluid resorption is due to congestion of the colonic mucosa, which in turn is maintained by irritation from the resulting hard fecal masses. He bases his contention on abnormal redness of the mucous membrane, shown by these cases on sigmoidoscopic examination, and on the demonstration that, in such patients, a larger proportion of a physiologic soft enema is absorbed than in the normal. The oil enema breaks in on this vicious circle by keeping the feces soft, and soothing the mucosa.

The keeping of the feces soft by the oil enema must not be confused with the dissolving of hard fecal masses. Hertz<sup>2</sup> has shown that oil is a great deal less effective than water in breaking down hard scybala. He found, by actual tests, that water produced a greater softening effect on hard feces in fifteen minutes

than could be achieved by oil in twelve hours. The only manner in which oil enemas are of use in dealing with hard scybala is to facilitate their expulsion by lubrication.

It is easy to understand, therefore, why, after the first oil enema, patients usually pass hard fecal masses, together with soft, mushy material and some of the oil. It is to be noted that some of the injected oil is retained, exerting its effect on the bowel movement of the next day, and even of succeeding days. Fleiner speaks of oil's having been found in evacuations as long as a week after discontinuance of its injection. When a daily injection is employed, scybala presently disappear, and soft, mushy stools are passed. This Fleiner considers an indication that the maximum effect has been obtained, and that the quantity and frequency of the oil injections may be reduced.

The evacuant action of injections of petrolatum, liquid or soft, is entirely due to the physical effects just described. The saponifiable oils have a chemical action, in addition, which is due to decomposition of the oil by lipase present in the colon. In this manner,

some of the oil is changed to glycerin and fatty acids, a portion of the latter combining with bases to form soaps. All of these products are irritant; and, to the effect of these, a large part of the evacuant action of such enemas must be ascribed. The feces passed contain more free fatty acid than the oil did that was introduced, and the fecal odor becomes more offensive by admixture of the odor of rancid oil. Indeed, this decomposition and the irritation resulting therefrom may become excessive, leading to peristaltic unrest, even colic or rectal tenesmus. To minimize the occurrence of such disturbances, it is of greater importance that the oil be pure and free from rancidity (of an acidity not exceeding 40 to 55 [Fleiner]), than that it come from a certain source. Thus poppy-seed oil, oil of sesame, or cottonseed oil, when pure, are just as good for this purpose as olive oil. It would seem that petrolatum would be preferable to all of these, as it can never become irritant.

Lipowski advocates the injection of petrolatum of a melting point of 38 C., that is, slightly above rectal temperature (37.5 C.). He claims not only absence of irritation and of offensive products of oil decomposition in favor of such enemas, but also lack of liability of leakage from the anus, which is at times most annoying when liquid oil is used. He also asserts that petrolatum enemas are less expensive.

The proper melting point is of importance in connection with Lipowski's petrolatum injections, for the material is introduced in melted condition and is intended to congeal to a salve after it has spread itself over the rectal mucosa. This consistency is obtained

The enemator consists in a curved rectal tube of hard rubber, the end of which is olivary shaped to make it self-retaining. This tube is made curved so that it comes up in front of the pubis; to this end is attached a 10-ounce Politzer bag, the connecting soft rubber tube being of a convenient length for the patient. The rectal tube is made with such a curve that it is readily passed from the front of the body to the anal opening; here by a slight traction movement it enters the anus in the proper direction, pointing toward the umbilicus. It has been demonstrated that this new form of tube is much less awkwardly introduced than by reaching around behind the buttocks. The Politzer bag is fitted with a stopcock having a small hole in one side, which permits the bag to fill with air when the cock is closed. The method of taking the injection is simple; the bag is allowed to fill itself, and is then placed in warm water to warm the oil. The patient lies on the back with the hips somewhat elevated and introduces the rectal tube with soft rubber tubing attached. The bag is then attached and the stopcock turned to permit the oil to be forced slowly into the rectum. The bag being emptied, the stopcock is turned and air dilates it so that all oil may be forced from the tubing; by shutting off the stopcock we prevent the return of any oil into the tube and obviate the danger of soiling the clothing and bedding.

by melting together paraffin of a melting point of 78 C. with liquid petrolatum in the proportion of 1:8. The difference between administration of these petrolatum injections and of those of other oil lies in the somewhat higher temperature at which the material is injected and the necessity of having the injecting apparatus warm, so as to avoid congealing within it. To make certain that the injection is not too hot, the patient might dip his finger in the fluid. A colon tube and funnel suffice for the self-administration of these enemas, as the patient need not lie down during or after the injection. The patient might, after having passed the colon tube, seat himself at the edge of a chair and, bringing the tube up between his thighs, conveniently pour the melted petrolatum into the funnel. The quantity injected does not need to be more than 200 c.c. to obtain satisfactory results, as a rule. It would seem that enemas thus given might suffice and be preferred for the treatment of affections of the rectum and pelvic colon; while, for affections higher up in the colon, the technic presently to be described should be employed.

The indications for oil enemas might be thus summarized:

1. To soften feces, in constipation characterized by formation of hard scybala and that due to partial obstruction of the colon.

2. For evacuant action, in so-called "spastic" constipation, in pelvic rectal constipation, and in any other form of constipation in which oral administration of cathartics is contraindicated by gastric disturbance.

3. For soothing action, in excessive colonic and rectal irritability. Herschell and Abrahams<sup>3</sup> consider oil enemas, next to appropriate diet, the single most important method of treatment in colitis. They are also useful in proctitis.

4. It has been suggested that oil enemas might inhibit the absorption of toxic products. That the oil has the power of removing substances soluble in it is shown by the fact that it is passed dark yellow or olive green and of offensive odor. We have no definite knowledge, however, of the degree to which this property might be of clinical value.

The chief contraindication to oil enemas is diarrhea, mainly because, in this condition, the oil would not be retained for a sufficient length of time to be of use; although another objection against the introduction of saponifiable oils would be the possibility that excessive peristalsis might carry unusual amounts of intestinal juices far down the colon, the results of the excessive oil digestion being liable still further to increase the irritation.

*Technic.*—For self administration, the patient should have everything prepared before going to bed, so that he does not have to get up after having taken the injection. The bottle of oil is placed in a basin of hot water until it has acquired blood heat (100 F.). An ordinary fountain syringe might be used, provided the nozzle has a sufficiently large bore to permit the oil to pass readily. Though it is intended that the oil shall be introduced slowly, the bag usually has to be hung from 2 to 3 feet high owing to the viscosity of the oil, which makes it run rather slowly. The clip should be placed within easy reach of the patient. Having poured the warmed oil into the bag, the patient lies on the left side with a folded towel and a firm pillow underneath the buttocks. The nozzle is inserted into the anus, and

the oil permitted to flow. Should the patient experience distress or desire to move the bowel, the flow of the oil is checked and the patient remains quiet until the desire has passed. It might then be possible to introduce an additional quantity of oil. It is usually best, however, to be satisfied with the introduction of an amount that can easily be retained. After a while the patient turns on the back and finally on his right side, in which position it is recommended he should remain over night. A piece of absorbent cotton or a woman's sanitary towel or both may be applied to prevent accidental soiling of the bed, for the passage of flatus may be accompanied by a spurt of oil.

If the injection produces discomfort and interferes with sleep, it may be taken early in the morning and the patient might lie in bed for three or four hours afterward. It should be understood that, unless the oil remains in the intestine for several hours at least, satisfactory results cannot be expected.

The total quantity to be injected depends on the patient's ability to retain it. This is so variable that no definite figure can be stated for any one person. The principle to be followed is to have the patient gradually increase the amount injected on successive nights, until a satisfactory amount can be introduced and retained. The patient may not be able to retain more than 70 c.c. at first, but is likely to be able to take, in course of time, as much as 250 and even 500 c.c. When satisfactory results have been attained, the quantity introduced as well as the frequency of injections is gradually diminished. The injections may then be given on alternate nights, unless resumption of daily administration is necessitated by the patient's condition. Later on, enemas are given every third night, and finally only on the evening of the day on which the bowels were not opened. A single injection may cause daily evacuations for several days.

For children, the quantity injected may range from 50 to 150 c.c. For infants, 15 c.c. may suffice.

When the injection acts well, it is followed by a very soft stool in the morning. If the morning evacuation is not obtained, an enema of physiologic sodium chlorid solution should be taken after breakfast.

In bed patients, administration in the morning would be preferable. When an attendant gives the injection, a colon tube and funnel is all the apparatus required.

In spite of its excellent theoretical foundation and the enthusiastic recommendation of numerous clinicians, this treatment is not very popular, probably because of the troublesomeness of the procedure, the annoyance, and the expense. An enemator was described by Dudley Roberts,<sup>4</sup> by the use of which the procedure may be simplified.

**Diet and Health.**—A well selected diet is one of the key-notes to health. Unfortunately, we are not able to regulate the diet through legislation; it must be done through education. In many cases education may be done through pamphlets sent to the homes and through lectures to groups of people, but there are hundreds and thousands of families where the mother has too many children to get away from home, or where she needs more help for her own personal problem than a pamphlet can give. To help just such families as these the Dietetic Bureau has been established in Boston.—L. L. Gillett, *The Commonwealth* 6:110 (May-June), 1919.

## THE QUESTION OF LOW PROTEIN DIETS

There are many lessons taught by the experience of war time that should not be lost, even if the recurrence of its restrictions and hardships is an unlikely event. The shortage of food is an accompaniment of conditions that may arise quite apart from war. Famine may make its appearance in the midst of peace; harvests sometimes fail even when there is no clash of arms among nations. It is therefore the part of wisdom to learn how to live in times of food stringency so as to avoid as far as possible any detriment to human health and impairment of human efficiency.

The reports circulated with respect to the food restrictions enforced in many localities by the exigencies of war are more or less conflicting. We are assured by certain enthusiasts that the more economical modes of nutrition have frequently been attended with beneficial results. One heard the remark, earlier in the war, that the necessity of a lowered protein intake among the population of the Central Empires had on the whole been without detriment. The advocates of the so-called low protein standard welcomed such statements as evidence of the wisdom of their long heralded claim that most of us among civilized races tend to overeat. According to Friedrich Müller of Munich, the average German lost 10 per cent. in weight in the early years of the war. Surplus tissue must have been at a premium. Are we to look on such a state of nutrition as adequate if not advantageous?

In order to test some of the questions that arise from such considerations, Benedict and his collaborators at the Carnegie Nutrition Laboratory in Boston conducted an elaborate investigation on human vitality and efficiency under prolonged restricted diet.<sup>1</sup> Some of the results have already been referred to in THE JOURNAL.<sup>2</sup> As a result of the diminished food intake with a resulting decrease in body weight, amounting to more than 10 per cent., there was no pronounced decrease in physical endurance or capacity

for work. The depression in the total metabolism was the most prominent feature in the research, particularly as it was accompanied by a depression in other physiologic factors, such as blood pressure and pulse rate. The changes were accompanied by a large loss of nitrogen from the body, amounting to 175 grams or more per person. Benedict argues that this loss is the most probable cause for the lowering of the plane of metabolism; for the withdrawal of a large amount of nitrogenous material from the fluids bathing the tissue cells is conceived by him to remove a potent stimulus to cellular activity. The picture presented by the men on reduced diet is similar to that noted with diabetics, who have been undergoing the Allen fasting treatment. Loss of nitrogen and loss of flesh bring about a lowered metabolism.

The Carnegie report states that "judging superficially from the appearance of these men at the end of their long period of restricted diet and from the amount of their intellectual and physical activity, one could assert almost with certainty that a reduction of total caloric intake of one-third was an assured possibility." We must not, however, overlook the occasional secondary anemia indicated by the blood findings in Benedict's subjects, the marked repression of all normal sex expression, to which earlier reference was made,<sup>3</sup> and a certain degree of mental unrest and dissatisfaction expressed by the men. Perhaps Benedict and his collaborators are justified in asserting that "to instil into the world at large a belief that a pronounced lowering of rations is not necessarily accompanied by a complete disintegration of the organism and collapse of mental and physical powers may, after all, be of real service."

The report to which we have referred in some detail goes a step farther, however. Experimental evidence has accumulated in sufficient amounts, we are assured, to justify a serious consideration of a material reduction in the intake of protein, which is one of the most expensive factors in human food. We are told that it is not clear that a low protein diet is harmful, and that much of the available evidence suggests a lack of any danger therein. At this juncture we may pause to listen to some of the European experiences bearing on the problem. Von Hoesslin<sup>4</sup> has studied the realimentation of a considerable number of undernourished persons in Germany. They had been reduced to an average of from 44 to 55 kilograms in body weight on enforced diets poor in protein and low in calories. In many cases, edemas so characteristic of war-time dietary restrictions of the severer sort had made their appearance, though these signs of insufficient diet were by no means regularly present. The unexpected outcome was the demonstration of great difficulty in securing gains of weight, despite a considerable sup-

ply of calories, unless protein was liberally furnished. In other words, the supply of protein was the determining factor of real restitution. Under ordinary conditions of nutrition, fats and carbohydrates may have a marked protein-sparing action; but when the rock-bottom level of nitrogenous exchange is reached, no gains can be made by large increments of nonprotein foods alone in the diet.

So long as the limit of protein reduction without detriment is not understood, and untoward results of protein starvation can be cited along with the less conspicuously unfavorable experimental findings with the laboratory groups, we may hesitate to accept Benedict's conclusion that for all practical purposes the low protein diet is "perfectly justifiable as a war measure and in all probability is a logical procedure that cannot be accompanied with any untoward effects, even by long-continued practice." We may, indeed, be forced to accept it as a war measure; but let us hesitate to condemn nitrogen storage in the body until more is known regarding its real physiologic meaning and function. Science and human welfare alike are most concerned, not with the minimum in times of stress, but with the optimum in an era of plenty.

---

#### CHANGES IN MOTHER'S MILK UNDER WAR CONDITIONS

The lactating human mother is responsive to her own nutritive conditions, as are the milk-producing females of other species. Poor food, underfeeding and bodily hardships are likely to decrease the flow of milk whenever these instigators of unsatisfactory nutrition arise. Hence an inability to nurse their young adequately has been noted in the case of many mothers of warring peoples ever since statistics of this sort have been deemed worthy of record in medical literature. The countries of Europe have not escaped the consequences of an unsatisfactory milk supply as it affects nursing mothers, who have been compelled to endure unusual dietary restrictions both in quantity and in quality of available nutrients during the past four or five years. Actual inability to nurse the young has been reported from centers where the food stringency was the greatest; and since the best substitute for human milk, namely, cow's milk, has also been extremely scarce at a time when it was needed more than ever, the penalty paid by the innocent young for the combats of their fathers became doubly severe.

An unexpected deficiency in the nutrition of the very young has been admitted of late by a number of German pediatricians.<sup>1</sup> This involves authentic instances in which infants failed to make adequate gains during the war despite the absence of any signs of organic inability to utilize nourishment or of pathologic condi-

tions that would warrant the expectation of a failure to thrive. In a considerable group of such cases, Kaupé<sup>2</sup> has determined the amounts of milk consumed by the sucklings at the breast and found them to be sufficient according to conventional standards. The composition of the mother's milk has likewise not revealed any deficiency in fat, the component most likely to be decreased, as has heretofore been believed, when the quality of the milk suffers.<sup>3</sup>

In the face of failure of infants to grow properly despite a reasonable food intake of breast milk of seemingly normal fuel value, it has become necessary to postulate some as yet inexplicable cause for the unexpected phenomenon; for these cases have a history of feeding with mother's milk, presumably the ideal mode of infant nutrition. Kaupé vaguely ascribes the situation to an undefined psychic factor that seems to affect all persons in war time. We recall, however, that in not a few instances human milk that was of normal composition, judged by the conventional standards of its content of protein, fat and sugar, has failed to furnish all the needed food factors. This is true of the milk of mothers suffering from beriberi. The mammary secretion lacks essential vitamins. It has also been shown that the young of animals maintained on rations deficient in vitamins fail to grow adequately, presumably because the milk lacks these accessory food factors that the maternal organism cannot produce *de novo*. The reports of unsuccessful growth in infants under dietary conditions hitherto regarded as suitable for proper development warn us to have some concern, in the future, for food properties heretofore not adequately evaluated. To determine them, chemical analysis is as yet without resources. The biologic method of investigation by actual animal feeding, which has furnished so many important contributions of late to the science of nutrition in the hands of American research workers, must for the present remain the first recourse of the investigator.

---

#### PHYSICIANS AND STATISTICS

While there have always been those who have cast discredit on the scientific value of statistics, it remains a fact that some medical knowledge must be derived from statistical investigation. Statistics may, of course, be juggled, and it is also fair to assume that statistics are often prepared by persons not skilled in the fundamental principles underlying their preparation. It is probably true that the bulk of medical statistics of the past has been prepared by medical men not trained as expert statisticians.

Recently Mr. Raymond Pearl,<sup>4</sup> professor of biometry and vital statistics in the Johns Hopkins School of Public Health, has analyzed, from the point of

<sup>1</sup> Momm and Kramer, *München, med. Wchnschr.*, 1917, No. 44.  
<sup>2</sup> Pearl, Raymond, A Statistical Discussion of the Relative Efficacy of Different Methods of Treating Pneumonia, *Arch. Int. Med.* **24**: 398 (Oct.) 1919.

<sup>3</sup> I. Kaupé, W. Muttermilch und Krieg, *Monatsschr. f. Kinderh.* **15**: 83, 1918.

view of a trained statistician, certain figures in a paper published by Head<sup>4</sup> concerning the efficiency of various methods of treatment in pneumonia. In this paper Dr. Head himself suggested that the lowered mortality shown in favor of closed ward treatment might be merely a coincidence. In his analysis of the figures, Pearl shows that while Head's conclusions are qualitatively correct, they are quantitatively out of the way on account of the neglect to take into account the factor of random sampling. Another neglected factor, frequently overlooked by medical writers, is the natural history of the disease under investigation. It has been asserted by numerous observers that the mortality from influenza pneumonia at the end of an epidemic is usually much lower than it is at the beginning of the outbreak. Pearl shows that this is the case, and that Head, although recognizing the possibility, did not take it into account in evaluating his figures.

If the statistical method, first extensively introduced into clinical medicine by Louis and the French school, is of value, it goes without saying that the statistics which are used must be based on the well-recognized principles utilized by professional statisticians. So far as mortality statistics are concerned, it may be assumed that the correct methods are usually employed; but it is certain that this is not the case when ordinary clinical statistics are concerned. In any textbook on medicine or surgery, one may find numerous statements covering statistically such matters as the age at which certain diseases occur, the relative proportion of the sexes involved, the frequency of complications, and the relative frequency of different diseases in a given organ or system. It is quite certain from the figures presented that these statistics would be regarded as valueless by a professional statistician, and that while they are perhaps not valueless to the clinician, they are not nearly as valuable or as correct as properly prepared statistics would be. In differential diagnosis, as Southard has pointed out, it is desirable that the physician should know the possibilities. In 10,000 patients with convulsions, what proportion is likely to be due to epilepsy; what proportion to uremia; what proportion to general paresis, etc.? With correct knowledge on such a point, the physician knows when he encounters a case of convulsions that there are certain chances in favor of a given disease, and he can make what Southard calls a diagnosis by orderly exclusion, which is more satisfactory than the old-fashioned diagnosis by exclusion in which the probabilities were ignored. In the matter of treatment, too, the application of correct statistical principles would prevent the flooding of medical periodicals with the views of therapeutic optimists based on uncontrolled observations. The checking of medical statistics by trained statisticians will doubtless serve as a stimulus to more accurate statistical methods.

### THE HABITS OF LICE

The rôle of insects in the transmission of disease is becoming more prominent each year. The fly, the mosquito, the flea and the louse have come to represent not merely irritating and offensive nuisances which interfere with the comfort of man but also positive menaces to his very existence in a state of unimpaired health. Features of insect life, such as the habits, migration, reproduction and distribution of these lowly forms of animals, are no longer the concern of the scientific entomologist alone; they also inevitably interest the medical investigator and the sanitary expert. It almost seems as if no item respecting the behavior of insects can be neglected in microbe-bearing species.

Lice are sensitive to temperatures that approach the body temperature of man. Nuttall<sup>1</sup> has observed that a rise to 35 C. (95 F.) may be distinctly inimical to these insects. Owing to the high temperature near the body in summer, they tend to wander out on ordinary garments. For the same reason they wander away from persons in fever. It is recorded<sup>1</sup> that persons leaving temperate climates for the tropics may become freed from body lice. Nuttall<sup>2</sup> has more recently found that black clothing may repel lice. This is not due, as has been conjectured, to the reaction of the insects to color, but rather to the fact that black cloth, in contrast with lighter colors, absorbs the maximum of heat rays. Consequently, under favorable conditions in warm weather, black clothing may prove inimical to lice and cause them to wander away where it is cooler. Perspiration induced by warm clothing will hasten the exodus, because lice do not tolerate excessive moisture.

Having observed that lice examined from various parts of the world possess different degrees of pigmentation, Nuttall<sup>2</sup> ascertained that the most darkly pigmented specimens of *Pediculus capitis* are derived from dark-skinned black-haired peoples. Head lice tend to grow paler on yellow or moderately pale races possessing black hair. The palest head lice are found on white races whose hair is often light. Experiments conducted in his laboratory at the University of Cambridge, England, have convinced Nuttall<sup>2</sup> that pigmentation in *Pediculus* is not a hereditarily transmitted character, but depends on the nature of the background on which the insect lives. Eggs hatched and allowed to develop on white surfaces will appear pale; those raised on black cloth will remain pigmented at all stages. The occurrence of pale body lice on dark-skinned races is, according to Nuttall, doubtless attributable to the white or light-colored clothing worn in hot countries. It has been suggested that the change in pigmentation of lice, in harmony with the color of their background, may afford a measure of protection to these parasites in nature when the hosts use their eyes in the search for the insects.

## Current Comment

### WORK AND INCOME: A PHYSIOLOGIC PROBLEM

In the ideal division of income usually proposed by economists, the expenditure for food has been placed at approximately 30 per cent., or one third of the total funds available. Prior to the war, Miss Gibbs<sup>1</sup> showed the expenditures for food to be far larger than this proportion among the less well-to-do classes, the percentage of the total income devoted to food commonly exceeding 50. She concluded that the income must evidently go beyond \$1,200 per annum—in prewar values—before a reasonable decrease in the percentage spent for food may be expected. The data collected by the English Board of Trade in 1904 showed that for families in receipt of less than 25s. weekly, 67 per cent. of total outgoings were expended for food, the proportion falling as low as 57 per cent. only in families earning 40s. or more weekly. Data collected by the Working Classes Cost of Living Committee in England in 1918 indicated that skilled and unskilled workers alike spent for food 60 per cent. or more of their income, in contrast with about 55 per cent. as determined in 1914. These facts may serve at this time as a text for the discussion of the actual food needs of workers. The high cost of living is everywhere in the public mind. Consequently it is important to review anew the evidence regarding the physiologic demands made by physical work on the food purse. The war has for the first time made considerable demands on women to expend their energies in toil of an exacting sort. Hence the need of including them in the newer calculations of food requirement in relation to industry. The Food (War) Committee of the Royal Society has just published the results of investigations by Greenwood, Hodson and Tebb<sup>2</sup> dealing with the metabolism of female munition workers. Grouping the operations of these persons in the sequence of severity of the labor involved, it is concluded that light turning and forging need about 100 calories per square meter per hour. The data for other operations are as follows: for tool setting, heavy turning, stamping, finishing and shell hoisting, 125 calories; for gaging, walking and carrying, 160 calories; for more arduous labor, 180 calories. Translating these findings into food fuel requirements for the entire day, after allowance is made for culinary and alimentary waste, etc., the needs amount to 2,800, 3,100, 3,500 and 3,800 calories, respectively, per day. The figures cited show that the energy requirement of the lightest class of workers may be only about three-quarters that of the heaviest. Nevertheless, the remuneration of the kind of work conducted by the latter is often much less than that of several operations calling for many fewer calories. Even after making allowance for one and a half nonworking days, the weekly calory requirement of the two most unlike groups ranges from 17,000 at

one extreme to 21,500 at the other. Any scheme of remuneration that aims to make returns adequate to keep the cost of food at a reasonably low proportion of the total income must take into account the decidedly greater food needs of those who often represent the least well recompensed group. Thus, a food allowance of \$10 a week which just suffices for the less active worker must be augmented to \$13 in case the greater effort is expended. As the English experts now remind us, in any scientific appraisal of the income needed to maintain an accepted standard of living, it is essential to determine the minimal expenditure necessitated by the occupation of the wage earner. Variations in physiologic demand translated into terms of money may nowadays be not inconsiderable.

### COLLEGE HEALTH ADMINISTRATION

Many of our colleges and universities maintain supervision, varying in extent and effectiveness, over the physical welfare of their students. In a considerable proportion, attention is paid to defects observed in a physical examination and to the care of patients who apply for medical treatment. But health supervision should not stop here. Howe<sup>3</sup> has again pointed out that the sanitation of the college plant as a whole has received altogether too slight notice, and in only exceptional cases is any really systematic attempt made to control hygienic conditions. Failure seems to be due largely to the lack of properly constituted health organizations. It makes little difference what department of the college is responsible for the health administration, so long as it is in the hands of qualified experts, with power to utilize all the facilities of the institution, who will cooperate with municipal authorities. In some instances the physical education department would be the natural center, in others the department of public health or of bacteriology; local conditions must determine this. Some specialist must be available—perhaps he may actually have the title of health officer—who as a part of his regular duties will be responsible for the general hygienic condition of the college. Besides directly affecting the health of the college community, a health administration will serve as a means of educating the students to the need of supervision of city, town and rural sanitation; thus, when they leave college, their influence will be with the movement for a more active health administration.

### THE ANTISEPTIC POWER OF THE GASTRIC JUICE

The antiseptic properties of the gastric juice have been recognized for more than a century. The advantage of the existence, near the beginning of the alimentary tract, of a reservoir within which fermentation and other microbial changes in the food ingested can be checked became apparent early in the days of modern physiology. It was not until comparatively recent times, however, that the role of the free acid of the

2. Greenwood, M., Hodson, C., and Tebb, A. K.: Report on the Metabolism of Female Munition Workers, *Proc. Roy. Soc. Section B* 65, 67 (Aug. 6) 1919.

3. Howe, Am. J. Pub. Health 9:749, 1919. *Anderson, Am. J. Hyg. Ed. Rev.*, April, 1917, p. 30. Winslow, *Schulz and Sato's J. Dent.*, 1916, p. 997.

gastric contents in relation to its antiseptic behavior began to be understood. The gastric hydrochloric acid has proved to be of immense advantage in many ways. Not only does it facilitate the normal cleavage of protein foodstuffs by enzymatic means and retard other modes of their disintegration by micro-organisms, but it undoubtedly checks the development of bacteria that are more directly inimical to the body. We are now taught to appreciate that a copious, acid gastric juice is destructive to the cholera and typhoid germs; hence the physiologic duty of maintaining a healthy stomach function as one of the safety devices of the organism against dangerous invaders. How vigorous the antiseptic power of normal gastric juice may be has lately been demonstrated anew by Scheer<sup>1</sup> at Strasbourg. Facilli of the typhoid, paratyphoid, Flexner and Shiga groups were killed thereby in two minutes; the colion bacilli are somewhat more resistant. These striking facts must not, however, be transferred directly to the interpretation of conditions as they exist in the body itself. When bacteria are enclosed in larger food masses they are reached only slowly by the penetration of the gastric secretion; in fact, they may occasionally escape into the small intestine without destruction. This is particularly true when the gastric functions are repressed or inadequate. Hence it is no mere chance that dysenteric bacterial disease is most likely to arise when the activities of the stomach are below par.

#### THE NEW QUACKERY

There are fashions in quackery. The 1919 Model is that which commercializes the trend of the public toward the so-called drugless methods of healing. A mail-order course on "How to Cure What Ails You, Without Drugs; in Six Easy Lessons," by Dr. Quack or Professor Fake, is the lure. It proves a veritable gold mine for those who promote the scheme and for the magazines whose advertising pages furnish the point of contact between seller and purchaser—the spider and the fly. The theories so solemnly pronounced by the exponents of the new quackery are usually made up of about 5 per cent. banalities of elementary science and 95 per cent. of pseudoscientific hodgepodge. The occasional rational, if obvious, things that quacks of this type say mislead intelligent people into accepting the ridiculous theories that are thus commercialized. Because the product sold is not put up in a bottle, the public assumes that it is free from quackery; therein it is mistaken.

#### FRIEDMANN IN A NEW RÔLE

To those who recall the punctilious care with which appointments to posts of importance in the German universities were made during prewar times, an incidental announcement of a recent addition to the Berlin medical faculty will come as a great surprise. Through ministerial orders and without the cognizance of the faculty, Dr. Friedrich Franz Friedmann was appointed assistant professor of tuberculosis. This is probably the same Friedmann who appeared in this country a

few years ago with preposterous claims for the therapeutic virtues of products prepared by the use of tubercle bacilli obtained from turtles. His story has been told in THE JOURNAL, which at the same time exposed the untenability of his claims. The consternation of the German medical profession at this unheralded academic preferment is voiced by the *Deutsche medizinische Wochenschrift*<sup>1</sup> which says: "This is, as far as we are aware, the first time that an investigator has, without cognizance of the medical faculty, been assigned to a teaching post for a single chapter in medicine, despite the fact that his qualifications have not hitherto been tested in any way. Just as today Friedmann has been made professor of tuberculosis, so tomorrow," the *Wochenschrift* proceeds to lament, "a call may be issued to an incumbent for diabetes, for treatment of syphilis without arsenamin, for non-surgical therapy of cancer, or for drugless therapy." Such is the new regimen in Germany. It will be interesting to watch the reaction of the Berlin medical faculty to such developments in the educational procedure of the new German state.

### Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST, SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

#### ALABAMA

**Hospital Notes.**—The new Jackson Infirmary which has just been opened is a building of brick and hollow tile with concrete finish. The cost of the building and equipment exceeds \$30,000.—The hospital erected at Fairfield by the Tennessee Coal, Iron and Railroad Company was opened to the public for inspection, October 29. The hospital occupies a site overlooking the Fairfield and Ensley industrial district.

**Health Department Appointments.**—The committee of public health at a meeting, held October 22, in Montgomery, confirmed the appointments of Dr. Paschal P. Salter, Good Water, director of the state laboratory, and appointed Dr. James L. Bowman, Union Springs, director of the department of communicable diseases, and Dr. G. L. Reynolds as first assistant director of the state laboratory, and continued W. C. Blasingame in his duties as director of the department of social control.

#### ARKANSAS

**Medical Society Organized.**—The physicians of Blytheville organized a society for Blytheville and Mississippi County, electing Dr. Joseph A. Saliba, president; Flem D. Smith, vice president, and Isaac R. Johnson, secretary-treasurer, all of Blytheville.

**New Society Officers.**—The council of the Arkansas Medical Society at its meeting in Little Rock, November 7, elected Dr. William R. Bathurst, Little Rock, to fill the vacancy caused by the death of Dr. Clinton P. Meriwether. Dr. Robert L. Saxon, Little Rock, was elected treasurer, succeeding Dr. Bathurst.

#### FLORIDA

**State Board Office Moves.**—The offices of the state board of health which have been located in San Carlos Hotel, Pensacola, have been transferred to the State Laboratory Building.

**Personal.**—Dr. Lorin A. Greene, Greenville, has been appointed chief of the bureau of venereal diseases of the state board of health.—Dr. J. W. Bueck has been appointed assistant state health officer.

**Resolution on Leper Colony.**—The Duval County Medical Society at its meeting in Jacksonville, November 4, adopted

1. Schrer, K.: Ueber die keimtödtende Wirkung des Magensaftes auf die Bazillen der Typhus, Kolik und der Ruhrgruppe, Arch. f. Hyg., 130, 1919.

1. Deutsch. med. Wchnschr., July 10, 1919, p. 725.

a resolution setting forth that the opposition to the establishment of a leper colony by the United States Public Health Service on an island off the coast of Florida is unfortunate; that from a medical standpoint there should be no opposition to it, and that the arguments advanced against it should be met by the medical profession with an educational propaganda for the purpose of showing that a leper colony controlled, will be of no disadvantage to the state, and will be of advantage in taking care of Florida's lepers, now at large. It was further resolved that copies of these resolutions should be sent to the daily press and the Surgeon-General of the United States Public Health Service.

### ILLINOIS

**Cook County Civil Examinations.**—The Cook County Civil Service Commission will hold examinations for the attending staff of the hospital in the various subjects, beginning December 4 and continuing to December 19. In these examinations knowledge of the special subject is rated at 9 points and experience at 4.

**Southern Illinois Physicians Meet.**—At the forty-sixth annual meeting of the Southern Illinois Medical Association, held in East St. Louis, November 6 and 7, the following officers were elected: president, Dr. Henry H. Roth, Murphysboro; vice presidents, Drs. Charles E. Eisele, East St. Louis, and H. M. Ross, Carbondale; secretary-treasurer, Dr. Alonzo B. Capel, Shawneetown, and assistant secretary, Dr. Charles W. Lillie, East St. Louis. The next meeting will be held in Carbondale.

