

AN

+ ILLUSTRATED + WEEKLY + MAGAZINE. +

FOR THE

ARCHITECT, ENGINEER, ARCHÆOLOGIST, CONSTRUCTOR,
SANITARY REFORMER, AND ART-LOVER.

CONDUCTED BY

H. H. STATHAM,

FELLOW OF THE ROYAL INSTITUTE OF BRITISH ARCHITECTS.

~~~~~  
"Every man's proper mansion-house, and home, being the theater of his hospitality, the seat of self-fruition, the comfortablest part of his own life, the noblest of his sonne's inheritance, a kinde of private princedome, nay, to the possessors thereof, an epitome of the whole world, may well deserve, by these attributes, according to the degree of the master, to be decently and delightfully adorned."

"Architecture can want no commendation, where there are noble men, or noble mindes."—SIR HENRY WOTTON.

"Our English word TO BUILD is the Anglo-Saxon Bylðan, to confirm, to establish, to make firm and sure and fast, to consolidate, to strengthen; and is applicable to all other things as well as to dwelling-places."—DIVERSIONS OF PURLEY.

"Always be ready to speak your mind, and a base man will avoid you."—WILLIAM BLAKE.

- Windows, Glass, designed by E. Burne Jones, A.R.A., 354-355

\* \* A Map of London and Suburbs, showing the Boundaries of the various Surveyors' Districts under the Metropolitan Board of Works, was given in the first four numbers of this Volume, in four quarter sheets issued January 1, 8, 15, and 22. Where not mounted on rollers or strainers for hanging up, it is suggested that they may be pasted together and inserted as a folding-plate at the beginning or end of the Volume.

### Historic Towns: London.\*

ESSRS. LONGMAN & CO. are to be congratulated upon their present undertaking, which is to issue a series of volumes upon the widely-extended subject of the historic towns of our

kingdom. They are to be of readable size, and of such moderate cost as to place them within the means easily of every reader. Dr. Freeman and the Rev. Wm. Hunt are the editors, and the intention is to treat of such towns of our country as have played a conspicuous part in the general history of the kingdom. There are, to quote from the preface, "the old Roman cities, restored in some cases after a period of ruin, and the old head-towns of shires, some the same as the Roman cities, others different. There are towns, like Bristol in one age and Hull in another, which, without being heads of shires, rose to importance through commerce." There are towns which have gathered around a castle or church; there are others which have risen to great wealth within the last two centuries. "York, once imperial, then royal, has kept more than any other city the character of a local capital on to our own day. Exeter is the city which, as not becoming English till Christian times, has lived the most uninterrupted life."

Winchester is pre-eminently the city of both English and Norman royalty. Carlisle, the

\* Historic Towns. Edited by Edward A. Freeman, D.C.L., Regius Professor of Modern History at Oxford; and the Rev. William Hunt, M.A., of Trinity College, Oxford.—London. By W. J. Loftie, B.A., F.S.A. Longmans, Green, & Co. 1887.

bulwark against the Scot, Shrewsbury against the Briton. Twelve of these volumes are either nearly ready or in preparation, one of them being devoted to St. Andrews, showing that the intention is, we are glad to see, not to confine the volumes only and exclusively to English towns. In addition, another volume is actually ready. This is rightly devoted to London, and it is from the pen of Mr. W. J. Loftie.

It is hut right that the beginning should thus be made with the Capital city, not only on account of its long existence, from Roman, or earlier than Roman, times, and of the important part it has played in the annals of our country; but from the fact that its charters and its privileges have stood as models for the framing of similar ones by the Norman and later kings to other municipalities. Its history will therefore serve a good purpose for comparison with the others to follow, and its beginning this series of volumes will afford benefit in consequence, while this volume renders the post of honour, as hy right, to the metropolitan city.

The tale of the growth of London from its beginnings in such early times of the dim past that we can only dubiously trace them in still more dubious tradition, and by discoveries few and far between, is of so much interest that a new book on the subject is always welcome, even although the number of existing hooks is already legion. The author's intention and object are best stated by a rapid extract or two from the summary with which he closes it. "I have endeavoured," he says, "without writing a continuous narrative, to show, first, by the investigation of recently-discovered evidences, how London attained its paramount position in the kingdom; secondly, how its municipal institutions, the models on which

those of almost every other English city and town have been moulded, grew up from the combination of the English shire system with the foreign commune, and partakes of the characteristics derived from both; thirdly, how in spite of the legal snjhection of Middlesex and part of Surrey to the city, the suburbs grew and extended under the control, not of the citizens, but of the ecclesiastical land-owners and their successors." The work consists of 213 readable pages, each of which will at least set the reader thinking, even when he may fail to agree with several of the author's conclusions. There is undoubtedly a difficulty which must always be felt by a writer who would take London for his theme, and that is the impossibility for him to deal with it adequately in a hook of moderate size. The subject is so vast and the issues so important that hardly any single volume is sufficient to afford us all the information we may desire. In the moderate-sized work before us it is, therefore, impossible to expect very deep or full information, and we may be prepared for only reference to a general narrative such as an ordinary reader may be satisfied with. We consider that the series of volumes in contemplation may fairly be expected to address themselves mainly to ordinary readers, or not much more. On this account we must confess to a certain feeling of regret, not that the pages do not tell us all that we may wish to know, but that they are written as they are. The narrative form, which we consider has many advantages for the production of such histories as are proposed, is almost entirely laid aside, and the writer assumes that the reader already knows the subject that may be desecated upon. When the narrative form is adopted, as it is in parts of the two last chapters, the pages may

be followed with much more interest and satisfaction.

In the case even of some of the recent discoveries, too, the reader is supposed to know of them, and we obtain insight into their nature only by some stray allusions. Thus, for instance, we hear of the discovery of a part of the northern gate of the City, but we are not told of the whereabouts in Camomile-street, under what circumstances, or when. Similarly, it is only by some stray references, one on one page, another elsewhere, that we are made aware of the nature of Mr. Lyte's researches among the St. Paul's monuments. We are already supposed to know all about them.

The book consists of nine chapters, arranged as follows:—London before Alfred, the Portreeves, the Mayors and the Wardens, the Municipality, London and Middlesex, and the Church in London, come in for a chapter apiece, while London Trade and the Relation of the City to the Kingdom are treated of in the two last chapters. These subjects will be of interest to many others besides Londoners, but it is, perhaps, in the growth of the City and its buildings that our readers will be most interested. The author unfortunately has not gone at all deeply into architectural matters, and says so. Still, there are a great many references which fairly well come within the scope of architectural studies, and particularly the chapters upon the early settlement of the City and the church in London. The derivation of the name of London is traced to two British words, *Llyn-Din*, the lake fort, with which the author appears to be satisfied, and upon which he bases a description which might as well have been reserved or modified, as to what the locality was in the British period. The Roman settlement is illustrated by a map, which is, of course, as may be said of all the other and numerous maps which have appeared in other works, different from any of them. It might as well have been omitted. According to Mr. Loftie, the original Roman fort was in form a long parallelogram, extending from the east a little beyond London Bridge, westward to Wallbrook, where it terminated in three impossible bastions, which, when laid down to scale on a map of London, measure more than 300 ft. in diameter each.

After this plan and the description we are not a little startled to find that this was not altogether London. But, on this novel subject the author had better speak in his own words, which we briefly summarise. "It will be desirable to examine a statement made by Ptolemy, the geographer, whose extraordinary accuracy is not to be lightly doubted. He sets London in Cantium, that is, on the south side of the Thames where Southwark is now." "We may account for this assertion by remembering that, until much later than his time, the Roman settlement on the northern bank consisted of very little more than the small fort." "Moreover, there have always been very extensive Roman remains found in Southwark."

"It is very possible that at the time Ptolemy wrote the foundations of Southwark were considerably larger than those of London, which, as we shall presently see, owed a short-lived importance to one of the very last of the great works carried out in Britain by the Romans." "We need not follow the suggestion that if 'Wall-Worth' means the farm by the wall, and if a wall went there, the wall around Southwark would be larger than that around London, but we may glance at the statement. 'Ptolemy is, therefore, right, and London, until the end of the third century, was a city in Cantium, with an outlying fort and bridge-head on the opposite side of the Thames.'" Elsewhere he says,—"I have already shown that London was not a walled city in 314, when Restitutus attended the Council of Arles." "Restitutus is, in fact, more real than London." "We may well close this series of extracts with this statement. We really wish that writers on London topography would be a little more content to study the discoveries of their predecessors, as well as those of our own day. It would prevent much random writing. The discoveries made along the line of Sherbourne-lane and Lombard-street more than

100 years ago, well outside the area of Mr. Loftie's small fort, indicated beyond a doubt that a large number of timber buildings had suffered from a conflagration, and that this was of early date was indicated by the presence of a gold coin of Galba's, with earlier ones, found in the midst of the burned ashes. Similar evidences of conflagration have been found over a great part of the City, and indicate that it was a universal calamity, and that London was then of fairly large size. The older writers are, doubtless, correct in assigning this fire to the time of the revolt of Boadicea. If we go to the Guildhall Museum we shall see a number of bricks inscribed "PRB. LON., P.P.R. LON.," and others,\* indicating beyond doubt that they refer to London, whatever may be the exact meaning of the inscription. They were found in London. Not a single one of the series has been found in Southwark, and to the best of our knowledge, not a single brick so inscribed has been found on the south side of the Thames; although, had it been so found, it would not have been an extraordinary matter. Roman remains in Southwark are numerous enough, but only a moderate distance down High-street, and nothing has yet been found of special interest, or different from what might be expected to be found on the sites of what were doubtless those of suburban villas. We are glad that a Roman origin is granted to the City wall of London, which, notwithstanding the evidence of its construction, has been denied by a recent writer.

We pass on to another subject, of no little interest to all students of English history,—the descent of Roman institutions to our own time. To state the case briefly, with fitting regard for the space at our disposal,—it has been observed by several historians that the municipal system of government by a mayor and aldermen, common throughout the Middle Ages to our own time, is very similar to the old Roman administration, and the inquiry naturally suggested itself, Did the system survive the advent of the Saxons and the intervening time until recorded history shows it to us as being in existence? Or, did it come into being in Norman times without regard to the antecedent state of things?

Believers in the continuous existence naturally lay stress upon the widely-extended use of the system, let the officers be called by what names they may be, and upon its rapid development as soon as charters began to be granted by the Norman kings to the various cities and towns, and it does not appear to be an unreasonable belief. It derives some additional strength from the fact that the earliest Saxon settlers in England appear to have avoided the towns for the open country. That the towns did actually continue, with what security their Roman walls could give them, is sufficiently apparent by the existence of many of them to our own times. Side by side with the town's government is that of the trading guilds. Recent researches have helped to confirm the belief that the various craftsmen of Roman times were united together in companies so analogous to the guilds of Mediaeval times as to render it equally reasonable to believe that the guilds whose existence is apparent at an early date in Norman times, are more likely to have been a survival than a new creation. Our author is, however, decisive in his opinion upon both these subjects. Of the first he says that "not a single fact of any kind has yet been adduced that will go even a little way towards proving this romantic theory"; "we have the king's officer, the wick-reeve, or portreeve,"—"the two words mean exactly the same,"—"mentioned as existing at the latter part of the seventh century; and he was still the chief civil authority in the latter part of the eleventh." "There is not," as the late Mr. Toulmin Smith well remarked, "the shadow of an analogy between Saxon and Roman institutions of this kind." The belief is expressed elsewhere that London was so completely burned by the Danes that King Alfred's reparation amounted, in fact, to a new foundation.

If we turn to other portions of the book, we shall find, however, that there must have been other authorities in the City than that of the portreeve. On page 191 we read with satisfaction,—"In the election of a king, London had long taken a great constitutional part. The voice of her citizens had long been accepted as representative of the popular assent in the election of a king. When Æthelred died, all the witan that were in London, and the burgesses, chose Edmund to be their king, says the chronicle." "On the death of Cnut, the citizens joined with the Danes in raising Harold Harefoot to the throne." In these narrations of facts, and others could be referred to, there is, singularly enough for our author's decisive assertion, no reference whatever to the portreeve, but only to the burgesses and citizens. It must be evident that a single governor could not get on for very long in the government of a large trading city without some sort of a Council. But then, this brings us closely to the model of an old Roman municipality. It may be remembered, too, that William the Conqueror's Charter is addressed not only to William the bishop and Gosfrith the portreeve, but also to the burghers. An interesting article not long since appeared in Walford's *Antiquarian*,\* from the pen of Dr. Pring, in which a clever line of argument is elaborated, suggesting that the office of portreeve itself descended from Roman times, and that the actual name, "porta," a city gate, itself shows the survival of a Roman official, having charge of the space at the city gates where the markets were held.

This subject is likely to receive much illustration from the series of volumes to be issued. Perhaps their appearance will be decisive upon it, for their production will require the searching through of many of the provincial municipal archives, and much important information may be the expected result.

The chapter devoted to a record of the portreeves is an interesting one, as is also that of the creation of the office of mayor. We hear of the mayors giving charters to the craft guilds; of many of the shopkeepers at an early period living at Stepney, Stratford, or Hackney; of many curious changes of name, showing that what is so familiar to us in the varying orthography of names in the seventeenth century had much earlier beginnings. The record of the appointment of the wardens is ably written, and is full of information, although assertion is now and then adopted when a little implied doubt would have been more suitable. We have reference to the guarding of some of the City gates by certain of the wards, in which we can readily recognise a resemblance to the defence of various parts of a castle by the feudal system of castle guard. There is hardly space in these crowded pages for reference to the old London legends, and none is made either to Gog or Magog, or to King Brutus. This is an advantage. Still, we were not prepared to hear that Ludgate meant only a "postern." The presence of the Jews in London is briefly referred to, and we learn that "the Jews were already remarkable for their skill in building, and theirs are among the oldest stone houses we hear of." The large amount of property held by the various monastic churches around the City is mentioned, and the causes why the suburbs of London were not included in the scheme of government of the City, are alluded to, as also the curious essays at the government of Bridge Without Ward. Of Westminster Abbey doubt is expressed with respect to genuine evidence of its being a very ancient foundation. "So far, I have not found any unquestionable evidence that Westminster Abbey was in existence before the Danish Conquest." The references to the earliest mention of the City wards are briefly but well rendered, having regard to the importance and extent of the subject.

The chapter devoted to the Church in London is all too short for fair justice to be done to the extended subject, and due allowance has therefore fairly to be made. There is a great deal contained in it which will

\* See the *Builder*, vol. II, p. 795.

\* The Ancient Name and Office of Portreeve. By J. H. Pring, M.D. *The Antiquarian*, magazine, iv., p. 264.

amply repay for the perusal; as, for instance, when the work of the Canons of St. Paul's is discussed, their non-residence, their finding a parochial congregation irksome, and the growth of a number of parish churches around the Cathedral and the Minster of St. Martin-le-Grand. "The Bishop and his Canons could assign a parish to a church as a modern rector assigns a district to a chapel-of-ease." Reference is made to the dedications of many of the churches, and it is ingeniously suggested that since several of the churches dedicated to All Hallows, St. Mary, and the like, stand close to one another, they, in fact, show the subdivision of some primitive parish having such a dedication, the later churches having the same dedication as the parent one, with a suffix for distinction. There is, perhaps, too much said to suggest that many of these parishes are of late rather than of early formation,—say, as we understand it, of post-Norman rather than of ante-Norman date. We think the balance of evidence is the other way, and that this chapter would have been the better had some of the statements been a little less positive. Thus, we are told that "St. Magnus only died in 1110, and his church, therefore, must belong to the great church-building epoch of the twelfth century, at the earliest." Other writers have, however, shown that there was more than one saint of this name, and that more probably the church is named after an earlier one. Then, too, there is no documentary evidence of the separation of this or of several others of the parishes, which might reasonably be expected to exist were their formation of the later Norman times. St. Bridget is hardly likely to have been the Swedish saint, as is suggested; and surely the existence of the steeple of All Hallows-the-Less, over the gateway of Cold Harbour, can hardly be accepted as evidence that the church was built by the owner of the mansion. Does it not rather point to an extension of the building, when the gate being in the way, the steeple was placed over it,—such as, in fact, we see in several existing buildings? We cannot support the statement, p. 167, that, with some exceptions, "no City church was conspicuous for any fine feature." While there were doubtless a good many small churches, Hollar's views are alone sufficient to show that they must have possessed many very interesting characteristics. A tribute is rendered to the genius of the "greatest English architect, called in to give the world a series of models of unapproachable beauty and convenience, designed, not like the old churches for the celebration of mass at many altars, but with the object of accommodating the largest number of hearers within sight of the pulpit." We concur in every feeling of admiration for Wren as a true man and a born architect; but to speak of his churches as of "unapproachable beauty" is merely a piece of the exaggerated cant fashionable at present among a certain clique of aesthetes.

The two concluding chapters, on London Trade and London and the Kingdom, are the best in the book. The former refers to the growth and extension of the mercantile influences of the City, not only in England but abroad, reference being made to the extended privileges of the citizens and of their dealings with foreign nations on reciprocity principles. "The men of other nations coming to London were to be treated as their countrymen treated the London traveller abroad." The closing chapter refers to many an event of which the Imperial City may be proud, for it speaks of her prowess and her influence for good in many a momentous event of English history. A parallel is drawn between Paris and London, and it is stated that while the influence of Paris on France has usually been bad, that of London on England has been good. Its voice has been potent in the setting-up of kings, in sustaining the liberties of our country, in many a noble and good act. Its influence has been the turning-point of many an event, and in the long run its support has caused success, the want of it failure.

While it is no ordinary task to write a book on London that is capable of satisfying the many and varying demands upon it, it is,

in like manner, no easy task to review any such book. When a volume is not sufficient to render justice to the theme, the ordinary compass of a review is hardly capable of reference to all the subject-matter of the book. We have only touched upon many points which deserve reference; we have passed over many more altogether. Still, while several things have been pointed out which we consider to be defects, we have, we hope, said sufficient to show that this moderate-priced volume is deserving of a place in the library of every man who desires to know more than he does at present of the rise and progress of the City of London.

A NOTE ON SIENA CATHEDRAL.\*

BY T. MANLY DEANE.

**T**O give a description of Siena Cathedral in a short space and short time is no easy matter, considering the number of works of art it contains, both in sculpture and painting, quite apart from the architecture of the whole, which, as a piece of Italian Gothic, may be considered the best that nation ever produced, being only rivalled by Orvieto and Milan; but, as most people know, the Italians never cared for Gothic work, and all their attempts at it are tinged with Classic, both in composition and detail. Siena is an instance, and no student of Gothic would ever come here to learn his art, beautiful as this building is. In composition, the façade certainly surpasses Orvieto; it is plainer and broader, and more logical; it is crowded with ornament; but this, in a climate like Italy, does not seem out of place, and certainly does not interfere with the whole effect, but rather gives scale and dignity. The west front, being so striking and more elaborate than any other part, naturally attracts all one's attention, and when one has described it he may be said to have described the exterior of Siena Cathedral; though the lofty campanile,—a work of much earlier date than the west front,—is a beautiful feature, and resembling in detail most of the campanili in Tuscany, beginning low down with one window on each face, in each story the number increasing towards the top. The church is built of black and white with some red and other coloured marbles in stripes. The campanile is all black and white.

Like the country itself, its people and their habits, one needs to be accustomed to this sort of thing before it becomes pleasing; but so it is this tower is beautiful when you know it. The dome is very little visible from outside, and is not a pleasing feature, with the exception of the lantern on the top, which is pretty. It will be well just to explain that the church, as it now stands, is an enlargement of an older church (of which, however, it would be difficult to find any traces), which was built in the twelfth century, and this enlargement is in its turn only part of a great scheme to build a huge cathedral, which would have been the largest in Italy, the present church being only the transept to this; but after working for years they were stopped by the plague and by the foundations giving way. This work was going on from about 1225 to 1259, and again till 1321; the nave of the present cathedral was lengthened in 1339. The principal dimensions are now,—300 ft. long; width of nave, 80 ft.; length end to end of transepts, 170 ft. John of Siena was the architect to the alterations of the west end; Maestro Lando also is mentioned as an architect, whose work also appears.

The inside of the cathedral is a picture. It would be impossible to say anything was good from an architectural point of view, but it has a lovely tone of colour, and from every point of view it groups well. There is no triforium, but simply very high side arches resting on clustered columns of black and white marble in stripes, and over these the vaulting arches spring close down to the string, with three-light tracery windows between. The aisles have large single-light pointed windows. There are five bays to the nave. The transepts have

aisles, with a chapel in each towards the east. The choir also has aisles. The dome and lantern is not over the centre of transept and nave, but towards the west end of the crossing; it is hexagonal on plan. There is a small apse to the choir. Over the side arches, as a sort of cornice between consoles, is a row of linceus heads, all done at one period, but supposed to represent the popes, among whom originally were some which had to be removed.

The pavement is a most remarkable work, and illustrates in stone Bible history, old and new, together with some classical mythological characters. This work is done by different hands, and is principally fifteenth-century. Beccafumi and others worked at it. The drawing is very good. It is now always covered up with wood so as to protect it, but it can always be seen without difficulty.

The pulpit is by Nicolo Pisano, thirteenth century. Either a copy of this or one very like it is in South Kensington Museum. The carving is too crowded, and though well executed, not satisfactory, nor to be compared with thirteenth-century work at Amiens or other Northern work. The steps up to the pulpit have a beautiful balustrade and other work in the best Italian Renaissance style. There are tombs, and fonts, and holy-water stoups also in this latter beautiful style, throughout the church. The west window, which is circular, is filled with good stained glass, representing the Last Supper, date about 1549. The choir-stalls are beautifully carved by one Bartolo. Negroni, 1567; they are very elaborate, but a little past the best period of wood-carving, and want the crispness of treatment so essential to good wood-carving. There is a room off the north aisle of the nave, entered through a doorway round which is some fine Renaissance work, called the Library. This room is enriched with beautiful frescoes by Pinturicchio and by Raffaele while a student; these were finished 1503, and are perfectly preserved; they represent scenes in the life of Pius II., Æneas Silvius Piccolomini. The room was erected and this work procured for it by Pius III., his nephew. The choir-books, which are splendidly illuminated, are kept in this room; these illuminations are late in style, and, though wonderful, are not, in the writer's opinion, very beautiful or worthy of study; but the frescoes certainly are, and, to those interested in the costume of the Middle Ages, this is a rich find. The pavement also of the Library is an interesting piece of majolica tiling, and the ceiling is beautifully painted in the best manner of the Renaissance, and is quite fresh and brilliant. It is a scheme of colouring which is suitable to good Gothic work and Classic alike, and from it one may judge of the effect of clear pure colouring harmoniously blended, showing that there is no difficulty in using red and blue and gold,—pleasant brilliant colours,—instead of melancholy greens and greys. It is said this room was built specially for the reception of these choir books.

Below the choir is the baptistery, but to reach it one must leave the church. It has a painted vault and walls, fifteenth-century work, but it is very dark; the font, date 1423, in the centre, is a beautiful bit of work, and exhibits sculpture by Gio della Quercia, Ghiberti, Donatello, and Michelozzo.

NOTES.

**I**T appears that any project for founding the proposed Imperial Institute in a central position will probably have to be abandoned for want of funds to purchase a site anywhere in the Westminster district, and it is proposed that the promoters of the Institute should appeal for a portion of the site in the bands of the Commissioners of the Exhibition of 1851. No doubt the cost of such a site as is required would be enormous in the neighbourhood of the Houses of Parliament, and no doubt the Imperial Institute would have a very good claim on such property as that held in trust by the Commissioners of the 1851 Exhibition; but for all that, the neigh-

\* See Illustration in this number.

hourhood of our Government buildings is where the Imperial Institute ought to be, and we greatly doubt if it would be worth while to erect it out at Kensington.

AS usual after a heavy fall of snow, the daily papers resound with paragraphs, easily written and neatly turned, making great show of indignation against "vestries" and all other bodies who might be supposed to be responsible for clearing away the snow, for not doing it quickly enough. We say advisedly "a show of indignation," for we suspect that this kind of indignation paragraph is simply thrown out as seasonable and popular, and likely to hit the public feeling at the moment when snow is making every one uncomfortable. As we have pointed out on a former occasion, this indignation is to a great extent senseless and misplaced. If heavy falls of snow occurred over London a dozen or a score times in the year even, there would be something to be said for keeping an army of men in readiness to clear it all away each morning it occurred. But the expense of doing this would be enormous, and as it is, a heavy fall occurs, perhaps twice, often only once, in a winter, and to keep a sufficient number of men and carts at call to clear it all away at once would mean an expense completely out of keeping with any ratepayer's notion of economy. The makers of paragraphs probably never stop to calculate what is the area and what the cubical mass of a fall of snow of a few inches thick over London; if they did, they would perhaps see the absurdity of their expectations from the authorities. There are certain discomforts which, though considerable at the time, are too exceptional to be worth providing against as if they were regularly recurring evils. Thus, in regard to drainage, it has been long recognised by the best authorities that it is more reasonable to risk an occasional overflowing of sewers by storm water than to go to immense extra expense to construct sewers of capacity for the heaviest possible storm. So in the matter of snow; it would be mere waste of money to keep in readiness for a whole winter the men and *matériel* necessary to make a rapid clearance of such an immense mass of matter, which will clear itself in two or three days. If people would make a few simple calculations, they would find that out; but then the oburgatory paragraphs would be all spoiled!

IT would seem that the Government have at last awoke to the necessity of preventing open spaces in the neighbourhood of London from being absorbed by railway companies, although it must be confessed that they have taken rather a singular method of showing their interest in the subject. The Home Secretary has forwarded to the Metropolitan Board of Works the plans, book of reference, and *Gazette* notice deposited in connexion with the proposed introduction into Parliament of the Latimer-road and Acton Railway Bill, and has requested the Board to favour him with their remarks with regard to an anticipated interference with commonable lands. The action of the Home Secretary is satisfactory so far as it goes, but why should he select the Metropolitan Board of Works to do the work? The Board is, in all probability, as ignorant on the subject as he appears to be himself. It has charge of some few open spaces which are handed over to it by Act of Parliament, but it is not likely to be acquainted with the local circumstances of open spaces which are not under its control.

A REPORT has been addressed by Mr. James Lemon, M. Inst. C.E., to the Local Board of Cowes, on the main sewerage of that district, which comprises about 570 acres. The population of the district in 1881 was 7,072, the rate of increase being 18.7 per cent. in ten years. The present sewers drain upon the foreshore by fourteen outfalls at all states of the tide, the result being the deposit of sewage mud on the shore, and the issue of sewer gas from the tide-locked sewers into the town, at certain states of the tide. Mr. Lemon proposes to divide the town into two districts. The high-level portion is to be drained by an

18-in. iron drain pipe, with a gradient of 6 ft. per mile, and there is to be a reservoir sewer, to act as a flushing tank, to hold 5,000 gallons, into which the low level sewage will be pumped. The discharge is to take place at half ebb, at a distance of 630 ft. from high-water mark. No means are proposed for defecating the sewage; and Mr. Lemon speaks with hesitation as to how far it can be got rid of in its crude state without nuisance. That is a point as to which attention should be given to the facts collected by Messrs. Robinson and Melliss, in their work entitled the "Purification of Water-carried Sewage." In the present case, as may be expected from the levels, the sewers of the upper district, Mr. Lemon remarks, become ventilators to the sewers of the lower. It is proposed to provide manholes or lampholes at every hundred yards, which will act as ventilators; that is to say, will diffuse the sewer gas formed through the town, instead of allowing its escape at the outfall or through the higher portion of the sewers. How far sanitation is promoted by such a diffusion of sewer gas is a moot point; and we are thus brought face to face with the two main evils that attend on the treatment of water-borne sewage, when no steps are taken for its disinfection. The estimate of the cost is 5,600*l.* for intercepting sewers; 4,538*l.* for reservoir and outfall; and 5,620*l.* for new sewers, manholes, flushing chambers, gas engines, ejectors, and ventilators. Adding 15 per cent. for contingencies and engineering, the sum arrived at is 18,121*l.*, or 2*56* per head on the population of 1881. The cost of a very similar arrangement at Brighton was 100,000*l.* for a population of about 109,000 persons, as stated by Messrs. Robinson and Melliss.

AN instructive measure of the activity of the builder in London is furnished by the annual report on the monthly returns of district surveyors, published by the Metropolitan Board of Works, of which the thirtieth has just appeared. The fees received in 1885 were more than double those received in 1856, but there have been waves of advance and decline. The first maximum was attained in 1863, from which year there was a decline to 1873. A rise then took place, and was tolerably steady until 1881, amounting to rather more than eighty per cent. in these eight years. A decline succeeded, and has been nearly continuous since 1881, the fees received for which year amounted to 51,383*l.*, while for 1885 they only came to 41,395*l.* In 37 out of the 71 districts specified in the return, the fees received were under 500*l.* each. In seven they were over 1,000*l.* each, the highest being in the district of St. Giles, Camberwell, where the total fees received amounted to 1,733*l.* The expenses of the various districts amounted to 9,292*l.*, or nearly 22½ per cent. on the receipts. The sums added or lost came to 2,561*l.*, or a little over six per cent. of the receipts. The number of new buildings erected in 1885 was 7,669, the additions, alterations, and other works being 10,530. Arrears were received in respect of 3,435 new buildings and 2,348 additions, &c. The total number of works dealt with in the report for 1885 was thus 23,982, the highest number, 29,275, having been attained in 1881. The number returned in 1856 was 14,654.

IN the last issue of the *Bullettino della Commissione Archeologica di Roma* (xiv. 9) appear fac-similes of sculptors' signatures from the plinths of statues recently discovered at Rome, near the Via delle Sette Sale. Fragments only of a few of the statues remain, and these are being diligently pieced together. The signatures, however, are in themselves of great interest for the history of Græco-Roman art, as they throw light on a flourishing school of sculpture down to about the fourth century A.D., at Aphrodisias, the chief city of Caria. The representatives of this school so far best known are Aristæus and Papias, the sculptors of the two famous black marble Centaurs in the Capitoline Museum. Another sculptor, Xenos, of the same city has left us a seated male statue, now in the Ludovisi Palace, on the drapery of which he has inscribed his

name and birth-place; also he has left us a Heron, with a long metrical inscription, in which he boasts of Aphrodisias as "happiest of towns," and says that, "trusting in his art he wandered through many cities." It appears from the number of new Aphrodisias signatures that have turned up in Rome that Xenos or some of his successors must have settled in Italy. The plinths are of Carrara marble, so the statues must have been made on the spot. Three of the names bear the cognomen Flavius,—Flavius Xenon, Flavius Chryseros, Flavius Andronicus. These two last appear for the first time, and are, judging from the style of the letters, of somewhat later date than that of Flavius Xenon. He boasts himself a high priest and a man of fame (διδάσκαλος).

THE *Berliner Philologische Wochenschrift* (December 25) reports the discovery of a well-preserved bronze statue in the excavations still going on between the Erechtheion and the Propylæa. The statue is 27 centimètres high, and represents a female figure wearing a shirt of mail. Her right hand is stretched out; in her left she holds hack a piece of the long robe that falls to her feet; this robe is presumably beneath the coat of mail. The style of the statue is reported to be similar to that of the numerous archaic marble statues recently found. With the figure were discovered twelve bronze vessels,—wine-cups, kraters, and the like. One of these, an amphora, is 29 centimètres high. From the presence of so large a number of bronze vessels it is conjectured that the excavators may be close upon the site of the Chalkotheke, built by the orator Lycurgus. If so the Chalkotheke stood at exactly the opposite corner of the Acropolis to its usually supposed site, *i.e.*, near the modern Museum. But at present this is mere conjecture.

WE are glad to see that the votive Corinthian tablets (in the possession for the most part of the museum at Berlin and the Louvre) are beginning to attract the attention they deserve. In a paper on the "Monuments Grecs Publiés par l'Association pour l'Encouragement des Etudes Grecques en France (11--13)," M. Collignon publishes eight of the most important specimens in the Louvre: his paper can be had as a "tirage à part." The tablets were found at Pendé Skouphia, a little village close to the Acrocorinthos, by a peasant. There can be no doubt as to their intention, they are exvotos, such as frequently appear on vase painting, and in these particular instances they are manifestly intended to be hung up in a shrine sacred to Poseidon. Probably the shrine got too full, a clearance had to be made, and the old exvotos, having served their end, were thrown outside the temenos to make room for new dedications. Two of the tablets represent Poseidon upright, with the name of the dedicator written pillar fashion (σπονδίων) behind him. A third has Amphitrite with her trident, and the words "I am Aphirite [*sic*], the wife of Poseidon." Another has two horsemen starting for the battle, no doubt under the protection of the sea-god. A fourth has two beautiful swan-heads decorating the end of a ship,—the Greek name, *χρυσόκερα*, compels us, if we desire to be accurate, to call them goose-heads, but the beautiful waving necks must have been inspired by a swan's notion. Further, the tablets give us a new potter's signature,—M(ι)lonidas painted (me) and dedicated. The signature of a second Corinthian potter, Timonidas, also appears. He is known to us already by a very curious vase of the shape known as lagynos, found at Cleonæ. The tablet is additional evidence, if any were needed, that Timonidas had his workshop at Corinth. The style of the tablet is more finished than the vase. Besides these mythological designs many scenes from daily life occur, well worthy of study, but which space compels us to omit.

THE Art-Union of London have produced for their annual engraving one of Mr. Leader's landscapes, "Strealey-on-Thames," engraved by Mr. Willmore. It is a good specimen of an old school of line engraving, and the distance is treated with much breadth

and softness of effect. The landscape, like many others by the same artist, is of that superficially sentimental type which appeals best, we suppose, to the popular taste, for which the Art Union, we believe, professes to cater. We are glad that the very large and coarse type of engravings that used to be issued seem to be given up.

MR. EMERSON'S assistant, Mr. Ellis, has thought it incumbent on him, in the absence of his principal, to write to the *Liverpool Courier* and deny our statement that Mr. Emerson made a selection of the drawings of his design for the Liverpool Cathedral for publication in our columns. It is a pity Mr. Ellis did not take the trouble to ascertain the facts before rushing into print. We have Mr. Emerson's letter, dated 6th January, 1886, before us, in which he says:—

"You have full permission to get what drawings from Messrs. Sprague you may require for illustration in the *Builder*, but I do not wish any beyond the following published, from which you may take your choice, viz., a in. scale plan, showing steps at the west end; west perspective ditto; south elevation; east elevation; longitudinal section, with enriched channel; transverse section through west elevation, showing steps, &c.; and interior perspective, and perspective from the east."

The plan and elevation "showing steps,"—an expression twice used,—is the "Design B," which overruns the limits of the site, and which was, as will be seen, the only plan that Mr. Emerson authorised us to publish. After this, perhaps Mr. Ellis will write to the *Liverpool Courier* and withdraw his statements.

#### LETTER FROM PARIS.

THE Ministerial dislocation of the last few weeks has also put a temporary check on the work of the Commission for the 1889 Exhibition; but M. Lockroy, the Commissaire-Général, though turned out with the other Ministers, has been reinstated, and all goes on as before. Besides the architects already mentioned, MM. Contamin, Chabron, and Pierron are engaged as engineers for metallic construction. For the architectural work M. Formigé has the collaboration of MM. Gaston Hénaud and Devienne; M. Bonvard is in relations with MM. Bergon and Gravigny, and M. Dutert with MM. Blavette and Degloze; lastly, M. Laforcade, the able chief gardener of the city of Paris, is charged with all the plantations and gardens on the Champs de Mars and the Trocadéro. The work has fairly begun. The excavation and foundation contracts have been let, and are about to be commenced, as well as the work for the iron supports of the galleries, which will be commenced in April. This last work is estimated at 2,000,000 francs.

As to the Eiffel Tower, there is talk of certain artistic clothing to be given to it, to show people that we are not quite in an age of iron and electricity; but whether the application of a quantity of coloured faience will do much to ameliorate the scheme may be questioned.

The machinery committee, on its part, has been studying the question of motive power, which will play an important part in the Exhibition, and will have to be provided to the extent of 2,500 horse power.

The opening of the Hôtel des Postes, which was announced for the beginning of July last, seems to be adjourned to the Greek Kalends, and it is even said that the building will not be utilised by the State, but is to be sold to the Magasins de Nouveautés. This is an exaggeration; the hôtel will not be sold, but improvements will have to be made, the number of pipes and heating centres increased, the artesian wells deepened, and many other expenses gone into at the cost of the shareholders. Whether all this is the fault of the former Minister of "Postes et Télégraphes," M. Cocheru, or of the present minister, M. Granet, or of the architect, M. Guadet, may be matter of dispute.

The building of the Guimet Museum in the Avenue de Trocadéro, intended to contain the Oriental collection bequeathed to the city by M. Guimet, is actively proceeding; it will probably be opened in 1887; more fortunate than the long-talked-of Musée of Decorative Art, which is still a matter of talk only. According to the official scheme, this building,—which

is to be erected on the site of the ancient Palace of the Cour des Comptes,—is to cost 8,876,000 francs. It is a great outlay for what is after all only the embryo stage of a museum; and thinking persons (there are some still) say it would be much better, instead of all this ostentatious expense, at once to purchase or rent a more modest building in the region of the bronze or furniture establishments, where the Parisian artisan may come and study the work of the finest epochs of French art.

At its meeting again the Chamber will probably proceed to consider the interrupted Metropolitan Railway project, with the Minister of Public Works and the Parliamentary Committee. The latter has suppressed the line from the Halles to the Place Denfert-Rochereau, by which move a saving of thirty millions of francs, making the whole cost 190 millions, instead of 220 millions. But how long it will be from this arrangement to the commencement of the work, and what portion will be ready for 1889, who shall say?

While waiting for the Metropolitan Railway, Paris is to be amused by an International Exhibition, outside the walls, in honour of the fiftieth year of the establishment of railways in the country; for which exhibition the Municipal Council has devoted a very large space in the Bois de Vincennes. The first line opened in France was, in fact, that of St. Etienne, not that of Paris and St. Germain; but the matter is really a private speculation of considerable interest to railway people, and not quite deserving the title of "International."

Though we have already in Paris Houdou's statue of an aged and decrepit Voltaire, and Caillé's presentation of him in middle age (a work heavy and devoid of character), the Municipal Council have accepted a statue of a young Voltaire, by M. Lambert, a sculptor of talent, who is owner of the Château de Ferney, where Voltaire lived, and who, therefore, possesses all the documents and data for making a complete likeness. The statue is not a bad one, but the fashion of Voltaire statues of all ages rather recalls the story of the showman who exhibited the skull of "Voltaire when a child."

In regard to this subject, we may correct a mistake in our last letter, as to the statue of Voltaire which M. Monnier has been commissioned to superintend at St. Claude; the sculptural portion of this is to be by Mdlle. Gagneur, who exhibits annually in the Salon, under the pseudonym of "Syamour."

The Municipal Council has voted 45,000 francs for a pedestal for the Étienne Dolet statue by M. Guilbert for the Place Maubert. The work itself is very mediocre, but, as the pedestal will be ornamented with bas-reliefs of which the most important will be "the City of Paris reviving Free-thought," one may presume that the object of the expenditure is anti-clerical rather than artistic. In regard both to this statue and that to Étienne Marcel there are no materials for a historical likeness, the portraits being merely imaginative. In regard to this latter statue, there is a curious piece of litigation going on, the founder having been under contract to cast it in one piece, while the sculptor, M. Marquette, affirms that it has been cast in fractions. The question is submitted to a special committee.

The Académie des Beaux Arts has been enriched with two fine busts in marble; one, that of Victor Massé, is the work of Aimé Millet; the other, that of Ambroise Firmin Didot, has been presented by the family of the celebrated printer, who had commissioned it long ago from the sculptor Perrand. We have also to note with admiration the recent fine bust of the Abbé Lagarde, founder of the Stanislas College, from the chisel of M. Chapu.

The *Journal Officiel*, on the favourable report of the Conseil d'État, has at last definitely put on record the acceptance of the magnificent gift of the Duc d'Anmale; and the Institut has been authorised, on certain conditions imposed, to accept the ownership of the domain of Chantilly, and of the books and furniture and works of art in the château. The *Journal* adds that "at the expiration of the title of the Institut, and after the reservation of the annual sums necessary for the endowments created by the donor, the revenues of the domain will be consecrated to the keeping up of the buildings, parks, and collections, the development of the library and galleries, the creation of pensions to men of science, artists, and literary men; the foundation of prizes to encourage those entering on

the careers of science, art, or literature; and, lastly, to all expenses incidental to visits of the public to the Musée Condé." We may add here that the fine equestrian statue of M. Paul Dubois, an illustration of which appeared in our pages on June 19 last, has been placed on its pedestal in the courtyard of the château.

The recent losses in the personnel of the Ecole des Beaux Arts have been filled up by new appointments. M. Delaplanche, the sculptor, has been entrusted with the modelling classes in the place of the lamented M. Houlle; MM. Mauduit & Julien, the architects, have been also named professors, the first of construction, the second of perspective, in place of MM. Brune and Chevillard.

The competition for a new school for girls in the Rue des Martyrs, before referred to, has been decided by a jury, presided over by M. Alphand; the design of M. Cassien-Bernard being placed first, those of M. Gennys and M. Breton second and third respectively.

We learn that on the recommendation of the Conseil d'État, the administration intends to "désaffecter" the Church of the Assumption, Rue St. Honoré, against which the anger of the Municipal Council has been long directed. Why should this building have escaped the zeal of the first Revolution? The church, which served as parish church before the erection of the Madeleine, was built about 1670, from the designs of Charles Errard, one of the twelve founders of the Academy of Painting. Eight Corinthian columns support a portico in front of the church, which is in the form of a rotunda with a large cupola, painted in fresco by Delafosse. This maladroit laicisation will not alter the character of the building, and, speaking on artistic grounds merely, it is to be regretted that this system should be pursued of endeavouring to bring under the domain of the State all the great monuments of architecture erected for religious purposes.

Politics mixed up with art generally produce unfortunate results. Without going back to David, who expiated in exile the part he had played in the violent deeds of the Convention, we have seen, nearer to our own day, Gustave Courbet play, in the evil days of the Commune, the part which we all know. The sculptor Baffier, inflamed possibly by such illustrious examples, endeavoured the other day to stab a deputy whom he regarded as too lukewarm. M. Baffier, whose recent works have shown more of artistic violence than artistic feeling, was the author of a "Marat" purchased two years ago by the Municipal Council. Was his attack on M. Germain Casse the result of political fervour or mere derangement of brain? Judging by some of his recent works, especially the "Jacques Bonhomme," in the Salon of 1885, we should lean to the latter conclusion.

The artistic world has learned with great regret that poor François Bonvin has been struck with blindness and paralysis. This conscientious artist, to whom we owe so many pages instinct with observation and talent, is in danger of want, and a committee has been formed to organise a sale of his work, as was done fifteen years ago in the case of the painter Anastasi, who also became blind, and lived to be forgotten by those who had formerly admired his works.

Several artists of merit have died during the past month. The painter Joseph Mélin, who has died at the age of 72, had been a pupil of Paul Delarocbe and of David d'Angers. He was especially occupied with animal painting, and received medals in the Salons of 1843, '49, '55, and '58. We may mention also M. Victor Deroche, a landscape painter of talent; M. Paul Arvise, one of the best designers for Sèvres ware; M. Abel Orty, another landscape painter, who has died at the age of 47; and M. Edouard Lièvre, a former pupil of Couture, who had recently turned his attention to decorative art, and is the author of some very interesting works on furniture.

A curious exhibition of ancient pictures will be open, by the time these lines appear, at the Ecole des Beaux Arts, for the benefit of the sufferers from the inundations in the South of France. One cannot too much praise the zeal and generosity of collectors,—usually very jealous of their treasures,—who at the call of charity are ready to lend their most precious and valued works. It is superfluous to add that the Rothschild family play the most important part among the lenders of pictures. The Baroness de Rothschild contributes a fine Teniers, an admirable landscape by Hobbema,

and a "Jeune Fille à la Rose" by Goya. Baron Alphonse de Rothschild sends a "Portrait of a Young Man" by Raffaello, the "Singer" of Ostade, and a fine example of Cuyt. The Wouvermans and Cuyts of Baron Gustave are there in great force, and among the loans of the Baron Edmond is the famous "Oak" of Ruysdael. The Spitzer collection has also been despoiled of some of its finest works, including the portrait of Edward VI. (of England) and of the Duc d'Albe, by Antonio More, a curious Cranach, and a sketch of the "Mars" which Rubens painted at the Pitti Palace. M. Hector Crémieux has lent three fine Géraults. Among works of the English school will be Lawrence's portrait of the Duc de Richelieu, a "Mother and Child" by Reynolds; and among less known works are some landscapes by Hubert Robert, pictures by Van der Helst, and a hull-fight by Goya, the latter lent by M. Henri Rochefort, who also sends a curious painting of Æneas at Carthage, by Tiepolo. The exhibition will be a very interesting one, and, probably, profitable for those in whose interests it is being held.

#### TWO OLD PARISIAN JEWELLERS: BOURGUET AND BOURDON.

I.—JEAN BOURGUET.

"Mon dessin en faisant ce livre a esté d'instruire le Jeunesse, et de soulager leurs mères, c'est pourquoi c'est aux jeunes gens à qui j'adresse ces instructions, les exhortans de faire attention à ce qui suit et à ce qui est écrit au bas de quelques-unes des planches de ce livre. Premièrement, il faut que l'élève ait un bon couteau et un bon ciseau, et bien desiné, en moins d'ornement. Pour cela je leur ay fait plusieurs tiges de feuilles d'une grandeur suffisante pour pouvoir les desiner au crayon ou à l'encre de la Chine, de plus je leur produit deux belles grandes frises qui sont desja au jour il y a du tems pour les accoutumer à bien rendre une feuille avant que de commencer à graver, je trouve cela si nécessaire que je ne pense pas qu'on puisse réussir aisément sans cette étude; ceux qui me croiroient en demeurant convaincus par l'expérience, et ils verront que quand ils commenceront à graver, cela leur donnera de la facilité et du goût et même pour le pinceau; ce livre les conduira pas à pas par la quantité des morceaux de taille d'espargne et de bas reliefs en émail de toutes sortes de formes et grandeur, — oval, rond, carré, et d'autres figures, puis de les accoutumer à remplir toutes sortes d'ouvrages. On remarque que quand ils n'ont jamais fait que des ovales, des ronds, et des carrés ils se trouvent embarrassés quand ce qu'ils ont à faire a une autre forme; le grand nombre d'élèves que j'ay fait me confirme dans ce que je dis icy: je leur donne dans le bas de cette feuille plusieurs têtes de bagues, où ils remarqueront comme il faut premièrement tailler en taille basse et nette, en sorte que quand on a cossillé, et usé, les contours soient bien formés afin qu'il n'y ait plus que les coups de force à donner au pinceau, car pour les tendresses ce doit être l'or qui les forme, ce que je n'ay pu exprimer que par un trait fin, qu'il ne faut pas absolument faire au pinceau. C'est pourquoi tout consiste à tailler nettement, et de bon goût; avec un peu de soin et d'application ils connoîtront la vérité de ce que je dis; mais si quelques-uns sont assés négligens pour ne pas faire attention à ce que je leur enseigne qu'ils s'emprennent à leur peu de bonne volonté; si quelques-uns en profitent qu'ils m'en sachent gré. Pour moy, j'ay fait ceci de bon cœur pour leur rendre service; Dieu leur fasse la grace d'en profiter."—Preface to Bourguet's "Second Livre de Taille d'Espargne."

AMONG some absolutely or comparatively unknown masters of decorative art whose work we propose making our readers acquainted, we have selected for our first article two French jewellers who lived in Paris in the early part of last century, Jean Bourguet and Pierre Bourdon. Each of them published a little oblong octavo book full of the choicest designs from his own hands. The curious piece of old French at the head of this article forms the preface to Bourguet's volume; it is packed full of lessons for all who are learning and all who, having learned, have also learned to love, the art of decoration. So far as we have been able to ascertain, the books are not only not to be procured, but scarcely to be seen in this country. The only copies we have traced are an almost complete set of the plates of both books, very clean and well preserved, in the Print-room of the British Museum, and one copy of Bourdon's work, in a fair state of preservation, in the Art Library of the South Kensington Museum. Possibly the book-boxes on the quays by the Seine may contain many scattered fragments of the masterpieces of these two old and, we trust, in their days, respected citizens of La Belle France; but, alas! beyond such few copies of their books as may still exist, all their memorials have perished with them. An industrious and peaceable citizen's life naturally contains but few incidents worth recording; so, perhaps, after all, it is not to be wondered at that the art books are almost silent about these two jewellers. But it is a matter of wonder that not their lives merely, but their works, are passed by in solemn silence by the compilers of our books of refer-

ence. We have been unable to trace a single recorded opinion upon the artistic excellence of those works in all the host of books which have been written on the art of decoration. Even Reynard, in his valuable album of reproductions of the best specimens of the decorative work of the fifteenth to the eighteenth centuries, has

he certainly must have been at the zenith of his powers at that time. Its title runs thus:—"Second Livre de Taille d'Espargne, et de Bas Reliefs en Esmail, ou noir d'Escaille, Bas Reliefs pour Tabatières et Ouvrages d'Orlogerie, par J. Bourguet, Marchand Orfèvre à Paris." The first page contains the preface already

Fig. 1.

only condescended to give us one page from each book, and Reynard, with all his appreciation of the beauties of the art, refrains from giving critical opinions on any of the plates he reproduces. Designs good, bad, and indifferent are given one after another, the reader, or

given, very neatly engraved. We cannot do better than at once to make some notes upon the lessons he teaches in it.

There is a charming old-world sincerity and cordiality about the exhortation to the young pupils, for whose benefit he undertook his labour

Fig. 2.

rather the beholder, being left to draw his own conclusions from, and make his own reflections upon, them. It is our pleasant task, therefore, to commence this series of articles with two artists so completely unknown as Bourguet and Bourdon, and we may proceed at once to judge

of love; and about the kindly remembrance of the pangs endured by their masters,—pangs which, doubtless, had given him the acutest suffering during the lessons he gave to his own apprentices. Then there follows a short application to his own peculiar industry of a

Fig. 3.

them by their works, so that by them in the future they may be known.

Jean Bourguet, then, lived in Paris quite early in the eighteenth century. (The date given in Bryau's Dictionary is "flourished about 1702.") His "Second Livre" (which from certain *scintille* of internal evidence we take to mean second edition) bears date, however, 1723, and

principle which in truth lies at the root of the whole matter, which is the keystone of all industrial art. "First, it is certain that to become a good gold and silver smith, you must begin by knowing at least how to draw and design (the use of the word *desiner* seems to be clearly elliptical) ornament." The true function of ornamentation is surely a very high one: it is

one of those mysterious influences which charm away the tedious monotony of life. What would existence be like under a sky of never-changing grey or endless sunshine? Those who have been forced to bear it tell us it is unendurable, and that a ray of light, or a patch of cloud or shadow, is welcome as flowers in May. Could we live in a world where bricklayers and masons only built dead walls? Watch how the light, even in this dull, smoke-bespattered London of ours, glances off the changing curves of the massive cornice on that large commercial edifice over the way, which day by day brings premature night upon our office. Mark how the eye wanders over the monotonous surfaces, seeking rest and finds it in that line of light, and there will be no uncertainty in the answer. Ornamentation makes our world of variety instead of a dead-level world of monotony, and variety is always very charming. In all forms of work, from the highest to the lowest, ornament has its proper place; in some that place is a more prominent one than in others; but a place it must have always. And yet it is by no means certain, indeed, in a great number of cases it is assuredly uncertain,—that the workers, master and men, do devote the proper attention and study to it. "Oh! anything will do." "Shove in something, somehow and anywhere." The matter and the manner, the form and the execution, are too often utterly neglected. The ghastly devices that meet us on all sides as we take our walks abroad tell their own gruesome tale of neglect of the commonest ideas of beauty and of grace. This principle, then, which

given in fig. 1, we think that this conjecture amounts to an absolute certainty; the two finals given in fig. 2 reveal more of the draughtsman's own spirit, working in new lines, and imbuing outlines more formal than Van Meekenen ever attempted with the master's grace. In addition to the plates on which he drew a considerable number of these *tiges de feuilles*,

Fig. 5.

he produced two very fine scrolls, which, with pardonable vanity, he calls "*deux belles grandes frises*"; they are, indeed, masterpieces of constructive skill and of the very greatest beauty. In fig. 6 we have given a sketch of the best of the two, and in fig. 5 one

Fig. 6.

of a smaller and more compact composition of the same class. The lesson which he expressly meant to force upon the attention of his pupils in these acanthus studies was, as he expresses it, "*pour les accoutumer à bien refendre une feuille avant que de commencer à graver.*" A *feuille refendue*, that is, to cut or split up the outline of the leaf properly. The ultimate

success of the design must obviously depend on the care and accuracy with which this is done. The deeply-serrated leaf of the "bear's breech" has always exercised the greatest fascination over the designer, perhaps on account of the great difficulties which it puts in the way of accurate conventionalising; but when they are overcome, the result more than repays the labour which the achievement has cost. It is, of course, perfectly easy to let a pupil copy a model of an acanthus leaf and "lay it on" where it may be wanted; but this feeble method of instruction would not suit an artist such as Bourguet was; his scholars must realise the why and the wherefore which make the model worthy to be copied; they must understand the principles on which it is constructed, so that afterwards they may be able to work independently of the work of others; that they may be able to adapt their foliage to the necessities of every case, and that each leaf should, as in nature, have its own peculiarity and its own charm.

It will not perhaps be out of place here to dwell shortly on what we understand by accurate conventionalism. We have on previous occasions insisted on the importance in ornamentation of keeping the line between representative art and decorative art rigidly fixed. We have also pointed out how decorative art can derive its inspiration from nature without passing from the right to the wrong side of this line. When it does go to nature for inspiration it conventionalises natural form, adapting it to the capacity of the materials in which the work is to be executed. But if, while drawing from this fount of inspiration, it adopts nature's work in part only and in part rejects it, the result can only be commonplace and often vulgar and offensive. As in the broad structure of conventional work generally nature's tangential law cannot be neglected with impunity, so in the smaller detail of the conventional foliage a most rigid observance of the laws of leaf-growth is an absolute necessity. To illustrate our meaning, let us consider one of the simplest of the well-known decorative leaf forms, the ivy, so much used by the Mediaeval illuminators, either with its three or five points. As we all know it, it is difficult to realise a figure more full of simple grace; but imagine one of the parts unduly distorted or one of them omitted, or the angles at which the side lobes spring from the stem altered beyond the limits which Nature allows herself; the result would be at once most hideous and uncouth. Or imagine one of the petals of the Tudor rose displaced and made to spring from nowhere in particular; or the whole of the petals, instead of clustering round the centre, decentralised. Could anything more grotesque, uncomfortable, or impossible be devised? And so it is with the serrations of the acanthus leaf. Nature has her own laws, which she implicitly abides by in furnishing the leaf with these indentations. They are closely allied to those which govern the spring of the fern fronds, although in that plant they are more easily to be discerned. Each serration is, in fact, a separate leaf with its own separate structure; but instead of standing out distinctly, as in the fern, the greater part of its form is merged in the main body of the leaf, leaving nothing but the points distinct, the size of these distinct points varying in every leaf and in every lobe. The main stems of all the dependent lobes in nature are connected in a clearly-defined manner with the main stem of the parent leaf, and their connexion must be preserved in the conventional foliage. In much of the acanthus foliage with which our houses are beautified in the present day, it is a perfect puzzle to find the stem of the lobes, and, when found, to discover what on earth it has to do with the main body of the leaf. The same principle, it need hardly be said, must be observed in the "bellying" of the leaves. If the decorator who uses the acanthus for his model ignores this structural principle he can only produce something which cannot fail to be repulsive to the eye.

But this principle, as we have said, is only an illustration of the broad general one; in both the large designs Bourguet has shown himself a master of the broad principles of construction. In fig. 5 he has adopted with the greatest fidelity the general idea of the plant growth of the acanthus, tapering gradually with less and less foliage up the flower stem. In fig. 6 the design is based on an imaginary and fanciful plant growth, but the flow of the curves is based with the most rigid fidelity on Nature's

Fig. 4.

Bourguet first insists upon, with regard to his own profession, we take to be a true, a lasting, and a universal one. Are you architect? Are you builder or stonemason? Are you worker in woods or metals or precious stones? Do you weave the soft threads of silk or wool, or homelier cotton? Do you mould the clay into vessels whose uses may be noble or ignoble? Do you put the commonest of the products which Nature has laid at your feet to the services which necessity has taught? Before you can do any of these things well, before the world can take pleasure in looking upon your work, above all things it is of the first importance that you should be able to devise some pleasant breaks to the uniformity of the broad surfaces which first come from your hand. This is the first rule Jean Bourguet instilled into the minds of those who sat at his feet:—If you would become a good goldsmith, learn the nature and the power of design. To this end he devotes some of his plates exclusively to studies of conventional or decorative foliage. The leaf he makes use of without exception is the deeply-serrated acanthus, which has so often, and with so much charming variety, stood in such good stead to the art-workers of many centuries. His methods of treating the leaf, of twisting out floral excrescences, and of manipulating the stems, is based, as it seems to us, entirely on that of Israel van Meekenen, some of whose charming productions we considered in our issues of Dec. 5 and 12, 1885. Van Meekenen's work certainly found its way into France at some time or other; the writer of these articles remembers in his early years to have seen in a cheap French book of alphabets some reproductions of Israel's celebrated alphabet, stated to have been copied from the collections of the Luxembourg. But Bourguet was not a mere servile imitator of the great German master; he studied him at his best, he caught the grace and charm and all the niceties of his spirit, and thenceforward made it his own. If we look carefully at the three floral studies

tangential law; and the whole of it is wrought with the most subtle charm, the grace of the drooping flower being especially noticeable. We think that these *deux belles grandes frises* will well repay the most careful study.

There is a dash of worldly wisdom in the worthy jeweller's next remark, and we cordially echo his words, for there is nothing so difficult as getting people with ideas of their own, and who, having a certain amount of taste, consider that they know all about the matter, to realise that there are such things as canons of decorative art; or, if they like it better, a right and a wrong in decoration. "Those who believe what I say, experience will confirm . . . but if there should be some negligent enough not to pay attention to what I am teaching them, they must lay the blame on their own lack of good will."

Another of Bourguet's remarks we cannot pass over.—"It is to be observed," he says, "that when people have only ornamented ovals, circles, and squares, they find some difficulty when they have to ornament some other form. The great number of pupils I have had confirms me in what I am saying." The necessary correspondence between the structure of the ornament and that of the space ornamented is another of the great canons of the art.

In figs. 3 and 4 we have given some specimens of Bourguet's work where the play of his fancy was confined within set spaces: fig. 4 is probably for the lid of an enamelled snuff-box; the others are medallions in the same style designed for the embellishment of the pages of the book. There is a wonderful charm in the way in which in all the cases the design adapts itself to the outline without the slightest appearance of constraint, and also in the remarkable manner in which the surface is covered. The use of straight lines occasionally breaking up the flow of the curves is also noticeable, in every case without in the slightest degree marring the continuity of the design, but rather giving it a force of its own. The other specimen given is a curious arabesque pattern of great originality and beauty.

Here we must leave the excellent Jean Bourguet, master of his craft, and worthy instructor of many apprentices, who, doubtless, in their day also gave good work to the world. The instruction that he conveyed to them he preserved in his carefully-engraved pages; it is not too much to hope that 160 years after their first appearance the remnant of them which survives may still be pregnant with life and vitality to influence and instruct the youth of this later generation, "*et de soulager leurs maîtres.*" "If some shall profit therefrom let them admit their indebtedness to me; for myself I have done this with good heart to do them service. May God give them grace to avail themselves of it."<sup>\*</sup>

#### LONDON AND THE SESSION OF 1887.

With the last day of November expired the time for the official deposit of plans and notices relative to the various public works which will be submitted to Parliament in the Session next ensuing. The numbers of railway Bills and provisional orders are both less than on the same occasion in 1885, when the totals were respectively 53 and 62. This year they amount to 48 and 40. Of plans 132 are lodged, as compared with 176 twelve months ago. So similarly with the miscellaneous and tramway groups, the respective figures being severally 48 (1885) and 33 (1886); and 13 (1885) and 11 (1886). Various "notices" are also given by the Metropolitan Board of Works for projected operations, as well as by the School Board for London in respect of a further batch of provisional orders for supplying additional school accommodation. Confining our observations for the present to within the home district we proceed to briefly indicate what are the more important schemes under contemplation.