### LOUISIANA

**Sanatorium Notes.**—Providence Sanatorium, an institution for negroes at Delachaise and Robertson streets, New Orleans, is almost completed. The building is already being equipped. —It has been definitely decided by the Lincoln Parish Memorial Association to erect, in memory of the men who went to war from that parish, a sanatorium, for which a site has been donated by the town council of Ruston on condition that the Memorial Association spend \$50,000 on the building. Half of this amount has already been secured.

**Child Welfare Lectures.**—Four lectures on the care of young children are being given in New Orleans, under the auspices of the Child Welfare Association. The first lecture was delivered by Dr. John P. Leake, New Orleans, November 3, on "The Care of the Eye, Ear, Nose and Throat of the Growing Child." November 10, Dr. C. Jeff Miller, New Orleans, delivered a lecture on the subject of "Frenatal Care"; November 17, Dr. William H. Harris, New Orleans, is to speak on "Germ Producing Diseases in Children," and November 24, Dr. Maude Loeber, New Orleans, will deliver an address on "Nervous Diseases Common to Children." In addition to this course the committee has organized a series of addresses by specialists on the feeding and care of babies.

### MARYLAND

**Personal.**—Dr. C. Hampson Jones, health commissioner of Baltimore, has appointed Dr. T. C. Buck to be third assistant in the bacteriologic laboratory, to fill a vacancy.—Dr. George F. Sargent, head of the men's department of the Sheppard and Enoch Pratt Hospital, Towson, for ten years, has resigned. His resignation will take effect next month.

**Queen Visits Hospitals.**—During her short visit to Baltimore, Queen Elizabeth of Belgium, because of her great interest in hospital work, made a hurried trip to the Johns Hopkins Hospital, where she and her party were received by Dr. Winford H. Smith, Baltimore, the superintendent, and conducted through all the departments of the hospital. —The Red Cross Vocational School for Blinded Soldiers at Evergreen Junior, Roland Park, was also visited by the queen, who was much impressed by the splendid work being done there by the blinded soldiers.

**Funds for Hospital Pass Goal.**—In the campaign which has just been brought to a successful finish in Baltimore, to secure \$750,000 for the proposed Union Memorial Hospital, which will replace the old Union Protestant Infirmary, the subscriptions aggregated \$769,018.47. Dr. John M. T. Finney, Baltimore, was chairman of the drive and as a special honor to him and also to inspire other young men who may enter the medical profession to emulate the virtues and habits which have made Dr. Finney one of the foremost surgeons in this country, the "Committee of Nine," in charge of the drive, with about sixty others, gave to the hospital on the

final day of the campaign an operating room, to be known as the John M. T. Finney operating room, to be constructed at a cost of \$35,000.

### MASSACHUSETTS

**Professor Strong Sails for Europe.**—Dr. Richard P. Strong, professor of tropical medicine in Harvard Medical School, Boston, sailed, October 2, for Europe, where he is to be chief medical director of the League of Red Cross Societies, with headquarters in Geneva, Switzerland.

**Hygiene Lecturers.**—The Massachusetts Society for Social Hygiene announces that it is prepared to send lecturers, both men and women, who thoroughly understand the vital relation social hygiene bears to the home and public health. The subjects of especial interest in this work are "The Instruction of Children Regarding Life and Birth," "Problems of Adolescence," "The Menace of Venereal Diseases to the Community," "The Girl Problem," "Feeble-Mindedness," "Juvenile Delinquency," and "Alcoholism." Arrangements for lectures or personal consultations may be made by writing to the office, 50 Beacon Street, Boston.

**Benefactor Announced.**—In the obituary notices of this week, appears the notice of the death of Dr. Henry K. Oliver, Boston. Several years ago, when Dr. Oliver's health began to fail, he made over to Harvard University, practically his entire fortune, arranging for a reservation sufficient for his living and personal needs, and stipulating that his gifts be received as from an anonymous friend, the name of the donor to be disclosed only on his death. This gift was to found a department of hygiene at Harvard, through which the general welfare and health of undergraduates could be carefully considered, and receive proper attention and oversight. Dr. Roger Irving Lee, Cambridge, has been serving as the first occupant of this professorship. Hereafter this department will be known as the Dr. Henry K. Oliver Foundation.

**Medical Examiners Appointed.**—Dr. Winthrop Adams, Cambridge, has been appointed associate medical examiner (coroner for the first Middlesex District. The following reappointments of medical examiners have been announced: Dr. William P. Stutson, Cummington, associate, first Hampshire district; Dr. Johnson R. Woodward, Oxford, associate, eighth Worcester district; Dr. Richmond B. Root, Georgetown, associate, sixth Essex district; Dr. Samuel C. Tucker, Peabody, associate, eighth Essex district; Dr. Nathaniel K. Noyes, Duxbury, third Plymouth district; Dr. Andrew J. McGraw, Taunton, associate, second Bristol district; Dr. Charles A. Atwood, Taunton, associate, first Bristol district; Dr. A. Elliot Paine, Brockton, associate, first Plymouth district; Dr. Gary de N. Hough, New Bedford, associate, fourth Bristol district; Dr. Frederick V. Murphy, Attleboro, associate, first Bristol district, and William J. Clarke, Milford, associate, sixth Worcester district.—Dr. Henry M. Pollock, Boston, has been renominated as a member of the commission on mental diseases.

### MICHIGAN

**Michigan Practitioner Arrested in Indiana.**—Dr. A. W. Van Bysterveld, Grand Rapids, is said to have been arrested at Milford, Ind., October 20, charged with practicing medicine in Indiana without a license. The defendant claims that he is not a physician but a chemist.

**Given Prison Term.**—Dr. George A. Fritch, Detroit, who it is said has previously been in prison for manslaughter, is reported to have been found guilty on three charges, of performing illegal operations and to have been sentenced, October 28, to serve from one to fifteen years in Marquette Prison.

### MINNESOTA

**Personal.**—Dr. Charles E. Smith, Jr., St. Paul, was elected executive officer and secretary of the state board of health, October 14, succeeding Dr. Henry M. Bracken, resigned.

**Mayo Properties Association Formed.**—The formation of the Mayo Properties Association was recently announced at Rochester. Drs. William J. and Charles H. Mayo have turned over through gift, all the clinic properties, real and personal, and all funds and endowments to the association, which is to be a holding corporation to perpetuate for all time the Mayo Institution. The management of the clinic will be unchanged, and Drs. William J. and Charles H. Mayo, Henry S. Plummer, Edward S. Judd, and Donald C. Balfour, and their assistants, will continue to devote their entire time to the clinic.

**Failure to Report Venereal Disease.**—The Minnesota State board of Health is following up all cases of failure to report venereal diseases. When an omission to make such a report is discovered, a letter is addressed to the physician responsible in order to give him an opportunity to make the necessary report. In a recent instance a complaint was filed against a physician treating many cases of this class and who ignored letters from the board urging him to report them. The physician was found guilty and fined. This case is a precedent establishing the validity of the regulations requiring these reports.

#### MISSISSIPPI

**Personal.**—Dr. W. E. Nollm, Yazoo City, has been appointed health officer of Yazoo City to fill the unexpired term of Dr. James B. Anderson, resigned.—Dr. Thomas E. Royals, Meridian, has succeeded Dr. James Bennett as county jail physician of Lauderdale County.

**New Officers.**—At the annual meeting of the Mississippi State Public Health Association, held in Jackson, October 22 and 23, the following officers were elected: president, Dr. William H. Friell, Brook Haven; vice presidents, Drs. Thomas E. Hewitt, Amite County, Paul G. Cope, Columbia, and Thomas L. Underwood, Monroe County, and secretary-treasurer and executive officer, Dr. Waller S. Leathers, University. The meeting for 1920 will be held in Jackson.

—At the semiannual meeting of the Homochitto Valley Medical Association, whose membership is composed of physicians from Adams, Amite, Jefferson and Wilkinson counties, held in Natchez, October 9, the following officers were elected: president, Dr. Charles E. Catchings, Woodville; vice presidents, Adams County, Dr. J. W. Dix; Amite County, Dr. H. K. Ritter; Franklin County, Dr. C. G. Mullins; Jefferson County, Dr. J. M. Barrier, and Wilkinson County, Dr. Charles E. Catchings, Woodville.

#### MISSOURI

**New Board Appointments.**—Governor Gardner has appointed Judge J. G. Greensfelder of Kirkwood, Rev. E. F. Leake of Springfield and Col. J. A. Corby of St. Joseph, members of the board of charities and corrections. The board recently inspected the eleemosynary institutions of the state. Mr. J. L. Wagner, secretary of the board, announces that nearly all the circuit judges have appointed probation officers for the counties to meet the provisions of the law recently enacted for the protection of children.

**Changes in Washington University Faculty.**—Dr. Eli Kennerly Marshall, Jr., Washington, D. C., formerly associate professor of pharmacology in Johns Hopkins University, has been appointed head of the department of pharmacology at Washington University Medical School; Dr. Everts A. Graham has assumed his duties as professor of surgery; Dr. Ernest Sachs has been promoted to professor of clinical neurological surgery; Dr. Leland B. Alford has been promoted to associate in clinical neurology, and Drs. Drew W. Luten and William H. Olmstead, St. Louis, to instructors in clinical medicine. In addition to these changes, the following appointments have been made: A. W. L. Bray, associate in anatomy; Alfred C. Kolls, associate in pharmacology; Edgar Allen, instructor in anatomy; Edward A. Dossy, instructor in biological chemistry; Frederick Ebersson, assistant in dermatology; Dr. Arthur E. Strauss, assistant in clinical medicine; Dr. Lionel S. Luten, assistant in clinical medicine; Dr. Isaac D. Kelly, Jr., assistant in clinical ology, and Drs. Frederick O. Schwartz, Harvey D. Lamb and Lawrence T. Post, assistants in clinical ophthalmology.

#### NEW JERSEY

**Physician's License Revoked.**—The New Jersey State Board of Medical Examiners, Oct. 20, 1919, it is reported, revoked the license of Dr. I. Alfred Lawrence, Elizabeth, to practice medicine and surgery in the state of New Jersey, on a charge of criminal abortion.

**New Officers.**—Camden County Medical Society held its annual meeting at Camden, October 14, and the following officers were elected: president, Dr. Edward B. Rogers, Collingswood; vice president, Dr. Joseph E. Roberts, Camden; secretary, Dr. Daniel Strook, Camden; assistant secretary, Dr. William H. Pratt, Camden, and treasurer, Dr. Milton M. Osmun, Camden.—The centennial meeting of the Cumberland County Medical Society was held at the Cohansick Country Club, October 6. The following officers were elected: president, Dr. Leonard F. Hatch, Vineland; vice

president, Dr. Charles E. Sharp, Port Norris; secretary, Dr. H. Garrett Miller, Millville, and treasurer, Dr. W. Leslie Cornwall, Bridgeton.

#### NEW YORK

**Rochester Districted.**—In a communication addressed to the Commissioner of Public Safety, Health Officer George W. Goler Rochester, suggests a tentative program for curbing an outbreak of any epidemic disease which may occur in the city. The plan contemplates the organization of an emergency corps (of twenty-five or more physicians, and of a group of more than twenty-five nurses who will constitute an emergency reserve corps). The central organization will be at the health bureau where there will be a twenty-four-hour telephone service. The city has been divided into twelve districts in which there is a health physician, and in which an emergency health station has been located either in the police station or fire house. At the central station of the health office a list of all vacant beds in the hospitals for men, women and children will be filled each day.

#### New York City

**Health Department Provides New Positions.**—The 1920 city budget provides for the following: for new positions in the drug addict bureau an appropriation of \$43,030; ten positions at Bellevue Hospital, including a medical superintendent at \$2,520, a dietitian at \$2,500, and an investigator at \$1,800.

**Semicentennial Anniversary of Dermatologic Society.**—The New York Dermatological Society, which is said to be the oldest dermatologic society in existence, celebrated its fiftieth anniversary with a dinner at the Yale Club, November 8, at which Dr. George Henry Fox, one of the oldest members of the society, delivered an address.

**Personal.**—Dr. William Lintz, Brooklyn, has been appointed chief of the medical staff of the Bikur-Cholim Koshers Hospital, Brooklyn, succeeding Dr. Henry Joachim, resigned.—Dr. Alexis Carrel, who has completed four years' service with the French army hospitals, has returned to this country to resume his work with the Rockefeller Institute.

**To Improve Nutrition of Schoolchildren.**—Arrangements have been made for cooperation between the bureau of child hygiene of the department of health and the department of education for the working out of plans designed to improve the nutrition of schoolchildren. In general it is expected that a campaign of health education will be started throughout the city with particular reference to the undernourishment of schoolchildren. Lectures on dietetics will be given and the physicians and nurses of the department of health will examine the undernourished children and take measures necessary to correct physical defects when found. School lunches will be started as soon as possible, and general systematic weighing of the children will be part of the program. Surveys are now being made in thirty-five schools in Manhattan for the purpose of ascertaining the percentage of children attending these schools at the present time who are suffering from malnutrition.

#### NORTH CAROLINA

**Personal.**—Dr. John Hey Williams, Asheville, one of the oldest and most esteemed practitioners of North Carolina, suffered a cerebral hemorrhage, October 23, and is still in a serious condition.

**Health Inspectors Named.**—The bureau of sanitary engineering and inspection of the state board of health has announced the selection of L. A. Allen, High Point; H. M. Fowlkes, Rockingham; Claude Hussey, High Point; H. G. Blackwell, Wake Forest; T. J. Moseley, Raleigh; W. J. Steele, Salisbury; A. M. Surratt, Denton; L. G. Whitley, Elm City, and G. E. Hapgood, Fall River, Mass., as sanitary inspectors to administer the state sanitary law. The state has been districted and one inspector will be placed in charge of each district of approximately ten counties.

**Hospital Items.**—Waynesville Hospital has been incorporated with \$25,000 capital authorized and \$2,000 subscribed by Thomas Stringfield and others.—Wilmington is to have a new hospital to be known as St. John's Sanitarium, and to be conducted under the direction of Dr. John F. Miller, Ashboro, and John T. Hoggard, Atkinson. A campaign is being launched to raise funds for the completion of the Ellen Fitzgerald Hospital, now in course of construction at Monroe.—A movement is on foot at Dunn to raise \$100,000 for the erection and equipment of a modern hospital.

The initial subscription of \$50,000 was given by Mr. J. D. Barnes of Dunn.

### OHIO

**Illegal Practice of Medicine.**—Mrs. Helen Platz, Cleveland, charged with the unlawful practice of medicine, is said to have been released on a suspended sentence on her promise to discontinue practice.

**Hospitals Must Register.**—Of the 300 hospitals of the state more than 200 have already filed the necessary blanks with the health department in obedience to the law recently passed, directing the department of health to define, and classify hospitals and to make a survey of the state hospital facilities.

**Women Physicians Organize.**—Women physicians of Toledo met, October 22, and organized the Women's Medical Club of Toledo with an initial membership of sixteen, and elected the following officers: president, Dr. Lamora Shuey; secretary, Dr. Bertha King Hobart, and treasurer, Dr. Maude L. Marks.

**Examination for District Health Commissioners.**—The new district health commissioners, to be appointed in each county, are to receive their civil service examinations at the hands of an extra state constituted board, consisting of five public health experts. This special examining board, as announced by the state civil service commission, will consist of Dr. Allan J. McLaughlin and Dr. L. L. Lumsdon of the United States Public Health Service; Dr. W. S. Rankin, executive officer of the state board of health of North Carolina; Dr. Otto P. Geier, industrial physician of Cincinnati, and Mr. Sherman Kingsley, secretary of the Cleveland Welfare Federation. Applications for health commissionerships should be addressed to the state civil service commission. Applicants will not be assembled for examination, but each will be required to submit a statement as to experience and a thesis or published article on a public health subject.

### PENNSYLVANIA

**Safety Campaign.**—Other communities are following Philadelphia's lead in connection with the campaign for personal safety. The Bethlehem Chamber of Commerce, which is sponsored by Charles M. Schwab, will conduct a "cross at crossings" campaign similar to the one now being observed in Philadelphia.

**Western Pennsylvania World War Officers Organize.**—The Western Pennsylvania Association of Medical Officers of the World War was organized at Pittsburgh, July 31. Dr. Lawrence Litchfield, Pittsburgh, was elected president, and Dr. Theodore Baker, Pittsburgh, secretary. Any physician who reported for active service in the United States Army, Navy, or Public Health Service or the service of the Allies of the United States is eligible for membership.

### Philadelphia

**Sculpture and Anatomy.**—At the meeting of the Section on the Medical History of the College of Physicians of Philadelphia, held November 15, Fielding H. Garrison, Lieut.-Col., M. C., U. S. Army, Washington, D. C., and Dr. Edward C. Streeter, Boston, presented a paper on "Sculpture and Paintings as Modes of Anatomical Expression."

**Personal.**—Dr. R. Randolph Paxson has been appointed by Director Krusen, first assistant resident physician in the Hospital for Contagious Diseases. In the list of officers nominated at the business meeting of the Philadelphia County Medical Society, held October 15, the name of Dr. J. Norman Henry for first vice president was unintentionally omitted by the printer.

**The Gross Prize.**—The Philadelphia Academy of Surgery announces that essays in competition for the Samuel D. Gross Prize of \$1,500 will be received until Jan. 1, 1920. The stipulations are that the prize "shall be awarded every five years to the writer of the best original essay not exceeding 150 printed pages, octavo in length, illustrative of some subject in Surgical Pathology or Surgical Practice, founded on original investigation." The candidates for the prize must be American citizens, "the competitor who receives the prize shall publish his essay in book form, shall deposit one copy of the work in the Samuel D. Gross Library of the Philadelphia Academy of Surgery and on the title page it shall be stated that the essay was awarded the Samuel D. Gross Prize; the essay must be written by a single author in the English language, must be typewritten, distinguished by a motto, and accompanied by an envelop bearing the same motto, containing the name and address of the writer, and

must be sent to the trustees of the Samuel D. Gross Prize of the Philadelphia Academy of Surgery, care College of Physicians of Philadelphia, 19 South Twenty-Second Street, Philadelphia, on or before Jan. 1, 1920."

### TENNESSEE

**Dispensary for Drug Addicts Opens.**—A dispensary has been opened at Memphis, by the city health department, under Dr. James L. Andrews, at which drug addicts may be treated.

**Hospital Item.**—The Jewish people of Memphis are launching a movement to erect a \$350,000 hospital, primarily for Jews in Tennessee, Mississippi and Arkansas, but accepting patients from all denominations. There will be 100 beds, one fourth of which will be for charity patients.

**Office Building for Physicians.**—The Doctors' Building Company has been organized at Memphis by Justin D. Towner and others, and an option has been secured on a site at Court Avenue and Third Street, on which it is proposed to erect a building to cost \$200,000. The building committee consists of Dr. Max Goldman, Elby T. Martin and Charles D. Smith, and the finance committee of Dr. Edwin D. Watkins, John T. Ogden, and Dr. John L. Jelks.

### Texas

**Funds for Public Health Work.**—The executive secretary of the Texas Public Health Association announces that \$180,000 will be available to the association, during 1920, for the fight against tuberculosis and the betterment of the general health conditions in the state. This amount will be realized from the sale of the Red Cross Christmas Seals, which began, November 1.

**Hospital Items.**—The Benevolent War Risk Society has decided that the sanatorium for the Texas soldiers afflicted with tuberculosis shall be located at Carlsbad. The responsibility for raising \$500,000 for building and equipping the sanatorium is placed with the service that had charge of the draft in Texas, with Major John E. Townes of Houston as supervisor. The Mexia Commercial Club has agreed to raise \$2,500 for the purpose of aiding the physicians of the city in their movement to build a sanatorium.

### VIRGINIA

**Personal.**—Dr. William H. Evans, Lynchburg, has been commissioned first lieutenant, M. C., Virginia National Guard, and has been assigned to duty with the local National Guard company. Dr. Charles V. Carrington, Norfolk, was operated on at St. Elizabeth's Hospital, October 24, for duodenal ulcer.—Dr. H. Stuart Smyth, Plasterco, was painfully injured in a collision between his automobile and a wagon, September 25.

**State Association Meeting.**—The Medical Society of Virginia held its fiftieth annual meeting in Richmond, October 28 to 31, under the presidency of Dr. Emmon G. Williams, Richmond. A feature of the opening session was the address on "The Semicentennial History of the Medical Society of Virginia," by Dr. John N. Upshur, Richmond. Petersburg was chosen as the next place of meeting, and the following officers were elected: president, Dr. Paulus A. Irving, Farmville; vice presidents, Drs. Marshall J. Payne, Staunton, George T. Klipstein, Alexandria, and George J. Williams, Newport News. Dr. Irving has served as secretary of the state association continuously since 1910.

**Hospital Notes.**—The G. B. Johnston Memorial Hospital, which was formally dedicated at Abingdon, is a tribute to the memory of the late Dr. George Ben Johnston, who developed a hospital at that place. After his death the people of that section raised money and built this new hospital. The capacity is fifty beds.—The Lynchburg Chamber of Commerce has agreed to contribute \$50,000 for the proposed Baptist Hospital provided the Baptist general convention of Virginia will locate the hospital in Lynchburg. The Providence Hospital Association, Danville, has secured a site on South Main Street on which there is already a two-story brick building. Additions will be made to this building, and it will be remodeled, so that the institution will accommodate thirty patients. The improvements on the building will cost \$10,000, and it is expected that the hospital will be ready to receive patients in January.—The University of Virginia, Charlottesville, has asked the legislature for improvement costing nearly \$300,000, to include a new dormitory for fifty-two men, a new medical building, and an isolation ward for contagious diseases to the University Hospital.

## GENERAL

**Interprofessional Conference.**—An interprofessional conference is announced to convene at the Hotel Statler, Detroit, at 11 a. m., November 28, and to continue two days. The conference is organized at the invitation of the postwar committee on architectural practice to bring the professions together in order to plan more effective relations to each other and to the social problems of the day.

**Treasury Decision on Alcohol Prescriptions.**—Treasury Decision No. 2940, which has just been issued by Daniel C. Tappan, commissioner of internal revenue, provides that under the new prohibition enforcement act, physicians who make application for intoxicating liquor must make an application for permit in Form No. 737 and must make a statement that the liquor is for use in the course of their professional practice only, and that it is to be used either in the compounding of medicines or for use without charge for non-coverage purposes only. If more than 2 quarts are purchased in any one year, bond will be required.

**Milk Commission Elects Officers.**—At the annual meeting of the American Association of Medical Milk Commissions, which has been holding its meetings concurrently with those of the American Public Health Association, Dr. Laurence R. DeBuis, New Orleans, was elected president; Dr. Ben C. Frazier, Louisville, Ky., secretary-treasurer, and Drs. Arnold F. Farrer, Cleveland, Louis C. Ager, Brooklyn, and Walter S. Haines, Chicago, members of the association council. At this meeting the employment of a field inspector was recommended and a committee was appointed to consider affiliation with the American Public Health Association.

**Meeting of Western Surgical Association.**—The twenty-ninth annual meeting of the Western Surgical Association will be held in Kansas City, December 5 and 6, under the presidency of Dr. Roland Hill of St. Louis. This year's meeting will be held during the same week and at the same place as the association of Rock Island railway surgeons. Thomas S. Cullen, Baltimore, professor of gynecology in Johns Hopkins University, will be the guest of the association. The headquarters will be at the Muehlbach Hotel, where the sessions will also convene. The annual banquet will be held on Friday, December 5. Dr. Howard Hill, State Building, Kansas City, is chairman of the committee on arrangements.

**Investigation of Influenza.**—The Metropolitan Life Insurance Company has provided resources to carry on investigations into the cause, mode of transmission and treatment of influenza and its complications. A commission has been appointed consisting of Dr. George W. McCoy, director of the hygienic laboratory, U. S. Public Health Service, Washington, D. C.; Dr. William H. Park, director of the research laboratory, New York City Department of Health; Lee C. Frankel, third vice president of the Metropolitan Life Insurance Company; Dr. A. S. Knight, medical director of the Metropolitan Life Insurance Company; Dr. Milton J. Rosenbaum, chairman, professor of preventive medicine and hygiene, Harvard Medical School. Later, Prof. Edwin D. Jordan, of the University of Chicago, and Dr. Sale H. Frost, of the U. S. Public Health Service, Washington, D. C., were invited to join in the work. Work has already been begun in Washington, New York, Boston, and Chicago and may be extended to other places as occasions arise.

**Outbreaks of Food Poisoning Traced to Ripe Olives.**—Recent outbreaks of food poisoning at a country club near Detroit, in which eight deaths occurred, was traced to an outbreak of the state department of health to the eating of ripe olives. *B. botulinus* was found in the olives, and that all quantities of the olives and of the liquor in which they were contained were extremely toxic to guinea pigs. A recent outbreak of food poisoning in Michigan, causing five deaths, was traced to the same source, and the same bacteria were recorded. Following this last outbreak the state department of health and the dairy and food board of the agricultural commission issued a joint statement, which was given wide publicity, warning against the use of ripe olives and forbidding their sale until further investigations had been made. It is alleged that the authorities in Michigan found *B. botulinus* in samples of ripe olives on the shelves of various stores. An extensive investigation is being made by the state department of health to determine whether ripe olives now on sale in Ohio are safe for consumption.

## FOREIGN

**International Congress of Electrology and Radiology.**—It is announced that the Seventh International Congress is to be held at Paris in August, 1920, with Dr. Oudin to preside.

**Typhus in Siberia.**—A representative of the American Red Cross, who has been in West Siberia for six months, reports that the cases of typhus fever among the Siberian troops, since January 1, have aggregated 120,000, and that since July 1, 40,000 cases have occurred. Near Omsk, 30,000 persons are without shelter, and sanitary conditions are reported as frightful.

**Italian Radiology Congress.**—The first meeting of the Italian Society for Medical Radiology since the beginning of the war was held recently at Genoa, with E. Maragliano, professor and senator, presiding. Professor Ghilarducci of Rome opened the discussion on the biophysical bases of radiotherapy; Professor Ceresole of Venice on the dosimetry in radiology, and Professor Alessandrini of Rome on radiology in pulmonary tuberculosis. An exhibition of electric appliances was held in connection, and the army, the navy and the Red Cross were all officially represented.

**Training of Nurses in France.**—The *Journal de Médecine de Bordeaux* publishes a notice from the Florence Nightingale Training School for Nurses in that city that the American Red Cross and Vassar College have founded some scholarships at the school for the benefit of young women wishing to take the course of training. The preference will be given to daughters of physicians living at home in Bordeaux or living at the school if they come from a distance. The school gives training not only for hospital and dispensary nursing, but for home visiting nurses and supervision of schoolchildren. The stipend allowed is 110 francs per month during the two years of the course.

**German Physicians Oppose Plan to Make Them State Employees.**—The *Niederländisch Tijdschrift* states that at the forty-first annual representative meeting of the medical profession in Germany, the *Arztetay*, to be held at Eisenach, the president of the Leipzig League was to speak on contract practice; Mugdan, member of the National Assembly, on the "socialization" of the practice of medicine; Schwalbe on reform in medical education, and others on measures to repress quackery and on social insurance. The cable has reported since that the delegates voted unanimously against the government's proposal that all physicians should be made state employees. The chief argument presented against the plan is the necessity for physicians to maintain confidential relations with their patients.

**Deaths in the Profession Abroad.**—Dr. A. Rovighi, professor of medical pathology at the University of Bologna, aged 63. He has published numerous works on disease of the spinal cord and of the brain, on the murmur with stenosis of the right branch of the hepatic artery, etc., and he is said to have been the pioneer in demonstrating the cirrhosis-inducing properties of indol and skatol.—Dr. B. Brunacci, instructor in physiology at the University of Rome, aged 39.—Dr. V. Tedeschi, professor of pediatrics at the University of Padua and a leading organizer in various fields of welfare work for children, aged 65.—Dr. U. Gosselin, professor of physiology at the University of Caen.—Dr. G. Marchesi, professor of pathology at the University of Rome.—Dr. M. Gangolphe, formerly professor at the University of Lyons, aged 61.

## LATIN AMERICA

**Yellow Fever in Nicaragua.**—The sanitary authorities of Guatemala have established a quarantine against ships arriving from Corinto, Nicaragua, on account of the occurrence of several cases of yellow fever in the latter place.

**Foot and Mouth Disease in Uruguay and Argentina.**—On account of an epidemic of aphthous fever among the cattle of some of the ranches of Uruguay and Argentina, the packing houses have been compelled to reduce their operations.

**Cyclone Damages Hospital in Chile.**—The *Revista de Beneficencia Pública* of Santiago, Chile, reports that a recent cyclone destroyed one of the wards of the hospital at Chimirango, besides damaging some of the other parts of the building.

**New Hospital for Panama.**—Plans are being prepared for the new Santo Tomas Hospital, which was commenced by the republic of Panama, November 1. This institution is to be located on the leach in the suburbs of the city of Panama in the center of a tract of about 20 acres. The main building will be four stories in height and will be of concrete construction. The estimated cost of the hospital is \$600,000.

**Medical Society Meeting.**—The 174th meeting of the Ancon Medical Society was held in the administration building, Ancon Hospital, October 18. A program largely devoted to problems arising in the laboratory service of the American Expeditionary Forces was presented. Col. H. C. Clark, who was actively engaged with the Chemical Warfare Service during two years, presented a very interesting summary of his experiences.

**Deaths in the Profession.**—Dr. L. Felipe Mujica, physician in chief of the Hospital de Salvador, Santiago, Chile. He succumbed suddenly to pulmonary edema while making his rounds.—Dr. J. M. Espín of Santiago, Cuba, recently serving in the national laboratory of the public health service.—A cablegram from Rio de Janeiro announces the death of Dr. Jaime Campello, one of the most prominent Brazilian physicians.

**Municipal Drug Store.**—The officials of the Asistencia Pública de Santiago, Chile, are now considering the feasibility of founding a pharmacy to be open to the public day and night to sell drugs and fill prescriptions at cost price plus a percentage to cover costs of operating and 10 per cent. for deterioration and losses. The *Revista de Beneficencia Pública* declares that something of the kind is indispensable on account of the high prices of drugs and the increasing difficulty in controlling the practices of the present proprietors of the pharmacies.

**Smallpox in Havana.**—Although the smallpox epidemic seemed to be decreasing and the total number of cases is very small, five new cases were reported, November 5 and 6. Eighty-two blocks of the city have been quarantined. Among the several measures adopted to eradicate the epidemic, are the vaccination of all steerage passengers coming from the United States, the establishment of a quarantine against ships from New Orleans, the enforcement of compulsory vaccination in Havana, and the closing of public schools. It seems that smallpox was introduced by the merchant ship *Venezia* from Spain, one of the passengers being taken sick with smallpox thirty-six hours after landing.

## Government Services

### Personnel of the Medical Department

Up to Nov. 7, 1919, 28,269 officers had been discharged from the Medical Corps of the Army, from a total of 30,591 on active duty Nov. 15, 1918. There were 3,737 officers in the reserve corps, an increase of sixty over the previous week.

### Legislation to Increase Pay of Medical Officers

An increase of 10 per cent. in the base pay of all members of the Army and Navy Medical Corps, for both commissioned officers and enlisted men, and also for members of the U. S. Public Health Service is provided for in Senate Bill No. 3383, introduced by Senator James W. Wadsworth of New York, chairman of the Senate Committee on Military Affairs. The same measure provides for an increase in pay for the members of the Female Nurse Corps of the Army and Navy to the extent of 50 per cent. The compensation for officers on the retired lists would be computed with this increase included in their basic pay. The measure has been referred to the Senate Committee on Military Affairs for action.

### Surgeon-General Braisted Elected Fellow of the Royal College of Surgeons of Edinburgh

On October 15 Surgeon-General William C. Braisted of the U. S. Navy Medical Corps was elected an honorary fellow of the Royal College of Surgeons of Edinburgh. At the same time the Director-Generals of the British Medical Services and of the Belgian, French, Italian and Japanese medical services were honored with membership.

### MEDICAL OFFICERS, U. S. NAVY, RELIEVED FROM ACTIVE DUTY

<p>NEW YORK Brooklyn—Brahdy, L. Little Falls—Drake, N. I.</p>	<p>PENNSYLVANIA Masontown—Johnson, S. L. WASHINGTON Manette—LaMotte, H.</p>
---	---

## Foreign Correspondence

### PARIS LETTER

PARIS, Oct. 16, 1919.

#### Appropriations for French Universities

The minister of public instruction has introduced in parliament a bill covering an appropriation of 12,120,000 francs for the benefit of the universities, to be used in the construction of new buildings, for repairs to old buildings, and for the installing of scientific equipment. This demand for an appropriation is in connection with work which has already been begun but which was interrupted by the war. The institutions mainly concerned are the Universities of Paris, Nancy, Grenoble, Lille and Poitiers. The sum designated for the University of Paris exceeds 10,000,000 francs. The minister of public instruction also demands 900,000 francs in order to complete the construction work at the Institute of Applied Chemistry; 5,243,000 francs for the extension of the work of the departments of chemistry; 800,000 francs for the enlargement of the Radium Institute, and 1,500,000 francs for the construction of a laboratory of physical chemistry, etc.

#### Milk for Infants and for the Sick

The *Journal officiel* publishes the following order:

All hotels, boarding houses, restaurants, cafés, coffee-houses, dairy lunch establishments, lunch counters, canteens, tea rooms, and all other establishments serving food and beverages, are hereby prohibited, as of Oct. 15, 1919, from serving or from using fresh milk or fresh sweet cream in the preparation of any beverage, such as tea, coffee or cocoa.

In the report that precedes the text of the foregoing order, M. Noulens, minister of agriculture and of food control, explains that this measure is justified by the fact that a scarcity of fresh milk is beginning to be felt at the approach of winter, and likewise by the necessity of assuring to infants and the sick an adequate supply, since for these two classes milk is indispensable. The aforementioned establishments will, however, still be privileged to serve condensed milk. As I have already mentioned in previous correspondence, special milk tickets have been brought into use which insure preferential treatment in case there are infants, old persons or the sick to be provided for.

#### Operative Treatment of Cancer of the Cervix of the Uterus

At the first meeting of the Association des gynécologues et obstétriciens, held recently in Brussels, one of the six subjects discussed was operative treatment of cancer of the cervix.

Dr. Fougère, professor of clinical surgery at the Faculté de médecine de Montpellier, recommends, as the operation of choice in this condition the following technic: Along with the whole uterus as much of the parametrium as possible should be removed, the dissection about the uterers having been previously made. Excision of the upper part of the vagina should be done. The advantage lies with hysterectomy by the upper route, abdominal hysterectomy, or, more exactly, vaginal-abdominal hysterectomy, for the operation is begun in the vagina, keeping well away from the cervix, since by this means the vagina is excised beyond the suspected region, the raising of the uterus is facilitated, and, by first opening the vesico-uterine cul-de-sac and Douglas' pouch, the excision of the pericervical region is simplified for the abdominal stage of the operation. One must use every precaution to prevent peritoneal infection originating from the ulcerated cervical neoplasm. The surest guarantee against infection lies in closing the cervical canal by suture before the uterus is removed. The vagina should also be securely roofed over. There are two ways of accomplishing this: (1) by the abdominal route alone, the incision of the vagina being done while the ulcerated lesion is held down firmly by two stout tenaculum forceps, and (2) by the vaginal-abdominal route, the preliminary operation being begun in the vagina, a circular incision of the vagina being made and the vaginal segment of the cervix dissected away from below upward, the cervical canal is cut and securely roofed, so that when the uterus is lifted from the surrounding parts, no danger of spreading infection to the surrounding parts.

As for the matter of recurrence, these recur most frequently during the first year after the operation (more than

half of the cases; during the second year there are recurrences in 25 per cent more of the cases. So, we may say, if the patient goes three years without a recurrence the chances of recovery are good. The recurrences, moreover, appear especially frequent and rapid in cancer of the uterus in young women, in cancer in women having a hereditary taint well established, and in cancer in pregnant women.

### BELGIAN LETTER

LIÈGE, Oct. 19, 1919.

#### Meeting of Gynecologists at Brussels

In my preceding letter (*THE JOURNAL*, Oct. 18, 1919, p. 1228) I stated that Belgian physicians were gradually becoming more active. The communications addressed to the academy and the meetings of the principal medical societies were only a prelude to the activity in medical circles that the month of September was to show. From September 25 to 27, at the time the Belgian Surgical Congress was being held, the first meeting of the Association des gynécologues et obstétriciens de langue française took place in Brussels. It was a special honor conferred on our country that our capital should have been chosen for the first meetings of this pursuant society of learned men of French tongue. The variety and significance of the subjects brought up for discussion helped to give this congress a high degree of importance, for most of the current problems of gynecology and obstetrics were studied into and discussed at length. [Our Paris correspondent, in his reports published this week and last, covered most of the papers at this meeting.]

#### Indications and Technic of Hysterectomy in the Treatment of Adnexal Suppurations

Faure and Béguin, in a well illustrated report, pointed out the operative indications for hysterectomy. Leaving out of consideration acute infections that may be cured without operation, and chronic infections that can be treated by colpotomy, the uterus should be removed in the case of multiple abscesses, the Douglas pouch filled with pus, or bilateral suppurating adnexa. The authors recommend in very decided terms subtotal hysterectomy except in cases of inflamed cervix combined with suppuration, pain and the menace of carcinoma; however, such cases are rare, and the dangers of the complete removal of the uterus are infinitely greater. Faure and Béguin believe, than of the subtotal removal. The technic of the operation is based on the fundamental principles of pathologic anatomy. The adhesions are found chiefly above, in front and behind. The operation should be begun, then, with the free part, that is, from below and from within, and proceed in a forward direction. This manner of procedure affords better protection to the ureter. This point decided, there are four ways of proceeding with the operation: (1) hysterectomy by posterior or preferably anterior incision of the cervix; (2) the Kelly procedure, in which the surgeon passes from the adnexa on one side to the uterine body and thence to the adnexa on the other side; (3) the Terrier procedure; (4) bisection of the uterus in case of bilateral adherent adnexa.

The Belgian authors, Mayer, Schockaert and Henrotay, as well as Hartmann and Walther of Paris and Kecasos of Madrid, prefer complete hysterectomy in case of adnexal suppuration. All emphasize the paramount importance to be ascribed to peritonization.

#### The Value of Various Incisions Used in Laparotomies by the Gynecologist and the Obstetrician

M. Puffart of Brussels ended his report with these conclusions:

1. The median longitudinal incision, while it takes account of all the exigencies connected with the act of operation, sometimes results in hernia, and this is especially frequent when the wound heals by second intention.

2. Every median longitudinal incision should be sutured in such a manner as to permit the reinforcement of the cicatrix by the muscular tissue of the recti abdominis.

3. Extramedian longitudinal incisions which sever the muscles and disturb their nutrition through section of the nerves are contraindicated as predisposing to hernia.

4. The superiority of the transverse incision over the longitudinal incision from the anatomic and clinical standpoint will cause it to be chosen in the majority of gynecologic and obstetric laparotomies.

These conclusions provoked considerable discussion and did not receive unqualified approval. The French school especially, headed by Faure, Walther, Brindeau and Béguin, was inclined to favor the longitudinal incision.

### Protection for Women Workers

M. Keiffer of Belgium, in his report on protection for women workers, gave his hearty support to the protective measures suggested by the Academy of Medicine of Paris at its meeting of March 6, 1917. M. Levy Solal demands, in order that the protective measures may be effective, that pregnancy be made reportable by law. Every woman worker should be compelled to give up her work in the factory, or elsewhere, when pregnancy is six months advanced and while nursing her baby. In compensation she should be allowed a special indemnity by the state. Medical surveillance of the homes should be organized, and deserted women should be given ample protection. In order to carry out these ideas, institutions should be established where mother and child might be hospitalized.

### A Successful First Meeting

This first meeting of the Association des gynécologues et obstétriciens de langue française, held in Brussels, was crowned with success and may doubtless be taken as a harbinger of the rebirth of scientific activity in our country.

### LONDON LETTER

LONDON, Oct. 15, 1919.

#### The Prevention of Venereal Disease

As previous letters to *THE JOURNAL* show, the prevention of venereal disease has been under discussion for some time. The ministry of health has decided that the official recognition of self-disinfection in civilian venereal disease is neither desirable nor practicable, but recommends the establishment of centers for delayed disinfection. This attitude has provoked a protest in the *Times* from a number of leading physicians who have formed themselves into a venereal prevention committee. They point out that provision of centers for delayed disinfection can never be adequate. The London County Council, the greatest urban authority in the country, has rejected the scheme. No method is even suggested that could work in rural districts. The committee maintains that venereal disease is preventable by immediate disinfection; that authoritative teaching on the subject is urgently required, and that the means, together with approved instructions for their use, should be readily accessible to the public. They fail to recognize any moral distinction between the provision for delayed disinfection at centers and the provision for immediate self-disinfection. One of the members of the committee, Sir Archdall Reid, has put forward in the *Times* the proposal that "brief and clear instructions for swift personal disinfection shall be posted in public lavatories." He is also publishing a book on the medical prevention of venereal disease in which he says: "Instructions, of which the really effective part was conveyed by posters, were given to soldiers inhabiting a group of barracks in a large seaport. The force usually present averaged 2,000, and 20,000 passed through these barracks in two years. Not one man who followed instructions acquired disease, and only seven men, all of whom failed to follow instructions, acquired disease. The rate of infection was therefore 1.75 per thousand per annum. In a still larger naval unit not one man who followed instructions acquired disease, and only one man failed to follow instructions. In a large military hospital for venereal diseases not one man of all those who passed through it had acquired disease after immediate disinfection, but nearly every patient had practiced 'early treatment.' In India and South Africa, results equally remarkable have been achieved by the same simple and inexpensive method. I believe there is not on record a single instance of the failure of the method of quick disinfection. The operation is actually about as difficult and dangerous as washing the hands with soap and water." The method referred to is careful sponging with a solution of 1:2,000 potassium permanganate. Sir Archdall Reid considers that more elaborate methods, such as urethral injections and the use of calomel ointment, are unnecessary.

#### Crowded Medical Schools

Students released from army service are flocking to the universities, some of them as freshmen, others to resume studies interrupted by the war. The number of medical students is particularly large, and in some cases in excess of the accommodations. In London the average attendance before the war was between 1,400 and 1,500; this session has begun with 2,000. In addition to men demobilized from the army, freshmen have come from all parts of the world. The accommodations are generally sufficient, but some schools

are unusually crowded. In Edinburgh the session is a record one in point of attendance. The rush of students has been so great that 300 have had to be refused admission. During the war, women students flocked to the university; last year half of the medical students were women. The authorities realize the need for expansion of the buildings, and schemes are in hand for erecting a new chemical department and also for the establishment of a Lister institute for pathologic teaching. In Glasgow the accommodations are taxed to the utmost. New enrolments cannot be accepted for the winter session except in the case of students returning to their studies from active service.

#### Women Physicians

There are now over 2,250 women studying medicine in this country—an enormous increase over the number before the war. There are over 1,000 women physicians in practice, and the prospect is that at the end of five years the number will be doubled, which opens the prospect of overcrowding.

#### Scottish Vital Statistics

The vital statistics of Scotland for the year 1917, which have just been issued, are remarkable. The birth and death rates were the lowest recorded. The births registered numbered 97,441, which was less than in all years since 1856. The birth rate of the year was 20.07 per thousand. Marriages registered 30,482, which number was 2,180 less than the mean of the preceding ten years. The marriage rate of the year was 6.28 per thousand, which was 0.62 below the mean of the preceding ten years, and was the lowest Scottish marriage rate since 1887. Deaths registered numbered 69,483, which was 5,017 less than the mean of the ten preceding years. The death rate of the year was 14.31 per thousand, as already stated, the lowest rate recorded. The infant mortality rate of the year was 107.5 per thousand births, being 3.4 below the mean of the ten preceding years. An endeavor was made to verify the ages of all reputed centenarians whose deaths were registered. There were six deaths during the year, and in two of them satisfactory proof of the attainment of the age of 100 was obtained. The number of deaths attributed to typhoid, diphtheria and tuberculosis was smaller in 1917 than in any previous year. Deaths from malignant diseases were more numerous than in previous years.

#### The Influenza Epidemic in Scotland

The total number of deaths ascribed to influenza during the epidemic in Scotland in the latter part of 1918 and the earlier part of this year was 17,575, a figure which includes not only those deaths of which influenza was the sole named cause, but also those deaths of which influenza was one of two or more named causes, the latter being by far the more numerous. Deaths from influenza and pneumonia in association numbered 11,236 out of the total of 17,575. The mortality from the epidemic greatly exceeded in amount those of epidemics of other infectious diseases, and a large part was among adults, fully 50 per cent. occurring between the ages of 15 and 44, and 23 per cent. between the ages of 25 and 34.

## Marriages

PAUL PERROT, French Army Medical Corps, to Miss Norman Derr of Atlanta, Ga., at Clifton Springs, N. Y., November 3.

REUBEN ANTHONY McBRAVER, Sanatorium, N. C., to Miss Louise Ludlow of Winston-Salem, N. C., November 7.

JAMES A. DUGGAN, South Bend, Ind., to Miss Alma Gehhardt Stevenson of Maplewood, N. J., October 30.

GEORGE J. HERMANN, Newport, Ky., to Miss Catherine Nordwieh of Alexandria, Ky., October 22.

SOL BERNARD KOSITCHER, Chicago, to Miss Josephine Kapp, at Battle Creek, Mich., October 30.

WILLIAM PENN VAIL, Philadelphia, to Miss Virginia Moore of San Diego, Calif., October 1.

JOHN LEONARD KANTOR to Miss Ina Duff Downes, both of New York City, October 20.

LOUIS S. DUNN, Chester, Pa., to Miss Sari Rosenberg of New York City, October 28.

FRANK MILAN BARNES, Abilene, Neb., to Miss Ruth Purch, at Landers, Wyo., October 8.

LOUIS SAVITT to Miss Bess Sparberg, both of Chicago, October 26.

## Deaths

John Young Brown \* St. Louis; Bellevue Hospital Medical College, 1887; aged 54; major, M. C. U. S. Army; who served as a member of the General Army Medical Board; city physician of Henderson, Ky., from 1887 to 1891; assistant superintendent of the Central Kentucky Asylum for the Insane from 1891 to 1894; chief surgeon of the Louisville, St. Louis and Texas Railroad; professor of surgery in the St. Louis University; chief surgeon to St. Johns Hospital; surgeon in charge of the St. Louis City Hospital from 1903 to 1907; president of the Mississippi Valley Medical Association of Obstetricians and Gynecologists, Southern Surgical and Gynecological Association and St. Louis Surgical Club; died in Phoenix, Ariz., October 30, from heart disease.

Thomas Barker Eastman \* Indianapolis; Central College of Physicians and Surgeons, Indianapolis, 1893; a son of Joseph Eastman, the pioneer gynecologist of the Middle West; died, November 10, from carcinoma; aged 50. He was a member of the American Association of Obstetricians and Gynecologists; professor of abdominal surgery and diseases of women in his alma mater, and later clinical professor of gynecology in the Indiana University School of Medicine, Indianapolis; gynecologist to the Indianapolis City Hospital; surgeon to the Joseph Eastman Hospital; also a member of the staffs of the Methodist and Deaconess hospitals. He was appointed a member of the Indianapolis City Board of Health in 1914.

Clinton Palmer Meriwether \* Little Rock, Ark.; Missouri Medical College, St. Louis, 1893; aged 45; secretary of the Arkansas Medical Society; and a member of the House of Delegates of the American Medical Association from 1916 to 1919, inclusive; professor of operative surgery and rectal diseases in the College of Physicians and Surgeons, Little Rock; major, M. C. U. S. Army, and honorably discharged, Jan. 4, 1919; who had been ill at the Arkansas Tuberculosis Sanatorium, Booneville, for several months; died at his home, Novem<sup>r</sup> 2, from tuberculosis.

Henry Kemble Oliver, Boston; Harvard University Medical School, 1855; aged 89; medical in pector of camps under the United States Sanitary Commission during the Civil War; one of the visiting physicians to the Massachusetts General Hospital, and also a member of the staff of the department of laryngology; at one time lecturer on diseases of the throat in his alma mater; who endowed the Henry K. Oliver Foundation for the department of hygiene of Harvard University; died, October 25.

Francis Valk \* New York City; New York University, 1878; aged 74; a fellow of the New York Academy of Medicine, and a member of the American Academy of Ophthalmology and Oto-Laryngology; a veteran of the Civil War; consulting surgeon to Thrall Hospital, Middletown, N. Y.; surgeon to the Randall's Island Hospital; a consultant surgeon at the Manhattan Eye and Ear Hospital; ophthalmologist to the New York Dispensary; died in St. Luke's Hospital, New York City, November 5.

Michael B. Corrigan, Monticello, Ark.; University of Edinburgh, Scotland, 1871; aged 67; president of the Drew County Medical College; health officer of Drew County; formerly a major, R. A. M. C., with service in India and Africa; for ten years surgeon in the Royal Navy; also a clergyman of the Methodist Episcopal Church; died, October 24, from nephritis.

William Lincoln Shindel \* Sunbury, Pa.; Medico-Chirurgical College of Pennsylvania, Philadelphia, 1893; aged 52; formerly president of the Northumberland County Medical Society; surgeon to the Mary M. Packer Hospital, Sunbury, and physician to the Northumberland County Prison; a specialist in proctology; died, October 26, from kidney disease.

William H. Judd, Janesville, Wis.; Bennett Eclectic Medical College, Chicago, 1883; aged 65; once president of the Rock County, Wis., Medical Society, for five terms a member of the city council, and at one time its president and acting mayor of Janesville; was struck by an automobile, October 25, and died in Mercy Hospital, October 26.

Charles Fremont Taylor, Philadelphia; Central College of Physicians and Surgeons, Indianapolis, 1889; aged 63, a member of the Medical Society of the State of Pennsyl-

\* Indicates "Fellow" of the American Medical Association.

vania; editor of the *Medical World* since 1883; editor and publisher of *Equal*, a quarterly periodical; died at his home, November 4, from disease of the heart and kidney.

**Chauncey W. Courtright** \* Chicago, Cleveland University of Medicine and Surgery, 1877; Northwestern University Medical School, Chicago, 1887; aged 69; a member of the staff of the Englewood, Washington Park, Lakeside and Fort Dearborn hospitals; died, November 9, from carcinoma of the bladder.

**Charles Elbert Woody**, Springfield, Mo.; Kentucky School of Medicine, 1893; aged 58; for several years physician of Green County; for one term health commissioner of Springfield; clerk of the criminal court of Green County from 1910 to 1914; died in a hospital in Nevada, Mo., October 25.

**James Knox Polk Gleason**, Washington, D. C.; George Washington University, Washington, D. C., 1869; aged 75; a member of the Medical Society of the District of Columbia; a veteran of the Civil War; died in the Takoma Park (D. C.) Sanitarium, October 23.

**James Welch** \* Tampa, Kan.; College of Physicians and Surgeons, Kansas City, Kan., 1903; aged 50; a veteran of the Spanish American War; commissioned first lieutenant, M. C., U. S. Army, in recent war; died suddenly in his office, October 16, from heart disease.

**Algernon Sydney Garnett** \* Hot Springs, Ark.; Jefferson Medical College, 1856; aged 80; a pioneer practitioner of Hot Springs; said to have been the last survivor of the crew of the Confederate steamship, *Merrimac*; died, October 30.

**Charles Wilbur Patton** \* Laurel, Iowa; State University of Iowa, Iowa City, 1910; aged 38; who was honorably discharged as first lieutenant, M. R. C., Dec 7, 1918; died, recently, from an overdose of a poisoning drug.

**Joseph A. Richmond**, Bellevue, Ky.; University of Nashville, Tenn., 1908; aged 37; a member of the Kentucky State Medical Association; died at his home, October 21, from tetanus, due to a punctured wound of the foot.

**John Frederick Beiermeister** \* Rochester, N. Y.; Albany (N. Y.) Medical College, 1910; aged 32; who served as first lieutenant, M. C., U. S. Army, during the world war; died in his office, October 24, from angina pectoris.

**Clinton Brotemarkle**, Salisbury, Md.; College of Physicians and Surgeons, Baltimore, 1881; aged 59; a specialist in diseases of the eye, ear, nose and throat; died in a sanatorium in Philadelphia, about October 23.

**Arthur George Patterson** \* Lisbon, N. D.; Trinity Medical College, Toronto, Ont., 1889; aged 54; died in the Heron Memorial Hospital, Chicago, October 22, from pneumonia following cholecystectomy.

**Miller Young**, North Liberty, Iowa; Jefferson Medical College, 1873; aged 74; president of the Farmer's Savings Bank, North Liberty; died at Young's Station, near North Liberty, October 25.

**Robert H. Jenkins**, Hovansville, Ga.; University of Louisville, Ky., 1871; aged 68; also a pharmacist; once representative to the Georgia legislature; died, October 14.

**Charles L. Swimley**, Roll, Okla.; Starling Medical College, Columbus, Ohio, 1895; aged 50; died suddenly, from heart disease in Strong City, Okla., October 14.

**James Alexander Smart**, Fort Covington, N. Y.; New York University, New York City, 1882; aged 61; died, September 24, from chronic nephritis.

**Robert Richard Lawrence** \* Hartford, Mich.; University of Michigan, Ann Arbor, 1875; aged 69; died, September 10, from chronic nephritis.

**Eugene Jackson Smith**, Harlan, Iowa; Rush Medical College, 1872; aged 70; was found dead in bed in a hotel in Harlan, October 21.

**Thomas Primmer** \* Centralia, Wash.; Trinity Medical College, Toronto, Ont., 1886; aged 65; died, September 4, from heart disease.

**Daniel G. Smith**, Arkoe, Mo.; American Medical College, St. Louis, 1877; aged 72; died in a hospital in St. Joseph, Mo., October 14.

**Charles E. Newcomb**, Grantham, N. H.; University of Vermont, Burlington, 1880; aged 63; died, October 1, from heart disease.

**John M. Gass**, Knoxville, Tenn.; University of Tennessee, Nashville, 1882; aged 83; also a clergyman; died, October 16.

**George Vincent Hudson**, Brooklyn; New York University, New York City, 1867; aged 76; died, October 24.

## The Propaganda for Reform

IN THIS DEPARTMENT APPEAR REPORTS OF THE JOURNAL'S BUREAU OF INVESTIGATION, OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORY, TOGETHER WITH OTHER MATTER TENDING TO AID INTELLIGENT PRESCRIBING AND TO OPPOSE FRAUD ON THE PUBLIC AND ON THE PROFESSION.

### "PHYLACOGENS"

A physician in Florida writes:

"I am enclosing a copy of a circular letter just received from Parke, Davis & Company, and will call your attention to a marked paragraph in this letter on which I would like to have an expression of your opinion."

The circular letter which the doctor forwards is devoted to singing the praises of "Pneumonia Phylacogen." It opens with the statement: "Influenza, we learn, has appeared in your section." The paragraph marked by our correspondent reads:

"Pneumonia Phylacogen has been found to be a dependable means of preventing and treating pneumonic complications of influenza. In one large city it became a routine measure to give all persons affected with influenza an injection of Pneumonia Phylacogen as a prophylactic of pneumonia. The results were remarkable. Not only did the cases improve rapidly, but in a great majority of them the pneumonia did not occur."

The "Phylacogens" were repeatedly discussed in THE JOURNAL during 1913 and 1914 when these products were being pushed with much vigor by the manufacturers. We know of no evidence that calls for a revision of the statements then made regarding them. The injection of phylacogens is simply the administration of a mixture of the filtered products of several bacterial species. The results which follow represent the reaction of the bacterial protein—a reaction for good or evil. There is no scientific evidence to show that they possess any specific prophylactic virtue. To recommend their use in patients with influenza, as a prophylactic against pneumonia, is unwarranted, and the physician who acts on the advice of the manufacturer must assume the responsibility for the results. In case of mishap he cannot fall back on the manufacturer; he will find no scientific evidence to support him.

### ACRIFLAVINE AND PROFLAVINE, N. N. R.

#### Conclusions to Be Drawn from a Study of the Literature\*

REPORT OF THE COUNCIL ON PHARMACY AND CHEMISTRY

Acriflavine and proflavine have been accepted for New and Nonofficial Remedies. A description of these drugs, with a discussion of the uses and dosage and tests of identity and purity was published in the New and Nonofficial Remedies Department of THE JOURNAL, Nov. 8, 1919, page 1443. The following report briefly summarizes the literature at present available on these drugs. The abstracts themselves occupy too much space to appear in THE JOURNAL, but will be printed in pamphlet form. This pamphlet will be sent to any physician on receipt of a self-addressed, stamped envelop.

W. A. PUCKNER, Secretary.

It has been known for some time that certain dyes possess bactericidal and amebicidal properties, while others have no effect as antiseptics or germicides. After this discovery was made, chemical research was begun in the effort to produce substances which should have higher bactericidal potencies than those already known. In these studies it was found that certain of the acridine derivatives were especially active as amebicides. Acridine is a substance first obtained from coal-tar. Some of its derivatives have been known and used as dyes for many years, certain of them being known as flavines because of the yellow color they impart to fabrics.

\* The matter published in THE JOURNAL is in pamphlet form and will be sent to physicians on receipt of a stamped, addressed envelop.

Most of the acridine derivatives have no amebicidal properties; but, as already stated, there are some marked exceptions. One of these (diamino-methyl acridine chloride) was found by Ehrlich to have notable therapeutic effects in trypanosome infections and, on this account, he called it "Trypallavine." Most of the studies on this substance, both bacteriologic and clinical, have been conducted by English investigators, who call it "Acridiflavine." A closely related substance having similar properties is "Proflavine." Acridiflavine and proflavine are claimed by some to have high anti-septic power, together with freedom from toxic or irritant action and without inhibiting effects on the phagocytic action of the leukocytes or on the healing processes. Acridiflavine and proflavine have been extensively used in the treatment of wounds, and acridiflavine has been highly praised in the treatment of gonorrhoea.

In view of the interest manifested in the therapeutic properties of acridiflavine and related compounds, as evidenced by numerous inquiries from physicians to the Council on Pharmacy and Chemistry, the Council has deemed it worth while to prepare and publish an abstract of the available literature on the subject.<sup>1</sup> Tentative descriptions and standards for acridiflavine and proflavine are published in New and Non-official Remedies for the information of manufacturers, pharmacists and physicians.

It should be borne in mind that the therapy of these dyes is still in the experimental stage. The evidence at present available does not permit a determination of their value in the treatment of wounds, trench fever, or gonorrhoea. A number of papers have been omitted purposely from this abstract of the literature because they presented no additional contribution to the knowledge of the dyes or their therapeutic properties.

#### SUMMARY

A review of the literature abstracted shows that of the thirty-four reports twenty-five, or 73 per cent., may be considered as favorable. Seven, or 20 per cent., are distinctly unfavorable, and two, or 7 per cent., are in the negative or doubtful class. Of the favorable reports, eight are based for the most part on bacteriologic studies or are of a discursive nature, fourteen are based principally on clinical trials, and three appear to be deduced from a combination of bacteriologic and clinical methods. Of the unfavorable and doubtful reports, five are based on bacteriologic studies and four on clinical trials. Because of the contradictory nature of the reports and the conflicts in the clinical evidence, it would appear that judgment as to the therapeutic value of the flavine dyes should be suspended pending further study.

#### MEDINAL

##### Report of the Council on Pharmacy and Chemistry

The Council has authorized publication of the following report on Medinal (Schering and Glatz, Inc.).

W. A. PUCKNER, Secretary

Medinal is a proprietary name applied to barbital sodium (sodium diethylbarbiturate) the sodium salt of barbital (diethylbarbituric acid). The latter was first introduced as Veronal.

Medinal was deleted from New and Nonofficial Remedies in 1916 because the advertising issued by Schering and Glatz (who then acted as agents for Chemische Fabrik auf Aelchen vorm. E. Schering, the German manufacturer) contained misleading and unwarranted therapeutic claims. The Council did not publish its report because by the time the report was ready for publication the product was practically off the American market, and it was hoped that when Medinal again became available, Schering and Glatz would revise the claims and thus permit its acceptance.

Medinal, said to be manufactured in the United States, is now marketed by Schering and Glatz, Inc. In October, 1918, the firm sent to the Council a typewritten copy of a

proposed circular for Medinal. The firm was informed that this leaflet was subject to the objections that had been raised when Medinal was deleted from New and Nonofficial Remedies. In April, 1919, the firm submitted a printed circular which it was sending out. This contained numerous misleading statements, among them, these:

"MEDINAL removes its [diethylbarbituric acid] one objectionable feature—insufficient solubility—and thus fulfills the three prerequisites of a truly rational hypnotic: Quick absorption, insuring prompt action, rapid and complete excretion, affording protection from cumulative toxic after effects, and the choice of rectal and subcutaneous administration."

There is no justification for the claim that diethylbarbituric acid (barbital) has only one objectionable feature and that a minor matter of "insufficient solubility." The Council has called the attention of Schering and Glatz, Inc., to the fact that the difference in the time of absorption between Medinal (barbital sodium) and barbital is, at the most, but one of minutes and that there is no evidence that Medinal is excreted more rapidly than barbital. Hence the claims that the danger of toxic side-actions and that cumulative after effects are avoided in this product, are wholly unwarranted.

It is also claimed, and the claim is unsupported by satisfactory evidence, that Medinal is useful in the insomnia of tuberculosis in which condition it is said to have a double advantage owing to its favorable effects on the night-sweats. It is claimed that Medinal is used in the withdrawal treatment of morphin addiction with great success; there is no evidence that Medinal has any special usefulness in this treatment of the morphin habit. It is claimed further that success has been reported with Medinal in the treatment of whooping cough. The Council knows of no satisfactory evidence to show that Medinal is of special value in whooping cough; on the contrary, it is capable of doing a great deal of harm. The recommendations that Medinal be used for the control of labor pains and in acute neuralgic pains that resist other forms of treatment are wholly unwarranted as the value of the drug in such conditions is inherently improbable and until satisfactory evidence in support of them is forthcoming, must be deemed misleading.

## Correspondence

### "DESENSITIZATION OF PERSONS AGAINST IVY POISONING"

To the Editor:—Under the subject, "Desensitization of Persons Against Ivy Poisoning," THE JOURNAL, Nov. 1, 1919, p. 1382, L. E. Warren of Chicago cites a dosage of a non-volatile resin as "0.001 mg." As printed, that spells one one-thousandth milligram or one one-millionth gram—rather a small dosage to juggle with, but perhaps large enough under the circumstances. But what I started to say was, Did he really mean 0.001 mg. or did he mean 1 milligram (0.001 gm.)? I have noted this apparent (to me) error in different articles and wondered whether or not I was reading comprehensively. Kindly advise me.

A. L. MANN, M.D., Elgin, Ill.

[The foregoing letter was referred to Mr. Warren, who replies.]

To the Editor:—The statement referred to by Dr. Mann, which is due to Dr. Franz Pfaff, formerly of the Harvard Medical School, is quoted correctly as printed. Several years ago I attempted (*Pharm. J.* 83:562, 1909) to verify Dr. Pfaff's experiments, using the purified resin from the poison sumach instead of that from the poison ivy (the two poisons are believed to be identical). These attempts to obtain an exact quantitative limit to the amounts which would produce symptoms were discouraging, probably from want of a sufficiently sensitive subject on which to make the tests. The fact was verified, however, that the substance is poisonous in extremely minute quantities—far less than 0.001 gm. The minute dosage is obtained by suitable dilutions in alcohol.

L. E. WARREN, S. Chicago.

1. The abstract will be sent to any physician on receipt of a self-addressed, stamped envelope.

## PREPARATION OF DICHLORAMIN-T

To the Editor—I believe I have found a simpler method for preparing dichloramin-T than that described on the packages put out by the pharmaceutical houses. My method is:

Weigh out amount of powdered dichloramin-T, place in mortar and rub up with small amount of chloroform (carbon tetrachlorid may be used) until all is dissolved, then add chloroacetic to the dissolved dichloramin-T. The chloroform is easily evaporated and thus leaves the dichloramin in solution in the solvent. By this method can be prepared a fresh solution of dichloramin-T in a few minutes, whereas the heat and cold methods take a much longer time. In the heat method, there is danger of overheating, in which a precipitation is caused, which renders the dichloramin-T useless and very irritating.

V. J. ANDERSON, M.D., Chicago.

[COMMENT—We can see no advantage over the heat method, if the chloroform or carbon tetrachlorid must be removed by evaporation. However, the use of carbon tetrachlorid (10 per cent) has been recommended for lowering the viscosity of the chloroacetic (Dakin and Dunham: Solvents for Dichloramin-T, *Brit. M. J.* 1:51 [Jan. 12] 1918); therefore Dr. Anderson's note suggests the possibility of first dissolving the dichloramin-T in carbon tetrachlorid, and then adding the proper amount of chloroacetic to make the solution of the desired strength.—Ed.]

## "THE CAUSE OF INFLUENZA AND ITS BEARING ON TREATMENT"

To the Editor—In the current comment with this title (*THE JOURNAL*, Nov. 1, 1919, p. 1367), the work of Bradford, Bashford and Wilson (*Quart. J. Med.* 12:259 [April] 1919) is mentioned as the most convincing work on the filtrable virus of influenza. Evidently the writer of this comment had failed to see the paper of Arkwright (*A Criticism of Certain Recent Claims to Have Discovered and Cultivated the Filter-Passing Virus of Trench Fever and of Influenza*, *Brit. M. J.* 2:233 [Aug. 23] 1919) and the notes appended thereto by Sir John Rose Bradford (p. 236) and Capt. J. A. Wilson (p. 237). In these notes Bradford and Wilson withdraw the claim that their work has proved that the filter-passing organisms of the diseases in question have been grown in pure culture. The action of these authors in publicly withdrawing their claim is as commendable as it is unusual in scientific controversy. In fairness to them it would seem that their retraction should receive publicity at least as prominent as the discredited work for which they no longer vouch.