The School Board schedule a total of twenty sites, representing a gross area of about 15½ acres. A deduction, however, will in effect be made of four sites, equivalent to, say, either 2½ or 3½ acres, from the grand total as a set-off on the score of alternative sites. The twenty sites fixed upon are situated in the parishes of St. Peter and St. Paul, Hammersmith (2, being alternative); St. Mary, Stoke Newington (3, two of them being alternative); St. John, Hackney (1); Stretcham (1); St. James,

Clerkenwell (3, one being alternative with that in Islington); St. Ann, Limehouse (1); St. George-in-the-East (1); St. Giles, Camberwell (3); Islington (1, being alternative with one in Clerkenwell); Wandsworth (1); St. Paul, Deptford (1); and in the Hamlet of Peuge (2, being alternative). The plans for the parcels of land may be seen at the offices of the Board, on the Victoria Embankment; and the provisional orders will be submitted, we believe, for confirmation to the Educational Office, Whitehall, for ultimate ratification by the Queen in Privy Council.

We will now turn to the Metropolitan Board of Works. In virtue of a Metropolitan Management Act Amendment Bill the Board seek to get conferred on them and on certain vestries and district boards further powers over the laying of mains and pipes for water, gas, or hydraulic power purposes; and this Bill will provide for giving the vestries and boards additional powers as to the formation of streets and roads, besides extending, it may be, the powers of gas and waterworks companies. Their Theatres and Music Halls Bill is designed, as last year, to extend their "powers as to the inspection of houses or other places of public resort . . . kept open for the public performance of stage plays; and of houses, rooms, or other places of public resort . . . kept open for dancing, music, or other public entertainments of the like kind." This Bill may require that before such a place is licensed it shall obtain a Board's certificate, to run for a year, as to the efficiency of its structural and other arrangements and appliances for public safety; and that such places shall be deemed to be unlicensed unless such certificate have been granted, and also as to the efficiency of arrangements, &c., for protection from fire; and that the Board make by-laws or regulations for carrying out, under penalty, their requirements. Under another Bill, also as last year, the Board seek to alter so much of the Metropolitan Fire Brigade Act, 1865, as relates to the contributions towards expenses of carrying out the Act which are to be paid by companies insuring property from fire, and to fix the companies' contributions on a new basis. The Board's intentions are very vaguely expressed, but in the result they mean that the limit of one 3d. rate on the gross value of the property, as defined in their Loans Act, 1863, shall cease to be the maximum estimate. They propose to make a bridge across the Surrey Canal in Canterbury Bridge, Deptford, in lieu of the existing swing-bridge, and to secure that the cost shall be partly borne by the Camberwell Vestry and the Greenwich District Board of Works; and to make a means of communication beneath the Thames at Blackwall in the shape of a tunnel (single or double) for vehicular,—but not tramway,—and pedestrian traffic,—the tunnel with its approaches to lie between the Artichoke Tavern, Poplar, and Ordnance Wharf, Greenwich. They will ask for an extension of the time which is now limited by the Metropolitan Bridges Act, 1881, and their own Bridges Act, 1884, for the compulsory purchase of lands for the new Battersea Bridge and its approaches, together with the alteration of Vauxhall Bridge. As touching open spaces, they propose that the Commissioners of H.M. Works and Public Buildings shall transfer to them all functions in relation to Victoria Park,\* Battersea Park (250 acres, *olim* Battersea-fields), Kennington Park (25 acres, *olim* Kennington-common), the public garden adjoining to the Museum at Bethnal-green, the Thames (Chelsea) Embankment, including the river wall and works in connexion therewith; and Westminster Bridge, with its approaches. The costs of maintenance would thus be shifted from the Consolidated Fund on to the metropolitan ratepayers, so far, indeed, as they are not met by the incomes derived from the properties in question. It is further contemplated to enable the Lewisham District Board to acquire and maintain as an open space or recreation-ground a parcel of land between Dulwich-road and Laurel-grove at Peuge, the Metropolitan Board defraying one-half of the expense; to purchase and throw into Bostall Heath, Plumstead, a piece of land on its northern side; to make an addition to Brook-green, Hammersmith; and to agree with the owners for purchase of certain houses, buildings, and lands,

—about 32 acres in all,—known as Ravenscourt Park, Hammersmith, for future maintenance as a public recreation-ground. Under this head, too, falls their decision to insert powers into their Various Powers Bill for the transfer to them of all the duties and privileges at present discharged by the Wandsworth-Common Conservators. Here arise certain vexed questions, and we are told that the Board's proposals do not receive the unanimous approval of the inhabitants mostly interested. The Common, or rather the 160 acres which alone remain open, yet retains some *beau-vestes* of its once suburban attractions. There is a strong local feeling against its being subjected to the ultra-Puritanical régime that prevails at, for instance, Hampstead Heath and Clapham-common. Within our own memory that charming bit, the old "Black Sea," has been appropriated for the villas of Spencer Park; whilst the dealings of the Commissioners of the Patriotic Fund with the sixty acres which they secured about thirty years since scarcely encourage the Conservators to hope that the Common might not eventually disappear. They assert that from 1794 to 1866, as many as fifty-three enclosures were made, varying in area from a quarter to ninety-six acres, that the total area of common land enclosed during the past century in Battersea and Wandsworth parishes alone exceeds not less than 500 acres, and that nearly 3,000 acres locally subscribed, has been spent in preserving the 160 acres which are left. We may here add that, as we mentioned two or three weeks ago, an adverse poll of the Hornsey ratepayers has decisively shelved, for the present, the Local Board's scheme for the sale to them by the Ecclesiastical Commissioners, for 25,000*l.*, of the fifty-three acres known as Churchyard Bottom Wood, Highbury. It is contended that the Commissioners do not own the freehold to sell, but that they, as vested with manorial rights, could be compelled to keep that area open for public use and enjoyment. Mr. H. R. Williams's exertions largely contributed to the successful negotiations whereby the neighbouring Gravel Pit Wood was acquired, without purchase, for the care of the Corporation of London, and it is to be hoped that no legitimate efforts will be spared to complete his good work.

The Corporation of London are minded to construct a new approach to Leadenhall Market by altering and straightening the existing thoroughfare leading (westwards) from Lime-street, by the Peterwells' Hall, to the market. The changes will be made in the parishes of St. Dionis Backchurch and All Hallows, Lombard-street. They will also apply to Parliament for an Act whereby at all municipal elections within the City limits the voting, in case a poll be demanded, shall be taken by ballot.

Of railway schemes the first in point of magnitude is that promoted under style of the West London Extension and Commercial Docks Railway. It is proposed to construct a line from the West London line, at a point just north-east of Clapham Junction, to a point in Onegar-yard by the Norway Dock of the Surrey Commercial Dock Company. Its several junctions with the East London, South London, Thames Junction, and North Kent lines will add considerably to the hewling-ganglion of lines that already exists in the market gardens between Hatching New Town and Deptford. This Bill empowers the new Company to purchase, of the Dock Company, the Grand Surrey Canal and its branch, known as the Peckham Branch, and the Croydon arm or Railway Lay-Bye. And since it provides for the discontinuance of such canal with its branches, and for relieving the two companies from any obligation to maintain the same, we gather that part of the proposed railway will lie in the bed of the canal, between Camberwell-road (eastern side) and the Russia and Norway docks of the Dock Company. With this may be compared a recent project for laying a railway in the bed of the Regent's Canal. The direction planned out for the new railway brings back to mind King Cnut's cutting a trench from Redriff (Rotherhithe), over against Wapping Old Stairs, to Lambeth, across the morasses of Bermondsey, Southwark, and St. George's Fields. There

\* Nearly 300 acres. Its prime cost was covered by the sale (1841) to the second Duke of Sutherland, for 75,000*l.*, of the Crown lease of York (now St. Stafford) House, St. James's Park. *Tithe statutes* 4 and 5 Vict., cap. 27, and 5 and 6 Vict., cap. 20.

\* The Patriotic Schools were erected in 1857 (girls\*) and 1870 (boys\*). The latter, with about 11 acres, has been sold (1882) for 30,000*l.*, to the Governors of Emmanuel Hospital. A fence has been set up to separate the 20 acres not needed for the former, and this land the Commissioners have leased for farm buildings and a house.

\* To be continued.

can be no doubt that such a canal was really made in the course of the siege of London by the Danes, though it failed to answer the purpose designed for transporting shallow-draught vessels, or, rather, galleys, to westwards of London. There is some evidence that the same sovereign also made or devised a similar canal around the northern side of the City. The former trench is reputed to have been used as a tideway during the building of Peter of Colechurch's stone bridge across the Thames. The Great Eastern Railway Company have in view a branch from their Colchester line in St. Mary's, Stratford-le-how, to Victoria Park, with a junction to the thickly-populated and just-incorporated borough of West Ham. They mean to enlarge their Liverpool-street terminus, and to widen the railway leading thereto, along the eastern side thereof (the North London Railway being to the west), for the length between Norton Folgate and Two Swan-yard. The enlargement of Liverpool-street station and the line northwards will involve the removal of St. Botolph, Bishopsgate Without, ward and parish schools, with the chapel and cradle's residence appertaining to them in Primrose and Skinner streets. We can merely mention the new City of London and Southwark Sub-way (Kennington Extension), and the Latimer road—at Notting Hill—and Acton Railway. On the other hand the London, Hendon, and Harrow Railway is abandoned. The North London, South Eastern, Metropolitan, Lewisham and Greenwich and District Tramways are generally to be extended in various directions. Of a scheme affecting Clissold Park, Stoke Newington, and of the Government New Bankruptcy Offices Bill we must reserve our notice, for the two sites concerned demand a few words in regard to their historical and topographical features.

THE RATEABILITY OF MACHINERY.

"The decided cases upon the question of the rateability of machinery exhibit considerable difference of opinion among the judges as to what is and what is not rateable, differences which it is impossible to reconcile." This is the statement to be found in the latest edition of Mr. Castle's well-known work on the law of rating. A few pages further on he thus alludes to the case of Laing v. The Overseers of Bishopwearmouth, "The most recent case seems to have unsettled the law more than ever." Under such circumstances as these, the case of Regina v. The Tyne Boiler Works Company (Limited), which was recently decided by the Court of Appeal, seems to deserve the most speedy notice; for it can scarcely be questioned that it puts an end to the doubt which has recently been felt on the subject, and, as a decision of the Court of Appeal, must be regarded as settling the law upon this point. In effect, though not in name, it was an appeal against the decision in the Bishopwearmouth case, because the Justices at Quarter Sessions, and also a divisional court of the Queen's Bench Division, acted on that decision, so that the propriety of the decision in the Bishopwearmouth case came directly under review by the Court of Appeal.

In the Tyne Boiler Works case, the machinery as to which the question arose consisted of a hydraulic riveting machine, resting by its own weight alone on a cement foundation, and of two travelling cranes, running on rails fixed on halks of timber. There was no intention that these articles should be permanently annexed to the works, and it is clear they were not permanently attached to the ground. In the Bishopwearmouth case some of the machinery was bolted to the ground, but in a manner that enabled it to be removed at will, and some, as in the last case, was retained in its place by its weight only. In delivering judgment in the former case the late Chief Justice Cockburn observed that all the machinery was rateable,— "The whole of it, though some of it may be capable of being removed without injury to itself or to the freehold, is essentially necessary to the shipbuilding business, to which the premises are devoted, and must be taken to be intended to remain permanently attached to them so long as these premises are applied to their present purpose." Now, let us follow up this dictum with the rule as enunciated last week by the Master of the Rolls:—"Things on the premises are to be rated which are there for the purpose of making and which make premises fit, as premises, for the particular purpose for which

they are used; these ought to be taken into consideration, as enhancing the rateable value of the premises." Therefore it is now quite clear that the doctrine that machinery must be physically attached to the soil in order to be rateable, or, it would be more correct to say, to be included in the rateable value of the premises, is now absolutely at an end. Again, the test proposed by Mr. Castle, viz., whether such machinery would be landlord's or tenant's property from year to year, seems now equally to have no legal authority. It is, no doubt, true that this decision may cause some difficulties, because it may be that things not hitherto included as adding to the rateable value of premises will, in future, have to be taken into account. Furniture is not rateable, but would a billiard-table in public billiard-rooms be regarded as adding to the rateable value? We mention this as an instance of an article which may be regarded as belonging to two classes. Difficulties or no difficulties, however, there can be no question that this decision of the Court of Appeal has finally settled a point upon which there has long existed doubt, though the balance of judicial decisions seems to lean towards the solution now reached by the Court of Appeal.

MAP OF LONDON, SHOWING THE BOUNDARIES OF SURVEYORS' DISTRICTS.

We publish this week the first section of a map of London, showing the boundaries of the Surveyors' districts under the Metropolitan Board of Works, accompanied by a list giving the addresses of the district offices and their hours of business. The remainder of this map will follow in three other sections with the three succeeding numbers of the Builder, so arranged that the four can be mounted as one map if desired.

The boundaries have been put on with great care by a draughtsman who had access to the best documentary information, and we hope that the map may be of use to architects and builders, especially when on work near one of the district boundaries, when a mistake as to the actual district may easily be made, and has often been made, resulting in loss of time and other inconvenience which, we hope, may be obviated henceforward.

Illustrations.

THE HOTEL DE VILLE, PANTIN.

WE have previously given illustrations of two of the suburban Town-halls or Mairies rising up around Paris, those of Neuilly\* and St. Denis†, and we give this week an illustration of another more recent erection of the same kind at Pantin, one of the most important communes of the Department of the Seine, the population of which has been augmented since the war by a great number of emigrants, or immigrants, from Alsace. The previous town-hall was a mere villa, "une folie," as it was called, originally erected by the Marechal de Sombise for a certain lady once famous in the dancing world and otherwise. The new building, erected from the designs of M. Léon Guélorget, erected for the inhabitants of Pantin with an official building more adequate in its requirements as well as more dignified in its origin.

The new Hôtel de Ville occupies a central site between the houses of "Vieux Pantin" and those of the new Alsatian colony, known as the "Quatre Chemins." The building is a large one, the principal front, shown in the view, being about 150 ft. long. The style adopted is that of the Renaissance under Henri II. Remarkable care has been bestowed by the architect on the treatment and execution of the ornamental detail.

The three entrances of the principal front lead to a vestibule decorated with an order of columns and pilasters, leading to the main staircase lighted by a large stained-glass window, executed in the style of the close of the six-

teenth century, after a cartoon by M. Guélorget; a composition symbolising the industry and commerce of Pantin.

The Salle de Justice opens from the entrance vestibule; the other public rooms are arranged on various stories as convenient. The Salle des Fêtes is on the first floor, with the Salle des Mariages on the one hand of the same floor, and the Council-room on the other. This arrangement, unavoidable, has a little cramped the Salle des Fêtes. This latter contains a fine chimney-piece in white marble, unfortunately disfigured by a very bad bust representing "La République." The principal doorway to the Salle has a pediment decorated with the arms of the ancient Dukes of Pantin, which date from 1204.

The illustration is engraved from a photograph, by Mr. J. D. Cooper.

"THE ENCHANTED CHAIR": SCULPTURE.

ALL who visited the last Academy exhibition will remember, or ought to remember, this fine life-size group in terra cotta, by Mr. A. Gilbert, which occupied a prominent position in the octagon hall, and is one of the most imaginative and original works by an English sculptor which we have seen there of late years. It is not merely a finely-modelled study; there is a poetic suggestiveness about it; the dragon wings coiled up under the seat, the Cupid among them, the eagle with outstretched wings above, suggest we know not what of glamour. There is a whole "Arabian Night's" tale in the group; one can fancy all kinds of legends for it. The feeling of deep sleep is finely conveyed in the figure. We have much pleasure in giving an illustration of a work which, both in technique and in imaginative power, gives us reason to look with much interest for its author's future productions.

It may be right to add that Mr. Gilbert speaks of the work as "unfinished," and we presume the minor details are not worked out entirely according to the ultimately intended form.

THE CHANTRY OF HENRY V., WESTMINSTER ABBEY.

HENRY V. is said to have cherished a peculiar veneration for Westminster Abbey as the scene of the great reformation of his character. He not only ordered the great architect of his age to continue the building of the nave of the church, but also, in his will (made just before the expedition to France which led to the battle of Agincourt) declared that he would be buried in the Abbey, and gave minute directions as to the position and form of his tomb.

On Henry's death, at Vincennes, the body was brought, with great magnificence, to Westminster, notwithstanding large offers of money by Paris and Rouen to be allowed the honour of retaining it. The extreme east end of the Confessor's Chapel, hitherto devoted to the sacred relic, was cleared out, and the present magnificent Chantry erected at a level where it could be seen from the body of the building. The form of the structure is said to be based upon that of the letter H, the first of Henry's name. He was the first king to order the erection of a separate chantry over his tomb. The larger statues represent the patron saints of France and England,—St. Denis and St. George,—as well as King Arthur and Edward the Confessor. The smaller sculpture represents the personal peculiarities of Henry V., and scenes from his life.

CHURCH OF THE HOLY INNOCENTS, HAMMERSMITH.

THIS church, designed by Mr. Jas. Brooks, is a fine example of simple and solid work, producing its effect by massive construction and picturesque outline and grouping, without any adventitious aid from decorative detail. The plan is designed on the system, which has been tried from time to time by modern church architects, of making the side aisles narrow alleys for passage merely. This treatment is unfortunately rather difficult to carry out architecturally without going to the opposite extreme and making the aisles too narrow, as is certainly the case with Street's Church of All Saints at Clifton, where this plan was tried

\* Builder, January 2nd, 1886.

† Builder, October 30th, 1885.

and where the passage past the piers is too narrow for two people to walk abreast conveniently. We hope this has been avoided in the design shown here. The exterior architectural treatment is very solid and effective.

#### THE AMERICAN CHURCH, PARIS.

We give some of the geometrical drawings for this building, which is, we understand, much admired in Paris. It is situated in the Avenue de l'Alma, Champs Élysées.

Some of the small scale drawings were prepared during the lifetime of the late G. E. Street, R.A., the other drawings and details have all been made by his son, Arthur Edmund Street, M.A., under whose supervision the work has been carried out. Mr. Arthur Street also

designed the vestry buildings and all the furniture and fittings of the church, the bishop's throne, stalls, sitters, &c.

The walls are built in dressed ashlar, and inside, and outside of Conflans stone; the arcade, columns, and other portions of the building are executed in Ancy-le-Franc stone.

The woodwork is all of oak; the roofs are covered with green Eureka slates. The floors are all of marble, in patterns executed by Messrs. Farmer & Brindley, who also carried out the stone carving.

The heating was carried out by Messrs. Jeakes & Co., and the wrought-iron screens and hinges and tower gates by Mr. Barford. Messrs. Potter executed the altar-rails and candle standards in the church as well as in the mortuary chapel below the vestry buildings, and likewise the railings outside. Mr.

Robinson, Bloomsbury, made the oak sedilia; and Mr. Gibbons the liany-desk. Mr. Earp executed the Bishop's throne, the altar, retable, and font.

Some of the stained glass which has been fixed has been carried out by Messrs. Bell & Beckham, and the scheme and a great part of the design was the conception of the late Mr. Jas. Bell, under Mr. A. E. Street's direction.

Mr. Lovatt, of Wolverhampton, was the contractor, and the cost of the buildings may be taken at about 50,000*l.* for the church, and 14,000*l.* for the vestry buildings, in addition to which there have been many special gifts. Mr. Wallis has been the clerk of works.

**Obituary.**—Mr. John Warrington Wood, the sculptor, died on Sunday last in Warrington, his native town, after a short illness.

IRIS, LILIES, AND WATER.

Carved Pierced and Coloured Wooden Balustrades (Japanese Work).

JAPANESE CARVINGS.

The illustrations of Japanese carvings are reproductions in black and white of coloured drawings by Mr. Josiah Conder, of Tokio, who recently contributed a paper on "Japanese Architecture" to the Royal Institute of British Architects. They are examples of the ornamentation of partitions and screens, and are treated in the same way as the ram-ma, or ventilating openings common to all Japanese buildings. They are usually carved in camphor wood, the wood being pierced, and frequently displaying a different design on each side. After being coated with a mixture of whiting and size to preserve them from the attacks of insects and decay, they are coloured with as near an approach to a reproduction of the beautiful hues of nature as is compatible with their decorative nature. The same fidelity to nature is found in all Japanese work, so beautifully conventionalised in the many different materials in which their art is displayed, that, as will be seen in these illustrations, it is almost impossible to detect, excepting upon close scrutiny, where nature ends and art begins. These drawings represent carvings of (1) ducks swimming amongst lotus plants; (2) jays flying amongst chrysanthemums, water being again represented; and (3) the Iris, lilies and water. They are so delicately coloured that these reproductions fail to convey more than a slight idea of the beauty of the originals.

A Billiard Room for the Constitutional Club, Poplar, is in course of erection from the designs of Mr. Brett A. Elphicke, architect, Tunbridge Wells. The room will be 42 ft. in length, by 20 ft. wide, and will be lighted by a leaded lantern over each table. Mr. Riddle, of Poplar, has been entrusted with the execution of the work.

THE "APPARTAMENTO BORGIA,"  
VATICAN, ROME.\*

In the spring of 1885 the Department of Science and Art obtained permission from the Pope to have copies of the frescoes and other decoration taken, and a model made of one of the Stanzas of the Appartamento Borgia in the Vatican Palace. This concession was obtained with difficulty, owing chiefly to the fact that the suite of rooms in question is now the "Library of Printed Books," and thus contains an important and considerable portion of the famous Vatican Library. It is greatly to be wished that the Vatican authorities may ere long give consent for photographs of the whole of the decoration of these rooms being taken.

The model, which is destined for the South Kensington Museum, has been carried out in plaster with great care and fidelity to a scale of one-tenth of the original by Signor Consolani, of Rome, who had a principal share in the construction of the model of the great monument to Victor Emmanuel, which will some day clothe the north side of the Capitol. The coloured decoration of the ceiling and the wall-frescoes are being copied by Count Lemmo Rossi Scotti.

The "Appartamento Borgia" was so named after its founder, the Borgia Pope, Alexander VI., and its decoration is for the most part the work of Bernardino di Betto (or di Biagio), better known as "Pinturicchio," or the little painter.

The position of the rooms will be seen on the sketch-plan, and will be best recalled by those who know something of the Vatican, as being immediately below the stanze of Raffaele, the rooms of the former suite coinciding in shape and size with those of the latter and having their look-out over the great cortile de Belvedere.

A door opens directly from the loggia on the

first floor of the cortile di San Damaso directly beneath the door of the Sala di Constantino which leads into the loggia of Raffaele, but access can only be gained through the great hall of the library from the Gallery of Inscriptions.

Unfortunately it is only with difficulty and by special permission that the visitor to the Vatican can obtain access to these rooms, which, apart from what they contain, are only second in interest and hardly second in general beauty of effect to the stanze of Raffaele.

In the following description of the rooms they have been taken in order as approached from the library. It may also be mentioned here that when the right or left hand is specified it is that of the spectator and not of the personages of the pictures.

Although the decoration of Stanza I. is by some attributed to Benvenuto Bonfigli, the friend and possibly assistant of Pinturicchio, it may well be that all this work is from the designs of Bernardino himself, who was a man, as hinted above, much affected by outside influences at different times, now showing signs of the study of Signorelli, now of Raffaele. The main part of the ceiling is flat, and rests on a deep, vaulted cove springing from a shallow cornice. Except in the case of the Borgia arms occupying the centre octagon, the whole of the mouldings and other ornamentation of this ceiling (and that of Stanza II.) is painted only, therein differing from the other and more characteristic work of Pinturicchio, which is largely in relief stucco. Part of the centre of this ceiling is given in the illustrations, with notes of the colours used.

The vaulted cove forms three lunettes on each wall, in each being painted three-quarter length figures of a prophet and sybil in converse. The soffits above the lunettes are occupied by armorial bearings and other devices, and on the

\* See Illustrations in this number of the Builder.

cove itself are two octagons on each side of the room filled with representations of the planets in the upper part, and allusive incidents beneath them. Thus we have a hunt with falcons beneath Jupiter, below Mars a drol in presence of a lady, below Apollo a throned king, a wedding presided over by Venus, people reading and conversing under Mercury, fishing under Luna, a massacre taking place beneath Saturn, and, lastly, a figure of Astrology as embracing the study of the whole.

The effect of the flat part of this ceiling is good; but the cove is somewhat ineffective, on account of the small scale of the figures, though the merit of the composition is considerable.

The form of the next stanza is rather irregular, the width increasing from 20 ft. 3 in. to 24 ft. 7 in., while an arch, springing from responds of considerable projection, spans it at about two-thirds of its length. From a cartouche on the ceiling we learn that the work was done in 1494. It is often attributed to Bonfigli, though this is very doubtful, and, perhaps, it would be fair to suppose that the main scheme is due to the master, though certainly the assistant, whoever he may have been, to whom the execution was entrusted, seems to have allowed himself much freedom in carrying out the master's ideas. In this second chamber, in particular, there are especial differences in the manner of the work from that of the three succeeding chambers, such as an absence of gilding and of relief stucco work in mouldings and ornaments, and the use of secondary colours in the decoration. Though the work of decorating these six chambers extended only from the end of 1492 till some time in 1495, or about three years, yet even this period,—short, when we consider the extent of the operations (for the rooms extend nearly 200 ft. and average 35 ft. wide),—was not entirely spent by Pinturicchio in Rome. It is therefore obvious that he must have left much to be done by assistants, and in the smaller and less important rooms we may conclude that we have a correspondingly larger proportion of their work.

A brief of Alexander VI., dated March 29th, 1493, requires the people of Orvieto, for whom Pinturicchio was then painting certain figures in the cathedral, to wait till his palace was done; nevertheless, they seem to have got the painter there again, for, in March, 1494, the Pope sends for him, and in this year and the following his suite of apartments is completed.

The general arrangement of cove and flat space, in Stanza II., is similar to the room already described; but the treatment of it is unsatisfactory and ill-adapted to the space. The lunettes have half-length figures of prophets, apostles, and sybils, holding long rihand-like scrolls, with inscriptions upon them. These are much too intricately arranged over the blue ground, and produce a disturbed effect. Probably these figures, as well as much other of the work, have suffered from unskilful re-painting.

The succeeding three rooms are, undoubtedly, the work of Pinturicchio. Each averages 28 ft. wide by 34 ft. deep by nearly 30 ft. high, is divided transversely by an arch with a soffit some 4 ft. wide, and has one window rising but little above the spring of the semicircular vault, which is intersected by nearly pointed transverse vaults on either side of the great arch. The rich colouring and brilliant effect of gilded stucco-work in these rooms is admirably calculated for the amount of light admitted by the one window, placed low, and near the outside of walls nearly 5 ft. thick.

The cross walls of these rooms are set obliquely, but hardly enough to be perceptible, except on plan. Sketches of a pendentive of the ceiling, and part of the decoration of the wall, &c., facing the window, are given among the illustrations. The ribs are of gilt stucco, with fruit and foliage in low relief, with outer mouldings, &c., partly painted, partly in relief. The greater part of the ground of the ceiling is a rich dark blue colour, varying considerably in depth in different parts. The spaces above the side lunettes are filled with some rather clumsy ornament in relief, introducing hills, amorium, and crowns, the smaller spaces having crowns or rosettes. The arms of the Pope, wherever they occur, are generally in full relief, carved in wood, and attached to the wall or ceiling, and are on a party red and blue ground.

In the Siena library above the two end windows, there are somewhat similar shields of arms supported by angels (Fig. 1).

The soffit of the large arch had probably

relief stucco panelling similar to that of the next two stanzas, but this is now replaced by painted ornament of lake design but poor execution. Five octagonal panels are included, that at the crown of the arch having a figure of Justice, the others subjects illustrative of its administration drawn from Biblical and classical history.

Allegorical impersonations of the seven Sciences fill the lunettes beneath the ceiling. Beginning with those opposite to the window, that on the left hand shows "Rhetoric" sitting in a canopied niche-like seat in the centre. She, as well as all the others, is represented as quite youthful. She hears a sword in her right hand, and a suspended golden ball in her left, while winged genii on either hand bear respectively the same symbols. On each side stand three men reading, or in contemplation. The background is a landscape on an embossed gold ground. This fresco is in fair preservation. It, as well as the "Musæ," shows the influence of Perugino, with whom Pinturicchio had worked as assistant in the "Moses and Zipporah" of the Sistine Chapel in 1484. Next, on the right, is "Geometry," holding a golden quadrant in her right hand. At her feet sits a man describing a problem on a tablet, while other male figures hold instruments or scrolls. The background of this and the next three is similar to that of the "Rhetoric." Still proceeding to the right is "Arithmetica" holding compasses and an abacus in her hands, and seated on a throne, with a canopy like a sounding-board over, from the angles of which hang festoons.

Fig. 1.

"Music" comes next, seated on a throne, with green hangings around, held up by flying genii. At the back is a terrace wall, beyond a landscape. Music herself plays on a violin; a genius on each hand, standing on the step of the throne, plays on a flute. A youth, in rich red garments, upon the left, has a guitar in shape like a violin; another, robed in blue, sitting on the step or dais, plays a harp; a third stands behind. Three girls, upon the right, are singing, while one beats time with a small golden baton, and with them is an old man.

Very little relief is used in this fresco, though some of the decorations of the throne and personal ornaments of the figures are of stucco. In some of the other subjects it is more freely used, especially in the constructive features. This is, perhaps, the finest in composition and colour of the series, and is, fortunately, in good preservation. Its refined identity and graceful treatment suggest the thought that in this work the painter was inspired by a more thorough sympathy with his subject than was the case with some others. Over the window the lunette is undivided and is occupied by "Astrology." The representative figure holds an astrolabe; two genii on either side have mystical emblems and instruments, while nine other figures fill up the sides. This is much faded and injured by smoke or damp, a result not to be wondered at when we know that for some time these chambers were actually used as guard-rooms for the Swiss guard.

"Grammatica" sits in a large arched niche with wings, which extend across the picture; she holds a book in her hand but looks upward. This and the last of the series, representing "Dialectica," who sits with hands crossed one

over the other, are much damaged. "Dialectica" occupies the centre arch of a screen of three, of very good design, festoons in relief stucco depending from the crown of each. The effect of the whole scheme of this room is admirable, owing to the decorative value of the similar treatment of the lunettes throughout, and the harmonising effect of the gold backgrounds.

The division of the large semicircle opposite the window into two spaces, with the arms in the spandrel, is also an improvement in some respects on the plan of treating it as a single subject. There is a good stone cornice to this room, though not so deep and important as that of Stanza IV., the frieze being carved with ox skulls and festoons.

The next room, numbered IV. on the plan, is that of which the model has been executed. As before remarked, the general arrangement is similar to that of No. III., the difference consisting chiefly of the want of a like coherence in the subjects of the frescoes, the use of figure decoration in the ceiling, and the greater use of stucco in the pictures themselves. It is indeed a striking characteristic of the painter's work, and is used by him to an extent which suggests the influence of Crivelli and his sympathy with earlier methods. His faces are evidently portraits, and are expressive and lifelike, while the treatment of his subjects is often unconventional, and the attitudes natural when not biased by the influence of Perugino, whom he occasionally outdoes in affectation of pose. In this series, besides personal ornaments,

all parts, with green hangings around, and, generally speaking, all parts which require gilding, we have large architectural features in four of the lunettes modelled with a projection of several inches. The soffit of the large arch is panolled in octagons and oblongs, the former, five in number, containing figure subjects illustrating the myth of Argos Panoptes. The ornament and mouldings are gilt, the ground being blue. The gilding having become much worn and perished, the red mordant employed shows through with decidedly pleasant effect. The mouldings have been fixed up in short lengths, and the ornament on the ground is poorly modelled, the idea having been apparently to break up the ground rather than to give effect in detail. The general scheme of the interior is shown in the perspective illustration, details being given of the principal parts.

It will be observed how much of the decoration is illustrative of myths in which a bull or cow figures. This is in allusion to the bull charged on the Borgia shield. The appropriateness is but superficial, though as the stories of the "Golden Calf" and of Jupiter and Europa have not been made use of, it suggests the possibility that those were avoided of which the application was more obvious or more appropriate.

The figure decoration of the vault gives in eight scenes the myth of Isis and Osiris. These are painted with a limited scale of colours, in a more conventional style than the wall subjects, the affectedness of attitude being very noticeable in some. Each has some central feature, such as a shrine or altar, in high relief. All the subjects of the wall-paintings are drawn from the Lives of the Saints, except the Visitation of the Virgin, which is apparently chosen to balance

the Visitation of St. Paul adjoining it. That opposite the window represents St. Catharine before the Emperor Maximian at Alexandria. A large triumphal arch, resembling that of Constantine, occupies the centre middle distance. The emperor under a canopy in front of a group of courtiers listens to the saint before him, while a doctor in a yellow robe combats her arguments from a book held up by a kneeling boy. A large group of people behind him is good in colour, and presents interesting types of the painter's fellow-citizens. Several horsemen fill up the right of the fresco; the cloak of gold brocade of one of them is modelled in stucco. In Nos. 2 and 3 are shown events in the career of SS. Barbara and Juliana. The former has the tower from which the saint has been miraculously delivered for its central feature, a rent in its side showing the manner of her escape. She departs towards our left, her father hurries away, sword in hand, in the opposite direction, two men accompanying him. The figure of the saint, in a pale crimson dress, is a good deal damaged; the father, whose principal garment is of the splendid deep crimson, inclining to scarlet, found in several other of these works, is better preserved. In the distance are small figures showing further episodes in the story. A large fountain with deep polygonal basin raised on steps occupies the middle of No. 3. The principal action concerns St. Juliana, who is here being bestowed by her father in marriage to an idolater. These three figures are to the right; a stag, some rabbits, and other small animals fill up the foreground. These are well drawn, contrasting favourably with the animals found in most contemporary works. A highway runs across

him are two disciples, poorly dressed, in striking contrast to the three figures on the opposite side behind St. Anthony. These are shown in the sketch, and of course refer to the famous Temptation of the saint. The centre figure has a crimson dress, shaded in darker self-colour; her attendant on the left, who bears a box of perfume, a yellow robe over blue; the other has one of rich blue with brown sleeves. The Satanic origin of this group is obvious from the horns, claws, and wings. The distance has pleasant bits of lake and mountain scenery. Some of these glimpses of landscape show observation and study of nature. Atmosphere and distance are very fairly given, though there is often too much small detail introduced. It is to be noted that Pinturicchio executed for Innocent VIII. (the predecessor of Alexander), in the Belvedere of the Vatican, a series of landscapes of Italian cities, which have now nearly disappeared. In this, as in other of the frescoes, especially the St. Catherine, we have numerous plants painted in the foreground, the flowers being composed of little beads of stucco, clustered or singly. They become more frequent in proportion to the distance of the field represented, so that the ground in the rear of the arch is quite thickly strewn with them. The same means are then taken to represent the glow of the descending sun, where the heads become less closely studded together as the distance increases.

Over the door, below No. 3, in a circular stucco frame, is a three-quarter length of the Virgin teaching the infant Christ to read from a book. It is much damaged and faded in colour. The cornice of this room is of stone. The upper ovolo is cut with a deep gullitoe,

No. IV., and the similar painted ribs and panel borders,—themselves interlaced, too,—of Stanza II.

The face of the main arch is now quite plain, having apparently been deprived of its decoration. Part of the soffit is shown among the sketches. Taking the frescoes in the order of events, we begin with that on the left, on the wall facing the window. This is the "Annunciation." Gabriel on the left, in red, the Virgin in blue, kneel on either side of a vase of white lilies. There is a composition of two smaller arches flanking a much larger one in the background, the Deity, surrounded by cherubs, filling the centre compartment. No relief is employed, and some parts have become smoky and hurred, but the decorative effect of the whole is very good, owing to its simplicity and symmetrical arrangement. Malachi, with the text, "Ecce, ego mittam angelum meum, nomen timentibus orietur vobis," has reference to this subject.

Proceeding to the right we have the Nativity. The Holy Child lies on the ground in the centre, his mother and Joseph in adoration kneel on either side, and two angels behind. Others are shown in the sky and standing on the thatched roof of the stable to the right. To this subject pertains the figure of Isaiah in the ceiling with the text "Cognovit vos possessorem."

The "Adoration of the Magi" follows. The colour throughout this has been very good, though now rather damaged in parts, especially the Holy Family to the left. It is very noticeable that even where the draperies, &c., may be much affected by damp, the flesh tints still come out well and appear to have suffered little.

The medallion above represents David with the prophecy "Adorabunt enim omnes reges." The next subject is the Resurrection. Above the tomb is Christ in a large vesica surrounded by cherubs. He is in a white robe lined with blue, has a white flag with a red cross in his left hand, and his right raised in benediction. One soldier sleeps in front of the empty sarcophagus, two others kneel in adoration on the right. On the left is a portrait of Alexander VI., kneeling with hands raised in prayer. The background is an open landscape. Zephaniah (Sophonias) with the text "Resurrectionis mee expecta in die," occupies the circle above. The Ascension is shown in the large space over the window. Christ, in a white garment, is surrounded by a golden vesica with a rainbow-tinted border. High up an angel kneels on either side, and many cherubs and birds are in the air around. The Virgin and five Apostles are standing or kneeling on the left, and seven on the right. The horizon is placed rather high and the landscape behind has a lake and trees with hills on either hand. A dark purplish red or plum colour is used in one of the dresses, which the painter has not used elsewhere in these stanze. The figure of Micah, with the inscription "Ascendit pendens iter ante eos," refers to this event.

The "Descent of the Holy Spirit" is here shown as taking place in the open air, the virgin kneeling in the centre of the picture, the apostles ranged equally on either side. The dove descends upon them surrounded by a nimbus of rays and an effulgent company of cherubs.

The prophet Joel in the circle above has the inscription "Et in die de Spiritu meo spernem carnem."

The "Assumption of the Virgin," the only subject drawn from traditional sources, is the last of the series. The sarcophagus occupies the centre foreground, the mouldings being in stucco. The Virgin, clothed in white in a dark blue vesica with a gold centre, is in a sitting attitude, the border of the aureole being composed of cherubs and small purplish clouds. Two angels hold a crown above her head, while two on each side have musical instruments, like those in Pinturicchio's picture in the Vatican gallery. St. John kneels on the left in a blue dress, with rich red robe or cloak over it, while on the right is a kneeling figure, apparently a cardinal, in a plain rich scarlet dress. There is a dark landscape background. The colour and state of this work are alike excellent. In the ceiling we have Solomon bearing the inscription "Exaltata sum in Libano quasi cedrus"; an eighth prophet, Jeremiah, having apparently no special reference to any design.

We now come to the largest chamber of the series, corresponding to the Sala di Costantino of the Stanze of Raffaele. As originally deco-

Ceiling of Stanza VI.

Fig. 2.

the landscape, along which a procession of people leads the saint to execution.

Above the window is the "Martyrdom of St. Sebastian." It is in good preservation, but has been much restored. In many respects it is a fine work: the nude figure of the saint is well drawn and free from affectation; the action of some of the archers is vigorous and not overstrained, and, owing presumably to its position, where relief work would have had no effect, no stucco decoration has been used. There are three or four figures on either side, chiefly the archers, and an old man sitting on the ground on the right, who appears to be superintending the execution. St. Sebastian is bound to a column against a ruined mass of brickwork, such as the painter might have sketched then, even more readily than now, in Rome itself. The left background is a landscape of a lake and hills,—on the right we see the Colosseum and other buildings in ruins. An angel above bears a crown of martyrdom.

No. 5 shows the "Visit of St. Elizabeth to the Virgin." Two-thirds of the background is filled with an architectural composition of arches, supporting a balcony and loggia. There are some good female figures spinning wool on the right, but the work is smoky in appearance and faded in parts.

The subject of No. 6 is the "Visit of St. Antony to St. Paul the Hermit in the desert of the Lower Thebaid." They are shown seated on the rocks, which rise in the middle of the picture, in the act of dividing a small loaf which a raven has brought. A rill of water issues from the rock between them, and a bell is hung on the crag above St. Paul. St. Antony, a fine venerable figure, in a rich purple robe and white tippet or cowl, faces St. Paul, whose only garment is of a plaited texture, very coarsely woven, as if of straw or grass. Behind

and the bed-mould with the "egg and tongue." The corona has crowns in high relief, alternating with foliated and other ornament in great diversity. The variety of ornament in the frieze is also noticeable. All this work is reproduced in relief in the model executed for the Department, which terminates in front of the main arch, and thus includes frescoes 1, 2, and 6.

Although hooks remain from which hangings have been suspended, it has been suggested by some, not without foundation, that the walls beneath the cornice were decorated with painted and gilt representations of drapery, like those below the older paintings in the Sistine Chapel. The cornice was also probably partly gilt.

In Stanza V. the main arch has no responds. The scheme of ceiling decoration is shown in the drawings. Half-lengths of prophets take the place of the Osiris series in the last room, each having reference, through a prophecy inscribed on a scroll, to the subjects on the walls, which, with the exception of the last described, are taken from the Bible. The arabesque of bills and foliated ornament on a blue ground is very rich and beautiful, the effect of the whole ceiling being even finer than that of No. 4. The preponderance of the primary colours,—red, blue, and gold, and the use of the low reliefs in stucco,—inevitably bring to mind the colour-design of the Moors, and suggests comparison with it. In the Italian work, blue decidedly preponderates over the red, and gold is not quite so freely used. In both, however, the ground is hardly ever gilt, and is always broken up by small unobtrusive ornament, so as to prevent flatness and poorness of effect. Here and there are certain direct resemblances to Moorish ornamentation: as, for instance, in the interlacing ornament of the ribs of ceiling

rated by Pinturicchio it was known as the hall of the Martyr-Pontiffs, from the circumstance of a series of portraits of these Popes having filled the lunettes. Most unfortunately all this work was destroyed within a few years by Leo X. (1513-22) and replaced by the work of Giovanni da Udine and Perino del Vaga in their well-known style. There is a deep cove pierced transversely and forming three lunettes on each long wall and two on each end wall. The general arrangement of the ceiling is shown on the plan (fig. 2). The circle has four female figures hand in hand, some of the other larger divisions having the heads of the week represented by various deities. Thus we have Jupiter in a chariot drawn by eagles, Mars drawn by horses, Venus by doves, Mercury by cocks, Luna by female figures, Saturn by dragons, and Apollo by horses. There are also the signs of the Zodiac and other emblems. The evidence which these chambers afford of the progressive secularisation of art is interesting. We note a marked advance in this direction in the art of Pinturicchio himself, though, as already noted, his sympathies in many respects were with earlier ideas as to treatment and technique, and the choice of subjects was probably not entirely his own. As an instance we have classic and mythological subjects put on the same footing as Biblical ones in the illustrations of Justice, and such a subject as the history of Osiris freely chosen. In this room his work is soon swept away to give place to a merely mythologic scheme. The martyred Popes are ousted to make room for the pagan deities whom they regarded as devils and whose cult some of them had given their lives to destroy, and "thus the whirligig of time brings in his revenges."

The spirit which informs the work of Pinturicchio is no longer that of the intense personal belief seen so plainly in the earlier masters. Biblical or theological subjects, or even the Lives of the Saints, hardly move him to his best efforts. It is in allegory that he puts forth his full strength and most loving care, and his thought is not so wholly given to edification but that he can bestow much pains on individual portraiture, especially in the subordinate personages, where convention has not decided on certain types, can indulge his predilection for gorgeous colour, for wealth of decorative detail, and for the added charm of landscape, architectural or natural. In short, for the earlier singleness of aim concentrated or telling the story, and inculcating the moral, is substituted a multiplex charm and attraction, whose aim, if single in any sense, is to produce beauty and harmony of decorative effect. His work marks the transition from the Umbrian to the Roman style, from the spiritual grace and religious sentiment of Perugino to the dramatic vigour and individuality of Raffaello's Roman period. The change is only a part, of course, of the great change going on in the outside world, from the moral earnestness and serious spirituality, the richness and fulness of invention (within certain prescribed limits) which marks the temper of the Medieval mind, to the cheerful secularity and eclecticism of the Renaissance.

But, although the signs of change in this painter's work are strong and unmistakable, we feel that he is hardly so far removed from the earlier spirit as from that which animates the style of the Cinque-cento. The inequality of value to be observed in his work is to be attributed to the dependence he must have placed on the work of assistants and pupils. He was apparently a man of great facility, and an indefatigable worker, and this was what, as Vasari remarks, made him in such request with impatient patrons in a period of feverish haste, not, as in the nineteenth century to grow rich, but to have beautiful surroundings. The extent of his work in Rome alone, extending over eighteen years or thereabout, is very great, and he was not employed during the whole of this period (1484-1502) at Rome for in 1491-2 he executed some decorations in Orvieto Cathedral, in 1496 several altar-pieces for Perugia, and in 1500 a series of frescoes in the collegiate church at Spello. Perhaps the accusation of his contemporaries that he let the love of gain weigh with him in the too rash acceptances of commissions was justified; still, with all its inequality of merit, it is not going too far to say that we owe to the genius of Pinturicchio some decoration which may be ranked among the fittest and most beautiful ever produced.

F. W. WOODHOUSE.

### "MEASURE AND VALUE."

"Scalpi salubris ictibus  
Et tunicae plurima.  
Fabri polita malleo.  
Hanc Sæva molens construat.  
Aptique junctis nervibus  
Lecturam in festigio."

"With many a cunning stroke by mallet wrought,  
The ringing chisel o'er the surface sped,  
To shape this mass, of stone with labour brought  
And laid with level joint on even bed,  
What patient skill did vaults and arches close  
From base to gable, as the building rose."

THE above Latin quotation is taken from a well-known Medieval hymn used at the dedication or anniversary of the consecration of a church. It is not possible to translate it exactly, because there are some idiomatic words and expressions used, the meanings of which probably refer to methods of workmanship which are no longer practised, so we have endeavoured in the translation to give rather an impression of the meaning than a paraphrase. This singular passage, however, serves to show how, in Medieval times, the mere material act of building was, to a great extent, regarded as a religious work. At the present day we should scarcely think of celebrating the operations of the mallet or the chisel, or the careful jointing of stonework, in a hymn, yet it may be a very pertinent question to ask whether the writers of the Middle Ages are remarkable in giving this religious aspect to building, or whether we are remarkable in not doing so. At first sight, it is a ridiculous one to say that there cannot be the slightest doubt that the Medieval usage was, at any rate, tinged by a kind of superstition, and that the superior intelligence of the present day must undoubtedly take the correct view of the case. If, however, we come to this conclusion, it is very difficult indeed to account for the minute and circumstantial descriptions given in the Sacred Scriptures of the erection of the Tabernacle in the desert, and of Solomon's Temple. It may be said that these were special cases, and, therefore, it was necessary for the cause of religion itself to give an account of them; but, surely if this alone were the object sought, a few words speaking of the magnificence of the structure, describing it in a poetical manner, and giving a sort of general notion, would be quite sufficient for the purpose. But instead of this, what we read is a detailed architectural description, entering into constructive particulars and peculiarities, giving dimensions of various parts, names of architects, builders, &c., and that, singularly enough, in cases where they were not Jews, but strangers. Then, again, in the Sacred Scriptures we find denunciations against slovenly buildings and slovenly builders. The most remarkable example of these is in the book of the Prophet Ezekiel, where proceedings strongly resembling those of the nineteenth-century "jerry-builders" are described and denounced:—

"... And one built up a wall, and, lo, others daubed it with untempered mortar. Say unto them which daub it with untempered mortar that it shall fall; there shall be an overflowing shower, and ye, O great hailstones, shall fall, and a stormy wind shall rend it. Lo, when the wall is fallen, shall it not be said unto you, Where is the daubing wherewith ye have daubed it? Therefore, thus saith the Lord God: I will even rend it with a stormy wind in my fury; and there shall be an overflowing shower in mine anger, and great hailstones in my fury to consume it. So will I break down the wall that ye have daubed with untempered mortar, and bring it down to the ground, so that the foundation thereof shall be discovered, and it shall fall, and ye shall be consumed in the midst thereof; and ye shall know that I am the Lord. Thus will I accomplish my wrath upon the wall, and upon them that have daubed it with untempered mortar, and will say unto you, The wall is no more, neither they that daubed it."

Now, although this is to be understood in a figurative sense to apply to the false prophets of Israel, yet there cannot be a doubt that it is also intended, to a certain extent, to be understood literally as a very strong denunciation against bad and slovenly building, and we could scarcely imagine the operation referred to being so carefully described unless special attention was intended to be directed to a dishonest and dangerous practice connected with the art of building, and a species of fraud probably somewhat extensively in use in the time of the Prophet Ezekiel. The "untempered mortar" referred to undoubtedly means mortar without lime in it, i.e., mud,—we have more than one reference to the practice of using mud for mortar in Scripture. As we have previously pointed out, this description might be taken as applying to our present "jerry-building," and

\* Ezekiel xlii. 10-14.

it shows the antiquity of that abominable institution. Very much has been written of late years against modern builders and their practices, but at any rate they cannot be blamed for having introduced the system, though it was probably never so extensively practised as at the present time, and undoubtedly a good deal of the abuse levelled at the jerry-builder is well deserved. There are, however, two sides to every question, and when we denounce men for dishonest practices, it is well to see to what extent these men may be victims instead of culprits. If, for instance, the defective state of the laws, general usage, or the avarice and cupidity of others, make it difficult for a man to be honest in his business, or hold out such a premium to dishonesty that a man can only remain honest greatly to his own personal loss and risk, it is clearly our duty, while denouncing the evil practices, to attempt in some way to remove or mitigate those circumstances which have led to the prevalence of the evil. And now the question arises,—can we point to any particular cause for the present great prevalence of false and slovenly building? We think we can. There is an impression among a large portion of the public, that all builders are rascals, but there is really no reason why this should be the case, and there are some reasons for supposing that the builders are more sinned against than sinning. Amongst the circumstances which are so detrimental to architecture, building by contract is one of the worst. And our chances of getting really good work and honest workmen would be greatly enhanced by giving up contracts altogether, and adopting the system of "measure and value." The writer was informed by an architect of very high standing in his profession, that in building a very costly and elaborate church, he had found the cost only one-fifth more by "measure and value" than by contract; whereas the superiority of the workmanship far more than made up the difference. Pugin also was strongly opposed to the present system of contract, and his beautiful little church at Ramsgate,—the most poetical-looking building of modern times,—was erected without a contract. It is quite evident that when a builder is bound down by contract, it is his interest to do the work as badly as it can possibly be done, and to avoid anything like variety or originality of ornament or construction, and to use the cheapest material that he can possibly come across. We do not say for a moment that builders always do this; on the contrary, the builders of many of our largest and most important public buildings have had to seek relief in the Bankruptcy Court from attempting to carry out their work in an honest manner. This, too, in cases where the client was well able to afford the extra outlay which had resulted in the cost of material; but no, there was the contract, and the client stuck to it as Shylock did to his bond: he would have the pound of flesh. Those who know how our public buildings are erected cannot but feel a kind of shame when they realise the fact that instead of being a source of credit and gain to the contractors they have in too many instances been the cause of ruin and intolerable vexation; and what makes the matter worse is the fact that the honourably scrupulously just man it is who suffers, whereas the man who scamps the work, or the jerry-builder who runs up a series of abominable "semi-detached villas" often makes a fortune.

It does certainly seem contrary to all sense of justice that a builder should be bound to carry out a work which, owing to causes over which he has no control whatever, may ruin him. Yet how often is this the result of building by contract? All agreements between men must be to a certain extent conditional, even when that agreement is ratified by an oath. Thus, for instance, the Queen in her coronation oath promised to maintain the Established Church of Great Britain and Ireland. Circumstances arose which rendered it necessary or advisable that the Established Church of Ireland should be no longer maintained, and Her Majesty had to give her consent to an Act of Parliament which put an end to the establishment and endowment of that religious body. Yet we think no man would dare to draw from this fact the deduction that the coronation oath had been violated.

Now if in such matters as this circumstances alter cases, why should it not be the same in simple matters of contract? Of course we do not for a moment suggest that the man him-

self should be a judge of his own case, but we think there should be some kind of court of appeal or of arbitration which should have the power of releasing builders from being forced to carry out contracts which, owing to some alteration in the circumstances of the case, render it certain ruin to him and a most unfair advantage to his employer. But probably the best way would be to do away with contracts altogether, for as long as they exist we shall never again see the kind of work which was done in the Middle Ages; and as to any religious element in building, where every one connected with it mistrusts and tries to take a rise out of his neighbour the very idea is an absurdity. Where client, architect, builder, foreman, and workmen are all playing a "game of grab," so as to put the most money into their pockets without the slightest regard for the work, how can we expect to find poetry or art in our buildings? If we read two great accounts of building given in the Sacred Scriptures,—that of the Temple of Solomon and of the Tower of Babel,—the former reads like work being done according to measure and value, and the latter was evidently "a contract job." "The people is one and they have all one language . . . Let us go down and there confound their language that they may not understand one another's speech."<sup>\*</sup>

Before this tower was built, the people had all one language, and understood one another; but afterwards they were all scattered abroad, and they left off to build the city." The one language in building has gone from us. We have no one language, but a Babel of styles, and we have no combined interest in the work, but every one is simply working for himself. Our language has been confounded. We no longer understand one another, and our views and interests are scattered. Now may it not have been the fear of this happening, and the warnings contained in the sacred writings, which led men to regard building as a religious act? And by depriving building of that religious aspect, may we not have destroyed the ancient safeguards, and opened the doors to selfishness, corruption, and dissension?

Our drawing is intended to show the varied treatment which results from building without contract. It will be noticed that the great church has its towers placed obliquely to the axis of the building,—an uncommon treatment, examples of which, however, exist at the church of Ingolstadt, in Bavaria, and foundations of towers so placed were formerly to be seen at St. Onen, at Rouen. They were, however, destroyed during the "restorations," and the new towers placed square with the front, in the ordinary way. With the exception of this, we believe the whole treatment of the front to be original, both in composition and detail.

H. W. B.

BUILDING IN ABERDEEN.

DURING the year just ended trade has been fairly active both in the building and granite-polishing departments. Neither employers nor employed have had any reason to complain as to the volume of business, although the former grumble very much as to the effect of over-competition in forcing prices down to unremunerative rates. A number of private persons have laid out detached parts of streets, while a more systematic attempt in this direction has been carried on by the City of Aberdeen Land Association in the Fountainhall and West End districts. The Municipal Corporation has also engaged, either alone or in conjunction with other parties, in extensive public improvements. The first section of the Rosemount Viaduct, viz., the part from South Mount-street to Union-terrace, was completed in the spring, involving a present expenditure of about 50,000*l.*, and the demolition of a number of buildings, displacing about 600 individuals. The extension of the Viaduct to the Schoolhill by a mound and three arches, has also now been contracted for and commenced. In addition, the Corporation has dealt with an unhealthy area at the Shorelands, near the Harbour, where both cholera and fever used to be prevalent, and in virtue of the powers obtained by a provisional order under the Artisans' Dwellings Improvement (Scotland) Act, has razed a number of buildings in certain former lanes in that quarter. The level has now been raised about 4 ft., and a new street,

40 ft. wide, called "Mearns-street," leading from Regent Quay to Virginia-street, opened up. This new thoroughfare will be very convenient for the erection of warehouses in connexion with the harbour and docks. The population displaced here amounted to about 800 persons, generally of the poorer classes, and unable to pay a large rent. These consequently migrated temporarily to the Gallowgate and Justice-street districts, thereby aggravating the pre-existent overcrowding in these quarters. Some relief has now been afforded by the opening up of Summerfield-terrace,—a street in the east end leading between King-street and Park-street,—which has already been wholly fenced and built on with working-class houses. Urquhart-road, farther to the east, has also been extended to the Links by the Town Council in conjunction with the Trades Hospital, and fencing has commenced there, as well as an extension of Colville-place. Fonthill-road has been widened to about 50 ft. throughout, and opened up to Holburn-street, while Bon Accord-street has been extended at an improved level by a bridge over Rosebank-terrace. The much-talked-of Riverside-road, including a new elliptical arch at Wellington Bridge, has been constructed, partly by the Aberdeen Harbour Commissioners, and partly by the Town Council. The total extent of this carriage-drive is about one mile and a quarter, from Victoria Bridge to Allanvale. The increase of the population has compelled the construction of a new water-house and pumping machinery at Cults, while the new supply reservoir at Mannofield has been partly finished and partly contracted for, at a total cost of 15,310*l.* The small estate at Westfield has been purchased by the Town Council, and new streets are being laid out there, while the level of Correction-wynd has been lowered, and various paving and minor improvements have been executed.

COMPETITIONS.

*New Market, Carlisle.*—At the meeting of the Carlisle Town Council on the 21st ult., Mr. Creighton moved "That the plan marked 'Arm'd at All Points' be selected as the design for the new market, subject to the author satisfying the Market Committee as to cost, construction, and other details." Mr. R. S. Ferguson seconded the motion, which was agreed to. Messrs. Cawston & Graham are the authors of the design in question, which will cost about 20,000*l.* to carry out.

*Townhall, Bethnal-green.*—The plans sent in for the proposed new Townhall at Bethnal-green were exhibited in the Board-room of the Vestry last week. The first premium (one hundred guineas) was awarded to the set of plans marked "Orient." The second premium (fifty guineas) was awarded to the plans bearing the motto "Use and Profit." According to a local journal, the third and fourth premiums were not awarded, and the names of the successful competitors were not appended to the premiated drawings.

THE RIGHT OF DISTRICT SURVEYORS TO ENTER DWELLINGS.

MR. F. M. B. CALCOTT, of 52, Lincoln's Inn-fields, was summoned by the Metropolitan Board of Works, at the Marylebone Police-court, last week, before Mr. Cooke, for the payment of 4*l.* 6*s.* 9*d.*, being fees incurred in the inspection of Nos. 8, 10, and 12, Eresby-road, West Ham, impudged, by Mr. Thos. Blashill, the District Surveyor.

Mr. Norman Bavan represented the Metropolitan Board of Works, and Mr. Holloway, solicitor, was for the defence.

At the outset of the case, Mr. Bavan drew the magistrate's attention to the fact that while the 72nd section of the Building Act gave the Metropolitan Board power to shore up dangerous buildings in order to secure the safety and protection of the public passing by, the 80th section stated that if the interior of the building was dangerous, it was within the power of the magistrate to order the removal of the inmates. He therefore contended that the Act gave the District Surveyor the right to enter a building for the purpose of inspection where there was a doubt as to the safety of the inmates, owing to the condition of the house. He called

Mr. Leach, the tenant of No. 12, Eresby-road, deposed that about 4 ft. square of the ceiling in the middle of the top bedroom of his house fell down, leaving other portions in a faulty condition. The ceiling on the top landing also fell.

Mr. Thomas Blashill, District Surveyor, said he received directions from the Metropolitan Board of

Works to inspect several houses in Eresby-road. He did so, and sent a certificate to the effect that the structures were dangerous, and that the owner should be called upon to take down the plaster ceilings of the houses. Parts of two of the ceilings had fallen, work was in progress at the time, pieces of zinc being placed over cracks in the ceilings of some of the other houses, and screwed to the joisting above. By the Magistrate.—In his opinion the ceilings were dangerous. He produced some of the material which fell. Instead of being of hair, lime, and sand, it consisted of dirt, a little lime, and instead of hair he found here and there a little string or such like stuff. The houses were put up, he believed, in the spring of last year. There was nothing to form a good key. The weight of the material should be about 24 oz. the square foot, but this weighed about 7 lb., and the thickness was nearly 2 in., or about double what it should be. In his opinion the Act fully entitled him to inspect the interior of the houses, because the internal portion of the structure might be dangerous, and not the external portion.

Mr. Holloway, for the defence, said his contention was that the Act was not intended to apply to the interior of a house simply for the protection of the inmates, except in the matter of fire, drainage, or the size of rooms where they were of so small a size as to be injurious to health. He denied the right of the District Surveyor to go in and inspect the premises under the circumstances.

Mr. Cooke.—You admit the right to go in to inspect a flue or a drain. And if that is so, if they have the right to go in for that, surely they may go in for other matters? It is a very important power, which ought to be exercised, because, as houses are now being built, the inmates are often in great peril. The houses are built like straw, and I fear there are a very great many of them about.

Mr. Holloway then called Mr. W. Matthews, who said he had been a surveyor for sixteen years. He received a letter from Mr. Calcott on the 9th of July, and went to inspect the houses. He found Mr. Tebboth, a builder, had taken down the loose portions of the ceilings and had repaired them. The other parts of the ceilings were quite safe. He (witness) gave directions that entirely new ceilings should be made, as that would be the best way of doing the work, both in the rooms and on the landings. The part which fell was exceptionally thick, owing to the joisting being out of the level.

Mr. Tebboth, a builder, having given evidence of doing the work,

Mr. Cooke said: I have no doubt this house was dangerous, to a certain extent, and that inspection was necessary, and must be paid for. The only question is as to whether they had a right to inspect the inside. I shall hold that in regard to No. 12 the inspection was rightly done.

Mr. Bavan asked for costs.

Mr. Cooke made an order for the whole amount claimed, with 2*l.* 2*s.* costs.

PROVINCIAL NEWS.

*Birmingham.*—With the end of the year the members of the Birmingham Conservative Club will vacate their present quarters in Union-street, and early in the year just entered upon will take possession of the new building which has been erected for them in Temple-row. The building, which is from the designs of Messrs. Osborn & Reading, architects, Birmingham, has cost about 13,000*l.*, exclusive of site, &c. The site contains 800 square yards, and the whole of this area is covered by the new buildings, which are three stories in height, with a ground floor and basement. The frontage to Temple-row is only 45 ft. in length, so that the building is of rather narrow elongated form, but the architects have contrived to provide conveniently-arranged and well-lighted and ventilated suites of rooms. The style of architecture adopted is a Roman type of the early Italian Renaissance, and the chief features of the front are the boldly-outlined entrance portico and lofty bay windows which are carried up on either side to the level of the third story, with balconies and parapets on the two principal floors. The main entrance from the street is by a broad flight of steps beneath the portico, and leading to the ground floor, which is raised sufficiently above the street level to secure the privacy of members from curious passers-by. The whole of the facade is in white stone, from the Portland and Hollington quarries. Messrs. Barnsley & Sons, of Ryland-street, have carried out the whole of the building work.

*Cockermouth.*—Messrs. Jennings Brothers, of Cockermouth, are now doubling their brewery, and also increasing their maltings. The architect entrusted with the work are Messrs. H. Stopes & Co., London.

*Silloth.*—The Carlisle Journal publishes a description of Messrs. Carr & Co.'s new mill at

\* Genesis xi, 6-7.

Silo, which is now nearly completed. The mill is situate on the west side of the new dock, and parallel to the extensive grain warehouse belonging to the North British Railway Company. It is claimed that the new mill will be absolutely fireproof, every portion, down to the smallest detail, being of incombustible materials. The walls are of a specially hard brick, manufactured by the Birkby Brick Company, near Maryport, tested before use and found to stand a crushing strain of over 70 tons to the superficial foot. The fireproof floor and roofs, which have been carried out by Messrs. Homan & Rodgers, engineers, Dawson-street, Manchester, are formed with their patent section rolled iron girders and joists, and filled in on the flat-arch system with concrete of a special kind. The surfaces are faced in quartz finish, and the roofs are laid with Scryssal rock asphalt. The ceilings have been done by the same contractors with Robinson's patent cement. The contract for all the ironwork has been carried out by Messrs. Cairns & Co., and Messrs. Tweedy & Co., of Carlisle. All the windows are fitted with Lindsay's patent wrought-iron sashes, and are of malleable iron with stamped boss intersections. A strong iron roof, nearly 40 ft. span, designed by the architect to suit the numerous iron worms over the silo bins, has been erected at a height of 56 ft. above the ground by the same firm, and covered with Vieille Montagne zinc Italian rolls, supplied by Messrs. Braby, of Liverpool. The engine and electric light-houses are decorated with glazed bricks and Burman-tofts faience ware, manufactured by Messrs. Wilcock & Co., of Leeds. The engines are compound and of 300-horse power, being manufactured by Messrs. Douglas & Grant, Kirkcaldy. Lines of rails have been laid on both sides of the building and through the warehouse to facilitate the transit of goods to all parts. The chimney-shaft rises to a height of 120 ft. above the ground. It has about 300 ft. of the capacity from the boiler furnaces, and possesses one of Green's patent fuel economisers in the centre of the feed-passages. The shaft is circular from the foundation, and has a massive square base and terra-cotta cap. This material has been adopted instead of stone for the window sills, cornices, parapet walls, pediment, and ornamental work, and has been supplied from the well-known works of Messrs. Edwards, Rnabou, North Wales. To admit of the rapid erection of the buildings, hydraulic mortar grout in mills has been used throughout, one-half being supplied by the Jarrow Cement Company and the other half by Mr. Armstrong, from his recently-opened quarries at Kershopfoot, near Penton. The general builders' work has been carried out by Messrs. Beatty Bros., contractors, Carlisle, in about nine months. Mr. T. Taylor Scott, of Carlisle, is the architect.

**Walsall.**—On Sunday last the new "church house" for the parish of St. Matthew, Walsall, was opened by the Bishop of the diocese. The building, which is situate at the corner of Temple-street, and opposite to the principal entrance to the parish church, has been designed by Mr. James Davis, architect, Walsall, and erected by Mr. T. Taylor, of Walsall. It is in the Perpendicular style.

#### CHURCH-BUILDING NEWS.

**Aylesbury.**—The Bishop of Oxford on the 21st ult. opened Walton Church, Aylesbury, which has been considerably altered, under the superintendence of Mr. Brett A. Elphicks. The interior has been thoroughly cleaned, refloored, and re-seated. A baptistery, bell-tower, and two porches have been added, and a new three-light lancet window inserted in old wall. The work is in Monk's Park Bath stone and flint; the baptistery in red brick. Mr. Landon was the clerk of works.

**Tharston.**—Tharston Church, Norfolk, has just been reopened, after complete restoration of the tower (the stair turret of which fell a few years since) and also of the north porch. The bells have been entirely rehung. The work has been done by Mr. E. L. Semmence, builder, of Wymondham, under the superintendence of Mr. E. Preston Willins, Diocesan Surveyor, Norwich.

**Warrington.**—All Saints' Church, Warrington, about three miles and a half from Croydon, has recently been restored, under the superintendence of Mr. P. M. Johnson. It was partially restored in 1857 by Sir Gilbert Scott, but at that time no repairs worth mentioning,

either to the roof or the walls, although they must have been required, were undertaken. The church consists of a nave without aisles, and chancel, with vestry on the north side and a porch on the south side. The total length is about 56 ft. and the width is about 19 ft. There is no mention of the church in Domesday, but there are traces of Norman masonry in the low-side window of the chancel. The plan and general arrangements show clearly that the church must have been enriched in the thirteenth century, and it is, in fact, a very perfect specimen of Early English, the original plan remaining unaltered, the only additions being the porch and the vestry, the former built about 1678 and the latter about sixty years ago. The walls are of flint and rubble, rough-cast externally with a sort of pebble concrete; the ashlar is a soft calcareous sandstone, probably from Reigate or Gostone, which was much perished in places, the weatherings of the buttresses having been tiled. The roof, which is covered with red tiles, has a tiled bell-turret at the west end, erected in 1820. In the interior of the church, close beside the north door, is a painting in distemper of the legend of St. Christopher. This painting is about 9 ft. high, and, from its style of execution, appears to be of the same period as the church. It is in very good preservation, and has not been interfered with during the recent restoration. The tracery of the east window, which is modern, was inserted in 1857, and probably follows the lines of the original Decorated late window. The drop-arch and jambs are original. Prior to the year 1857 the church had a seventeenth-century pulpit, with carvings of Adam and Eve, &c. (described in a paper by Mr. Ralph Nevill, F.S.A., in the Transactions of the Surrey Archaeological Society, vol. vi.), which has disappeared.

**Wishaw.**—The parish church of Wishaw, near Birmingham, has just been renovated and re-seated in pitch-pine from the designs of Mr. A. B. Phipson, of Colmore-row, Birmingham. The work has been executed by Messrs. Jones & Willis, who have also supplied the new choir stalls, pulpit, Communion fittings, lectern, &c.

#### Northern Architectural Association.

An ordinary sessional meeting of the Northern Architectural Association was held on the 22nd ult. in the Old Castle, Newcastle. Mr. E. Shewbrooks presided. The Hon. Secretary (Mr. F. W. Rich) intimated that a communication had been received from the Royal Institute of British Architects stating that a general conference of British architects would be held in London during the week commencing 2nd May, 1887, and asking that the Northern Association should nominate a member to sit as representative on the special committee. Mr. Hoskins was appointed to represent the Association. The Hon. Secretary also read a communication from the Manchester Society of Architects, pointing out that preparations were being made for a Jubilee Exhibition at Manchester, and stating that the primary object of the Exhibition was to illustrate the art progress of the nation during the Queen's reign. The Committee of the Exhibition were willing to allot a space as an Architectural Court in proximity to the Fine Art Section, in which might be exhibited designs for, or drawings and photographs of, buildings erected since her Majesty's accession to the throne. The Secretary was instructed to say in reply that the communication had been laid before the members, and also that the Exhibition about to be held at Newcastle would perhaps claim the attention of the members first. The Hon. Secretary then read a paper on "Architectural Pupillage, and its Bearings on Federation."

**Sewerage Works, Maryport.**—The main sewerage works here having been completed, the engineer, Mr. H. U. McKie, of Carlisle, has presented his report to the Trustees for the Town and Harbour. He states that the contractors, Messrs. H. Fisher & Co., of Cockermouth, broke ground in July, 1885. Eighteen months were allowed for the completion of the works, but they were completed (with the exception of a few details) in October last. The total cost of the works was 13,150*l.* Mr. J. McKie was resident engineer, and Mr. R. Fisher was clerk of the works. The trustees, the sewerage committee, and the officials, to celebrate the completion of the works.

## The Student's Column.

### FIELD WORK AND INSTRUMENTS.—I.

#### INTRODUCTION.

THE object of the following articles will be, first, to give the student a good practical knowledge of the construction and handling of surveying instruments, and then to deal with their practical application in setting out work. In so doing, we intend to make the various diagrams which will illustrate the subject as self-explanatory as possible, to avoid the tediousness of continuously turning backwards and forwards from the diagram to the letter-press. Some general description will, however, be added, in which we shall state the object of each diagram and the best way to study it. The value of understanding not only the use but also the practical construction of an instrument is shown by the importance set upon this information in the professional examinations annually conducted by the Surveyors' Institution and other bodies, in which examinations a knowledge of land surveying and levelling is required. An acquaintance with the subject also forms an indispensable part of the study of both architects and engineers. A man could not be expected to know thoroughly how to deal with a plan unless he knew how to make it, and those who are most conversant with the instruments employed for the purpose will know best how either to set about the work themselves expeditiously or to direct their assistants to do so in the most approved manner. Special attention will be directed to the methods usually adopted for testing the accuracy of the instruments described. Unless an instrument is in proper adjustment the most careful use of that instrument must of necessity fail to secure accuracy.

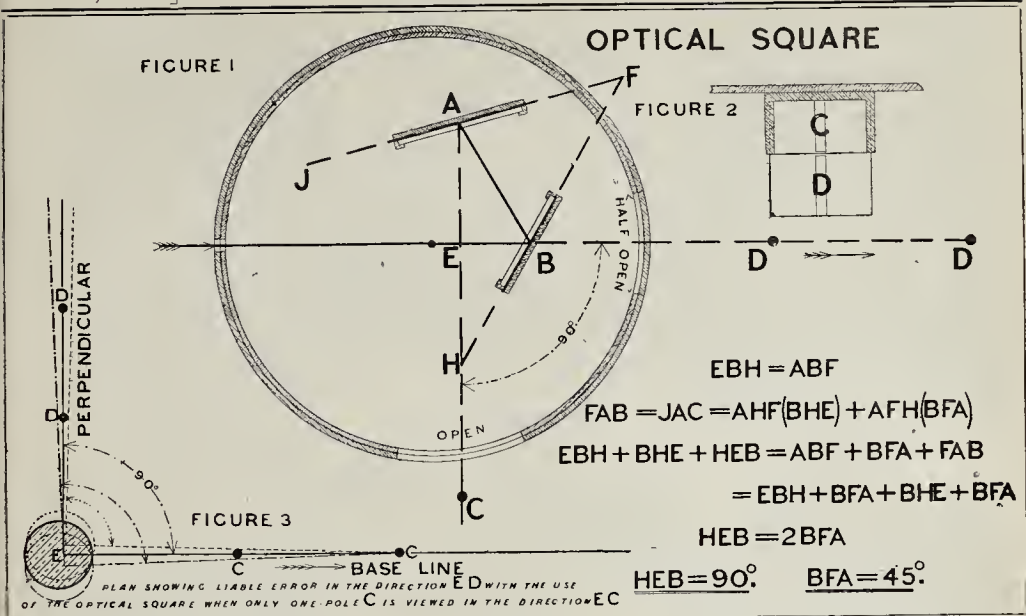

#### Surveying Instruments.

##### I.—THE OPTICAL SQUARE.

This instrument is used for setting out perpendicular lines and long offsets. It commends itself on account of its portability, being about the size of a large watch, and consists of an outer circular tube attached to one side of the box, and an inner circular tube attached to the other side of the box, the one sliding inside the other, and maintained in position by a small fixed screw connexion, which will be seen in the outer rim or side of the instrument. The inner circular portion can thus be twisted round by the hand to allow of three apertures through both tubes at the side, one open for nearly the whole depth of the side, one open for about half the depth of the side, in addition to a small circular hole to serve as an eye-piece. When not in use the inner tube can be twisted round to close the apertures, and thus prevent dust working its way to the inside.

Fig. 1 illustrates an enlarged section of the top-plate of the inner tube removed, so as to show the two glasses marked A and B, which are permanently fixed by the maker in vertical planes intersecting one another at an angle of 45 degrees. The glass marked A is formed entirely of silvered glass, while the glass marked B is silvered for only half its depth, as indicated in fig. 2, which shows the attachment to the upper plate in the diagram. In using the instrument, the surveyor holds it horizontally in one hand; placing his eye opposite the glass B, at the arrow in fig. 1, and looking towards D, he observes the pole D, through the plain or unsilvered portion of the glass B, while a pole at C, if the angle CED forms a right angle, will be reflected from the looking-glass at A, and seen in the silvered portion of the glass at B, one pole coming in line over the other, as indicated in fig. 2. The mathematical proof given in the diagram depends upon the angle of incidence JAE being equal to the angle of reflection JAF so far as the glass A is concerned, and the angle of incidence ABF being equal to the angle of reflection EBH so far as the glass B is concerned. The exterior angle of the triangle AHF is equal to its two interior and opposite angles, and these angles can be named for purposes of further application as the angles BHE and BFA, as shown in brackets on line 2. Then the three angles of the triangle EBH being equal to the three angles of the triangle ABF, and one of the angles in the triangle ABF being proved equal to the sum of the two angles BHE and BFA, we obtain, by substituting these values, an equation in which the angles EBH and BHE appear common to both sides: hence the remaining angles are

equal, and the angle HEB formed by the intersection of the lines ED and EC at the point over which the instrument is held, is seen to be double the angle BFA formed at the intersection of the planes contained by the mirrors.

Fig. 3 shows a precaution to be observed when great accuracy is required by viewing two poles instead of one in the required direction. It is evident that if the dotted lines be continued for any length, the direction of the required perpendicular would deviate considerably from that indicated by the full line, while the position of the surveyor at E might depart but very slightly from the direction of the given line EC. With the use of a second pole in the line EC this error of deviation would be at once detected, and by setting two poles with the instrument in the line ED, the direction could be more accurately continued than when only one pole is employed. Fig. 1 may be taken to illustrate setting out a perpendicular to the right-hand side of the surveyor, in which case the optical square is held in the left-hand, and the surveyor directs his assistant with his right-hand. Fig. 3 illustrates setting out a perpendicular to the left-hand of a given line, in which case the instrument is simply turned over, held in the surveyor's right-hand, his assistant being directed by his left-hand. Thus the open portion of the side, which allows the pole to be reflected in the mirror at A, is left unimpeded by the surveyor's hand holding the instrument. In each case the assistant has to keep his pole upright, and to follow the direction of the surveyor as to moving the pole to be set out, either right or left, until one pole is reflected over the other in the glass B. When this coincidence takes place the pole is fixed in the ground, and the right angle is said to be set out.

**Cremation in Denmark.**—The first cremation in Denmark was recently performed at Copenhagen. The whole process lasted an hour and a half, but it is anticipated that it will be greatly shortened when the furnace has been used a few times more. There was not the slightest trace of either smoke or smell. The body cremated was that of a Swedish convict. The crematory is built according to the design of a Danish architect, but has been constructed by a Milanese firm of engineers. The length of the building is 32 ft., and the breadth 21 ft., there being two stories. In the lower one the gas furnace is placed, whilst in the upper one stands the real cremating furnace. There is also a small room for relatives, &c., who desire to be present during the operation. A bridge of stone leads from the ground to the upper story, along which the body is carried to the cremating furnace.

**Books.**

*Ornamental Interiors, Ancient and Modern.* By J. MOYR SMITH. London: Crosby Lockwood & Co. 1887.

THIS is far too ambitious a title for what is really only a series of pleasantly-written, but rather rambling, notes on the subject of interior decoration. The book, which is mainly a reprint of a series of articles, is, however, well illustrated and handsomely got up, and contains some true criticism and a good many good examples of decorative treatment. There are a great many descriptions of various "treatments" of interiors given, which may be read with interest as descriptions and with advantage as suggestions. There is a rather amusing off-hand style about the book, and in the manner in which various decorative designers are referred to in a kind of clapping-on-the-hack fashion, as "Fred" this and "Alf" the other; indeed, Mr. Smith seems mostly to consider the usual prefix of "Mr." as an unnecessary formality in speaking of his contemporaries, though he is every now and then seized with a recollection of it. About the author's decorative recommendations there need be no crossing of swords; they are in general marked by good taste if not by any very remarkable originality. Some special point is given to the book, however, by the audacious manner in which the author assails some prevalent ideas and existing reputations. Among other things, he does not scruple to knock Mr. Ruskin about in a way that would deeply shock that prophet's fair idolaters. He observes that Mr. Ruskin did not discover the Doge's Palace, any more than Turner's genius, but they were not "blindly worshipped" before him. The author shows a want of the sense of proportion in coupling together Turner's genius and the Doge's Palace, as if they were two things in the same category, whereas Turner is worth all the Doge's Palaces that ever might, could, or should have been. But when he goes on to say that "the difference between the work of an incompetent and a competent critic may easily be perceived by comparing Ruskin's 'Stones of Venice' with Fergusson's 'Handbook of Architecture'"; and that beside Fergusson, the mature man who has studied all styles, Ruskin appears like "an un instructed amateur," we may say that he shows himself a competent critic as well as an outspoken one. Mr. Smith is not unhappy either in some of his criticisms on the architectural profession. There is only too much illustration of the truth of his remarks on page 81 as to the way in which the second or third-rate architect struggles to follow the fashions of the leading

men and frames principles for doing so. "When fashion decrees that a woman shall wear a dress that violates the usual canons of good form she does not defend the principle or want of principle; she simply says that she wears it because it is the fashion. Architects, however, while showing all a woman's eagerness to adopt a new fashion, always manage to convince themselves that the mode they adopt is the best possible, and of irreproachable principles." For "always" read "often"; but the remark is true enough with that limitation. We are also very glad to see the author's hearty appreciation of the architectural qualities of that much under-rated building, the Houses of Parliament.

Mr. Moyr Smith gives, in a chapter on "Amateur and Architectural Amateur Decoration," an amusing sketch of the days when ladies and decorators were quite agreed that there was nothing so tasteful in a drawing-room at least as "white and gold," with doors grained to represent satin wood, &c. But we do not see the sense of Mr. Smith's sarcasms at the "high-souled men" who have since come boldly forward and denounced "the awful iniquity" of graining and of realistic flowers, &c. We quite agree that a tone of absurd solemnity has often been taken by the denouncers of "shams" of this kind; but there is really no common ground between imitation of graining and imitation of the human figure in sculpture and painting, which is a comparison the author draws. The grain markings of wood are not matters worth the trouble of an imitative art of reproducing, for one thing; and further, there is no doubt that the main object of graining, whatever may be pretended, is to convey the impression of a better and more costly wood than has really been employed. As such it is a vulgarity; and we may add that "we" considered it so before the fashion of criticism turned against it; and shall continue to think so after it is revived, if it is revived. It is a foolish employment of human ingenuity. The author is probably right in his estimate of the part played by good fortune, and the support of literary friends, in the reputation of "the Morris papers." The first patterns introduced by the poet, however, embodied a new idea in wall-paper designs, which is something.

"Now, most can raise the flowers,  
For all have got the seed."

We cannot help thinking that Mr. Moyr Smith could have produced a much better book on the subject he has treated if he had taken the trouble to go into it systematically, instead of merely putting together a collection of rather rambling essays. As it is, the book is a pretty and a readable one, and that is about all.

**Freehold Disfranchisement: A Defence of the Leasehold System.** Second edition. By GEORGE BEKEN. London: Liberty and Property Defence League, Westminster-chambers.

This is a second edition of a carefully-compiled pamphlet to serve as a counterblast to the speeches and publication of those who advocate the enfranchisement of leaseholds. There is much sound argument in it, and much which will not hold water. Thus, Mr. Beken says that the more building land rises in value, the more likely are good houses to be built, and costlier ones to be erected in place of existing buildings. This, he says, gives a great deal of employment, and every kind of occupation is benefited directly or indirectly. But this is altogether an irrelevant argument against leasehold enfranchisement, neither is it by any means clear that a workman who is obliged to be in some particular locality benefits by the increased size of the houses where he is obliged to live. The fact is that Mr. Beken, like many unskilled advocates, scarcely distinguishes his strong and weak points, and marshals them all with equal confidence before us.

### RECENT PATENTS.

#### ABSTRACTS OF SPECIFICATIONS.

905, Door Lock Spindle. T. Young.

Instead of being made as usual in square section, the spindle which is the subject of this patent is made of any convenient section. Upon it is fixed a roller capable of rolling or of sliding against a corresponding inclined plane. The return of the spindle is effected by a feather spring assisted by a spiral spring (compressed when the spindle is pulled or pushed), which also prevents the handles or spindle shaking loosely in the lock.

923, Water-closets. H. W. Buchan.

The improvements which constitute this invention have reference to closets of the Bramah pattern, and consist in an alteration of the basin. The trap is combined with the basin, dispensing with the separate trap or S-bend in the discharge-pipe or outlet. The overflow also is taken from the lower end of the basin at a point which is always sealed, and prevents the admission of sewer gas into the basin from the soil-pipe into which the overflow discharges.

979, Fanlights, Ventilators, Casements, &c. W. Leggett.

The patentee's improved apparatus is arranged in such a manner that the inventor is enabled to dispense with the ordinary hinges, and the fanlights are also locked or secured in any position to which they are moved within the range of the apparatus. A toothed quadrant gearing is preferably employed; the quadrant gearing into a toothed rack that is secured to an internal worm worked upon an external worm, which, when actuated, operates a nut and quadrant, causing the casement or ventilator to be moved on the transoms.

981, Skylights. W. Leggett.

This invention consists in an adaptation of somewhat similar mechanism to the opening of skylights, and is principally designed with a view of operating the skylights from the floor, so as to avoid the use of a step-ladder or other apparatus. The skylight is locked also in any position to which it may be raised.

1,086, Paint. F. Wendling.

The paint which forms the subject of this patent is designed for specially resisting atmospheric influences and variations of temperature, and is intended to be washable. Silicates, lime, potash are mixed, and caustic potash afterwards added. It is said to mix well with colours, and to be cheap.

1,130, Bricks, &c. W. Johnson.

According to this invention the clay, as it passes from the hopper, is covered on the top and the sides with sand, and to ensure the attachment of the sand it is passed between rollers which press the sand firmly into the surface of the clay. The bricks are made in an expanding mould, which is not closed until the brick has been placed in position, ready for pressing, the mould being opened or expanded before the brick is forced out.

1,149, Door-checks. H. Hartung.

This invention consists principally in the combination of two sliding-rods, arranged at right-angles to each other; one of these rods is formed telescopically, and the other with a piston and cylinder, and the rods are connected together and compounded by means of links.

#### NEW APPLICATIONS FOR PATENTS.

Dec. 17.—16,545, H. Sulley, Pavement Lights.—16,570, E. Abercrombie and C. Hall, Push and Pull Bar-handle and Door-knob.—16,612, C. Harris, Gasoliers and Gas-brackets.

Dec. 18.—16,637, E. Mileson, Mantel-board.—16,665, J. Johnson, Locks.

Dec. 20.—16,676, W. Pressland, Burglar-alarm.—

16,694, J. Seymour, Window-fastenings.—16,705, A. Clarke, Chimney-caps and Ventilators.—16,708, M. Syer, Syphon Cisterns for Flushing Closets, &c. Dec. 21.—16,730, A. Dawson, Door Locks.—16,752, J. Honeyman, Ventilators.

Dec. 22.—16,809, E. Hughes, Circular Saw-benches.—16,811, H. & H. House, Door Checks or Buffers.

Dec. 23.—J. Rowland, Flange Joint for Connecting Lead Pipes, &c.

#### PROVISIONAL SPECIFICATIONS ACCEPTED.

5,206, W. Thompson, Bridges.—14,011, J. Buckland, Spindle for Locks, Latches, and Handles.—14,124, H. Freese, Wood Pavements.—14,423, H. Tucker, Corrugated Iron Roofing.—14,527, T. Cox, Fixing Tiles, Panels, and other Ornamental Wall and Building Linings.—14,848, C. Barker, Ventilating Buildings.—14,888, J. Brown, Window-sash Fastenings, &c.—15,389, A. Hildipe, Indicator Bolts or Fastenings for Doors.—15,456, C. Appleby, Heating Chambers, &c.—15,759, R. Da Ridder and W. Bennett, Heating Public Buildings, Dwelling-houses, &c.—15,542, J. Fisher, Latch for Doors, Windows, &c.—15,603, F. Baker, Buttions or Fasteners for Doors or Windows.—15,949, J. Beryl, Metallic Trellis Work.

#### COMPLETE SPECIFICATIONS ACCEPTED.

Open to Opposition for Two Months.

2,374, C. Groombridge and J. Rickman, Door-chain, &c.—2,457, W. Sanderson, Door Lock and Latch Furniture.—10,207, J. Garvie, Jun., Excavators.—13,273, C. Straub, Compositing or Building Material for Architectural Purposes.—14,374, E. Theadam, Chimney Tops.—2,861, T. Panario, Water Waste-preventer.—11,460, T. Robson, Window Frames, and Mode of Balancing the Sashes.—15,212, D. Grove, Water-closets.

#### RECENT SALES OF PROPERTY.

##### ESTATE EXCHANGE REPORT.

DECEMBER 18.

By BAXTER, PAYNE, & LEPPER.  
St. Mary Cross—A plot of freehold land ..... £200  
Berkley 4, Vine-st. place, freehold ..... 210  
Cucham—Two freehold cottages in South-street ... 210  
Widmore—33 to 39 (odd), Lycey-road, 78 years, ground-rent 74, 12s. .... 470

DECEMBER 17.

By NORTON, TRENT, WATNEY, & CO.  
Hackney—Leasehold ground-rent of 10s. .... 190

DECEMBER 21.

By HAMNETT & CO.  
West Kensington—8, AYOUBPORA-road, 94 years, ground-rent 12l. .... 910  
32, Glazbury-road, 90 years, ground-rent 16l. .... 830  
31, Fulham Park-gardens, 91 years, ground-rent 12l. .... 405

Mile End—46, Harford street, 31 years, no ground-rent ..... 330  
20, Jubilee street, 23 years, ground-rent 4s. .... 200

By A. CANCELLOR.  
Taichenham—Three plots of freehold land ..... 663

By REYNOLDS & EASON.  
Islington—12, Canonbury-place, 68 years, ground-rent 10s. .... 650  
50 and 62, Dowland-road, 31 years, ground-rent 12s. .... 610

Bethnal Green—1 to 4, Turville-court, freehold ..... 650  
Hackney—91 and 93, Wick-road, freehold ..... 630

#### MEETINGS.

SATURDAY, JANUARY 1.

Association of Public Sanitary Inspectors.—Mr. James Eastman on "Sewage Irrigation Applicable to Small Areas." 6 p.m.

MONDAY, JANUARY 3.

Royal Academy.—Mr. J. E. Hodgson, R.A., on "Art a Universal Language." I. 8 p.m.

TUESDAY, JANUARY 4.

Birmingham Architectural Association.—Mr. T. Camm on "Art in Glass in relation to Architecture." 7.30 p.m.

WEDNESDAY, JANUARY 5.

Civil and Mechanical Engineers' Society.—(1) General Meeting. (2) Mr. C. H. Cooper on "The Treatment of Sewage at Wimbledon." 7 p.m.

Builders' Foremen and Clerks of Works' Institution.—Ordinary meeting. 8.30 p.m.

THURSDAY, JANUARY 6.

Royal Academy.—Mr. J. E. Hodgson, R.A., on "Art a Universal Language." II. 8 p.m.

Edinburgh Architectural Association.—Mr. Harry Chebb on "Ancient, Medieval, and Modern Locks and Keys." 8 p.m.

FRIDAY, JANUARY 7.

Architectural Association.—Mr. T. M. Rickman, F.S.A., on "The Complement of Architectural Instruction." 7.30 p.m.

#### Miscellaneous.

**The Slate Trade.**—Meetings of the Welsh Quarry Proprietors were held last week and prices fixed for the coming year. The quarries in the Carnarvon district continue the lists now in force, but with smaller discounts, and there are some slight alterations in the Bangor and Portmadoc lists. At the last-named place trade is expected to be very brisk owing to the increased facilities given by the London and North-Western Railway Company for the Continental trade.

#### Sales of Building Land in Surrey and Hants.

—A few days since Mr. H. J. Brake submitted for sale, at his auction rooms, New Bridge-street, several plots of building land in the counties of Surrey and Hampshire. The Surrey property is situated in the parish of Fresham, near the Haslemere station of the London and South-Western direct Portsmouth line, and about forty miles from London. All the plots offered were sold; those having a frontage of 135 ft. and a depth of about 400 ft., realising 80l. each, whilst the plots having a frontage of 132 ft. were sold for 42l. each. The Hampshire property comprised twenty building plots, some of which are situated at Fleet and Headley, and others at Farnborough, near the North Camp and Farnborough stations on the London and South-Western Railway. The plots comprising the Fleet property, having frontages of 140 ft. and depth of 100 ft., and containing an area of about one-third of an acre each, were sold for 40l. The Headley plots, containing an area of about an acre each, were sold at prices varying from 14l. to 17l. 10s.; and the Farnborough plots, having frontages of 20 ft. and depths of 173 ft., realised 30l.

#### Faithful to his Duty.

—We cut the following from the interesting survey of the state of the country after the snowstorm which the *Times* furnished its readers on this as on other similar occasions:—"The driver of the mail cart between Staplehurst and Rochester had a narrow escape while on his way to Rochester on Monday morning. When he arrived at the bottom of Blue Bell-hill, a mile from Maidstone, he drove into a deep drift, and the horse becoming frightened plunged further into the accumulation. After failing in his efforts to extricate the cart, the driver, a young man named Hayes, took out the mail bags, tied them round his body, mounted the horse, and cutting away the traces, left the cart buried. Several times during the journey the horse fell, haring itself and its rider in deep snow. After a terrible experience of five hours in a blinding storm, Hayes rode up to Rochester Post-office and handed in the mails in safety." Well done, Hayes!

#### A New Baptist Chapel at East Moulsey.

A Baptist chapel has just been erected at East Moulsey, and was opened last week. The building, which is situated in Bridge-road, is in the Gothic style of architecture, and is faced with red brick and stone dressings. The edifice is entered by a prominent stone porch. Internally it is 55 ft. in length, and 30 ft. wide. The interior walls are faced with cement and stucco work, the building being covered in by an open-timbered roof. The seats are of stained pitch-pine, and a dado of the same material is carried round the lower part of the walls. There is a raised platform for the use of the minister, and in front of it a baptistry 4 ft. 6 in. in depth. Attached to the chapel are the minister's and general vestries. Messrs. Potterton & Gould are the architects.

#### The Attorney-General (Sir Richard

Webster, Q.C., M.P.) entertained the employes of Messrs. Kirk & Randall and others connected with the building of his mansion "Winterfold," at dinner at the Onslow Arms, Cranleigh, on the 23rd ult. The vice-chair was occupied by the architect, Mr. E. Talbot, supported by Mr. Unwin, the clerk of works, and Mr. May, the foreman of works. After the cloth was removed, and the usual loyal toasts had been given, Sir Richard proposed in complimentary terms the health of the contractors, after which the host's health was proposed by Mr. May, and received with great enthusiasm.

#### A Granite Sarcophagus.

—We are informed that the Empress Eugénie has commissioned Messrs. Alex. Macdonald & Co., Limited, of Aberdeen and London, to prepare a polished red granite sarcophagus to contain the remains of the Prince Imperial. It will be an exact reproduction of the massive sarcophagus which was presented by the Queen to the Empress on the death of Napoleon III., and, along with it, will be placed in the Mausoleum now in course of erection at Farnborough-hill.

#### The Catholic and Apostolic Church.

Bridgenorth, has been enriched by the addition of a reredos of Caen stone and alabaster. It is in the style of the Decorated period, and has three crocketed gables. In the centre one is a carved and gabled canopy, under which the tabernacle is fixed. The work has been executed by Messrs. Jones & Willis.

The vacant District Surveyorship.—We are informed that Mr. Alfred Conder, F.R.I.B.A., of Palace Chambers, Westminster, and District Surveyor for Woolwich, has been appointed by the Metropolitan Board of Works to act as Temporary Substitute in the District of Charlton, Lee, and Kidbrooke, rendered vacant by the decease of Mr. J. Collis, the late District Surveyor.

The New Medical Examination Buildings.—The New Examination Hall on the Thames Embankment is rapidly nearing completion, and the question as to the uses to which the vacant plot of land not required for the building should be applied must soon be determined by the authorities of the combined colleges. If pecuniary reasons are not urgent (and, considering the large incomes now derived by the two colleges from their examinations, we should not suppose they could be), we would recommend that it should be left as it is, and should not be built on until the requirements of the examining board have been fully tested by one or two years' experience. It will then be time enough to decide whether class-rooms and laboratories for elementary or advanced scientific teaching and work could be added with the greater advantage. If, as is rumoured, there is a great divergence of opinion on this point, there is the more reason for delay, and for not taking any definite step which cannot be subsequently retraced if such a course should then seem expedient.—Lancet.

The Channel Tunnel Scheme.—Notice has been given that application will be made to Parliament next session for an Act authorising the South-Eastern and other railway companies to continue their experimental borings, and making provision (in the event of these trial works being so successful as to demonstrate the practicability of constructing the Channel Tunnel) for vesting in the Lords of the Treasury the sole right of determining the expediency of continuing or prosecuting the permanent works of the Tunnel, and for the ultimate transfer of the undertaking to the Government.

Steel Rails in Construction.—We understand that the framework of the building for the American Exhibition at Earl's-court is being constructed of steel rails, such as are used for railways. Two of these, bolted back to back, with the T-side out, make a column, and the only casting required is an angle iron and eyebar, into which the ends of the rails are slipped. This frame will then be covered with plates of glass and sheets of corrugated iron.

A New Kind of Paving Stone.—Trials with a new kind of paving stones are now being made on the Charlottenberg Bridge in Berlin. They are made from a composition of iron slag, coke, and cement, and weigh from 18 lb. to 20 lb. each. It is claimed that the new stone is cheaper than ordinary natural paving stones, and lasts longer. The stones are manufactured at ironworks in Upper Silesia.

Robert Boyle & Son, Limited.—The first annual general meeting of this company is fixed to be held on the 11th of January, at the Cannon-street Hotel, when it is proposed to declare a dividend at the rate of 12 per cent. per annum on the ordinary shares of the company, a substantial proportion of the profits earned being carried forward to the credit of a general reserve account. We are informed that the company have completed arrangements for the manufacture and sale of their various ventilating and sanitary appliances in Germany, France, Belgium, Holland, Spain, and Denmark.

Table with columns: Commodity, £. s. d., £. a. d. Includes sections for TIMBER (continued) and METALS.

Doubling Freestones.

The stone from these quarries is known as the "Weather Beds," and is of a very crystalline nature, and undoubtedly one of the most durable stones in England. It is of the same crystalline nature as the Chelwyck Stone, but finer in texture, and more suitable for fine moulded work.

HAM HILL STONE.

Greater facilities have been provided for working these quarries, and the stone can be supplied in large quantities at short notice.

Prices, and every information given, on application to CHARLES TRASK & SONS, Norton-sub-Hamdon, near Ilminster, Somerset. London Agent — Mr. E. WILLIAMS, 16, Craven-street, Strand, W.C. [ADVT.]

Doubling Free Stone

### Municipal Records of Liverpool.\*

N the first volume of "Liverpool Municipal Records," brought out by Sir Jas. Picton three or four years ago, the author hinted that there was much of interest in the later records beyond the period with which he then dealt, but concluded that he must leave them to some future chronicler; and we expressed a hope in reviewing them at the time that such a chronicler would be found. We are glad to find that Sir Jas. Picton has, after all, been able himself to carry on the work which he had begun, in another thick and goodly volume, a suitable companion to the first one, and which brings the record down to the extinction of the old Corporation by the Municipal Reform Act.

These "Records," our readers may remember, are based on the MS. archives of the Liverpool Corporation and Council; and the first volume, ranging from the thirteenth to the seventeenth century, was full of passages throwing the most curious and interesting light on the manners and ways of past generations, and on the early history of the city which in recent days has, from a variety of causes, developed with such extraordinary rapidity from a sleepy little hamlet with a precarious coasting trade to one of the most noted seaport towns of the world. It can hardly be expected that the present volume, dating from 1700 to 1835, should have the same kind of interest as its predecessor; but it was certainly quite worth undertaking, and we cannot help questioning how much of interest might be found if the municipal records of some other leading towns were similarly looked up, selected, and edited: the records thus unearthed having a "local colour" and character of their own which can hardly be imparted to a formally written history, though perhaps founded on some of the very same class of documents.

The progress of Liverpool commences, the author tells us, from the beginning of the eighteenth century, up to which time the town had been all but stationary. At this period the population of Liverpool was about 8,000. The first chapter of Sir James's book is devoted to Municipal Government, which now, as in the former period, seems to have had a good

deal of the storm in the saucer about it, and "the proceedings in the Council at this period were anything but harmonious, being mixed up with party national politics on the one hand, and the local disputes about the charter on the other"; for at this time there was fierce dispute and recrimination as to the real meaning and power of the charter granted to the town in 1695. Into these semi-political portions of the history it is not so much our special interest to enter, though they contain a deal that is of interest in its way, and show the Town Council of the period as an amusingly pedantic and peppery body, very jealous of its privileges and very snappish in calling those to order who showed any disposition to encroach. We turn rather to some of the records as to the engineering and architectural doings of Liverpool as illustrated here. At the early part of last century it appears that the water supply question had already begun to cause trouble. Natural springs at the outcrop of the sandstone strata had been the source of supply for a long time, but as the town began to increase these failed in quantity and became polluted as to quality, and various tentative schemes are recorded, one after another, for bringing water into the town from the springs at Bootle, three or four miles off, all of which seem to have proved abortive for lack of energy or of money; an Act of Parliament was even obtained for making a grant to Sir Cleave Moor, "to bring water into Liverpool from Bootle Springs"; and eight years after two other proposers came forward; but all with the like result of a *fiasco*. 1731 and 1749 brought other schemes, all conferred about and all coming to naught. In 1779 the Bootle scheme again appears in reference to a dispute between the Council and Mr. John Jordan, "who is, or pretends to be, the assignee of the late Sir Cleave Moor" (these little amenities are quite common in the documents of the period); but the quarrelling did not bring the water; and it was not till 1797 that the matter (become pretty urgent by that time, we may suppose), was really taken up seriously, and the proprietors of the Bootle Springs received powers to treat for a water supply; and even then the Council, in one of its fits of jealousy, tried to stop the matter by asserting their own privilege to look for and supply water. However, two companies seem at last to have been formed, one on the part of the Bootle owners, and one under the name of the "Liverpool and Harrington Waterworks Company," on the part of the Corporation; and these existed till 1846, when they were superseded by the Rivington scheme, now in its turn to be superseded by the Vyrnwy scheme.

In turning to the chapter on "Trade and

Commerce," we come on the record of the construction of the first dock, which was set about in 1709; a characteristic minute recording that:—

"One Henry Huss, of Derby in Derbyshire, who came to survey the place where to make a dock with Mr. Sorocold, and draw a plan and estimate of the charge thereof, is admitted free of this Corporation *gratis*. But this is not to be a President."

The first intention was to deepen the stream which fed the Pool (a creek now completely extinct) and make a kind of ship's canal, but ultimately ground was granted for a dock properly so called, to be used for the purpose "for ever." This improvement appears to have been due to Thomas Steers, an engineer of ability and energy, who was at that time settled in Liverpool, and who was also appointed Harbour Master, and was architect for the erection of St. George's Church, still one of the Corporation churches. He was elected Mayor eventually. His "salary" as Dock Master, on starting the work, was 20*l.* per annum from the Corporation and 30*l.* from the Dock. There was some quarrelling, however, over the making of the new dock; complaints that the "cawsey of the dock is so low that the tide overflows it into the adjacent cellars, to the great damage of the town," and subsequently a denunciation from the Council in regard to "a most unjust insinuation and groundless protest" which had been circulated, "as if the Common Council (except a few of them) called and represented therein by the style of a Sett of men, have sold the dock to themselves and all the strand, in manifest breach of their trust" &c. That the council should be called "a Sett of men" was probably the great offence of this scandalous proclamation. On the next page we find a claim made by a certain Captain Nicholas Webb, who had taken the unusually bold step of building "a large ship, by recommendation of our representative in Parliament Thomas Bootle, Esq.," to the effect that having agreed to take some lead upon freight from Wales, "which he runs the risque of hither by boat rather than take his ship to fetch it or load it from thence," he should be excused the town's custom for such lead; a request granted, but in the usual cautious manner, viz: that he should pay the usual custom, but the town's treasurer is ordered to return it to him again; apparently lest any kind of inconvenient "President" should be established. Then comes an order in Council to send thirty pounds weight in gunpowder and seven pounds in cash "to blow up two great stones that lye just at the edge of the chaunell into Bowmaris (where many of our ships frequently putt into);" which shows what strides Liverpool was now making in foreign commerce.

\* City of Liverpool, Municipal Archives and Records, from A.D. 1700 to the passing of the Municipal Reform Act. Extracted and Annotated by Sir Jas. A. Picton, F.R.S.A. Published with the sanction of the City Council. Liverpool: G. G. Walsley, 1856.

In commencing the chapter on streets and buildings, the author remarks that the founders of Liverpool "seem to have been singularly blind to any provision for the extension and improvement of the town." This, however, cannot be regarded as anything uncommon in the history of the development of a town; witness the narrow streets in the City in London, now so inadequate to their traffic. The chapters devoted to the subject of streets and buildings in the four periods into which these Records are divided contain much interesting information, and give a very graphic picture of the architectural and sanitary growth of Liverpool. In 1719 the unsatisfactory state of the pavement attracts the paternal Government, and it is ordered "that the Corporation do allow eight pounds towards amending the same, on the condition that the person who shall undertake to do it shall do it effectually or repay the said 8<sup>l</sup>." In the same year a contract is entered into with Alderman Gildart and Mr. Samuel Dove, to take away all the muck and dirt in the streets and passages twice every week, "and that they have liberty at their own charge to make a convenient hole, with an iron grate over it, at every street end, to be approved of by the mayor." In case of failure in this duty they were to forfeit 5s. a week. The same subject comes up in February, 1731:—

"The mayor now propounding that a proper person be appointed to take away the dirt out of the streets; it is now Ordered that if any person will undertake to carry away the dirt in the streets twice a week, he shall have the muck for his pains, and two or three guineas a year, and that every inhabitant shall be obliged to clean their respective streets every Wednesday and Saturday, whereof public notice to be given."

The "great necessity" of cleansing the streets seems to have been increasingly evident, however, a few years afterwards, and in 1742 Mr. W. Hornby, the Surveyor of Public Streets and Highways, was specially commissioned to take the matter under his charge, and see "that all the dirt and filth should be immediately carried away, and not suffered to lie or remain in the streets"; all former by-laws on the subject to be confirmed, and a bell to be rung to warn all persons to bring out his and their ashes and dirt to the carts. An improvement in lighting the streets was instituted, or attempted, in 1731, on the offer of several persons to be at the expense each of maintaining a street lamp, "if they can have such lamps placed at or near their dwelling-house free of the charge thereof,"—a curious mingling of public spirit with a regard for personal interests. In 1749, however, lamps at the end of the principal streets were ordered and provided for by the corporation.

The building of the Exchange, now the Town-hall, comes in question in 1740, the mayor representing that the Exchange is become decayed, "and that the pillars and one of the arches below have given way and are greatly sbrunk, and that it is apprehended the great weight of the turret doth greatly tend thereto"; it was accordingly ordered that the turret be immediately taken down, and a survey made of the state of the rest of the building. This Exchange (the second) was built in 1673. In 1749 the plan of the new Exchange, "now laid before this Council by John Wood, Esq., architect (of Bath)," was approved, and the freedom of the town was conferred without fees ("be admitted free, gratis," are the words) both on "John Wood, Esquire, Architeck," and on "John Wood, junior, gentleman"; the latter, the son of the architect, acted as resident architect during the work; and Mr. Wood was to receive five per cent. on the cost of the building, and his travelling charges whenever he should come to Liverpool to superintend the building; young Mr. Wood's services as resident architect being given as a *quid pro quo* for this latter accommodation. Wood's building, tame though it may be in detail, is a very elegant structure in its way, and perhaps superior to any one of the buildings which he carried out at Bath, where his reputation was made. It appears, however, that the construction of the building was not con-

sidered satisfactory, for in 1764 occurs the memorandum:—

"Ordered that a survey of the Doom [sic] of the Exchange be made as to the expense of taking it down and fitting up a lantern in lieu thereof, to give light into the court room, as it is represented to the council that a continuance of the said Doom may endanger the building."

Twenty years or so improved the municipal spelling, for in an entry in 1786 it is written "Dome." After this latter entry there follow (1787) some directions for the alteration and further carrying out of the building, one façade of which it seems had not been completed; these plans to be submitted to a London architect of eminence; the consulting architect finally selected being Mr. Jas. Wyatt. It is worth noting that nearly a century later it was Mr. Thomas Henry Wyatt who was employed to design the present Exchange buildings surrounding the quadrangle in the rear of Wood's building. In connexion with the Town Hall there are some interesting entries about the presentation of some decorative paintings by "Mr. William Martin, historical painter," who wrote what would probably have been spoken of as a "very handsome letter" to the Council, expressing his admiration for all the improvements going on in Liverpool, and offering to present for the decoration of the Town Hall four large historical paintings of his execution, besides some smaller works in tempera, on the sole condition of the cost of carriage, frames, and packing-cases being paid, and permission given to have them engraved by Bartolozzi. The subjects of the paintings were: Lady Macduff surprised in her Castle at Fife; Cleopatra arming Antony; Queen Katherine's Vision; and Ferdinand's first interview with Miranda. The offer was gratefully accepted; but the pictures were destroyed four years afterwards in a fire in 1795.\*

An entry under March 6, 1765, shows how the present duties of Borough Surveyor, in the absence of any Building Act, were anticipated:—

"It having been represented to the Council that Mr. Pickance and Mr. John Parr are going to project out Bow windows from their houses in Water-street, which designs, if carried into execution, may be attended with great inconveniences and annoyance to the town and inhabitants from the narrowness of the streets. It is Ordered that the Town Clerk do write to those gentlemen or any other persons who have formed such designs, desiring them to desist carrying the same into execution."

How far this request was successful does not appear.

The subject of street improvement on a large scale seems to have first come up about 1774, in and after which year there are several entries referring to schemes for the purchase of premises with the object of widening the streets; but these efforts seem to have been rather desultory until, in 1785, an Improvement Committee was formed, and an advertisement inserted in the Liverpool papers that this Committee would sit at the Exchange on every Tuesday till further notice to consider the best methods of improving the town, and that the Committee would be ready to receive and inspect such plans from any person who might please to offer them. The next year it is "the unanimous opinion of the Council" that a Bill should be drawn and brought into Parliament for the purpose of improving and widening the streets; and two or three weeks afterwards it is ordered "that Mr. Statham, Mr. John Gregson, and Mr. Brooks do, as soon as they conveniently can, go up to London to solicit the intended Bill for improving the streets," and they were to have a discretionary power to alter, defeat, or add such clauses as they might think proper. The petition was read, and the common seal affixed, on the 6th of February, 1786, and that one at least of the delegates earned the gratitude of the Council appears from the following entry of the same date:—

"Ordered unanimously. That the thanks of this Council be given to Mr. Richard Statham for the very great professional services he has rendered to this Corporation as one of the Select Committee in the purchasing of houses for the purpose of widening the streets in this town, and for the improvement thereof."

The Act, Sir James tells us, gave power, among other things, to improve the sewerage, which was now becoming a cause of great trouble, in very much the same way as it frequently has in parts of London, from the flooding of the lower streets, especially those on the line of the old "Pool," at high water; and an interesting passage, too long to quote, under date March 22, 1791, records the distress arising in the lower-lying parts of the town from the flooding of the cellar dwellings, many of the people not being acquainted with their situation till they found the water coming into their beds. The committee concerned with the matter take it very seriously, and say: "we should be wanting in our duty if we did not in the most earnest manner point out the means by which this dreadful evil may be remedied." They suggest enlarging the sewers and making some re-arrangement of levels to secure a better fall, but the author notes that this flooding from the continued action of rains and tides continued to be a source of serious mischief for half a century after.

We have touched only on a few of the points of interest in these curiously naïve and outspoken records, which, in spite of the selfishness and intolerance not unfrequently discernible in them, on the whole bear out Sir James Picton's claim for the old corporation, that its proceedings and policy were marked by vigour, tenacity, courage, and in the main by good sense. The two volumes furnish a remarkably realistic record of the struggles and progress of a city community, and the author is not saying too much in his concluding sentence, that "if five hundred years hence the Municipality of the coming age can present a record as full of interest and progress, of difficulties overcome, and of bright anticipation of the future, the task of its historian will be as pleasing as the one now brought to a close." We congratulate Sir James Picton on having so ably completed his self-imposed task, which has evidently been a labour of love, and may congratulate his local subscribers also on possessing so graphic a record of the history of their city.

#### THE TREATMENT OF SEWAGE.

**T**HEN dealing with sewage on the practical scale of daily necessity, the command has always been to take the sewage to the land, and this has always commended itself to common sense. It has been known for long enough that sewage, after passing properly through the soil, does not pollute rivers or other streams of water, and all that town authorities have to do is to procure the land. They are not confined by any necessity to certain land not suitable, for if suitable land does not lie conveniently for receiving the sewage from the town by gravitation, it can be raised at very moderate expense to land which is suitable; and perhaps if there had been no chemists, with their bottles and laboratories, landowners might have been persuaded with a little pressure to come to fair terms with the town authorities. But because of the objections which have been made by the owners of land in suitable situations and of suitable quality for the purpose, town authorities have in many instances been driven to deal with the sewage in tanks. When that system has once been adopted it is not readily given up for another, notwithstanding that the proper working of it is a very expensive affair. It has been said by one, and confirmed by so many other men of experience as to have become an axiom, that towns must pay for getting rid of their sewage, and not, as they formerly did, look upon it as something out of which they could make money. That is the case in every instance, and however moderate the expense may be under favourable circumstances of situation; but where the tank system has been adopted and is continued, there seems some likelihood that the expenses will become enormous; for,

\* In connexion with the town-hall it may be noted that there is an entry, Feb. 14, 1782, for the surveyor to consult Mr. Wyatt about the propriety of getting the four figures for the north front of the Exchange executed "in artificial stone," also in Portland, with a comparison of the cost. What "artificial stone" was this?

according to a paper read before the Society of Arts in April last by Dr. C. Meymott Tidy, the sewage ought, after undergoing the tank process, to be conveyed to land to effect the purification which cannot be wholly effected in the tanks. A smaller area of land is required for this purpose than is required for dealing with the sewage *in toto*, but, nevertheless, the expense of its conveyance must be the same, and what land is required must be purchased out and out; for, the area being so contracted, it cannot be farmed with profit, but will be a filter merely. An acre for from 5,000 to 7,000 of the population is what Dr. Tidy says would be required. If this would be sufficient,—and we are not doubting that it would be,—the requisite space of ground might be purchased at or near the outfall of the sewers, and the expense of conveying it to land at a distance would be unnecessary. But there are many things to be considered before we come to that detail. We will give them in the order in which Dr. Tidy stated them, not in his own flowing language when he read an abstract of his paper in April, but as they are stated in the full paper afterwards sent in, and printed in the Society's *Journal* of the 8th of October. Herein we find that the various precipitants which have been suggested to throw down in tanks the suspended and coagulate a part of the dissolved slimy organic matter of sewage,—lime, chloride of magnesium, sulphate and phosphate of alumina, and salts of iron,—are those for practical purposes to be used, alone or in conjunction with each other. In addition to these, clay and other weighting bodies, together with charcoal and other absorbing substances, have been added under various patents. In selecting a chemical precipitant five main points must be attended to:—

1. That, consistently with purity of effluent, the chemicals used should be cheap.
2. That the precipitant should act as a deodoriser and disinfectant as well as a precipitant.
3. That the precipitated matters should subside rapidly.
4. That the maximum purity should be obtained with the minimum of deposit,—in other words, with the smallest quantity possible of chemicals.
5. That the sludge should part with its water readily. If lime and the sulphate of alumina combined be adopted as the precipitant, the quantity of lime, which is to be added first, should be such as to render the sewage faintly alkaline; probably at the rate of from five to seven grains per gallon will be needed for this purpose. It should be added as a milk of lime, and should be thoroughly stirred in by means of a paddle-wheel or other efficient mixer. A flow of a few yards should now be allowed, to permit the aggregation of the precipitate. This having taken place, a solution of crude sulphate of alumina, in the proportion of about five grains of the sulphate of alumina, is to be added, and the sewage again actively stirred. In the alkaline condition of the sewage the alumina will be precipitated, and will then combine with a portion of the organic matter, forming together an insoluble precipitate. Thus treated, the sewage should be allowed to flow into tanks, for the precipitated matter to collect. A portion of the lime will be at once converted into carbonate of lime, by combining with the carbonic acid present in the sewage, and serve as a weighting material, to aid in the deposition of the lighter flocculent materials. This mechanical action of the lime carbonate is of great importance. The flocculent suspended matter is, no doubt, one of the most important materials to remove, because it is that ingredient of the sewage which readily putrefies, and in this way causes a nuisance. It is, moreover, so light that, unless weighted, it is difficult to precipitate. A second portion of the lime combines with some of the organic matter in solution, producing an insoluble precipitate (of uncertain composition) of a compound of lime and organic matter, the subsidence of which is again assisted by the formation of the carbonate of lime previously described, and a third portion of the lime renders the sewage slightly alkaline. The alumina salt is now to be added. The alumina is precipitated, owing to the alkalinity effected by the slight excess of lime.

This alumina combines with some of the organic matter in solution, not precipitated by the action of the lime. The power of alumina in combining with dissolved organic matter, and so removing it from solution, is taken advantage of in many commercial processes.

Respecting the iron salts, one strong objection to their use is that if the effluent be discharged into a river the stream is liable to be blackened from the formation of a sulphide of iron, a condition likely to be mistaken by the general public for a sewage deposit. As regards the use of phosphates as precipitants, the effluent is almost certain to contain some phosphoric acid, which greatly aids the growth of low forms of fungoid growths, amongst which may be included the so-called sewage fungus.

It is advisable that the effluent, before its discharge into a stream, be at least neutral and preferably slightly acid. This condition is easily brought about by the addition of a small quantity of acid to the effluent before its escape.

These directions are, no doubt, highly judicious and important; but there are others, as, for instance, that it is essential that sufficient chemicals be employed to effect complete precipitation, disinfection, and deodorisation of the sewage. No greater mistake can be committed than to starve the chemicals. To this must be attributed many cases where a precipitation process has proved a failure. A local authority will spend a large sum in erecting works, perfect in architectural detail, excellent for sewage treatment, whilst they shirk a small annual payment for the necessary chemicals. It is essential that after the chemicals are added the mixture should be well stirred; if not, they do not precipitate so much as they might, the process of flocculation is imperfect, and the difficulty of obtaining a clear effluent is correspondingly great. It is essential that there should be sufficient tank accommodation, so that, as well as for other reasons, the sludge may be frequently removed; otherwise, the freshly-precipitated sewage may be contaminated by the decomposing materials of a previous precipitation, or a nuisance result from a collection of decomposing matter. Many a good effluent is spoiled by foul materials being allowed to collect in the subsiding tanks. These materials undergo putrefaction, the gases given off contaminating the effluent. The solid matters becoming specifically lighter than the liquid by the gases of putrefaction developed in and amongst them, rise to the surface, the floating black masses presenting an objectionable appearance, and discharging offensive products into the air. After a time these black masses sink, and thus, by constant commotion of the precipitated matters, a turbid effluent results, which has a more or less foul smell. The defecated water should flow through a shallow open conduit of not less than a quarter of a mile before being discharged into the stream. The volume of the stream into which the effluent is discharged should be not less than eight times the volume of the stream of defecated sewage. The tanks should not only be emptied of the sludge, but thoroughly cleaned before being refilled. It is essential that the sludge should be frequently removed from the tanks. This frequent removal is necessary, firstly so that the effluent may not be polluted, and secondly, so that no nuisance may result during the removal of the sludge and the cleansing of the tanks. It is not enough merely to empty the tank of sludge, but it is imperative that, after being emptied and before being refilled, the tank should be well cleansed,—in other words, that the matters which stick to the sides of the tank should be completely and efficiently removed to prevent nuisance or fouling by subsequent decomposition.

We strongly recommend these observations of an eminent chemist to the attention of the managers of the sewage-tank works at,—we were going to mention places, a few, but will refrain. We desire to throw no obloquy upon the tank system of dealing with sewage because it is badly carried out, almost everywhere; but, having a strong impression of the difficulties of carrying it out properly anywhere, we desire to

represent in contrast both the objections to and the advantages of the two chief systems of dealing with sewage, which are, on the one hand, the direct application to the soil of the sewage of towns,—whether by gravitation or by pumping; is but a small consideration; and, on the other, the treatment of sewage in tanks in the manner we have pointed out. Much praise, well deserved, has been given to the staff of persons engaged in the A B C process, the effluent from which is unobjectionable, as the process is carried out at Aylesbury. Dr. Tidy speaks much in favour of the process. The company who manage it appear to sell the residue at a considerable profit, and discharge from the works a clear and unobjectionable effluent water. Whether there is anything in it more than a strict obedience of orders by the staff we do not know, those orders being to give a full dose of each ingredient day by day without exception, and intelligently to deal out and use the chemicals proportionately to the strength and volume of the sewage from time to time. Perhaps herein lies the secret. But let anybody go and see the tank process daily carried on at,—again we refrain, although the knowledge is common enough,—certain large towns where the tank system is that by which the sewage is dealt with before it is discharged. He will surely be convinced that the common way of carrying on the tank system of sewage disposal is one which is to be avoided if possible, unless the perfection of management of which Dr. Tidy speaks can be ensured. If this cannot be ensured the better way is to revert to the disposal of sewage on land directly. Much to-do is made of the possible neglect to turn the sewage this way and that from time to time upon different parts of the land. Proper attendance, of course, is necessary, and always with a responsible foreman, and neglect of this duty is sheer idleness. But let the turning of the sewage upon different areas of ground from time to time, and keeping the gutters in order, and ploughing the soil every second year, or third, as may be required, be compared with the numerous little things to be done to satisfy the chemist in the treatment of sewage in tanks, and if it be asked which is the more likely to be observed, it may safely be said that the open and above-board duties will be the better performed.