WARD J. MACNEAL, M.D., New York.

## "THE RANGE OF THE GENERAL PRACTITIONER IN PSYCHIATRIC DIAGNOSIS"

To the Editor—I have just read Dr. Southard's article in *THE JOURNAL*, October 25. I like to read and hear psychiatrists and neuropsychiatrists. It reveals stupidity, leads to investigation, and results in humiliation, and then there is hope for regeneration.

Why all this esotericism? Here in this astonishingly uninformative report made, it was discovered, by one of the best of our former psychopathic hospital interns, is the phrase, "diagnosis of a somatopsychic character." I went to my second dictionary, a good one of recent issue, to find the word "somatopsychic," but it was not there. I consulted the *Century* and Webster, the very latest editions, with the same disappointing result. Now I should like to know just what and if it is that has a "somatopsychic character." Do these people have a little etymological dictionary that they keep chained to the desk in the inner recesses of some sanctum sanctorum? Again, why this word "disoriented"? Bishop Whately would say confused, and he is not bad authority. This pedantic terminology affected by some writers makes me tired.

If some of these writers would read Professor James a little more and supplement that with a little book not read

much in this country, written by an Englishman under the title of "The New Word," we bungling provincial general practitioners might be benefited a little in our ideation and orientation.

O. I. HESS, M.D., Scottsdale, Pa.

## Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

## EFFICACY OF VACCINES IN PREVENTING INFLUENZA

To the Editor—Although there is no vaccine recognized as a real prophylactic against influenza, will you kindly say which, in your opinion, is the best one to try, and where it can be obtained? I presume influenza will probably come to this district again, if one can judge by past epidemics. I shall very greatly appreciate your valuable advice on this matter.

J. A. STANBING, M.D., El Paso, Texas.

Medical Director, Southern Baptist Sanatorium  
for the Treatment of Tuberculosis.

ANSWER.—The efficacy of vaccines in preventing influenza was discussed in an editorial in *THE JOURNAL*, Oct. 4, 1919, p. 1064. It was there pointed out that when the available data on the results attained by prophylactic injections of various combinations of vaccines are carefully analyzed, the conclusion seems unavoidable that their value in the prevention of influenza is unproved. The question may then be raised whether vaccination has any value in preventing respiratory infections either primary or secondary to influenza, or in ameliorating their severity in case they are not prevented. It is understood that there are at present under way in various parts of this country certain investigations which it is hoped will furnish data in answer to this question. One factor in this problem which no doubt will be taken into consideration, but on which there has been thus far but little emphasis laid, is the diversity of the pathogenic organisms which are found in the pneumonias following influenza in different parts of the country. In one region a high percentage of Pfeiffer bacilli is found, and in another a very low one; in other places streptococci predominate and in still others pneumococci, and even in the same community the dominant group of organisms today is often not that of six months ago. It is thus evident that, granting that a vaccine adjusted to one locality should turn out to be effective, it would not necessarily be equally valuable elsewhere. Much has been written, but the number of adequately controlled reports is very small. Thus far hope and imagination have exceeded scientifically controlled facts. Many vaccines come highly recommended by their manufacturers, but very little dependable evidence is submitted to show just how much, if at all, the patient will profit therefrom. If the patient desires to try the experiment knowing it to be such, there is perhaps no serious objection to the trial. Under such circumstances, just which vaccine is "the best one to try" we are not at this time in a position to advise.

## ALCOHOL IN PRESCRIPTIONS

To the Editor—In writing a prescription for alcohol, and placing the patient's name and the purpose for which it is used on the prescription, is the pharmacist compelled to put a little phenol or other poison in it or can he dispense the alcohol pure? Kindly omit name.

J. A. M.

ANSWER.—Whether denatured alcohol is used in filling a prescription depends on whether the prescription is for internal or external use and on what kind of alcohol the prescription specifies. Alcohol can be prescribed like any other drug. The strength and degree of purity is usually indicated on the prescription. Nauseabeverage alcohol, medicated or denatured so as to be unfit for beverage purposes, may be used for filling prescriptions if so indicated. Physicians' prescriptions calling for alcohol must be in duplicate, must be signed by the physician, and must be for a patient under the constant personal supervision of the physician. The prescription must give the name and address of the patient and the condition for which prescribed, and the name of the pharmacist to whom the prescription is to be presented for filling. The physician must keep a record giving a separate page to each patient and must enter it under the patient's name and address, the date of each prescription, the amount and kind of liquors dispensed, and the name of the pharmacist filling the prescription.

### COMING EXAMINATIONS

**DELAWARE:** Dover, Dec. 9-11. Sec., Regular Board, Dr. P. S. Downs. Dover. Sec. Homeopathic Board, Dr. H. W. Howell, 824 Washington St., Wilmington. Pres. Medical Council, Dr. Henry W. Briggs, 1026 Jackson St., Wilmington.

**FLORIDA:** Jacksonville, Dec. 15-16. Sec., Dr. G. A. Manch, 1306 Franklin St., Tampa.

**FLORIDA:** Tampa, Dec. 1-2. Sec., Regular Board, Dr. Wm. M. Rowlett, Citizens' Bank Building, Tampa.

**ILLINOIS:** Chicago, Dec. 1-3. Mr. F. C. Dodds, Supt. of Registration, Springfield.

**IOWA:** Des Moines, Dec. 16-18. Sec., Dr. Guilford H. Sumner, Central Bldg., Des Moines.

**KENTUCKY:** Louisville, Dec. 2. Sec., Dr. A. F. McCormack, 532 W. Main St., Louisville.

**LOUISIANA:** New Orleans, Dec. 1-3. Sec., Regular Board, Dr. E. W. Mahler, 141 Elk Place, New Orleans.

**MARYLAND:** Baltimore, Dec. 9-12. Sec., Dr. J. McP. Scott, 137 W. Washington St., Hagerstown.

**OHIO:** Columbus, Dec. 2-4. Sec., Dr. H. M. Platter, State House, Columbus.

**TEXAS:** Galveston, Nov. 18-20. Sec., Dr. M. F. Bettencourt, Mart Texas.

**VIRGINIA:** Richmond, Dec. 9-12. Sec., Dr. J. W. Preston, 511 McBain Bldg., Roanoke.

### Alabama July Examination

Dr. Samuel W. Welch, chairman of the Alabama State Board of Medical Examiners, reports the written examination held at Montgomery, July 8-11, 1919. The examination covered 10 subjects and included 100 questions. An average of 75 per cent. was required to pass. Of the 22 candidates examined, 18 passed, and 4 failed. Ten candidates were licensed by reciprocity. The following colleges were represented:

College	PASSED	Year	Per Cent.
Birmingham Medical College	(1913) 76.3,	(1918)	75.8
University of Alabama	(1919) 85.5,	86.8

**THE STUDENT'S TEXTBOOK OF SURGERY.** By H. Norman Barnett, F.R.C.S., Major, and Officer Commanding 32d South-Western Mounted Brigade Field Ambulance. Cloth. Price, \$7.50. Pp. 794, with 143 illustrations. St. Louis: C. V. Mosby Company, 1919.

It is frequently difficult to give a just appraisal of a book, and there is always danger of doing an injustice to the author by allowing a few minor faults to warp our judgment so that a really meritorious product fails to receive just appreciation. Nevertheless, works that are intended as models for students and as authoritative sources of information for the general profession must maintain a high standard; inaccuracy and dogmatic dismissal of accepted belief cannot be tolerated; and truth must not be sacrificed for the sake of brevity. This book is a British book, and in its failure to appreciate the contributions of American investigators, is a typical expression of the European state of mind. In most sections the work is excellent; in others, we miss much that has seemed of importance. For instance: In the discussion of the treatment of burns, the picric and boric acid methods receive brief attention to the exclusion of all others. In the section of surgical infections, we look in vain for mention of blastomycosis, sporotrichosis and coccidioidal granuloma. Shock is said to be due to exhaustion of the vaso motor center, although physiologists have shown that in experimental shock the vasomotor center is not exhausted. Pancreatitis is described as being always due to infection of the pancreas, this in spite of the fact that at least 50 per cent. of pancreatic abscesses are sterile, and without regard to the work of Flexner, Opie, Archibald and others showing the extreme toxicity of pathologic bile when regurgitated into the pancreas. Cholecystotomy is mentioned as the method of choice in the treatment of the great mass of surgical gallbladders, regardless of the fact that in most of the great American clinics cholecystectomy is the rule. For the man who has sufficient knowledge of surgery to read with discrimination, this book may be of considerable value; for the student, for the man who is just beginning the study of surgery, it were wiser to choose a more catholic guide.

**DYKE'S AUTOMOBILE AND GASOLINE ENGINE ENCYCLOPEDIA.** Containing 532 Charts, Inserts, Dictionary, Index, and Supplements on the Ford, Packard, Airplanes, and Liberty "12" Engine. Treating on the Construction, Operation and Repairing of Automobiles and Gasoline Engines. Also Trucks, Tractors, Airplanes, and Motorcycles. By A. L. Dyke, E.E. Tenth edition. Cloth. Price, \$5. Pp. 940, with 3,262 illustrations. St. Louis: A. L. Dyke, 1919.

This book is what its title expresses, and contains excellent diagrammatic plates of the various automobiles, engines, ignition systems, carburetors, etc. Special attention is devoted to the Ford car. For instance, the book states how to rebuild a Ford so that it will go sixty miles an hour—if one has the courage to make that speed in a Ford. It also illustrates the new electric system of this car. A thorough search, however, fails to reveal any methods for making the back seat comfortable or cutting out the rattle. To the physician whose automobile is as essential in his work as is his stethoscope, sphygmomanometer or thermometer, this book will be found useful.

**PSYCHIATRIC NEUROLOGIC EXAMINATION METHODS WITH SPECIAL REFERENCE TO THE SIGNIFICANCE OF SIGNS AND SYMPTOMS.** By Dr. ARND WIMMER, Director St. Hans Hospital, Roskilde, near Copenhagen. Denmark. Authorized Translation by Andrew W. Hosholt, M.D., Medical Superintendent, Napa State Hospital. Cloth. Price, \$2. Pp. 177, with illustrations. St. Louis: C. V. Mosby Company, 1919.

The author presents a systematic method for examining patients with neurologic or psychiatric disturbances. The book is instructive in that it gives numerous suggestions as to what to look for and how to describe what is seen or found. The language of neurology contains numerous trade terms with which the average general practitioner is usually wholly unfamiliar; e.g., "muscatating delirium," "motor stereotypy," "carphology." Those working in this field must of course familiarize themselves with this terminology. The translation is good, and the book a useful one.

### Power to Exclude Defective Child from Schools

*State ex rel. Beattie v. Board of Education of City of Antigo (Wis.), 172 N. W. R. 183*

The Supreme Court of Wisconsin, in this action of mandamus brought to compel the defendant board of education to reinstate and admit the petitioner's son to the public schools of the city, reverses a judgment that was rendered in favor of the petitioner, and remands the cause with instructions to dismiss the petition. The court says that the boy had been a crippled and defective child since his birth, being afflicted with a firm of paralysis which affected his whole physical and nervous make-up. He had not the normal use and control of his voice, hands, feet and body. He was slow and hesitating in speech, and had a peculiarly high, rasping and disturbing tone of voice, accompanied with uncontrollable facial contortions, making it difficult for him to make himself understood. He also had an uncontrollable flow of saliva which dribbled from his mouth on his clothing and books, causing him to present an unclean appearance. He had a nervous and excitable nature. It was claimed, on the part of the school board, that his physical condition and ailment produced a depressing and nauseating effect on the teachers and schoolchildren; that by reason of his physical condition he took up an undue portion of the teacher's time and attention, distracted the attention of other pupils, and interfered generally with the discipline and progress of the school. But it appeared that he was normal mentally, and kept pace with the other pupils in the respective grades. A representative of the state department of public instruction suggested that he be placed in the department for the instruction of deaf persons or persons with defective speech, but the boy refused to attend that department.

The right of a child of school age to attend the public schools of Wisconsin cannot be insisted on when its presence therein is harmful to the best interests of the school. This, like other individual rights, must be subordinated to the general welfare. It will be conceded, the court thinks, that the statement of facts presented a fair question as to the effect of the boy's presence on the school and the individual pupils attending it. The question then arose as to what body or tribunal was vested with the authority of determining the question. The trial court seemed to be of the opinion that, while such authority rested with the school board in the first instance, its action in that behalf was reviewable by a jury and subordinate to the jury's opinion thereon. But the supreme court holds that, the board having acted, its determination should not be interfered with by the courts unless it acted illegally or unreasonably. That it acted legally was without question. That it acted unreasonably could not be said. The duty confronting the board was a delicate one. It was charged with the responsibility of saying whether this boy should be denied a constitutional right because the exercise of that right would be harmful to the school and to the pupils attending it. He should not be excluded from the school except for considerations affecting the general welfare. But if his presence in school was detrimental to the best interests of the school, then the members of the board could not, with due regard to their official oath, refrain from excluding him, even though such exclusion would be displeasing and painful to them.

### Errors of Judgment—Evidence Requirements

*(Parker v. Apple (Kan.), 180 Pa. R. 771)*

The Supreme Court of Kansas, holding that, there being no evidence to justify a judgment against the defendant, it was error to grant the plaintiff a new trial after a verdict had been rendered in favor of the defendant, reverses the order granting a new trial, and remands the cause with directions to render judgment for the defendant. The court says that the action was to recover damages alleged to have resulted from the malpractice of the defendant in the treatment of a fracture of the femur of the plaintiff's right leg,

about three inches above the knee. But, in a city with many able and skillful physicians and surgeons, the only expert called to testify on behalf of the plaintiff was a physician who neither criticized nor condemned the methods employed by the defendant in the treatment of the plaintiff's injury. Non-expert witnesses can testify as to external appearances and manifest conditions observable by any one; but whether a surgical operation has been performed with a reasonable degree of skill, knowledge and care, and whether the patient was thereafter skillfully and properly treated, are questions of science, to be established by the testimony of witnesses of special skill and experience, and not by the testimony of those who are without special learning and skill as to such operations and practice. The burden rested on the plaintiff to show affirmatively that the conditions he complained of were caused by the failure of the defendant to exercise ordinary skill and care in performing the operation of reducing the fracture, or in the subsequent course of treatment for the injury. In a very early case, this court recognized the doctrine that a physician or surgeon is not held to the exercise of the highest degree of skill, or as warranting a cure or the success of an operation.

A physician or surgeon cannot be held liable for the results of an honest error in judgment, if it is shown that he possesses a reasonable degree of skill and learning in medicine and surgery, and that he used ordinary skill and care in the diagnosis, operation and treatment of the plaintiff. It is true that the physician is bound to possess and exercise that degree of skill which is ordinarily possessed by physicians in practice; but when his errors are those only of judgment, if he keeps within recognized and approved methods, he will not be liable for their consequences.

It has never been the rule that a lawyer who is not shown to be unskilled in his profession is liable because a client sustains damages by following his advice, honestly given, but which is subsequently determined by a final decision of a court to be erroneous. A physician stands in the same attitude as to liability for his mistakes as does a lawyer. No reason can be assigned for making a distinction between them, or for holding a physician or surgeon liable in damages for an honest error in judgment. A moment's reflection on the circumstances and emergencies under which physicians are frequently called on to act will demonstrate some of the disastrous results that would follow if the law permitted them to be mulcted in damages on testimony as to the character of their professional services given by nonexpert witnesses. If such were the law, physicians and surgeons might as well be held to guarantee a successful cure or a successful operation in each instance. Negligence of a physician or surgeon cannot be presumed from the mere failure to obtain the best results from an operation or treatment; and in this case, there being no proof of a want of skill or care on the part of the defendant it was error to set aside a verdict rendered in his favor and grant the plaintiff a new trial.

### Statements Made to Physician Long After Accident

*(Boulanger v. McQuestin & Lewis (N. H.), 106 Atl. R. 492)*

The Supreme Court of New Hampshire overrules an exception to the exclusion, in a personal injury case, of a question asked a physician as to what history the plaintiff gave him when he consulted him for treatment more than a year after he was injured. The court says that the history given the physician by the plaintiff over a year after the accident was not admissible as evidence of the accident or in corroboration of the plaintiff's statements at the trial. This was too plain for discussion, and the only ground on which the admissibility of the question was being urged was that the physician's information as to the cause of the injury was competent as explaining and giving weight to his conclusions. If the purpose of the inquiry was under the pretext of offering evidence of the foundation of the physician's opinion to violate the general rule excluding prior statements of the party, the evidence was properly excluded. Whether, if the ground of admission claimed was presented to the trial court, the evidence should be excluded because of lack of good faith in offering it, was necessarily for the trial court, as depending on the determination of a question of fact.

### AMERICAN PUBLIC HEALTH ASSOCIATION

Forty-Seventh Annual Meeting, Held in New Orleans, Oct. 27-30, 1919

The president, DR. LEE K. FRANKEL, New York, in the Chair

#### Spread of Typhoid in Massachusetts

DR. GEORGE T. O'DONNELL, Boston: The experience of the Massachusetts State Department of Health shows that flies, food (exclusive of milk), privies and sewage are relatively small factors in the spread of typhoid fever at the present time in the state. Very few cases are due to water, especially in recent years, and in general no municipal supply is considered as a dangerous source of typhoid infection. Milk as a means of spreading typhoid infection was responsible for 8.1 per cent. of the total cases reported in Massachusetts the past ten years. Contact with clinical cases of typhoid is the most frequent known method of the spread of the infection. Contact with noncarriers has been responsible for a few cases in homes and neighborhoods. Carriers were proved to be responsible for 41.6 per cent. of cases of milk-borne typhoid from 1915 to 1918, inclusive. Carriers are a larger factor in the spread of typhoid than at present known, and are the cause probably of an appreciable number of typhoid cases of unknown origin.

#### DISCUSSION

DR. HERMAN BUNDESEN, Chicago: No case of typhoid should be terminated until we have had two negative feces and two negative urine examinations in the case of persons who are not handlers of food. We require more than two negative examinations in food handlers. In Chicago we had eighty-seven cases of typhoid traceable to one carrier.

DR. H. W. HILL, Minneapolis: I should like to ask Dr. O'Donnell whether he attaches any importance to flies as carriers of typhoid infection; also, whether in Massachusetts they have compulsory hospitalization of typhoid patients.

DR. JOHN DILL ROBERTSON, Chicago: We believe in the strict enforcement of the pasteurization ordinance. Our death rate from typhoid is less than 1 per cent. In 1918 it was 1.4 per cent. We hospitalize every case in which proper care cannot be given the patient at home. No nurse is allowed to have anything to do with any other case while attending a typhoid patient; hence we have very few cross infections on that account.

DR. GEORGE T. O'DONNELL, Boston: We have failed to find an instance in which we could prove that secondary infection was due to flies. Hospitalization of typhoid cases is practiced throughout Massachusetts. As to the pasteurization of milk, of more than 8,000,000 quarts of milk, we know positively that more than one third of that amount was pasteurized. Over 90 per cent. of the people in Massachusetts have a pure water supply.

#### Leprosy

MR. JOHN A. VOGELSON, Philadelphia, introduced the following resolution which was unanimously adopted:

Resolved, That the health officers of this section of the American Public Health Association tender to the United States Public Health Service their hearty support and cooperation in carrying out the provisions of the act of Congress providing for the care and treatment of persons afflicted with leprosy, and to prevent the spread of this disease in the United States, and urge that such a provision be carried into effect at as early a date as practicable.

#### DISCUSSION

DR. ARCHIBALD HOYNE, Chicago: Cases of leprosy should be hospitalized the same as cases of tuberculosis. We have had a few lepers in Chicago in the last few years. Chaulmoogra oil, given once or twice a week, intramuscularly, in

increasing doses, has been followed by remarkable improvement.

DR. H. R. CARTER, Baltimore: There is good reason to believe that leprosy is rarely or never communicated to elderly persons. In taking care of lepers I would suggest that elderly nurses be employed, as the risk of such people contracting the disease is absolutely nil.

#### Report of Committee on Venereal Diseases

DR. W. F. SNOW, Washington, D. C.: We cannot do anything in a legislative way unless we have the support of the public. The outstanding points in civil life are the untreated cases of venereal diseases, on which we should concentrate our attention, and on those persons who never seek treatment. They do not know they are infected. Others, almost equally important as spreaders of the disease, are the missed patients who present themselves for treatment. Next come the uncured patients, who must be followed up. Failure to make a diagnosis and institute treatment in suspected cases and carriers is one of the great sources of the spread of these diseases.

#### Administrative Measures Against Influenza

DR. ALLEN W. FREEMAN, Columbus, Ohio: The hypotheses on which we have operated up to this time are that (1) influenza is caused by a specific living virus; (2) the portals of entry of this virus are the nose and the mouth; (3) this virus is contained in the secretions from the nose, mouth and respiratory tract, and (4) the virus is communicated by transference of sputum and nasal secretion through direct or indirect contact, and by droplet infection from coughing and sneezing. No convincing experimental evidence has been advanced in support of any of these hypotheses. On this basis, however, various preventive measures have been proposed, of which the most important are: (1) isolation of patients; (2) prohibition of public gatherings; (3) masking of the general population; (4) general vaccination with anti-streptococcal or mixed vaccines, and (5) general educational propaganda. The practically unanimous verdict of laboratory workers, however, is to the effect that the true virus of influenza has not yet been isolated and that such a vaccine cannot yet be prepared. Until additional evidence is produced regarding existing vaccines or until a truly specific vaccine is developed, general vaccination cannot be considered a sound administrative procedure. Our energies, therefore, must be directed rather to the prevention of fatal complications than to the prevention of influenza itself. For this purpose, adequate medical and nursing service and properly equipped hospitals should be organized and made available for instant use. In these hospitals and in the home care of patients, every effort must be made to prevent secondary and cross infection.

#### American Red Cross Health Crusade Against Influenza in Cincinnati

DR. WILLIAM H. PETERS, Cincinnati: Early in February, all of the institutions caring for dependent persons were crowded. Medical care, nursing service and maternal relief for those whose health and income had been shattered was given through the American Red Cross health crusade organized by the Cincinnati chapter influenza committee, cooperating with the board of health and the existing social agencies of the city. During the first four months of operation, 13,772 influenza subjects were listed, and 5,624 were found to be in need of some kind of medical, surgical or dental aid. Particularly well done was the follow-up of tuberculosis cases, which approached as nearly as is possible 100 per cent. Nearly 50 per cent. of the children under 5 who had influenza gave a positive von Pirquet reaction.

#### What Medical Examination of Influenza Patients Has Shown in Framingham, Mass.

DR. D. B. ARMSTRONG, Framingham, Mass.: Previous to the influenza epidemic, about 12,000 people in Framingham, out of a population of 17,000, had had a medical examination; hence the follow-up system after the influenza epidemic was considerably facilitated. Does influenza increase the tuberculosis incidence? It does not appear that there

has been thus far reported an increased tuberculosis incidence following the influenza epidemic, so far as our experience is concerned. Has the epidemic increased the tuberculosis mortality? Judging by the evidence as regards the incidence of the disease, we are forced to the tentative conclusion that there will probably not be an increase in tuberculosis mortality. What does influenza do to the arrested tuberculosis case? In Framingham, 4 per cent of tuberculosis patients had influenza. The disease stimulates a certain amount of activity, but in most of these arrested cases which have been in some degree lighted up by the influenzal infection, a very satisfactory rearrangement of the disease takes place, and most of these patients are back at work and are living fairly normal lives again. It has been said that influenza attacks husky persons rather than weaker ones. This raises a question which has a bearing on a general health educational problem, namely, is it really a hazard to be healthy? May it not be that the shoe is on the other foot; that it is not so much a hazard to be healthy as it is an advantage to be weak? People who had tuberculosis had very little influenza. In our community the Irish and Irish-Americans had ten times as much tuberculosis as the Italians, and had only one fourth as much influenza.

## DISCUSSION

DR. HAMILTON P. JONES, New Orleans: In my experience at Fort Bliss, Texas, during the recent influenza outbreak, all true cases of influenza were clinically cases of bronchopneumonia. Routine cultures were made from the nasopharynx for pneumococci, hemolytic streptococci, *Streptococcus viridans*, and later, for a new streptococcus which we called a methemoglobin producing streptococcus. We found that certain organisms apparently had a higher percentage of carriers than others; that there was a definite relation between the number of carriers in a given regiment and the number of cases of pneumonia entering the hospital—the higher the number of carriers the greater the number of cases of pneumonia and the greater the number of deaths. We succeeded in having a general order issued for the bacteriologic examination of all the men. They were given some form of nasal treatment—2 per cent solution of the Gramin-T in liquid petrolatum as a nasal spray, and the nostrils were painted with a 10 per cent aqueous solution of copper sulphate. In February, eighty-two cases of bronchopneumonia were admitted to the hospital. In March, nine; in April, none. No vaccines were used in this locality, except in one organization and with apparently no protective effect.

DR. FREDERICK GUEST, London, Ont.: In an overseas hospital in which many cases of influenza were treated, we adopted the plan of opening the windows at the top and bottom and establishing free ventilation, and to this measure we attribute our success in treatment and the low death rate.

DR. H. L. ROCKWOOD, Cleveland: There is no better way of increasing the immunity of individuals than to raise the resistance of the mucous membranes of the respiratory passage, and this measure will do this better than ventilation.

MR. LEWIS I. DUBLIN, New York: The mortality from tuberculosis of all forms was slightly lower in the first nine months of 1918 than in the first nine months of 1917. In the remaining three months of 1917 the mortality increased 1 per cent from tuberculosis, as against an increase of 1 per cent in 1918. The patients with advanced tuberculosis who were attacked by influenza died quickly. In 1918, from the time of the epidemic in the early spring of the year, there was a marked increase in the mortality from tuberculosis, as compared with the preceding five years. The conclusion is that influenza had an effect on tuberculosis, it had a beneficial effect.

DR. CHARLES A. HASTING, Toronto, Ont.: Disinfecting the throat and nose is not an absolutely safe procedure. A preparation that is strong enough to be of any value in that connection irritates the mucous membranes and thus lowers the natural resistance of the individual and makes him more susceptible to the disease. One reason why husky individuals are more frequently attacked with influenza than frail persons is that the latter go to bed, they rest, they

take good care of themselves, while the robust individuals stay up late at night, and if they feel a little indisposed they will not go to bed and take proper care of themselves as they should; hence they lower their resisting powers and become a prey to influenza and its complications.

DR. JOHN DANIEL ROBERTSON, Chicago: Every health officer should utilize to the fullest extent the medical and lay press for public health education. In Chicago we have established a training school for home nursing to meet the needs of the people when an epidemic of influenza is prevailing.

(To be continued)

MEDICAL SOCIETY OF THE STATE OF  
PENNSYLVANIA

Sixty-Ninth Annual Meeting, held in Harrisburg, Sept. 22-25, 1919

(Continued from page 1468)

## Diagnosis of Cholecystitis and Gallstone

DR. DAVID RIESMAN, Philadelphia: There are few conditions in the body that create such confusing pictures as disease of the gallbladder. Gallstone disease appears in two principal forms: (a) in the form of recurrent attacks with intervals of fairly good health, and (b) in the form of ill-defined gastro-intestinal symptoms that may point to gallstone, gastric ulcer, duodenal ulcer, appendicitis and other conditions. As a normal gallbladder can never be felt, a palpable gallbladder is *ipso facto* proof of disease. There are several points of value: A history of acute indigestion or of ptomain poisoning should arouse suspicion. Acute indigestion, so often given as the cause of death or as the cause of very sharp abdominal pain, is generally a misnomer. If it comes on without any warning in an adult in middle life, it is usually either angina pectoris or biliary colic. The presence of gallstones in the feces is not common, but I think if we had our patients look for stones systematically after all sudden attacks of pain in the upper abdomen, they would be found more frequently.

## DISCUSSION

DR. J. J. GILBRIDE, Philadelphia: No part of the body is more neglected than that involved in disease of the gallbladder. Therefore, in these cases one should not wait to find all the symptoms, for in such cases the disease dates back many years. In chronic disease the common symptoms are indigestion, distress and periodic pain. A stone in the gallbladder may not produce any symptoms whatever, except indigestion and pain. If there is an infection, there will be jaundice. In stone in the common duct there is practically always jaundice. Sometimes there is nothing but a history of pain. In the absence of jaundice, a clear history of pain is the most valuable symptom. It may be referred to the right shoulder, to the left shoulder, or to the left side. Occasionally the pain may be referred to the umbilical region. I have seen cases of gallstones in which pressure over the gallbladder did not produce any tenderness whatever.

## Value of Roentgenologic Study of Gastro-Intestinal Tract

DR. HENRY K. PANGOST, Philadelphia: The roentgen-ray examination of the gastro-intestinal tract is in no way to be regarded as a substitute for a careful and thorough clinical study of a case. It has a well recognized and established place as a method of examination to assist in reaching correct conclusions, just as has the clinical study, and it has well defined limitations with which every one should be conversant. An examination of the gastro-intestinal tract is in a large measure, aside from the observation of filling defects, a physiologic study by an unusual means of watching the mechanism of the progress of an opaque meal for the purpose of detecting interference with normal physiologic action. It therefore requires time and patience on the part of both patient and examiner. A complete study cannot be accomplished in less than three days. The making of three or four roentgenograms without a proper roentgenoscopic study is not the correct or accurate way of making a gastro-intestinal study. Such examinations are usually a waste of

time and also a poor investment, and the conclusions, being without foundation, may be misleading and even dangerous. More men are specializing in roentgenology now than ever before. The new man has usually completed a thorough course of training, but he must continue to read, study, attend meetings and visit others and see their work, because advances in roentgenology are so rapid that one soon falls behind, and the hermit roentgenologist rapidly becomes a useless member. Roentgenology is not a field for fanciful diagnoses unless one is very certain of his premises.

DISCUSSION

DR. JOHN H. GIBBON, Philadelphia: The advancement in the diagnosis of gastro-intestinal lesions has been greatly due to what the roentgenologists have done, but we must avoid the danger of operating on the interpretation of an inexperienced roentgenologist or on the apparent lesion shown in the roentgenograms.

Surgical Treatment of Lesions of the Gastro-Intestinal Tract

DR. ALFRED C. WOOD, Philadelphia: The perforated ulcer is always a surgical condition. Each hour of delay lessens the chance of recovery. On the other hand, chronic ulcers, including those accompanied by hemorrhage, should be treated medically, at least for a time. After medical measures have been given a fair trial without permanent relief, it would be proper to have the surgeon join the physician in the case. After operation for ulcer, the patient should be returned to the internist for a prolonged course of observation, and such dieting and other treatment as may be necessary to promote rapid and complete healing of the ulcer, as well as to restore the normal gastric functions. Patients with carcinoma of the stomach come to the surgeon when only a palliative operation can be done, and in many instances even this is not possible. If a larger measure of benefit is to be offered these patients, operation must be done much earlier in the future than it has been in the past. Every case of carcinoma of the gastro-intestinal tract is a surgical problem from the beginning, yet almost every one of these patients has been under medical observation and treatment for a more or less prolonged period if not throughout its whole course. Pancreatitis is frequently, if not in most instances, the result of infections of the bile tract; the only means known at present to prevent pancreatitis is to deal promptly and radically with cholecystitis and cholangitis. The most important factor in its treatment is efficient biliary drainage.

DISCUSSION

DR. HAROLD L. FOSS, Danville: Errors in diagnosis are due to carelessness rather than to lack of knowledge as to how the diagnosis should be made. A number of years ago I investigated the errors in the diagnosis of abdominal conditions in one of the largest clinics in this country and found that the gross errors as proved at the operating table were about 10 per cent. That is in a clinic where every possible means is exercised in determining the correct diagnosis before the patient is sent to the hospital. There are experts in every particular branch, so the patient receives the benefit of these examinations; and yet in that great clinic they are making about 10 per cent. gross errors in abdominal disease; 65 per cent. had to do with the duodenum, gallbladder and appendix. Roentgenology does not help us in any part of the body to such an extent as it does in early carcinoma of the pylorus.

DR. LAWRENCE LITCHFIELD, Pittsburgh: I have observed a case in which root pains from a growing tumor pressing on the spinal cord had caused several abdominal operations. How many surgeons test the patient who is suffering from acute or chronic abdominal pains for ankle clonus or disturbance of sensations in the lower extremities? How many surgeons have operated on the abdomen in the presence of ankle clonus? Another question for the internist: Patients come with glycosuria, the condition is diagnosed as diabetes, and treatment is begun, when a careful search into the history may give vague symptoms of gallbladder disease which may lead to the diagnosis of pancreatitis, and dram-

age of the gallbladder may clear up the glycosuria. The case may not have been one of true diabetes at all. Many cases of perforative peritonitis do not present the traditional picture as to gravity. The history may strongly suggest perforation, but the physical examination does not seem quite to warrant entering the abdomen. I have seen two deaths in which surgeons had refused to open the abdomen because the patient did not seem ill enough. In cases of suspected malignancy, abdominal section will do no harm and may be an eye opener as well as an abdomen opener.