#### THE EIGHTEENTH EXHIBITION OF "OLD MASTERS" AT THE ROYAL ACADEMY.

THE present exhibition is undoubtedly one of the most interesting that has ever been brought together under the auspices of the Royal Academy. This is due partly to the fact that it contains more than fifty pictures belonging to Mr. R. S. Holford's famous collection, and some of the gems of the Duke of Wellington's gallery. The show of early Italian pictures is indeed scanty, compared with what we have been accustomed to look for in Gallery IV. Amongst Madonna pictures there is a small and genuine panel by Matteo da Siena (169), one (172) of the School of Francia, a signed picture (entirely repainted) by the Umbrian Tommaso di Fadino (175), a typical Crivelli (180) dated 1472, and a large archaic panel (189) in good preservation, bearing the signature of Cola dell'Amatrice, and the date 1512. The gem of this room is a small, finely-finished picture, ascribed to Pesellino (204). It represents the Madonna enthroned between six standing saints. The faces are all beautiful and well characterised; and the chord of colour is particularly pleasant; and the foreground is filled with a lovely carpet of plants in flower, the execution of the whole being Flemish in care and completeness, the design Florentine in gentleness and grace. A "Flight into Egypt" (195), by Cosimo Tura; a small "Crucifixion" (205), perhaps by Albertinelli (certainly not Umbrian); a Milanese fancy portrait (177), wrongly ascribed to Luini; a fine portrait of a lady (170), ascribed to Lorenzo Lotto, but really by Dossò Dossò; and a charming little "Holy Family" in a landscape (161), credited to Titian, but more probably by

Bonifazio Veneziano, also deserve attention. The portrait of a lady (156) does not represent Anne of Austria, and cannot be by Coello; it is a moderately good painting by some imitator of Sir Anthony More. The portrait of the Marquis of Caspice (158) is only a poor copy of the original by Murillo, which is in the Louvre. The study of a head (168) is perhaps a copy of some drawing by Leonardo, but is certainly not an original picture. "The Madonna" (171), ascribed to Fra Bartolommeo, is a copy of a well-known original, in an Italian gallery. Col. Sterling's full-size black chalk drawing (173), which agrees with the Rogers Madonna by Raffaele, is not the cartoon for that beautiful picture, but is an old copy from the picture itself, perhaps done by Andrea del Sarto. The complete picture, from which the little panel (206) has been cut out, must have been a fine Madonna by one of the best Flemish artists of the fifteenth century. In some respects it reminds one of the "Exhumation of St. Hubert," at the National Gallery, by whomsoever that may be. Mr. Willett's Madonna (179), ascribed to Piero Pollainolo, deserves careful attention. It is a well-preserved example of a work of the important school of Verrocchio, and may be compared with the fine Madonna in the National Gallery, which it somewhat resembles, the position of the angel being changed. The forms of the features, the build of the child, the shape of his legs, and the brown tones of the whole are all clearly perceptible characteristics of the school.

The last picture in this room to which reference need be made is the magnificent bust portrait of Pope Innocent X. (160), by Velasquez, certainly one of the finest works of portraiture which it has been our good fortune to behold, and in faultless condition. The three-quarter-length portrait of the same pope, seated, in the Doria Palace at Rome, is world-renowned. The Duke of Wellington's picture is in every respect as fine as that. We need not waste space in attempting to describe the beauties in it, which every spectator can see for himself, and which are practically impossible of translation into words.

Three more pictures in the Long Gallery claim the same master for their maker. The bust portrait of Francesco Gomez de Quevedo (111), likewise lent by the Duke of Wellington, is certainly the work of a good Spanish painter, but can scarcely be by Velasquez. The full-length portrait of Philip IV., with its fine scheme of colour, its powerful design, and its unequal execution, may not improbably have come from the master's studio, and have been touched by him in certain parts. The full-length portrait of "El Conde Duque" d'Olivarez is more reminiscent of Velasquez's touch, but in it also the hands of assistants have taken the largest share. The bust portrait of the Pope is the only picture here upon which no hand but the master's has been employed. Murillo's own bust portrait by himself (143) is a picture that should certainly attract attention. It is of unpretending character, low in tone, and simple in treatment, but it renders the aspect of the man as in a mirror, and bears unmistakable evidence of truthfulness to life. The same artist's picture of "Las Gallegas" (114), if it be by him, is a minor work.

No less than six pictures here are ascribed to Titian. One of these has already been referred to. Of the rest the portrait of Caterina Cornaro (129) can be at best a copy; the charming "Holy Family" (133), a good school piece closely connected with the fine original in the Louvre. The "Supper, Emmaus," lent by the National Gallery of Ireland, is an interesting school replica, but can scarcely be considered as an example of the master's handiwork. The influence exercised by Titian upon later painters is clearly seen in the very Venetian "Holy Family" (141) by Rubens and in the richly-coloured "Pan and Syrinx" (115) from Buckingham Palace, a picture not unnaturally ascribed to the same artist, but probably painted by Diepenbeek or some such person. Turner's "Venus and Adonis" (149) is no less intentionally Titianesque, and was, doubtless, painted by the English artist after

study of the "S. Peter Martyr," which perished in the flames at Venice.

A genuine Rubens, and a very fine one, is the "Elevation of the Cross" (123), the connexion of which with the famous Antwerp triptych is at once evident. It can scarcely be called a study for that picture, for it is a finished picture itself, and the grouping of the figures has been altered with a view to bringing the three parts together on to a single panel. The "Adoration of the Shepherds" (65) and the "Adoration of the Magi" (68) are genuine sketches worthy of notice. The latter subject handled by Rembrandt (123) in his most imaginative vein is the finest of the Queen's contributions to this year's display. It is in excellent preservation and quite unnecessarily authenticated by the artist's signature and the date 1637. Even more splendidly imaginative, more magical in execution, more lovely in effect is the glorious little sketch of an angel (183) by the same artist, lent by Mr. Sellar. The beautiful head is surrounded by a circle of mysterious lights framed within the outline of the shadowed wings. The portrait of Martin Looten (93), painted in the same year as the "Anatomy Lecture," is a first-rate example of Rembrandt's earlier style.

Lorenzo Lotto's noble portrait of a lady (124), of somewhat florid charms, is doubtless one of the three or four pictures by which this exhibition is likely to be remembered. The picture certainly requires explanation, for the drawing the lady holds in her hand and the inscription below it appear to be only interpretable as an insult. Holbein's "Lais Corinthiaica" in the Basel Museum may be mentioned as analogous in this respect. The "Portrait Group" (134), by Jacopo Bassano, is a good picture, and the "Holy Family" (136) is, perhaps, the best example in England of the work of that very unequal artist Gaudenzio Ferrari. A full-length portrait (138) of "Alfonzo d'Este" is ascribed to Dosso Dossi. It looks more like a Spanish picture, but might, perhaps, be an early Moroni. The portrait ascribed to Tintoretto (139) can scarcely be by that master, unless it is a very early work of his. In some respects, notably in the landscape, it recalls the work of Sebastiano del Piombo.

Two fine portraits by Van Dyck (140 and 142) are lent by Lord Leonfield. The first, representing "Anne, Countess of Bedford," is a very charming picture. The original of the full-length portrait group of the "Earl of Arundel and his Grandson" (144) will be found in the exhibition at the Grosvenor Gallery.

The long south wall of Gallery III. is, as usual, occupied by a fine set of large pictures of the English school. The series commences with an unusually stately Romney, a full-length portrait of Mrs. Townley Ward (145); a full-length by Gainsborough follows, and then a landscape (147) painted by the same artist in his middle period, and consisting of the usual elements,—figures, with horses, a pond, a bare tree-trunk, a grove of trees, and a glimpse of distance. The finest Gainsborough here is the portrait of the Countess of Buckinghamshire (148). She is seen in full length, standing. Her dress is of the fashion made memorable by this artist's brush, which he has here wielded with all the dexterity attained by him in his years of completest power. Constable's "Dell in Helmingham Park" (151) is a picture well known to all lovers of that artist's works, thoroughly characteristic, and well worth the amateur's most careful study.

We had almost forgotten to mention the "Jubilee" pictures which occupy the place of honour at the end of the room. They are all well known from engravings. The only one of the four which possesses any pictorial qualities is Sir David Wilkie's "First Council of Queen Victoria" (117). The interest attaching to the other three is historical rather than artistic.

The gem of the second room, in which so many fine Dutch pictures have in former years been shown, is Mr. Holford's wonderful Cyp (75), the long and narrow "View of Dort," once cut in half and framed as two separate canvases. It is flanked by two good examples

of the work of Wouvermans (73 and 79). One of the most attractive of the group of pictures ascribed to Anthony Palamedes, a little interior (64) peopled by nicely-dressed folk, finds a place in this room, as does a more than usually interesting portrait of a lady (85), by Grente. The sketch of a camp (88) ascribed to Watteau is more probably by Pater, who is again represented by another picture in the room. The landscape (92) is a more than usually good example of the work of Solomon Ruysdael, and the signed landscape (89) likewise shows Karel du Jardin at his best. Franz Hals is not so well represented as in some years he has been, but the portraits (80 and 97) are at all events genuine, whilst the sketch of three heads (95), if one of the slightest, is also one of the cleverest of the artist's works.

The exhibition of Turner's drawings commenced last year finds worthy continuance in the seventy-two examples with which two rooms are hung. The previous exhibition was memorable for the series lent by Mr. Fawkes, this year the place of honour is taken by Mr. J. E. Taylor, whilst Miss Swinburne and Mr. Vaughan also send important contributions. The drawings are hung in chronological order, we are thankful to observe, and the catalogue is unusually complete and accurate in its chronological data, doubtless owing to the co-operation of Mr. Rawlinson. Mr. Rawlinson's pamphlet guide to these two rooms (published by the Fine Art Society) should be in the hand of every visitor. The sketch of Winstead Church is one of the landscapes drawn by the lad of twelve, and which his father took to Mr. Hardwick, the architect; it is lent by one of Mr. Hardwick's descendants. The "Lambeth Palace" of 1790 was the first work contributed by Turner to the Royal Academy's exhibitions. The "Abbey Church, Bath," is evidence of remarkable advance in power of architectural drawing, whilst the two "Salisbury" drawings stand on the highest attainable level in this kind. The "Norham Castle" of 1798 is stated to have been the drawing which chanced to lay the foundations of the artist's fame. Then follow a series of fine and finely-preserved works of the painter's period of power. The Richmondshire series of 1817 is represented this year by two of its most famous examples. Many splendid drawings follow. An early view of Durham (the property of the Academy) is placed out of its right chronological position, for the sake of comparison with a late rendering of the same subject. The collection worthily concludes with the so-called "Black Rigi," whose two companions were so much noticed last year.

## NOTES.

WE have received some lithographs (plan, section, and view), issued by the "Niagara River Hydraulic Tunnel, Power, and Sewer Company," showing the manner in which it is proposed to utilise the fall of the Niagara for a perpetual power on a large scale. This, be it understood, is not by utilising the actual fall, but by diverting some of the water from the upper level through a long tunnel, with a fall of 1 in 200 over part of its course and 1 in 100 over the lower part, discharging into the lower river near the foot of the falls. This tunnel stream is to actuate a series of great wheels in pits at distances of half a mile apart, supplying power to a number of mills to be built on land to be conceded for the purpose, one section supplying fifty mills of 500 horse-power each. Of disfigurement of the actual Falls there appears to be no fear whatever from the scheme; but, of course, the country just adjoining the head of the Falls would be converted into a large manufacturing town. It must be remembered, however, that it will be free, to a great extent, from one of the great curses of manufacturing towns, smoke and vitiated air from furnaces. How far the scheme would be really beneficial to its promoters and the public depends to some extent on what may be thought of the convenience of the spot as a centre of manufacture. There is no doubt the scheme is prac-

ticable, and would supply an immense motive power at no cost after the first outlay, except ordinary wear and tear of machinery and plant. The first outlay would no doubt be large. It is difficult to make up one's mind how to regard such a scheme. It would sadly drive away the romance from one of Nature's great scenes; yet we cannot hastily condemn an idea which may prove a great practical benefit, although it is a shock to the feelings at first sight. At all events, if the commercial value of the undertaking is satisfactorily proved, we are of opinion that it will be done, and that protests will be unavailing. It might be otherwise if it were proposed to degrade the Falls themselves to the level of a mill sluice. Then the civilised world would probably be up in arms. But as the actual Falls will not be touched, there is room for two sides to the question.

THE fourth annual report of the "Metropolitan Public Gardens Association" indicates that the Association is very actively at work in schemes for securing breathing spaces and playgrounds for London. It shows a good record of work done, and a long list of places (disused burial grounds, &c.) which it is desired to secure and to lay out for public enjoyment. We wish the Association every success in its beneficent labours.

IT is not much to be wondered at that a certain feeling of suspicion is beginning to creep into men's minds as to the real intensity of the distress that is so prominently put before us each day. One would have thought that now, if ever, there would have been an eagerness to obtain a job, if only of a temporary nature, and that the only difficulty would have been to make a selection from the numerous applicants. But apparently there is no plethora of unemployed labour, for, notwithstanding earnest appeals, it is said that in different parts of London the offer was contemptuously refused. Mr. Hyndman, who of course sees no wrong in his socialist friends, defends them by various excuses, such as bad weather, too little pay, defective boots, &c.—all excellent reasons for not working when other and better labour is to be had for the choosing. Cases of refusal were so numerous that we are constrained to believe that Mr. Hyndman has a very rotten case, and that there is not that amount of distress which he avers,—at all events, not in that section to which he belongs. The report of the Belgian iron trade for 1885, lately issued, contains some useful statistics on labour points well worth studying by our artisans, though doubtless they would not be very palatable. The wages at the foundries where the pig iron is worked up were at the rate of 2-96 francs per head (under 2s. 6d.) per day; in the steel works, 3-28 francs (2s. 8½d.). The wages of men working the coal averaged for the greater part of the year 2-22 francs (1s. 10d.) for surface work, and 2-99 (2s. 6d.) for underground work. A worse feature than all, perhaps, is the continued employment of women underground, to the number of 4,256, and 1,612 girls under sixteen years of age. We have, at all events, got rid of that reproach in this country.

THE general spread of the conviction that the neglect of our inland canals has placed our agriculturists at the mercy of the railway companies, has led to the formation at Sittingbourne of an association for the conveyance of fruit and vegetables to London by water. During the few weeks that have elapsed since the establishment of the service, it is stated that nearly 800 tons of fruit and potatoes, consisting mainly of hard fruits, have been conveyed by it to the markets; and that the amount thus saved by the consignees, as compared with the cost to which they would have been put for sending the same consignments by railway, amounts to nearly 250l. A saving of 6s. 3d. a ton on so short a distance as that from Sittingbourne to London is a matter of no little moment for producers. One advantage of the short distance is that the difference,—the possible difference, that is to say,—between the time consumed by the two

nodes of transit, is comparatively small. As to the cost, apart from fancy charges, or attempts to put on any description of traffic "what it will bear," which is the avowed policy of many railway companies, the fact is indisputable that water carriage will pay a good 5 per cent. profit at less than a third of the rate of freight at which 4 per cent. can be earned on a railway. This is a fact depending on the two items of capital and working charges, and is independent of any other consideration. It is one of which manufacturers as much as agriculturists are gradually but practically becoming aware; nor can it be too widely known.

AMONG the hundreds of suggestions for commemorating the Jubilee Year of the reign of Queen Victoria, one of the most deserving of attention and support comes from our sailors. And perhaps it would be difficult to rear any monument at once so beneficial to the country, and so appropriate to the memory of the sovereign of our island kingdom, as would be a Harbour of Refuge for our fishing and mercantile navy. As to the urgent need of such shelter, there is no room for doubt. The Reports from the Select Committee of the House of Commons on Harbour Accommodation are most outspoken and decisive. On the East coast of Great Britain, with the exception of the natural advantages offered by Cromarty Frith, by the Firth of Forth, and by the Estuary of the Thames, there is not a single harbour which is adapted to meet the requirements of the Navy. During the five years from 1876 to 1882, the number of ascertained shipping casualties on the coasts of the United Kingdom averaged 3,300 per annum; of which 497 vessels per annum were totally lost, as were 738 lives in each year. Twelve million tons of shipping frequent the fairway of the North Sea. To provide a place to which this great fleet could run in time of danger would be a work worthy of the Jubilee of Queen Victoria. It would be an offering twice blessed in its results,—a means of saving picked and valuable lives, and a self-supporting mode of insuring mercantile property.

WE have received the preliminary prospectus of the "Roads Improvement Association," which has been formed with the view of taking up generally the question of roads in the whole kingdom, and digging an often much-needed spur into the sides of official bodies whose proper duty it is to keep the roads of their districts in good condition. The Association in its prospectus remarks that "various causes have operated to produce the existing state of things," which "state," we observe they do not define; but we are left to the conclusion that they consider it very bad. Among the "various causes" one of the chief is said to be "the employment of inefficient surveyors, ignorant of the first principles of scientific road construction and maintenance." This may be the case in many places, for aught we know, but we must say, on the other hand, that it is only a very short time since we received a letter from a county surveyor complaining of the apathy and indifference of his Board on the subject of roads, and that they would not allow him to carry out the treatment he thought necessary. The state of our roads, in fact, varies very much in different districts; in some places they are well looked after, in others they are, unquestionably, disgracefully neglected; and as far as we have noted we think this neglect is more common and more marked in suburban neighbourhoods than in the case of country roads. At all events, there is plenty of field in this country for the exertions of the Roads Improvement Association, and we wish them success. Lieut.-Col. Savile is the Chairman of the Association, and Mr. Frank Thomas the Secretary.

TWO old London landmarks will be obliterated by the widening of Little Tower Hill for making an approach, on the Middlesex side, to the Tower Bridge, which is in course of construction. On the left, or eastern side, is the site, at present partly covered by the

premises of the St. Katharine's Docks Company, of Hangman's, *alias* Hanson's (also Hamsden's) Gains. So strange an appellation carries us back to more than 300 years ago. It is, in fact, a corruption of Hammes and Guynes, and was given to a locality which was assigned to the poor traders therefrom when those places, along with Calais, were lost to the English. Across the road, and directly opposite, is a little burial-ground, lying within the Tower Gardens railing, and occupying part of the glacis to the counterscarp of the moat below. The graveyard is said to have been made for the use of the garrison on the breaking out of the cholera epidemic in 1832, and to have been finally closed twenty years afterwards. Now almost entirely occupied by Mr. John Jackson the contractor's temporary offices, it has hitherto escaped the notice of topographers. Some headstones may still be seen against the low parapet wall. The Corporation are about to remove the remains of interments therein to the City of London cemetery at Ilford. The memorial stone to the watermen's dog has also gone, together with the wall in which it was set, at the head of Iron Gate stairs. The recent destruction of Postern-row (*olim* St. Swithin's alley), and the southern side of George-street, just across the ancient London wall, on the northern side of the Tower, involves the disappearance of a once notorious quarter; for there used to assemble the press-gangs before setting out upon their expeditions amongst the parishes of East Smithfield, Wapping, and Ratcliffe.

SOME interesting particulars are given in the *Annales des Ponts et Chaussées* of the evils that may arise through the use of cement made from stone containing a large proportion of magnesia. In consequence of the favourable nature of some tests made in the laboratory of the Ecole des Ponts et Chaussées, and others made at the Port St. Nazaire, permission was given to use, in the construction of some railway bridges, a cement made in some newly-established works at Campbon, in Loire-Inférieure. The arches in which this cement was used were in three bridges over the River Oust, opened in 1881. It was also used in the abutments of a railway bridge at Nantes. About a year after completion fissures appeared in these works, and these were clearly attributable to the cement in the joints having expanded by absorbing moisture. In other parts of the country, too, the distortion of arches, destruction of walls, &c., in which Campbon cement was used, clearly indicated that it was not a suitable material for constructive purposes, even when not brought in contact with salt water. This Campbon cement contains a large proportion of magnesia, analysis of five samples showing the proportions to vary between sixteen and twenty-eight per cent., and the swelling of the cement was attributed to its presence, a view which was confirmed by comparative tests made with ordinary cements.

SINCE the excavation of the Temple of Æsculapius at Athens, and more recently of the mother temple at Epidaurus,—to which we have frequently had occasion to draw attention,—special interest has been roused in all monuments connected with the worship of the healing god. Prof. Von Duhn (in the *Bulletino* of the Roman Section of the German Archaeological Institute, vol. iii., part 3) publishes two bas-reliefs which have remained in the Palazzo Rondinini since 1764; they are valuable both as to subject and workmanship, and seem to have been two of a series connected with the cult of Æsculapius, on the Insula Tibernia, now known as the Isola di S. Bartolemeo. The first bas-relief represents the river god Tiber, in the form of a bearded man, rising from the reeds of his bed and extending a cup to catch the water flowing from a fountain on the rocky island. In the background, on the island, is a temple; the sacred snake (the symbol, and, indeed, in some cases, the incarnation, of the god) issues from a hole in the rock, and seems to be stretching out its head to drink. It will be remembered that about 290 B.C., when Rome was attacked

by a pestilence, her citizens sent an embassy to Epidaurus to ask help of Æsculapius; the ship on its return was followed by a sacred snake, which swam up the Tiber, and then chose the place for its own temple. The pestilence, of course, ceased.

**G**REAT interest attaches to the bas-relief because it is closely analogous to a coin of the time of Antoninus Pius, of which a good impression exists in the British Museum. On the coin we have, in a very similar composition, the snake, the rocky island and temple, and the river-god, but the Tiber seems here to be welcoming the snake instead of drawing water. The new element in the relief is the fountain, represented conventionally by an urn overturned. *A priori*, we should, of course, have expected that the snake would select a spot where a spring of water was close at hand, for the temples of Æsculapius were, to a great extent, hydropathic establishments. The spring is now lost, but, oddly enough, in the Medieval church of St. Bartolemeo, founded by Otto III. (A.D. 1001), there still exists between the third and fourth steps that lead to the presbyterium, an antique puteal, with the inscription, "*Qui sinit ad fontem veniat potumque salubrem aurial ex vena . . .*" and we may fairly suppose that the *vena* represents the spring from which, in ancient days, the serpent of Æsculapius drank. The meaning of the second relief is less clear; it represents a woman figure crowned, seated in a ship, of which she holds the helm. Taking it in conjunction with another coin in which Tiber is seated near the prow of a ship, it may possibly represent the sacred embassy to Epidauris. The style of both reliefs dates them securely about the time of the Antonines.

**T**HE same number of the *Bulletino* contains an account of the terra-cottas found at Nemi. The excavations there should have some claim on English attention, as they are being carried out by Sir J. Savile-Lunley, our ambassador at Rome. Dr. Rohden, who writes the account, is perhaps the first European authority on ancient terra-cottas, and we must refer to his paper for details. The terra-cottas are both architectural and sculptural; a number of akroteria have been found with figures of Diana as the huntress, but the cult of the place was for the most part addressed to the goddess in her life and health-giving aspect as Lucia. In this capacity an immense number of figures were offered to her, with hands, feet, legs, and wounded limbs showing surgical treatment.

**A** DESCRIPTIVE Guide to Kirkstall Abbey\* has been sent to us, headed with the title of the "Leeds Literary and Philosophical Society," and presumably read by its author, Mr. J. Wreghitt Connon, as a "paper" before that society. Mr. Connon has turned to good account his opportunities for studying the great abbey ruin which is so easily accessible from Leeds, and he has produced a good and readable account of it, accompanied by a small restored plan and birdseye view of the abbey as it probably existed in 1190; a sketch which, to those who are unacquainted with the history and habits of the Cistercians, gives a better idea than any words could give of the stern and severe architecture of that rigorous order, whose iron rule must have slowly withered out the feelings and lives of its votaries. Mr. Connon follows Mr. Sharpe in the general restoration of the plan, and the appropriation of the long western building as the lay brethren's quarters,—an interpretation which seems more natural and probable than any other that has been offered. A conjectural restoration of the abbey in the sixteenth century is also given. The author notes the curious kind of Nemesis whereby, when the old sternness of Cistercian rule had long departed, the raising of a more ornate upper story to the tower met with a kind of practical rebuke in the falling of the piers, which were not designed to carry anything more than the low unpretending Cistercian

tower. Mr. Connon speaks, by the way, of the idea of a timber cloister or cloistral roof in the Cistercian building as conjectural only; it is surely about as certain as anything can be of which there are not the actual materials now remaining.

**T**HE German Cement Makers' Association is an important body, its members representing a production of cement not far off a million tons a year. At the annual meeting last year, held in Berlin, a report was presented of an elaborate series of experiments made upon German cements purchased in the ordinary way of trade. The following are some of the most prominent results. The quickest time in which any sample set was three-quarters of an hour, and the longest time thirteen hours. To test for coarseness, a sieve of 5,000 meshes per square centimetre was used (over 32,000 per square inch), and upon this 49 per cent. of the total remained as a maximum, while the least residue was 20 per cent. The greatest specific gravity of any of the samples under test was 3.137, and the lowest 2.976. The greatest tensile strength was 49.4 kilograms per square centimetre (702 lb. per square inch), and the least tensile strength 22.75 kilograms per square centimetre (323 lb. per square inch). These tensile strengths were obtained after twenty-eight days with hand-made briquettes. Some sand tests, made after the German method, first introduced into this country by Mr. Grant,—a mixture of one of cement to three of sand,—gave a maximum tensile strength of 23.45 kilograms per square centimetre (333 lb. per square inch), after twenty-eight days' immersion. The lowest results on such a test were 6.66 kilograms per square centimetre (94.7 lb. per square inch). Hand-made briquettes gave slightly higher results than those made by machine. Crushing tests of the same sand mixture gave a maximum of 235.43 kilograms per square centimetre (3,348 lb. per square inch), the minimum being 40.4 kilograms per square centimetre (574 lb. per square inch). Briquettes that were submerged for fourteen days, and then exposed to the air for fourteen days, had 50 per cent. increased strength compared to those immersed in water for the whole twenty-eight days. The table in which the results of the trials are set forth contains a great number of figures, there being three independent operators engaged in making the tests. A discussion arose on the paper, in which the subject of machines for making briquettes took a prominent part. Bohme's and Kemp's machines appear to have been used; but the latter is said not to be relied upon for regularity in result, and it was decided to use Dr. Bohme's apparatus, which compresses the material in the mould by means of a falling hammer for standard tests. In Kemp's machine any irregularity in lubrication was found to vary the results. The adulteration of cement was also discussed at some length. In the tests referred to, one sample was found to contain slag, and this took greatly from the quality. It was stated that the large export trade of cement once carried on between Germany and Australia had been greatly injured by the adulteration of German cements.

**T**HE two explosions of kitchen boilers which have occurred this week, and which were attended, unfortunately, with fatal consequences, suggest forcibly the urgency of supplying these domestic reservoirs with safety valves, or with lead or other fusible plugs which will melt or give way under high pressure or heat, and afford an escape for the pent-up steam. Without disparaging the general order of intelligence which is usually engaged in the kitchen, it may be said that it is not of that kind which is likely to be conversant with, or sufficiently on the alert to take at the proper time the necessary precautions to prevent, such explosions as occurred at Acton and Shepherd's Bush. In the former case it was a self-acting, high-pressure boiler. There had been no fire in the grate from six o'clock on Saturday evening till twelve o'clock next day; and the fire had been on for about two hours and a half

when the explosion occurred. In the interval between Saturday night and Sunday midday, the keen frost had rendered not only the cold-water tank, but the hot-water tank, and all the pipes connecting with both for a considerable length, one mass of ice. The sudden putting on of a fire, with the whole domestic water apparatus in a completely frozen state, with no escape for the steam generated in a boiler already partially filled with water, and gathering fresh sources of steam from the slowly-thawing ice in the pipes nearest the boiler, was followed by the inevitable result mentioned in another column.

**A** CORRESPONDENT of the *Pall Mall Gazette* on the snow removal question seems to have hit on the true solution of the difficulty. He says:—"Now that another snowstorm has come, let us turn the editors of the London papers into surveyors, and the surveyors into editors. The editors are the persons who know what should be done and how to do it. If there is any sceptic who would doubt this, let him read the leaders on the question which proceed from their pens, and he will see at a glance that they have the whole matter at their finger-ends." Cynical correspondent!

**M**R. EMERSON'S letter, which we print in another column, gives an explanation of his selection of drawings of his Cathedral design for publication. Certain drawings, it appears, were selected by the emissary of a certain journal who "called first," and then it was considered important that all other published drawings should agree with these. We are, of course, bound to accept the explanation, but we cannot regard it as an entirely satisfactory one ever from Mr. Emerson's own point of view. Surely it would have been easy to say "that design is an alternative suggestion and not in accordance with the conditions of the competition; it cannot be published alone, but only as a suggestion to accompany the main design." That is certainly how the matter would have presented itself to us. Instead of that, Mr. Emerson allows a design which was not in accordance with the conditions to be published as his design, to the exclusion of the less effective design which was within the limits of site prescribed in the conditions of competition. This, we must suppose, was no more than an unfortunate carelessness; but Mr. Emerson can hardly be surprised if it gives occasion for comment.

#### TWO OLD PARISIAN JEWELLERS: BOURGUET AND BOURDON.

II.—PIERRE BOURDON.

**A**ND now it is time to introduce Monsieur Pierre Bourdon to our readers. Here he is (or at least, here is part of him), cap on head and pipe in mouth (fig. 7), working out some new fancy in his mind, and by his side a little playful device which the smoke from his pipe very probably suggested to him. Like Bourguet's, his hook is printed in a small oblong octavo form; it consists of three hooks or parts, each with its own title-page, and in one of the corners of the first page of each, a sketch of M. Bourdon himself busy designing. The three title-pages are almost identical; here is the third:—"*Sic fana circuit orbem. Livre troisième. Essais de Gravure. Par Pierre Bourdon, Maître Graveur à Paris, où l'on voit de beaux Contours d'Ornements traités dans le Goût de l'Art, propre aux Horlogers, Orfèvres, Ciseleurs, Graveurs, et à toutes Personnes curieuses. Se vendent à Paris, chez l'Auteur, Place Dauphine. 1702.*"

The work therefore appeared at least twenty years before Bourguet's, and the designs it contains have little in common with those which were afterwards published by his fellow-craftsman and citizen. In the first place, he devoted himself entirely to practical work and not to the study of decorative principles pure and simple; that is to say, to designs intended for the beautifying of the objects he dealt in; and in the second place, his work is almost exclusively confined to pure Renaissance ornament. But though their work had little in common, the workers had much: they both strove towards one end,—the purification of the taste of those who wrought in silver and gold: "Ces livres on

\* MacCormac & Co., Leeds. 1886.

essais de gravure," says Bourdon, "sont auey utile à la Jeunesse pour apprendre le gont de l'art, et j'ai fait en Relief quelq'un de ces ornemens pour miecx conoître la vérité des contours listels et feuilles qui lui sont propre."

them for the benefit of those who would follow in his footsteps. The idea had already been utilised by Von Bommel about two hundred years previously, not as a study, but as part of the design, in one of the most curious of those

introduction of a number of extraneous objects, such as shields, torsos, heads, vases, fruits, *et hoc genus omne*, which have absolutely no part nor lot in the general structure of the design, has opened a smooth and easy way to a herd of incapable draughtsmen, who, not pausing to study the alphabet of their craft, have flooded the world with the veriest hodge-podge of heterogeneous rubbish that it is possible to conceive or dream of. We have said that in our estimation Bourdon's Renaissance work is excellent and worthy of the greatest admiration. Our criticism is directed not against the peculiar style of ornament which the Renaissance brought forth, but against those modern artists who, picking here a little, there a little, a torso or a shield from this, a vase or a scroll from that, have plastered our modern walls in every direction with monstrous nightmares of ornament. If there is one object more than another which designers in the Renaissance style affect to beautify, it is the long and narrow oblong panel on a plaster. We must admit the task they set themselves to be an exceedingly difficult one, but the grotesque way in which they almost invariably accomplish it is worthy only of the speediest form of obliteration that can be devised. If any one doubts what we are saying, he will find a dozen examples to his hand at every turn; let him study them carefully, and honestly say if he can see a *scintilla* of grace or beauty in the ribbon and bunches of fossil flowers with which the space is choked, in the inaccurate weapons and armour, in the impossible pillars and other architectural scraps, in the hideous masks and faces, and in the high-class confectionery style of the appendages generally.

Fig. 7.

It is, however, impossible to pass by without remark, the curious little drawing (from which we have only taken the bead, fig. 7), which he gives of himself and his "churchwarden." He has evidently been impressed by the grace

curious grotesques which so delighted the hearts of German designers in the seventeenth century, and of which we propose to give some examples in a subsequent article.

Although Bourdon has only preserved one of

Fig. 8.

Fig. 9.

of the curves of the smoke as it curls upwards from his mouth and the pipe-bowl, and, catching their airy spirit, he has deliberately set them on his paper in conventional form. It is a pleasant fancy, and though he was not the

his smoke studies, everything that came from his hand, however "cabin'd, cribb'd, confin'd" by the exigencies of the object to be decorated, reveals his mastery over this fundamental principle of the tangential flow of curves. We know

For ourselves, we think that the Renaissance style is at its best when the human or animal forms are worked into the general design and are more or less conventionalised, and that it begins to develop germs of weakness directly these forms are detached from the scrollwork and disport themselves among the branches thereof (in modern work we are frequently not even honoured by anything so homogeneous as a scroll); for this reason we prefer fig. 8 to fig. 9, though in this latter one the beauty and compactness of the scrollwork is such as to almost entirely conceal the bird and dog from view.

In fig. 10 we have sketched one of many designs for watch-backs, and a little piece of the interior economy of a watch: the former, as, indeed, all these watch-back designs are, is specially noticeable for the delightful way in which the surface is covered; the latter for its rigid simplicity and grace. In fig. 11 Bourdon has given his fancy greater play, and allowed it to run with greater freedom over the surface of a cup; and in fig. 12, over the slender form of what appears to be an embossed scent-bottle, or handle of some sort: in this the ascending and descending scrolls, with the stems and foliage working in opposite directions, seem to us especially good.

No other jewellers stand out so prominently as artists and designers as Bourguet and Bourdon. The collection of prints of ornaments in the British Museum reveals fragments of many books of designs of jewellery, which were issued as illustrated catalogues of the objects sold by the publisher. They must, for the most part, have been got up with considerable care and at great expense; but the designs are not of very great merit, and out of a great many plates we have been able to pick out two little designs for seals (fig. 13) as the only ones deserving of special notice; they are by F. J. Morrison, engraved by J. A. Pfeffel, and are interesting specimens of the goldsmith's art. It may be interesting to refer shortly to some of these catalogues. Louis Coquin, *alias* Corsin, *alias* Cauquin, published one, "fait par Gilles Legaré, Orfèvre du Roy," in 1663; the designs are fairly good and elaborate, but the whole of the details are realistic and bad; the chief features of the book are the jewels arranged as bunches of flowers tied up with ribbon. Balthasar Moncornet published in 1665 a similar book, with very weak designs; the special attraction to his customer being a series of landscapes, one of which appears at the bottom of each page; but the landscapes are as poor as the designs. Moncornet was a publisher, and merely issued a variety of "Collections" of works from other hands; the book in question has the following title-page:—"Livres nouveaux de toutes sortes d'Ouvrages d'Orfèvres recueillies des meilleurs Ouvriers de ce Temps, et se vendent chez

Fig. 10.

Fig. 11.

Fig. 13.

Fig. 12.

first who had caught an inspiration so directly from the ebb and flow of natural curves, the little study of them which he has preserved reveals his own clear insight into the leading principles of decorative art, and emphasises

of no pure Renaissance work that can beat it, little that even approaches it in excellence. These two little borders (figs. 8 and 9) we think will speak for themselves. The fact is that Renaissance ornament, by sanctioning the

Baltazar Moncornet, Rue St. Jacques, à la Belle Croix, vis-à-vis St. Yves. 1665."

Jean Vanquer's book, "Livres de Fleurs pour Orfèvres et Graveurs," contains some delightful engravings of flowers; but they are botanically correct, and as careful studies of real flowers as the most accurate botanist could desire. They are useless for the purpose for which they were designed. "Jardiniers" should certainly have been substituted on the title-page for "Orfèvres et Graveurs."

There is one other book of jewellers' designs, however, of great excellence, by Johann Bartholome Herbat, published in 1708; but he was a designer pure and simple, and not a goldsmith. His work has so many excellent qualities that we must reserve it for another article.

Fig. 14.—Tailpiece from a Plate in Bourdon's "Essais de Gravure."

#### THE ENGLISH IRON TRADE IN 1886.

In closing our review of the iron trade during the year 1885 twelve months ago, we observed that the future did not appear nearly so dark as the year then at its close had led people to anticipate. To some extent this anticipated forecast has not proved quite correct. The expected improvement did not set in quite so early as was hoped, although it made its welcome appearance at last. Now have the causes which, it was thought, would operate towards a better state of trade been quite those upon which our anticipations were based. Shipbuilding, for instance, did not give the desired impulse to trade, the tonnage returns for 1886 being lower than those of 1885. The replacement of old material by new also did not proceed at the rapid rate hoped for, industrial undertakings being carried out with a caution learned from previous experience. But in one respect the past year has not only fulfilled, but even exceeded, the opinions formed at the close of 1885. The United States once more have given the chief impulse so much needed by the English iron trade, the demand from that country having been far heavier than was expected. Taking it altogether, the past year shows a substantial improvement upon its predecessor.

This improvement finds expression in the Board of Trade Returns. For the first eleven months of 1886,—the complete returns for the year are not yet available at the time of writing,—we exported 3,123,264 tons of iron and steel, of a total value of 20,098,968*l.*, against 2,910,347 tons of a value of 20,123,374*l.*, in the corresponding period of 1885. It is estimated that the total exports of 1886 will exceed those of 1885 by about a quarter of a million tons. The serious feature in the above figures is the decrease in the value of the exported products, and this diminution is the chief characteristic of the trade of the past year. Prices, which were unremunerative enough at its beginning, steadily fell until the lowest ever paid were reached. Towards the last quarter of the year, an improved demand setting in from all quarters, and production, especially of crude iron, having been at last curtailed, values began to recover, until they are now better for pig-iron than last January, whilst finished iron and steel, if they have not quite reached the point they occupied at the beginning of the year, are at present exceptionally strong in price, with every prospect of reaching their former standards.

The chief causes of the drop in pig-iron, by the side of a decreasing demand, as shown by the shipments, were still production in excess of requirements, and the consequent accumulation of stocks. The total output of Scotch pig during the past year was 935,801 tons, against 1,003,562 tons in 1885; of Cleveland iron, about 2,403,000 tons, against 2,458,889 tons in 1885; of hematite iron in West Cumberland, 1,229,000 tons, against 1,219,300 tons in 1885. The quantity of crude iron at present stored in Scotland, according to latest returns, is 1,182,039 tons, against 1,050,633 tons at the

close of 1885, an increase of 132,356 tons; in the North of England, about 600,000 tons, against 517,488 tons in 1885; in West Cumberland and North Lancashire, 350,700 tons, against 368,600 tons in 1885, a decrease of 17,900 tons. Finally, the shipments of Scotch iron, for the year ending December 25th, 1886, were 332,637 tons, compared with 429,610 tons at the same time in 1885; of North of England iron, 774,813 tons, compared with 835,033 tons in 1885; of West Cumberland iron, 507,767 tons, compared with 487,884 tons in 1885. Exact returns of the English production of pig-iron and the stocks at the end of the year will not be published until about the beginning of March; but the figures given above are sufficient to show that the output of crude iron in 1886 was below that of the preceding year, although for hematite iron there is a slight increase, owing to the growing demand for steel.

The value of pig-iron No. 3 G.M.B. was, in January, 31*s.* 3*d.*; the lowest price of the year (29*s.*) was reached in July; after which, under the influence of a better inquiry and the restriction of production by the Cleveland ironmasters, far too long delayed, it began to rise steadily, until it has reached 33*s.* 9*d.* for early delivery, 31*s.* and 31*s.* 6*d.* being quoted for spring and early summer contracts. Scotch warrants were 41*s.* 0*d.* at the beginning of January last, from which price they receded to their bottom value (37*s.* 11*d.*) in the first week in March. Since then they have been fluctuating, but with a rising tendency, and they are now firm, with 44*s.* 7*d.* as the highest quotation of the year, or 3*s.* 6*d.* higher than in January. Hematite iron was pretty steady at 42*s.* for mixed Bessemer parcels in the north-west of England for the best part of the year, but with the revival in trade the price went up to 46*s.*, and was at the close of the year 45*s.* The rise in pig-iron, it will be seen, has been from 2*s.* 6*d.* to 3*s.* 6*d.* per ton on the year, and it need only be added that the crude iron produced in other districts has shared in this advance. The same cannot be said of finished iron, which has been very much depressed for ten months of the year, and consequently lost in value, although the difference in the quotations ruling at the opening and close of the past year was not great, the fact being that manufacturers could not go very much lower, and stopped work rather than take orders at prices involving positive loss. To give an idea of the general depreciation of finished iron, it need only be stated that the net average price of bars, plates, angles, and rails in the North of England at the end of October last was 4*l.* 11*s.* 6*d.*, compared with 4*l.* 15*s.* at the end of 1885. But the last two months of 1886 will probably show a slight recovery from the lowest price. On the whole, finished iron has never been bought so cheaply in this country as during the past year.

The steel trade presents by far the best record of the past year, and it will probably be found, when the returns for the year are published, that, notwithstanding the depression prevailing in other branches of the iron trade, the production of steel of all descriptions during 1886 was as large as that of any previous year, if it does not exceed it, and that it will more than counterbalance the deficit in the out-turn of manufactured iron. The extensive substitution of steel for iron in shipbuilding is making itself felt, whilst the growing employment of the former material for other purposes in which iron has hitherto been exclusively used will add to the bulk of steel produced. The revival in the construction of railways in the United States has brought important contracts for steel rails to this country, and, with the orders on colonial account and by home railways, has helped to steady prices again. Owing to the operation of the international rail syndicate, which, however, we are happy to say, ended in April last, it was possible to keep up prices of rails at 4*l.* 15*s.*; but as soon as the combination collapsed, they went down to 3*l.* 10*s.* In consequence of the increasing demand, and the rise of rails in America, their value has crept up, and is now 4*l.* per ton for average sections. Steel for shipbuilding has enjoyed a tolerably steady inquiry throughout the year, but, notwithstanding this, prices went down in sympathy with the downward tendency of other classes of iron and steel. Steel and ship plates were at the beginning of the year 6*l.* 7*s.* 6*d.* to 6*l.* 10*s.*, and angles 6*l.* 2*s.* 6*d.*, and they are now 6*l.* and 5*l.* 15*s.* respectively.

The past year has been a bad one for the shipbuilding trade, the total tonnage launched

amounting to only 473,675, compared with 540,422 tons in 1885, 750,000 tons in 1884, 1,250,000 tons in 1883, and 1,000,000 tons in 1882. The two latter years were abnormal as regards the tonnage of new ships, and the decline since then has been the direct consequence of the previous over-production. But there is every indication that the shipbuilding industry is reviving, and that 1887 will present a better record than 1886. Marine-engineers have felt the effects of the dulness in ship construction. It is hoped, however, that with its revival and through the introduction of triple-expansion engines, more work will be provided for them. Other branches of the engineering trade have been equally depressed, excepting for special work. The consequence of the dull state of trade has been an almost general reduction in wages, in some cases quietly acquiesced in by the workmen, but in others leading to cessation of work of longer or shorter duration.

It will be seen from the above brief review of the English iron trade that the long depression of the last few years is over. Whilst the demand from America has been the principal factor in the revival, it should not be left out of account that the colonies also are buying more largely, and that the home consumption is growing, the improved trade in shipbuilding having likewise given a slight impulse to the iron and steel making business. To conclude. The clouded political horizon is giving rise to apprehensions as to a coming great war and to its baneful influence upon trade and industry; but with this exception, and unless every indication is deceiving, appearances are for a much improved trade during the year upon which we have now entered.

#### EDINBURGH NOTES.

QUESTIONS regarding the proposed new Municipal Buildings continue to be debated in the Town Council, and considerable feeling has been exhibited between the contending parties. The *Scotsman* has taken up a position of rigorous antagonism to the proceedings adopted by the Lord Provost and the majority of the Council, advocating delay, and protesting that they have not the confidence of the ratepayers. Numerous letters have been published in that organ, and ward meetings have been held protesting against what is expected to be a heavy expenditure, which in the present state of the City finances would prove oppressive. Sir James Gowan made a very pithy speech in support of the scheme, maintaining that there was always sure to be opposition to any matter involving an increase of the rates, but indicating at the same time that a more modified plan might be adopted than what many might desire; that to retire from the position taken would be most impolitic, as speculators would be certain to acquire the property scheduled; and that the result of the competition for plans should be waited for, in order to see what may be learned from them. It has been resolved, in the meantime, to procure an Act of Parliament, reserving matters of detail for future consideration.

At the northern extremity of Inverleith-row, a new Episcopal Church has been commenced, from the designs of Dr. Rowand Anderson. This church supercedes St. James's in Broughton-place, which was in close proximity to two other Episcopal churches in York-place. The Broughton-place building has nothing outwardly to distinguish it as a place of worship, the facade being merely an end block in conformity with the dwelling-houses to which it is attached. The new church when completed will accommodate a congregation of 600, but the portion to be built at present makes provision for only half that number. The plan for the entire building shows a nave with aisles, and deep chancel, 36 ft. long. At the south-east angle is a tower 21 ft. square, having vestry and organ-chamber on the ground-floor, and choir vestry above. The style adopted is Gothic of the fourteenth century. The chancel is lighted by a window of five lights to the east, and two windows of two lights in the south side. The nave is divided into five bays, with three-light windows in each. Groped columns, having moulded bases and carved caps, sustain arches of two orders, and the roofs are open-timbered. The material to be used for exterior and internal dressings is Corsehill stone. The portion to be now completed will cost about 3,500*l.*

The Parliament Hall in Edinburgh Castle,

which is at present used as a military hospital, and has been divided by the introduction of floors and partitions, is about to be restored at the cost of Mr. William Nelson, publisher, under the supervision of Mr. Hippolyte J. Blanc, architect. The ball was constructed in 1431, and it is probable that when the plaster and other modern accretions are removed interesting features may be discovered. These will, of course, be carefully preserved and restored, and the open timber roof will receive due attention. The "garderobe" excrecence on the south front will be removed, and the built-up windows reopened. The number of patients at present accommodated in the building does not exceed a dozen, and arrangements have been made with the War Office whereby invalid soldiers of the garrison will be received into the Royal Infirmary.

A drinking-fountain has been placed in the Quadrangle of the University buildings. It is the gift of Dr. W. F. Cumming, and is designed by Mr. Sydney Mitchell in a style in harmony with the surrounding architecture. It is square on plan and 13 ft. high, and is built of freestone from Binny Quarry, which is of low tone and does not form a strong contrast with the time-coloured façade of the Quadrangle. At each angle are columns with green bronze bases and foliated caps of the same material. These support semicircular architraves, above which the roof slopes upwards, terminated by a foliated vase. At each angle of the roof there is a dolphin with its head slightly projecting, and their tails are gathered round the base of the vase. On each side of the square are semicircular niches with shell ornamentation at the top, and at the foot of this enrichment is a bronze head with two cups, attached to chains. From the bronze heads jets of water fall into projecting semicircular basins. The four pediments are enriched by the arms of Scotland, of the City, of the University, and of the donor respectively. The fountain is placed at the foot of the steps which lead up to the platform, on which stands the statue of Sir David Brewster.

The Warrender Private Baths Company, Limited, has received the sanction of the Dean of Guild Court to build baths in Thirlstane-road, at a cost of 8,000l. The plans have been prepared by Messrs. R. & R. Paterson, and the elevations, of two stories, are designed in the "Scottish Baronial style."

THE LION OF ST. MARK, VENICE.

SIGNOR GIACOMO BONI still pursues his indefatigable labours on the antiquities of his native city, and has addressed a long communication to the *Riforma* of Rome on the subject of the figure of the Lion of St. Mark; the one that acts "Stylites" on the column. It appears from Sig. Boni's two recent surveys, to one of which we recently alluded,\* that the figure of the lion belongs to different dates, the greater part being, as he asserts, of the twelfth century, when the columns were erected by the Doge Ziani (1176), but that considerable additions were made to the lion on its return from Paris in 1815, after the fall of Napoleon, by whom it was stupidly removed, together with the bronze horses in front of the basilica of St. Mark. From the hook which the lion holds between his paws, the words of the Gospel were effaced by the French, and the words "*Droit de l'Homme et du Citoyen*" substituted, which gave rise to the saying that St. Mark, like other folk, had turned over a new leaf. The wings, the paws, the tail, and the wreath upon the head appear to have been lost, as these parts are evidently modern. The Gospel is of lead, and the eyes of the lion are modern, and are not coloured. The other portions of the lion, including the body and the head and mane, are original, and are modelled without any parade of anatomical knowledge, but the details, where they occur, are remarkably well executed. The original wings, as was remarked by Mr. Ruskin ("*St. Mark's Rest*," i., 22), and corroborated by an old engraving and a picture by Bassano, were more extended than the present wings, and the feathers were more strongly marked so as to tell against the sky, as are the lions of St. Mark from the time of Jacobello del Fiore to the *donatus Venetus*.

The lion is 2 mètres 70 centimètres (about 8 ft. 6 in.) high; the capital upon which it

stands is 3 mètres (about 9 ft. 9 in.) wide, and is 15m. 20c. (about 49 ft. 6 in.) from the ground. The pieces forming the lion, which are of bronze, are supported upon an iron framework, and are put together by iron screws and nuts, which are extensively oxidised. The granite column upon which the lion is placed has an inclination of about 1 1/4 in. towards the south-east, and was damaged by fire in 1756, but the injury is only superficial. The capital of the column is split.

Signor Boni proposes to take down the lion, to remove the present iron framework in the interior, and to substitute a new framework of bronze, to restore the missing portions of the lion in the style of the twelfth century, and to replace the eyes by balls of crystal fixed in the bronze.

There can be no objection to the removal of the framework, provided it can be shown that there is any danger to be apprehended to the figure of the lion; but the proposal to restore the missing portions appears a mischievous suggestion, and may possibly lead to the entire figure, together with the capital upon which it stands, being entirely renewed, and this cannot be contemplated without a shudder by anybody who knows how these things are done in Italy.

The two columns on the piazzetta were brought from Constantinople, and are clearly Byzantine. They were placed in their present position by one Niccolò Barattiero, who claimed as his reward that games of chance which were prohibited in Venice might be played between the two columns. One of these columns is surmounted by the lion of St. Mark, and the other by a statue of St. Theodore Tyro by Pietro Guilombardo (1329). St. Theodore was the patron saint of the Republic, but was superseded by St. Mark.

MAP OF LONDON SHOWING THE BOUNDARIES OF SURVEYORS' DISTRICTS.

We publish this week the second section of this map.

Illustrations.

BANKING PREMISES, ETC., STEAMER POINT, ADEN.

BUILDING in Aden presents many difficulties quite peculiar to the place, consequent upon the exceptional circumstances.

There is abundance of stone, but most of it is excessively hard and difficult to work, but not one of the various kinds is durable or will stand the climate; and even did the place possess the most excellent of stone, there is no skilled labour to work it; consequently, all works are built of thick rubble, plastered, and are of the most unstable character.

Few timbers or woods will stand the effect of the climate, and none will stand the ravages of the white ant but the best teak.

There are a few Chinese carpenters, but they are not generally capable of working to drawings, and can only make what they are used to.

The great heat and humidity of the climate affects and rapidly destroys all unprotected iron.

Skilled labour of every kind appears to be conspicuous by its absence.

The excessive heat makes the great requirement of a comfortable house a constant current and free circulation of air, only attainable by many large openings; whilst sand and dust storms necessitate the ability to close all parts when they occur.

A building of iron enclosed with wood was suggested as the best way of meeting these last requirements, but the slight protection such a building would afford from the heat and the rapidity with which it would decay was fatal to the suggestion.

Referring to the building illustrated, the site, which was partially occupied by old buildings belonging to the same firm for which these have been executed, is situated at Steamer Point, Aden, facing the harbour, and is bounded by a roadway on three sides, and forms the end building of the crescent adjoining the premises of the Peninsular and Oriental Steamship Company, from which it is divided by a roadway.

The front portion of the site is occupied by the main building, attached to the adjoining premises on one side and surrounded by verandahs 10 ft. wide on the front and side, and 6 ft. wide at the back, on all floors.

This building comprises on the ground floor (which is raised on a plinth 4 ft. from the roadway) general office, European clerks' office, manager's office, strong room, store-rooms, &c., the upper part providing residential accommodation for the manager and some of the staff.

In the rear of the main building, in the centre of the site, is a compound, whilst the side and back is occupied by a smaller building, containing, on the ground floor, all the cook-houses, offices, and servants' quarters for the house, the upper story providing three complete suites of apartments for members of the staff.

The building as erected is a substantial framework of iron stanchions and beams all secretly bolted together, which carries the whole weight to be borne. The whole of these stanchions are incased in masonry, built up, after their erection, with local stone set in mortar, composed of cheram (coral lime), pumice, and sand, ground in a mortar-mill.

The whole of the front and side verandahs, and all pilasters, lintels, steps, landings, balusters, balustrades, and other architectural features of the main structure, are composed of artificial stone of a pleasant buff tint. The whole of this artificial stone was contracted to be made in England of a coloured cement facing and a backing of cement and coke breeze, and shipped ready to erect; but this was ultimately varied by one of the partners of the firm and two men going to Aden and, assisted by native labour, making all the large and simple work there, shipping only the moulds, mills, cement, and colour, and substituting pumice-stone for coke-breeze, whilst the ornamental and smaller parts were made and shipped in accordance with the original contract.

The walls are externally finished with a rendering of Portland cement stained a rich brown grey.

The plinth is built in coursed masonry, executed in a reddish-brown stone, but not tooled on the face.

The floors are formed of iron joists, 2 ft. 6 in. apart, filled in with 8 in. of concrete, composed of one of Portland cement, one of dust pumice, and four of pumice-stone broken to about a 1/4-in. gauge. This material has given the most remarkable results in strength. The flat roof is similarly formed of two thicknesses of the same material, one 7 in. and the other 4 in., with an air-space between, and forms a perfect protection from heat. The floors are finished with the borders and trowelled surfaces in coloured cements, whilst the undersides on ceilings are plastered with plaster of Paris.

This is stated to be the first concrete floor ever executed in Aden, and certainly the first plaster ceiling. The work was all executed by local labourers, who had to be first taught. The beams are also cased in solid concrete, and a mould run around all ceilings against beams and walls.

The walls internally are all plastered, the best rooms having skirtings, dados, walls, and friezes, all executed in Portland cement or plaster of Paris, stained with ground local marbles or other materials.

The windows are exceptionally large, and are all casements, and have fanlights nearly to the ceiling, glazed with stained glass. These open inwards, so that any current of air is directed downwards. All the ground-floor windows are fitted with outside shutters on jalousies so made as to fold into the thickness of the wall. On the first floor the verandahs are protected by lattice or jalousies on frames.

The doors and partitions inside the house are also all fitted with louvres, and all these louvres and those of the jalousies are made movable and adjustable, so that they can be closed and made to form a solid door or shutter, or open, so as to have in all cases thorough ventilation.

The whole of the fittings and fasteners, locks, keys, handles, casement (French and other), bolts, &c., were of special make and design, and executed in gun-metal and brass.

There are on the bedroom floor a great number of bath-rooms, this accommodation being necessitated by the climate. A large space in each of these rooms is formed as a water-tight tank, with a drain to the ground, and lined throughout with Dutch tiles, shipped direct from Holland.

The ironwork was executed by Messrs. Marshall & Hatch, of Birmingham Ironworks, and was so correctly set out, worked, marked, and numbered, that the whole was put together in Aden with the alteration of one or two bolt-holes only.

\* *Builder*, vol. II., p. 190.

Banking Premises, Steamer Point, Aden.

The artificial stone was executed by the Albion Concrete Company.

The excellent joinery, all executed in the finest seasoned Moulmein teak, kilned and put together with pins and red lead (glue being perishable in the climate), was from the shops of Messrs. F. Sage & Co. The fittings were supplied by Messrs. Boobbyer & Sons. All the cement used on the works was supplied by the Burham Brick Company.

The building is for Messrs. Luke Thomas & Co., Limited, of London and Aden, who themselves shipped all the goods sent from this country.

The architect is Mr. Alexander Henry Kersey, of London, who personally superintended everything in England; whilst the buildings were erected and all native labour and materials were procured and paid for, and the whole local business was transacted by a representative, Mr. A. Hemingway, whom he sent out for that purpose.

Drawings were made of every part of the building for each trade, and detailed everywhere full size, and the greatest care taken to prevent mistakes or mis-fits when the work had to be erected, and in all cases with the most perfect success.

Mr. Hemingway was supplied with duplicates of all drawings; and the greatest praise is due to him for his skill and energy in instructing the men in accomplishing the erection of a somewhat complicated building with unskilled labour, and under the greatest difficulties.

Some of the furniture was specially made from the designs of the architect, and shipped from England.

#### INTERIOR OF THE CHURCH, FOUNTAINS ABBEY.

THIS view shows a conjectural restoration of the choir of the abbey church, as reconstructed in the early part of the thirteenth century. The spectator, from his position in the south choir aisle, looks into the choir, and sees glimpses of the magnificent "chapel of the seven altars" beyond. Mr. Reeve was, some years ago, employed for a considerable time in making most careful and exact measured drawings of every part of the ruins of the abbey, for the Marquis of Ripon, and was naturally led to make conjectural restorations of many portions. Our illustration is a reproduction of the chief of these, which he describes as "the result of a considerable amount of study."

#### LADIES' HOME, WEST HOVE.

THIS Institution, now being erected at West Hove, from the designs of Messrs. Lamson & Son, is an asylum for ladies in reduced circumstances, and consists of eight separate tenements, each containing, on the ground floor, sitting-room, kitchen, scullery, &c.; and on the first floor two bedrooms and one w.c. The walls are constructed of stock-bricks with red tiles, brick facing; the dressings are of Douling stone; the gables are of framed timber, filled in with "rough cast" and backed by 9 in. walling. The walls are built hollow; the intervening space being filled in with  $\frac{3}{4}$  in. of asphalt, thus rendering the rooms perfectly

\* See report of a paper read by Mr. Reeve at the Architectural Association, and reported in the *Builder* of January 12th and 19th, 1881.

weather-proof. At the rear is a large garden, common to all the dwellings, with large shelter or summer-house in the centre. The cost of erection is being entirely defrayed by Mrs. F. H. McDonald, of Hove, who also intends to endow the institution. The builders are Messrs. Cheesman & Co., of Brighton.

#### ALL SAINTS' CHURCH, PETERBOROUGH.

THE design we publish this week, by Messrs. W. S. Weatherley & F. E. Jones, was placed second in the recent competition. The restricted nature of the site and the approaches to the same demanded some such treatment of plan as is here adopted. The church was also to be an exceedingly cheap one, and to be built in sections.

#### Masonry Classes for Architectural

**Students**—The next meeting of the large class of masonry carried on at the Guilds of London Central Institute, South Kensington, under the auspices of the Architectural Association, will take place on Tuesday evening, January 11th, at seven o'clock. It will be devoted to making the drawings and moulds required for cutting the voussoirs of a straight-arch, covering a doorway with splayed soft and sides. The members of the class are hereby informed that they will require cartridge paper and drawing instruments only. Students who wish to join the class are advised to join now while exercises in elementary masonry are still being done, for soon the class will be so far advanced that new comers will not be able to follow its studies.

THE PUBLIC HEALTH ACT, 1875:  
SUGGESTED REMEDIES OF ITS DEFECTS.

At two recent district meetings of the Association of Municipal and Sanitary Engineers and Surveyors, Mr. William Spinks, Assoc.-M. Inst.C.E., has read a paper on the operation of the Public Health Act, 1875, with especial reference to the 150th section, with suggested remedies of its defects. After a few introductory observations, he said,—

No great originality is claimed for this paper. Lumley, Glen, Chambers, and the Reports of the Local Government Board have been laid under obligation, and the digests of cases arranged in a convenient order for reference, together with a short summary on the cases, in the hope that it will be found serviceable and handy to those who so often have need of their assistance in carrying out not the least important of the varied duties which fall to the lot of the municipal surveyor. It is now rather more than ten years since this Act came into operation, and of the 343 sections of which it consists, there is, perhaps, not one which is more frequently put into practice and applied by members of this Association than the 150th. That the draftsman who drew the Bill and the House of Commons which amended its text in committee were not immaculate nor exponents of clear expression is proved by the very large number of cases which have gone to the Courts, and by the debate which took place in the House of Commons on March 10th on the second reading of Mr. Dodd's Bill to amend this and the 152nd and 153rd sections. It has, therefore, occurred to the writer that if the operations of this section were brought before you and a discussion taken upon it, much valuable information might be obtained that would serve as a guide to each of us in its working, and for this purpose I have prepared the following observations.

The course of procedure adopted by the writer in all cases is to report to the Board the condition of a private street, and to obtain from them a resolution calling upon him to prepare plans, sections, notices, and estimates of the works he proposes to execute. Upon the plan the houses are all numbered, and the full names and addresses of the owners given, the various widths, &c., are figured on distinctly, the lines of sewers and cross drains strongly marked, and also the positions of the manholes and gullies. The longitudinal section is plotted with reference to Ordnance datum, and shows the size, depth, and rate of inclination of sewer, and the intended level of the street and its relation to existing floor-levels. The transverse section is plotted on a large scale, showing the details of the formation, with the sizes and depths of the various materials clearly given, together with the rates of crossfall both of the carriage-way and foot-way. This he considers sufficiently clear and distinct for any owner to work to, should he elect to carry out the work himself as he has power to do. The notice is then drawn. For minor streets, which are not thoroughfares or only residential streets and not main arteries of traffic, a local sett is used in paving; the foundation is of macadam on rock pitching. In streets of the first class, granite paving is laid, and all joints are asphalted. Having thus prepared the plans, sections, notices, and estimates, he lays them before the Board for approval, who sign them and order the notices to be served, and pending the expiration of the stated time the documents lie in his office for inspection by the parties interested. Failing the carrying out of the work by the owners, the matter is again brought before the Board, who direct application to be made to the Local Government Board for sanction to borrow the amounts stated in the estimates. After the public inquiry has been held and the formal sanctions received, a resolution is passed to advertise for tenders, and a contract is entered into in the usual way. Prior to the contractor entering the street, a notice is sent to the owners calling upon them to remove all old materials. Upon completion of the works they are measured up and the total cost arrived at, to which is added five per cent. for superintending and expenses out of pocket, and this sum is apportioned amongst the owners according to frontage. Before laying the apportionment for approval, a preliminary statement of the sums arrived at as the portion of each owner is sent out, with a request that they will call and examine the apportionment and point out

mistakes, if any there be. This is found to be an admirable plan, saving much annoyance in submitting a revised apportionment. The success of this system is proved by the fact that of the seventy apportionments made during the past two years, not one has been revised, and only one has been objected to under the 257th section, the reason given being that the work was "too good." No apportionment is laid for approval until every doubt is removed as to its accuracy, and then it is signed and ordered to be sent out to each of the owners, and the money to be recovered in the usual way, either summarily or by instalments spread over a term of years, as the case may be.

Having made a careful study of and inquiry into all the cases which have arisen from the operation of this section and the other sections correlative to it, the digests of which are appended hereto arranged in direct order, i.e., commencing with the first line of the section and proceeding to the end, the writer begs to offer a few remarks explanatory of the meanings of terms and words as settled by the Courts, and also directions as to the procedure to be observed, and for that purpose will give them under the following heads:—

- |                                        |                           |
|----------------------------------------|---------------------------|
| 1. Street.                             | 8. Service of Notice.     |
| 2. Repairable by inhabitants at large. | 9. Deposit of Plans.      |
| 3. Notice to Owners.                   | 10. Default of Owner.     |
| 4. Owner.                              | 11. Apportionment.        |
| 5. Premises.                           | 12. Recovery of Expenses. |
| 6. Partial Works.                      | 13. Disputee.             |
| 7. Sewer.                              |                           |

**Street.**—A "street," defined by section 4 of the Act, is "any road, lane, footway, square, court, alley, or passage, whether a thoroughfare or not," but it does not necessarily follow that it is a street within the ordinary acceptance of the term, which is a thoroughfare with houses on each side; the *prima facie* meaning of the word is simply confined to the roadway and footway. A bridge over a canal or railway is also a street, and a *cul-de-sac* may be a street. The surveyor having satisfied himself that the road he proposes to deal with is a street, must then inquire as to its dedication. A road may have been used by the public as a thoroughfare; but if there has been no express dedication by the owner, this user does not constitute it a street, and the fact of its being laid out is not a dedication. A surveyor cannot, of course, ascertain what covenants are stipulated upon in leases as to the laying out of streets, but he should take all reasonable precaution to ascertain that the road has been dedicated. Unless a street is declared to be a "highway," under section 152, the provisions of this section may be put in force as often as occasion requires.

**Repairable by the Inhabitants at Large.**—These words are used in contradistinction to "repairable by individuals *ratione tenuræ*." The cases that have been decided under this head have been applicable to roads where tolls have been charged by the owners. In the case of Taylor v. Oldham, the Master of the Rolls (Jessel) delivered a very interesting judgment as to the operation of the Act upon courts and alleys.

**Notice.**—Particular care is to be exercised in drawing the notice and describing the work required to be done; and if words are added in excess of what is prescribed, it has been decided that the notice is bad; but a notice which is *ultra vires* as to part, but good as to the residue, can be enforced in respect of that which is valid. In cases where some owners do the works, and one or more are in default, it is not necessary to serve them with a fresh notice before doing the work. With regard to the service of notices, they may be given to the owner or occupier, but the owners only are responsible for the expenses if recovered summarily; and service is held to be good if delivered to the person who is *de facto* in receipt of the rent, and service at the owner's place of business by delivering and reading to his clerk is a good service. No provision is made in the Act for an objection to notice. Whatever objections an owner may have cannot be raised until section 257 comes into operation.

**Owner.**—The word "owner" includes any person receiving the rent of the property in respect of which that word is used from the occupier of such property on his own account or as trustee or agent for any other person, or who would receive the same if such property were let to a tenant.

**Premises.**—This word by section 4 means "messuages,—buildings, lands, easements, and hereditaments of any tenure." Under this

definition many important and interesting cases have been decided, which are a useful guide to a surveyor. A railway or canal running parallel to and adjoining a street are liable, as also a railway crossing over a street; but where a road was carried over the railway it was decided that neither the railway underneath nor the slopes of the cutting could be said to abut on to the road, nor even the parapet of the bridge. There are many cases of premises, such as school-yards and courts, only having access to a street by means of a passage; in these it has been decided that the benefit of access to the street was the foundation for the liability; but an opinion has been expressed that where the passage is common the liability would not attach. From the cases of canals and railways before mentioned, it will be seen that they may have no direct or consequential benefit from the street, and the owner of a wall at the end of a *cul-de-sac* is similarly situated; but directly the street is declared a highway under section 152, they may break openings upon it and enjoy the full rights of light and way. Bridges over a stream, it appears, are premises abutting on to a street. In one case where a man held a strip of land 4 in. wide on which was the fence of the street, he was held to be the owner of premises abutting on to the street; and in another case, where a party was sued whose land was divided from the street by a wall which did not belong to him, he was held not to abut on to the street. It has also been held that the soil of private streets abutting on a new street was land abutting on such street,—but not the soil of public streets. These decisions were under the Metropolitan Management Acts; but it has yet to be decided under this Act how the apportionment is to be made for the intersection of cross streets.

**Partial Works.**—It appears that separate works can be carried out, but they must be apportioned upon the whole of the owners, it being invalid if divided up into sections, according to a ruling under the Metropolitan Management Acts; but in a case decided under this Act it was held that the apportionment on the particular owners affected was right.

**Sewers.**—The Act does not define how the sewer is to be designed and calculated, but probably the principle of the Fulham v. Godwin case would apply to a sewer laid in a street under this section, i.e., that the street must be regarded as isolated, and the sufficiency of a sewer determined with respect to the street itself and not to the requirements of the neighbourhood.

**Levels.**—Under 11 and 12 Vict., c. 63, s. 69, a Local Board had power only to require a street to be levelled with reference to any want of equality or want of uniformity in the street itself. They had no power to require the level of a street to be raised or lowered so as to bring it into uniformity with the adjacent streets. The late Lord Chief Justice Cockburn said:—"Under the words of the 69th section the Board has no power to require the appellant to raise the footpath to the level of the adjoining streets. The object was to make each street uniform, and it must be looked at as one isolated street so far as this question is concerned. If there are inequalities in it, there is power to make it level. It may be that it would be a convenience for the neighbourhood if this street was made of the same level as those near it, but there is no power to throw the expenses of doing so upon the owners."

**Deposit of Plans.**—It is necessary that these should be on view at all reasonable times while the notices run; but as the provision is directory only, and not a condition precedent to the recovery of expenses, any lax compliance with it will not prejudice the action in recovering the expenses.

**Procedure on Default of Owners.**—It must be noticed that the Urban Authority have a discretion as to whether they will execute the works or not; but they are not permitted arbitrarily to interfere, and must afford the owner all reasonable opportunity of doing it himself; but if they choose they can arrange with owners to waive the notice and do the work by agreement. In many cases owners often endorse an order on the back of the notices; but it must be borne in mind that this submission does not relieve them from any responsibility as to any wrongful procedure or position on their part. Before proceeding to make a contract, the surveyor should ascertain that all the preliminaries have been rightly

observed. Large sums of money have been lost owing to notices having been invalid, and the Authority are presumed to be in a position to find the money even if they fail in collecting it from the right parties. It is not necessary, however, for the surveyor, before making a contract, to submit an estimate as to future repairs, nor does the omission in any way prejudice the right to recover the amounts apportioned on the several owners.

**Apportionment.**—This is the last duty almost that the surveyor is called upon to perform, and he must take care that the charges on his form are for the particular works described in the notices served, i.e. that each street is treated as a street *per se*; it will not do to lump the costs of a block of streets together, and apportion them amongst the owners of all. An apportionment if requiring to be corrected should be laid again, but a correction by the surveyor after approval by the Authority does not invalidate it. In one case an apportionment had been signed by a surveyor who had ceased to hold office, and it was a nullity, and so treated.

It is usual to add to the total sum expended on the works a charge for superintendence and incidental works. There does not, however, appear to be any authority for this in the Act; but a metropolitan District Board of Works were allowed to recover the costs of obtaining names, advertising, and collecting, &c. A charge is also generally made for interest from demand; this also is not very decided as to who is to settle the amount.

By the time the apportionment is made, very likely blocks of property may have changed hands, and the surveyor must bear in mind that the expense are a charge upon the premises, and that the party upon whom the notice was served cannot be made to pay if he has ceased to own the property. The direction of the late Lord Chief Justice Cockburn, in the case of *Reg. v. Swindon Local Board*, is very clear upon this point. There is no limitation of time during which to remain effective, and successive owners are liable, until the charges are reimbursed with interest. Yet the owner is personally liable in so far that summary proceedings may be taken against him.

**Recovery of Expenses.**—This part of the section hardly comes under the surveyor's direction, and more properly is a duty to be performed by the legal adviser to the Authority. The action of section 257 comes in here, and by that it is stated that the owner has a right to appeal and dispute the apportionment for three months after its receipt, and if on the expiration of that time no complaint is made in writing, then the apportionment is binding, and a demand can be made and the money recovered. The ordinary method is to proceed (within six months from the time when the matter of complaint arises) before two justices, who are to decide only upon questions of fact, such as to whether the road is a street, or repairable by the inhabitants at large, as to the liability of the person sued, &c.; but they have no power to deal with or amend the figures, such being the duty of the Authority and of them only; nor have the justices any power of committal in default of distress, as the charge is on the premises, and if they are worthless, then the loss is to the Authority.

Under section 213 the Authority may recover the expenses by levying a rate upon the property in addition to all the other rates, and recover the same from the occupier, and in case the property is unoccupied, then from the owner. In the first instance the Authority must decide which course they will adopt, and it appears that the levying of a rate on the property is not a system to be commended, for the Local Government Board, in a case at Goolle, cancelled a decision of the Authority so ordering, and settled that the expenses should be recovered in a summary manner.

**Installments.**—In some districts the expenses are not recovered summarily, but sanction is obtained from the Local Government Board to borrow the money required, and spread the repayment over a number of years allowed by them, interest being charged not exceeding five per cent. This is an alternative permission to section 213. Of late years there has been a tendency to reduce the period of repayment very considerably, five years being the outside limit; whereas, formerly, loans have been sanctioned for thirty years, which is absurd, as no work can be guaranteed for that length of time, and if it is necessary to renew the work before the expiration, and the road should have become

a highway, the Local Government Board will refuse sanction to a second loan unless the first one is paid off. Therefore the works will have to be paid for out of revenue, or else abandoned altogether.

**Arbitration.**—If the Authority and the owner agree, the matter can be referred to arbitration under the provisions of the 179th section; but the only question to be considered is the amount to be borne by the defendant owner, and not the question as to expenses being reasonable or properly incurred by the Authority. If an arbitration is held which concerns the whole of the disputing frontagers in a street, the consent of each one to the reference must be obtained, because each has the power to appoint a separate arbitrator, and an award is not binding upon a frontager not a party to the arbitration.

**Appeal to the Local Government Board.**—By section 268 it is provided that if a frontager feels himself aggrieved by a decision of the Authority with respect to an apportionment, an owner may address an appeal to the Local Government Board, asking them to interfere and inquire into the whole matter, which they have power to do, and their decision is final and binding on all parties. An appeal cannot be made upon receiving notice to do the works, nor on receipt of notice of apportionment, but only after having received a demand from the Authority which may be taken to be their final decision.

Advantage is often taken of this power of appeal, and the Local Government Board have interfered in several cases, but sometimes, owing to informalities on the part of the appellants, they have had no power to adjudicate.

The writer has recently been engaged in a case where it was decided to question the particulars of an apportionment by appeal to the Local Government Board. All the proper procedure was duly observed, and much correspondence took place, but no formal demand had been made for the money. A notice to arbitrate was served by the Authority; and thereupon the owner, taking this as their final decision, addressed a memorial to the Local Government Board, but they decided it was not a decision at which an owner could feel aggrieved, and they declined to intervene. The next step of the Authority was at a meeting of its Finance Committee, when it was decided to summon the owner in the county court; the day after this meeting, a letter to this effect was sent to the owner's solicitors, but no action was taken until the committee's minutes were confirmed by the Authority, and within twenty-one days from that date a fresh memorial was addressed to the Local Government Board, who replied that it was not in time, and should have been sent within twenty-one days from the receipt of the letter giving the decision of the Finance Committee. This decision of the Local Government Board is of the utmost importance, as it has hitherto been considered that minutes of committees were not binding, nor were they decisions of an Authority until the recommendations contained in them had actually been read and confirmed.

This is not necessarily the only method of appeal against a decision of an Urban Authority. A case may be stated and the appeal carried to Quarter Sessions, but the other will be found to be the more satisfactory, and is more beneficial when the ground of complaint is insufficient to obtain a legal remedy, or where such legal remedy if obtained would not satisfy the equity of the matter.\*

**The Institution of Civil Engineers.**—We are asked to state that supplemental meetings for the reading and discussion of papers by students of the institution have been appointed for the following Friday evenings:—January 7th and 21st, and February 4th and 18th. The papers to be read on these evenings are respectively: "Experiments on Steam-engine Economy," by Edward C. de Fegundo; "The Use of Cast Steel in Locomotive Construction," by Alfred J. Hill; "Recent Researches in Friction" (Part II.), by John Goodman, and "Diving, the Apparatus used and Work carried out under Water," by Geo. A. Becks. The chair will be taken at 7.30 p.m. on each evening.

#### SHROPSHIRE COUNTY SURVEYORSHIP: REMINISCENCES OF TELFORD.

By the death of Mr. T. Groves, mentioned under the head of "Obituary" in another column, the office of County Surveyor of Shropshire has become vacant.

At the meeting of the Court of Quarter Sessions on Monday last, the Chairman, Mr. Alfred Salwey, said, with regard to the appointment of Mr. Groves's successor, that it was very important that no time should be lost, and therefore the Court proposed to fill the vacancy on the 15th of January. The office was an exceedingly important one, when they considered that there were eleven lock-ups to look after, the Shirehall and Judge's lodgings, and no fewer than 269 bridges. The applications and testimonials would be referred to the Finance Committee.

Mr. C. C. Walker said he had seen the advertisements respecting the county surveyorship, but although the probable salary was mentioned, it was not stated whether the candidate was to be permitted to engage in private practice. This seemed to be necessary to be stated, for the amount of salary named\* was too small to attract a first-rate man unless he had private practice, and, as it was not intended to prohibit him from undertaking this, it seemed desirable that it should be known. Before he sat down, perhaps the Court would permit him to state what might not be generally known, and what would probably be interesting. It was a curious thing that just one hundred years ago this very year the county magistrates of Shropshire made an appointment of the county surveyor that was destined to have great historical results in civil engineering, and to leave a mark in our national history. In the year 1787, an excellent young man, named Thomas Telford, who had been a working mason, and the fatherless child of a shepherd, came to Shrewsbury to superintend some alterations at the Castle for Mr. Pulteney, whose residence it was, who was then member for the borough. While there, the county surveyorship fell vacant, and the magistrates appointed Telford to the post. He lived in Shrewsbury, and did much work for the county. He built the county gaol. The henevolent John Howard came there, and by his advice the plans were altered to the approval of the magistrates, and the building made more healthful and humanising to the prisoners. The bust of Howard, which graces the front of the gaol, is in remembrance of this circumstance. Telford did all the usual county work. He built no fewer than forty-two bridges in the county, several of iron, —then a new material for bridges, —and all his work bears the stamp of his genius and ability. The iron bridge at Buildwas is his, and was the third bridge built of iron in England. The magistrates were so satisfied with the performance of his duties that several of them introduced him to make the Ellesmere Canal, and, from the experience which he gained, he made the finest bridges and canals, harbours and docks of that period throughout Great Britain, and so many excellent roads that he became the most eminent road-maker in the world. The Holyhead road, with the splendid iron suspension bridge over the sea at Menai Straits, the wonder of its day, a beautiful thing always, was the eventual outcome of the experience he gained while faithfully performing his duties as County Surveyor of Shropshire. Indeed, it is not too much to say that, by the confidence in iron for bridge construction inspired by Telford, the progress in civil engineering has been so advanced, and we see the result in those grand iron bridges and viaducts that are made and being made all over the world. There is no appointment that the county magistrates can look upon as made by their predecessors with more satisfaction than the appointment of Telford. Every Shropshire man should read his life. He became not only the first civil engineer of his day, but the first President of the eminent Institution of Civil Engineers, which he held till his death. This distinguished man always remembered what he owed to the magistrates of Shropshire for his introduction to public works. He received many decorations from foreign sovereigns in his long, laborious life, was a great benefactor to his race, and, moreover, to our country. An example to all, and revered by everybody, he now resides with the illustrious dead in Westminster Abbey.

\* The remainder in our next.

\* 250l. See advertisement in last week's *Builder*.

The Chairman said the Court could hardly expect a man to devote the whole of his time to county work for the salary offered; but, according to the conditions of the appointment, the surveyor could not be either directly or indirectly interested in any work by or with the county. That rule would be strictly upheld.

SEWAGE IRRIGATION FOR SMALL AREAS.

ASSOCIATION OF PUBLIC SANITARY INSPECTORS.  
 ON New Year's Day, Mr. Jas. Bateman, of Pewsey, Wilts, read a paper before this Association on the application of sewage to cultivation. Mr. Jerram, the Chairman of the Council, presided, and there was a fairly numerous attendance of members. Schemes for dealing with the drainage of large towns, said the lecturer, were numerous, but they were often absent in overgrown villages and small towns in England having a population of 2,000 or 3,000 persons, but not coming under the provisions of the Local Act. In such cases he believed the remedy must be sought in sewage irrigation. In assuming a population of between 2,000 and 3,000, where the water supply depended on wells or the private storage of rain-water, and situate within easy distance of a watercourse,—he had in mind several localities in Wiltshire where the conditions exactly applied,—the sewage would contain, not manufacturing refuse, but the drainage of closets, baths, sinks, washhouses, tanyards, slaughter-houses, brewhouses, and such refuse as was always left in market-places where horses, cattle, pigs, and other animals were offered for sale. Allowing for moderate rainfall, and a water consumption of twenty gallons per head of population, he calculated that the discharge of 105,000 gallons every twenty-four hours would have to be provided for, and allowing for a prospective increase of population, the sewers leading to the deposit tanks should have a sectional area of 18 in. by 27 in. In the working out of irrigation schemes in such districts, the most burdensome condition was the high standard of purity fixed for the resulting effluent by the Rivers Pollution Act, which required that no "liquid containing in suspension more than three parts by weight of dry mineral matter, or one part by weight of dry organic matter in 100,000 parts, shall be admitted to any stream; or which shall exhibit by daylight a distinct colour when a stratum of it 1 in. deep is placed in a white porcelain or earthenware vessel." This condition was absolute, and must be complied with, and where the soil was not on the one hand a too heavy clay or on the other a too porous or loose one, the condition could be fulfilled. A soil well adapted to the purpose, varying from a light to a stiffish loam, could almost always be found adjacent to a stream, and with proper under-draining and due discrimination in the application of the sewage to the land, highly satisfactory results might be reckoned upon. The public mind had been much prejudiced against irrigation schemes by the absence, in such schemes, of efficient subsoil drainage, the results in those cases being often the creation of a sewage marsh in winter, or in summer of a pestilential hot-bed. As had been pointed out by Sir Robt. Rawlinson, no hard-and-fast rule could be laid down. A system which answered admirably in one area might fail in another. Everything would depend upon good management. At Doncaster, some 600,000 gallons of sewage per day were distributed over an area of only from two to five acres, without swamping it, the weight pumped upon it reaching the enormous amount of 2,700 tons of sewage daily. On another point he agreed with Sir Robt. Rawlinson, "that tanks could not properly filter sewage." They only acted as storage places for subsequent mechanical or chemical treatment. The most important consideration was the expense to the ratepayers of all such schemes. Assuming the cost of a scheme like that he had outlined to be 3,000l., which, borrowed at three per cent. for thirty years, would involve for interest and repayment of principal a charge of 190l. for the first year (diminishing every year), a cess of 104d. per head of the population for the first year would suffice. This *per capita* plan the lecturer considered better than charging by assessment on rateable value. In conclusion, Mr. Bateman, maintained that while the welfare of the larger communities

was being well looked after, the smaller ones were being neglected. The operation of the Sanitary Acts was very slow in rural districts, and obstacles were often placed in the way of their administration; but it must commend itself to the mind of any one who studied the question that Nature had placed many of our towns in such a position that very little was required by man to reduce the standard of mortality below its present average, and the authorities that best endeavoured to carry out this great humanitarian principle were the authorities who might be said to be the pioneers of a better age.

In the discussion which followed, the Chairman, Mr. Middleweck, Mr. Dee, Mr. Clarke, and Mr. Easton took part, the general opinion being in favour of water-carriage and irrigation in the disposal of sewage in localities such as those dealt with in the paper, as against the pail or earth-closet system.

A cordial vote of thanks was accorded to Mr. Bateman.

The Chairman announced that the annual dinner of the Association would be held on the first Saturday in February.

THE NATIONAL AGRICULTURAL HALL, KENSINGTON:

THE STABLES OF "OLYMPIA."

This immense building was opened on Boxing Day. It is not necessary here to describe the structure, inasmuch as we have on previous occasions done so very fully.\* The architect was, in the first instance, the late Mr. H. E. Coe, who was succeeded by Mr. James Edmeston. The ironwork of roof and columns was designed by Messrs. Max am Ende & A. T. Walmsley, and erected by Messrs. Handyside & Co., of Derby, and the glazing and zinc work of roofs and flats has been done by Messrs. T. & W. Helliwell, of Brighstone, on their patent systems. The general contractors were Messrs. Lucas Bros., of Kensington, whose contract amounted to upwards of 130,000l.

The stables for the large number of horses accommodated present some noteworthy features. The whole of the fittings were supplied by the St. Pancras Ironwork Company. It was necessary to have the divisions of the stalls readily removable, in order to make room at a future time for dog shows, &c., and they were also to be changeable into loose boxes, required for shows of thoroughbred and other valuable horses. At the same time the stall divisions had necessarily to be firm and strong. These requirements have, we are informed, been satisfactorily fulfilled without the aid of bolts and nuts, which, when left for some time, are apt to set fast. All the divisions and posts were made to one set of templates, and are interchangeable, and all the moving parts are formed in brass carefully turned. Accuracy of work was essential, as a difference of thickness hardly perceptible with ordinary callipers would throw the posts out of upright to a very evident extent. About 150 stalls in addition to loose box and other fittings were modelled, made specially and fixed complete at a moderate cost in the short space of six weeks, a feat requiring much resource and energy. Some of the stalls are made small on purpose for ponies, and in addition there is a series of

permanent loose boxes, and a large harness-room fitted with strong portable standards and ornamental japanned brackets to suit the numerous saddles and driving harness.

BOYLE'S PATENT VERTICAL CURRENT EXHAUST VENTILATOR.

This ventilator, which is made by Messrs. Robert Boyle & Son, Limited, of 64, Holborn Viaduct, is a modification of the latest improved form of Boyle's patent (1882) self-acting air-pump ventilator, and is intended to utilise a descending current of the external air to create an up-draught or exhaust, the wind passing downwards over the deflecting plates, which are placed horizontally instead of vertically, as in the ordinary form of the air-pump ventilator.

This form of ventilator, an illustration of which we here give, is intended to be fixed on the roofs of buildings which are surrounded or overtopped by higher buildings, when it is not found expedient to carry up a shaft to the top of the higher building.

OBITUARY.

Mr. T. Groves.—The death is announced of Mr. T. Groves, the County Surveyor of Shropshire. He was appointed to the office in 1866. As is mentioned in another column, the appointment was once held by the distinguished engineer, Thomas Telford.

Mr. James Horsford, formerly Borough Surveyor of Bedford, died on the 24th ult., in his 81st year.

Mr. M. Davis.—Mr. Maurice Davis, a well-known builder in the West of England, carrying on business at Langport, recently died very suddenly at Ashford, in Kent, where he had retired only a fortnight previously. He had been engaged in the restoration of upwards of seventy churches in Somerset, Dorset, and Devon, work for which (according to an architect who knew him for thirty years) he was peculiarly qualified, as he possessed a good knowledge of archæology.

M. Dirks.—The Brussels correspondent of the Times announces the death of M. Dirks, principal engineer of the Waterstaat, in Holland, and formerly a member of the Dutch Chamber. He was one of the first authorities in Europe on harbour and canal construction.

"Jubilee" Projects.—It would be interesting to see a tabulated list of all the suggestions which have been made for keeping the Queen's Jubilee. What may be called the Jubilee Year is already setting in with considerable intensity, not only in large cities, but in towns and even villages, and it is curious to note the variety of proposals which have been put forward, embracing well-nigh every conceivable project, from a system of complete drainage to a people's park, and from an almshouse to a public baths and washhouses. At some enterprising towns they are not content with one or even two projects. At Bridge-water, for instance, the scheme includes a park, some public baths, a chain of office for the mayor, and a statue of Admiral Robert Blake. At Brighton, Alderman Abbey suggests a plan which will transform the Western Lawn of the Pavilion into a winter garden by roofing it in at a considerable height with glass. At another town it is positively proposed to celebrate the auspicious occasion by the exceedingly prosaic plan of laying down a wooden pavement.—*Sussex Daily News.*

\* See *Builder* for Oct. 3, 1885, and for May 29, 1886.

## A CONTRACTOR'S CLAIM.

WOOD V. THE TENDRING UNION SANITARY AUTHORITY.

On December 16th last, Mr. Justice Wills and Mr. Justice Grantham gave what may prove to be the final decision in this case. They decided that the Guardians of the Poor of the Tendring Union were wrong in law as well as in morality in endeavouring to deprive Mr. Wood, the contractor for the Clacton-on-Sea sewerage, of the money earned by him and agreed to be paid to him for the construction of the sewers.

The legal advisers of the Tendring Union at once decided to appeal against this decision, and instructed their counsel to apply to the Court to stay execution under the judgment until the appeal would be heard. This, however, the Court declined to do, pointing out that in their opinion the case was perfectly clear, and that there was no ground for appeal.

Still the defendants were not satisfied, and on the 21st ult. counsel were again instructed to make application to stay execution. Again they were unsuccessful, and Mr. Justice Wills informed them that the case was one containing nothing to move judicial sympathy in favour of the defendants. There was only 168*l.* worth of delay, and they claimed to forfeit 1,000*l.*

Mr. Justice Grantham concurred, and the application of the Authority was dismissed with costs.

Their counsel were then instructed forthwith to appeal to the Court of Appeal against their decision; but that Court, without hearing Mr. Wood's counsel, also dismissed the appeal with costs.

Mr. Finlay, Q.C., and Mr. Edwin Jones appeared for the Tendring Union (instructed by Mr. Oldman, London agent for Mr. R. J. Daniel, of Manningtree); and Mr. Phillbrick, Q.C., and Mr. J. F. Bottomley Firth for Mr. Wood (instructed by Mr. Wm. Tanner, of Chelmsford).

## LIVERPOOL CATHEDRAL COMPETITION.

Sir,—Mr. Ellis, while thinking it advisable during my absence to reply to certain remarks, which called forth a rejoinder in your journal, was evidently quite unaware of my letter to the editor of the *Builder*, quoted in last week's issue [p. 5].

The explanation is simple, and is, that the representative of another journal first called at my office, and, with my permission, made his selection of those drawings he preferred to publish, and that without my expressing any wish on the subject, or influencing him in any way whatever in his choice.

I imagine he chose what he thought best, and after his selection was made (to which I had no manner of objection, seeing that I also consider the alternative plan B my best general arrangement) the letter quoted was written to the *Builder* to ensure the illustrations appearing in the various papers agreeing with each other. You were, therefore, correct from your point of view in saying I had selected the drawings you published.

That I did not mind this alternative arrangement being published goes without saying, for it requires no vindication on my part.

By plan A, I had absolutely complied with the clause in the instructions to which reference has been made, viz., "to provide for the erection of a cathedral church on such a scale as the site will admit."

And in submitting plan B I maintain that I was warranted by the intention, as it seemed to me, of the continuation of the same clause of the instructions, which has hitherto been unmentioned publicly, viz., "having regard to convenient approaches and accesses, the proximity of St. George's Hall, and other buildings," in making a suggestion in which I endeavoured to the best of my ability to duly consider how the present approaches and accesses could be improved, to which point this clause called our special attention, and this is the reason of the introduction of the flight of steps at the west end, the principal variation in the plan.

The extra bay suggested in this plan I do not consider a necessity, and it is so stated in my report, and no other drawings show it, either in elevation or section, nor does it make any difference whatever to the general tenour of the design, as is clear from the largest perspective, which shows the plan A exactly fitting the site, and with no alteration to the approaches.\*

Mr. Christian says in his report,—“The plan B, No. 2, which I take to be legitimate

\* The print published of this large general view is copied from the only lithograph I had done, it being an expensive process, and was taken with a slip over the foreground to show the alternative arrangement of the high-level approach.

as a suggestion, shows a somewhat ambitious scheme for combining with the erection of the cathedral a much-needed municipal improvement, in the formation of a high-level road from Dale-street, past the cathedral and the important buildings to the northward of the site, and leading onwards to St. George's Hall and the London and North-Western Railway Station. In this plan the cathedral is shown as elongated by one bay of the nave, placing it that much nearer to St. George's Hall, and at the western end by projecting a large flight of steps into the old Haymarket, occupying the space, at present but little used, at the side of the main roadway of traffic. By this plan the level of William Brown-street would be lifted, and fine space given in front of the public buildings; but the descent to the main arteries of communication on the lower level would have to be diverted, as to the possibilities of which I am unable to judge." And this, with the exception of stating further on in the report, "that he is by no means certain that the steps shown in the large perspective drawing, and which, under the present circumstances of the site, could not be had, would not be better omitted," is the sole reference he makes to this alternative plan; it is, therefore, certain he did not base his report on it.

WM. EMERSON.

January 4, 1887.

## SANITARY INSTITUTE OF GREAT BRITAIN EXAMINATIONS.

Sir,—Most notable amongst existing sanitary examinations is that held by the Sanitary Institute of Great Britain for Local Surveyors and Inspectors of Nuisances, concerning which, with your permission, I wish to make a few brief remarks.

The constitution of the Examining Board in connexion with this Institute is sufficient indication of the high-class nature of the examination, and a perusal of the actual questions of past examinations will dispel any doubts as to its practical and useful nature. Whilst, therefore, fully acknowledging its value, as also the obligations which the profession, and especially the younger members thereof, owe to the Sanitary Institute, I nevertheless desire to point to an important defect, not in the nature and scope of the examination, but in the mode of rewarding successful candidates.

To all such, a certificate of "competency to perform the duties of a local (sanitary) surveyor" is awarded, the result of which is that any young man, in his teens or otherwise, who possesses, as evidenced solely by his answers to a given number of questions, a fair knowledge of municipal law and of sanitary engineering, as extracted from books, is declared by a semi-official body of great repute to be capable, in their opinion, of performing all the duties of a local surveyor, notwithstanding the absence of proof, or may be with proof to the contrary, of even a day's experience in the actual work of a surveyor's office.

Possibly though "competent" he may be unable to use a level or theodolite, make a survey or get out a drawing, may never have seen a sewer laid, nor appreciate the importance of "grip" in mortar. Concerning also the multitude of important questions daily arising in a Sanitary Surveyor's practice, which are not, nor well could be, included in the scope of an examination, but for the solution of which a Sanitary Authority looks to its chief surveyor, a certificated "local surveyor" may have no knowledge.

In view of this possible absence of necessary information under the existing arrangements, it would obviously appear, as a remedy thereto, that the awarding of certificates drawn up in such comprehensive terms, and intended to serve as an inducement to Sanitary Authorities in their choice of a surveyor, should only be consequent upon the fulfilment of certain other conditions by the candidates, viz.:—That they shall have had a certain number of years (say five) previous experience in the office of a general engineer and surveyor, or, better still, of a municipal or local surveyor, the absence of such experience, though not necessarily preventing the candidate's sitting for examination, to preclude the granting of a certificate until after the expiration of the period of probation.

The value and prestige of the examination would thus be greatly enhanced, the reputation of the Sanitary Institute as an examining body greatly increased, and the confidence of Local

Authorities in "diplomas" much strengthened, since the condition imposed would prevent young and inexperienced fledglings hawking their certificates from place to place in their efforts to obtain an appointment, the which, in the absence of practical experience, despite guaranteed "competency," a Sanitary Authority, if well advised, refuses to confer.

J. A. A.

## THE NEW AMERICAN CHURCH, PARIS.

Sir,—In your last excellent edition of the *Builder*, with its accompanying drawings, representing, amongst others, the above building, you observe that the church has been much admired; and its chaste appearance affords little room, certainly, for criticism. Architecturally, there is one feature apparently noteworthy, namely, the alternation of size in the nave columns. So far as can be discerned by the drawings, no constructional reason demands the variation to the extent shown; the small columns carry almost as much as the large ones, assuming that the weight of the roof and vaulting is equally distributed on each.

Of course, taking the small columns as representing the true requirement of the building, it is obvious that artistic reasons, *par excellence*, may have determined the size of the large ones. Artistically, is the combination a happy one? Do not the large columns give an appearance of weakness to the small ones? Some time since interest became excited regarding this building, consequent on the reported defection of several of the columns when fully weighted.

The late Mr. G. E. Street, as is known, with somewhat rare discrimination, dwelt much on the need of economic construction;—in other words, he studied *durability* as well as erection, a matter nearly ignored in many modern erections,—it is somewhat strange, therefore, to hear of weakness in his work.

Mr. A. E. Street, having placed the design under public notice, would benefit your readers generally by stating the result of his experience in this matter, especially if he gave, in general terms, the principle upon which the weight is distributed on the nave columns, and their proportionate strength; also the influences traced as causative of the defection therein. Remedial measures, in a case like this, are costly, and future mishaps may be avoided by a clear enunciation of the difficulties laboured under at the Avenue de l'Alma.—Yours truly,

DAVID WALKER.

Cowes, Isle of Wight, January 4th, 1887.

## GREAT NORTHERN HOSPITAL.

Sir,—Being one of many other architects interested in hospital buildings, and a non-competitor, I availed myself of the opportunity to examine the drawings submitted in a limited competition for this new building at the time they were open to public inspection.

In comparing the plan as published in the *Builder* of Dec. 25 with the competitive design, it appears evident that the principle of circular *versus* rectangular wards has in the modified plan been almost entirely ignored.

I was informed at the time they were on view that it was purely a question of principle which induced the governors to award to Messrs. Young & Hall the first prize. Why, therefore, the abandonment of this most important point? In the original plan three circular wards were shown, in the modified and adopted one only one circular ward is to be erected when funds are available for the purpose.

I hardly think this course of procedure is quite fair to the other competitors.

ARTH. ARDRON.

## "FRED." AND "ALF."\*

Sir,—I am much obliged for your notice of my new book, "Ornamental Interiors," but should like to correct the impression given in your review that I have treated the names of contributors somewhat flippantly.

In the few cases where such contractions as "Fred." and "Alf." occur, the names are given exactly as these gentlemen sign themselves in their business communications, and I fancy it would be discourteous to express or even to contrast their signatures. The owner of a name has often a good reason for a peculiarity of signature which is not apparent to one outside his family circle.

I have found by experience that it is hazardous to attempt to expand contracted names. "Fred." may refer to "Alfred" and not to "Frederick";

\* Vide "Books" review in last issue.

"Alf." may be "Alfric" and not "Alfred." Once I described a correspondent who signed "Hy," as "Henry"; he wrote to implore me to print a correction, as he was christened "Harry," and would not be recognised under the name I had given him.  
J. MOYR SMITH.

**DANGEROUS PLASTER CEILINGS.**

SIR,—My evidence in the case reported in the *Builder* of the 1st inst. [p. 63] appears to have been misunderstood in one particular. I stated that the specimen which I exhibited weighed 9½ oz.; not that this was the weight per superficial foot. I calculated that a foot of such plaster would weigh 7 lb. at least, and that a piece measuring a superficial yard (which was less than was stated in evidence to have fallen) would weigh upwards of half a hundredweight.

THOS. BLASHILL,

District Surveyor of West Hampstead,  
3, Blackburn road, West Hampstead,  
January 5th, 1887.

**Books.**

*Specifications for a Frame or Brick Building, costing from \$1,000 to \$10,000.* Copyright, New York: Palliser, Palliser, & Co. London: Trübner & Co. 1886.

THE law-stationers' shop-windows have familiarised us with a certain class of eviscerated legal instruments,—wills of anonymous testators who demise unspecified properties to unnamed recipients; forms in which the only really interesting matter is, like *Viola's history*, "a blank." American enterprise has adopted the hint and applied it to architecture instead of,—or rather perhaps as well as,—to law. A sample "Specifications for a — to be erected for — at —, — architect" (published by Palliser, Palliser, & Co., New York), is before us, and is a somewhat curious document. It will be observed that the nature of the building even is not disclosed,—whether a town house, a country house, or indeed whether it is a dwelling-house of any kind. It is simply a "Frame or Brick Building." The desire to be comprehensive enough to suit many customers has naturally resulted in vagueness, and the document in question fails in the first requisite of a specification, inasmuch as it is not specific. Under some headings, indeed, the work is described in considerable detail; but under such as "iron work," "cut stone work," and a multitude of others not a word is said. It is too full for the purpose of a mere *aide-memoire* for the professional architect, and too fragmentary and incomplete to serve as a guide to the amateur.

The order of the trades is not our order,—the slater, for instance, coming after the painter, a sequence which it is difficult to harmonise with any rational system of building. General conditions precede each trade, and would appear to point to the Scottish plan of letting each trade separately. There are, as may be supposed, many novel phrases, all terse and expressive, although not many novel processes, and some variations on the traditional nomenclature; a gas-fitter, for instance, appearing as a gas-piper, and bringing a spiece of bumour into a literature which seldom errs in that direction.

On the whole, we should be inclined to think that this document has not been framed by a professional architect,—who would surely have had something to say under the forty-four (or more) headings which are followed by blanks,—but by a "literary ignoramus" who has had access to a collection of chancery materials the supply of which, for some trades, has run short.

The whole is neatly bound in grey covers, which are used as the medium of advertisements for building materials and appliances; and although this specification will not supersede the necessity for the services of an architect, any more than similar legal forms have effected the lawyers' employment, it may prove useful to builders in outlying districts where architects are not at hand.

*Hints on Woodcarving, for Beginners.* By ELEANOR ROWE; with a Preface by T. H. POLLEN.

THIS little book, by the Manager of the School of Art Wood Carving at the City and Guilds Institute, and apparently issued by the said school, is a short and very practical treatise, commencing with information as to the tools used in woodcarving and the methods of using them, with a passing sarcasm

on "glass paper and files," and a recommendation (in which we entirely concur) to aim at a sharp and steady cut from the first. Six lessons are given for the amateur to start with, illustrated by large cuts, with descriptions of the method of going to work to produce the various modellings. The designs given serve the practical purpose. They might, however, have been a little more artistic, and not quite so commonplace.

*Sculpture: Renaissance and Modern.* By LEADER SCOTT. London: Sampson Low & Co. 1886.

THIS is one of the series of "Illustrated Handbooks of Art History" of which we have noticed some previous issues on other branches of art. It gives a concise sketch of sculpture from the thirteenth century to the present day; a good deal of attention being bestowed on the early Florentine sculptors, in treating of whom the author recognises fully the eminently sculptural genius of Donatello, as opposed to the pictorial treatment of the art by Ghiberti. In the illustrations of the subject of the Sacrifice of Isaac, as treated by Brunellesco and Ghiberti, we observe the titles have been transposed, and the design of Ghiberti is assigned to Brunellesco, and vice versa. The book may be recommended as a useful compendium of its subject, marked by good critical taste, though somewhat dry in style. It is, however, a very good shilling's-worth of information and illustration.

*The Industrial Self-Instructor and Technical Journal: containing Instruction in the Leading Branches of Technical Science and Industrial Arts and Processes.* Vol. II. London and New York: Ward, Lock, & Co.

THIS is one of those omnium gatherum books which are supposed to be "useful presents for boys," and which contain a little information about an immense number of heterogeneous subjects. We can hardly see that much good is done by this type of publication, except so far as that a young reader's interest in some subject may be so far stimulated that he may wish for more and fuller information. The practical portions of the book seem to be the best; the artistic suggestions and examples are very bad.

**RECENT PATENTS.**

**ABSTRACTS OF SPECIFICATIONS.**

1,243, Bricks, Tiles, and Furnace Linings. A. Fould and P. Geneau.

This invention consists in using two substances chemically antagonistic to each other, but fused by means of a third substance introduced. These materials are dried and baked as in ordinary brick-making. The chief claim is the use of special "agglomerants" whereby refractory substances are brought into a plastic condition and moulded. The said substances will afterwards resist great heat.

1,282, Securing Door Knobs, &c. J. B. O'Callaghan.

According to this invention a small nut turns on the spindle being moved thence by working a bradawl or similar tool in a hole made to receive it. This nut draws up the knob to its proper position on the spindle.

1,349, Gas-fittings. H. Harper.

This invention consists of a sliding lever so arranged that when lifted it releases the globe, and when pulled downwards in a perpendicular direction the globe is held fast.

1,372, Domestic Stoves. J. S. Watson and H. S. Morwood.

This invention relates more particularly to grates and fireplaces of a portable character, and consists in the construction of a canopied dog-grate and hot-air stove combined of a portable or semi-portable character, which may be used as a domestic fire-place for heating and ventilating.

1,711, Economy of Fuel, &c. R. W. Hewett. By this invention a bellows or fan exhauster is so fixed that when worked a vacuum is created, and hot air or gases caused to pass through the fuel.

15,830, Apparatus for Teaching Drawing. J. H. Russell.

This invention consists essentially in the combination, by means of suitable ties and connexions in metal, of diagrams in metal or rigid material, representing plans, elevations, and sections of a similarly-made model in outline of the solid object from which the said plans, elevations, and sections are taken. Wires are sometimes used, or different lines of colour to denote the different parts as combined one with another.

1,803, Lining, &c., in Painting. T. Heighway and J. Smithies.

This invention consists in arranging movable templates, not unlike parallel rulers, which thus allow of any thickness of line, which is generally stencilled in the ordinary way. The framework can be utilised for holding ordinary work in lieu of pins.

10,829, Scoria Paving Blocks. C. J. Dobbs.

To prevent the slipperiness usually experienced with blocks made of furnace-slag, they are cast in larger moulds and broken to pieces by a blow, when the fractured surface is used as the wearing part and the slippery skin which forms on the mould is turned inwards.

**NEW APPLICATIONS FOR PATENTS.**

Dec. 25.—16,945, C. Swindell, Stove Grates, and Fireplaces.—16,959, W. Stevens, Ventilating and Flushing Water-closets.—16,997, A. Deslandes, Automatic Door Curtain-raiser and Draught-preventer.—17,013, J. Alston, Flushing Cisterns for Water-closets, &c.—17,016, O. Flagstad, Window Construction.

Dec. 29.—17,019, G. Henley, Building Hollow Walls.—17,065, J. Tall, Facing for Concrete Structures, &c.

Dec. 30.—17,098, W. Sonnett, Manufacture of Portland Cement.

**PROVISIONAL SPECIFICATIONS ACCEPTED.**

10,055, A. Andrews, Window and Door Fasteners.—11,453, W. Fox, Joiners' Braces.—14,448, H. Johnson, Lock-bolt for Doors and Windows.—14,602, E. Hedgman and F. Villiers-Stead, Automatic Self-replacing Indicators for Electric Bells.—14,872, T. Fawcett, Machinery for Pressing Bricks, Tiles, &c.—15,170, M. Crofton, Ventilator and Man-hole for Buildings.—15,184, G. Stierlin, Fanlights, Windows, Ventilators, &c.—15,962, S. and S. R. Chatwood, Locks.—16,171, S. Hazeland, Machinery for Planing Wood.—16,312, W. Illingworth, Joiner's Adjustable Bench Stop.

**COMPLETE SPECIFICATIONS ACCEPTED.**

*Open to Opposition for Two Months.*

1,126, C. Alison, Cements or Plasters.—2,419, J. Hicken, Fixing Door-handles, &c., to Spindles.—3,195, F. Harrison, Barrel Bolts for Doors, &c.—3,988, H. Dempewolf, Smoke-consuming Fireplaces.—4,103, R. Elliott, Apparatus for Setting the Teeth of Saws.—4,288, J. Walker and H. Worsley, Sash, Casement, and Door Fasteners.—12,109, R. Price, Electrical Drop Indicator.

**Society of Arts.**—The following are included in the arrangements made for the meetings of this Society for the present session. *Ordinary Meetings* (Wednesday evenings, at eight o'clock):—January 19, "Cameo Cutting as an Occupation," by J. B. Marsh; February 2, "Electric Locomotion," by A. Reckenzann; February 16, "Handicraft Training," by Henry H. Cunynghame. Amongst the papers for which dates will be hereafter announced are:—"Miners' Safety Lamps," by Edward H. Living; "Machinery and Appliances used on the Stage," by Percy Fitzgerald; "Irish Industries," by the Rev. Canon Bagot; "Progress in Telegraphy," by William Henry Prece, F.R.S.; "Railway Brakes," by William P. Marshall; "The Living Organisms of the Air: the effect of Place and Climate on their Prevalence," by Dr. Percy Frankland. *Indian Section* (Friday evenings, at eight o'clock):—February 11, "The Economical Condition of India," by Dr. Watt, C.I.E.; March 4, "Our Trade Routes to the East," by Major-General Sir F. J. Goldsmid, K.C.S.I., C.B.; April 29, "Village Communities in India," by J. F. Hewitt. *Applied Art Section* (Tuesday evenings, at eight o'clock):—Feb. 1, opening address on "The Present Condition of Applied Art in England, and the Education of the Art Workman," by T. Armstrong, Director of the Art Division, Science and Art Department; February 22, "Wrought Ironwork," by J. Starkie Gardner, F.G.S.; March 15, "The Application of Oems to the Art of the Goldsmith," by Alfred Phillips; April 26, "Ornamental Glass," by J. Hungerford Pollen; May 24, "The Importance of the Applied Arts and their Relation to Common Life," by Walter Crane.

**Professional Partnership.**—Mr. T. Thornton Oreen, surveyor, Poultry, announces that he has taken into partnership Mr. P. Pieteresen, who has for some years past been associated with him as principal assistant. The style of the firm will be "T. Thornton Green & Pieteresen."

—THE VERNIER—

The Student's Column.

FIELD WORK AND INSTRUMENTS.—II.

Surveying Instruments.

II.—THE VERNIER.

**B**EFORE proceeding to describe instruments which measure fractional proportions of given lengths, it is necessary clearly to understand the principal of a vernier.

The vernier scale is made to slide evenly along the graduated limb of an instrument, and is constructed of a total length consisting of a number of divisions of the primary scale, less by one than the number of smaller divisions into which those primary divisions are to be subdivided. By its use, distances or amounts of deviation, can be minutely measured with a degree of accuracy unattainable with the application of a single scale closely subdivided, as in the latter case the strokes indicating the divisions would come so near together that it would be difficult to distinguish one from the other, even when read through a powerful lens. The principle may be thus stated: If a line be divided into  $m$  number of equal parts on one side, and into  $(m + 1)$  number of equal parts on the other side, the length occupied by the difference between each of these divisions will be equal to the length of the line divided by the product of the number of parts taken on each side, or mathematically expressed by the fraction

$\frac{1}{m(m+1)}$ ; thus in figure 1, the line AB being divided into three and four equal parts, the difference between these parts equals  $\frac{1}{3 \times 4}$  or one-twelfth ( $m=3, m+1=4$  and  $\frac{1}{m(m+1)} = \frac{1}{12}$ ).

This will be evident upon reference to the foot-scale shown under the line AB. If the line AB be supposed to be 12 in. long, the difference between one-third and one-fourth is one-twelfth, or 1 in., the difference between two-thirds and two-fourths is two-twelfths, or 2 in.; and the difference between three-fourths and three-fourths is one-fourth, or 3 in. Applying this principle to fig. 2, we obtain by dividing the line CD into nine and ten equal parts respectively, a length between these divisions equal to  $\frac{1}{90}$  of the whole line.

Now if the upper line of divisions be supposed to represent the vernier, and the zero point indicated by the arrow in fig. 3 be moved forward so that the line at 5 upon the upper scale coincides with a line or stroke upon the lower scale, then the arrow will have travelled  $\frac{5}{90}$  of the whole length of CD along its edge from the zero upon the lower scale of divisions, or half way from the zero towards the next division upon the primary scale.

The limbs so graduated may be either straight or circular. In circular instruments which record angles, the primary scale is graduated into degrees, each degree of the circle being sub-divided into two or three equal parts, denoting 30 or 20 minutes respectively, while the introduction of a vernier will enable this scale or division to be read to minutes or such parts of minutes as may be required. For instance, let us suppose, as shown in fig. 4, that we have to deal with an instrument in which the primary scale is divided into degrees, and half-degrees, and that we desire to construct a vernier which shall enable us to read to minutes. One minute being a thirtieth part of each sub-division of the primary scale, we must take 29 divisions on this scale, and divide it into 30 equal parts upon the vernier. Thus, if  $m+1=30, m=29$ , and the product  $\frac{1}{m(m+1)} = \frac{1}{29 \times 30} = \frac{1}{870}$  of the whole length of 29 divisions so taken; but as each of these divisions is equal to half a degree, we have  $\frac{1}{870} \times \frac{29}{2} = \frac{1}{60}$  of a degree as the result of the division obtained by the vernier: hence the vernier will read to minutes. It will be observed, in figs. 4 to 8, that the numbering upon both the primary and the vernier scales reads from right to left. This is because the two scales in circular instruments are placed upon a circle situated at or near the outer edge, and the instrument is worked round

with the sun from the centre of that circle. Circular protractors and theodolites are thus constructed, but in the box sextant, as will be seen by our next article, the numbering reads from left to right.

Fig. 5 shows the same vernier as fig. 4, but with the zero point in the centre. This arrangement is adopted by some makers in the manufacture of their circular protractors, which we shall hereafter describe. The divisions are the same as in fig. 4, but the right-hand half of the vernier, numbered 15 to 0, is placed upon the left-hand side of the half numbered 30 to 15. To understand this better, we may compare it to a foot rule or split-divided scale, in which the inches are marked 6 to 12, and then 1 to 6, instead of 1 to 12, as is usually done. In Figure 6 the primary scale consists of degrees and thirds of a degree, and a vernier is constructed reading to 30 seconds: thus a length of 39 divisions on the primary scale is divided into 40 equal parts upon the vernier: 30 seconds being one-fortieth part of a sub-division on the primary scale, each of which sub-divisions equals 20 minutes. Hence  $m+1=40,$

$m=39$ , and  $\frac{1}{m(m+1)} = \frac{1}{39 \times 40} = \frac{1}{1560}$  of the whole length of 39 divisions, equal to 13 degrees, or  $780$  minutes, hence  $(\frac{1}{39} - \frac{1}{40}) = \frac{1}{1560} \times \frac{1}{1} = \frac{1}{1560}$  minute.

In order to read the minutes correctly upon the vernier, every alternate division only is numbered, the intermediate divisions, which are made shorter, for sake of clearness, indicating half-minutes. In our diagram the curved graduated limbs are shown developed into horizontal or straight members. This curved lines, however, in practice, are omitted by the best makers, and the strokes indicating the divisions are carefully cut and numbered upon the circular plates at the works by a machine, so fixed as to reduce them from a large pattern, upon which the figures and lines have been accurately set out.

Fig. 7 indicates the same primary scale of divisions and the same vernier as in fig. 6; but in fig. 7 the arrow at the zero point has travelled forward a certain proportion of the full sub-division of one-third of a degree on the primary scale. Now, the vernier enables us to see that this amount equals 8 minutes, according to the principle illustrated in fig. 3. In reading off the graduated limb of the instrument, we must first look to the arrow at zero on the vernier, and having read the number on the primary graduated scale of divisions next this arrow, which appears upon the zero side of the primary scale, we next look along the movable vernier, and add the number of divisions indicated by the stroke which most nearly coincides with a division on the primary graduated limb. We are not concerned as to what division upon the graduated limb is so cut, our object being only to arrive at the fractional proportion of the division upon the graduated limb [at which the arrow on the vernier stands, this fractional amount being indicated by the number on the vernier which coincides with a stroke on the primary scale. When a coincidence is observed, as in fig. 6, simultaneously at the zero and the last stroke on the vernier, it indicates zero to be added, and the division on the graduated limb which coincides with the arrow marked at zero upon the vernier indicates exactly the amount. Fig. 8 illustrates a vernier reading to 20 seconds, 59 divisions on the primary scale are divided into 60 divisions upon the vernier, and the result gives  $(\frac{1}{59} - \frac{1}{60}) = \frac{1}{3540}$  of a length of  $19\frac{2}{3}$  degrees, or  $\frac{1}{3540} \times \frac{59}{3} = \frac{1}{60}$  of each sub-division or 20 seconds. Hence upon the vernier scale, for sake of clearness in reading, every third stroke only is marked. Other verniers can be similarly constructed, but figs. 4 to 8 illustrate those most generally adopted.

**Flour Mill, Silloth.**—In the paragraph which appeared in our last (pp. 63-64) relating to this building, mention was made of the adjoining North British Railway Co.'s warehouse (or granary). We are asked to state that the whole of the constructional ironwork for the granary was supplied and erected by Messrs. Gardner, Anderson, & Clarke, with the exception of the concrete floors and window sashes.

MEETINGS.

MONDAY, JANUARY 10.

Royal Academy.—Mr. J. E. Hodgson, R.A., on "Art a Universal Language." III. 8 p.m.  
The Surveyors' Institution.—Continued discussion on "The True Question." 8 p.m.  
Inventors' Institute.—Mr. S. J. Mackie, C.E., on "The Origin and Objects of the Inventors' Institute." 8 p.m.  
Liverpool Architectural Society.—Mr. F. M. Evanson on "Public Hydraulic Power for Lifts and Warehouse Machinery." 7 p.m.  
Leeds and Yorkshire Architectural Society.—Major J. Whitacre-Allen on "Drawing: its Importance in Education." 8 p.m.  
Society of Antiquaries of Scotland (Edinburgh).—3 p.m.

TUESDAY, JANUARY 11.

Institution of Civil Engineers.—Further discussion on Professor Kennedy's paper on "The Use and Equipment of Engineering Laboratories." 8 p.m.  
Society of Biblical Archaeology.—The Rev. C. J. Ball on "The Inscribed Stones from Hamath." 8 p.m.  
Manchester Architectural Association.—Mr. W. H. Littlewood, A.R.I.B.A., on "Recollections of an Italian Tour." 7.30 p.m.

WEDNESDAY, JANUARY 12.

York Architectural Association.—The Rev. E. M. Cole, M.A., on "The Stratigraphical Geology of Yorkshire, with reference to Building Materials." 7.45 p.m.

THURSDAY, JANUARY 13.

Royal Academy.—Mr. J. E. Hodgson, R.A., on "Art a Universal Language." IV. 8 p.m.  
Society of Telegraph-Engineers and Electricians.—8 p.m.

Miscellaneous.

**The Engineering Trades.**—Messrs. Matheson & Grant's "Engineering Trades' Report" for the half-year ending Dec. 31st, says that the year just closed has been one of the worst ever experienced in the engineering trades, but in several branches a slight improvement has set in which bids fair to continue, and the prospects for the coming spring are brighter than they have been for the last two years. The revival of railway enterprise in the United States has given great impetus to the iron and steel trades of that country, and though free exchange with Great Britain is restricted by their fiscal system, the intimate connexion between the two countries has always led to a corresponding improvement here. Coal has been cheaper than ever during the last year. The continued fall in the prices of pig-iron during the first half of 1886 was arrested by the natural remedy of a reduction in the output, and prices advanced in consequence. The prices of rolled iron have fluctuated during the last six months, and are now slightly higher than in the summer. They would be still higher but for the competition of steel, not only in shipbuilding, but in boilers, bridges, and other structures. At many of the leading rolling-mills Siemens and other steel-making plant has been established to meet the altered demand, and at some of the works favourably situated for suitable ore and fuel the puddling furnaces and other appliances for making wrought iron are likely to be abandoned altogether. Steel, which in the spring and summer of 1886 fell even more rapidly than iron, has during the last few months recovered from 5s. to 10s. per ton. Owing to the collapse of the English and Continental rail-makers' combination, prices of heavy steel rails fell as low as 3l. 12s. fid. per ton, but the price now is from 4l. to 4l. 5s. Although this recovery is assisted by the considerable manufacture of ship and bridge steel, the immediate cause has been the revival of the American demand. In regard to iron and steel structures, a very large tonnage of bridge work has been made during the past year, most of it for export. International competition depends more than ever on cheap transport. A revision of railway rates to the ports, a simplifying of dock dues, and the utilisation of canals, are immediate remedies which would help British trades, while ocean freights as low as those from Antwerp and Germany, which at present favour Continental manufacturers, are necessary if the export of engineering material is to be maintained and extended.

**Discovery of an Old Viking Ship in Norway.**—The remains of an old Norse Viking ship were discovered in Norway last autumn. The ship was found in an old tumulus on the farm Gjunarstorp, in Southern Norway. Its length is 26 ft., but the vessel, though of oak, is not in a very good state of preservation. Wool has been used for caulking. In the tumulus were also found eighteen semi-globular pieces of amber, apparently used for playing with, and seventeen conical stones. It is believed that the vessel dates from the tenth century. There are several other tumuli in this part of Norway.