DR. JOHN A. LICHTY, Pittsburgh: Dr. Pancoast struck the keynote in roentgen-ray work, that is, it has to be coordinated with conditions in general. The roentgenologist who establishes a diagnosis will have to be a pathologist and a clinician. An operation for cholecystitis should not be done without making a Wassermann test to determine whether or not syphilis is present. A colleague opened the abdomen for chronic appendicitis and found a gumma on the ileum.

DR. THOMAS McCRAE, Philadelphia: Mistake in operation is often made on account of careless examination. It is often contributed to by bad palpation. The physician often starts in with what I call the finger-poking method and palpates the abdomen with the tips of the fingers. The first point in abdominal palpation is to use the flat of the hand and palpate gently. A disease responsible for a certain number of wrong diagnoses is prostatitis. Many abdomens have been entered for this with referred pains. Many of the statistics as to gastric ulcer cured by operation are based on observations that do not extend sufficiently long. As regards carcinoma of the stomach, I have seen many cases in which operation was out of the question, except to relieve pyloric stenosis. I feel very doubtful of making a tremendous advance because we do not get the patients early enough. A campaign of education may help in ten, fifteen or twenty years.

DR. ALFRED C. WOOD, Philadelphia: I have one clear recollection of a carcinoma studied in the medical ward because the signs were obscure. The physician said: "He has symptoms that might point to ulcer or carcinoma; his hemoglobin is 60 per cent., his red cells, 3,000,000. He is a little sallow, but we will treat him for ulcer, and, if he improves, we will know that he has ulcer." He was treated *secundum artem* and improved. The red cells increased to 4,500,000. He gained in weight, and the diagnosis was "ulcer." He was sent home. In a short time he came back to the hospital. He was much worse. He was then subjected to operation, when an inoperable carcinoma of the stomach was found. A patient with carcinoma can be built up in regard to blood, weight and so on.

Epidemic Cerebrospinal Meningitis: Diagnosis and Treatment

DR. JOSEPH SAUER, Philadelphia: The two features of importance in the management of meningitis are prophylaxis and serum treatment. Prophylaxis at the present day can be accomplished by the recognition, segregation and treatment of carriers. Chronic carriers may require segregation for a long time, and there is no known certain method of clearing them. Treatment of the disease by serum is specific, and the most important method of administration is intrathecal. The intravenous administration may also be employed, particularly in cases in which there is found general blood infection, or evidence of purpuric eruption or of localization in some of the internal organs. The amount of serum should be the most that can safely be administered, and it should be given from one to three times a day in the early stages and at the earliest possible moment in the case. We are still in doubt regarding the efficacy of vaccines. Other methods of treatment are either useless or of such minor importance that they do not demand consideration. Great care should be taken not to administer serum during serum fever. The latter may be mistaken for a recrudescence.

DISCUSSION

DR. LAWRENCE LITCHFIELD, Pittsburgh: I gave Flexner's serum intravenously as well as intraspinally in all my meningitis cases. It seemed to me that the patients did better.

two men with pneumonia recover! In my meningitis patients who refused water and to whom we could not give a sufficient amount by the bowel I found that the very free use of glucose intravenously was very often decidedly beneficial and in many cases apparently life saving.

Dr. M. HOWARD FUSSELL, Philadelphia: When Flexner first advised the treatment of meningitis with serum, it seems to me our results were better than they are at the present time, and I would ask whether Dr. Sailer has noted any difference in the serums made by different manufacturers.

Dr. B. FRANKLIN RYER, Philadelphia: Much depends on when the serum is used in the epidemic as well as in the disease itself. Certainly, our results were better when treatment was given as early as the second day.

Dr. THOMAS KLEIN, Philadelphia: In 1916 I treated a number of cases of cerebrospinal meningitis in Dr. Sailer's service, giving the antimeingitococcal serum intravenously. In a series of seventy-seven cases the mortality was 18 per cent. Then and at Camp Dix we thought the intravenous administration obviated the necessity of the large dose in the spinal canal, and in that respect I think the intravenous method has the advantage over the intraspinal method alone. Our mortality in cases not treated by the serum was about 40 per cent. The intravenous administration was begun as early as possible, with 30 c.c. of diluted serum, repeated every eight or sixteen hours as demanded.

Dr. JOSEPH SAILER, Philadelphia: I believe the indication is that in all cases of meningitis, isolation of the most careful character should be practiced. That ward infection is rare is no reason why every possible precaution should not be taken.

(To be continued)

#### MINNESOTA STATE MEDICAL ASSOCIATION

Fifty-First Annual Meeting, held in Minneapolis, Oct. 1-3, 1919

(Concluded from p. 1465)

#### A New Operation for Pyothorax: The Trephine Operation

Dr. A. C. STACHAUER, Minneapolis: This operation consists of trephining a rib. It affords an air-tight joint for the ventilation of the continuous, even, negative pressure suction pump with provision for irrigation with surgical solution of carbated soda. The operation may, and usually has been, performed under local anesthesia. Mutilation deformity, and permanent fixation with fixation of the adjoining ribs, is avoided. All discharges are collected in the receiving bottle, obviating the necessity of repeated dressings. The suction prevents the accumulation and retention of pus in the pleural sac, and the absorption of the contained toxins. The likelihood of introducing secondary infections is less than in open drainage.

#### Rational Treatment of Carcinoma of the Uterus

Dr. J. WARREN LITTLE, Minneapolis: In carcinoma of the body of the uterus, a panhysterectomy should be done followed by prophylactic radiation. In cervical carcinoma in the operable stage, either a panhysterectomy followed by radiation or cauterization or a thorough radiation without operation.

Axillary or enter results can be obtained from radiation alone. It is usually no danger or pain to the patient, and is not particularly hazardous at which the knife can be used. In general cases, radium is much superior to any other treatment. Large fungating masses producing hemorrhage may be removed with the cauterium followed by radium. I have abandoned the Percy cautery for radium. I do not advocate the Wertheim operation because of its high mortality, mainly its serious sequelae, and because there are too few cases for the difficulties and dangers encountered.

#### Paralysis of Abducens Nerve Secondary to Mastoiditis

Dr. GEORGE C. DITTMAN, St. Paul: I have had two cases. In both patients recovered one after mastoidectomy and the other with conservative treatment and the injection of 2 c.c. of 1 per cent. (ear) neutralized will gum camphor, into the middle ear every other day. No doubt the condition is due to an an anlysis of the sixth nerve in its relation to the petrous portion of the temporal bone. I believe that

the infection spreads by way of the tympanic cavity and not through a mastoid route. Mastoid operation or early and free drainage of the middle ear is indicated in all cases.

#### Sustaining Value of Repeated Blood Transfusions in Pernicious Anemia

Dr. FREDERICK H. K. SCHAAF, Minneapolis: A patient who had pernicious anemia was transfused fifty-four times, receiving a total of 34,235 c.c. of blood. Forty-nine transfusions were necessary to produce the second remission, which was of five months' duration. The sodium citrate method is the method of choice, especially since the percentage of reactions has been reduced and their harmlessness has been proved. It is the procedure of choice in hemophilia, purpura and melena neonatorum. Blood transfusion is far superior to the injection of salt solution, when more than merely a momentary effect is desired. It will often save a case of acute or chronic bleeding, and permit surgical intervention otherwise impossible. In cases of severe streptococcal infections, transfusion is of no value, but in low grade subacute infections, and in toxemias, it will increase the patient's resistance and help toward recovery. In pernicious anemia in a majority of cases, it will produce immediate general improvement and facilitate feeding by increasing the appetite and causing the disappearance of nausea and other annoying symptoms when other therapeutic measures would require weeks to produce the same effects. In many cases of pernicious anemia, transfusion may cause a remission, but whether by direct stimulation of the bone marrow or indirectly by improving the general condition and circulation has not been decided. Transfusion may have to be repeated again and again to keep the patient alive until another remission occurs. In pernicious anemia the transfusion of blood has a decidedly beneficial influence, but has no curative value whatsoever.

Hysteria in Light of Experience of War. A. F. Hurst, London, Eng.—p. 562.

Cutaneous Sensibility in Peripheral Nerve Injury.—A review of the experimental and clinical work on cutaneous sensibility Cobb claims indicates that the epicritic and protopathic hypothesis of Head and his collaborators should be abandoned. Dissociations of sensation due to peripheral nerve lesions arise from comparing stimuli not only quali-

tatively different but quantitatively unequivalent. In short, they are artefacts. Clinical examinations should be simple, and since areas of dissociated sensation in peripheral nerve lesions are shown to be due to artefact, examination for one mode of sensation suffices for diagnosis. For clinical sensory examinations quantitatively standardized stimuli should be used. Subcutaneous pressure is best tested with an instrument which gives the threshold values in grams. Hyperalgnesia may follow the course of superficial veins.

**Eye Symptoms in Pseudotumor Cerebri.**—Lutz records the case of a woman in the prime of life who fell suddenly ill, without any increase of temperature or signs of infectious meningitis, presenting all the symptoms of brain tumor: choked disk, headache, vertigo and vomiting. These symptoms, after having appeared most alarming for fourteen days, slowly recede, the choked disk included, so that four weeks later the patient feels normal. In the subsequent two years a unilateral deafness develops, followed one year later by the unilateral loss of the vestibular function, and from time to time attacks occur which tend to show an alteration in the left cerebellopontile angle. The patient shows no indications of the unilateral Romberg sign, which can be explained by unilateral lesion of the homolateral tractus spinocerebellaris. Pseudotumor can be diagnosed with certainty only by necropsy. Lutz says that he does not in this case make the diagnosis of benign tumor of the cerebellopontile angle, but he inclines to that of pseudotumor, for the following reasons: sudden onset of the disease; retrocession of all the symptoms within a short time, especially of the choked disk; negative reactions of the cerebrospinal fluid and increase of its quantity; the fact that the unilateral deafness did not appear as a first symptom; the lack of a constant progressive paralysis of the other cranial nerves; the increase of the patient's weight, and, finally, the time that has elapsed since the first attack.

**Fecal Flora of Children.**—This article contains the description and interpretation of a bacteriologic method applicable to the examination of fecal specimens of children apparently suffering from "intestinal intoxication." It is furthermore shown that a strongly putrefactive flora is associated with certain groups of intestinal disorders of infancy, and that clinical improvement is practically always accomplished by a strict carbohydrate diet. The progress in the transformation of the intestinal flora is readily controlled by the cultural tests described.

**Virus of Epidemic Encephalitis.**—A filtrable virus was obtained by Loewe and his associates from the nasopharyn-

geal mucous membrane in fatal cases of epidemic encephalitis. The virus is capable of producing in monkeys and rabbits lesions similar to those found in the human brain. The virus has been carried through four generations in the rabbits, transmitted to a monkey in the fifth generation, and then brought back to rabbits. The virus can be recovered from the nasopharynx of animals inoculated intracranially. A natural immunity was found in approximately 50 per cent. of the rabbits. An acquired immunity was demonstrated in one monkey. A possible connection of this disease with influenza was hinted at in a previous report and studies are now being undertaken to establish such relationship.

**Pfeiffer Bacillus in Influenza Epidemic.**—It is maintained by Duval and Harris that the micro-organism known as the bacillus of Pfeiffer may be isolated from the material of the respiratory tract lesion in all cases of epidemic influenza, and recovered only occasionally from persons not infected. There is inadequate proof that the Pfeiffer bacillus is a member of the normal upper respiratory tract flora. That it may occur in normal individuals during epidemic times or persist for months in those who have recovered from the infection, is well recognized. These persons are the interim carriers of the bacillus and constitute an important means for transmission of the infectious agent. During the course of the infection and for a variable time after recovery, the blood contains specific immune bodies for *B. influenzae* while those not infected are without these substances. The subcutaneous inoculation of persons with influenza protein causes the production of specific immune bodies. The reaction occasioned in the inoculated person is definite evidence of its toxic property. Secondary infections with one or more of the ordinary respiratory tract flora is common in epidemic influenza and is usually responsible for the occurrence of pneumonia. The Pfeiffer bacillus is the primary cause of epidemic influenza for the reason that sufficient postulates in the recognition of its etiology can be fulfilled.

**Influenza Epidemic at Camp Grant.**—With the decline of the influenza epidemic at Camp Grant, the changes noted at postmortem examinations were chiefly such as occur with a healing or complicated pneumonia. The postepidemic pneumonias differed from the epidemic in that changes commonly recognized as due to a hemolytic streptococcus were frequent. Occasionally, the epidemic type of pneumonia was noted within three months after the epidemic, but more recently the classical gray lobar variety was observed. The postmortem bacteriologic studies demonstrated a high incidence of hemolytic streptococcus infections, less frequently pneumococcus. The virulence of pneumococci recovered from diseased lungs since the epidemic is less in rabbits and guinea-pigs than the epidemic strains. Hemolytic streptococci recovered during and since the epidemic, according to Holman's classification, belong chiefly to the pyogenes group.

**Serum Reactions in Pneumonia.**—The serum of rabbits immunized by means of suspension of mixed cultures of *B. influenzae* gave for the most part negative immunity reactions. Fixation antibodies were found in high dilutions, using a preparation of the same mixed cultures as antigen. Agglutination reactions were negative when incubated for a short period at 37 C., but positive in from three to six hours at 55 C. The immune serum failed to react with two strains of *B. influenzae* that had not been used in immunizing, thus suggesting the existence of separate groups of *B. influenzae*. The serum of acute influenza cases gave a positive agglutination reaction at 55 C. in dilutions of 1:80 and above, in the majority of instances (88 per cent.) with one of the strains of *B. influenzae* tested. A few tests with another recently isolated strain were also positive in a few instances. Another strain was uniformly negative. Fixation reactions were negative in all but one case with a mixed antigen. The serum from individuals that had recovered from influenza gave agglutination reactions at 55 C. in about two thirds of the instances. Fixation reactions were negative. The serum of individuals that had been vaccinated gave agglutininations at 55 C. in 45 per cent. of the cases.

fixation reactions were positive in 40 per cent. The normal cases, although few in number, were uniformly negative.

**Transmission of Influenza.**—This investigation was made for the purpose of ascertaining some possible factors in the mode of transmission of influenza through the use of human subjects for experiments. Two objectives were sought: first, to determine the infectious nature of bacteria-free filtrates as reported by Nicolle; second, to test the pathogenicity of various typical strains of influenza bacilli for man, and ascertain if their use will result in the production of the disease. The nasal application of a filtrate from a pneumonic lung of an individual dead from typical influenza bronchopneumonia failed to call forth any abnormal symptoms. The application to the mucous membrane of the nares and nasopharynx of five healthy men (four inoculated from four to six weeks ago against influenza with a polyvalent influenza vaccine; one unoculated) of freshly prepared suspension of four different live strain of *B. influenzae* (one, in the second generation from the fatally infected human host) even in massive doses, failed to produce any abnormal symptoms. The implantation of living suspensions of influenza bacilli produced no material alteration besides the addition of the influenza bacillus itself. When experimentally implanted the influenza bacillus disappears from the nares in a relatively short time, in from twenty-four to seventy-two hours. When experimentally introduced in the nasopharynx of man the influenza bacillus exists and multiplies for a considerable length of time, two weeks or more, and apparently shows much resistance to the action of dichloranin-T. In the examination of the nasopharyngeal secretions of patients who were suffering from infections diagnosed clinically as typical influenza and in tissues of the respiratory tract of patients who died of influenza bronchopneumonia, it was found that the oleate plates frequently gave positive results when the blood and chocolate plates were negative and in addition, by inhibiting the growth of streptococci and pneumococci, greatly facilitated the isolation of the influenza bacillus. In every case the chocolate plate gave more information than the blood plate, which was useful only in picking pneumococci and making a hasty diagnosis of the type of streptococcus present. It is recommended by Wahl and his associates that in the routine bacteriologic examination of all suspected influenza cases, plain infusion, chocolate and oleate or soap agar be used. The blood plate should not be discarded, because it gives information regarding the presence or absence of streptococci and pneumococci that are liable to be missed otherwise and that may play a not unimportant part either in a symbiotic rôle or as a complicating factor.

**Experimental Investigation of Pituitary Extracts and Histamin.**—The intravenous injection of 4 c.c. from a 1:100 dilution into the femoral vein) of a 1:5 dilution of a commercial pituitary extract caused a contraction of the uterus, a very considerable and prolonged rise in blood pressure but scarcely any appreciable effect on the bronchioles. After

the effects of the pituitary had mainly worn off another injection of 0.7 mg. of histamin (ergamin) was made. This produced a more marked contraction of the uterus, a sharp fall in blood pressure and considerable contraction of the bronchioles. This contraction of the bronchial musculature tended to pass off but slowly, so that a later injection of 5 c.c. of pituitary extract (1:5) was made in order to determine whether or not this would counteract the action of the histamin. This produced contraction of the uterus and a rise in blood pressure, but no perceptible increase in the previous slow rate of dilatation of the bronchioles. Jackson and Mills conclude, therefore, that this indicates that commercial pituitary extract does not possess much power toward counteracting the constricting influence of histamin on the bronchioles. Various brands of pituitary extract were tested by the authors. They found that certain commercial preparations of the pituitary gland apparently contain very small and very variable proportions of histamin, and the amount of this substance is probably great enough in some samples to exert some therapeutic action. But it is in nowise a necessary constituent of first-class preparations of the posterior portion of the pituitary gland. The true active principle of the posterior portion of the pituitary gland is a simple body of the sympathomimetic amin type, which in the dog produces contraction of the uterus but fails to contract the bronchi. This is in all probability due to an action of the substance on certain nervous elements and not to a direct muscular action. It is suggested that the action of histamin on the bronchioles can be used as a commercial test for the presence of small amounts of this substance in ordinary commercial extracts of the pituitary gland. If the findings reported in this paper are substantiated, then there are very obvious clinical advantages in favor of the pituitary extracts rather than of the very intense bronchoconstricting and blood pressure lowering histamin for obstetric uses. But in all probability very small amounts of histamin would not be of any serious disadvantage in these preparations.

**Delayed Negative Wassermann Reaction.**—McConnell considers it advisable that readings should be taken every fifteen minutes after the hemolytic system has been added and the tubes placed in the incubator or water bath. By so doing there will be a certain number of cases, about 1 per cent, that will give a so-called "delayed negative" reading. Of these patients nearly three fourths will give either a positive or a very suspicious history in regard to venereal infection.

**Relation of Aortic Insufficiency to Wassermann Test.**—Benjamin and Havre report thirty-three cases of aortic insufficiency unassociated with any other organic cardiac disease from a clinical standpoint. Wassermann reactions, taken in each case, were positive in only 11 per cent, as against the reported higher rates of other writers. Undisputed histories of rheumatism were obtained in 57 per cent. of cases. Questionable histories of rheumatism and histories of frequent attacks of tonsillitis were noted in 15 per cent. A tabulation of results as regards occupation, age, race and incidence is given.

**Action of Alcohol on Heart and Respiration.**—The experiments performed by Hyatt indicate that when alcohol is administered to an unanesthetized animal by mouth there is a rapid rise in blood pressure and respiratory rate and an immediate return to normal. This is due to local action. Intravenously, gradually, in quantities sufficient to kill in one or two hours, there is no effect until just before death, when a rapid fall of pressure takes place. Given rapidly there is a sudden fall followed by an immediate return to the normal. There is no effect if the vagi are cut. When alcohol is introduced by means of a stomach tube there is no effect. When alcohol is introduced intravenously without excitement in the normal dog, there is no stimulation of the heart or respiration.

**Simple Method for Determining the Reaction of Feces.**—Bruce uses a 1 per cent. aqueous solution of alizarin as the indicator. Two small drops are placed on a glass slide about 1½ inches apart. A small portion of the specimen is mixed

thoroughly in one of the drops of the indicator, using the other drop as a control. An alkaline reaction is indicated by a reddish violet to violet color, neutral reaction, no changes, and acid, by a light yellow color. The density of these colors will depend on the amount of acid or alkali present.

**Mental Defect in Georgia.**—This is the report of the Georgia commission on feeble-mindedness and the survey of the national committee for mental hygiene prepared with the assistance of Anderson. This report emphasizes the conditions found elsewhere, viz., that mental deficiency forms the very root of crime, prostitution, hereditary pauperism, and the like, conditions for which the state is spending vast sums of money. These problems are preventable. Expense is not an excuse. It is simply a question of whether the state will pay blindly or intelligently—whether it will pay in crime, in courts, in reformatories, in prisons, in almshouses, or in prevention, in intelligent care and training of these feeble-minded children in schools and institutions suited to their particular needs, in special class instruction of them in the public schools, and proper supervision of them in the community. The report recommends the establishment of a training school and farm colony for feeble-minded persons; special classes in the public schools; state wide supervision; mental clinics, and laws for the commitment of the feeble-minded.

**Care of the Mentally Defective.**—The program outlined by Fernald includes the mental examination of backward schoolchildren; the mental clinic; the traveling clinic; the special class; directed training of individual defectives in country schools; instruction of parents of defective children; after-care of special class pupils; special training of teachers in normal schools; census and registration of the feeble-minded; extra institutional supervision of all uncared for defectives in the community; selection of the defectives who most need segregation for institutional care; increased institutional facilities; parole for suitable institutionally trained adult defectives; permanent segregation for those who need segregation; mental examination of persons accused of crime and of all inmates of penal institutions; and long continued segregation of defective delinquents in special institutions.

**Syphilis as Cause of Epilepsy.**—In Booth's experience the proportion of epileptics giving a Wassermann reaction in some degree is much greater than that given in available statistics, and he feels confident that the laboratory has not detected all cases in which syphilis was either directly or indirectly an etiologic factor. Though some of his cases of epilepsy have shown only a two plus Wassermann and a few only a one plus reaction, he is treating them as though specific in origin and with encouraging results. Those giving a one plus Wassermann have been almost entirely children or women in whom Booth had reason to believe that if syphilis were present at all it was hereditary.

**Congenital Pyloric Stenosis.**—Hill's personal experience in congenital pyloric stenosis comprises twenty-five cases with sixteen recoveries and nine deaths. Of this number fourteen patients were operated on by posterior gastro-enterostomy with only six recoveries. Hill has done eleven operations by the method of Ramstedt and ten of the patients recovered. Hill concludes that all cases of congenital pyloric stenosis should be submitted to operation if the patient does not make immediate gain on tube feeding. The patient will only gain on tube feeding in case the obstruction is very slight.

**Etiology of Achylia Gastrica.**—Beck and McLean made a study to determine if possible, the existence of some relationship of achylia gastrica with any particular disease or group of diseases, in addition to the influence of age, sex, habits, etc., as etiologic factors. It was present in approximately 11 per cent of gastro-intestinal cases. One hundred and forty-three focal and systemic infections occurred in seventy-seven achylic patients. Of these, 108 were definitely focal and thirty-five were systemic. And of the focal, sixty-nine were about the head, chiefly as some form of oral sepsis. Chronic cholecystitis, appendicitis, arthritis, pyelitic and rectal abscess, comprising thirty-nine infections, formed the remainder of the group. In thirty-three cases there was disturbance of the endocrine functions, including the thyroid, parathyroids, pituitary and gonads. None of the cases of suprarenal insufficiency were achylic. Nervous or reflex disturbances in themselves are not etiologic factors. Exclusion of carcinoma of the stomach and advanced stages of chronic interstitial gastritis, gastro-intestinal disturbances are either incidental or secondary to achylia. It would appear that cardiorenal and metabolic diseases occur coincidentally with chronic infections and play an unimportant part in the etiology of achylia gastrica. Alcohol and tobacco excess without focal infections will apparently not produce achylia. The excessive use of tea and coffee may result in it.

**Duodenal Lavage in Catarrhal Jaundice.**—Ousley has not considered any unpleasant by-effects from the use of duodenal lavage and clinical cures have resulted in all his cases. He has used the following diet with satisfactory results: milk, cream, milk, green vegetables, peas, beans, lentils, apples, a parsnip, spinach, celery, lettuce, watercress, radishes, and celery. Fruits of all kinds, except those high in starch or sugar, orangeade, lemonade, and one orange and lemon three times a day between meals, lean meats, chicken and eggs, soup, all stock soups and bouillions soups to be served twice a day; bread, crackers and dry toast, oatmeal, cream of wheat, farina and rice; and desserts, such as sweet corn, oatmeal, plain, praline, stewed and baked apples and grape fruit. No tea, coffee or cocoa is allowed.

**Significance of Sigmoid Adhesion.**—Royster emphasizes the etiologic relationship between left sided pain and adhesions of the sigmoid. He has operated on sixty patients with good results. Attention was directed to the adhesion in many instances by the failure to cure left sided pain by previous operations only to discover the overlooked sigmoid block on reopening the abdomen and to secure a cessation of symptoms by cutting and suturing the adhesion.

**Enterostomy for Postoperative Paralytic Ileus.**—In cases of ileus which will not warrant any prolonged operative procedure or the handling of the bowel any more than is absolutely necessary, Culley says, all that should be done is to protect the peritoneum as much as possible and to make an opening into the distended loop or loops of intestine, provide adequate drainage and thereby relieve the distention and eliminate the toxic substances.

**Enema and Purge in Preoperative and Postoperative Treatment.** From a study of the physiology of the intestinal tract and digestion, Moore is convinced that there is no reasonable basis for giving a laxative or purge preceding any operative procedure.

**Use of Radium.**—Lee would restrict the use of radium to inoperable cancer of the uterus, giving it in heavy dosage and intra-uterine. The dosage should be repeated every four or six weeks, and the case carefully watched for changes in the parametrium, etc. Should the uterus become mobile and removable by hysterectomy, that should be done, with due regard, in deciding the question of operation, to the shrinkage and sclerosis of the tissues and the increased difficulty of operation. Operable conditions should be dealt with surgically, and should be preceded and followed by exposure to the gamma rays, with careful dosage, regulated in conformity to the character of tissues exposed. Recurrences in the vagina should be treated persistently, but with very moderate and repeated exposure.

**Cure of Crippled Children.**—Jones and Girdlestone bring forward proposals for the establishment of a system of orthopedic hospitals and clinics for the active treatment of cripples, and more particularly of crippled children, throughout the country. In Shropshire a system of hospital and outpatient treatment has been organized. As a direct consequence many hundreds of children have been cured or greatly benefited. Further, through the outpatient clinics many cases have been brought to light which would otherwise have remained unknown and untreated. The proposals put forward concern the multiplication of this organization throughout England and Wales, under the ministry of health. Kickets and surgical tuberculosis taken together account for 40 per cent. of the crippled children under treat-

ment. Patients under treatment for congenital deformities and paralysis constitute 45 per cent. of the total number of cases. The authors propose the division of the country into a number of districts; the establishment in each district of (1) an open air country orthopedic hospital; and (2) a system of scattered outpatient clinics. The organization of efficient treatment and the general coordination by a committee working under the ministry of health. The expenses of maintaining such a series of hospitals and dispensaries are to be met by the government, the local authorities and the patients: Private wards for those who could pay full fees; arrangements by which all patients should make a contributory payment who could afford to do so; arrangements by which local authorities should pay at least part of the cost of the poorer patients.

**Coexistent Suprarenal and Renal Disease.**—The outstanding clinical features in the case reported by Sparrow and Soden were those of profound Addison's disease, but the presence of albuminuria and of purpura rendered diagnosis very difficult. In this case, occurring at the time when malignant malaria was rife among the troops of the Egyptian expeditionary force, the patient received quinin treatment in spite of negative blood films. The postmortem appearances were not those of true Addison's disease. An interesting point in the case is the absence of all visible signs of cardiac hypertrophy so common in renal disease, explicable, perhaps, by the deficiency of epinephrin.

**Treatment of Inoperable Carcinoma with Selenium.**—Although Williams has seen some good result from the use of selenium in cases of inoperable cancer, he has seen nothing so far to suggest that selenium will cure carcinoma.

**Removal of Foreign Body from Lung.**—In Pringle's case a rifle bullet was lodged in the lower lobe of the lung for two and one-half years. The patient suffered considerable pain with any exertion, and Pringle felt justified in advising its removal. Four inches of the seventh rib were excised subperiosteally from the midaxillary line backward. On opening the pleura no adhesions were found. The hand was passed into the chest and grasped the part of the lung involved, which was delivered through the incision, and then caught in a rubber covered forceps. The bullet was easily felt about an inch deep in the lung. An incision was made over it, and it was easily extracted. The space in which it lay was swabbed with ether, and obliterated by two mattress stitches of catgut, which completely controlled the slight hemorrhage present. The whole area involved was buried by a continuous Lembert suture of the visceral pleura. The part of the lung which had been withdrawn from the chest was sponged with ether and returned to the thoracic cavity. The parietal pleura was then sutured by a continuous mattress stitch everting the edges. Before the last stitch was tied the lung was expanded tightly against the pleura, thus expelling the air from the pleural cavity. The muscles were stitched in two layers, and the skin was united with a continuous suture. No drainage was employed. Immediately after the operation air could be heard entering the lung freely. The patient made a rapid recovery without interruption apart from a mild bronchitis of both sides and a slight amount of localized surgical emphysema.

**Flagella of Spirochaeta Carteri.**—Bhandarkar and his associates succeeded in demonstrating one or two flagella at one or both ends of the organism, using the method of Nicolle and Morax.

**Snake Venom as a Therapeutic Agent.**—Many snake venoms have an immensely toxic effect on all forms of animal life, and it seems probable that they might prove destructive to such pathogenic animal organisms as the trypanosoma, *Spirillum obermeieri*, *Spirochaeta pallida* and the plasmodium. It is a general rule, so far as the higher animals are concerned, that the lethal dose of snake venom depends on the size of the animal. If this holds good all down the animal kingdom, a dose of snake venom necessary to kill such lowly organisms as those enumerated above, would be innocuous to the host infected by them.

**Passage of Micro-Organisms Through Normal Organs.**—Terauchi carried out experiments on the problem whether micro-organisms pass through normal organs. He employed mostly rabbits and albino mice. He affirmed the fact that the conclusion arrived at by some investigators, that micro-organisms do not pass through the normal kidneys, was reached by employing animals that had a strong bactericidal property in their blood. The fact is that micro-organisms really pass through normal kidneys but the passing of the micro-organisms into the urine depends on the strength of the bactericidal property of the animal's blood. Under ordinary conditions the normal placenta does not allow *B. subtilis* to pass through its tissues, but when the resistance of the peripheral blood vessel of the mother is lowered, micro-organisms can be made to pass through the placental tissues. *S. duttoni* passes through the normal placental tissues into the fetus. Micro-organisms injected into the fetus passed through the placenta into the maternal body.

**Action of Radium and Mesothorium on Vaginal Tuberculous Lesions.**—Shiraki found that radium and mesothorium destroy the lesion and the fibrous change of the local tissues, and even after three years no remission has been observed to occur. The destruction of the superficial tissues occurs in the pathologic lesions as well as in the normal tissues. They are neoplasms and slough off, while in the deeper tissues the degeneration of the connective tissues takes place until cells assume the embryonic state, from which reformation of the new tissues takes place. The author has been unable to demonstrate microscopically the action of these rays against the bacilli. It seems highly possible, however, that the infecting bacilli are so enveloped by the connective tissues that they are unable to maintain life. Amelioration of the general symptoms, restoration of the normal temperature the gain in body weight, the

increase of the hemoglobin, the gain in appetite, etc., are brought about as the local improvement is attained.

**Change in Ovary Following Injection with Alcohol.**—Fifty per cent. and 25 per cent. solution of alcohol was injected by Yamazaki into the articular vein of rabbits. The ones that had been given a moderate quantity of alcohol for a long period of time continuously showed severer changes than any others. The most conspicuous changes take place in the medullar tissues of the ovary. The interstitial connective tissues are seen to increase considerably, while the interstitial gland cells degenerated. From the fact that around the interstitial cells a remarkable increase of the connective tissues has been demonstrable, it would seem very probable that the increased growth of the interstitial connective tissues must be the primary change, while the change in the interstitial gland cells must be the secondary. Other changes are the increased growth of the cysts and also the thickening of the cyst walls.

**Complement Fixation Test of Serum of Uncinariasis.**—By testing the serum of uncinariasis as to the complement fixation with the alcohol extract of the hookworm as antigen, almost all cases produced positive results. It was not only positive against the serum of the patient infested by ascaris. The complement fixation, therefore, is by no means specific. It is, however, noteworthy that the hookworm antigen produced a negative result against the serums of tuberculous cases, of syphilitic and also of normal persons, who had been proved free from any parasites.

**Scheme of Treatment of Tuberculosis.**—The essential units of a complete tuberculosis scheme according to Thomson are: (1) An improved method of notification to provide fuller information regarding the type of the disease and the circumstances of the patient. (2) An efficient and coordinated system of dispensary and domiciliary treatment. (3) The provision of adequate hospital accommodation for acute and advanced cases of tuberculosis with compulsory powers of removal. (4) The provision of up-to-date sanatorium accommodation combined with facilities for the industrial training of parents. (5) The provision of large hospitals for the conservative treatment of nonpulmonary tuberculosis; each hospital to serve a large district and population. (6) The provision of sanatorium accommodation for children and of facilities for open-air instruction in connection with hospital, sanatorium and schools. (7) The incorporation in the scheme of an after-care unit with an emigration and employment bureau. (8) And lastly, the carrying out of a comprehensive scheme of scientific investigation and preventive effort with a view to the control and final abolition of tuberculosis.