**The Wood Market.**—Messrs. James Smith & Co.'s (Liverpool) Wood Circular and Prices Current for the 3rd inst. says:—"The wood market shows more than the usual falling off in the consumption at this season of the year. This has been caused by the stormy weather and hard frost (suspending building operations), the hardening of the Money Market, complication on the Continent, and the unsettled state of our Government at home. This state of things has tended to deter buyers from increasing their stocks until the year is fairly advanced, when business may be more settled. Another stoppage in our trade this week has not tended to strengthen confidence, and goes to show the weakness of our trade, caused by the last few years' unsatisfactory business. On the other hand, the stocks are light, and sellers show more firmness, but, our markets being so sensitive, it is doubtful if this can be maintained should the supplies be at an excessive. Railway traffic returns continue to show an increase, which is a favourable feature."—Messrs. Foy, Morgan, & Co.'s "Annual Wood Report, 1886," says:—"The year just elapsed has been another in the cycle of bad years, from which the wood trade, in common with so many other interests, has suffered severely. Profits have been all round on the usual vanishing scale, and competition has been as keen as ever. Importers have, as a rule, done little more than get their money back, and market buyers have secured but a meagre return for their labours. The cause of this dulness is undoubtedly to be found in the general commercial depression which has enveloped all European countries, and almost every interest. The building trade has been in a deplorable state, as evidenced by the unremunerative prices at which contracts are eagerly taken, and in the depressed value of building land. Although all the principal wood-producing districts have diminished their supply to this country, and notwithstanding the fact that the dock stock is moderate, there seems no immediate prospect of any revival in business, and the deliveries from the docks, smaller by 20 per cent. than the average of the last four years, betoken that the supply is fully equal to any demand that can reasonably be anticipated. Auctions have not been so heavy as in the preceding years, the market having been obviously too weak to bear the pressure of large forced sale."

**The Roman Baths at Bath.**—At a meeting of the Bath Town Council on Tuesday last, one of the items on the agenda had reference to some communications received by the Mayor from the Society of Antiquaries and Mr. C. Roach Smith on the subject of the Roman Baths. Alderman Wilkinson moved that the consideration of this matter be postponed till their next meeting. His reason for making the request was that the Baths Committee considered it very desirable that an unbiased opinion should be obtained after a thorough inspection by an independent architect as to the construction and stability of the work now being carried out in York-street and Stall-street, and also as to the best arrangement of the basement with regard to the Roman remains on the site of the two houses lately removed. They therefore requested the Town Clerk to write to Sir James McGarel Hogge, Chairman of the Metropolitan Board of Works, to ask him to name an architect to undertake this duty. Sir James recommended Mr. Waterhouse. Negotiations were entered into with him, and he arranged to be here on the 3rd. In accordance with that arrangement he commenced his inspection on Monday, and his report would be presented in due course. Under those circumstances, the Committee asked that the report of Mr. Waterhouse should be considered in conjunction with the others. He therefore moved that the matter be postponed.—This was agreed to.

**The "Black and White" Buildings of Cheshire.**—At the last meeting of the Chester Archaeological and Historic Society, Mr. Alfred Rimmer read an interesting paper on "The Black and White Half-Timber Architecture of England, with Special Reference to Chester and its Neighbourhood." In his concluding remarks he recommended, for the purposes of timbering, the black walnut of America, a wood which, he said, deserved to be better known in this country. "By getting it ready cut and mortised from the United States they would be able to erect timbered houses very cheaply, and perhaps see a revival of this beautiful, irregular, and picturesque style in England."

**New Public Washhouses in St. Marylebone.** in connexion with the St. Marylebone Baths, in the Marylebone-road, were opened on the 25th ult. There have been washhouses there for many years, but they were in many respects inconvenient, and the Commissioners lately resolved to pull them down and erect new ones, fitted with every modern convenience. The work was entrusted to Mr. J. Waldram, C.E., of Craven-street, Charing-cross, who has designed the new buildings and superintended their construction. In the basement is a new main room, where the various mains, also new, are painted of different colours, according to their uses, the manipulation of them being thus rendered more easy and certain. Also in the basement are four boilers, for supplying water and steam; a new engine of six horse-power nominal, for driving the machinery, and furnaces to heat the drying closets. Over the basement is a fireproof roof, on which rests the floor of the laundry, which is paved with slates, and adequately supplied with drainage, so that it cannot be sloppy. The laundry is of the same size as before, but the roof, now of iron and glass, has been carried to a height of 30 ft. Here are the washing boxes, sixty in number, each box having one division to serve the purpose of a copper for boiling the clothes, and another for washing them, with taps for hot and cold water and steam. Formerly the wringing machines were worked by hand, but now there are three steam wringers, working at a speed of a thousand revolutions a minute. The drying closets are twice as numerous as before. There is also an ironing stove. For the use of all these appliances,—for everything, in short, except soap and soda,—the washers pay three-halfpence an hour, and a fortnight's wash of a working man's household is commonly done in two hours.

**Explosions of Kitchen Boilers.**—An inquest was held on Tuesday by Dr. Diplock, at Acton, touching the death of Fanny Prichard, housekeeper at No. 1, Oakfield House, Avenue-gardens, Mill Hill Park, who was killed instantaneously on Sunday afternoon by the explosion of the kitchen boiler. Harriet Prichard, sister of the deceased, and engaged as cook in the same house, stated that previous to lighting the fire on Sunday at twelve o'clock, they had no fire on that day. James Hedges, builder, who was called to the house shortly after the explosion, gave it as his opinion that there had been no fire on for some time. The water in the supply-pipes was frozen, and a fire being lit in the kitchen for a few hours on Sunday would cause the water in the boiler to boil away. The supply pipes being frozen would leave the boiler dry, and after a time the boiler would get red hot, and the heat from it would be conducted up the pipes until it reached the ice, which would melt and run suddenly into the boiler. The boiler being, as it were, sealed, with no escape for the steam, an explosion would result. A jurymen (Mr. Halls, a builder) stated that there was a valve sold for placing on kitchen boilers which prevented explosions, and should be used in every case. The jury returned a verdict of "Death from the accidental exploding of a kitchen boiler," the Coroner remarking that during his nineteen years' experience as a coroner he had had before no similar case. That day he had two; the other case was that of a boy at Shepherd's Bush, who had been killed by the explosion of a kitchen boiler.—*Times*.

**Birmingham Architectural Association.** The fourth ordinary meeting of the current session was held at Queen's College on Tuesday evening, January 4th; the Vice-President (Mr. John Cotton) was in the chair. Messrs. W. H. Bidlake, M.A. (Cantab.) and E. J. Hickin were elected members of the Association. A paper was read by Mr. T. Camm on "Art in Glass in Relation to Architecture." The lecture was illustrated with some very fine drawings and examples of various periods of glass. A vote of thanks, proposed by Mr. W. Henman and supported by Mr. Victor Scruton (hon. secretary) and the Chairman, was unanimously accorded to the author for his interesting paper. After a response from Mr. Camm the meeting terminated.

**Reddish.**—A two-light window in the chancel of St. Mary's Church, Reddish, near Stockport, has lately been filled, to the memory of members of the present rector's family. The subject is the Resurrection, and the artists entrusted with the work were Messrs. Mayer & Co.

**New Buildings in Eastcheap.**—Amongst the several new buildings which have just been erected in Eastcheap, consequent upon the widening of that thoroughfare in connexion with the Inner Circle Completion Railway, is a large and prominent structure, not far from the junction with Gracechurch-street, and which is now ready for occupation. The building has been erected with a view to its utilisation for the tea and foreign fruit trades, two mercantile industries which have their centres in this part of the City. The building has a frontage of 100 ft. in length, and is 85 ft. high, containing six stories, and occupying a ground area of 10,000 ft. The ground floor portion of the frontage is relieved with polished red Aberdeen granite pilasters and columns, surmounted by capitals containing carving in stone emblematic of the fruits produced by various countries. The elevation of the upper floors is in six bays, divided by fluted pilasters, and again sub-divided by moulded and fluted multifoil windows. Above the ground-floor a deep carved frieze runs across the frontage, enriched by a profusion of carving. The interior of the building has been elaborately fitted and decorated. A large corridor 10 ft. in width, on the ground-floor, connects Eastcheap on the north with George-lane on the south, whilst on the floors above the east and west sides are also connected by corridors. In addition to the staircases access to the upper floors is also obtained by two hydraulic lifts running from the basement to the top of the building. They are worked from the mains of the Hydraulic Power Company, and fitted with Messrs. Waygood's patent safety check. A large amount of ironwork has been used in the construction of the building, some of the stanchions and girders weighing forty tons each. Mr. Delissa Joseph is the architect, and the general contractors Messrs. Perry & Co., of the Treadgar Works, Bow; Mr. Richardson being clerk of the works. The mosaic flooring has been supplied by Messrs. Diaspek & Co. The stoves and mantels are by Messrs. Chambers, Monery, & Co., and the carving by Mr. Gilbert Seale.

**Monument to the Emperor William.** In view of the nineteenth anniversary of the birth of the Emperor William of Germany, which will take place on the 22nd of March next, the Berliners are already making preparations for celebrating this event, but how the design is to be carried out is not yet settled. One committee has been organised which proposes to erect a huge obelisk at one of the most prominent points in the city in honour of the monogenarian Emperor. It was at first suggested that the structure should be an imitation of one of the ancient Egyptian obelisks of which we still possess several samples, and should even be ornamented with hieroglyphics, but it was subsequently decided that if this project is carried out the obelisk shall be of an entirely new design. A majority of the population of the German capital, however, appears to be opposed to this scheme. It is contended that Berlin is not by any means rich in monuments, and that the idea of an obelisk is quite unsuitable. Why not, it is asked, erect a pyramid or even a Greek temple? What may be the ultimate form of the monument will, however, have to be decided upon very soon, as the date for laying the foundation-stone will be the Emperor's birthday.

**Churches Burned Down.**—On Sunday morning last, the Church of St. John the Evangelist, at Hammoor, which is a suburb of Sheffield, was destroyed by fire. The church was opened nine years ago to meet the needs of the increasing population at the west end of Sheffield.—The Roman Catholic Church of St. Thomas of Canterbury at St. Leonard's was completely destroyed by fire on Tuesday morning.

**Results of Auction Sales in 1886.**—From official particulars contained in the *East Exchange Registers*, we learn that the total amount of the sales at the Auction Mart for the year ending 25th of December last was 4,120,044. The totals for the three previous years were as follow:—1883, 5,147,655; 1884, 5,976,931; 1885, 4,453,878.

**The Last of the Colonial and Indian Exhibition.**—It will be seen by an advertisement in this week's *Builder* that Messrs. Horns, Son, & Eversfield will, on Wednesday, January 19, and following days, hold an important sale of materials at South Kensington "Old London" and the Indian Palace will soon be things of the past.

**The Plumbers' Company.**—At the Quarterly Court held on the 29th ult., beyond the formal business, special Christmas gratuities were made to each of the pensioners on the company's pension list, and in addition the Master of the Company (Alderman Stuart Knill) presented the widow of each freeman with an annual grant of ten shillings payable to poor widows out of the City cash and in his gift as Alderman. A valuable piece of plate was presented to the late Master of the Company (Mr. George Shaw, C.C.) upon his retirement from three successive years' Mastership, in recognition by the Company of his able and zealous services in promoting the better education and registration of plumbers. It was reported that upwards of 250 plumbers (masters and journeymen) had been passed during the quarter by the Registration Committee (of which Mr. Shaw is chairman) as having qualified themselves for enrolment upon the company's register by giving satisfactory evidence of experience, or passing a practical examination.

**The Jubilee and Sanitary Improvement.** Mr. Mark H. Judge, as a member of the Paddington Victoria Jubilee Committee, has given notice that he will propose the following resolution:—"That in the opinion of this Committee the dust-collecting and other trades which are carried on in connexion with the canal basin, between Warwick-crescent and Praeger-street, besides being a continual menace to the health of the parish, are, during the summer months, a serious danger to the inmates of St. Mary's Hospital, and a source of annoyance to the Great Western Railway Terminus, which is often visited by Her Majesty the Queen and the Ministers of the Crown; that the Committee therefore considers that no better memorial of the Victorian Jubilee could be devised in Paddington than for the Vestry to purchase the canal basin and adjacent property, in order that this long-standing nuisance may be abolished and the site profitably utilised for residential and other purposes."

**Innholders' Hall.**—The new hall of the Innholders' Company, which has been erected upon the site of the old one in Little College-street (formerly Elbow-lane), was opened last month. The old hall is believed to have been the joint work of Wren and Mr. Jarman, the then City Architect, and was erected soon after the Great Fire in 1666. In some way not made quite clear in the account published in the Citizen, the building was allowed to get into a very dilapidated and even dangerous condition, and in November, 1882, the architect of the new hall, Mr. J. Douglass Mathews, was requested to make a survey of the old buildings, and some temporary repairs were made, but in December, 1884, other defects occurred that made it necessary for something of an extensive nature to be done, especially to the roofs and walls. The Court being extremely reluctant to destroy the traditions and old associations by entirely removing the buildings, considered the best means to be adopted to repair it; but this being found in a great measure impracticable, adopted the recommendation of the architect to preserve the old Court-room and the Livery Hall, as being the special portion of interest, and take down and rebuild the remainder of the premises. The works were commenced in the Autumn of last year. They comprise the re-building of the front portion and re-roofing the Livery Hall. The old doorway has been carefully reproduced in moulded brick, and the old door and frame, with canopy and arms, fixed. The entrance-hall, which is panellied in oak, has an angle fire-place, and an ornamental oak screen to the staircase. On the right is the old Court-room, which is unaltered, except that in re-building an extra width has been obtained. The paint from the wainscoting has been removed, and the oak is again visible, whilst the ceiling has been repaired where defective, and effectively decorated. A new panolled ceiling has been placed in the Livery Hall, which is entered from the entrance-hall by a new doorway, and has been re-roofed. The works have been carried out by Messrs. Brass & Son, builders, of Old-street; the cooking apparatus by Messrs. Waller & Son, of Fish-street-hill; the gas-fittings by Messrs. Strode, of St. Paul's-church-yard; and the stained-glass by Messrs. James & Co., of Kentish Town. The whole has been executed from the designs and under the immediate superintendence of the architect, Mr. J. Douglass Mathews, of Dowgate-hill.

**The Late Mr. Colin Minton Campbell.**—On Saturday afternoon the Duchess of Sutherland unveiled a bronze statue of the late Mr. Colin Minton Campbell, head of the firm of Mintons, and late M.P. for North Staffordshire, at Stoke-upon-Trent. The Marquis of Lorne said the Duchess wished him to express the very great pleasure she had had in being present on the occasion, and being able to greet that most admirable, most excellent likeness of the late Mr. Minton Campbell. He was glad to see that statue as a memorial of the great success which English manufacture had always achieved in the ceramic art, a success which each exhibition in every succeeding decade had emphasised more and more. In whatever branches foreign nations had been able to get the better of us, certainly in the ceramic art they had never got the better of Stoke-upon-Trent. [Mr. J. C. Horsley, writing to the Times in reference to this utterance, says that the Marquis of Lorne was "presumably in happy ignorance of the fact that the very firm (Mintons) he was so eloquently applauding has been for years past and is now entirely in the hands of foreigners as far as the art of ceramic work is concerned, it being in this respect under the sole direction of a Frenchman, who controls everything in the shape of design, which is carried out by French modellers and French painters to the exclusion of English artists, save in very subordinate positions."]

**Trade Memoranda.**—Mr. Frederick Higgs, builder, of Station Works, Loughborough Junction, announces that he has taken into partnership Mr. Henry F. Higgs (younger son of the late Mr. Wm. Higgs, of Crown Works, South Lameth). The style of the firm will be "F. & H. F. Higgs."—Messrs. J. Wontner Smith, Son, & Co., hot-water engineers, of Finchbury-pavement, announce that Mr. George Gray, jun., who has assisted in the management of the business since the death of Mr. Joseph Wontner Smith, sen., has now become a partner, and that in future the style of the firm will be "J. Wontner Smith, Gray, & Co."

 G. Hatfield .....

**KENSINGTON.**—For the erection of the Queen's Club, West Kensington. Mr. W. C. Marshall, architect. Quantities by Mr. E. J. Paine:—  
 Colls & Sons ..... £14,761 0 0  
 Patman & Fotheringham ..... 14,507 0 0  
 Rider & Sons ..... 14,328 0 0  
 Nightingale ..... 14,175 0 0  
 Bywaters ..... 13,852 0 0  
 Brass & Son ..... 13,869 0 0  
 Perry & Co. .... 13,500 0 0  
 Peck Bros. (accepted) ..... 13,530 0 0

**LONDON.**—For alterations at the Millford Haven public-house, 214, Caledonian-road. Mr. R. A. Lewcock, architect, Bishopsgate-street, Within:—  
 General Contractor.  
 T. Walker ..... £370 0 0  
 J. Heath ..... 125 0 0  
 J. Steadman ..... 91 0 0

**LONDON.**—For alterations at the Ploagh farm, 201, Horton-street. Mr. R. A. Lewcock, architect:—  
 S. Goodall ..... £173 0 0  
 J. Walker ..... 398 0 0  
 C. Hatchfield\* ..... 398 0 0  
 Finch ..... 391 12 0  
 Birch & Co. .... 359 0 0  
 J. Ivory ..... 344 10 0  
 Steel Bros. .... 330 0 0  
 Jackson & Todd ..... 329 0 0  
 Spencer & Co. .... 325 0 0

Steadman ..... £20 0 0  
 Unger ..... 19 17 0  
 Christian ..... 18 7 0

**LONDON.**—For improvements at 331, Edgware-road, W. Mr. R. A. Lewcock, architect:—  
 Batchelder ..... £203 15 0  
 Pringle ..... 167 0 0  
 Belloni ..... 129 10 0  
 Dainton ..... 128 0 0

**LONDON.**—For new coffee-tavern, Victoria Dock, E. Edward J. Thomas, A.R.I.B.A., architect, Mark-lane. Quantities supplied:—  
 Shepherd ..... £2,724 0 0  
 Madisson ..... 2,715 0 0  
 J. H. Thorns, Leeds ..... 2,575 0 0  
 Holland ..... 2,349 0 0  
 Elkington ..... 2,280 0 0  
 Patman & Fotheringham ..... 2,130 0 0  
 Priority ..... 2,070 0 0

**SUNDERLAND.**—For the erection of the new Municipal Buildings, Mr. Brighton Eynon, architect, Ipswich. Quantities by Mr. G. D. Irwin, Sunderland:—  
 G. Grimwood & Sons, Sudbury ..... £27,690 0 0  
 W. Scott, Sunderland ..... 25,383 0 0  
 J. H. Thorns, Leeds ..... 24,967 10 0  
 W. Thornton & Sons, Liverpool ..... 24,435 0 0  
 C. Jackson, Newcastle ..... 24,433 12 0  
 J. Elliot, North Shields ..... 24,265 0 0  
 T. P. Shatto, Sunderland ..... 24,191 10 0  
 J. W. Beadland, Bradford ..... 23,967 0 0  
 S. Warburton, Manchester ..... 23,900 0 0  
 E. H. & G. Allison, Sunderland\* ..... 23,870 0 0  
 \* Accepted.

[Architect's estimate, 25,000].  
 \* \* The above tenders are exclusive of the heating and ventilation, which it is estimated will not exceed 1,100.

**TIVERTON.**—For the erection of four houses on the St. Aubyn's Estate, Tiverton, for Mr. W. Helling Lloyd. Messrs. Wilkinson & Warren, architects and surveyors, Exeter:—  
 Pyle & Grater Bros., Tiverton ..... £3,940 0 0  
 Barrons, Tiverton ..... 3,600 0 0  
 Scadding & Son, Exeter ..... 3,200 0 0  
 J. G. Stephens, Exeter (accepted) ..... 3,175 0 0  
 Manning & Collard, Tiverton ..... 2,858 0 0

**SPECIAL NOTICE.**—Lists of Tenders frequently reach us too late for insertion. They should be delivered at our office, 48, Catherine-street, W.C., not later than four p.m. on THURSDAYS.

FIRE BRICKS.

**E. BOWEN, Fire Brick Manufacturer, STOURBRIDGE.**  
 Manufacturer of Best Stourbridge Fire Bricks, and Cement Fire Clay Gas Reports, Quills, &c. Fire Bricks and Blocks for the Highest Heats, for Iron Blast Furnaces, Forge, Rolling, Puddling, and Steel Furnaces, Factory, Boiler, and Blast Glass Furnaces, Roasting and Refining Furnaces, Chemical Works, Coke Ovens, &c. Boiler Sealing Blocks, Fire Clones, Locomotive Bricks, Tapers, Steel Runners, Grade Bricks.  
 Special Sizes and Shapes made to Engineers' Drawings. Prices quoted to any Railway Station. London Agents:—  
**R. CULL & SON, Palmerston-buildings, E.C.**  
 Stores:—Railway Arches, Corner of London-street and Brady-street, near Bethnal Green Station.

GLAZED BRICKS.

**OATES & GREEN, HALIFAX.**  
 GLAZED BRICKS (White and Coloured), Special Salt Glazed Bricks, Sanitary Pipes, Glazed Earthware Bricks, Cattle, Sheep, and Pig Troughs, Horse Mangers, Patent Automatic Trough Closet, Patent Flush Tank, Channelling for Sinks and Yards, Salt Glazed Bricks for Stables, &c. &c. Ventilating Bricks, Patent Ventilating Gallies and Traps, Garden Fencing, Patent Chimney Flues and Curbs for Down Downpipes, &c. &c. **PRIZES AWARDED.**  
 six Prize Medals. Copies of Testimonials sent if required.  
 London Agents:—  
**R. CULL & SON, Palmerston-buildings, E.C.**  
 Stores:—Railway Arches, Corner of London-street and Brady-street, near Bethnal Green Station.

BLUE BRICKS.

**THE KETLEY BRICK COMPANY, Manufacturers of Staffordshire Blue Bricks, BINGHAM FORD, near Wolverhampton.**  
 London Agents:—  
**R. CULL & SON, Palmerston-buildings, E.C.**  
 Stores:—Railway Arches, Corner of London-street and Brady-street, near Bethnal Green Station.

DRAIN PIPES.

Lime Cement, Bricks, Slates, Laths, Hair, Sand, Plaster, Stable, Paving Bricks, Wall Copings, Channel Bricks, Blue and Red Tiles, Red Fish Tiles and Pav Tiles, Closet Pans and Traps, Drain Pipes, Bends, Junctions, &c. all sizes. Chimney Pots, Red and White Fire Bricks, Lungs, Tiles, Fire Clay. **PRICES ON APPLICATION.**  
**R. CULL & SON'S** Stores, Railway Arches, Corner of London-street and Brady-st., near Bethnal Green Station. Chief Office:—72, Palmerston-buildings, Old Broad-street, E.C.

### The Trade Guilds of Europe.

IN a previous article we sketched the progress of the rise and organisation of trade guilds in past times.\* Turning to the more modern aspect of the subject, we find that the status of trade

guilds in Germany was fixed by the passing of an Act for regulating trade and industry, in 1871. By that Act trade guilds were deprived of many privileges, and reduced to the position of voluntary associations. Guilds and guild statutes were allowed to exist, but it was at the option of any one to enter or withdraw from such societies at pleasure. The duty of inspection and supervision was transferred to the Government authorities, who also were to decide all questions as to duties and rights of members. All persons belonging to a trade might form a guild under similar conditions. The relations between persons in industries or trades and their apprentices, assistants, and journeymen was to be a matter of contract, and the old system of workmen's books, books delivered to the workmen by the police, and intended to control their entering and leaving the service of employers, was abolished. In 1878 another change was made. The workmen's books were restored, and the guilds, though not made compulsory, had some of their old privileges restored. Power was given to create industrial schools, to make rules for advancing industrial and technical instruction, to establish a system of examination, for testing the capacity of apprentices, journeymen, and masters, and to appoint tribunals of arbitration, whose decision should be final. In 1884 another Act was passed, prohibiting masters who did not belong to a guild from taking apprentices. This Act, though much wished for, has not given entire satisfaction to the tradesmen, especially in Bavaria. On the whole, a new era seems dawning for the guilds, with some signs of its being a successful one.

The tailors' guild of Berlin, though not one of the trades with which we are specially concerned, may be conveniently cited as typical of the general formation and regulation of the guilds. Statutes enact that as apprentices only such young persons shall be taken as have the requisite elementary school education, and are neither mentally nor physically unable to learn the trade. The master has, either himself or through a competent representative

expressly appointed for the purpose, to superintend the training of the apprentice and instruct him in everything pertaining to the trade. The Stettin guild rules require every apprentice before being admitted a journeyman to pass an examination before a committee of the guild. If he fails to pass the examination the committee can order him to serve from three to twelve months longer as an apprentice. If the committee are of opinion that the apprentice's deficiency of knowledge has been caused by the fault of the master, they may allow the apprentice to pass the further time required with another master, while his former master has to pay him the customary wages of a journeyman. The time served by apprentices varies from one to four years,—the average is generally three years. As a rule, it is only the art trades, such as jewellers, modellers, and ornamental painters, that require four years. Some guilds have trade schools, *Fachsschulen*, but they suffer from the competition of the *Fortbildungungen Schulen*, attendance upon which in some cities is compulsory, and in other cases are insufficiently sustained by the guilds themselves.

Great stress is laid upon the systematic training of the apprentices for their respective trades, and upon the proficiency of the journeymen. People both in official and private circles do their best to raise the condition, education, and well-being of the productive classes, and to enable workmen to compete successfully with foreign competition; yet the feeling between employer and employed is described to be that of desperate enemies, especially in manufacturing districts. The hours of labour vary in different parts of the empire from sixty to seventy-two hours a week. Wages also fluctuate, some trades being better paid in certain districts than others.

In Austria, owing to causes somewhat similar to those in Germany, some craft-guilds have been re-founded. Membership of them is compulsory upon all carrying on the particular trades in connexion with them. They exercise a certain trade control as far as the test system of proficiency, which is compulsory, has been re-established. In all other respects every one can carry on whatever trade he pleases. The relations between employer and employed are excellent.

In France no bodies resembling the ancient corporations exist. What organisations exist are more of a social than a business nature. In 1884 an Act was passed for the purpose of allowing the formation of working men's guilds. It gives little more power than formerly to form associations which shall have the exclusive object of studying and protecting industrial interests.

With the exception of the building and

mechanical trades, labour is unorganised. In Marseilles the question of wages is largely controlled by the 50,000 Italian workmen who live there. They work for less wages than the French, and no strike can be successful while these Italians stand aloof. Women are employed in almost every calling, from agriculture to street cleaning. Saving is one of the leading principles of the workpeople, and all are taught the economy of helping to swell the general family fund. In the production of machinery France is becoming eminent, and the advance in wages is marked,—the amount being equal to that of England, and in special cases superior. The hours of labour are from 60 to 84 a week, the average being 70.

In Switzerland, the old corporations have long disappeared in the character of active industrial organisations. Those which exist are kept up for social purposes, or for the management of the property which they have inherited. So far as apprenticeship is concerned, there are no regulations or restrictions of any kind. A person desiring to learn a trade can do so wherever he can find any one to teach him, and whosoever can may give him instruction. There are, however, efforts made in various places to afford apprentices facilities for acquiring the technical knowledge necessary for perfecting themselves in their respective occupations. Among the tradespeople generally there is a strong feeling of the necessity of cultivating and developing the thorough practical and theoretical knowledge required for practising the various trades successfully. The subject of technical education is left entirely to the State. The feeling between employers and employed is pleasant. In some cantons the organisation of labour is generally based upon the idea of permanency, and workmen are usually engaged by the year. There is a Swiss general trades-union. Among its objects are:—Obligatory examination in all trades of apprentices; laws governing apprenticeship; laws and regulations in general more protective than at present, but not so as to introduce the old system of the compulsory guilds. The hours of labour are seventy a week.

In Italy, none of the ancient guilds survive. There are no laws or regulations governing apprenticeship. Much attention has been paid to technical instruction since the acquisition of Venetia. All the so-called special schools then existing have been remodelled into a general plan of instruction for the entire kingdom. They seem to have partly failed in their object, and to have been more frequented by the well-to-do middle-class than by those for whom they were intended. "It is difficult to foresee the time when their usefulness will find its full scope. The facts

\* See *Builder*, March 8, 1868, p. 361.

so far seem to confirm the supposition that the Italian genius and temperament are not favourable to systematic industry, the masses being impatient of the constraint, while the rural population regard the occupation as demoralising and unwholesome. Millowners generally complain that the want of training, both for foremen and operatives, is a heavy disadvantage in conducting their establishments, only compensated by the extremely low price of labour. When it is remembered that even where these establishments have existed from father to son on the same spot, they have not succeeded in forming a body of capable hands, the fact certainly adds force to the presumption of inaptitude." But perhaps the view of technical instruction on the employers' part may be to blame. In Venetia the technical institutes and trade schools are gaining in number, but "are far from serving the purpose intended, or receiving the adhesion and confidence of the population. They are still regarded as impractical or unnecessary by the mass of labourers wedded to their antiquated routine, and whose numbers are recruited from the swarming hordes of untutored and half-savage children, tempted to the workshop where they are employed for a few centimes a day to do odds and ends of work, and pick up what notions of the trade they can gather. And such is the natural aptitude and intelligence of the race, that where the occupation interests and attracts, and particularly in all those more or less elegant fabrics which appeal to the artistic instinct, they need no other training to become accomplished workmen."

In the peculiar and characteristic Venetian industry of glass-making all public teaching of its practice has been tacitly proscribed. Each establishment is jealous of its imagined monopoly, and the processes employed are guarded as trade secrets. As, however, all the processes of the manufacture are extremely simple and depend almost entirely on dexterity, tact, and taste, it may be doubted whether systematic instruction could add greatly to the skill acquired by practice in the workshop, or replace the aptitude implanted by nature.

The relations between employer and employed are good. Much fault is found in the neighbouring countries, especially in Germany, at the importation of Italian labourers whenever any large contract is to be executed. These labourers are supplied to any number by contract agents, and they arrive on the ground with something like the mobility and precision of troops. Their work is promptly and thoroughly executed. The hours of work are at Turin sixty a week.

In Holland there are no guilds and no restrictions upon trade or its exercise. With regard to the absence of all laws or regulations relating to apprenticeship, the want of system is extremely unsatisfactory. A change in this respect is urgently called for, and is likely to take place soon. The feeling between employers and employed is satisfactory and improving. Trade organisations are numerous. One of the principal is the Grand Dutch Trades Union, which aims at the amalgamation of all trades. Among its objects are: ten hours to constitute a day's labour, the limitation of the work of children, and general advancement of the interests of labour through co-operation. In general trades the hours of labour are sixty a week, though in some they reach seventy-two.

In Belgium there are no corporations, civil or religious. There are no laws or regulations governing apprenticeship. Trade-unions are numerous. Many factories are carried on in partly paternal principles: invalids receive medical attendance free of charge during illness, and are allowed half their wages. Food is supplied to the operatives at wholesale prices. A pension for life is paid after a certain number of years' service. Houses are also provided at low rents. The hours of labour are sixty-nine a week.

In Denmark guilds of journeymen exist, but only as benefit societies. The relations between employer and apprentice are in no way controlled by law or regulations, but are a matter of agreement between the two parties. On the

side of both there is a desire for some readjustment of the relations between them. Technical schools for the advancement and instruction of the working classes are numerous. They are nearly all held in the evening, and are mainly supported by the State. The hours of labour in Copenhagen are sixty a week.

In Russia guilds exist, but only nominally. Of their rules, which are very numerous, hardly any are carried out. Bob in Poland and Russia apprentices are required to pass an examination before becoming journeymen. The Russian peasants are strongly imbued with a tendency to unite in associative societies having a community of interests. One of the most interesting examples is the Russian "Artes," or associative labour society. These societies are established on communistic principles, and are liable for any loss caused by their individual members, and permeate all branches of trade. The labour conditions of Russia are peculiar to that empire. Although serfdom is abolished, the feudal relationship still exists to an extent which makes comparison difficult. The system of boarding and lodging employes in the factories prevails. Some attention is paid in the large towns to technical education, but in the villages the only instruction available is a certain amount which it is the duty of the village priest to impart, but over which there is no control. Wages in St. Petersburg are regulated more by individual bargaining than by any fixed rate, and are of such a discrepant character that they cannot be included in the general average. The hours of labour average seventy-two a week.

In Turkey there are trade guilds existing, but they are chiefly co-operative societies for mutual benefit. Of their nature that of the *hamels* (porters) furnishes an example. Each quarter of Constantinople has its own porters, all being under one chief or head, who is recognised by the Government and who buys his place. The chief pays to the Government the taxes of all the members, who can only work in their assigned quarters. The total earnings of each day are divided *pro rata*, and in cases of disability or illness they relieve each other. There are no labour organisations. The hours of work are from daylight to one hour before sunset. The wages in Constantinople are about the same, perhaps on the whole a little higher, than in other large cities of Europe. In villages distant from the capital and rural districts they are extremely low. The great cost of internal communication, and

the absence of highways, railways, and waterways, have had the effect of localising industries, hence each community has conditions of trade peculiar to itself. In Turkey, everything being accomplished by hand, manual labour is in great demand.

In Spain what guilds remain are only for purposes of assistance and benevolence. There are no laws or regulations governing apprenticeship, nor are there any schools in which trades are taught. Generally boys enter a factory or workshop, and gradually develop into workmen, the time depending upon the capacity of the individual and the difficulty of the pursuit.

In Portugal there are trade companies existing, but as voluntary associations. Wages are very low around Lisbon; general trades run from 2s. 6d. to 3s. 4d. a day; in exceptional cases they reach 6s. 3d., and sometimes are as low as 2s. 1d. The hours of labour are from sunrise to sunset.

In the United Kingdom guilds survive in a few places, but under changed conditions. Their importance as an aid or protection to trade has long disappeared, and they now only exist for benevolent and social purposes. The goldsmiths' guild of Edinburgh retains a few of its ancient features. Every member must have served an apprenticeship of seven years in the trade, and must either have served two years additional under a master or have been in business a similar time on his own account. By the term of his indentures the apprentice is bound to the guild and not to the master whom he is to serve.

The greatest stimulus to technical education has been given by the City and Guilds of London Institute, which not only carries on schools of its own, but subsidises other institutions that have a similar object. It extends its assistance to all the principal industrial centres of Great Britain. Instruction of the better class is its main object, and it in no way interferes with the relation between employer and employed.

The labour organisations, especially in the North of England, are both numerous and powerful, hardly any trade being without its union, and few workmen who do not belong to a benefit or protective society.

The subjoined table, showing the advance or decrease in the wages of the principal building trades in most of the European states from 1879 to 1885, compiled from recently-published statistics, may be of interest in connexion with the subject:—

Table showing Comparative Average Weekly Wages in 1879 and 1885:—

| Occupations.     | Germany. |       | France. |       | Belgium. |       | Italy. |       | Denmark. |       | Switzerland. |       | England. |       |
|------------------|----------|-------|---------|-------|----------|-------|--------|-------|----------|-------|--------------|-------|----------|-------|

VANDYCK AT THE GROSVENOR GALLERY.

All foreign artists the two who exercised the most important influence upon English art were Holbein and Vandyck. Holbein's influence was less permanent, because the demand for portraits was relatively small in the times of Henry VIII. and Elizabeth, and so no considerable school of artists could be maintained. Holbein was not forced by circumstances to surround himself with a great number of assistants. In the time of Charles I. there were many more people who desired to have themselves portrayed,—so many, in fact, that Vandyck alone was utterly unable to supply the demands made upon him. He had to call in the aid of numerous assistants in order to complete, with their help, the various orders thrust upon him. Of ten pictures sold out of his studio scarcely one was even mainly his handiwork, and many he hardly touched. His assistants were, therefore,

obliged to imitate his style, and carry out in that the works which he would sell as his own. Thus Vandyck impressed his style upon a whole group of men in his employ, and that style, having once become popular, soon became national. In this way Vandyck became the father of the true English school of painting, and his traditions were more or less closely adhered to, generation after generation, by Sir Peter Lely, Sir Godfrey Kneller, Richardson, Hudson, and the rest, till in due time the school of Reynolds and Gainsborough arose to carry them to fresh developments.

Thus, an exhibition of the works of Vandyck, and especially of those painted during his residence in England, is of peculiar interest to all students of English art; and from such an exhibition the works painted by assistants in the master's studio ought by no means to be excluded. The collection now brought together at the Grosvenor Gallery satisfies all our requirements. It contains a sufficient number of typical works of the artist's earlier period to enable us to trace the growth

of his style. It contains several very fine specimens of the best works done by the master himself in England; and it completes and supplements them by a tolerably large number of those school pictures whose origin and influence we have explained.

It is but natural that some of the pictures exhibited should have crept in on false pretences. We will mention only a few of the most conspicuous imposters. The finest of them is Mr. Holford's "Portrait of a Spanish Officer" (68), which has only recently been attributed to Vandyck, and which certainly cannot be by him. It is painted in the style of Caravaggio, though probably not by that master either. Neither can the "Portrait of a Lady" (6) have been painted by a pupil formed in the school of Rubens and newly arrived in Italy. Mr. Claude Phillips ascribes it to Justus Suttermans, and the ascription is well worth consideration. The "Sir Anthony Vandyck on Horseback" (70) should not have been included in this or any other exhibition of admirable works of art. The "Sir William Killigrew" (119) does not depict that personage at all. It is a painting by Dobson, which once belonged to Horace Walpole. He relates that when found by the man from whom he bought it the left side and bottom of the canvas were ruined, and the name, "John Milton," was on the back. The inscription, now clearly legible upon it, was painted in by some forger between the time of the Strawberry Hill sale and the purchase of the picture by the Duke of Newcastle.

The catalogue is carefully composed, but contains much information with which a visitor could dispense, and lacks much which he might well expect to find in it. The following, amongst other corrections, require to be made in it. No. 24 is not George, but William Villiers, Viscount Grandison, father of the famous Barbara Villiers. Endymion Porter (31) was not a knight; the gentleman depicted in No. 32 holds a pear in his hand, and is not in the character of Paris; the Countess of Southampton (42, 123, and 148) is not represented as "Fortune," but as "Juno." Nos. 52 and 75 both portray Charles Louis, Elector Palatine, son of Frederick V. No. 95 should bear the name of Edward Sackville, fourth Earl of Dorset, and No. 101 that of Frances Leigh, second wife of Thomas, Earl of Southampton, Lord High Treasurer of Charles I. The "Portrait of a Lady" (106) used to be known in the family as the portrait of "Viscountess Boyle of Kenelmekey," daughter of the first Earl of Denbigh. The Queen's picture (109) represents not Sir William, but Thomas Killigrew, and No. 119 does not represent a Killigrew at all. Count Gondomar is not seen in No. 116, but some other fine Spanish gentleman. It should be stated that the St. Martin (134) is a study for the famous Saventhem picture, and the St. Sebastian (136), a study for the well-known picture now in the old Pinakothek at Munich. No. 140 represents Margaret Smith, afterwards Lady Herbert.

The visitor to the Grosvenor Gallery will scarcely expect us to supply him with a guide to the collection. It will be enough if we point to a few of the most representative works exhibited, briefly indicating the period of the artist's development to which they belong. Vandyck was born at Antwerp in 1599. In 1609 he was a pupil of Hendrick van Balen of Antwerp. In his fifteenth year he entered the studio of Rubens. In 1618 he attained the rank of master in his craft. The "Betrayal of Christ" (125) is an excellent specimen of his style when he was working under the immediate influence of Rubens. It is ugly, no doubt, but it shows great vigour, and is rich in such as yet unrealised possibility. In 1621 Vandyck determined to visit Italy; before doing so he painted the famous picture of "St. Martin" at Saventhem, near Brussels, the study (134) for which has been mentioned. He then visited Venice, where the works of Titian and Tintoret must have produced a profound impression upon him. This is plainly shown in the picture of "Armida and Rinaldo" (19); study for it, 73, where the Venetian style is found in conjunction with clear reminiscences

of Rubens. The very Titianesque head of Armida reappears upon the shoulders of St. Catherine in the Madonna picture (51), but the type of the Virgin is there borrowed, perhaps, from Parmegino. Rome and Genoa were the Italian cities in which Vandyck resided for the longest time. His two visits to the latter city may almost be regarded as settlements there. The pictures painted for Genoese patrons are amongst the finest of the artist's works. The present collection contains some fine examples of the period, the best being, perhaps, the Marchesa Balhi (77), and the charming group of her three children (29); the Marchesa de Brignolè-Sala and her son (18), Lord Cowper's fine full-length portrait of a gentleman (26), and Don Livio Odesalchi (37). About 1626 or 1627, Vandyck returned to Antwerp, and his second Flemish period commenced. It was then that he painted the picture of Snijders and his Wife (23), and the other portrait of the same lady (79). The original replica of the "Christ taken down from the Cross" (144),—the large version of which is in the Antwerp Gallery (No. 403 there),—dates from the same period. If the portrait of a lady (106) be Viscountess Boyle, of Kenelmekey, it must, at any rate, belong to this period.

Early in 1632 Vandyck arrived, for the second time, in England,—the country which was henceforward to be his home. He made a few visits to his native land afterwards, probably during one of which he painted the noble portrait of the Abbé Scaglia (54),—a picture scarcely inferior to any that ever came from his brush.

Vandyck's portraits of Charles I., Henrietta Maria, and their children, are very suspiciously numerous. Doubtless the majority of them were sold by the painter on the clear understanding that they were only produced under his supervision and from his designs. None of the portraits of Charles I. here shown possess any valid claims to originality. The best is a half-length of the king and queen (25), upon part of which the master may have worked. The half-length in armour (39) is a good replica of a well-known type. The full-length with the Marquis of Hamilton (63) is a late copy of the Louvre picture, and No. 99 bears the same relation to the Windsor canvas. With Henrietta Maria we are more fortunate, the full-length of her with Sir Jeffrey Hudson, the dwarf of "Peveril of the Peak," being one of Vandyck's finest English pictures. The Queen's picture (41) is a worthy example of the attractive group of paintings which depict the royal children, though it is doubtless surpassed by the bewitching picture in the Turin Gallery.

It was fitting that the artist should employ all his skill upon the likeness (8) of the cultured patron to whom he owed so much, the Earl of Arundel, father of English amateurs of art. With respect to the replica of this picture, now on view at the "Old Masters," it may be observed that that picture has been very ill-treated by restorers. Originally it must have been fine, but besides being flayed and re-painted in parts, it has had great strips of canvas added above, below, and down the right side, and on the lower strip hideous legs have been painted, thus making both figures into full-lengths. Vandyck was no less lavish of pains when painting his own portrait (1) where he holds the chain which the king had given him and points to the sunflower, speaking symbol of the man who would sun himself in the smiles of royal favour. One of the signs of that favour, or, at any rate, interest, was the wife provided by the king for the artist. Her portrait (114) be painted with similar care and completeness of surroundings. It is a pity that Lord Fitzwilliam's fine portrait of Stafford is not included in the collection. Its place is but poorly supplied by two canvases (43 and 46), upon neither of which is the master's handiwork apparent. The larger of the two bears a striking portrait nevertheless. Three full-length groups, each of two expensively-dressed youths, will attract the attention of every visitor. Two of them (47 and 105) represent the same pair. Lord John

and Lord Bernard Stuart. The third (112; 120 is a poor copy of it) shows the pucious forms of the Earl of Bristol and the Duke of Bedford. All three are painted in Vandyck's most gorgeous manner. Much less striking, but far more interesting for the sake of the personality displayed, is the portrait of Lord Falkland (87). The smiling face and lambent eyes will not fail to rivet the attention when once it has been directed to the picture. The group of Killigrew and Carew (109) possesses something of the same quiet charm, but is painted with more care and elaboration. It is, perhaps, with its quiet reserve and low tones, the finest picture in this most interesting exhibition.

NOTES.

**T**HE American iron and steel trade has been exceptionally active during the past year, whilst the prospect for the present year is even more favourable. The production of pig-iron for 1886 is estimated at 5,600,000 tons against 4,044,526 tons in 1885; of Bessemer steel ingots, 2,000,000 tons against 1,519,430 tons; of Bessemer steel rails, 1,500,000 tons against 959,471 tons; of open-hearth steel, 200,000 tons against 133,375 tons in 1885. Notwithstanding the increase in the output, prices have advanced but slightly. Anthracite Foundry pig-iron No. 1 was worth, at Philadelphia, 18'50 dols. per ton on January 1, and 20'50 dols. on December 23, 1886; grey fore pig-iron No. 1, at Pittsburgh, 16 dols. and 20 dols. respectively. Best refined bar iron sold at Philadelphia at the beginning of the year at 40'32 dols., and at its close at 44'80 dols. Steel rails at Eastern mills rose from 34'50 dols. to 37 dols. During 1886, over 7,000 miles of new railways were constructed in the United States, compared with 3,131 miles in 1885. This large increase has contributed greatly to the improvement in the American iron trade. Close upon 800,000 tons of steel rails have already been ordered for delivery in the present year, this being about half the producing capacity of American rail mills.

**T**HE meeting for the promotion of the scheme of the Imperial Institute was, no doubt, a success, in spite of the irrepressible mover of amendments who was finally invited out by the police; but no attempt was made to settle the question of site, although the subject was alluded to in the course of the proceedings. We are very strongly of opinion that Kensington will not do, either from the point of view of sentiment or practical suitability, and we hope an effort will be made,—even a national effort, if necessary (for is it not a national interest?),—to raise the funds for securing a site in the neighbourhood of the Houses of Parliament and public offices. Unless this is done, the Imperial and Colonial Institute will not be the great success which it ought to be, and which we hope to see it.

**T**HE Town Council of Glasgow intend to oppose the Clyde, Cart, and Kelvin Main Sewerage Bill, which is a straightforward measure, intended to remedy the present intolerable state of those waters. The Bill proposes the constitution and incorporation of a joint Board, which shall be the governing body of the united district, to consist of fifteen *ex officio* and twenty-five executive members, the latter to be elected by the Town Councils of Glasgow and Paisley, the Police Commissioners of Govan, and the local authorities of various parishes named in the schedule. The purposes for which the district is to be formed are the purchase of land and property, the erection of buildings, machinery, and plant, construction of main drains, and the purifying of the sewage so that it may be discharged into any stream, river, or water-course, without breach of the Rivers Pollution Prevention Act, or any other provisions of the law. It does not, however, seem that the promoters of the Bill have taken the proper preliminary step of obtaining a professional report as to how so important and unprecedented a result is to be obtained.

THE Tottenham Local Board have contrived to fit things together very successfully in their application for a loan to enable them to employ labour in improving the roads in the parish. It seems that these roads, taken over a good many years since, are in a very bad state, and that the parish cannot afford to repair them out of the current rates. The present is a good time to get the work done cheaply, and it is work that requires to be done. We have the strongest opinion against the well-meant but pernicious and delusive system of creating work for bands that are out of employ; but this seems to be a case in which a clear-sighted economy has been combined with beneficent intentions. Mr. Ritchie, M.P., who received a deputation from the Tottenham Board on the subject, promised that an inspector should see the roads in question, with a view to the authorisation of a loan.

PRINCE TORLONIA, by draining a lake formed in the crater of an extinct volcano, in the Apennines, transformed an insalubrious belt of swamp and marsh into good productive land, at the same time carrying out a work that was commenced in the reign of the Roman Emperor Claudius. Sir F. de Lesseps, who is one of the honorary members of the Institution of Civil Engineers, has contributed to the Transactions of that Institution some particulars of a work carried out in Tunis for a like purpose, although the means adopted are exactly the reverse of those pursued by Prince Torlonia in the case of Lake Fucino. It appears that Colonel Roudaire has spent many years in Tunis, levelling, boring, and making experiments of various kinds, and has satisfied himself that the four "shots," Tedjedj, Djerid, Rbarsa, and Melrir, situated 77 ft. 6 in. below sea level, could by means of a canal be formed into an inland sea. This would influence the climate and fertility of the surrounding country to a considerable degree, the area being 3,164 square miles, which is about forty-times that of Lake Geneva. Owing to the expense that would be involved in carrying out this scheme another method has been devised. From the discovery of Roman aqueducts formerly employed in irrigation, the idea was suggested of rendering the country fit for cultivation by sinking artesian wells, which would supply the necessary water. The water-rents obtained were to be in part devoted to the construction of the canal. The first well was started in 1855. At a depth of 295 ft. water was found, which rose to a height of 15 ft. The flow for the first year averaged about 1,760 gallons per minute, and is now 19,800 gallons per minute. "The banks of the river Melab," says Sir Ferdinand, "which, fifteen months ago, were deserts, are now populated, and very shortly the canal is to be commenced." Marshal Bugeaud has said that the civilisation of the French African possessions would come from below,—that is, would depend on the subterranean water-supply.

IN the current number of the *Fortnightly Review* Sir Lowthian Bell goes into the subject of "The Iron and Steel Trade," mainly with the object of comparing the state of the trade in America with our own, and estimating the probability or possibility of America generally outbidding us in all the markets of the world. The article contains much interesting information and suggestion, which would be more readable and appear more to the point had it been arranged in a more connected, logical, and argumentative form. As it is, it is not always easy to see what the writer is specially driving at in the facts which he adduces, or what is the connexion between the observations of one paragraph and the statistics of the next. The general conclusion we are brought to at last, however, is that while America possesses a sufficiency of the raw material in the shape of ore (the limits of which are, in fact, not fully known yet) and a splendid stock of fuel, the fuel is too far from the ore, and consequently from the smelting furnaces, and the latter too far from the sea-coast, for America to be able permanently to undersell us in the pro-

duction of iron. "We hope here be truths." It should seem that in some lights the size of a country may be a drawback to its business working; and Sir Lowthian's conclusion is practically the same as that arrived at by an eminent English comedian who was asked, when on a tour in the States, if he was not impressed with the size of the country, and replied that he had noticed it took a very long time to get from one town to another, "but he did not see the advantage of it."

THE recent case of *in re Carus-Wilson v. Green* helps to make clearer the difference between a mere valuer and an arbitrator. In this case timber on land was to be paid for at a valuation; each party was to appoint a valuer; the two persons before they began to act were to appoint an umpire, so that if they disagreed he should give a decision. The disagreement came about, and the umpire made a valuation, and the question then arose if this was an award so as to come within the cognisance of the High Court. The Court of Appeal, as well as the Divisional Court, held that it was not an award by an arbitrator. The reason of the decision is thus shortly given by Lord Esber:—"The umpire 'was merely substituted for the valuers to do what they could not do, viz., fix the price of the timber.' This is a simple and clear *ratio decidendi*, and it is well that it should be borne in mind, for it will often be applicable in the business practice of most persons."

THE Proceedings of the Institution of Civil Engineers contain some particulars of an American pumping dredger, which has recently been at work at Coney Island, near New York. A strongly-built barge has a heavy framework, 25 ft. high, erected on it. This is closed in, and contains two platforms, on the lower of which the boilers and machinery are placed. Round the top of this framework an outside overhanging road is placed, upon which a truck runs, having a dredging pulsometer steam pump suspended from it. An iron suction-pipe is fastened to the lower end of the pump, at the bottom of which is a digger, consisting of about eleven vertical prongs, which surround and protrude below a horizontal circular strainer. The digger, bearing the weight of the pump, which is about two tons, has an oscillating movement imparted to it by the pump, and thus loosens the material on which it rests. An iron discharge-pipe extends upwards from the discharge of the pump, and delivers the dredged material into a central hopper at the top of the framework in the barge. From thence it is conveyed ashore by means of a trough supported on a floating staging. Owing to the elevation, the material can be deposited 1,000 ft. from the barge. In actual work, this dredger has raised an average of 50 per cent. of solid material out of the total volume lifted, and under favourable circumstances it has a capacity of 10 cubic yards per minute. Illustrations and a fuller description of the Badger Dredger may be found in the *American Mechanist* of February 6, 1886.

A NEW type of steam excavator has been designed for use in the work of constructing the Panama Canal. The ordinary chain of huckets is used, but the supports are placed some distance back from the edge of the cutting. It will excavate over a range of 26 ft. 3 in. deep, 14 ft. 9 in. wide, and any required length, without changing the road. The material is carried away to a distance of 180 ft., to be deposited by means of a transporter worked by travelling hands. There are two platforms one above the other. The lower is carried on twelve pairs of wheels, 14 ft. 9 in. centres, which run on rails. The upper platform is traversed across the lower one upon sixteen rollers. For propelling the machine, and traversing the upper platform, there is a 15-horse-power engine placed on the lower platform. The excavating machinery consists of a chain of twenty-three buckets, each having a capacity of about 10½ cubic feet. The motive power for excavation is supplied by a 100-horse-power engine. To work the

machine the upper platform is carried to the inside edge of the lower platform, and the buckets are set to work. When they have reached their limit of depth, i.e., 26 ft. 3 in., the platform is gradually moved back as the excavation goes on working at a speed of twenty-three buckets per minute, 438 cubic yards per hour could be removed.

SOME particulars are given in a recently published volume (vol. iii, fourth series), *Nouvelles Annales de la Construction*, of the Seine quay walls that have lately been constructed at Rouen, in a manner somewhat unusual, if not entirely novel. The bed of the river Seine, at the spot where these walls are constructed, is 22 ft. below the required quay-level. It is composed of a layer of silty sand, resting on chalk, the latter being 25 ft. below the bed of the river. Four rows of wooden piles were driven down through the sand until they reached the chalk. These piles slope forward towards the front, and on them a wall, 18 ft. high, has been built. Up to a height of 5 ft. 6 in. this wall is composed of concrete, and is 11 ft. wide. The rest is built of rubble masonry, and is 6 ft. 6 in. at the bottom. In order to keep the thrust that would be exerted by the filling off the wall, a platform was constructed on piles, and on this rested a layer of rubble stone, the whole extending back far enough for the natural slope of the filling. The wall is faced with brickwork, and cost about 24s. per foot run. The characteristic feature of this method of construction is its low cost. A somewhat similar plan was followed in constructing quay-walls on the Hudson, and so long ago as 1837 sloping piles were used for extending forward the foundations of quay-walls on the Clyde.

THE Municipal Council of Paris appears to have solved the difficulty of providing public conveniences for both sexes in a satisfactory manner, and, although what has succeeded in Paris might not be successful in London, on account of the differences in the habits of the inhabitants of the two capitals, the requirements of the two peoples are practically the same, and it may serve a useful purpose to put on record the manner in which this public want has been supplied in Paris. The concession to erect what the French call *châlets de nécessité* has been granted to a company for a period of thirty years, the company providing the châlets, and undertaking to keep them in repair, and paying a sum of 800l. a year to the municipality by way of rent. At the expiration of the concession, the whole of the buildings erected by the company are to become the property of the city, the fittings and furniture being taken at a valuation. The company have erected 101 châlets, eighty-four with ten compartments, and seventeen with four compartments. The cost of the larger of these buildings is about 560l. each, and of the smaller type about 360l. each, and the total capital expended is about 53,000l., the greater part of which will revert to the municipality at the expiration of the concession. The cost of maintenance of the buildings, irrespective of the fittings, is about 600l. a year. The amount authorised to be charged for the use of the châlets varies from 2d. to 1d., but the sums actually charged by the company do not exceed three-halfpence, and in some instances are as low as one halfpenny. The success of the enterprise appears to be greatly due to the low tariff of charges fixed by the company. Each châlet is placed in the charge of a woman, who is required to keep it in order, and is enjoined to use the greatest civility towards the public. The buildings are under the control of a superintendent, assisted by an inspector, and there are three collectors for the receipts, which are checked by a mechanical apparatus placed over the doors of the several compartments.

IN a recent number\* we indicated the particular houses which are appropriated for an extension of the Adelphi Theatre in the Strand. One of these is the Nell Gwynne Tavern in Bull

\* See *Builder*, November 27, 1886, p. 763.

Inn (or rather Bullen) court. That sign has hitherto commemorated the associations of Nell Gwynne with this quarter of the town. Yet it is in the neighbouring Exchange-court that we should look for the traditional abode, or, rather, dairy-house, of her who was uppermost in the thoughts of the dying king. We mean the old Thatched House Tavern on the eastern side of Exchange-court, which has just been taken over to serve as additional premises to the barracks of the Corps of Commissionaires. We are thus reminded of the popular tale which would attribute to Nell Gwynne the foundation of Chelsea Hospital for old or disabled soldiers. Few of our readers, perhaps, are familiar with the several alleys that open into the northern side of this end of the Strand. But they will repay a visit if it be only by the glimpses they afford of the rear premises of many old houses whose main Strand fronts are for the most part considerably modernised. Standing at the top of the steps of Lumley-court, for instance, and looking down across the Strand beyond, it is difficult to realise that, as we are told, our field of view has arisen in course of ages above the morasses that bordered the vast lagoon which here formed the estuary of the Thames.

**I**MPORTANT Roman remains have been discovered at Lescar (Basses Pyrénées). It is conjectured that the explorers have lighted on the site of the Roman town Beneharnum, which was destroyed by the Goths as they passed onwards to the invasion of Spain. The foundations of a fortified camp have been laid bare, and on a hill at a short distance, connected with the camp by a road, the plan of an extensive palace, with large baths, can be made out. All the rooms so far excavated are paved with mosaics. From the coins so far found, it is supposed that the palace is of the time of the emperor Gordian III. Between the hills or valleys and table lands on which the palace and the camp lie in all probability the town of Beneharnum stood.

**W**E are glad to learn that the students' drawings sent in to the Institute of Architects this year form so large and remarkable a collection that it has been decided to have a public exhibition of them, as will be seen from a notice in our advertisement columns, from Friday, 14th, at noon, to Saturday, the 22nd, at 4 p.m. As the Royal Academy students' drawings are thrown open to public inspection every year, there seems no reason why the Institute drawings should not be; and we venture to predict, even before seeing the collection, that a comparison of the drawings with those of the Architectural Section of the Royal Academy will suffice to indicate how secondary is the position occupied by that body as a school of architectural drawing and design.

**T**HE Trustees of the Alexander Thomson Memorial are offering a prize of 60*l.* for the purpose of encouraging the study of Classic architecture. It will be awarded for the best set of measured drawings from any Classic building, sent in on the 15th day of December, 1887. The conditions in detail are to be obtained from Mr. John Shields, the Secretary to the Trustees, 122, Wellington-street, Glasgow. We observe that no definition of the words "Classic building" is given in the conditions; it is not even mentioned whether it is intended to include Renaissance or modern Classic; probably not, but this should at least be made clear. We should prefer to see the prize given for the best design based on Greek detail and style, and adapted to some building for a modern purpose.

**L**AST year (on May 15th, 1886) we gave an account of the recent restorations by Señor Pablo Vera, at the Alcázar, Toledo, which has, after many vicissitudes, been converted into a training school for officers of the Spanish infantry. Last Sunday night the whole building, with the exception of one wing, was burned down by a fire, the extinc-

tion of which was rendered very difficult on account of a severe frost which stopped the supply of water. We understand that the fire broke out in the new library, where, as we pointed out in the above-mentioned note, all the fittings, including the bookcases, were of pitch-pine or some similar dangerously resinous wood. This is the third time the building has seriously suffered from fire,—in 1710 by the Austrian troops and in 1810 by the French.

**S**OME notice should be called to the works which the South-Western Railway Company are carrying out at the various stations on their loop line to Richmond, Barnes, Putney, and Mortlake. These were fairly pretty country stations, of red brick with black lozenges, mullioned windows, and Tudor chimney-stacks, &c., all quietly and nicely designed. They have now been "translated," and are the ugliest stations near the metropolis,—that at Mortlake being an especially abominable "contraption" of iron, wood, and zinc. We ought to improve in railway architecture as we have done in other branches of the art. The South-Western Railway are retrograding. Have they an official salaried architect? and is that the reason? or is it mere parsimony and callousness? In any case it is deplorable.

**T**HE Royal Academy have raised Mr. Marcus Stone to the full dignity of R.A., and created Mr. Gilbert, the sculptor, an Associate. No one will contest the claims of the latter artist to the honour, considered on his own merits; but we are inclined to ask, with some emphasis, why one or two older men who have done admirable work are to be continually passed over for younger aspirants, and by what arrangement it is that the author of "Cleopatra" and the "Spartan Dancing Girl" and "Summer" is left on one side? The appointment of Mr. Stone to the position of full R.A. will be a popular one, we surmise, with the general public, rather than with those who take art seriously. His pictures are pretty and attractive, but can much more be said for them? And when we think of some of the names that are still left in the list of Associates, or even outside altogether, the discrepancy between cause and effect seems the more marked.

**T**HE inquiry in regard to the proposed site for the Sutton Cemetery has resulted in the refusal of the Local Government Board, on receiving the report of their Inspector, Mr. Harrison, to sanction the use of the site for a cemetery. It appears this is the third site which has been refused in Sutton, and while sympathising with the Sutton local authorities in the difficulty and disappointment which must result from these unsuccessful attempts to find themselves a burial-ground, we cannot see, on the evidence given, how the Local Government Board could possibly have found otherwise. It was pretty clearly shown that the water-supply of the district, which is a chalk one, must come more or less by percolation through the proposed site of the cemetery, and though some courageous attempts were made to prove that water does not percolate through chalk, the received creed on that subject cannot be said to have been weakened. The conclusion is that chalk, under modern sanitary regulations, is an excellent formation to live on, but a bad one to die on; and for the present the only recommendation to be given to the good people of Sutton, who cannot get a burial-ground, is that which Jane Eyre gave when asked what naughty children must do to escape a certain place:—"They must keep in good health, and not die."

**Corporation of West Ham.**—The Town Council of this new municipality (which adjoins the eastern boundary of the metropolis) have appointed Mr. Lewis Angell, M. Inst. C.E., to the office of Borough Engineer and Surveyor, at a salary of 1,200*l.* per annum, with privilege of consulting practice, arbitrations, and evidence. Mr. Angell previously held a similar position under the West Ham Local Board during the past twenty years.

THREE DECORATIVE DESIGNERS.

HERBST, DE BLOND, AND GENTSCH.

To the books of designs "propre aux orfèvres," which we have already noticed, we now add to one which, although it must be ranked as inferior to those of Bourguet and Bourdon,\* is yet very remarkable for the originality and grace of the drawings it contains. It is "A Book of Several Ornaments fit for Jeweler, made by J. B. Herbst, 1708." Its author's name in full was Johann Bartholome Herbst, and his book would be specially interesting, if for no other reason, because it is one of the few of the class which seem to have been published in England. Paul van Somer is another foreigner who has sought a reputation in a similar way in this country, but his book, which was "sold in Newport-street," contains only some very uninteresting and weak borders for panels, and must be passed over. Herbst's designs may be divided into three classes: first, a great number of settings for jewels, rather heavy and of no special merit; secondly, some calligraphic flourishes; thirdly, a series of panels, suggestions in all probability for the chasing of silver cuff or pounce boxes, of peculiar charm, and of which we give two as specimens. It is necessary to speak of the calligraphic flourishes first because they undoubtedly influenced his more serious work. This calligraphic work has exercised a considerable fascination over more than one artist. We gave, as our readers will remember, in our issue of Dec. 19, 1885, a specimen of a quaint series of such designs which came from the pen of Albert Dürer. The fascination of this work may possibly not extend beyond the deviser of it, but for him there can be few exercises so interesting and useful. It must promote freedom of drawing and steadiness of line: being the mere skeletons of design, as it were, the eye can detect at once the slightest flaw; it teaches the art of clustering the main and subordinate lines at the point of spring, or *point d'appui*, of the design; and to execute it accurately and with precision demands a knowledge of the whole of the fundamental principles of decorative work. We confess, however, that when the style is used not for study but for absolute design, the result is the reverse of pleasing, and we must rank Herbst's devices of skeleton flowers done up in bunches with streaming ribbons with those of a similar nature produced by Coquin and referred to in our last article.

Turning to his more serious designs, their first characteristic may possibly appear to some as a blemish; it is a certain fineness and uniform thinness of line. But if we are right in our conjecture that silver-chasing was what Herbst had in his mind, this objection should be removed. It must not be forgotten that, although we talk of these engravings as designs, they are, in reality, in many cases drawings of the effect to be produced when the design itself shall have been executed in wood or metal. If it is intended to be embossed, the shadows caused by the raised surfaces must necessarily be introduced, and thus very often the thick lines produce a more effective drawing than one of a bit of chasing on which there will obviously be no shadows. Their second feature is the intensely floral nature of the designs. The first impression, indeed, is that the leaves and flowers are realistic and not conventional; but a closer inspection of them reveals at once that they are decorative and not imitative work. The broad undulating petals of the flower which figures in both figs. 1 and 2 seem to mark the poppy or the single peony as the fount of inspiration; in these two little designs it appears in no less than five different positions, now bending forward to the beholder, and now turning from him, and each of them with a peculiar charm of its own. The leaves are as clearly conventionalised as those of the acanthus, and the whole is so evenly covered that no one part is more prominent than another by reason of excess or lack of work upon it. Lastly, we would draw especial attention to the number of centres of design which the little oblong panel contains: there are no less than four, one above and one below the central flower, and one on either side of it. We are not sure but that this characteristic is not the one which makes many of Herbst's designs so charming: it is certainly one that is very rare. When the tangential principle of flowing lines is mastered, it is possible to cover closely any given space with

\* See "Two Old Parisian Jewellers," pp. 6, 74, ante.

flowing curves all springing from one centre: one of the chief pleasures of well-wrought design is the ease with which the eye travels along the numerous branches of the curves, and at length finds rest in the point from which all spring. This sensation of pleasure is enhanced when these centres are multiplied, and when, as in fig. 1, no one is made more prominent than another, and no one subordinated to another. Each centre has its own mission to perform, sending out sprays of foliage to cover a certain part of the space, but each covers approximately the same amount of space, and all four spaces are so closely interwoven one with another that an effect of symmetry, uniformity, and homogeneity is given to the whole. This same multiplicity of centres is to be noticed in the long narrow design sketched in fig. 3, and in less degree in the short one, fig. 4. Herbst's work very much resembles in spirit some of the best examples of Hindoo design.

From Herbst we pass to a designer of rare skill, but of less striking originality than Herbst, Michel Le Blond, who was born at Frankfurt in 1580. His best work was almost exclusively drawn for the gold and silversmiths, the most noteworthy among the pieces which are preserved in the British Museum collection being several series of elaborately-designed handles for knives, forks, and spoons. From these we have selected four examples (figs. 5, 6, 8) and one design of a kindred nature (fig. 7), as to the express object of which we are, however, unable even to offer a conjecture. These examples show the artist at his best and afford good illustrations of the three styles of ornament which he chiefly adopted. The two in fig. 5 are a very pure form of Renaissance, differing, however, from Bourdon's style in not a few particulars. In the first place, although the volutions of the main scroll are fine, the entire design is not so massive in construction, and the detail is slightly flimsy. One of the most apparent reasons for this is, we think, that where pure lines are used they are not of equal thickness throughout but are drawn of gradually increasing and diminishing thickness, like curves coming from a quill pen. Such lines constitute a more important feature in the general effect of the design than the corresponding curves in Bourdon's frieze, say in fig. 9 on p. 75, *ante*; and this because they do not lend themselves to branches, but are perforce left to themselves. There is consequently less scope for the origination of subordinate branches and detail, the foliage is necessarily confined to, and can only spring from, the ends of these "quill-pen" curves. The animal forms tolerated by the style of the ornament follow as a matter of course, and so we have the birds slung as usual among the branches. But although less massive than Bourdon's work, Le Blond's has a peculiar graceful charm of its own. The quill-pen line introduces some very pleasing varieties in some of the well-known conventional forms. Note more especially the bird close to the bird's head in the centre of the large handle in fig. 4: its under limb stretches away to four or five times the length of the upper one, and, besides forming a perch for the bird, allows the little seeds to be introduced with charming effect. The little spoon-handle in fig. 5 is in the same style, but from another series with a more elaborate outline. The handle (fig. 6) is a simpler example in the same style. From this first style the transition to the second is marked only by one peculiarity, but it is of sufficient importance in principle to demand separate attention. There is a great deal of it to be found all through Le Blond's work, but fig. 7 is one of the most striking illustrations of it. The general structure of the design resembles that of the examples already noticed, the volutions of the quill-pen lines being, however, much more elaborate; but the curve complications are so numerous and intricate as to leave no space for bird, beast, or little fish. The noticeable feature is the introduction of a species of perspective by means of the dotted lines. Our criticism of this new feature, which, so far as we are aware, has never been used before or since Le Blond's invention of it, must be considerably influenced by the object for which the designs were made. If we may make the assumption that the drawing is intended to be a representative one of a piece of complicated metal work composed of interlacing curves, not worked out in the flat, but in which the curves do actually go behind and before each other, then the dotted

lines sufficiently accurately express the effect which would be produced. But if the intention of the designer was, as there is very little doubt it was, merely to ornament a flat surface, and if the drawing is meant to be a piece of decorative and not of representative art, then we are compelled to confess that he has fallen into the grievous error of making things seem that which they are not: in the special instance, of giving to a flat surface the similitude of a deeply embossed one. Michel Le Blond may be pardoned this fault for the general excellence of his work; but we may well pause for a moment to emphasise how great the error is, for it is in these modern days a too prevalent one. In the first place, it breaks through that essential line of partition separating representative from decorative art, on the existence of which we have so much insisted. From this almost every other canon of the art flows naturally. One of these canons is that in the effect produced the existence of the surface decorated must never be obliterated. If it is obliterated, the whole art and purpose of the ornament is destroyed. In both representative and decorative art there must, of course, be a surface

of the chief charms of this pure line form of ornament.

It is with some feelings of sadness that we come to the designer of the iron gate-handle, fig. 9; it is some compensation in studying the work of an age long past, though we know but little of their lives, to know the workers at least by name. To the writer of these articles the names Bourguet, Bourdon, Herbst, and Le Blond have become, through long study of the work, something more than mere names. Their own creations have in their turn made of the shadow that is left of them a substance, an actual person who lived and moved and had his being some time since, and with the workings of whose brain we can have actual and practical intercourse. But now we come to one of whom we cannot speak by name, who in a catalogue can only be described as "Designer Unknown," or thus with a dash "\_\_\_\_\_" not to be distinguished from others similarly described or dashed, save by the appalling title of the "Designer of the Iron Door-handle," or knocker, as the reader wills. In the British Museum Collection there are six of these handles, all of the greatest merit, and they are too evidently but the slender remains of a book, or

Fig. 1.

Fig. 10.

Fig. 4.

Fig. 11.

on which the work has to be executed, in the former, by so much as its existence makes itself felt through the presentment which is limned upon it, by so much does it mar the effect intended to be produced; but in the latter its existence is the very *raison d'être* of the ornament which is wrought upon it. Obliterate the surface, and the design ceases to have any meaning; feebly alter its character, by artificial means change its appearance, the design then has a double meaning, one of which at least is beyond the capabilities of the art to fully express. The third style in which Le Blond worked is a curious thin-lined arabesque. It is a style which was much in vogue in the seventeenth and eighteenth centuries among both French and German decorators. The ornament is cut in very thin lines on a black ground, and is at first sight most unattractive to the eye. The designs were probably, however, intended for enamels, and, executed in colours of a less violent contrast than black and white, their heaviness would become apparent at once. We have in fig. 8, translated one of the handles ornamented in this style, the black lines in our sketch representing the white ones in the original engraving; it is a very fine specimen of intricacy and clearness combined, which is one

of the choicest work. The floriated arabesque chasing is twined round the plain part of the handle, gradually increasing in proportion with the gradual swell of the handle itself towards the centre. The centre-piece itself is a masterpiece of design; we can easily imagine the lion's head standing out in bold relief on a species of escutcheon to which the two snakes act as supporters, they themselves binding the wreath of acanthus leaves on to the simple iron bar. Iron-smiths are busy to-day turning out charming work for the beautifying of our houses; here are six models of the finest beauty, well worthy of the skill of the most capable of their craftsmen.

From the unknown we now go further into the past to introduce to our readers the work of a man who is, at least, known to us by name,—Andreas Gentsch, who flourished at Augshurg about 1616. The two designs, figs. 10, 11, are the only two in the collection which can be attributed with any certainty to him, on account of the monogram, A.G., which, in the little oblong panel he has placed in the tiny escutcheon in the centre, and in the circular one he has woven into his design, after the manner of the German masters, with whose work we are already familiar.

THE COMPLEMENT OF ARCHITECTURAL INSTRUCTION.\*

SINCE I last addressed the Architectural Association, the Examination in Architecture, once voluntary, has become, for those intending to take architectural status, compulsory. Not only that, but there is a large sprinkling of the members of the Institute, Fellows and Associates, who have passed an examination of a much more general and searching character than was then open, viz: that for the certificate of competency for the office of District Surveyor.

The consequence has been that those now entering the profession have set before them at once an object, and means to obtain that object. The Institute is only an examining body. The Architectural Association furnishes the younger members with means for comparing their knowledge together, furnishes that emulation in learning which is the real stimulus to exertion.

This emulation in learning opens up to us the great pleasure which learning confers. It is also the opening up of the great conflict which is to come to us all,—the conflict between the younger and older members for employment.

In this conflict two preparations are needed: the learning which can be taught; the experience which can be gained.

Learning can be taught by preparation for an examination; experience can only be gained by the persistent study, the mastering of each fresh detail of business, which comes before us while we lie under the responsibility of mastering it.

This learning is like the coral growing at the proper depth in the sea. This experience is like the comminuted fragments which cluster round the base of the coral, and which time and chemical action convert with the coral into a hard stone. One part may be calcite, another aragonite; the two may seem alike, but fire and frost will find out the difference, and fire or frost will come to test the student's stock sooner or later.

I have been asked to write you a paper, and I feel honoured by the invitation; and lest I should be thought to take unduly the standing of one who has a right to discuss design in building from having had the special practice of an architect, let me at once say that it is as an onlooker at the profession that I come before you, as one who has devoted the best years of his life to what by many is considered drudgery, but which I shall continue to believe is a legitimate part of an architect's business, one also which, I must admit, requires all the interests which can be found in the subsidiary charms of architecture to enable those who follow that branch to retain in its practice the professional aspect rather than the mere curriculum of business. Such labours, though they do not enable one to point to any building as the fruit of their exercise, at least have this recommendation to you, that they bring such a worker into acquaintance with a great variety of the aspects of the profession which you are now entering. Therefore, without more ado, I address you as fellow students in a calling which I trust each one of us will leave, so far as our own influence is concerned, not less honourable than we found it.

In these times there must come many thoughts to all thinking men as to the progress of our profession. There are many coming into it. There are older ones who had not your education, but who have collected much experience. There are younger men who have better education than your elders, but who are yet collecting their experience. Their coral construction stands up above the general surface of the surrounding material, construction of which they are liable from time to time to have such points as have been their glory fed upon by the bottom-browsing fishes of the profession, knocked off and carried to form the support of other individuals, less adventurous as regards personal growth.

It is as regards this struggle for existence and your personal preparation, as to your taking part in it and obtaining enjoyment from it, on which I would address you.

You have to study human character, the materials at your command, the forces of nature, and the constitution of society; with all these you will have to deal by your personal

\* A paper read at the meeting of the Architectural Association on the 7th inst., by Mr. Thos. M. Rickman, F.S.A. (Past-President).

With regard to his monogram, he shared the pleasure with Altdorfer and Aldegrever, of possessing a capital A in his name, and the consequent pride of being able to model his monogram on the well-known one of Albrecht Dürer. The solitary criticism on Gentsch's work which we have found in the books is that he produced designs of great inferiority to those of Aldegrever. We profess ourselves quite unable to find the least resemblance between the work of the two artists; and if comparison must be made between them, it is certainly not unfavourable to Gentsch. But "comparisons are odious" and we do not intend to make them, but to leave the work of each to stand on its own merit. This article has, however, stretched beyond the limits we had assigned to it, and we therefore leave the more detailed criticism of these two charming panels to a subsequent article, in which we shall deal with a series of designs, all, unfortunately, without signatures, but which may all be grouped as the product of a school of which Andreas Gentsch was, without doubt, a very prominent master. We close this article with a sketch of a charming little floreated arabesque panel, fig. 12, by Friedrich Brentel, who flourished about 1608.

and of whose work, alas! we have come across no other example.

**Architectural Lectures.**—The evening lectures on the Science of Construction and American Survey Practice, delivered by Mr. Gribble at Exeter Hall, are to be renewed on the 20th inst. These lectures have drawn, we understand, a considerable and increasing attendance, which has encouraged the Committee of Exeter Hall to continue them at their present very moderate entrance fee.

Fig. 13.—Small Circular Panel for Chasing. Designed by Michel le Blond.

character and by your knowledge. In the fight for business you will seldom think of history. Language you must use as a tool, your physical strength you must first exercise, then husband; after that will come a time when it will be remembered only.

Whether any one of you will attain to the first rank or not depends, first on your parentage, then on yourselves. If your parents have restrained themselves and you from self-indulgence and unnecessary expenditure, then you may draw on their resources and your own during the ten years after your articles are over. This will enable you to mix with those from whom you may gain and to bring up yourselves, your pupils, and your own children in the habits of self-restraint, and of economising your and their resources in every way.

Your future position depends on what you have made yourselves to be. You must learn to respect yourselves, to become such persons as those in whom you yourselves would have confidence. Few persons are guided by strict reason, more in number are guided by the influence of others. Is a person likely to have formed sound opinions? Then listen to what he tells you. It is your duty to select your own guides, and mainly by your own personal character, for the formation of which you are each responsible, will you stand or fall.

Such is the object of each of you; what are the incentives you have? What are the pleasures by the way to be obtained? That you may be led on in your professional course, that you may hand down what you have received to your pupils, and, if you have that happiness, to your children.

The threads of your study are very various; you may pursue, each of you, a separate course, and for each it will be found to be a life's labour. You have, if walking alone, the fatigue of travelling on a straight and tedious road with an end at an unlimited distance; but combine your pursuits and each throws light on the other's course, the mass of life-threads does not become entangled, but each point of crossing of different sets of ideas is a mark by which you may recognise progress, a step which you can register, a pleasure which you can enjoy, a cross light which brings into relief the modelling of that particular district of science and art which you take to be your individual study.

What are these cross lights of the profession? Those matters which will continue to interest you without the use of a telescope, things of which we are all bound to know something, and an architect more than others. Let me jot some of them down otherwise as they occur to me.

Our old churches when carefully cleaned and repaired, are their chantry to be used? Is such a building most suitable for the services of the Church of England?

Are old City gates to be retained when they block up the entrances of our ancient towns? Are they not in the way? Are the entrances established for several generations for access to the profession likely to last better? In either case must not the entrance for those who succeed us be where it has been, perhaps with more extensive use, but with unaltered purpose?

Can we learn anything by the lines taken by old Roman roads through this country and by their succession to the British roads, and their expression by Medieval routes and their successors? Do the roads we pass recall to our minds the pack-horses, the wagons, the coaches, the steam and varied traffic of successive periods?

What has the present low price of building work to do with the appreciation of gold or the difference in comparative value of gold and silver?

Are we to take materials or labour as the basis for monetary value? Is not the value of materials that of labour, plus or minus the influence of local circumstances such as may affect production?

Are we to view capital, our own or our clients', as the unexpended surplus of our fathers, for which we are trustee, or as our own savings? Is there any other view of it which we should be justified in adopting, without the expectation of coming to grief?

Is the proprietorship of land more than the duty of giving tenants quiet possession? To what extent does continued use of land confer on the tenant a right of continuance in occupation?

The law of England, written and unwritten, as regards tenancy; the customs of England as

regards connexion of landlord and tenant; if they are being dissolved, is it our duty to support them, or ought we to assist in their dissolution?

Can we recognise the special qualities in stones, from finding some weathering down in the centre, leaving the joints projecting and others weathering in the joints and leaving the centre part projecting?

If when we are leveling, we use the walt on a tree trunk as a bench-mark, does it convey to our mind any idea of its nature and of the story of the virus or domestication of an insect?

Have we any hopes of finding a carver who will stop off his carving to etch the fossil in a stone or adapt his carving thereto?

Do we treat of drawing division lines in our profession, let us remember the Roman wall; what does it now keep out? The foss round an old earthwork, what does it now protect? The Tyne, the Tweed (shall we say the Tay and the Forth?), what do they now separate? Do we not now look on both sides of its crumbling remains to know anything of the history and purpose of the old wall? are not the bridges over the ancient chasms ties where before was a recognisable boundary?

Are the present recognised divisions of the profession, such as the separation of the duties of architect and surveyor, likely to last any better than that magnificent device of disciplined force against barbarism or the obstacles of nature which now we have learned to subjugate?

Such are among the questions which will interest you, and on which you will take varied views as you proceed in professional practice; and each question, as you learn its bearings, will tend to send you back to your business avocations with a fresh view of your duties.

Let us now consider some of the principles which are likely to influence you, unawares perhaps, as you proceed. I treat not of your every-day dealings with the business men of many varieties whom you will encounter, but of those opportunities which may influence your character and give you the power to make friends among those whose opinions you will value, and will enable you to take steps upon the ladder,—the ladder of advancement to upper stories to which you are called, not the treadmill to which you are condemned.

I have said history will be seldom in your remembrance: you must think of something else when you are designing. Buildings make the record of history,—your buildings can be fixed to your own time, as you cannot avoid using the inventions and practices of your day. Your footings will stand on concrete, if your floors are not laid on or made of that material; your bricks will have frogs; your paving may be machine worked, your stone facing likewise; your rough timber will be cut with a circular saw, and be of trade sizes; your joinery machine-made; a scrap of cast iron or rolled iron joist will tell its tale, as well as the nails and screws and bolts you may use; a scrap of trade ironmongery or plumb's brass work will tell its date; your lead will be milled, your pipes drawn, your glass made in the French manner, or, if thick, will be cast; and your paint will carry with it elements of its own destruction. Mætic, Medina, Roman, and Portland cement and terra cotta of all sorts will, so long as they last, date themselves.

Other interests you may find,—in ancient earthworks, which tell of the state of attack and defence in the old times, and of the situations desirable for defence; in the outlines of parishes on the hill sides, which help you to study and perhaps to fix the date when those districts were settled; in the outline of enclosures which tell of the conversion of common field to closes, while the outline of hedge-tops of ancient cultivation, and the division of land tells of common husbandry. In the study of groups of churches you will become acquainted with the handiwork of a mason of old days, and the locality of such combinations of fine buildings will introduce you to the causes of the local opinion whence came the necessary expenditure to produce them; in the mixing of a plinth or of a string course you will obtain a hint of the history of a building; in the alteration of form in a corresponding moulding used in works of successive periods you will see a likeness to the variations which have occurred in words in our language. All these and many others are matters which we can learn by experience only to value.

For examination it is necessary to receive accurate instruction. The information must be given lesson by lesson and put together in your minds,—you must learn the several matters in the form in which they appear to the minds of others; you must pass your mind through their rollers, you must be moulded to their cutting edges: your information must be built up.

And here let me note how much it is to be learned by, and how much of the best practice of our art has come from, the special difficulties under which each building is executed. It is not for all works that an original design is obtainable. In two of Professor Cockrell's best works, the continuation of Fitzwilliam Museum, and the completion of St. George's Hall, Liverpool, in each case the design was another's.

In two of Sir Charles Barry's most interesting works,—Frothingham Hall and Harewood House,—the old building was comparatively unaltered. Much of Sir Gilbert Scott's labour was expended on restorations, and whatever excellence they have must be derived from the appreciation of the original design. Sir James Pennethorne's completion of Somerset House displayed its originality in the acceptance of a previous design. In Mr. Waterhouse's two largest domestic works, the plan of Eaton Hall remains to a great extent; the outer walls with their time marks still enclose the new building at Heythorp.

After examination you will have to grapple with the selection of materials suitable for your client's purposes, and, if you are up to the age, the style you adopt will be adapted to the inventions of the time. You will learn whether to select bricks for their fire or their acquired colour and tone. Brickwork is a material which will sooner of any toll of your knowledge by its weathering; your success or otherwise in the colouring of brickwork will depend more than anything upon having a similar finished surface on all your bricks though they are of different colour. Your stone must be used as needed: it will, so long as it lasts, tell, by the size of the pieces used, the liberality or otherwise of your client and of your own views. The use of the rolling-mill for preparing wrought iron is the key to the practical support of weights; for some time past each iron has been used horizontally; probably, in the coming time, it will be used vertically. The advantages of large sheets of glass and the cheapness of other metals will also affect your compositions.

The work which you are engaged upon before Examination and before commencing practice is to that of the practising architect as syntax is to prosody. When you come to look on your own work in execution,—when you have learned to make a building which will sustain itself, which will contain with convenience its proper occupants,—after that you will find out that there are such things as false quantities in architecture. This sense is an acquired one. Every section of moulding has a date of its own besides having a meaning, every breach of the known periods and collocation of details is an offence to the educated eye, every mixture of motives in a design is an offence to the knowledge of those whose eye can criticise, every jarring contrast of colour is an offence to those who have a sense of colour: in each case the offence has the same effect as the dropping of an aspirate, or the misplacement of an accent or an emphasis, or as a false quantity in verse. Your training for these sensations, which you will specially feel in your own works, is what you have to look forward to; your practice without breach of such artistic etiquette is only the work of an experienced, as it is the severest test of the executed works of a true architect.

And as regards colour, let me allude to two of its aspects. It affects us first as a sense of the material used and also, by refraction and reflection of light, as a sense of surface; surface only is paint or shine polish, other meaning is the material itself; these, if you have an architectural mind, you will discriminate and learn to see. Without the preservation of the polish, few materials retain their original colour, for weather and time attack all,—a warning to us all that colour is only a momentary beauty, put on by the plant in the flower and the fruit; shown in the granite at its fracture, existing only in the shell at its seasonal development, and by all other things which are admired, visible only at the moment of their supreme beauty. True colour is the mark of perfection and of evanescence. It is to be used by architects, either by emphasising contrast or adopting

harmonious arrangements; in contrast meant to give pleasure to the active mind, in harmony to give rest to the jaded senses.

After examination you will have a stock of fixed impressions to which you can add; you will occasionally do this by meeting some one whose mastery of his subject at once impresses you, some one under whose instruction you will willingly sit, but the principal source for increasing your power of scrutiny and your stock of impressions will be the careful examination of whatever fresh points of practice or of art may come before you. You will then begin to put yourself in the place of the man who did the things you look at. How did he do it? will you ask yourselves. What made him do it? For what purpose did he do it? By this you will learn to change the order of your learning from synthesis to analysis.

The pleasure of the first is in feeling the capacity of reception. The second pleasure is that of exercising the mind. The use of all your learning is in its application, and each must learn it for himself. Thus the practice, the science, and the art of architecture grows into one; each of them basits pleasure, but the practice is confined, the science is limited, the art is disappointing.

Another and more excellent thing is analogy.

If a mathematician wishes to make the line of his diagram represent a force of which he is treating, he must put arrows thereon to signify direction, accustomed forms of growth take the place of these arrows in natural objects, but how does the architect represent his forces? William of Wykeham, when he changed the aspect of the old bays of Winchester Cathedral, which had been Norman, builded up of stones, and which he left one whole design springing from the ground, marked his lines in a manner that emphasised the direction of them in a manner which still tells its story, and though he added material, he left the effect of lightness. I commend this change specially to your consideration as involving the *modus operandi* of a great architect. And in the same view let me ask you to consider how it was that that great architect when he had before him repeated in Winchester Cathedral, as it then was, the beauties of the perspective view of the central portion of a Norman moulded arch, and had also such specimens as are there seen of the graceful meeting of the mouldings at the upper third of a pointed arch, wherein each side is struck from a single curve, and of elaborate Decorated characteristics, should have preferred for his own use a four-centred arch. In such an arch, only the stiffest portions of the curve are contrasted at the apex, and neither the gradation nor the contrast of the earlier work is seen.

Was it the fashion of the day which guided him? or was there in this form some hearty which he recognised and which we ought also to appreciate? or, on the contrary, was it in this manner that the progress towards decadence in style was manifested in this country? Are we to contrast or to compare with this the progress marked in the French Flamboyant in the treatment of the junction of the pier and the arches which it carries, a combination of those members which in the earlier and purer style of French architecture has been so completely severed? Such are some of the questions which your later experience may practically treat.

Ancient buildings are true representatives of the permanent portions of the art, science, and resources of the times whence they come down. The successive changes of style which they exhibit are the direct representatives of the ability and of the motives of those who made them. To the architect their succession goes beyond that mere superficial notion, it conveys to his mind the evolution of an idea. A series of evolutions produce from decadence a fresh spring of life, when some new purpose was in the hands of mankind to carry out.

Imitation with purpose may be seen in the tracery of a bird's nest; geometry, and the true result of the doctrine of chance, without formality, in the surface of a coral, and in the smallest specks of lime through which life has passed or which formed part of a living being, and which the deep-sea dredgings of the Challenger have shown us.

If our study of architecture leads us to find out how means should be used by the ingenuity of mankind for their own purposes, we should not confine our attention to buildings, but we should consider also, beside the mineral, the

other two kingdoms of nature, vegetation and animal form; and for ingenuity of contrivance, perhaps the greatest pleasure which an architect may have in his building, none that he can attain to can match the folding up of flowers before they burst; we should notice them also in their unfolding, which we may sometimes watch and see,—we should take note of shells in their origin and in their growth, and all of these objects of nature in their unlimited variety of form and in their varied colours. The bending of the stems of plants will attract our attention under the increasing weight of the flower and fruit, and the outward form, when once we have learned its mode of growth, will tell of the unseen tap roots and the spreading bases of the trees. Beside their botanical interest, these all tell of means to an end. The mineral kingdom, in its details, the result of past forces, whose order, whose interferences, whose nature microolithology teaches; the vegetable kingdom of present active forces, whose organism chemistry and physiology are now dealing with, and which repay in interest a hundredfold every hour spent upon them by an observer with an open eye; the animal kingdom in the forms veiling and maintaining the powers of action, the septa, the centres of action and of radiation, the internal and external skeletons, the teeth, the vertebrae, the limbs, the bones of the extremities, the object of each illustrated by their relations and position, needing but the muscles to exhibit their action: all point to a future use. Forces which have been exerted, forces which are in action, forces which are in hand.

These are some of the analogies which the architect, who has to use the materials of nature for the purposes of mankind, has at his door for his professional uses as well as for his own interest and instruction. Interest and instruction which will give him pleasure in life and make the science the art and the practice more than a business, will make it an avocation worthy of his highest powers.

One more illustration: the chick, when it has been incubated, has for its first business in life to break its shell,—need I say that nowadays the architectural pupil, like the humbler being to whom I have dared to liken him, has a large store of materials ready to his hand? So soon as he has assimilated these he must break his bonds and commence solving the enigma of life, how to get on, whether as the chick which assails that symmetrical work of art, the eggshell, from the inside; or, like the great navigator who found a way to make his egg stand by breaking it from the outside. In any event each of you has to find an opportunity first of all of breaking his bonds of pupillage and then of finding some one who will have confidence in his abilities. First of all he must have confidence in his own.

The instruction we have received has been didactic. The course we have to pursue is still the gathering of information, but it is to be accumulated upon a nucleus which has been already formed.

The basic system of mineralogy is a step for us on the ladder; the new chemistry and the structure of molecules; the last botany; the arrangement of the parts of flowers and fruits; comparative anatomy, and the number of the bones of a living creature. Every study we may take to is another opportunity for analogies to help us,—another opportunity for us to study the architecture impressed on every object which is the subject of natural science. Let us be thankful for them, and learn to make use of them, not that from new views we are to receive lessons contrary to those which our fathers have taught us, but for us to obtain additions to our stock of knowledge, and to the ideas we possess, and to our powers of application, through which alone we can employ the teaching we have received, and the further experience of our lives.

We may work a long time at collecting facts, but in the course of time we begin to see the reason of things, and then, instead of mere facts, we have the knowledge of a truth, and then we are initiated into a new mode of learning, the learning of a man who has to practise, not that of a man who is getting up a subject.

Thus we shall learn to judge building, as designed now by an architect who practises in a style to which he bends materials, and again by another architect who sees in materials the means of accentuating a style, and shows in his constructive details the principles inherent in

that style. This and that man each displays a mastership in art, not one which we are to follow, but from which we are to learn.

And need I dwell upon the pleasures that such knowledge and such an aspect of our art afford? Such list contains the delight at finding out the purpose of the varied parts of a flower; in noting the adaptation of the various processes of a bone; in tracing the history of a shell either in the individual life of its occupant, or in its deviations from ancestral forms; the tracing of the strata on a ground surface of rock; the recognition of outline of a *roche moutonnée* and of the drift which slopes up to it in one or in another direction; acquaintance with the mode of weathering of rocks, which brings out the different character of the strata, or the different components of the material, which tells us of the history of the cooling of the earth's crust, in gneiss, in granite, in trap, or in basalt. Observations of the interpenetration of a crystal, and its almost geometrical instinct, and its mineralogical character. In meteorology as affecting temperature, winds, vegetation, soil, water, and the amenities of life. Many of these may be of use in determining the materials or the aspect of our houses, but for the purposes of our present view, they have a greater value, as they show us that life has another object than earning five per cent., and that ours is a profession which should make us, above all men, persons of individual character, thinking individuals who study cause and effect, not men who are content with the next and immediate consequence of our actions.

[Of the discussion which followed, we give a report on another page.]

CHELSEA TOWN HALL.

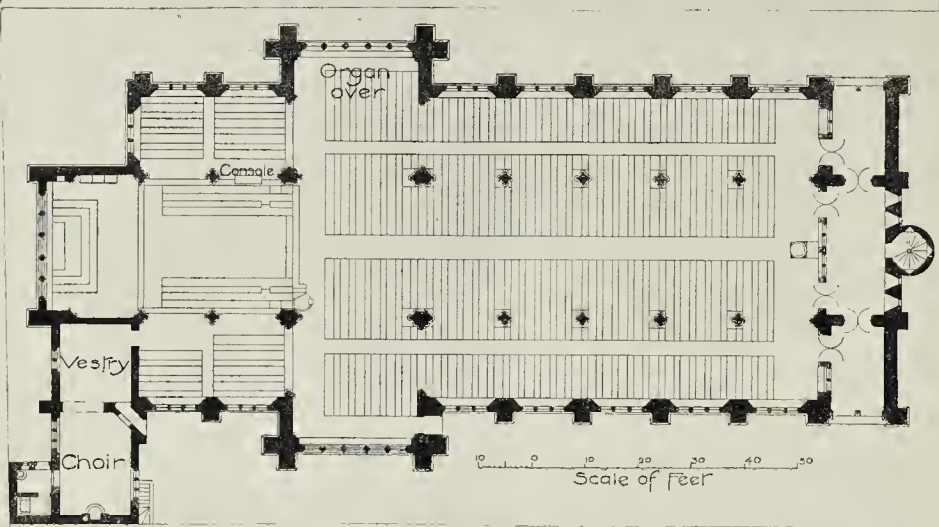

ADMIRERS of the richness and fancy of seventeenth century Renaissance architecture will not fail to be more than pleased with this beautiful work of Mr. J. M. Brydon's. Seeing how many of our most celebrated and best-known London churches are in the same style, it is, perhaps, unavoidable that, to a Londoner, any hall arranged and decorated in the same manner should have a slight ecclesiastical flavour about it; indeed those well acquainted with the style in Italy and other countries cannot help being struck with the same feeling at first, merely from the force of association. In fact, however, the luxuriance of the style, the freedom and fancy of its ornaments, and the way in which it in every part seems to laugh at all rule and constraint, make it far more appropriate for a building like a modern "town hall," to be used, we imagine, among other things, for banquets, balls, concerts, and such frivolities, than for a church.

The hall itself is a fine apartment, with a recessed *daïs* at one end, and a gallery over the entrance lobby at the other. Surrounding the walls to a considerable height is a  *dado*  of walnut, sumptuously moulded and luxuriantly carved in places; this forms a continuous base to the walls, which are divided into bays by grouped pilasters of Devonshire marble. At each end a pair of columns of Breccia is introduced, those flanking the *daïs* being exceptionally beautiful. The segmental arches connecting these pairs of columns seem to spring somewhat awkwardly. We should have liked better to see them elliptical: the form of the ellipse is introduced in the shallow domes of the beautiful ceiling, and would not have been out of place. The light is ample, and, being all high in the walls, is very pleasant. The coats of arms of old Chelsea families are introduced in the lunettes, but all other colours, both in the windows and on the walls, is reserved for future consideration.

The council-chamber and committee-room are essentially comfortable apartments, or will be so when they get a little colour on the walls, or at least in the way of carpets and furniture. The fireplaces, with their dog-grates, old Dutch tiles, and carved mantels, are gems, and so is the charming little minstrels' gallery in the council-chamber.

The kitchen is a fine apartment in the basement, fitted with apparatus to cook for a very large number of people, chiefly by means of gas. There is also a smaller hall in the basement, chiefly for political meetings, but not yet completed.

The accommodation generally is greater than in the original plans, and the whole scheme has evidently been thought out with a great deal of

Plan of Competition Design for Church of St. Paul, Kensington.—Mr. Jas. Brooks, Architect.

care since the first drawings were made.\* The architectural details show Mr. Brydon's masterly knowledge and taste.

Mr. Charles Wall, of Obelsea, was the general contractor for the works. All the carving, which is very good, both in design and execution, was executed by Mr. W. Ammonier; and the decorative plaster, which is also very good, is by Messrs. J. & S. Saunders. The marble work is by Messrs. Good, of Plymouth, and Mr. Houghton, of Portland-road; and the Breccia columns, mentioned above, by Messrs. Farmer & Brindley. Mr. Kemp executed the stained glass. The heating arrangements are by Messrs. Bacon & Co.; the fireproof floors by Messrs. Homan & Rogers; the fire-extinguishing appliances by Messrs. Merryweather & Son; the gas-fittings by Messrs. Verity & Sons; and the cooking arrangements by Messrs. Beuham & Son. Mr. Charles Osborn was Mr. Brydon's clerk of works.

#### OXFORD MARKET.

"I SHALL have it tender and hot from the most classic market in London,—that of Oxford," urges James Barry in inviting Edmund Burke to eat a steak with him one memorable evening at No. 36, Castle-street. Burke broils the steak meanwhile that Barry has gone out for the porter, which loses its "fine foaming top," pleads his host, in the wind across Titchfield-street. The Metropolitan Board of Works have decreed that Oxford Market shall be known no more. The market-house, its vane bearing date 1721, was pulled down six years ago for the Oxford Mansion. A view of it is preserved in the series published by the late Society for Photographing Relics of Old London. It was built by Edward (Harley), second Earl of Oxford and Mortimer, but was not opened for a market until 1732, says Allen in his "London." About that period,—authorities do not agree as to the precise date,—houses along the northern side of the then Tyburn-road were completed under the style of Oxford-street. That street formed the southern boundary of the old Tyburn estate, from Tottenham-court-road to Marylebone-lane. Hanway-street was already in existence, and Gibbs's elegant little church, St. Peter's, in Vere-street, was erected circa 1724.† With the exception of a few isolated houses,—one of them the Castle tavern,—the northern area between those two limits was open country, extending to the Bowling Greens and the old

parish church near to the Aye Bourne. Within Pennant's memory Oxford-street formed a rugged road, frequented by foot-pads and cut-throats. John (Holles), fourth Earl of Clare, who had married the Lady Margaret, third daughter and co-heir to Henry (Cavendish), second Duke of Newcastle, was gazetted Duke of Newcastle on April 30, 1694, three years after his father-in-law's decease. In 1710 he bought the Marylebone, or Tyburn, property, excepting the Park or Crown lands, from Sir John Austen for 17,500*l.*, the rental being then 900*l.* per annum. This estate devolved in the year following upon his only child, Henrietta. She brought it in marriage (1713) to Edward Harley, who in 1724 succeeded to his father, Robert, as second Earl of Oxford. By the union of their only daughter and heir, Margaret, with William (Bentinck), second Duke of Portland and Marquis of Titchfield, on July 11, 1734, the property passed to her husband's house, its present possessors.

#### MAP OF LONDON SHOWING THE BOUNDARIES OF SURVEYORS' DISTRICTS.

WE publish this week the third section of this map.

#### Illustrations.

##### SCULPTURE FOR THE HARRIS FREE PUBLIC LIBRARY, PRESTON.

WE give this week a general view and several enlarged groups from the sculptural decorations of the Harris Free Public Library and Museum at Preston.\* This is one of the most important works of late years in which sculpture of a high class has been employed as a decorative accessory to architecture; and we hope other examples may follow.

The subject of the design is the "School of Athens, Age of Pericles," it represents the Athenian statesman with the most famous of his contemporaries in philosophy, poetry, literature, and art:—

"The dead, but scepter'd sov'rans, who still rule  
Our spirits from their urns."

In the centre, Pericles, with his friend and adviser Anaxagoras, confers with Pheidias and Ictinus respecting the Odeon and the Parthenon: Pindar celebrates a Victor in the Games.

\* We gave a view of the building, showing the pediment filled by the sculpture, in the *Builder* of Sept. 9, 1852.

On his right, Parmenides, Zeno, and Socrates discuss Philosophy; and Thucydides meditates History. On the left are Eschylus, brooding over the future of Athens; Sophocles and Euripides in converse upon the Tragic Art; and Herodotus with his completed Books.

The sculpture is entirely designed and modelled by Mr. E. Roscoe Mullins. If we understand rightly, the general idea and arrangement is due to the architect, Mr. Jas. Hibbert.

#### CHURCH OF ST. PAUL, KENSINGTON.

MR. BROOKS'S design in the late competition is illustrated by us this week. It was submitted under the motto "Credo," and its principal features are described in the following short extracts from the report to the Committee, which accompanied it:—

1. Being intended for a mission church in connexion with the parish church of St. Mary, Kensington, pains were taken that it should not have too prominent an appearance, but rather that of a chapel of ease, so that it might not be mistaken for a parochial church.

2. The situation being very circumscribed, not only as regards approaches, but from its being almost surrounded by very high houses, there would be an impossibility of obtaining a satisfactory view of the exterior, or, indeed, of obtaining any perspective view at all. For this reason a most simple treatment is applied to the exterior, and a more finished and complete appearance is given to the interior.

The church was to be built of brick, the outside faced with red bricks, and the inside surfaces plastered. All the dressings would have been of Bath stone. The principal feature of the interior is the formation of the ceilings, which throughout were intended to be of wood graining, as in the choir of St. Alban's Abbey Church. This arrangement adds materially to the acoustic properties of the church, and the formation of a tympanum on the walls at the end of each bay gives an opportunity for coloured decoration or fresco subjects.

The accommodation was for 1,100 worshippers, and the seats were arranged so as to bring a large proportion within sight and hearing of the preacher.

A tender from Messrs. Kilby & Gayford was obtained for the work, including all the fittings and furniture, for 9,050*l.*; architect and clerk of works, 620*l.*;—in all, 9,700*l.* The amount allowed by the committee for the church, complete with its fittings and furniture, and including the clerk of works and architect's charges, was 10,000*l.*

COMPETITION DESIGN FOR CHURCH OF ST. PAUL, KENSINGTON, BY MR. JAMES BROOKS, F.R.I.B.A.

PLATE 1. THE SUPR. OF 4. 22 MARTIN LANE LONDON E.C.

THE PUBLIC HEALTH ACT, 1875.\*  
SUGGESTED REMEDIES OF ITS DEFECTS.

It is highly probable that the Bill dropped at the end of last Session may be revived in another form, and it would be well for each of us to point out and discuss cases that have come to our knowledge, and which we may consider require providing for in any future legislation. I therefore propose to deal with the paragraphs of the section consecutively.

**Street.**—The term "street" should include a dedicated road, whether built upon or not. A road may be an important thoroughfare largely used, but in a deplorable condition, and being confined only by walls and fences, the owners cannot be reached under the present Act.

**Boundaries.**—In some instances roads have boundaries running down the centre or along the building line: possibly the adjoining Authority may be a rural one. The present method of dealing with these cases is by mutual agreement. The Authority proposing to do the work should have power to treat the external premises as if in their district, and to recover the expenses in the usual way.

**Notices.**—It will be generally admitted that the present method is unsatisfactory and unreliable, however great pains may have been taken to be precise. The Manchester method of posting in the street and advertising in the newspapers is an admirable one. The great difficulty in describing the works in the notice is to decide upon the class of materials to be used and quality of work to be executed. This is very seldom done so as to give universal satisfaction. In some towns a hard-and-fast line of equality is adopted throughout: in others distinctions are drawn at the instance of the surveyor or his committee, and neither plan can he said to be equitable. In most towns the character of the streets will admit of their being divided into classes as follows:—

**Class 1.** Streets being main arteries of traffic and means of communication between one populous locality and another; or lined with important property.

**Class 2.** Streets running crosswise between main arteries, and only having light and local traffic.

**Also cul-de-sac.**

**Class 3.** Courts and alleys.

**Class 4.** Roads amongst better class residential property, such as suburban roads.

I would propose that these roads should be dealt with in this manner:—

**Class 1.** to be formed of the best materials and workmanship throughout.

**Class 2.** to be formed of secondary materials, but not inferior workmanship, and on sanitary grounds to have an impervious pavement, as residents in this class of property almost universally throw their slops and waste out of doors on to the roadway, which certainly should not be a filter-hed nor straining-tank.

**Class 3.** Having regard to the quality of the property and the convenience and comfort of the inhabitants in this class, it might be desirable to form these roads of macadam or asphalted carriage-ways with gravelled footpaths.

If the Local Government Board were to hold an inquiry in each town, and their inspector were to view the character of the streets it was proposed to classify, he, by hearing evidence as to the quality of materials the locality afforded, would be enabled to set up a standard to be used in each case, and this would go far to settle the present dissatisfaction and prevent costly and cumbersome litigation. The owners should have power to appeal to the Authority if the proposed works were considered excessive; and if no arrangement could be arrived at, then to a bench of magistrates, who, from local knowledge, could soon decide the equity of the matter. The great object should be to arrive at a satisfactory understanding before commencing the works, and thus prevent disputes as to facts arising afterwards which ought to have been decided at the outset. There should be no difficulty in doing this.

**Estimate and Preliminary Apportionment.**—The estimate of the works prepared by the surveyor should also include an approximate apportionment of each owner's share. The present method is to apportion by frontage only, although it is a popular notion that each party pays for the exact amount of work from the

building line to the centre of the road. To prepare separate accounts for each block would entail an enormous labour on the surveyor, and by particularising the items would enable each party to check the quantities in his own style, and would lead to interminable disputes and demands for amended accounts. Some method must be devised that will remove the present injustice of charging in streets of varying widths the owners of premises in the narrow portion a share of the costs of the works in the wider portion, and which relieves the owners in that part of a considerable amount of their proper burden.

**Intersections of Cross Streets.**—This question is also a very vexed one. The present plan of measuring the frontages net and apportioning the costs of the intersections over the whole area is the simplest if not apparently the most satisfactory method, and it would cost far more than the amount involved for any frontage to contest the fairness of the charge. It would certainly be very difficult where a street in a rectangular block running say east and west was paved to terminate at the west side of a street of less width running across it north and south; the streets at the end and both sides abutting on to it being unpaved, but likely to be, and to have an equal use and enjoyment of the intersecting area. The question to decide would be how far in each direction (other intersections being adjacent) will that user extend, and in what proportion are the expenses of completing it to be borne? Is there any man living who would hope to decide in a satisfactory way?

**Consequential Benefits.**—Collieries, workshops, and other premises using team labour are often situate a short distance from private streets, and having a communication therewith by means of a cart-road which may run between two rows of dwelling-houses. In many cases these places by their traffic cause the carriage way of what, for the requirements of the property, would be a fair and satisfactory street, to be cut up and rendered impassable, and bring down the Authority upon it with the powers of this Act; and when the works are completed, these destroying angels escape scot free and carry on their business at greater convenience and economy. They ought, in equity, to contribute to the cost of these works, and some system on the sliding-scale method should be devised to regulate the apportionments in these cases without the liability being incurred of going to arbitration on each one.

**Railways and Canals.**—A great deal has been argued about the hardship of compelling railway and canal companies to pay according to frontage. Certainly when railways are on viaducts or down in cuttings they cannot derive much if any use from the formation of the street; but, on the other hand, the roads may be a means of communication to their depots, and if they can be used for carrying thereto and therefrom, and from which the companies derive their revenue, then they ought to contribute towards the cost of completing such roads, which also may very likely in many cases reduce the distances to their premises, and provide them with a good and easy road; and further, if the railways and canals are upon the level, a use can possibly be made of the road at some future time by the erection of wharfs, &c. Certainly where main lines, not in the vicinity of any station, shut on to a road on a viaduct or in cutting, it can be of no possible benefit to them, and they should not be called upon to contribute to the cost of its formation.

**Sewers.**—Powers should be given to an Authority to contribute, if necessary, towards the cost of sewers in certain cases; that is to say, if for the purposes of a sewerage scheme it is desirable to construct an intercepting or trunk sewer in a private street, then the excess cost of such a sewer over one sufficient for the requirements of the street should be borne by the Authority. The writer has recently had a case of this sort in a road running along the boundary of one portion of his district, and this course was followed. It should be made plain to the surveyor that he must only design sewers sufficient for the necessities of the street he is dealing with. The writer knows several cases where sewers have been made as large as 3 ft. by 2 ft. when by no possibility could more sewage arise than would be discharged by a 9-in. pipe, and the defence for this has been that it is customary in the district to build sewers large enough for a man to traverse. Such reasoning is ridiculous, and for the sake of the

profession should be made impossible. There is one more difficulty with regard to sewers, and that is the character and condition of old sewers; in many cases these are large but loosely constructed, sufficient, perhaps, to carry off the drainage, but are without manholes and ventilation, and may discharge at undesirable points, and be incompatible with a drainage scheme for the district. Although the property owners may have paid to the parties who laid the sewer the cost of so doing, yet they should not be relieved of the responsibility of constructing another at the instance of the Authority, if the surveyor, as their professional referee, advises from structural and other reasons against their taking it over. The position and duty of the surveyor should be clear and well defined in such cases, as these matters of scientific knowledge cannot well be decided by magistrates or any other lay court.

**Levels.**—Frequently in altering the levels of streets it may be necessary to alter gas or water mains. Now, by the 47<sup>th</sup> Act, the only parties who have power to do this are the undertakers and the Authority, and one or other must bear the cost. The undertakers may have come upon the road when it was simply marked across a field, and laid their mains under the sod without any reference to future levels or requirements. When the Authority comes to deal with such cases, acting, as it were, as agent for the property-owners, it is manifestly unfair that such charges as will be incurred in altering these pipes to the requisite levels should be borne by the district rate; they ought, in all fairness, to be part of the works, and charged accordingly.

The writer has lately had a case of a road where on one side was a high bank sloping to the road, the sides of which continually slip down. Under the Act there is nothing to control this, and it appears the parties cannot be dealt with until the road is taken over, when they could be prosecuted at common law for an obstruction. It would certainly seem to be hard upon an owner in such a case to compel him to slope his banks at a given inclination, because he might fairly say it would rob him of so much land at the top level which he might reserve if he built a retaining wall, which it may not be convenient to do at the time the road is being formed. These cases may not often occur, but when they do they occasion considerable trouble,—probably some provision can be framed which will deal with them fairly to all parties concerned.

**Partial Works.**—It would often be a great convenience to a locality if parts only of a road could be dealt with and taken over by the Authority on completion. For instance, a road may be an important one as a thoroughfare, but may be only sparsely built upon; and there may be no pressing necessity for flagging the footways, which would be a useless expense to the owners, but the paving of the carriage-way would be a great public advantage. The writer has such a case, which is urgent; but in the present state of the law it is considered by his Authority that it would bear harshly upon the owner to deal with it according to the section.

**Method of Executing Works.**—Another question about which there is great difference is the procedure to be observed on executing the works. Some Authorities do so by their own men, while others let all work by contract after publicly advertising for tenders. The former is open to grave abuses, and nearly always gives dissatisfaction; whereas the latter is fair and above board, and removes ground for complaint as to the works being too costly and above market price. It would be well if this system could be made compulsory.

**Apportionments.**—The apportionment of the costs of the work should include all incidental works, such as searching for and examining sewers, advertising, surveying, plans and specifications, &c., and 5 per cent. for superintending and office charges. Many works are extensive, and must necessarily extend over a long period of time, consequently a considerable sum is incurred in interest on the money employed by payments on account. Under the present law this money if paid must be provided out of the rates, and cannot be recovered from the owners. This should be rectified, as the owners, if doing the work themselves, would certainly have to find the money from time to time for payments, and consequently to pay interest for it.

**Conclusion.**—This is now the completion of my task; and I may be told that many of the views I have advocated in the latter part of the

\* By Mr. W. Spinks, Assoc. M.Inst.C.E., Borough Surveyor, Dulwich, Read before the Association of Municipal and Sanitary Engineers and Surveyors. Continued from p. 99, ante.

paper have already been dealt with in the defunct Bill. Some, I know, have, and they were inserted at my instigation and through the instrumentality of the honourable and learned member for Ashton-under-Lyne, Mr. Jno. Addison, Q.C., who at very great trouble went with me through the Bill first printed (dated January 22, 1886) line by line, and to his kindness in affording me valuable suggestions and criticisms I am greatly indebted, and desire publicly to acknowledge it; for mainly by his endeavours the Bill was reprinted and re-issued to the House on March 29th, 1886, containing many of the above suggestions; but nevertheless I venture to bring them before you to elicit more information on the various cases, and in the hope of obtaining sounder views on such important points from the more matured judgments and longer experience of older and more able Members of the Association.

[In a letter received by us from Mr. Spinks he says:—"It is very desirable indeed now to get all the information we can as to the working of the 150th Section, and I am collecting, with a view to proper compilation, the results of the practice of several Borough Surveyors who have not been able to attend the meetings of the Association."]

#### THE ARCHITECTURAL ASSOCIATION.

The sixth meeting of this Association for the present Session was held at 9, Conduit-street, on the 7th inst., Mr. J. A. Gotch (President) in the chair.

Mr. Thomas M. Rickman, F.S.A., read a paper on "The Complement of Architectural Instruction," which we print *in extenso* on another page.

The Chairman, in opening the discussion, said that Mr. Rickman's paper struck him as being one of considerable value and interest, inasmuch as it dealt with aspects of the profession too apt to be lost sight of in the course of business and in the struggle for existence. It was pleasant to have attention diverted from the carking cares of getting one's bread and cheese to those allied pursuits, many of which Mr. Rickman had mentioned. At the same time, those students who were in the boyhood of their education ought not to feel themselves overwhelmed by the long list of sciences that had been touched upon. These sciences were extremely interesting, as throwing side-lights upon the profession, but he took it that Mr. Rickman did not insist they should be wholly mastered; indeed, it was obvious that though a knowledge of them would be of interest, it was impossible for an architect to master them, as well as his own particular duties. From this they might learn a moral which had been impressed upon them more than once during the session, viz., the extreme value to the architect of a good early education. The various "ologies" could, at any rate, be partly mastered in that period of the education closely following school, so as to be of extreme use and interest in after-life. Mr. Rickman had said that it was possible for any one of them to attain in time to the first rank in architecture, but he (the Chairman) was a little bit inclined to doubt that. At the same time, architecture was as varied as poetry, and just as there were various branches in poetry, so there were various branches in architecture, and a man might be a distinguished proficient in one branch, though unable to touch another. For instance, they could not conceive Milton doing the work of Shakespeare, nor Shakespeare doing the work that Milton did. And again, in poetry there were men like Herrick, and men like Gray, each of whom in his turn had done work of which any one might be proud, but they would not compare Herrick with Shakespeare, nor Gray with Milton. Some comfort, therefore, might be taken from the thought that though they were not all born to necessarily great and magnificent works in the way of Law Courts and cathedrals, they might yet give pleasure to the world by some less pretentious buildings; and that their capacities as architects were not measured by the enormous size of the buildings they erected. Mr. Rickman had further referred to false quantities in architecture, and they would all agree that a false quantity, whether in verse or in architecture, should be avoided. He would like to point out, however, that in Shakespeare's works there were thousands of false quantities to be met with. Shakespeare abounded in bad puns, bad

rhymes, and other blemishes of the kind, which in themselves were distinct blemishes, but, on the other hand, were completely lost in his wonderful power in other and greater matters. From this he would argue that it was possible, by endeavouring to avoid false quantities, to become really tame. Mr. Rickman had urged them to be many-sided, but in considering this advice they must be careful how they displayed their learning to the world. He was reminded of a passage in Rabelais, where Pantagruel, after listening with astonishment to a man who addressed him in a string of long and unusual words, exclaimed,—"I think thou must become kind of heretic." So, if architects made a display of unusual knowledge to the unlettered people they met, they might also be regarded as "heretics," and then their condition would be a very parlous one indeed.

Mr. E. C. Robins, F.S.A., in proposing a vote of thanks, said that he had heard several of Mr. Rickman's papers, which were always full of matter for very serious thought. Mr. Rickman himself was an example of concentration of purpose and of determination to master one thing before attempting to master any other. He did not know any member of the profession who had set himself so earnestly to the study of that particular branch in which he was so well known to be an expert in his business proper. While making that business no one could have accused Mr. Rickman of diverging to the right hand or the left to seek out those things which were not seriously allied to his own particular practice. Now that he had succeeded so well he had hallowed his mind to take a wider range, and the year or two ago had read before the Institute a most interesting paper on the lessons of a boulder,\* it being one of Mr. Rickman's holiday delights to geologise and find out evidences of the truth of what might be found in books. There were two ways of learning things, one from the book side and the other from the practical side, or from the things themselves. There was no doubt that if, on the Saturday afternoons, they acquired information from the outside objects instead of from the mere inside of books, they would gain a much larger idea of the beauty of nature, and collect a greater number of examples, than by mere continuous reading. The thoroughness with which collateral knowledge was grasped was in direct proportion to the thoroughness with which special or expert knowledge was attained. Mediocrity in the latter meant mediocrity all round, as a rule, but that was not without its exceptions.

Mr. Cole A. Adams seconded the vote of thanks. Mr. Rickman, as a Past-President, who had filled the chair many years ago, must have revisited the "Locksley Hall" of the Architectural Association, with perhaps mingled feelings of pleasure and some pain; because since the year he was President almost a revolution had been effected in matters of art. In that room the "Battle of the Styles" had been fought over and over again, and Gothic, which at one time every member of the Association swore by, had now been partially set somewhat on one side, while Classic was pushing to the front. He did not suppose that Mr. Rickman wished them to master all the "ologies," but that when they came across this, that, and the other, they should endeavour to find out something about it, thus adding to their store of knowledge, and their interest in life. He remembered some years ago staying in a country house where the great philosopher, Herbert Spencer, was also a guest. Talking of the advantage of taking up subjects apart from one's own calling, Mr. Spencer said, "I advise you very strongly to take up some subject which is quite apart from anything connected with your business. In my own case, I have always made a practice of doing that, and I do it for this reason, that the man who sticks too closely to any branch he may take up, is in very great danger of becoming a monster. He develops in one direction; his mind is forced into an unnatural training, and in that way he becomes a danger to himself and a danger to society." He (the speaker) had always noticed that the men who took up subjects outside their daily work had a power of expression and information upon such matters that not only added to the charm of their own lives, but also to that of those with whom they came in contact. Following out these lines, they would take up the tiny shell,

see in it "a miracle of design"; "and sermons in stones, and good in everything."

Mr. Lawrence Harvey remarked that he had been much interested by Mr. Rickman's paper, because it had entirely confirmed the teaching of his own master, Professor Semper. Some time since he (the speaker) had treated of the question of style in that room,\* and perhaps they might remember that the definition of style which he then gave was that it was the stamp which the surrounding elements printed on a work of art when that work was generated. It was evident that one of these elements would be the society in which they moved, and as architects had to do with well and ill educated people, with rich and poor, it was necessary to be in thorough harmony with the society around them, and have a good general education. What Mr. Rickman had laid before them was not at all beyond what such an education should be. It was not necessary to know every subject thoroughly, but they should be able to understand it. One of the elements of style was, of course, the purpose which a building, or any work of art, had to fulfil; and that was the reason why a theatre was not like a church. The second element of style was the material to be used, and, if they appreciated the elements of style rightly, they would not design a building in brick on the same lines and with the same mouldings as a building in stone, but would even make modifications in the design according to the stone used. The third element was the kind of tools or machinery used in working the material. If they admitted the first of these elements,—the purpose of the building,—they must study in the architect's office, mixing in society, and getting such a general education as to understand everything that came before them. As to the questions of materials and tools, he could see no other way of properly understanding these than by labouring with their own hands, working at joinery, turning, and carving, both in wood and stone. It was not essential to become first-rate workmen, but they must have a correct knowledge of what could be produced with tools, thus enabling them to give a thoroughly good style from that point of view, to their work. Therefore, every science referred to by Mr. Rickman was of practical importance to the architect. It would, of course, be only putting a Tantalus' cup before the members if they had no means of learning these, but he believed that lessons were to be given at the City and Guilds of London Institute on wood-working tools, affording opportunities for those who wished to acquire a knowledge of the subject.

The motion was then put, and carried by acclamation.