\*Prevention of Mosquito Breeding. J. A. Delmege.—p. 181.

**Prevention of Mosquito Breeding.**—Delmege describes the methods for the prevention of mosquito breeding carried out in Madeira in an area of which the chief natural features were rocky streams and deep ravines intersecting the hills; scattered marshy areas and isolated chains of pools on the plain, and large cultivated areas provided with irrigation channels. The methods used were those suitable to an army in occupation of a mosquito breeding area for a comparatively short period, and were therefore of a temporary nature, although they should be easily adaptable in a modified form to the needs of any small community living in a malarious district. The methods used were constructional, canalization, etc., and larvicidal, use of cresol and paraffin.

\*"Idiopathic Tetanus"; Recovery. W. B. Cosens.—p. 646.

\*Long Retained Foreign Body in Bronchus. A. W. Lemarchand.—p. 646.

**Antimony Tartrate in Bilharziasis.**—Five cases are cited by Low and Newham in which antimony tartrate was used with good effect. The dose varied from 16 to 30 grains. The authors recommend that the dose should be small to begin with (one-half grain), and then gradually worked up to see how the patient will stand it; 2½ grains at a dose may be considered the maximum, any increase on that being dangerous. The dilution of the drug is also important; the authors always give it dissolved in 60 c.c. of sterile physiologic sodium chlorid solution, and run it in through a fine needle as near as possible at blood heat. The solution is made up fresh a few hours before the time of administration, an important point; it must not be given old or after standing a long time. Too concentrated solutions are dangerous. Generally, the drug is given twice a week; it should not be administered more frequently than this. The best plan is to keep the patient in bed the day of the injection, and only to let him up next day if no untoward symptoms have taken place. All symptoms must be carefully recorded, and any indications of gastric or constitutional disturbance must be considered in detail, and if had and recurring at each injection may contraindicate further injections. The urine must be examined to exclude nephritis and faulty elimination from the kidneys. Albumin of itself does not contraindicate the injections if this is part of the disease, but the injections should then be given with the greatest caution. Rigors are not uncommon after some of the injections, and cough immediately after is often troublesome.

**Vaccine Treatment of Arthritis.**—The causes of failure in the vaccine treatment of these conditions are grouped under six heads by Crowe: (1) false diagnosis; (2) errors in bacteriology; (3) incorrect or inefficient vaccine; (4) faulty administration of vaccine in regard to dosage and interval; (5) peculiarities in the constitution of the patient and in his response to vaccines; (6) mistakes in general treatment.

**Diurnal Body Weight in Tuberculous Patients.**—Out of a total of 962 recorded weights, Scott found that 146 showed no variation, 205 showed an increase, and 611 showed a decrease. The average increase was 0.77 pound. The average decrease was 1.03 pound. Scott concludes that a tuberculous patient will record a greater fall in weight in the morning, as compared with the afternoon weight, than a person who is merely a suspect. Also, that where an increase is recorded in a positive case, that increase is likely to be less than an increase in a suspect case. The more serious and advanced the disease the greater the variation in weight recorded.

**Relation Between Chorea and Rheumatism.**—The relationship between chorea and rheumatism in childhood is shown in a striking manner by Cronk's findings in two series of 200 cases each, the patients being children, from 2 to 14 years of age.

**Long Retained Foreign Body in Bronchus.**—Lemarchand cites the case of a woman, 50 years of age, who retained the cervical vertebra of a rabbit in a bronchus four years before it was expelled by coughing.

### Annales de Médecine, Paris

September, 1919, 6, No. 4

\*Diaphragmatic Hernia. A. Cade and R. Montaz.—p. 245.

\*Mechanism of Death in Influenza. M. Renaud.—p. 267.

\*Hypertrophy of Nerves. G. Roussy and L. Cornil.—p. 296.

\*Lethargic Encephalitis. J. Lhermitte.—p. 306.

**Latent Diaphragmatic Hernia.**—Cade and Montaz describe three sets of symptoms with a possibly unsuspected diaphragmatic hernia according as the digestive organs, the heart or the lungs are most hampered by the hernia. Treatment can be only surgical, but in the well tolerated congenital cases, there may be no need for operative measures if the patient is kept under relative medical surveillance.

**Mechanism of Death in Influenza.**—A similar article by Renaud was summarized recently in these columns, September 27, p. 1016, and he here reiterates the importance of regarding and treating influenza from the start as an epidemic form of pneumococcus infection inducing multiple foci of consolidation in the lung and thus hampering the heart action. This conception imposes the necessity for bed rest from the first symptoms of catarrh and slight congestion in the lungs. Nothing is more effectual in combating congestion, he says, than hydrotherapy, extensive cold packs, etc. The hydrotherapy should be supplemented with digitalis, and in the graver cases an intravenous injection of 0.25 or 0.5 mg. of epinephrin followed in twenty minutes with 20 or 40 c.c. of antipneumococcus serum. (He used the antiserum made by the Pasteur Institute.) The reaction to this is dramatic, the pulse running up to 140 and growing smaller, the temperature to 104 F. or higher. But this crisis is brief and transient, and in all the twenty-seven cases was followed by entrance on convalescence, the fever dropping with profuse diuresis and the signs of congestion in the lung subsiding. Three typical charts show the unmistakable benefit following this treatment, the temperature in one day dropping from 40.8 C. to normal; from 41.8 C. to subnormal, and from 41.8 C. to 38.5 C. The injection had been made the eleventh, the fifth and the third day, respectively, in these three cases.

**Hypertrophy of Nerves.**—Roussy and Cornil report a case of progressive hypertrophic neuritis in an agricultural worker of 44, resembling Dejerine's progressive and hypertrophic interstitial neuritis in children except that the onset was at the age of 40, that there is no Argyll Robertson sign, no myosis, nystagmus nor general atrophy of muscles, while there is intentional tremor. It differs also from the Marie type by the lack of a familial tendency, scanning speech and exophthalmos, and the atrophy of muscles is limited to the arms. It thus forms a third type of progressive hypertrophic neuritis, nonfamilial, and occurring in adult life.

**Lethargic Encephalitis.**—Lhermitte declares that the disease called by this name is an infectious process involving the midbrain. He does not regard it as a form of influenza but suggests that the latter seems to pave the way for it, possibly by enhancing the virulence of the pathogenic agent responsible for it. Treatment with convalescents' serum is promising, but there are so few convalescents that this treatment is not practicable. The only drug that seems rational to date is hexamethylenamin as this in the nerve centers and cerebrospinal fluid displays some bactericidal efficacy. He gave it by the mouth and by the vein in daily doses of 1 or 1.25 gm. In one particularly severe case he injected the drug intravenously several times, immediately after withdrawal of fluid by lumbar puncture, hoping thus to facilitate the passage of the drug into the cerebrospinal fluid. Whether due to coincidence or effect, general and local improvement followed at once. This method, he says, is entirely harmless.

### Archives Médicales Belges, Liège

May, 1919, 72, No. 5

\*War Wounds of Joints. L. Delrez—p. 513.

\*Partial Epilepsy. F. D'Hollander—p. 537.

\*Gastritis from Corrosive Fluid. H. Koettlitz—p. 562.

Modifications in the Blood after Wounds and Operations. H. Friederich—p. 569.

**Wounds of Joints.**—Delrez recalls that the synovialis has to be protected against both blood and infection, and he reviews his experience in this line in 190 cases of wounds of the larger joints. Infection developed in only twenty-one cases, including 16 in the knee. Treatment by arthrotomy and Willems' method of active mobilization gave extremely satisfactory results. It requires great energy on the patient's part and makes great demands on the physician's time, but

it well repays for all this. In cases in which active mobilization is out of the question, he applied passive mobilization and the results even of this were better than after resection.

**Partial Epilepsy.**—The woman of 50 in D'Hollander's case developed partial epilepsy, motor incoordination, attacks of petit mal, hypo-esthesia, monalgia, etc., but all this train of sensory-motor symptoms was restricted to the left arm. There was a history of healed pulmonary tuberculosis, and the sudden appearance of the partial epilepsy and its final retrogression incriminate some acute tuberculous process as responsible for it, some small patch of meningoencephalitis such as is common in the tuberculous. He discusses each of the symptoms in turn, and reiterates that this and similar cases confirm that the so-called psychomotor sphere is in reality a mixed motor-sensory region.

**Gastritis from Corrosive Fluid.**—Koettlitz relates the case of a young woman who was given hydrochloric acid by mistake on the eve of an operation for chronic appendicitis. She was given milk of magnesia at once and was fed for a week with only ice and diluted milk. Then she went home but returned to the hospital within a week vomiting repeatedly, and gastro-enterostomy became necessary by the end of the eighth week. She was then doing well when hemorrhagic purpura developed and later aphthous stomatitis and she succumbed the tenth week. The caustic fluid had evidently passed through the esophagus and the cardia so rapidly that the walls had not been injured, the pylorus region bearing the whole brunt of the corrosive action.

Sodium Cacodylate. H. Maréchal—p. 492.

Sept. 13, 1919, 33, No. 39

\*Purpuric Nephritis in Children. P. Nobécourt—p. 503.

**Purpuric Nephritis in Children.**—Nobécourt's patient was a girl of 15 who for four months had been presenting symptoms of rheumatoid purpura, but there had been no epistaxis, hæmatemesis or melena, and the purpuric eruption had never progressed to ecchymoses. Blood was noted in the urine on two occasions, and from 0.3 to 0.5 gm. albumin per liter was found constantly in the urine. These findings testify to simple albuminuous nephritis persisting after the subsidence of the purpura. This purpuric nephritis is rarely accompanied by edema, uremia or high blood pressure. Even with retention of chlorids, this is slight and transient. On the other hand, purpuric nephritis without hæmaturia may be more tenacious; the albuminuria may persist for two, four or six months. Osler has published a case in which the purpura progressed in severe waves, with violent abdominal crises, and edema. The urine contained albumin and casts but no blood, and the child finally died in uremic convulsions. In Nobécourt's own experience, bacteriologic examination was always negative. He never found a septicæmia, and the nephritis only exceptionally passed into a chronic phase. The hæmaturic form may subside completely in four or five weeks after an acute course, but usually it runs a subacute course and gradually improves, or it may persist indefinitely. It proved rapidly fatal, or only after several months, in about 25 per cent of the cases cited. The characteristics resemble those of what we call primary nephritis or nephritis of unknown origin. Treatment should be addressed both to the purpura and to the nephritis. He has been successful in some cases with subcutaneous injection of peptone. Calcium chlorid should also be tried. If it does no good, at least it does no harm. To act on the renal hemorrhage, tannin, ergot and krameria have been tried but without much benefit. The main reliance is on dietetic measures, milk for a short time, then milk and vegetables, with a small amount of mutton or ham. Salt need not be discarded unless there is retention, but not much should be allowed as it may increase the hæmaturia. The child should be kept in bed a long time. Getting up may bring a wave of purpura and increase the albuminuria. Marini's patient eliminated 505 gm. of albumin in ten hours' reclining, and 150 gm. when she got up. Careful treatment may ward off complications but it does not modify the course materially.

## Journal de Chirurgie, Paris

Sept. 4, 1919, 15, No. 3

\*Cancer of the Tongue. H. Morestin, p. 241.  
 1. Incision for Gastro-Enterostomy. R. Toupet, p. 153.

**Radical Operation for Cancer of the Tongue.** Morestin emphasizes that the key to success in operating on a cancer of the tongue is the removal of the glands. This is more important here than with cancer elsewhere, and the mutilation has to be extensive even for a small neoplasm on one edge of the tongue. The entire tongue must be sacrificed if the lesion straddles the middle. His fifty-page article has fourteen illustrations showing the preferable technique. The incision in the neck has three straight branches of nearly equal length, one vertical, one running to just below the tip of the chin, and one to just below the lobe of the ear. The portion removed should comprise, he reiterates, the entire half of the tongue, the mucosa of the floor of the mouth on that side (sublingual region and glossomaxillary groove), the sublingual glands, the mylohyoid muscle, the anterior belly of the digastric, the submaxillary gland, and the median suprathyroid glands, along with the submaxillary anterior lymph glands and the entire retrojugal chain, and they must all come away in a single block, the lymph glands still surrounded with their cellular atmosphere. Two of the illustrations show the mass thus excised; in one it included the lymph glands also on the opposite side as the neoplasm had crossed the middle of the tongue. The patient is fed afterward through a retention catheter passed through the nose in the course of the operation, before tamponing or suturing. There is every advantage in getting the patient out of bed early, immediately if possible after he has been thoroughly warmed and rested. If the two first days pass without mishap, the clinical cure is practically certain. The operative mortality of cancer of the tongue is still 20 or 25 per cent, but he knows of cases free from recurrence for one, two, five and even ten years. The functional disturbance from loss of the tongue is much less than might be anticipated; mastication suffers most.

## Lyon Chirurgial

March-April, 1919, 16, No. 2

\*Chronic Intestinal Stasis. Victor Panchet.—p. 135.  
 \*Ankylosis of Ribs after Trauma. L. Bécard and Dunet.—p. 147.  
 \*Traumatic Pulmonary Tuberculosis. V. Cordier.—p. 153.  
 \*Reflex Action from the Pleura. R. Montaz.—p. 159.  
 \*Nine Cases of Aneurysm. L. Desgouttes.—p. 164.  
 \*Parotitis after Typhus and Relapsing Fever. P. Bonnet and S. de Nabias.—p. 172.  
 \*Indirect Operative Treatment of Fistula of Parotid Gland. R. Olivier.—p. 204.  
 \*Flail Elbow. R. Massart.—p. 207.

**Chronic Intestinal Stasis.**—Panchet always examines for kinks and bands at every laparotomy, and corrects anything of the kind he discovers, reducing the size of the dilated bowel and suspending sagging loops. In cases in which it proved necessary to short-circuit the bowel or resect more or less of it, he had 2 fatalities in the 60 in which he joined the ileum to the sigmoid flexure; 3 fatalities in 19 total colectomies, and one in the 36 hemicolectomies, but none died in the 11 colectomy cases in which the operation was done in two sittings. He remarks that this latter method and simple ileosigmoidostomy are comparatively harmless interventions. Extreme care is necessary after the operation to ensure proper diet, massage, physical culture and psychotherapy. The cure or the improvement become apparent only very slowly, as it takes time for the effects of the chronic intoxication to wear off and the patient to regain poise.

**Traumatic Pulmonary Tuberculosis.**—Cordier is disinclined to accept the possibility of a traumatic origin for pulmonary tuberculosis, as sclerosis such as forms after traumatism is Nature's method of curing tuberculosis and, still more, preventing its development. A foreign body in the lungs starts formation of sclerosis, so that there is no sense, he says, in removing a foreign body solely from fear of tuberculosis settling in the lesion. Devic reported in 1917 a case of a man wounded in the lung many years before, who died finally from pulmonary tuberculosis but necropsy

showed that the tuberculosis had invaded all of the lungs except the track of the projectile so long before.

**Syncopal Attacks from Irritation of the Pleura.**—Montaz warns that when localized irritation of the pleura keeps up and induces recurring syncopes, nothing but removal of the irritating factor will put an end to the disturbances. He reports a case in a young man with a scrap of shell impinging on the pleural cavity. He presented all the symptoms of internal hemorrhage although there had been scarcely any bleeding. At each respiratory excursion the lung bumped against the sharp edge of the metal, and the syncopal attacks proved fatal in less than twelve hours from the injury. When the thorax was opened, the projectile did not seem to be in a dangerous point and it was left unmolested, the syncopal attacks being regarded as contra-indicating further search. Piery has reported a similar case of sudden death from pleural reflex action, the pleura being irritated from a fractured rib. Evidently there are certain zones in the pleura which are particularly sensitive to irritation, and this is liable to induce shock. Morphine in large doses is best to attenuate this reflex action.

**Parotitis Consecutive to Typhus and Relapsing Fever.**—Bonnet and de Nabias give the clinical histories of 38 cases in which extreme swelling and pain in one or both parotid glands had followed typhus or relapsing fever at a French surgical hospital in Roumania in 1917. The parotitis seemed to be more common after typhus, and gangrene from arteritis after relapsing fever, but these complications occurred in some of both. The number of cases was very large, but the 38 reported were the only ones of which careful notes were kept. Parotitis used to be considered a feature of typhus, as much as the bulbo in plague, but we know now that it is due to secondary infection, the streptococcus predominating. All but 2 of the 38 cases progressed to suppuration; the 2 exceptions were in relapsing fever cases. In another case the bilateral parotitis was accompanied by gangrene of the foot. Seven of the 38 cases terminated fatally, all in the relapsing fever group. Erysipelas of the face was frequently a further complication. Rinsing out the mouth every three hours with iodized water did not seem to ward off the parotitis, but the parotid did not suppurate in the cases in which this was done in typhus and relapsing fever. They add that if the patients could have been fed properly during the disease and the secretion of saliva thus kept up, there would have been less chance for the parotitis to develop. There were some days in February and March when there was absolutely no firewood, bread or tea, and an onion was all the food available for the whole day for each patient. They incised the parotid gland from the back, starting from the mastoid and turning the angle of the jaw a fingerbreadth below. This incision respects the facial nerve, is less disfiguring, and heals better than in the stretched tissues over the parotid.

**Nerve Resection to Cure Fistula in the Parotid Gland.**—Olivier adds three new cases to the list of those in which a long rebellious salivary fistula into the parotid gland healed spontaneously and promptly after the auriculo-temporal nerve had been resected and the central stump seized with forceps and torn off by rolling it up gently on the forceps. He located the nerve by tracing its branches back. In one of the cases the operation was done to ward off impending fistula, after removal of an aberrant and enlarged parotid gland.

**Flail Elbow Joint.**—Massart describes the principles that should be followed in correction of loose elbow, and reports with illustrations some typical cases. Surgical measures are giving good results with ankylosis or neo-arthritis according to the indications.

\*Syphilis in Joints. Lacapère and C. Laurent.—p. 221.  
 \*Migration of Projectiles in the Abdomen. Barthélemy.—p. 234.  
 \*Bacteriology of Tuberculous Cold Abscesses. A. Demolon. p. 234.

**Syphilitic Processes in Joints.**—Lacapère and Laurent relate that in 1,200 syphilitics examined at the Dispensaire

antisiphilitique at Fez, Morocco, no case of involvement of a joint was noted among 178 syphilitic Europeans, while there were specific joint lesions in 112 of 979 Mohammedans. Fully 75 per cent. of the native population are syphilitic, and the joints are affected in about 10 per cent. The joint lesions are more common among Arabs from the rural districts than in the city, and the percentage of joint cases jumps from below 10 to over 28 in the colder months of the year. They think that malaria is another predisposing factor. They give illustrated descriptions of a number of cases of different types, affecting the knee, the elbow, the shoulder, some with fistulas, some entailing ankylosis. In some the joint lesions were the work of inherited syphilis. They emphasize in particular the cases of ankylosis from "syphilitic rheumatism." The Arabs pay no heed to lesions of any kind unless they become quite painful, so this articular syphilis is allowed to progress to an advanced stage before medical aid is sought.

**Migration of Projectiles in the Abdomen.**—In one of the two cases reported the bullet was found on repeated examination in the left hypochondrium, 3 cm. from the median line and 2 cm. in front of the spine. The day after the last roentgen examination an incision at this point failed to reveal the bullet, and it was found embedded in the ascending mesocolon close to the cecum. In the other case the projectile was seen 3 cm. deep and 3 cm. to the left of the entering point, 2 cm. below the umbilicus. It was found three days later in the exact center of the peritoneal cavity.

**Bacteriology of Tuberculous Abscess.**—Demolon found inoculation of guinea-pigs the most reliable means to determine the bacillary nature of a cold abscess, as he shows by three typical case reports. The inoculations may prove positive up to the very last traces of the healing abscess. It is evident therefore that the healing of these abscesses is due to some clinical process other than sterilization. Under vigorous disinfectants the pus may give negative findings for a time, but as soon as the disinfectant is stopped, the bacilli may reappear from their lurking places in the deeper tissues. During the entire course of treatment, even with camphorated naphthol, the bacilli seemed to retain the same virulence, judging from the action on the inoculated animals.

- Recent Acquisitions in Typhus. A. L. Fourcade.—p. 548.

**Nervous Complications of Typhus.**—Paulian has had extensive experience with typhus on the Russo-Roumanian front, and he emphasizes that the lumbar fluid invariably shows a lymphocyte reaction in typhus. Whatever the form of the disease, the nervous system is affected from the beginning. There is a meningeal reaction constantly during the course of the disease, and it may persist long afterward, for a year or more. There may be complications in the nervous system, symptoms showing involvement of the brain, pons, cerebellum, spinal cord, and mental impairment, neuritis or polyneuritis, or there may be various complications, functional or showing involvement of different organs or glands.

- Staining the Cilia of Bacteria. E. Lancereaux.—p. 565.
- \*The Physical Reactions to Aviation. L. Binet.—p. 566.

**Devices for Study of Tremor.**—Binet gives illustrations of various devices for recording the special features of the tremor in different diseases. They allow analysis of the special type of the tremor and its variation under fatigue, emotions, medication, and operative treatment. For instance, if the hand is held horizontal in front of a mirror, and a photograph is taken of the reflection in the mirror, the difference between horizontal and vertical tremor is very apparent, as he shows by two such photographs.

**Primary Paraneuritic Phlegmon.**—Bergeret emphasizes that the alleged primary phlegmon is in reality always secondary to some infectious process elsewhere. The contraction of the muscles and intense pain in the costovertebral angle on deep pressure at the top of the angle formed by the twelfth rib with the sacrolumbar mass are instructive and may permit an early diagnosis, especially if there is unilateral bacteriuria, or the kidney on that side shows reduced functional capacity. By comparing the costovertebral angle on both sides, the rigidity of the wall over the phlegmon is very apparent. The onset of the phlegmon is usually insidious, but it is extremely important to discover and evacuate it to ward off serious complications.

**Treatment of Pleurisy.**—Regard evacuates the effusion and replaces it with filtered air. Weil has reported successful application in fifty cases of this *pneumococcus therapeuticus*, and Regard's own experience has confirmed the advantages of this technic. It ensures complete repose for both the pleura and the lung, while the separation of the two sheets of the pleura prevents irritation and production of adhesions. The normal balance of the heart, diaphragm, etc., is restored; the heart is relieved, and pain from friction and inflammation is warded off. Some of his patients with 2 liters of effusion after two or three weeks of the pleurisy were cured so promptly that they returned to work in fifteen or twenty days, even those who required a second puncture.

**Staining Technic for the Cilia of Micro-Organisms.**—Lancereaux describes a simple modification of the Zettnow and van Ermenghen technics which shows up the cilia of bacteria.

**Influence of Aviation on the Organism.**—Binet analyzes twenty-five recent works on the medical aspect of aviation, and lists the reactions observed in aviators during and after their flights.

- \*Lumbar Puncture in Syphilis. P. Ravaut.—p. 573.
- \*Reconstruction of the Esophagus. Gussez.—p. 575.

**When to Test the Spinal Fluid in Syphilis.**—Ravaut expatiates on the importance of lumbar puncture, both for diagnosis and in treatment of syphilis of the nervous system, when it is done at the right moment. At other times it is not instructive and has no therapeutic value, and is an unnecessary infliction on the patient. He has made a special study of lumbar puncture in syphilis since 1902, and soon discovered that long before there are clinical manifestations of nervous syphilis, the meninges and vessels are being gradually injured by the spirochetes. When symptoms from this become evident, the destruction has gone too far for recuperation to be possible. In detecting the latent "meningovascularitis" which precedes and engenders most of the nerve processes of syphilis, lumbar puncture is most instructive and helpful. This meningovascularitis is liable to develop at any stage, early or late, of the syphilis. He charts the findings in 1,000 syphilitics classified according as they presented symptoms of nervous syphilis or not. They show that during the first three years, reactions of septilic origin are common. The reactions which persist after the third year in all probability are traceable to changes in the central nervous system, although as yet they may not have given a clinical hint of their existence. Between the beginning of the fourth year and the tenth year is the period of the maximum frequency of the occurrence of reactions in the cerebrospinal fluid testifying to a latent phase of meningovascularitis. At any stage of the syphilis, lumbar puncture will reveal the organic or neuropathic nature of nervous symptoms and the intensity of the meningitis. If there are no nervous symptoms, he advises puncture as a routine procedure at the fourth year, and would defer the puncture to this date, as a rule. After the tenth year, over 75 per cent. of those with a positive reaction in the fluid have also remarkable clinical nervous symptoms. When a patient without known syphilis presents puzzling nervous disturbances, lumbar puncture may clear up the case when of course the different causes might be incriminated. A distinctly positive reaction with syphilis known to be a factor indicates syphilitic meningitis, and this calls for treatment as long as the reac-

tion persists positive, which may take years. In several cases in his experience, notwithstanding persevering treatment, symptoms indicating grave lesions finally developed. Latent meningitis is less and less frequent after the fourth year. In conclusion Ravaut warns that certain slight syphilitic processes may run their course at points in brain or elsewhere without inducing meningitis. These must be excluded before drawing the prognosis from the normal cerebrospinal fluid.

**Reconstruction of the Esophagus.**—Günzev gives an illustrated description of the comparatively simple technic with which he reconstructed the missing upper three-fourths of the cervical portion of the esophagus in a woman of 66. The gap was 6 cm. long, and the woman was being fed through it. The portion above seemed to form a blind pouch, and swallowing movements were thus impossible as these have to start in the pharynx. This passage was made permeable, and at a second sitting a tube formed from skin was introduced into the esophagus and sutured to the stump above and below, the skin side inside the tube.

- \*Pancreas Extract in Gastric Cancer. M. Loeper.—p. 341.
- Pleuropulmonary Tuberculosis in Children and Adolescents. L. Ribadeau-Dumas.—p. 342.
- \*Fixation of Movable Kidney. Uteau.—p. 346.

**Pancreatic Extract in Gastric Cancer.**—Loeper has been giving intravenous injections of pancreatic extract in treatment of gastric cancer, and he here reports five out of the larger number of cases in which this has been done, discussing the theoretical bases for it. The results show that this treatment has a decidedly favorable action on certain of the symptoms from gastric cancer—"I do not say on the cancer itself." The weight increased in all, the number of erythrocytes increased and the antitryptic index showed higher values in two of the four patients tested. In the cancerous it acts the same as in healthy subjects and in dogs, increasing the antiproteolytic power of the blood serum and the resisting power of the blood corpuscles. The general condition improves, and the resisting power of the organism is enhanced, including the special defensive reactions against the cancer products.

**When Should a Movable Kidney Be Fastened in Place?**—Uteau remarks that a movable kidney may induce disturbances of three kinds, pain, dyspepsia or nervous instability, or all combined. With pain and dyspepsia accompanying a movable kidney, he keeps the patient in bed for several days. If the symptoms show marked relief, the kidney may well be incriminated as the cause of the disturbances, as also when there is retention of a few grams of urine in the kidney pelvis, found on catheterization of the ureter. On the other hand, he advises against any attempt at fixation when the displacement of the kidney forms part of a general tendency to ptosis. In this latter case, general gymnastic exercises and hydrotherapy to strengthen and tone up the abdominal wall are indicated, resting the sagging abdominal wall by frequent reclining. This will give these patients a living abdominal band which is better than all artificial measures. A strong and elastic abdominal wall is one of the best means for restoring a sagging kidney to place. The wearing of an abdominal band may also usefully supplement this. A course of treatment for the nervous instability may prove helpful in curing the subjective symptoms with movable kidney. In case an operation is considered, a neurologist should be consulted beforehand with nervous subjects and, still more imperatively, with insane subjects. Uteau warns to leave "silent movable kidneys" alone, and to operate only when the connection between the symptoms and the movable organ is definitely determined. The benefit from the fixation may be months in appearing.

- \*Gastric Stenosis in the Gassed. A. Clerc, and others.—p. 351.
- \*Functional Impotence and Reflex Contracture. A. Barbé.—p. 352.
- \*Tuberculous Membranous Cast of Bronchus. P. Meurisse.—p. 354.

**Genital Sequelae in the Gassed.**—The injuries of the external genitals from gassing healed promptly in all but nine of

the 108 soldiers presenting these lesions among the 441 *ypérites* at the special service for the gassed in charge of Achard. The nine exceptional cases are described and the medicolegal importance emphasized.

**Functional Impotence and Reflex Contracture.**—Barbé insists on the frequently unsuspected, remote cause for functional impotency and reflex contracture, describing several typical cases. In one the impotency of the arm was finally traced to nutritional disturbance from overtight dressings after a comparatively slight wound of the hand. The edema and paralysis of the arm were unmistakably due to an organic lesion. He warns that negative electric tests do not exclude organic mischief. Reflex contracture may occur from irritation of muscles from some bone lesion. This is particularly liable to occur after fracture of metacarpal bones. The lesions of muscles or tendons have more to do with the contracture than the primary bone lesion. The vessels and the nerve fibers may also be involved. The contracture perhaps interfering with the nourishment of the parts may set up a vicious circle.

**Tuberculous Membranous Cast of Bronchus.**—In the case described by Meurisse the man of 37 seemed to have been cured of pulmonary tuberculosis. He had had hemoptysis on two occasions, the last three years before and the hemoptysis had not been severe. Recently he expelled a membranous cast of a bronchus without effort or dyspnea. It was about 13 mm. long by 3 mm. in diameter, white, and rather firm, but easily shredded with a needle, and containing very large numbers of tubercle bacilli.

### Correspondenz-Blatt für Schweizer Aerzte, Basel

Sept. 18, 1919, 49, No. 38

- \*Regional Gastrosasmus with Cholelithiasis. M. Lüdin.—p. 1417.
- \*Comparative Study of Test Meals in Gastro-Intestinal Pathology. H. C. Frenkel-Tissot.—p. 1423.

**Regional Gastrosasmus with Cholelithiasis.**—Lüdin explains that it is extremely difficult sometimes to distinguish between spasmodic constriction of the stomach just above the pylorus and cancer in this region. Even repeated radioscopes may happen to catch the spasm each time. Administration of sedatives to abolish the spasm does not always answer the purpose. Consequently only an exploratory incision will reveal the true condition in some cases. This may allow correction of the cause inducing the gastrosasmus, as in two cases described in which the laparotomy disclosed pathologic conditions in the gallbladder, with stones, all previously unsuspected. Cholecystectomy put an end to all the disturbances, including the gastrosasmus.

**Test Meals.**—Frenkel-Tissot analyzes experiences with the ordinary test meals at the Virchow Hospital in Berlin. Each of the 250 subjects had the stomach contents aspirated usually seven or eight times in the course of several days—a total of 2,000 readings. The aim of the special research was to determine the length of time the test meal remained in the stomach according to local conditions, with ulcer, cancer, etc., and in the normal stomach. A series of standards for the characteristic evacuation of the stomach in these various conditions was thus obtained, and he expatiates on the important information to be derived from this hitherto comparatively neglected test of the motor functioning.

Among the points emphasized are the peculiarly instructive findings when test meals of different types, with and without "ballast," are used in the case. In 18 per cent. of the cases he found that organic stenosis of the pylorus was responsible for the twelve hour retention of the test supper (200 gm. rice and 30 gm. raisins or dried currants). The amount of the retention is no guide to the malignancy or not of the pathologic process. Twelve hour retention was never found with gastric neuroses, gastroptosis or gastritis. He found occult blood in the stools only in 63 per cent. of the certain cases of cancer, while it was evident in other cases in which necropsy failed to reveal a trace of cancer. Occult blood has been found with mere pancreas and gallbladder disease, polyps, diverticuli, and varices in the intestines. His experience shows further that small or microretention has

no significance from the standpoint of etiology; that persisting retention of the Kemp or Leube-Riegel test meal for seven to ten hours with gastritis is suspicious of cancer, but it may fall within the frame of simple gastritis.

Twelve hour retention with achylia points very emphatically to malignant disease. It is extremely rare under other conditions. It is possible, however, for cancer with total achylia to progress for months without retention; in two such cases the inoperable tumor lay along the lesser curvature to the esophagus. These patients had absolutely no disturbance in the evacuation of the stomach and no pains, and they had applied for treatment merely on account of their weakness. Hyperchlorhydria was evident with ulcer in only 48.5 per cent. of the ulcer cases, and retention in only 45.7 per cent. of the uncomplicated cases, and this only for seven hours. With actual stenosis, the test supper and the Kemp meal are equally instructive. With duodenal ulcer, the fasting stomach was always found empty, as also with reflex gastric secretory anomalies from lead poisoning, pancreas, gallbladder and bowel disease.

Sept. 25, 1919, 49, No. 39

- \*Radiotherapy at Zurich Gynecologic Clinic. G. v. Mandach.—p. 1449.
- \*Diaphragmatic Hernia. G. Jchok.—p. 1457.
- \*Congenital Cartilaginous Exostoses. H. Jaeger.—p. 1461.
- Attitude of Children in School. W. Loewenthal.—p. 1464.
- \*Surgical Disease of the Biliary Passages. C. Krähenbühl.—p. 1466.
- Postinfluenzal Psychoses. V. Demole.—p. 1468.
- \*Goiter and Iodine in the School. Weith.—p. 1474.

**Radiotherapy at Gynecologic Clinic.**—Von Mandach reports satisfactory results from roentgen treatment in almost every case of preclimacteric and climacteric hemorrhages and of myoma. In 45 cases of the former the hemorrhages were completely arrested in all but 4, and they had become insignificant in 3 in this group. The treatment failed completely in only one case. In 168 cases of myoma all were relieved from their hemorrhages but 5, but the myomas persisted unmodified. He agrees with those who think that the time has not yet come for relying on raying alone in all cases of malignant disease, but he is convinced that post-operative raying has great promise, although this technic has been introduced too recently for a final decision on it as yet. In 4 cases of carcinoma of the body of the uterus and 6 of the cervix, treated by operation and raying in 1914 and 1915, all the women have kept in good health since. Among the 2 cervix cases was a woman of 24 and another of 40 with a cancerous nodule in the labium minus.

**Diaphragmatic Eventration.**—Ichok applies this term to the condition when the thin and relaxed diaphragm allows the abdominal organs to slide into the thorax, but without any actual breach in the diaphragm. A case in a woman of 44 is described.

**Congenital Cartilaginous Exostoses.**—The remarkable feature of the new-born child reported by Jaeger was that some of the multiple cartilaginous exostoses of the ribs showed a distinct hinge or joint connection which allowed free play of movements in a horizontal direction. The only plausible explanation for this articulation formation, he thinks, is the assumption of movements of the fetal thorax analogous to the breathing movements after birth. Althfeld called attention in 1905 to rhythmical wavelike movements of the fetal thorax, as has been mentioned in THE JOURNAL. He said they could be easily seen and palpated during the last months of pregnancy, and this has been repeatedly confirmed by others. The joint production in the congenital rib exostoses in the case here described is still further corroboration.

**Surgical Disease of the Biliary Passages.**—Krähenbühl refers to Courvoisier's law that when the common bile duct is obstructed by a gallstone there is no distention of the gallbladder as this is already pathologically shriveled. With obstruction of the common bile duct from without, the gallbladder is not pathologic in the same way, and it soon becomes distended. When this distention has lasted a long time, cancer obstructing the biliary passages is usually the cause. In an experience with 41 operative cases of cancer of the gallbladder, this law applied in 34 cases and in 4 obesity prevented investigation. In only 3 cases the law did not

apply. Gallstones were found in 87.8 per cent. of these cancer cases. In 4 of the other cases no search was made for gallstones, and in still another, gallstones had been previously passed in the stools. In 37 of the 41 cases there was a history of gallstone colics long before the cancer. The larger proportion of gallstone cases which come to operation nowadays and thus ensure the removal of the gallstone irritant cause for cancer production, explains the progressive reduction in the number of cancer cases. The proportion in the last three decades dropped from 12.1 to 5.9 per cent. of the total 498 operative gallstone cases.

**Goiter and Iodine in the School.**—Weith relates that large mouthed bottles containing 20 gm. of 10 per cent. tincture of iodine were placed in all the school rooms of several of the school buildings at Lausanne. Examination of the children after two months of this showed only 495 with goiter when there had been 651 to start with, and more than 50 per cent. showed marked retrogression. This reduction of 13 per cent. does not compare favorably with Marine's 33 per cent. in the Akron schools, but Weith relates that in the school buildings at Lausanne in which no attempt at the iodine treatment had been made, the proportion of children with goiter had increased during this same period from 22.86 and 36.72 per cent. to 28.72 and 57.77, and in one of the schools the percentage among the girls had doubled (from 22.85 to 45.18). The contents of the bottles disappeared in the course of thirty days, that is, 2 gm. of metallic iodine passed into the air of the room, about 7 eg. daily, and were distributed among thirty to forty scholars. He thinks that iodine crystal-might work still better, and that twice the dose might be preferable. This "iodation" of the school rooms has a number of obvious advantages over administration of iodine by other means, and is, he declares, the true public prophylaxis, automatic and effectual.

June, 1919, 29, No. 6

- Co-Agglutinin in Immune Serums. C. Sarti.—p. 349.
- \*Radiotherapy of Chronic Malaria. Ant. nino Pais.—p. 359.
- Compulsory Notification of Tuberculosis. V. Puntoni.—p. 366.

**Radiotherapy in Malaria.**—Pais has been conducting research for some time on the way in which the chills and fever in chronic and rebellious malaria are influenced by raying. He bases this treatment on the assumption that minute doses of radiant energy stimulate the vital functioning of the cell, instead of having the destructive action of the large doses. The minute doses attenuate the gravity of the disease and sometimes abort the paroxysms of fever, and may cure the disease in its chronic form, refractory to or even without the aid of quinin. There is a great difference in the response in different forms of malaria and at different stages of the paroxysm. The results of his 3,000 experiences have convinced him that this is a practical and effectual method of treating cases in which ordinary measures have failed. He applies the rays diffusely to the spleen through an aluminum filter. The hematozoa disappear from the blood after repeated mild exposures. The number of erythrocytes increases. In one case, from 2,300,000 it ran up to 3,100,000 on the fifteenth day and there was no further fever after the second exposure. Usually the improvement in the blood picture is much more gradual. Pais reiterates that with the small doses he advocates, from 1 to 10 or 12 units, even the largest spleens yield to the action of the roentgen rays if applied in very small doses at long intervals. Too large doses and too short intervals cause the spleen to increase in size again. As the patients witness the subsidence of their spleen tumor and the disappearance of the pains and discomfort from it, they return with enthusiasm for further exposures.

### Gazzetta degli Ospedali e delle Cliniche, Milan

September 14, 1919, 40, No. 74

- \*Prophylaxis of Tetanus in Civilian Population. G. Zanetti.—p. 784

**Prophylaxis of Tetanus in Civilians.**—Zanetti discusses in particular the prophylaxis of tetanus in agricultural workers, especially from the standpoint of insurance against acci-

dents. He remarks that the lessons learned from the war in regard to the efficacy of antitetanus serotherapy should be applied to ward off tetanus in persons working on farms, etc. Italy has made compulsory insurance against accidents to workers in industries and on farms, and he pleads that antiserum should be made available for all such accidents. The large supplies of antitetanus serum now left on hand from the war should be sold at cost to the communities throughout the country so that effectual prophylaxis would be available everywhere.

### Policlinico, Rome

July, 1919, 20, Surgical Section, No. 7

- \*Bone Cysts. B. Poletti, p. 217. Concn.  
\*Experimental Ligation of the Ureter. A. Pignatti—p. 231.  
\*Cutaneous Hernia. G. Marchetti, p. 244.

**Solitary Bone Cysts.**—In two of the three cases reported with minute detail by Poletti, the femur was the site of the cyst in children of 8 and 9. In the third case, in a young man, the cyst was evidently of sarcomatous origin. In all three the clinical course, the symptoms, and the contents of the cyst were alike, and only histologic examination revealed the sarcomatous origin in the third case. The course was rapid and scarcely painful in all, the lesion was restricted to a single segment of the bone, and there was no involvement of glands. The cyst contents looked like blood and the cure was rapid and complete in all after the bone cavity had been scraped out. It filled up rapidly with new forming tissue. Notwithstanding the similarity in the course and findings, these three cases testify to the fundamental difference in the pathogenesis in different cases. A list of sixty-eight articles on bone cysts is appended.

**Experimental Ligation of Ureter Plus Nephrotomy.**—Pignatti ligated the ureter in a number of rabbits and then incised or decapsulated the kidney. When nephrotomy alone was done, the development of hydronephrosis was retarded, but when the kidney was decapsulated no tendency to hydronephrosis became apparent at any time, and there was no destruction of kidney tissue. The practical conclusions from his research are that when the ureter becomes obstructed from any cause, prompt nephrotomy with decapsulation might ward off destructive processes in the kidney parenchyma and thus do away with the necessity for nephrectomy later. The benefit is probably due to collateral circulation developing through the nephrotomy cicatrix and connecting with the intrarenal circulation.

**Ichiatic Hernia.**—Marchetti has been able to find records of only thirty cases of hernia in the ischiatic or gluteal region, and describes a case personally observed in which the hernia was formed of a large diverticulum in the sigmoid.

- \*Autogenous Therapy of Skin Disease in Children. G. Guidi.—p. 393.  
\*Microscopic Pioneer Work in Pediatrics. A. Spallucci.—p. 411.

**Autogenous Therapy of Pyodermitis in Young Children.**—Guidi reviews the history of autogenous vaccines and describes considerable experience with them at the children's hospital at Florence in the last three years. The micro-organism usually responsible is *Staphylococcus pyogenes-aureus*, the vaccine treatment was limited to the exceptionally severe and rebellious cases. In the twelve typical cases described, the progressive spread of the skin disease was arrested and the defensive forces reinforced. Most of the severe children whose case histories are related were infants under 2 years old. One 6 months infant had furunculosis, small abscesses over its body and confluent on the scalp. No local measures had seemed to do any good during two months of treatment, but under six injections of the auto-vaccine the skin cleared up. The last to heal was a vast ulceration on the scalp.

- \*Cirrhosis of Liver in Boy. Pietro Busacchi.—p. 449.  
\*Bean in Infant's Bronchus. Virgilio Craglietto.—p. 477.

**Cirrhosis of Liver in Child.**—In the boy of 10 whose case is described with comment by Busacchi, the kidneys and the

cardiovascular system seemed to be normal, and the only plausible explanation of the anasarca seemed to be the assumption of cirrhosis of the liver. This was confirmed by the metabolic findings and the improvement under treatment addressed to the liver. The latter organ must have been constitutionally inferior as to this might be ascribed the convulsions at the age of 18 months, and it may have been a factor in the inflammatory gastro-intestinal process from which the child had repeatedly suffered. The child died from intercurrent influenza about three years after the first symptoms. The child's brother has a much enlarged liver, but the Wassermann test was negative in both.

**Bean in Bronchus.**—The 14 months infant had repeated attacks of suffocation with loss of consciousness, with apparently normal intervals. Low tracheotomy at the third hour permitted the removal of the foreign body after two vain attempts, the bean being repeatedly drawn in deep again with the breath just as it was being fished out through the opening in the trachea.

- \*Bladder Stones in Children. F. Suñer Ordóñez.—p. 449.  
\*Case of Rat-Bite Fever in Spain. P. Escolano Sabater.—p. 456.

**Bladder Stones in Children.**—Suñer relates that in two of the forty cases in children which he has encountered at Valladolid, the stone was expelled spontaneously as the operation was contemplated. It measured 15 mm. by 2 cm. in one girl of 8 but it traversed the urethra apparently without damaging it. In the other girl of 12 the presence of the stone in the bladder was determined beyond question but when the bladder was opened four days later nothing was found, the stone having evidently been expelled in the interim without the patient's or the attendants' knowledge. The child died from shock six days later, the necropsy findings entirely negative. Since this occurrence he never operates without verifying the diagnosis anew just before the intervention, and he is particularly wary in the cases of calculi in girls. In another case the manipulations of the operation had dislodged the calculus in the bladder and it had slipped into the urethra. In still another case the calculus blocked the outlet of the bladder intermittently and the boy of 7 was almost moribund from uremia. The convulsions did not yield to chloral or hot baths, but they were arrested by withdrawal of 120 gm. of blood. This was the only case of uremic accidents in his forty cases in children, but it shows the possibility of sudden and grave disturbance from this cause. In the case reported the further history demonstrated that the kidneys were sound. In one boy of 4 a small calculus had perforated the lower urethra and the urine had collected in the region, with mortification of the skin from the distention. There had been nothing to suggest a tendency to lithiasis before, and the good general health and clear urine testified that it was merely a local process. Suñer confirmed in this case the statements of others in regard to the injury from a retention catheter in such a case; it seems to act like an irritating foreign body.

**Rat-Bite Fever.**—Escolano reports the case of an infant of nearly 2 who was lying in a low cradle on the ground floor when its mother was summoned by the child's sudden screaming, and she found blood on the cheeks and brow and a small wound in the brow. Fifteen days later typical rat-bite fever developed, with chills, hard swollen glands at the angle of the jaws, and eruption and swelling of the face, but the child took the breast normally and the bowel functions seemed normal. The symptoms lasted two days and then subsided, but eight days thereafter they returned in all their former intensity, and the edema of the face was accompanied with patches of redness, almost violet at certain points. This eruption erythem did not itch and it disappeared under pressure, but the doughy edema was tender. These attacks of fever, chills and prostration returned again and again with approximately normal intervals of one or two weeks. Frugoni has known them to recur during years, but recovery is generally complete in from two to five months. A colored photograph of the child in the case

operation had not reduced the condition. This amounts to 90 per cent. good results and 10 per cent. frankly bad. This latter group included cases of ulcer near the pylorus, ulcers remote from the pylorus, and duodenal ulcers. In the juxtapyloric and duodenal ulcers the outcome was good in all but 8 per cent., the larger proportion of bad results and fatalities being encountered in the hour-glass stomach cases. Simple gastro-enterostomy seemed to give as good results as resection in the juxtapyloric and duodenal ulcer cases. The dread of cancer later is not an argument against it as cancer has been known after resecting operations. The results of gastro-enterostomy with gastric ulcers at a distance from the pylorus are far from equaling those of the other groups.

The Nansen-Widberg Diffusion Phenomenon in Immune Serum  
T. Thomsen, 875. To be continued.  
\*Vaccines. G. H. M. Frøed Kr. No. p. 919.  
\*Chorea (Lia in Orbit). S. Holth, p. 939.  
\*Ascites. Christen Johannessen, p. 941.

**Ataxia.**—This is Mourad-Krohn's graduation thesis. He treats of the three great groups of ataxias, the spinal, the cerebellar and the cerebral, their pathogenesis and treatment. Systematic, minute clinical examination is, he says, the alpha and omega of neurologists, and the only guide to successful treatment. He explains how it is possible to substitute volitional movements, direct from the brain with the aid of vision, for the lost more or less unconscious reflex movements, the loss of which constitutes the ataxia of tabes.

**Filaria Loa in the Orbit.**—In the case described by Holth, the man had become infested with the filaria several years before but the parasites had probably all died except one. This seemed to live in the left orbit and occasionally could be seen under the conjunctiva. The man then hastened to the ophthalmologist but during the wait in the afternoon the parasite moved on out of sight. The filaria can move at the rate of 1 cm. per minute.

**Pseudo-Ascites.**—Johannessen gives radiograms of a case which suggested tuberculous peritonitis with ascites but this diagnosis was disproved by the lack of fever and negative tubercle tests. The area of dullness changed its outline from day to day, and the outline was curved or angular, instead of the even horizontal upper outline of true ascites. Occasional rams occurred at times but no tender points were discovered, and there were no symptoms such as would certainly have developed during the three years if there had been a tuberculous basis. There was chronic intermittent diarrhea with anemia and emaciation. The mucous membranes had become stretched and flabby from the profuse diarrheal secretions, the stools sometimes amounting to more than 1 liter, and the girth of the abdomen declined from 60 to 49 cm. after the bowel had been emptied. This never occurred with anuria. Another differential sign was that when the patient was raised the fluctuation showed little change, while in true ascites the fluid sinks down into remoter crevices of the abdomen. Nothing to suggest stenosis could be found. The chronic diarrheal condition and gas distention had attended the unobstructed intestines. As they sagged they caused the patient to lie down with them until the physical examination revealed these with ascites. The fermentation during the attack with dietetic and other measures to treat the diarrhea, and as the appetite and general health improved the distention of the abdomen subsided.

\*Erythrocyte Count at Different Ages. H. J. Berg, p. 433.  
\*Eclampsia. S. T. Tofte, p. 442.

**The Erythrocyte Count at Different Ages.**—Bing's tables show that the average number of red corpuscles in 19 pre- and 20 normal healthy men under 50 was 5.5 millions, the range from 4.2 to 6.1, with a hemoglobin average of 112 per cent. In 41 women the corresponding figures were 4.9; 4 and 5.9, with hemoglobin 105 per cent. In 22 men over 60, the erythrocyte average was 6.1 millions, the range from 4.9

to 6.8, with hemoglobin average of 104 per cent.; and in 21 women of 60, the erythrocyte average was 5.1 million, range from 4.2 to 6.4, with 96 per cent. hemoglobin average. Tests after drinking large amounts of fluid showed a higher erythrocyte count than before. Comparison of the count in blood from the ear, from a vein, from the abdomen and from the finger tip of the same person showed differences up to 1.6 million. The average count is thus 5.5 million for men and 4.5 for women, but the physiologic figure varies within wide limits. The erythrocytes are evidently not evenly distributed through the body. The higher erythrocyte average count in the elderly is not an absolute rule as in some of the younger persons equally high figures were noted, and, in some of the elderly, figures as low as the lowest in the younger subjects.

**Meningococcus Infection and Meningitis.**—Tobiesen reports what he thinks is a very instructive experience with two cases of meningococcus infection. A girl of 14 developed cerebrospinal meningitis; six days after the first symptoms her classmate showed meningococcus infection, but there were no signs of meningitis. Meningococci were cultivated from the throats of both girls, and both had the typical exanthem. But serotherapy was applied so promptly in the second case—the circumstances then allowing speedy differentiation—that prompt recovery followed before the meningococcus in the blood had had time to induce meningitis. Both the girls were left carriers for some time, showing that the brief febrile meningococcus septicemia is epidemiologically as important as actual meningitis.

\*Uveoparotid Fever. H. Thomsen, p. 1517.  
\*Eclampsia with Uremia. A. Tofte, p. 1521.

**Uveoparotid Fever.**—Thomsen remarks that during the ten years since Heerfordt described the first 3 cases of uveoparotid fever, only 15 other cases have been published; 10 of the 18 were in Scandinavian literature; 2 in Germany. This set of symptoms does not seem to have been encountered elsewhere. Thomsen's attention was attracted to it by the case he here describes in a girl of 18. The slow insidious chronic course of the bilateral iridocyclitis and bilateral parotitis was accompanied by unilateral facial paralysis. The latter has been recorded only in 5 of the total 18 cases and in all these there was peripheral paresis. All agree that the disease has nothing to do with mumps or syphilis. Bang in 1908 suggested that the disease had some analogy with pseudoleukemia, while others are inclined to incriminate the tubercle bacillus. In 2 cases on record a complete cure was realized under tuberculin and this occurred also in the case here described. None of the ordinary measures had the slightest effect, while there was a strong focal reaction to the tuberculin test and striking benefit followed systematic tuberculin treatment, progressing speedily to a complete cure. He thinks it is evident therefore that in a certain proportion of these cases tuberculosis is responsible, although as yet tubercle bacilli have never been discovered in any instance. If the tuberculin test proves positive, tuberculin treatment should be given a trial.

**Uremia After Eclampsia.**—The woman in Tofte's case had had severe pregnancy nephritis at her first pregnancy; then came three normal pregnancies in rapid succession. After an interval of thirteen years the fifth pregnancy was accompanied by severe eclampsia, blood pressure 200, and 15 per thousand albumin in the urine, with much methemoglobin. After vaginal cesarean section there followed anuria, uremia and spasms, but the eclampsia subsided. The woman lay in apathy, and the clonic spasms the fourth day seemed to be due to the uremia, the total amount of urine having been only 158 c.c. in the first three days. The prognostics of such cases of anuria and acute uremia after eclampsia is grave, and decapsulation of the kidneys may be the only means of salvation. This was contemplated in Tofte's case but did not prove necessary, the anuria being overcome by drinking of fluids, repose and a diuretic. He doubts whether the patient would have survived decapsulation of the kidneys. He supplemented the 1000 to 2000 c.c. fluid by the mouth with saline infusion of 800 to 1700 c.c.

## THE SKIN: A MIRROR TO THE SYSTEM

M. F. ENGMAN, M.D.

ST. LOUIS

I fear that the dramatic title of this discourse is rather misleading. I do not mean that the skin, as an organ, is of universal diagnostic value in relation to internal disorders. What I mean is that the skin may be of great diagnostic assistance in many groups of general conditions or diseases. In other words, it may reflect, as a mirror, certain fundamental truths relative to the pathology of diseases in general.

Dermatology, since the time of Hebra, has become a study of morphology. The lesions seen on the skin have been studied both histologically and clinically, generally without regard to the underlying connection they may have with any other organ or system whatsoever. Most of the literature on skin diseases consists of a clinical description of the disease and its histologic character. This custom has been extant for the past sixty years, and it has been only in the past few years that the proper study of certain diseases of the skin has been undertaken.

Leloir remarked some thirty years ago, in his graphic French way, that the skin was a mirror to the system, that is, certain signs and symptoms on it could be used, when properly understood, in the diagnosis of many systemic conditions.

Skin diseases are usually treated in the outpatient departments of hospitals and universities, without any direct connection with the departments of internal medicine. Those limiting their practice to diseases of the skin are apt, through routine and training, to pay attention only to the treatment of objective lesions on the skin, and in the very nature of this practice are not enabled to follow the case into the intricate mazes of internal or systemic conditions to which it may lead.

No one can properly study diseases of the skin and have a comprehensive knowledge of their pathology unless he is enabled to study profoundly all conditions relative to the case. This can be accomplished only in a well regulated and well equipped general hospital in which the full clinical data relative to the patient, or case, may be worked out; where he can have the cooperation of a trained internist and all of those facilities which constitute the conditions for proper clinical study.

During the past few years there have been signs of revolution in the present status of diseases of the skin, which has been brought about by the modern methods of diagnosis and clinical study.

The skin is obviously an organ of the body, as much so as the liver or kidneys, and is subject to the same laws of health and disease as those that govern the other organs of the body, the only difference being its exposed and external position. It receives its nourishment from the blood stream and is, therefore, affected as any other organ might be from anomalous conditions as to quality and quantity of the constituents of this fluid. It is affected, as any other organ, by the nerves and vessels of the body. Therefore, through this intimate internal relationship, the study of the changes that occur on the skin may prove of great assistance in the proper understanding of various systemic constitutional conditions.

This subject naturally embraces such a large field that it would be impossible in a short discourse to cover all of it. My plea is more for the purpose of drawing attention to a few striking groups of diseases in which the skin is of the greatest diagnostic assistance and importance.

For the purpose of discussion I will divide the subject roughly into, first, inherent factors that point to certain constitutional conditions, and second, blood-borne conditions which affect the skin.

### INHERENT FACTORS

Any one who has studied the pathology of skin diseases for a number of years must recognize the fact that there are certain inherent conditions in the skin, congenital or inherited, which, when understood, throw a flood of light on the proper understanding of the patient as a whole. Take, for instance, the early manifestations of that condition known as exudative diathesis, which appears very early in life and marks the infant a clinical entity, the first symptom of which is eczema. This is seen on the cheeks or body to be followed all through life by adenoids, asthma, bronchial conditions, and enlarged glands, and tells the observer, in unmistakable language, the phases of the pathologic conditions through which the patient will pass. This type of individual frequently never changes, and may be pursued throughout life with recurrent respiratory inflammations. Sensitization in infancy may be at the bottom of this condition. Improper feeding may show itself on the skin by a dry, scaly condition which may induce traumatic eczema. Heaping up of cells about the follicles on the extremities may point in early life to hypothyroidism.

How graphically may presenility be shown in those changes seen on the skin in the disease known as xeroderma pigmentosum. Although the disease is said to be due to the effect of the actinic rays of light on the skin in these persons, yet their skin is a senile skin. A senile skin at the age of 8 or 10 years does not differ fundamentally from that of an old man or of one

burned by constant exposure of the roentgen ray. This disease first shows itself by exaggerated freckles, followed by marked pigmentation, telangiectases, atrophy and, finally, the formation of carcinoma which frequently metastasizes. This skin is an old skin, and the person it covers is fundamentally senile. The signs and symptoms on the skin of these patients give one at once a clue to the equation of the individual.

Age, although usually computed by time and years, is indicated more on the skin. A man is not only as old as his arteries but also as his skin. The skin shows the first signs of senility, whether thirty or eighty years have passed since birth. These indelible signs of life-wear are seen first on the exposed surfaces and on the chest, in the form of atypical cornifications of the epidermis called keratoses senilis, of persistent freckles which do not disappear during the winter, discolored areas of the skin, and, finally, the wrinkled, atrophic appearance seen in old age.

It is curious to note how early these senile cutaneous changes occur in certain families, and usually they are seen in those who are prematurely old at 40. The skin on the back of the hand is a true gage as to the wear and tear of the body in relation to years.

The earliest signs of approaching puberty are seen on the face, indicated by the little comedo on the cheeks or nose and the increased oiliness of the skin in that region. The comedo and a mild or severe degree of the so-called oily seborrhea are as truly secondary sex characteristics as the appearance of hair on the pubes or face. They signal a systemic change, the awakening of a new phase of life, a chemical and physical change. Yet we are taught to look to the diet as the cause of oily seborrhea and the blackhead. That some systemic hormone has affected intrafollicular conditions and the fat metabolism of the epidermis is the only modern biologic explanation.

Acne vulgaris sometimes follows, with a lesion whose histopathology demonstrates its bacillary origin as truly as the military tubercle of tuberculosis is of bacillary origin. Yet we are taught to look to the diet with this histologic evidence before us. Dietetic or food-produced lesions, or, rather, lesions produced by chemicals (foods) taken into the alimentary canal or introduced parenterally, belong to the large erythema group and do not produce the organized inflammation, almost of a granulomatous character, seen in acne vulgaris. The intrafollicular flora is awakened into new life by a chemical change in the body; and not only this, but the folkle and the individual also enter a new phase of existence; the oily seborrhea, the comedo, and the acne vulgaris signal this change.

#### BLOOD-BORNE CONDITIONS

The inherent and physiologic conditions reflected by the skin are many, but we must consider the more important blood-borne conditions. The anomalous action of the ductless glands is frequently the cause of change in the skin in the form of telangiectases, pigmentation, dryness, scurfulness, darkening, etc.; all of which is well known in medicine. We will dwell, however, for a few moments on hypothyroidism, a subject which I have had unusual advantages in studying from a purely dermatologic standpoint.

The thyroid gland secretes several definite chemical compounds, each with a specific office as demonstrated by Kendall. I had arrived at this conclusion years ago from the experimental study of obvious hypothyroid

phenomena on the skin. Experimental thyroid feeding with the various thyroid preparations on the market demonstrated plainly the necessity of more exact specific preparations as, in a certain type of cutaneous change, thyroid feeding in certain cases would produce only a degree of improvement, while on increasing the dosage, untoward vasomotor and cardiac symptoms of hyperthyroidism would interfere. With Kendall's "Thyroid B" in which the vasomotor element was omitted, uniformly definite results were obtained. "B" of Kendall contained only the element which specifically affected the skin, at least, that was the obvious clinical conclusion.

The cutaneous symptoms of hypothyroidism are diagnostically more valuable than the reduction tests, the pulse, or any of the vague systemic symptoms. Sometimes the only symptoms are the skin changes:

1. There may be a dryness and scurfiness of the skin, frequently associated with pruritus.
2. A shriveled presenile appearance of the skin as a whole may exist, differing from other types of presenility in that the changes are more marked on the covered portions and on the palms and soles. The skin over the covered portions is more deeply lined, somewhat finely striated, of a very pale pear-gray, dry, maybe scurfy, and soft. The palms and soles are characteristic, dry, maybe fissured, the lines of the fingers and palms greatly multiplied by deepening of the furrows. Such a palm would puzzle a palmist. The skin of the dorsum of the foot is sometimes slightly atrophic.
3. There may be an erythema of a deep red to purplish hue on the nose and cheeks, curving downward around the corner of the mouth onto the chin. This area may be studded with small, fine, scaly papules due to secondary infection. The face is full and round, and the cheeks are prominent.
4. Myxedematous pads may be found in the supraclavicular depression. These are small, raised, tumor-like hemispheres, resilient to the touch. They may vary daily in size. Their peculiar resilience differentiates them from fat. Such pads may be found elsewhere on the individual, quite frequently on the arms, as occurred in a brother and sister in our series of cases. They can easily be discovered by careful palpation.
5. There may be loss of hair, particularly about the temples. The hair is dry and lusterless.
6. A sharply defined scorchlike dermatitis of the head, neck, face and chest may be present. The process stops abruptly just below the clavicle in a curved line, curving convexly upward and backward from the front to join the area from behind at the base of the neck. This type of marked dermatitis I have seen disappear again and again under proper thyroid therapy. It is usually accompanied by patches in front of the elbows and behind the knees. Other symptoms of hypothyroidism are usually present: headache, slow pulse, forgetfulness, pain in the back, slight resistance to cold, etc.
7. Pigmentary anomalies are frequently the sign of thyroid disturbance as well as that of other glands, the supra-renal glands, for instance. The thyroid pigmentations may be: in children, a slight deepening of pigment in a broad band about the neck, the deepening of color sharply defined; a similar deepening to a light café au lait tint about the trunk, *en cuirasse*; a darkening of the whole skin to a deep pearly or dirty, unhealthy, bluish gray, or a changing of the skin to a "skimmed milk" tint.
8. A scurfiness of the elbows and knees, when accompanied by the palmar and plantar changes, is characteristic of hypothyroidism in those past 30.
9. Acquired ichthyosis or ichthyotic-like changes appearing after puberty reflect thyroid deficiency.

When we say thyroid deficiency we do not know what we mean, and most frequently we do not obtain successful results from our present methods of thyroid feeding, as no one knows what specific elements are

contained in the products at present on the market. Therefore, a therapeutic test at present is misleading and frequently unsatisfactory. Exact, specific thyroid feeding, from the standpoint of Kendall, is needed.

OTHER BLOOD-BORNE REFLECTIONS ON THE CUTANEOUS MIRROR

*The Erythema Group.*—This group of skin diseases, including urticaria, angioneurotic edema, erythema multiforme, erythema nodosum, scarlatiniform erythemas, purpuras, certain cutaneous gangrenes and Raynaud's phenomenon, possibly certain types of pemphigus, dermatitis herpetiformis, and lupus erythematosus, is the most fascinating and alluring of all groups of skin diseases, because modern medical illumination has flashed its rays on the mirror. Our writers have not as yet seen the light relit by Osler through his epoch-making study of this group. That lesions of the erythema group were not infrequently pathognomonic of grave systemic disorders antedated Osler's observations, but the glow was dim, indistinct, flickering. Osler relit the light, trimmed it, and held it aloft.

The erythema group is always deserving of careful study and thorough clinical investigation, no matter in what eruption or form it may present itself on the skin. The eruption is always produced by something brought to the skin by the blood stream: a chemical which may produce a wheal or a papule, a tubercular lesion, a spreading plaque, a hemorrhage, gangrene or a node, through local vascular effect or an interference, physically and chemically, in the nutrition of one or more extremities—so-called Raynaud's disease. Similar results may be produced by embolic foci of micro-organisms brought to the skin. The offending chemical may come from numerous sources: a food-stuff rendered innocuous through sensitization, foreign serums parenterally introduced, focal sites of infection, drug sensitization, acute invasion of micro-organisms, as in the infectious diseases, etc. The study of an individual case presenting an eruption belonging to the erythema group is a task of no mean importance.

Many of the symptoms of this group are due to direct embolic disturbance of the skin by micro-organisms. A simple urticaria relieved by diet and salts is a therapeutic triumph; but how often do we obtain such results in other types of eruption belonging to this group? With recurrent erythema multiforme we are not so fortunate. The latter means a study which will tax all departments of clinical research. Cultural investigation may disclose a micro-organism in the general circulation when an aortic murmur may be well established or be just beginning. Sensitization tests may demonstrate a condition of allergy; the roentgen ray, an old appendical trouble; the dentist, an involved root; but this is rarely a factor; and so on.

Minute petechial hemorrhages about the edge of the lobe or concha of the ears, in the gluteal folds, in the tips of the fingers or toes, points always to emboli of *Streptococcus hemolyticus* and, not infrequently, these petechiae are associated with erythema multiforme, urticaria or angioneurotic edema.

In studying the erythema group it is well to remember that many organisms beside the spirochete of syphilis remain, we might say, latent in the system. This explains many of the recurrent, relapsing forms classically described by Osler. I have had the advantage of following several cases to the end. The most

murderous of the class of cocci that lurk in the system to appear probably at intervals in the blood stream is *Streptococcus viridans*.

This organism may not infrequently in its insidious invasive stage cause some type of erythema multiforme or urticaria; but I have never seen any eruption after the constitutional symptoms became constant. In one striking case from an old mitral lesion the new blood systemic invasion evidently began, ushered in by an urticaria, with some lesions characteristic of erythema multiforme. The subsequent course of the disease presented no cutaneous disturbance. *Streptococcus hemolyticus*, on the contrary, induces purpuric lesions with no inflammation or, at least, with very mild inflammatory phenomena, and gangrene is the frequent associate.

A child enters the hospital with erythema multiforme, purpura, or one of this group. It may or may not have intestinal crises or rise of temperature. A short sojourn effects a symptomatic cure, yet the child deserves watching unless the etiologic factors in the case have been convincingly demonstrated. Negative blood cultures are not convincing. A mitral harshness may be mistaken for an anemic murmur when it may be the incipient stage of a building colony on the valves. An erythema multiforme at 10 and 12 may explain the patient's death years after. Syphilis is not the only eruptive disorder which delays its sting for years.

I have seen the sting delayed for thirty-five years in a case of cutaneous gangrene with Raynaud's disease. To the surgeon this group is extremely important. How chagrined he must feel who has opened an abdomen in a case of Henoch's purpura; and it has happened many times and unavoidably, too. I remember a clever surgical friend sitting with a child writhing with abdominal pain, believing and hoping for an eruption which finally appeared on the skin—it was measles.

Again, an old inflamed appendix may produce an eruption. The blood count is then of great value.

One can readily discern, I hope, from this short sketch of the erythema group how important it is, into what mazes of clinical research it leads, and how fascinating is its elucidation. Dermatologists since the time of Hebra have treated these different types of eruption as clinical entities, have named them and labeled them as such. It is a rule of nature to reestablish an equilibrium; therefore, these eruptions may, and do, disappear, and in the great majority of instances their true pathology is never known, just as the eruptions of syphilis disappear, but not the disease.

Lupus erythematosus, whose eruptive phenomena frequently occur as one of the types of the erythema group, is, in a large percentage of instances, accompanied by tuberculosis, and may be pathognomonic of that disease.

Dermatitis herpetiformis, a type of eruption quite characteristic, often shades into the erythema group in some of its eruptive varieties, and is always a symptom of some systemic toxemia. It may be reproduced in certain individuals by drugs—iodids, for instance. To me, it is generally an indication of intestinal toxemia; yet other sources for toxic bodies may be found. Vaccination connects this group, in a symptomatic way, with pemphigus. How characteristic to the trained dermatologist is postvaccinal pemphigus. Yet we see exactly similar eruption with which vaccination cannot be connected. Reasoning, therefore, from analogy

on objective grounds, pemphigus is loosely related to the erythema group and is undoubtedly pathognomonic of some blood-borne principle—a chemical (toxin) or micro-organism. The kidney disturbance accompanying these variously named eruptions is significant. When death occurs from the continuous action of these agents which induce the disease, it is usually due to exhaustion or terminal infection.

The papulonecrotic tuberculids which occur most frequently in childhood and adolescence are fast attaining their true position as diagnostic signs of great value. Pediatricians are recognizing this. The skin in this instance reflects the individual's true biologic relationship to the tubercle bacillus as the tertiary lesion of syphilis does to *Spirochaeta pallida*. These lesions, as demonstrated by Rist and Rolland, indicate a condition of allergy to the tubercle bacillus. They are spontaneous examples of Koch's phenomena and are produced by endogenous reinfection from some active or latent foci of tuberculosis within the system—blood-borne emboli of live organisms.

The terrific immunizing forces set into operation by the bacilli at once destroy them and incidentally produce the tuberculid seen on the skin as papules or nodules—a mass of cells which are, more or less quickly, absorbed. The type of tuberculid depends on the location of the reaction in or under the skin or in the vessels in or under the skin, most of them being fundamentally and, in their incipency, vascular in origin. Other organisms beside the tubercle bacillus may produce similar lesions, as in the condition known as erythema nodosum. Rist remarks:

It is impossible to reflect on the anatomical and clinical evolution of human tuberculosis without meeting the problems raised by the study of the tuberculids, and one must recognize that no general conception of tuberculous infection will be legitimate if it does not take into consideration the question of the tuberculids and fails to give a satisfactory explanation of them.

The lesions produced by this terrific reaction to the bacillus may occur in the form of disseminated lesions, as small papules or large gummatous masses, especially marked on the lower limbs. They always heal readily under rest and proper food. The type known as erythema induratum of Bazin is frequent in young girls from the large shoe factories in and about St. Louis.

Raynaud's disease, portrayed for years as an affection or disturbance of the so-called vasomotor system, is rapidly losing this position as the light of careful clinical research illuminates these dark recesses. In fact, formerly, the whole erythema group was attributed to the effect of some toxin acting on the vasomotor nerve and centers. Prince Morrow's book on "Drug Eruptions" may be epitomized as the effect of the offending drug on this system. The vasomotor system has been a family bar rack on which our dermatologic family has hung anything we could not find use for elsewhere. It is a cloak, a waste basket.

The experiments of von Dühring, Phillipson and Goldrist in their investigation of urticaria, the fundamental lesion of all blood-borne phenomena on the skin, when grasped, convince one at once of the inflammatory nature of these lesions, and divorces them forever from their supposedly vasomotor origin. These investigations demonstrated beyond a doubt the local action of some poison or agent, at the site of the urticarial lesion, which set in operation terrific forces, local in action.

By discarding this warm and comfortable cloak, the vasomotor theory, the investigation into the fundamentals of all of the blood-borne group of eruptions will take on new vigor, virility and daring. So it is with Raynaud's disease—critical investigation most frequently tears away the cloak and removes it from the vasomotor phenomena and places it with the vascular obstructions, obstructions of the vessels by spirochetes, tubercle bacilli, streptococci, or any other organisms.

*Group in Which the Palms and Soles Are of Diagnostic Assistance.*—The plantar surfaces of the feet and the palmar surfaces of the hands are of inestimable value and assistance in the diagnosis of certain diseases, particularly (1) hypothyroidism, (2) arteriosclerosis and (3) diabetes. Hypothyroidism has been described.

Thickening of the epidermis on the soles of the feet, especially about the heel, with a skin of dry and calloused appearance is very suggestive of diabetes. Frequent vesication with a tendency to localized necrotic areas is quite characteristic. All of the local symptoms on the palms and soles may be attributed to nutritional changes from thickened vessels. In diabetes, the local changes do not occur until late—after arteriosclerosis has begun. These blisters and epidermic thickenings not infrequently signal the debacle in these cases.

Xanthoma tuberosum and xanthoma diabetorum are well known. Xanthoma striae on the palms and soles are often the earliest symptoms of diabetes, especially in the young. Pollitzer and Udo Wile were the first to introduce into dermatologic literature the true significance of those yellowish tuberous lesions about the joints—called xanthoma tuberosum multiplex. The lesions on the skin merely reflect, at points of irritation and frequent motion, the condition of the blood which contains in excess cholesterol—fatty acid esters which irritate and infiltrate the cells. Similar deposits are found in other organs on the body, especially the heart. Xanthoma diabetorum is probably an acute type of the same process, associated with sugar in the urine.

11 Princeton Avenue.

## OUR BLINDED SOLDIERS

C. C. WHOLEY, M.D.

Member of Psychiatric Staff, St. Francis Hospital; Assistant Neurologist, Western Pennsylvania Hospital; Instructor in Psychiatry, University of Pittsburgh School of Medicine  
PITTSBURGH

The observations on which this paper is based are drawn from studies made of the men in U. S. General Hospital No. 7, while I was psychiatrist to that institution. The men totally or practically blinded in the American Expeditionary Forces, as well as those losing their sight elsewhere in our army and navy during the war, were sent to this hospital. Hospital No. 7, "Evergreen," is situated on a large suburban estate, giving a country environment. At the time my notes were taken, the handsome residence was used for those patients needing hospital care, while the other blind men were housed and attended the classes of the educational department in barrack buildings on the grounds a short distance from the hospital.

My conclusions are drawn from a series of 115 patients. Of these, seventy were blinded by high explosives, twelve by machine-gun or rifle bullets, and six were gassed. There were five cases resulting from epidemic meningitis, five from syphilis, one from

gonorrhoea, and four from degenerative processes, probably specific. There were four cases of retinitis pigmentosa, two of glaucoma, and there were six resulting from various other causes—infections, accidents, etc. I am indebted to Lieut. L. G. Campbell, ophthalmologist to the hospital, for ophthalmologic data referred to in this paper.

The average age of these men was 25, the oldest being 36, the youngest 17. With the exception of five, they were American born. They were for the most part sturdy individuals. The majority of them had grown up on farms and were members of rather large families. Their average attainment in school was the seventh grade; fifteen had had some high school training; one could not read or write; three had had college training. The apparently medium grade of educational attainment was not due to inferior intelligence but to the fact that so many men, growing up on isolated farms and having to work in the winter, had had only limited advantages of short-term schools. On the whole, these were intelligent, practical boys of good judgment, from whose heredity and environment we would expect a stable nervous system, and in whom we would look for an average healthy reaction from the shock of the western front. Most of these soldiers participated in some of the most terrible fighting of the war. A goodly number had been cited for special bravery.

The studies were made, generally speaking, from three to four months after the date of the original injuries, and after previous hospital treatment had been received. The acute symptoms had, therefore, largely subsided. My diagnoses were based on the histories elicited and on the present condition of the patient.

#### REHABILITATION PROGRAM

General Hospital No. 7, in addition to providing hospital and purely medical care for the men, also carried out an extensive educational and rehabilitation program. The work of the two departments was, of course, closely interrelated; and an important function of the psychiatrist was that of advising in the assignments to be given the men, so that their work in kind and amount might be that for which they were best qualified in every particular, especially from the standpoint of their state of health and mental makeup. In these pages I have presented, first, the more definitely psychiatric conditions encountered at Evergreen, and later have briefly reviewed the kind of life one found there among the men—the men often referred to as sightless, but who themselves always spoke of seeing as naturally as though their eyes still existed intact.

#### TYPES OF CASES

There were forty-two concussion cases. In three of these the injuries were received outside of actual warfare, as a result of explosions—one from a torpedo and two from dynamite explosions in government construction work. The loss of the eyes in all but five of the concussions was due to high explosives. The eyes were destroyed in a few cases apparently from the violent concussion alone; but generally from penetrating wounds caused by shrapnel entering one side of the face, or one orbit, and making its exit on the opposite side. In cases of the destruction of the eyes by rifle or machine gun, the bullet followed a similar course. In the five cases above excepted, blindness was brought about in this manner. It must be borne in mind that

in addition to the atmospheric changes which are a most important element in the production of concussion, we have in these cases the direct effect on the brain by the shrapnel, or bullet, crashing through the eye structures themselves; and through the bony structures, of and about the orbits, which are in direct contiguity to the brain.

In all these cases in which violent trauma occurred, shock was present in varying degree. Thirty gave a history of unconsciousness. But it is difficult to say just what part was played in the disturbances of consciousness by the element of shock. We do not know to what extent in certain cases there may also have been organic damage to the brain. The portion of the brain in which this damage was most likely to occur was the lower frontal lobes, especially the inner depressed portions around the olfactory bulbs and tracts where definite neurologic sequelae would be lacking—except in the case of the sense of smell. Furthermore, because of the complicated nature of the bony structures about the anterior portion of the base of the brain, through which the bullet or fragment often passed, it is doubtful if in many cases roentgenography would reveal the fracture causing the brain damage. Several of the men gave a history to the effect that a portion of the brain substance had been exposed by reason of the injury.

In nineteen of the concussion cases the sense of hearing was affected, varying from a ringing in the ears, and slight deafness, to complete deafness on one side, and rupture of the tympanum in a few cases. This large proportion of auditory disturbances is a natural accompaniment of a group of concussions due to high explosives.

The sense of smell was affected either temporarily or permanently in sixteen of the concussions. In those cases in which both eyes were destroyed by the flying fragment, the ethmoid bone was usually shattered in its cellular portion, but at times through the cribriform plate as well, the latter being the most likely mechanism in the cases of complete anosmia.

The sense of taste was either destroyed or impaired in seven of these cases. This finding at once brings up the question as to how the lesions in these particular cases brought about damage to the sense of taste. We know that the chorda tympani carries the fibers for the sense of taste of the anterior two thirds of the tongue; but the further path of these fibers, to the brain, is still open to question. Erb, with others, maintains that this further path of the taste fibers is through the facial by way of the large superficial petrosal nerve and Meckel's ganglion into the second branch of the trigeminal to the brain. Meckel's ganglion lies in the upper part of the sphenomaxillary fissure, which opens into the floor of the orbit; and this fact affords an explanation of the pathologic conditions in those cases in which the floors of the orbits were fractured with injury to Meckel's ganglion, and consequent interruption to the path of the gustatory fibers. The tips of the inferior temporal lobes where the middle fossae constitute part of the walls of the orbits were in some cases in the path of injury. For this reason we must consider the possibility of damage to the motor cortical centers of taste and smell which have been charted just behind this area.

In twenty five of the forty two cases of concussion, operation was performed within thirty-six hours following the injury, thus imposing the additional trauma

of operation, and, in many cases, the toxicity of anesthesia. In some instances the operative element prolonged the period of unconsciousness and exaggerated the subsequent disturbed mental state.

#### CASES ILLUSTRATIVE OF THE CONCUSSIONS

CASE 1 (47).—The patient, aged 20, was blinded by a high explosive shell at Soissons in September, 1918, receiving at the same time wounds in left side of face and in right arm. This patient has no recollection whatever of his injury, and remembers nothing of events for a week or more preceding it (retrograde amnesia); and for the month following his memory is also a blank. The amnesic period was followed by several weeks during which he could not remember the names of people, nor call objects by their right names (parannesia). He suffered from insomnia, was highly sensitive to noises ("jump"), was very restless, and was unable to fix his attention. This motor restlessness is still present seven months after the injury; and his taste and smell seem permanently damaged. We have been unable to induce this man to avail himself of any of the advantages of the educational department in either mental or manual training. He remains restlessly from building to building; is irrationally jealous and irrational or dejected; in a rather good mood he is always dissatisfied, wanting to be some place where he is not. He has only slight insight into his condition. I find his deep reflexes all exaggerated. This is a case of brain concussion of moderate grade in which mental deterioration will progress.

CASE 2 (41).—The patient, aged 27, was blinded in October, 1918, by a high-explosive shell on the Verdun front, sustaining at the same time an additional head wound and injuries to the left arm and left hip. There was a history of unconsciousness extending over a period of weeks. When I saw him four months later he was still bedridden, and confused as to time, place and persons. He was extremely weak and emaciated. He was in a semi-stuporous state much of the time. At times he would be humming the same tune over and over, or laughing to himself. His memory defect was very marked. He would forget in the middle of a conversation that he was being talked to, and would ask irritably why no one was there. This patient improved to a noticeable degree physically, but his mental defect was still very marked even months after his injuries. His elbow and knee jerks were exaggerated and were greater on the right; there were double clonus in the left; the pulse was 96 (in bed). The picture was that of definite mental deterioration following brain and skull concussion—moderately well marked dementia. This case represents a severe grade of concussion.

CASE 3 (32).—This patient, aged 34, was blinded in September, 1918, by a high explosive shell on the St. Mihiel front, receiving at the same time wounds in the face (four upper lip, being knocked out) and in the left shoulder. He was wounded while on patrol duty, being one of a party of four men and a German due out. "I crawled into one of the holes, and a fellow got into the bank over mine, and it was a trap. . . . I am the only one of the four left." He gave a history of bleeding from the ears following the injury, and a discharge from them for six months. He felt that all went following the injury; he turned his gun on himself, but "the trigger wouldn't work." He walked a half mile, but lost consciousness; he was unconscious for ten days. His unconsciousness was followed by confusion that lasted two weeks. He dreamed for many weeks of "going over the top"; and depression was extreme. This patient is still (seven months after injury) troubled by extreme depression, and tires easily. "When I get up in the morning I try to make good, I go all to pieces. . . . I can't stand music either, when the fellows talk I think I'll go crazy. . . . I can never like this before I was hurt; my fellow was like a jump like that I'm in his right senses." The elbow jerks are normal; the knee jerks are about normal but slightly more active on the right.

This patient is an exceptionally fine type of man, courageous, modest, naturally well poised, a Westerner of splendid physique. He has stuck to bridle with unusual persistence.

In spite of this soldier's inherent health and vigor and his force of character, the shock that his nervous system has sustained has permanently reduced his ability to withstand strain. This is a case of concussion followed by marked neurasthenic symptoms.

#### DIFFERENTIATION OF SYMPTOMS

It is manifestly impossible when the trauma is so overwhelmingly physical to differentiate etiologically symptoms specifically dependent on concussion from those purely neurasthenic in nature. Observation over a long period would often be necessary for a satisfactory differentiation. In thirty-seven of the forty-two concussion cases, there developed a condition showing symptoms indicative of neurasthenia, in addition to symptoms such as the following more definitely characteristic of concussion: inequality and increase or decrease of the deep reflexes, dizziness, vomiting following injury, ringing in the ears and discharging ears, bleeding from the nose and ears, unconsciousness, pain in the head, and delirium. In those cases in which I made a diagnosis of neurasthenia in addition to that of concussion, there were found symptoms such as hypersensitiveness to sounds—"jumpiness"—dreams of the battle field, motor restlessness, paresthesias, and increased reflexes. The majority still presented, when coming under my observation, evidences of vasomotor weakness (lividity, tachycardia, lowered surface temperature, clamminess of extremities), and in a large percentage, muscular tremor.

I am impressed by the importance of being cautious in giving a prognosis for complete recovery in these cases of concussion. It is necessary to bear in mind that while, in some instances, return to physical health may be permanently maintained, in a fair number this apparent recovery may be succeeded by a slowly progressive deterioration. In all the severe cases I believe ability to withstand mental or physical shock has been permanently lowered.

Of the entire series (115 cases) fifty patients suffered from well marked symptoms of neurasthenia; four of these had not been subjected to actual warfare. The concussions, as has been stated, contribute thirty-seven of these neurasthenia cases. In addition to the fifty mentioned above, twenty-eight presented mild symptoms that were regarded as neurasthenic in nature. The term neurasthenia is used here as designating a state of exhaustion dependent primarily on such causes as physical trauma, concussion, shock, prolonged fatigue, infections, etc., alone or variously combined.

#### CHARACTERISTIC SYMPTOMS

Symptoms characteristically found in the neurasthenic group were, in the milder cases: transient depression, mild anxieties, fatigability, restlessness, insomnia, irritability, etc. In the moderately severe cases these symptoms were exaggerated and prolonged; and the depression sometimes carried the patient to the point where suicide was contemplated. Nostalgia in an exaggerated form often existed. Dreams of fighting in the trenches occurred. In these moderately severe cases, recuperation was slow, and clearly defined symptoms were still present when I saw the patients several months after the original trauma. Many showed, at this time, moderate lividity of the extremities and increased activity of the heart. Prognosis generally was good. In the severe types of neurasthenia the neurocirculatory aetiology was more grave; muscular tremors, tachycardia, palpitation, hyperhidrosis, and

increased reflexes were more in evidence. In this severe group, we find those patients who passed through marked anxiety states; sleep was disturbed for many weeks by dreams of fighting; many suffered from extreme exhaustion; in a few the neurasthenic state followed a prolonged period of amnesia or of delirium. Prognosis for complete recovery in the majority of this group is doubtful; in some, prognosis is definitely bad.

In some of these cases the term hysteroneurasthenia was used in the diagnosis to characterize the emotional element figuring in the syndrome. A fact noticed in these hysteriform syndromes was that in every instance the patient was constitutionally more or less unstable emotionally. On taking reflexes one met an over-reaction in which there seemed to be a voluntary element. These men were overfearful during examinations. They were often distrustful and querulous. It must be understood that the symptoms in this group were not major manifestations of hysteria.

#### DIAGNOSTIC VALUE OF ATTITUDE TOWARD BRAILLE

I have disregarded, in these tabulations, psychasthenia as a distinct diagnostic entity. A disturbed psychic condition necessarily exists in neurasthenia, and is more or less coextensive with the state of prostration. One of the evidences that I found of considerable importance in estimating the degree of mental inadequacy, or psychasthenia, was the ability of a man to apply himself to the study of braille, a system of raised characters by which, through his sense of touch, a blind man reads, and which is more of a tax on attention than typewriting or the other curative or educational work given to the blind soldiers at Evergreen. In certain cases this study seemed to cause especial distress and irritation. "I can take anything but braille; not braille, braille drives me crazy." This attitude toward braille varied with the severity of the neurasthenic symptoms. The memory-association with this particular work, when it had been inopportunistly urged on the patient, was in some cases so disagreeable as to prevent the resumption of this necessary study, even after sufficient recovery had been made for the men ordinarily to take it up without nervous strain. On the whole, the reaction toward braille, presenting in fair measure the degree to which these men were able to exercise their mental faculties, supplied an important diagnostic aid in estimating the extent of nervous shock sustained. In marked contrast to those reacting psychasthenically toward braille stood out the small number of sturdy individuals who found little or no difficulty in keeping up the sustained attention necessitated by this study.

#### INFREQUENCY OF SYMPTOMS OF MAJOR HYSTERIA

An interesting fact found in these cases is that in only two of the series of 115 did the condition presenting seem to be symptomatic of major hysteria. In one of these patients, a negro, aged 23, a typical "shell shock" condition arose a month previous to the time his blindness came on. This patient said he was "scared" all the time he was in the trenches. He related that his "shell shock" followed the explosion of a shell near him, though he "was not injured." He stated that for a half day following this he "couldn't tell what was going on, or what people were saying." He has been "kinda mixed up ever since." He related that he stuttered for two days. This patient still stut-

ters (seven months later) when excited. After this experience he was more than ever frightened, and his sleep was disturbed by dreams of fighting. This fear continued until he got away from the sound of the guns a month later. At this time he was taken sick with fever and headache. His vision failed and he was sent back to a hospital, where a month later one eye was enucleated. He was greatly depressed. The ophthalmologist's diagnosis was acute glaucoma. Six months later, examination revealed general hyperalgesia, with hysterical weakness of the left side of the body. This man had had pleurisy on the left side three years before going into the service. The knee jerks were minus; the elbow joint plus; there was tremor of the tongue and a pulse of 120 (sitting). The patient was overfearful during the examination.

The second patient with hysteria was a musician, aged 24. He was gassed but not sufficiently to account for the optic atrophy that was afterward discovered. There is a history of blood and spinal fluid examination; following lumbar puncture his right leg was paralyzed for three days; then it became numb with additional numbness of the entire body up to the nipples, the whole lasting about six weeks. His "body felt as though it was asleep." During this period he could not bend his knee or ankle. At the time of my examination, eight months later, the deep reflexes were slightly more active on the right. This patient presented a hysterical constitution, with a degenerative, probably syphilitic, neurotic process.

The absence of major hysterical symptoms among the men of this series, blinded at the front, is so striking that it calls for comment. Among those who received their wounds in actual battle there was an absence of stuttering, massive muscular tremors, tics, palsies, aphonias, hysterical deafness, etc.—in short, such phenomena as characterized the cases of major hysteria I saw at Plattsburg. The theory that hysteria does not develop when the wound is a "blighty," namely, so severe as to put the man definitely out of action, does not seem to afford a satisfactory explanation for the absence of hysteria in these men blinded under shell fire. For in only two or three instances did the soldier seem to realize at the time that his eyes were put out. In most cases the men did not know that they were blinded for weeks, and often for months, after the injury. Some were not told that they had permanently lost their sight, until after they had reached Evergreen. Very few suffered pain of any consequence either when wounded or subsequently; and thus many, their eyes being bandaged, did not suspect the seriousness of their condition. A number spoke of having expected to return to their "outfits" in a few days, and of being disappointed that they were not sent back to them. Nor could I discover from their talk that there had been any desire to escape from the fight, or any feeling of jubilation over being out of it. Their dreams, when such had occurred, were almost invariably of killing Germans, and of themselves coming out victorious. In the case of one patient, a boy only 17, who was somewhat unstable emotionally, a fear element came out in the dreams. He would awaken as "the boche was taking his trench." These findings are not such as we get in certain cases, when the absence of hysteria is attributable to belief in a disabling wound.

It seems reasonable to suppose that in so large a series there must have been men who were potential

candidates for major hysteria. The conditions under which the group received their knock out wounds were precisely similar to those conditions under which other men were wounded who did develop hysteria. However, there were two factors present in this set of injuries that did not exist in any other: the men were immediately blinded, and consciousness was at once more or less obtunded. The almost universal absence of pain is a tangible evidence of a general blunting of the sensorium. These two distinctive features seem to me of valuable consideration in explaining the absence of hysteria in these cases. Blindness shut out in a flash the horrible scenes of the battlefield. It is interesting to note in this connection that blindness was frequently encountered in soldiers as a hysterical phenomenon. This indicates the frequent importance of vision in connection with the scenes of the battle-field, when a psychic trauma supervenes. The second factor, the obtunding of consciousness, is of greater significance. Obtunding follows of necessity the peculiarly violent head injury sustained in these cases. In the dynamics of hysterical symptomatology formation, there seems often to be a critical moment during which consciousness is in a supreme state of awareness, and hyperemotional tension. This awareness and tension are, in fright situations such as confronted the soldier, most likely concentrated on some imminent hazard to life and overwhelming desire for escape from an unbearable situation. In the hysterical individual, the higher mental faculties seem, at this critical moment—the precipitation instant as it were—to be rendered suddenly inert by emotional panic, and the individual reverts to primitive biologic impulses having self-preservation or escape from an unbearable situation for their goal. In the reflex activities which occur, the higher mental faculties are shunted out of the arena, and the most varied and distorted associative mechanisms may be set in motion. It is from these mechanisms, coming into action in the lower biologic strata, with the controlling civilizational motives shut out, that the more or less autonomous hysterical symptomatology arises. I think I am safe in saying that because of the instant blunting of consciousness, along with simultaneous blinding, which occurred in these men, it was dynamically impossible for the mechanisms necessary for the acute onset of hysteria to come into play.

It may be remembered that the two men who developed major hysteria had not been wounded in battle or blinded, at the time of the onset of the symptoms. The first man developed symptoms following the explosion of a shell nearby, a month previous to the time his vision failed from acute glaucoma. In the second case, hysterical symptoms followed lumbar pain some time before the onset of blindness which was due to degenerative processes. There was a third man at Evergreen (Case 129), seen after the foregoing man was compiled, who developed hysterical symptoms; here, also, the symptoms arose independently of battle wounds or blindness. This patient lost his sight following influenza, his hysterical, "shell shock" symptoms ("I hollered and cried") came on in the trenches apparently during the prefebrile period of his influenza.

In the majority of the patients, operation was done within twenty-four hours after injury was received. Usually a general anesthetic was given. Almost with-

out exception those patients who were in an exhausted physical state at the time they received their injury experienced, while recovering from the ether, a condition of delirium in which they imagined themselves fighting in the trenches or carrying on in some violent war activity. In some cases a delirium succeeded the operation.

#### ABSENCE OF PAIN

A feature that has occasioned surprise is the fact that these patients almost universally, regardless of the manner in which the eyes were destroyed, give a history of having suffered very little pain. This was true even though both eyeballs were entirely evulsed from their sockets, and perhaps with considerable destruction of the surrounding tissues.

#### THE FORTITUDE SHOWN BY BLINDED SOLDIERS\*

There was surprisingly little depression experienced by the men as a result of the knowledge of being blind. As has already been said, many did not realize, often for weeks or months, that their sight was gone; and, when they at length found out their true condition, they had already made long strides toward adapting themselves to a state of blindness. Those who were much depressed over the loss of their eyes were either those who had sustained unusually severe injuries or showed signs of constitutional instability or had been isolated from other blinded men from the time of their injuries to the time they returned to the United States.

In any consideration of our blinded soldiers, we are confronted with the stern fact that these men are permanently disabled and with the handicap that is generally looked on as well-nigh insurmountable. The question of supreme interest for all of us, then, is to what extent this group of returned soldiers are going to be able to adapt themselves to the social and economic life of their communities. War compensation, which is generously supplied these men by the government, while it takes care of ordinary financial needs, can never of itself, except in a most inferior, vegetative kind of person, give happiness or content or make the man a useful member of society. These fellows were an active, energetic, often ambitious lot. For them to drag out an idle, vegetative existence, subsisting on government bounty, would mean certain deterioration and mental dilapidation. Better than this, for the individual, would be a beggar's post, the street corner; for that at least has, as an incentive, the question of the day's luck. If life is to be bearable to these men, and if they are to be other than a burden to their communities, they must be made again independent, active individuals with initiative, competing with a degree of equality with their fellows, in social and economic affairs. It was for the purpose of thus training the blind that the educational department of Evergreen was established. It is said that a blind man must be "125 per cent.," that is, he must be 25 per cent. more efficient in a particular calling than the sighted man with whom he has to compete.

#### RECREATIONAL AND EDUCATIONAL ACTIVITIES

Shortly after the men arrived at the hospital, as soon as their physical condition warranted it, they were granted a furlough, and immediately on their return to the post, they were introduced, on the psychiatrist's recommendation, into various activities, according to each individual need. At first these were largely recre-

ational in character, such as dancing, swimming, bowling, theaters and concerts. At the same time the man could take on some of the activities of the curative work shop, such as basketry, carpentry, weaving and netting. Wherever possible they were introduced at once to the typewriter and to as much study of braille as the condition of their nerves and attitude would warrant. Along with the foregoing, many of the patients immediately entered on some vocational and educational training: salesmanship, physiotherapy, literature, book binding, machine shop industries, different forms of agriculture, and many other pursuits. Chicken raising was being followed by a number of the men with great enthusiasm.

The response to the many avenues of rehabilitation open to the men was very general; but there were a few to whom the task of readjustment seemed insurmountable. In this group there were three men who were constitutionally inferiors; undisciplined, irresponsible individuals of nomadic habits, who would have been ne'er-do-wells and trouble makers, just as well, if they had not lost their sight. There were also four cyclothymic individuals of the constitutionally elated character. These men, on account of their native excessive activity and "press of occupation," had great difficulty in resigning themselves to the handicap of blindness. With this group there were periodic outbursts of insubordination to authority; they would become paranoid and violently resentful of authority and discipline. During the intervals they usually did good work. There were seven patients in whom hyperthyroidism presented a complicating factor in the matter of rehabilitation. In one the thyroid condition was a serious handicap. A few had always been unresourceful, phlegmatic and at times constitutionally depressed. In these cases it was rarely possible to counteract the inherent tendency to drift into a life of inactivity, with loss of ambition, and general deterioration.

Peripheral nerve injuries were found in twenty-one of the men. In two of these cases the nerve injuries seriously interfered with the use of one hand, but the majority of these lesions were of minor significance, and for the most part caused merely small areas of sensory disturbance, infra-orbitally or supra-orbitally. There was one man in the hospital who had lost one hand, and one man with both hands gone.

The impression prevails that a visitor to the hospital would encounter a depressed and unhappy lot of men. On the contrary, one found a cheery atmosphere of interest, joviality and activity. There was much "joshing" and fun-making. The boys always referred to each other as "blinks," and would speak of getting a "half blink" (a man with one good eye) to take them about. If a cane fell or some one blundered noisily, there was likely to be a chorus of: "Hey, blink, better get your eyes examined." There were stock jokes about being able to see when they got their glass eyes; and about getting jobs as night watchmen. The patients went about the grounds and buildings in groups or alone with almost no hesitancy or groping. It was not always possible to know that a man was blind from his manner or walk. They enjoyed doing certain things, like holding a coat for one to put on, or opening the door if going out or in with any one, etc. These things seemed to make them feel independent and less set apart from sighted men. The blind boys were especially fond of dancing. This was

one of the first things they were taught at Evergreen. It not only seemed to instill confidence, in a surprisingly short time, in their ability to get about, but the knowledge that they were not to be shut out from the good times of other young people was a big element in the matter of sane adjustment to life. These dances with their chaperones and hostesses to see that no boy was neglected, the daily tea and cakes at the Red Cross house, the quiet story-reading hours, with the interesting work of the school, opened a new world to many of the lads. The majority had grown up in very simple surroundings. It was interesting to see how quickly some of them threw off uncouthness and took on amenities.

A curious thing in connection with these young men was the fact that the majority of them, sooner or later, discounted entirely the loss of their eyes. Again and again one would hear: "No; I don't miss my eyes. I never think of them except when I go into strange places." Many men dismissed the subject of being crippled by blindness with an air of contempt. In daily contact with these men one got the impression that they had to stop to consider, to remind themselves that they were without eyes, when their blindness was brought to notice. The remaining senses, in some cases, became marvelously acute. There were men, totally blind, who could tell when they approached a building or a tree, possibly through appreciation of some echo or through a change in atmospheric pressure. One morning, one of the patients came into a class room, which ordinarily contained three typewriting tables with a chair at each. For some reason, earlier in the day, the back of the room had been packed with chairs. The man stopped suddenly inside the door to ask: "What's the crowd for?" We told him there was no one in the room but ourselves (myself and a teacher); but the young man was not satisfied. He kept turning his head about, and finally came out with: "There's something in this room; it's full of people, or something else."

#### RELIEF AFFORDED BY ASSURANCE OF FUTURE SUPPORT

In considering the reactions of these men it is well to take into account certain factors that undoubtedly played an important rôle. The men realized from the beginning that their future support was assured. Thus was removed the great anxiety that usually goes with the affliction of blindness. One of the great factors that contributed toward sustaining their morale and attitude of cheerfulness has been the fact of being associated with those similarly afflicted in a big common experience. The patients frequently declared that they were far happier when they were with other blinded men. It was noticeable that in a few instances when men had been placed in hospitals or posts, apart from other blinded soldiers, they had been lonely and unhappy, and unable to adjust themselves successfully to their handicap. It happened almost uniformly that the men were eager to return to the life at the hospital after they had been home on furlough. The discipline of military life was, I believe, of inestimable value to the blind men at Evergreen; modified as it was, and wisely applied with rare insight and administrative ability.