Mr. Rickman, in replying, expressed his pleasure at meeting the members of the Architectural Association once more. He was not aware of any subject under heaven that an architect or a surveyor could take up which he would not find of some use in the practice of his profession. In conversing with people on scientific matters, it was not necessary to use long words, such as could only be used by those who had the most accurate experience of a subject. The object of understanding these things was, that when they got hold of a man who knew them well, they might draw information from him. They must learn to be good listeners, drawing from the man who understood his subject the information he was capable of giving, but themselves understanding the sort of information they were likely to receive. They might be in company with men a long time, and yet not draw them out in any way, but some casual remark would call forth information, and that was the object of acquiring those subsidiary matters, and having them in their heads, rather than being able to give a lesson in class. Architects, as a rule, would not have very large buildings to do. They would begin with the smaller works, and it was by exercising their eyes on such buildings that their architect's experience would be gained. If they learned to recognise false quantities they would avoid them, and he was obliged to Mr. Harvey for his idea of what style was. The Chairman had found out by his paper how imperfect his (Mr. Rickman's) education had been, his notions of false quantities having been drawn from the Latin and not from the English grammar. Since he was at school the whole subject of Prosody had been metamorphosed. He used to be told that, as there were quantities in Greek and

\* "Professional Lessons from a Boulder: a Plea for Geology as Part of an Architect's Education." See *Builder*, June 13, 1885, p. 823.

\* See *Builder*, Nov. 23, 1885, p. 749.

Latin, so there were quantities in English; but now there was nothing except accent, and it was a great question with many writers of the present time whether Latin and Greek were not more dependent in their prosody on accent than on quantity. He was taught to look upon false quantities as the most heinous sin possible, and it was in that view of false quantities in Latin verse that he had adopted the term to the little mistakes, the errors in taste and in etiquette, which the young architect would invariably make in the first works he carried out. Whether they looked upon the points that influenced the eye in architectural work as accents or quantities, they must learn that there were proprieties to be followed if the buildings were to be a pleasure to the beholders. These proprieties which they hoped to produce must be obtained, to a large extent, by following the proprieties their predecessors had carried out, so that it was not for them to write jingling rhymes in architecture, but to study the buildings containing a higher rhythm and more noble rhyme than those put up by the speculative builder, or by the ordinary run of architects, who had no idea in their heads except that of earning their five per cent., and whose clients did not wish for anything more than the utmost convenience and accommodation that could be got for their money. He had to thank Mr. Robins for his kind expressions. He remembered that Mr. Robins many years ago was one of those who were good enough to have confidence in him, and, therefore, he esteemed anything that gentleman might say. Mr. Robins had recommended the use of the Saturday afternoons; he (Mr. Rickman) recommended the use of every opportunity they, as architects, might have. An education in London would tell them a great variety of things. Materials of all sorts were brought from the country, but they would not know, from London experience alone, the peculiarities of those materials, how they were obtained, and how much better the materials brought to London were than the ordinary materials found in the country. The advantage of travelling throughout England was that the materials could be seen in their own homes. The materials brought to London ought to be better than the ordinary ones found in the country, and the style of dealing with them should be different. At the same time, the very best materials were not always got in London; for instance, the best Portland stone was not always obtained, but rather that which was the most easily converted to London purposes. Thus the selection made for London might teach them, when they went into the country, to gather more information on the subject of the materials than they could obtain from their usual City life. An architect should travel a great deal, and might do so for the purpose of sketching. He himself had walked thousands of miles through England and had seen nothing but old churches, but he now looked upon that as a very great waste of time; not that it was a wrong thing to see the old churches, but the right course would have been to have studied other things as he went along. When he now read the shilling book on Saturday half-holidays, published at Birmingham, he found it contained an amount of information on the roads, hills, churches, buildings, and manufactures of the country he used to walk about, not a fiftieth part of which he had ever picked up as he went along. He would, therefore, advise his bearers, if possible, to learn to appreciate these matters before they had the opportunity of travelling, and when that time came let them keep their eyes open and make good use of them.

**Sanitary Registration of Buildings Bill.**  
At the monthly meeting of the Council of the Sanitary Assurance Association, on Monday last, the draft of this proposed Bill was reconsidered. Sir Joseph Fayer, K.C.S.L., M.D., F.R.S., presided; and there were also present Professor Roger Smith, Dr. Danford Thomas, Mr. Mark H. Judge, Mr. H. Rutherford, and other gentlemen. A report on the draft Bill was submitted, with several clauses re-drawn. The Bill was further amended, and ordered to be printed, for final consideration at the next meeting of the Council. The new Bill is proposed to be compulsory with regard to schools, hotels, asylums, hospitals, and lodging-houses, while clause 6 has been made much more stringent in the matter of qualification of persons entitled to give sanitary certificates.

ARCHITECTURAL SOCIETIES.

**York Architectural Association.**—The dinner in connexion with this Association was held on the 5th inst., at the Queen's Hotel, Micklegate. The president (Mr. V. Hepper) occupied the chair, and was supported by Mr. G. Benson, hon. secretary, and by Mr. E. Priestley Shires, of Plymouth, the vice-chair being occupied by Mr. Walter G. Penty, who was supported by Mr. Norman R. Yeomans, hon. treasurer. Mr. W. G. Penty proposed "The Health of the President," who, in thanking the members, said no efforts of his would he wanting in furthering the objects of the society. Mr. Dickinson submitted "Art, Science, and Literature," to which Messrs. Worthington, Shires, and Benson respectively responded. After "Success to the York Architectural Association" had been drunk, the President proposed the health of "Our Guest" (Mr. B. Priestley Shires), remarking that as hon. secretary, from the formation of the society until his removal to Plymouth, Mr. Shires had worked assiduously in promoting the aims of the society.

**Glasgow Architectural Association.**—The usual monthly meeting was held on Tuesday evening, the President in the chair, when a paper on "Colour in Decoration" was read by Mr. Wm. J. Boston, who said that while form must take precedence of colour in architecture, still the aid of colour, whether of material or applied, was so important as to demand the utmost thought and skill. The laws of harmony were explained, and some of the simpler rules, which may be learned from Nature, applied in a practical way to internal decoration. Throughout, reference was made to the writings of Ruskin, Goodwin, Dresser, and O. Jones, and instances given of decorated buildings which the essayist considered examples to be admired and imitated. A discussion followed, and a vote of thanks was awarded to Mr. Boston.

ARCHÆOLOGICAL NOTES.

**Hythe Church (Kent).**—Kentish papers mention an interesting discovery in the chancel of the parish church of Hythe, during the progress of the work of restoration. It is known that prior to the existing nave and transepts there existed a fine Norman church, of which a doorway, an arch, and some portions of two windows still remain, and have been embodied to the existing church. No trace, however, of an earlier chancel or aisle was to be seen. On the recent removal, however, of the plaster from the walls of the south aisle of the chancel, two complete Norman arches were found spanning the Early English arches, and themselves showing traces of rich ornamentation. It is added that now that the plaster has been completely removed it is found that the north chancel wall will have to be rebuilt, bringing the total cost of the renovation work to nearly 2,500l.

**Lincoln Cathedral.**—The *Lincolnshire Chronicle* says that some excavations which have recently been made in the south aisle of the choir of the minster, and in the retro-choir, have laid bare a portion of the foundations of the original eastern termination of the cathedral as erected by St. Hugh, and taken for the holding of the Angel Choir; and have also brought to light the tomb in which the body of that canonised hishop was at one time apparently deposited, with some small remains of its contents. The foundations prove that, as previous investigations at the close of the last century had given reasons for believing, St. Hugh's church ended in a polygonal apse with chapels attached, somewhat resembling that at Westminster Abbey. The apse formed a semi-hexagon with a semicircular chapel, similar to those of the eastern transept, projecting from the two sloping sides, and a polygonal chapel, forming a complete hexagon attached to the eastern wall. This was probably the Lady Chapel. Between this chapel, and the semicircular chapel on the south side, there is a small circular appendage, the purpose of which is not very evident. At first sight it appeared to have been the foundation of a turret for a novel staircase. But on the most careful investigation there is no trace of the central tower. If a chapel, it must have been one of unusually small dimensions. Perhaps, when the excavations are completed on the north side, some light may be thrown upon its destination. The sepulchre of St. Hugh was discovered where

it was anticipated, beneath the black marble table on carved supports, erected by Bishop Fuller, about 1670, bearing a Latin inscription of elegiac verses, of considerable elegance, stating that the saint's body lay below. The original place of the shrine was the centre of the space behind the retables.

**Queen Eleanor's Cross, Northampton.**—At a recent meeting of the Architectural Society for the Archdeacons of Northampton and Oakham, Mr. Scriven adduced a large amount of documentary evidence with a view to showing the original form of the top of this structure. He showed that nothing had yet been discovered to prove how the top was finished; and the mythical fifth figure with which it is sometimes credited he considered was never made for the Northampton Cross; indeed, the first evidence relating to the five or six figures made by William of Ireland mentioned "five for the Cross at Northampton and elsewhere." After quoting much historic evidence, Mr. Scriven said that his conclusion was that the termination consisted of a shaft springing from the original base now remaining, with a richly-carved ring either surrounding it or forming a junction of the shaft in the head of the cross, which head was magnificently wrought in a group of figures representing the Crucifixion. It was certainly not a headless cross, for there was proof of the head being taken from Corfe, carried to Northampton, and set up there.

**The Ruthwell Cross in Annandale.**—A Carlisle paper announces that steps are being taken to protect the celebrated runic cross at Ruthwell, in Annandale, from the influence of the weather. A design has been prepared by a Glasgow architect for a recess on the outside of the church wall, behind the pulpit, for the reception of the cross, the church wall to be opened, and the cross to be in view of the congregation. The entire cost will be about 300l.

CASES UNDER THE METROPOLITAN BUILDING ACT.

WOODEN VERANDAHS.

At the Worship-street Police court, on the 5th inst., before Mr. Hannay, Mr. Alexander Payne, District Surveyor of East Hackney (South) and North Bow, summoned Mr. G. Bethell Holmes, of 84, King Edward's-road, Hackney, for having erected a wooden verandah in the rear of his house, No. 84, King Edward's-road, without giving the requisite notice to the District Surveyor, and without conforming to the rules of the Act. The building was 8 ft. by 14 ft., and 8 ft. to 10 ft. high, open, and supported by posts towards the garden, and enclosed on the other sides partly by the walls of the dwelling-house, with which it communicated, and partly by wooden boarding and open lattice-work. The roof was formed of wooden boarding covered with zinc. It formed a covering over the back door of the house, to which it was an addition. The District Surveyor contended that the whole tenour of the Act was to reduce the woodwork round about a dwelling-house, on account of danger from fire, and that section 25, clause 1, plainly forbade an erection of this kind, unless constructed of fire-proof materials, and quoted a case in which the defendant had been ordered to amend a similar erection five years before, being a verandah and balcony communicating with a house in No. 2, Fremont-street.

The defendant, who was represented by counsel, endeavoured to show that this was an erection to which the rules of the Act did not apply, but only quoted, in support of this, cases under other sections which did not refer to additions to a building.

The Magistrate said he often had a difficulty in deciding cases under the Building Acts, but this was a very clear one, and unless the defendant could show that the erection was of brick, tile, stone, or other fireproof materials, according to section 25, clause 1, he should make the order to amend, in conformity with the rules of the Act.

Ultimately an order was made against the defendant to amend in twenty-eight days, and he was also fined 20s. for doing the work without notice, and costs.

EXCESS OF CUBICAL CONTENTS.

At the same court, on the 7th inst., before Mr. Bushby, the case of F. R. Meeson, District Surveyor for East Hackney (North) v. Connell, was heard.

It appeared that the defendant in 1879 erected extensive works at Upper Clapton for laundry purposes, and recently made an addition to them. The original building and the addition exceeded 215,000 cubic feet, and the District Surveyor required a party wall under sec. 27, sub-sec. 4. The defendant contended: 1st, That the premises were not used for trade purposes; 2nd, That the case of *Scott v. Legg* governed this case.

The District Surveyor pointed out that the case of *Scott v. Legg* referred to an addition to an "old"

building, whilst in this case the addition was to a "new" building, as defined by sec. 8.

The magistrate decided that the building was used for trade purposes, but that the case of *Scott v. Legg* governed this.

The summons was withdrawn.

#### NEGLECT TO GIVE NOTICE OF ALTERATIONS.

At the Marylebone Police Court, on the 4th inst., Mr. Charles Hedges, builder, of 17½, Upper North-street, Caledonian-road, was summoned for having commenced certain alterations at 159, Kentish Town-road, without having previously given notice to the District Surveyor.

Mr. F. Wallen, the Surveyor for West St. Pancras, said that on the 18th ult. alterations were discovered in progress involving two irregularities, one of them being of a somewhat dangerous nature, consisting of the cutting away of a chimney-breast and corbelling out the overhanging work above, built with one of the party walls, without any certificate from him, as provided for by sec. 20, rule 15. Moreover, the work was done in a very defective manner, and had to be amended. After the discovery the defendant called at the Surveyor's office and gave notice of the work, which, as then appeared, had been commenced on the 16th of December. The Surveyor pointed out the danger that was likely to arise from such works being done without a previous survey by him, in order that he might certify whether they could be safely done, and what precautions were necessary, and also, in case of alterations where an irregularity was found to exist, the difficulty of discovering how far the alteration had extended.

Mr. D. Rutzon, the magistrate, inflicted a fine of 40s., and 2s. costs.

#### THE TREATMENT OF SEWAGE.

Sir.—The question raised by Dr. Tidy, and referred to in the *Builder* of January 8 [p. 70], as to the area of land required for sewage purification, is one as to which it is essential to give accurate figures. In thirty-two of the principal places in which land has been used for the purposes of sewage filtration and irrigation, the area has been on the average 389 acres to a daily flow of a million gallons of sewage. If we allow the usual mean of 30 gallons per individual per day, this gives an acre of land to every eighty-five persons,—an enormous proportion as compared with that mentioned in your article; but one which is not hypothetical, but practical.

With regard to the effect of drainage through earth, it is necessary to give proper attention to the strength of the sewage. From 80 to 100 grains of solid matter per gallon is the ordinary amount of foreign matter contained in urban sewage. Land is unable to deal with sewage of this strength, as is shown in the case of Edinburgh. The sewage of that city contains 102.36 grains of impurity per gallon, as it is poured on the land. The effluent that runs off contains 64.94 grains of foreign matter per gallon, and is thus only a slightly-diluted sewage. On the other hand, in seven towns, the mean strength of the sewage of which is 62.66 grains of foreign matter per gallon, or a little less than that of the Edinburgh effluent after passing through or over the land, only 14.68 grains per gallon are removed by irrigation. This includes almost all the matter in suspension, but still leaves 47.94 grains of matter in each gallon of effluent. In fact, irrigation removes on an average only 26 per cent. of the foreign matter; but is especially effective as to the organic matter in suspension, and the organic nitrogen, where these elements are found in a low proportion in the sewage. It is, however, ineffective where they occur in ordinary proportions.

When these definite facts,—which may be verified from the reports of the Rivers Pollution Commissioners,—are properly considered, it will be seen that the small amount of purification effected by irrigation filtering is attained at an enormous cost, although it is somewhat special in its nature. A better effluent can, no doubt, be procured by going to the double expense of precipitation with subsidence, and subsequent filtration through land, than is produced by either of the processes alone. But the financial aspect of the question is one of cardinal importance, and the idea of providing an acre of land for every eighty-five persons is one that only needs to be distinctly stated as the actual practice, to show how little value attaches to theoretical accounts of the treatment of sewage.

Jan. 8th, 1887.

FERRONETER.

#### KITCHEN BOILER EXPLOSIONS.

Sir.—Referring to a remark of a jurymen last week [p. 104] with reference to safety-valves which were used for explosions, and which he said should be used in every case; this is perfectly right, providing the right kind of valves are used and fixed in the right place. Unfortunately, however, there are many so-called safety-valves in the market which are worse than useless, as, after being used a little time, they become set fast, and take a deal of force to open them with a chisel or similar instrument. This is no fancied or supposed case, for I have had to do it myself. The only kind of valve that is to be depended upon for this work is a properly made dead-weight safety-valve, which will not set fast, however long it may be fixed before coming into use; this is to be relied upon, and only requires to be properly fixed not far from the boiler and where it must be at once seen if, through extra pressure, it blows off; certainly not up the chimney, this being the last place to fix it. The valves that are not to be depended upon for this purpose are those with indiarubber seats and spiral springs, or metal with spiral springs, or levers and weights.

W. STAINON.

\* \* \* We quite endorse our correspondent's recommendations.—Ed.

#### COMPETITION, GLASGOW EXHIBITION, 1888.

Sir,—I beg to point out to intending competitors for the above building, that the guinea charged for the conditions and plan of site is not the usual deposit, which, on receipt of a bona-fide design, would be returned; but it is a sum paid for the privilege of competing. At least, I cannot look at it in any other light, as the principal matter supplied to competitors surely cannot cost so much.

GUINEA.

#### GELATINE MOULDS.

Sir.—Could any of your readers tell me the best way to prepare gelatine moulds for casting plaster of Paris ornament, and also of what oil used for painting the face of the mould is composed?

JOHN LIVINGSTONE.

#### MASONS' WAGES.

Sir.—May I ask, through your journal, whether it is true that several masons lately employed in the restoration of Buckingham Palace were last week called out by the Masons' Society, because they were only paid 8d. per hour? The insertion of this would greatly oblige.

A. B.

#### PROVINCIAL NEWS.

*Appleby*.—Mr. S. J. Smith, C.E., recently held an inquiry at the Town Hall, Appleby, in reference to an application by the Corporation to the Local Government Board for power to borrow 1,000l. for the purposes of street improvement, sewerage, and sewage disposal.

*Birmingham*.—The new artisans' dwellings, situate in Heath-street, are now completed. They have a frontage of nearly 900 ft. They are letting rapidly, being in the vicinity of many large works. The site having a rapid fall considerable care was necessary in adapting the buildings to the land. Stone carving and Minton's tiles have been freely used in the elevation. Mr. J. Statham Davis was the architect, and Mr. Edward Airey the builder (both of Birmingham).

*Kingston (Surrey)*.—New Municipal Buildings are about to be erected here by the Corporation. That portion of the intended buildings which will stand on the site of Clatters House will be 50 ft. high, the central tower rising 50 ft. above the main body of the buildings, which will contain two stories. The old Assize Courts adjoining are intended to be so reconstructed as to form a large assembly-room or public hall in connexion with the other parts of the building. The hall will be 96 ft. long by 42 ft. wide, with two dressing-rooms adjoining. At one end of the hall there will be a stage of large dimensions, and at the opposite end a gallery extending across the hall, and 32 ft. in depth. There will be several entrances, the old Assize Court-yard being utilised on one side for the purpose. At one side of the stage there will be a supper-room 32 ft. by 22 ft., which it is also proposed to utilise as the magistrates' retiring-room. The new buildings have three entrances from the front, and amongst other apartments which it has been designed to contain, one on the ground floor, 73 ft. by 37 ft., is proposed to be used for Free Library purposes. The municipal offices proper will be on the floor above, and will be nine in number, in addition to a strong

room. The assembly-room formed out of the old Assize Courts is proposed to be used as the magistrates' court as well as for other public purposes. The plans for the new buildings have been designed and prepared by Mr. Macaulay, the Borough Surveyor, and the cost of carrying them out is estimated at 14,000l.

*Lancaster*.—At the recent annual distribution of prizes to the successful students at the Lancasterian School of Art, the Mayor (Admiral T. Storey) intimated that in addition to his gift of a new School of Art and Art Gallery as a memento of the Queen's jubilee, he intended to make provision for technical education, and especially chemistry, and would provide a laboratory, class-rooms, and small lecture-theatre.

*Liverpool*.—A portion of the new Exchange Station of the Lancashire and Yorkshire Railway, has just been opened for traffic, and the old building is now in course of demolition, previous to the erection of the other half of the new premises. When the station is completed it will be one of the largest in the kingdom. It has frontages to Tithebarn-street and Bixth-street, and is built of stone and granite in the Italian style of architecture. The approaches to the platforms from Tithebarn-street and Bixth-street are by easy gradients, exhibiting a vast improvement on the approach to the old station by a steep incline and numerous steps. The platforms at the Pall Mall end of the building are practically level with the street. The total area of land devoted to the building is about 3,400 superficial yards. The main frontage to Tithebarn-street will contain the entrance to the hotel; also a row of fifteen shops abutting up to the street. Two passenger entrances, 15 ft. and 20 ft. wide respectively, are made from Bixth-street, and there are cab entrances and exits from Pall Mall; there is also a main carriageway from Moorfields. The station buildings proper consist of lofty dining-rooms, refreshment-rooms, waiting-rooms, lavatory accommodation, and the usual offices required for a railway station of the first class. The station, when completed, will have six platforms, each 255 yards in length, with eleven pairs of rails. The hotel will have an entrance from Tithebarn-street as well as entrances from the passenger approaches and cab landing, and will have seventy bedrooms. The buildings have been designed by Mr. Henry Shelmerdine, and the engineering works have been designed and carried out under the supervision of Mr. William Hunt, C.E., engineer-in-chief of the company; the contractors for the work being Messrs. Robert Neill & Sons, Manchester.

*Lyndhurst*.—The New Forest Hall, Lyndhurst, was opened on the 27th ult. It will seat from 300 to 400 persons. Mr. John Blizzard, of Southampton, was the architect, and the hall has been built by the proprietor, Mr. William Gerrard.

*Osselt*.—According to the *Leeds Mercury*, it is intended to celebrate the Royal Jubilee Year of 1887 by building public offices and a large hall in which public meetings, &c., can be held. Mr. Henry Holton, of Dewsbury, has been appointed architect. The plans show that the new premises will front to Bank-street, one side abutting upon Illingworth-lane. The front elevation is in the Classic style.

*Stafford*.—It is proposed to erect public baths here as a memorial of the Jubilee year, but the plans are not yet finally adopted.

*Tolworth (Surrey)*.—The Kingston Rural Sanitary Authority propose to erect a new infectious diseases hospital at Tolworth, an outlying locality within the district of the Authority. The building will contain four blocks, and the estimated cost, including furnishing, is 10,000l. The administrative block will contain, on the ground-floor, the visitors' room, matron's sitting-room, kitchen, surgery, hall, lavatory, and other conveniences. The first floor will contain a number of bedrooms, three nurses' cubicles, linen stores, and bath-room. In this block there will also be extensive cellars under the ground-floor in the basement. Another block, designated the special isolation block, the estimated cost of which is 2,400l., will contain two wards, each 36 ft. by 18 ft., and 13 ft. high, each ward being fitted with three beds. This block will also contain two smaller wards, each 24 ft. by 18 ft., to hold two beds each, and in addition the block will likewise contain two nurses' rooms. A third block is described as a two-ward pavilion, each ward being 36 ft. by 26 ft., and together will have accommodation for twelve beds. There will also be nurses'

rooms, and bath and store rooms. The laundry arrangements will be provided in the fourth block, and will consist of an ambulance shed, ironing and drying room, and disinfecting apparatus on the ground-floor, and on upper floor the washhouse and mortuary. Mr. Jacob Gibbon, of Verulam-buildings, Gray's Inn, is the architect, and Mr. Charles Ward is the contractor, the amount of his contract being 7,850l. This sum is exclusive of architect's fees, legal expenses, and furnishing. An official inquiry into the proposal was held on the 31st ult. by Mr. Arnold Taylor, on behalf of the Local Government Board.

**Wimborne.**—From statements made at the meeting of the Rural Sanitary Authority on the 31st ult., it appears that the late flood has done much damage in the town, the bridge over the river Stour being so injured that it will cost about 6,000l. to put it into a proper state of security.

**SEWERAGE AND DRAINAGE WORKS.**

**Dorking.**—A Local Government Board inquiry was held at Dorking on the 30th of December, by Mr. Arnold Taylor, into an application made to the Local Government Board for sanction to a loan of 7,000l. for the purposes of sewage outfall and disposal works. Mr. Urban Smith, C.E., of the firm of Smith & Ansdn, the Local Board's Engineer, attended in support of the application, and previously to the inquiry the Inspector went over the works (which are in course of construction) with the Engineer. There was no opposition to the proposed loan, and the proceedings were of a formal character. Both the sewerage works and the works of disposal at Dorking have been for some time in progress under separate contracts, and are now nearing completion. The anticipated cost is 20,000l.

**Guildford.**—At a special meeting of the Guildford Urban Sanitary Authority, held on the 31st ult., to consider a letter from the Local Government Board as to the sewerage of the district, a committee was appointed to make inquiries and collect information as to the best course to be pursued in the matter. It was stated in the course of the discussion that more than half the town sewage went into the river, but this was contradicted by the Mayor and other members of the Board.

**Newhaven.**—The tender of Mr. James Haywood, contractor, Eastbourne, has been accepted by the Newhaven Local Board for the construction of a complete system of sewerage with outfall sewer and storage culvert. The sewage will be delivered during the ebb tide in the River Ouse, at the mouth of the harbour, and close to the sea. The amount of the contract is 5,557l. The scheme has been approved by the Local Government Board and the Harbour Company, and negotiations with the War Department and Board of Trade are approaching completion. The engineer to the works is Mr. W. H. Radford, Assoc.-M. Inst. C.E., Nottingham, and the scheme was selected from more than twenty designs in open competition.

**Sutton (Surrey).**—On the 29th ult. Mr. Arnold Taylor, one of the Inspectors of the Local Government Board, attended at the Public Hall for the purpose of holding an inquiry into the application of the Local Board for powers to borrow a further sum of 7,000l. in connexion with the drainage of the town. The chairman of the Local Board (Mr. T. Wood) remarked that when the former inquiry was on, and when they obtained the sanction to borrow 13,000l., the sum of 16,000l. was mentioned, but Mr. Taylor thought they had better apply for 13,000l. first. Mr. Taylor said this was so. The Clerk (Mr. P. L. Marten) said the land acquired by the Board was 6a. 2r. 3p., the cost being 2,900l., together with expenses, with the exception of those of the arbitrators and umpires, which were not yet ascertained, but these might be put down at just over 200l. The amount of the No. 1 contract with Messrs. Cook and Smith was 4,120l., and the amount which had been paid them up to the present was 6,650l. Mr. Cunliffe's contract for the outfall works was 5,331l., and he had received 2,800l.—There was no opposition to the Board's proposals.

**Swarwick.**—A small farm of fifteen acres is now being laid out for sewage irrigation near Bulterley Reservoir. The land is a stiff clay, but it is being specially prepared and lightened to a considerable depth with fine ashes, and

close drained. It is believed by the method adopted the strongest clay land may be made suitable for the reception of sewage, and thus one of the great difficulties in the way of sewage purification in some districts will be removed. The farm will receive the sewage from a population of nearly 4,000. Mr. W. H. Radford, of Nottingham, is the engineer for the works.

**WATER SUPPLY.**

**Bristol.**—It is reported that at length an effort is being made to utilise the 14,000,000 gallons of water per day which the Great Western Railway Company are pumping at the Sudbrook springs on the Monmouthshire side of the Severn Tunnel, and which are at present allowed to run to waste, while it costs the company nearly 10,000l. a year to pump it into the Severn estuary. The water has been submitted to analysis, and has been declared to be the purest spring water, entirely free from organic matter, and the finest water that could be desired for domestic purposes. The Mayor of Bristol presided over a town's meeting in the Guildhall, on the 29th ult., in favour of a scheme for using the spring as a further water supply for Bristol by bringing it across the Severn by a tunnel beneath the bed of the river. A company has been formed for this purpose, and as a desire had been expressed that the Corporation should have the control of the water-supply of the city, the Bill which had been drafted contained a clause enabling the Corporation to exercise all the powers of the Act on payment of the costs and expenses incident to obtaining it, and sums expended by the company in exercise of its powers, with 5 per cent. interest. Resolutions in favour of the scheme were unanimously adopted.

**Carlisle.**—The new filter-beds constructed for the Corporation of Carlisle by Messrs. R. H. & H. Hodgson, of Workington, and making an important extension, at a cost of about 8,700l., of the means of supplying this city with water from the river Eden, have just been brought into use. Mr. Hepworth, the Engineer of the works, had printed for the occasion an interesting sketch of the history of the Carlisle water-supply from 1837 down to the present time. The new extensions include an subsiding reservoir, having an area of 5,353 yards super., and a sand-filter with an area of 2,401 yards super., the total area being about twice that of the old filter. The whole of the walls are of cement concrete, and the foundations are laid upon the rock for a considerable length, the remaining length being laid upon the gravel. The walls of the subsiding reservoir, which occupies the north end of the site, are 4 ft. in thickness at the bottom, and 2 ft. 6 in. at the top. The bottom of the bed is covered with Lazonby flags, having a fall from all sides towards the centre, where is fixed a 12-in. diameter pipe, by which all the water and sediment that may have deposited on the flags may be drawn off from the reservoir, when it is required to be cleaned. The water is admitted from the river into the reservoir by a 24-in. valve placed in a culvert at the north end of the reservoir. The outlets from the reservoir to the sand-filter are four in number, 12-in. diameter each, with valves attached, and are fixed at a height of about 2 ft. above the level of the flags. The water in the new reservoir will have ample time to settle before passing through to the sand-filter. The walls of the sand-filter are 4 ft. 6 in. thick at the bottom, and 2 ft. 6 in. at the top. The filtering material consists of six layers, through which the water has to percolate. The first or bottom layer, which is hedged round and over the tunnels for conducting the water into the service reservoir, consists of a layer, 15 in. in depth, of washed stones, from 4 in. to 8 in. diameter; the second layer, 12 in. in depth, of a bed of stones, 3 in. diameter; 3rd, a bed of stones, 1 in. diameter, laid 3 in. deep; 4th, a bed of stones 1-in. diameter laid 3 in. deep; 5th, a layer of pebbles not more than 1-in. diameter laid 3 in. deep; and 6th, a layer of fine sand, 2 ft. 6 in. deep. The water, after passing through the filtering media, is conducted into the old service reservoir.

**Penance.**—The *Cornish Telegraph* of the 23rd ult. contained an article describing the working of the "districting" system in conjunction with Deacon's waste-water meters, which afford a ready means of localising the points at which waste is occurring. Wa

described this system in some detail in the columns of the *Builder* a few years ago.

**Sevenoaks.**—The shareholders of the Sevenoaks Waterworks Company have authorised the directors to make application to the Board of Trade to grant a provisional order, to be subsequently confirmed by Parliament, for extending their limits of supply to the parishes of Brasted, Sundridge, Cbovening, Otford, and Kemring, all within the county of Kent; to levy rents and rates thereon, and to amend the Sevenoaks Water Act, 1878, and extend it, and the Water Clauses Acts, to the said parishes; to raise additional capital for the purposes aforesaid by ordinary or preference shares or stock, or by debentures, or debenture stock, and for other purposes.

**Sheffield.**—A public meeting of the ratepayers of Sheffield was held on the 28th ult., to ask their sanction, as required by Leaman's Act, to a Bill promoted by the Corporation for the compulsory purchase of the works of the Sheffield Water Company, and to the opposition to the application of the Water Company to be allowed to continue to charge the extra 25 per cent. granted to them for twenty-five years. After the hearing of the Bradford dam in 1864, Parliament authorised the Company to charge for 25 years an extra 25 per cent. on their rates. They are now going to Parliament to ask that the 25 per cent. might be charged in perpetuity. The Corporation have not only decided to oppose the application, but to endeavour to obtain possession of the Company's undertaking. The ratepayers were now asked to sanction their action. The meeting was held in the Montgomery Hall, and was presided over by the Mayor (Mr. H. Stephenson). The members of the Corporation were present, and the meeting was largely attended. Two resolutions were submitted, one authorising the Corporation to promote a Bill of their own, and the other to oppose the Bill of the Water Company, and they were carried almost unanimously. A poll was demanded, and it will be taken this month.

**SCOTCH NEWS.**

**Dundee.**—At a meeting held at Dundee on the 27th ult. it was agreed to erect a Technical Institute near University College, to be worked in connexion with the college. The new building is to be known as the Baxter Technical Institute, the late Sir David Baxter, Bart., of Kilmarnock, having left 20,000l. for its erection with a view to the improvement of working men in scientific knowledge.—The *Dundee Advertiser* says that the year just closed has been anything but remunerative to those engaged in the building trade in Dundee. Considerable additions have been made to house property within the burgh during the year, but the depression in the staple trade and the keen competition existing among the master builders have materially affected contract prices.

**Portobello.**—The works in connexion with the erection of a new railway station are just being commenced. The plans have been prepared by Mr. Carswell, chief engineer to the North British Railway Company, and the works will be carried out by Messrs. James Young & Sons, railway contractors, Edinburgh. Operations are expected to be completed about the end of June.

**Stirling.**—At a special meeting of the Stirling Town Council held on the 23rd ult. to consider a proposal to purchase a part of the Gowan Hills for the formation of a new cemetery, Provost Yellowlee moved that the Council accept the offer of the Commissioners of Woods and Forests of the proposed cemetery ground at 310l., and remit to the Cemetery Committee to take in estimates for inclosing the ground and levelling a section of it for interment purposes. This motion was carried by sixteen to two. Resolutions were also adopted, but by very small majorities, agreeing to purchase in addition, ten acres in one part of the Hills, and five acres in another, should the Crown be willing to sell them separately at the same rate as that asked for the whole of the hills, say 55l. per acre.

**"New Buildings in Eastcheap."**—In the paragraph with this heading which appeared in our last (p. 104), Mr. Richardson was mentioned as clerk of works. We are asked to state that Mr. Chas. Watkins was clerk of the works, and that Mr. Richardson is Messrs. Perry's foreman.

**The Student's Column.**  
 FIELD WORK AND INSTRUMENTS.—III.  
 Surveying Instruments.

III.—THE BOX SEXTANT.

THE principle of this instrument resembles that of the optical square, in depending primarily upon the following facts:—(1) when a ray of light is reflected at a plane surface the reflection takes place in a plane perpendicular to the reflecting surface, the incident and reflected rays making equal angles with this surface; (2) when a ray of light proceeds in a plane, at right angles to each of two plane mirrors, inclined at any angle to one another, and is successively reflected at the plane surfaces of the mirrors, the total deviation of the ray is double the angle of inclination between the mirrors. The angle so formed by the glass mirrors in the case of the optical square was seen to be fixed at 45°, giving a right angle between two directions; but in the case of the box sextant, one glass, namely, the one containing the complete mirror, is constructed to revolve upon a centre, and worked by means of a curved rack-and-pinion wheel, as shown in fig. 1. This glass is called the index glass, and is marked A in our illustration. The glass marked B is called the horizon glass, and is fixed in a plane perpendicular to that of the instrument. The angles observed by a sextant being double the angles moved over by the index, the limb of the instrument is graduated, as shown in fig. 3, as though it were double the size, in order to record absolutely the angle observed. The angles are marked to read from zero to 140°; but it is to be noticed that after passing 120° the angles become less reliable. The divisions zero to 140° are usually marked upon a silvered plate, and have a vernier scale attached, which works upon the end of a bar, to which is fixed upon the inside, below the top plate, the movable index mirror. This mirror, with its attached vernier-bar, is revolved by means of the milled screw R, in fig. 3, which acts on the rack and pinion shown in fig. 1. The horizon-glass is half silvered and half unilvered, and is attached to the top plate, as shown in fig. 2, connected in a manner capable of adjustment, as we shall explain in our next article.

For convenience of carrying the instrument it forms, when closed, a box of about 3 in. in diameter and 1½ in. deep. The top cover which protects the plate, shown in fig. 3, is reversible so as to be unscrewed and attached by an under screw beneath the box, thus forming a handle for holding the instrument when in use. These screws for attaching the box or cover to the upper or lower side of the instrument run round the outside lower edge of the circumference of the instrument. Before screwing the cover to the underside of the instrument a small slide shutter must be opened in the lower plate to allow of two darkening glasses being lowered by means of two levers, which appear in the side of the instrument, generally just under the zero point of the graduated plate. These two coloured glasses, which are made to fold inside when the box is closed, are intended for astronomical purposes and are to be used when observing the altitude of an object such as the sun, one or both of the darkening glasses

BOX SEXTANT

NOTE.—WHEN AN OBJECT IS VIEWED AT AN INFINITE DISTANCE, AND THE INDEX OF THE INSTRUMENT IS SET AT ZERO THE CLASS B SHOULD BE PARALLEL TO THE CLASS A.—THE ADJUSTMENTS ARE EFFECTED, WITH THE KEY K, (1) HORIZONTALLY, BY TURNING THE SQUARE HEAD OF THE SPINDLE L, WHICH HOLDS THE SPRING AS SHOWN, AND IS FASTENED BY A SCREW END TO ITS CONNECTION WITH THE UPPER PLATE.—(2) VERTICALLY, BY MEANS OF THE SCREW NEAR B WHICH RAISES OR LOWERS ONE SIDE OF THE UNDER PLATE, TO WHICH THE CLASS B IS ATTACHED.

FIGURE 6

FIGURE 7

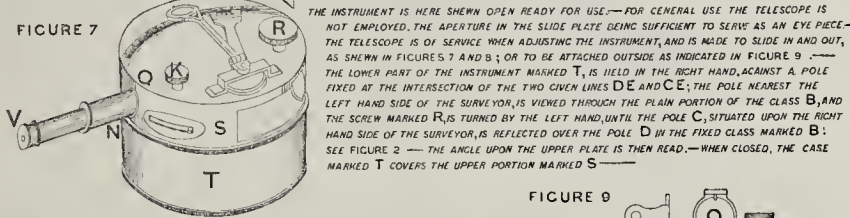

FIGURE 8

NOTE.—IN SOME INSTRUMENTS THE TELESCOPE IS CONNECTED BY THE ATTACHMENT MARKED Q IN FIGURE 8.

FIGURE 9

FIGURE 10

being left in position according to the brilliancy of the object viewed. Thus they are of service at sea as shades when obtaining the altitude of the sun; that is to say, you look at the horizon through the plain portion of the glass B, and then bring the edge of the sun to the horizon with the little milled bead R outside the instrument. To the sight is attached a telescope, omitted in figs. 1 and 3, but will be shown in figs. 7, 8, and 9. This telescope is made to slide in and out, and is provided with a sun glass for use in adjustment. The lenses employed have a concave surface in the eye-piece, with two lenses in the object glass, having the interior curves necessarily deep, about 2½ in. radius, on account of the short focus.

When, as in use at sea, you have to look through the plain glass with the telescope, the shades worked by the levers above described are absolutely necessary to be used, either together or separately, at the time of observation, but in ordinary land surveying work they must be lowered through the aperture, which is closed by the sliding-shutter, so as to be out of the line of sight when they are not required. The telescope also is found to be generally inconvenient as it takes time to arrange, and is, therefore, removed as soon as the instrument is known to be in adjustment. When the telescope is removed, a sliding-plate, shown in fig. 1, takes its place, and the eye is guided by a small aperture in this sliding-plate opposite the fixed half silvered glass. The vernier shown in fig. 3, and enlarged in fig. 5, enables the angles taken to be read to minutes. It will be observed that this vernier is the same as described by fig. 4 of our last article. It is not necessary to have the index or vernier, when about to read an angle, placed at zero to start with, as the angle depends entirely upon the conjunction of the objects viewed, appearing as one in the glass B opposite the eye-piece, but when it is desired to close the box it is necessary to place the vernier scale somewhere near the zero point by means of the milled-screw, R, otherwise the curved rack will project, as shown at P, in fig. 3, and prevent the cover passing over it.

SCHOOL-BUILDING NEWS.

**Basingstoke.**—New Board schools are in course of erection here, and the foundation stone was laid last month. The site of the schools is on the Fairfields. (The architect is Mr. Charles Bell, whose plans were selected in competition.) When finished, they will accommodate 1,300 children. Mr. H. J. Goodall, of Basingstoke, is the contractor for the work, the amount of the contract being 10,351l. The buildings will be in two blocks,—one for the infants and the other for the older scholars,—and the material used flint, with brick dressings; the central hall principle,—class room leading out from the hall,—is adopted. The heating apparatus is by Messrs. Rosser & Russell, of London. The infant school is a one-story building, excepting the caretaker's department, and the upper school is a two-story erection.

**Great Horton (Bradford).**—New schools, erected by the Bradford School Board, at Great Horton, have just been opened. The buildings, which consist of three blocks,—the mixed school, the infants' school, and the caretaker's house,—are designed in the "Queen Anne" style. The mixed school consists of a large assembly-hall, 88 ft. by 45 ft., well lighted at both ends and at the sides, above the roofs of the adjoining class-rooms. The height to the ceiling is 29 ft. The roof is of open timber-work, and the ceiling is panelled in wood moulds in a simple manner. Around the assembly-hall are grouped twelve class-rooms, about 25 ft. square, and capable of accommodating from fifty-six to sixty-four children each. Each class-room has glass partitions from the assembly-hall, and all are arranged so as to have left-hand light. The infants' school has an assembly-hall similar to the mixed school, but 53 ft. by 36 ft., and 26 ft. high. Five class-rooms are arranged around it, with glass partitions, as in the mixed school. Some of these rooms are arranged for desks, whilst others have galleries. The architects are Messrs. Morley & Woodbone, of Bradford and Bolton (who were appointed after competition). The contractors for the various works have been:—Messrs.

Holdsworth Brothers, of Wyke, masons; and Messrs. J. Moulson & Son, joiners; Mr. Smithies, slater; Mr. Wallace, painter; and Mr. Throp, plasterer, all of Bradford. The heating work has been done by Mr. T. Mears, of Bradford; the gasfittings by Mr. Laycock, Bradford; and the railings by Mr. Stork, Bradford. Mr. Johnstone, the Surveyor of Works to the Board, has superintended the work. The total cost of the building has been about 11,000l.

**Sheffield.**—New Sunday schools in connexion with Glossop-road Baptist Church were opened on the 28th ult. The new building continues the frontage of the original building of the church and former school up Shearwood-road, making altogether a street front of 330 ft. It harmonises in character with the old building, although it is somewhat less ornate in detail. The plan of the new central school presents a large central hall, surrounded with two tiers of class-rooms, capable of being added to the auditorium when required; and with a gallery on three sides. There are three separate entrances to the new portion, respectively for boys, girls, and infants, and separate retiring-rooms, also separate lavatories, &c., for male and female teachers. The total cost of the new premises, with certain alterations in portions of the old buildings, has been 3,530l. The work has been carried out by Mr. A. F. Ripley, of Rotherham, under the direction of the architect, Mr. C. J. Innocent, of George-street. The sub-contractors were Messrs. E. and W. Oxley, of Hanover-street, for the carpentering, &c.; Messrs. Bissett & Sons, of Wilkinson-street, for the plastering; Mr. J. E. Elliott, of Surrey-street, for the gasfitting and plumbing; and Messrs. Truswell & Sons, of Durban Foundry, for the heating, which is on the hot-water high-pressure principle.

STAINED GLASS.

**Coniston.**—Mr. Ruskin has presented a stained-glass window to the Church of the Sacred Heart of Jesus, Coniston. The window is placed in the west wall. It is triplet in form, and the subject of illustration is the vision of St. John in the

Isle of Patmos. The window is the work of Messrs. Hardman, of Birmingham.

**Hanney.**—A three-light stained-glass window has just been fixed at Hanney Church, near Wantage, Berks, in memory of the late wife of the vicar, the Rev. James Macdougall. The style of the window is that of late sixteenth-century Italian work. In each light a figure is represented, viz., "Faith" on the left hand, "Charity" in the centre, and "Hope" in the right-hand light, with emblematic floral ornament in the canopy and at the foot of each figure. The window has been executed from designs by Mr. George M. Macdowell by Mr. James B. Westropp, at the Royal Stained Glass Works, Old Windsor, under the direction of Mr. R. Owen Allsop, architect, Norfolk-street, London.

**Newmarket.**—A stained window has been placed in the east end of St. Mary's Church by Mrs. Joseph Dawson, in memory of her husband. The subject of the window, which has three lights, is the Ascension, and the work has been well carried out by Messrs. Lavers, Westlake, & Co.

**Northampton.**—Two stained glass windows have just been added to St. Edmund's Church, Northampton. They are the gift of Mrs. Franklin, in memory of her nephew, Samuel Taylor Mea. Mrs. Franklin was assisted in the choice and arrangement of the subjects by Mr. M. H. Holding, A.R.I.B.A., and the making was entrusted to Messrs. Hardman & Co., of Birmingham. The fixing was done by Mr. Wm. Tomes.

**St. Day (Cornwall).**—A stained-glass window has lately been fixed in the parish church here in memory of the Dowager Lady Williams. The window is the work of Messrs. Taylor & Son, of Berners-street, London, and its subject is the miracle of healing related in the eighth chapter of St. Luke's gospel.

#### RECENT PATENTS.

##### ABSTRACTS OF SPECIFICATIONS.

517, Improved Cement. J. & A. Bidwell.

This is a cement composed of zinc white and various varnishes. The advantage is that it will furnish to a bright gold or silver colour, and is thus of special use in decoration.

1,496, Electric Bells. T. Crampton.

This invention relates to a bell actuated by electricity, and constructed in such a manner that the armature, electro-magnets, and clapper, are contained within the bell proper. The clapper is balanced by gravity, without springs, but is moved whenever a current of electricity is passed through the armature.

1,913, Ventilating Cows. E. H. Shorland.

The subject of this invention is a square or angular cow, with upright louvers, fitted with shields, placed at an angle to the openings. It is claimed that it is a more convenient form for fixing than many in general use.

5,942, Improved Door-Spring. F. Stent.

This invention consists in a door-spring which is entirely concealed from view, and is capable of being readily brought or thrown out of action at will. The closing is effected by a spiral spring, and can be modified by a flexible band.

5,973, Tenoning Apparatus. J. Grant.

In this apparatus adjustable saws are used, the object of the invention being to obviate the great waste of time and loss of material that occurs with the use of machines as ordinarily constructed for this purpose.

1,654, Hinges. A. Gold.

By this invention the manufacture of the hinges is greatly simplified and economised, the complication of pinning, and the use of washers, and the riveting over joining, are dispensed with.

2,378, Kilns for Tiles, Pottery, &c. Geo. Lazenby.

The improvements claimed by the patentee are in the direction of keeping the kiln free from the products of combustion, and this is effected by placing an inner wrought-iron casing inside the outer shell of the kiln. The case then being heated, the articles are fired without the products of combustion coming in contact with them.

Jan. 3.—43, W. Martin, Domestic Firegrates.—73, A. Bonit, Electrical Indicators.—80, D. Balsar, Fixing Mouldings and other Woodwork.

Jan. 4.—83, H. Johnson, Downcast Ventilator.—

89, H. Owens, Opening and Closing Fanlights, Ventilators, Casement Sashes, &c.—115, W. Thompson, Portable Houses.  
Jan. 5.—133, W. Bessley, Ornamentation of Tiles, &c.—156, F. Wade, Wood Paving, &c.  
Jan. 6.—176, T. Wilson and I. Johnson, Ventilating Apartments.—178, T. Murgatroyd and J. Turner, Device for Painting and Varnishing Brushes.—209, K. Worrall, Distemper.—215, H. and A. Cunningham, Wood Screws.

##### PROVISIONAL SPECIFICATIONS ACCEPTED.

13,306, R. Scrivener, Enamelling and Facing Bricks, Tiles, &c.—15,227, E. & J. Verity, Sash and Casement Fastener.—15,419, J. Hodges, Mortise and Rim Locks.—15,534, P. Walker, Ventilators.—15,953, G. Courtier, Kitchen Ranges.—15,998, J. Bryant, Alarms for Doors, Windows, &c.—16,071, W. Meers, Joint for Earthenware Sanitary Pipes.—16,083, W. Sanday, Combined Mitre-vent, Shoot, and Cramp.—16,105, J. Craig, Outlet Ventilators.—16,336, K. Shouler, Drain-pipes, &c.—16,360, C. Ewing, Self-closing Sash-fastener.—11,208, H. Wilson, Drying Timber, &c.—14,505, S. Willett, Door Indicator.—14,538, W. Sargent, Circular Glass Ventilators.—15,312, G. Ewing, Flushing Apparatus for Water-closets, &c.—15,545, A. Henderson, Syphon Trap Closet-pans.—15,600, G. Courtier, Drain Traps.—16,471, G. Reidfern, Hearths or Fireplaces.—16,527, J. Harvard, Window-sash Fastener.

##### COMPLETE SPECIFICATIONS ACCEPTED.

2,967, J. Hicks and C. Tiptot, Levels.—3,006, H. Watson, Water taps, &c.—15,257, O. Lessing, Cut and Stained Glass for decorative purposes.—6,474, J. Barrett, Opening and Closing Doors in Connection with Hoists.—15,948, H. Haddan, Alarms for Doors, &c.

#### MEETINGS.

MONDAY, JANUARY 17.

Royal Academy.—Mr. J. E. Hodgson, R.A., on "Art a Universal Language." 7. 8 p.m.

TUESDAY, JANUARY 18.

Birmingham Architectural Association.—Mr. Edward R. Taylor on "Serpents of Architecture." 7.30 p.m.

Wednesday, January 19.

British Archaeological Association.—(1) Mr. J. Romilly Allen, F.S.A. (Scot.) on "The Crosses of the Isle of Man." (2) Mr. C. Kosch Smith, F.S.A., on "Roman Chichester." 8 p.m.

Society of Arts.—Mr. J. B. Marsh on "Cameo-Cutting as an Occupation." 8 p.m.

Civil and Mechanical Engineers' Society.—Mr. Francis Campin on "The Design of English and Foreign Iron Bridges." 7 p.m.

Builders' Foremen and Clerks of Works' Institution.—Annual Meeting. 8.30 p.m.

Royal Meteorological Society.—Two papers. 7 p.m.

THURSDAY, JANUARY 20.

Parkes Museum of Hygiene.—Mr. M. Ogle Tarleton on "Engineering and Architecture in relation to Sanitary Science." 5 p.m.

Edinburgh Architectural Association.—Mr. W. Scott Morton on "Taste in a Six-Roomed House." 8 p.m.

Royal Academy.—Mr. J. E. Hodgson, R.A., on "Art a Universal Language." 7. 8 p.m.

FRIDAY, JANUARY 21.

Architectural Association.—Prof. W. H. Corfield, M.D., on "House Sanitation." 7.30 p.m.

#### Miscellaneous.

**The Wood Trade of London.**—Messrs. Churchill & Sim's "Wood Circular" for January says,—"For the last five years we have had to report the wood trade of London as being in a very depressed condition, but of none of those years it is necessary to give such gloomy accounts as of 1886. Prices, which in January were believed to have touched the lowest possible point, continued to recede until the end of the year; and consumption, which, in spite of an abnormal cheapness of supply had been falling for some years, and which was also thought to have reached its lowest in 1885, has again experienced a further serious decrease. An idea of what this shrinkage in the demand has been will be quickly gathered from the following figures:—In 1881, the consumption of deals, battens, and boards was 29,650,000 pieces, from which total it has declined to 26,800,000 pieces in 1886. These quantities represent the delivery of deals, battens, and boards of the Port of London both from the ships' sides and from the docks, but they do not alone show the extent of the loss of consumption, for each year the average size of these goods grows less, and the falling off in actual quantity is consequently greater. It being impossible to arrive at any reliable estimate of the cubical measure of overside deliveries, we give the statistics published by the Dock Companies of their deliveries, which show an actual quantity of 250,000 Petersburg standard hundreds drawn from their yards in 1881, against 188,000 in 1886,—each intervening year the quantities growing smaller."

**Sale of the Stewart Collection.**—The valuable collection of works of art belonging to the late Mr. A. T. Stewart, of New York, is announced to be sold by auction on March 23rd, 24th, and 25th next, at Chickering Hall, in that city. The collection will be on exhibition from February 18th up to the date of the sale in the rooms of the American Art Association. The merchant prince was a lover of art, and gratified his taste in this direction by gathering together at a considerable expense a number of the most celebrated pictures, sculptures, and bronzes in existence. According to the catalogue, the collection includes three paintings by Meissonier, one of which is the famous "1807." For this latter work Mr. Stewart gave 12,000. Other great artists whose works are represented are Gérôme, with three paintings, including "The Gladiators" and "The Chariot Race"; Fortuny, with three works, amongst them being "The Snake Charmers"; and Rosa Bonheur, with "The Horse Fair." Other paintings which will, no doubt, be viewed with interest when exhibited are the following:—"A Scene in Morocco," by Benjamin Constant; Cattle piece by Auguste Bonheur; "Auction at the Fair," by Jimenez y Hernandez; "The Child's Party," by Knauts; a landscape with sheep, by Jaque; "The Disputed Boundary," by Erskine Nicol; "Niagara," by Church; and "The Prodigal Son," by Duhute. There are also works by the following artists:—Danigny, Troyon, Bongueren, Fichel, Madrazo, Jacquet, Alfred Stevens, Boldin, Horace Vernet, Detaille, Escosura, Piloty, &c. There are a certain number of works by American artists, viz.:—Albert Bierstadt, R. C. Minor, J. R. Tait, and William Hart. Amongst the numerous marble statues (about forty-five in all) are the "Greek Slave" and "Eve," by Hiram Powers; "Demosthenes" and "Flora," by Crawford; and "Queen of Palmyra," by Hosmer. There are also silver ware, Dresden, Sevres, and Royal Worcester ware, Japanese silver, and porcelain, silver ware, Dresden, Sevres, and Royal Worcester ware, Japanese silver, and porcelain, silver ware, Dresden, Sevres, and Chinese curiosities, rare enamels, and bric-a-brac, which probably attract general attention. The heirs of the estate belonging to Mr. Stewart's widow have decided to sell the whole of the contents of her residence, including the superb art-treasures which the interior of the mansion at present contains.

**British Archaeological Association.**—At the meeting of this Association on the 5th inst., Mr. W. De Gray Birch, F.S.A., in the chair, communications were read from Mr. T. H. Round and others, calling attention to the dilapidated condition of the remains of St. Bishop's Priory Church, Colchester. This well-known ruin was damaged by the recent earthquake, and the effects of the exposure to the elements for many years,—the buildings having been unroofed during the Parliamentary siege of Colchester,—are so serious that the nave arcades are likely to fall at any moment. A paper was read on the Roman stations at Piers Bridge and at Rokeby, by the Rev. Prebendary Scarth. The inscriptions discovered at both places were described and discussed. Reference was made to the recent discovery of a very perfect portion of a Roman road from Bowes to Binchester. In the course of the discussion which ensued, Mr. Cope called attention to the unprotected condition of the lapidary inscriptions at Rokeby, and Mr. Romilly Allen, F.S.A. (Scot.), described the injury which has resulted from want of shelter, to some other interesting inscriptions at Ilkley. A paper was also read by the chairman upon the works now in progress at the baths of Bath. Resolutions were passed in favour of the Ancient Monuments Act being extended so as to include Roman remains in its schedule, in addition to those of pre-historic date, as at present.

**Robert Boyle & Son, Limited.**—The first annual meeting of the shareholders in this company was held on Tuesday, the 11th inst., at Cannon-street Hotel, when a dividend at the rate of 12 per cent. on the ordinary shares was declared. The Managing Director, Mr. Robert Boyle, stated that, taking the general depression in trade into consideration, the business done by the company during the past year might be considered as very satisfactory, and that the prospects of the company at the present time were exceptionally bright, the business done during the first three months of the second year of the company being in excess of that done during any corresponding three months since the foundation of the business. The election of directors and auditors brought the proceedings to a close.

**New Tramways in South London.**—The London Southern Tramways Company, whose system, under the Act of Parliament which they obtained some years ago, extends from Vauxhall to Stockwell, Longborough Junction, and Camberwell-green via Goldborough-lane, and via Milkwood-road to Herne Hill, Tulse Hill, and Norwood, have up to the present time only been able to construct their lines in the direction of Vauxhall as far as the Swan at Stockwell, in consequence of the delay in the widening of South Lambeth-road, which the tramway route traverses on its way to Vauxhall. The Metropolitan Board having recently obtained possession of the property necessary to widen South Lambeth-road, the improvement has been carried out, and the tramway company are now laying down their lines along that thoroughfare from the junction of Stockwell and Clapham roads to Vauxhall. When this extended route is opened, the Southern Company's cars will be placed in communication with the cars of the South London Tramways Company at Vauxhall, and with those of the London Tramway Company at the junction of Brixton and Stockwell roads. There is also a probability of tramway communication being shortly extended from Clapham to Tooting. The South Metropolitan Tramway Company are again applying for Parliamentary powers to lay down lines from Clapham to Balham and Tooting, passing along the east side of Clapham Common, and the Wandsworth and Streatham local authorities interested have already given their sanction to the undertaking, subject to a junction being formed with the Clapham terminus of the London Tramways Company, and the widening of certain portions of the carriage-way between Clapham and Tooting.

**Identification of a Monument in Winchester Cathedral.**—The *Hampshire Advertiser* says that for many years a quaint and even ugly, though costly, monument, in the north aisle of the Cathedral, without inscription, has puzzled antiquaries. It has just been identified, however, by Mr. H. D. Cole, the heraldic antiquary, aided by the Dean, Dr. Kitchin. Mr. Cole discovered on the monument a shield of arms, in the Cathedral Registry the burial of a Mr. E. Cole, and in the Guildhall a portrait of a Mayor of that name, with a shield of arms upon it exactly like those on the monument. These are the arms of Cole and Holcroft, and solved the mystery at once. The monument is that of Mr. Ed. Cole, M.P. and Mayor of Winchester in the sixteenth and seventeenth centuries, and a subscriber to the fund for Defence against the Spanish Armada. The Dean, anxious to commemorate such a local worthy in Church and State, and a Mayor withal, had had a tablet designed by his son, and coloured like the Jacobean memorial, placed under it. This bears the joint arms of Cole and Holcroft, and the arms of Cole separately, and the following inscription:—"The monument above is to the memory of Edward Cole, Esquire, Burgess of this city, 1601; Mayor, 1587, 1598-1612. Principal Registrar of the Bishop of Winchester. He married Christian, daughter of W. Holcroft. He died in 1617, aged 63." Beneath the inscription, and under the Cole shield, are the figures 1886, to show the period of identification.

**Glasgow Cathedral: Lighting with Gas.** The work of lighting the cathedral with gas has been completed. In the interior the length and grandeur of the nave are developed by groups of light at the extreme ends, two handsome standards leading up to the choir. On entering the choir four lines of standards give vistas which culminate in two tall and delicately-wrought standards at the east end. The cathedral from this cause has its interior beauties visible for the first time. The plans and designs for the lighting and executing of the work are by Mr. Skidmore, of Coventry, who lighted the cathedrals of St. Giles's and St. Mary's, Edinburgh, Calcutta, and various cathedrals in England. The drawings and plans were approved by Mr. Robertson, Government architect at Edinburgh.—*Glasgow Herald.*

**Bridge across the Sound.**—With regard to the proposed tunnel under the Sound, a Swedish journal suggests that a bridge across it would be both cheaper and more advantageous. As the Sound is shallow a long way on to the Danish side it would be easy to fix pillars most of the distance. It is added that the distance is only a little more than between New York and Brooklyn.

**The Queen's Jubilee: Proposed National Institute for Wales.**—At a public meeting of the inhabitants of Cardiff and other parts of the Principality, on the 6th inst., an important work was resolved upon. Two proposals were submitted, one on behalf of the South Wales University College for a new building in the outskirts of the town; the other, a proposal for a National Institute, which had been carefully matured by Mr. Edwin Seward, A.R.I.B.A. This scheme was, after close discussion, adopted as the most appropriate to the occasion. When the building is completed it will combine accommodation for the Royal Cambrian Academy, the Cardiff Naturalists' Society, the Cardiff Literary Society, the Cambrian Society of South Wales and Monmouthshire, and the Cymmrodorion and other learned societies, including the Cardiff Photographic Society. This will form a much-needed extension of the Municipal Library, Science and Art Schools, Museum, and Art Gallery of Cardiff, for which building Mr. Seward has acted as architect.

**The Hughli Bridge at Bengal.**—The Hughli Bridge at Bengal, which is now in course of construction, will, it is stated, be completed and opened before the end of the cold season. One of the enormous girders has just been successfully placed in position. Great difficulty was experienced in removing it to the required place, which was fortunately accomplished, however, without a hitch. The girder consists of steel, and weighs no less than 1,200 tons. The span is 420 ft. This is the longest cantilever span that has hitherto been constructed in India, although that of the Indus bridge at Sukkur will be an even more prodigious scale. The work is being carried out under the superintendence of Mr. Bradford Leslie.

**Proposed New Railway in Dorsetshire.**—A meeting of Dorsetshire landowners and others was held the other day at Dorchester, to promote a new line of railway from Dorchester through the famous vale of Blackmoor to Templecombe, so as to obtain more direct communication with London, and effecting a saving of more than an hour in the journey. The line is estimated to cost 223,000*l.* Lord Alington and other landed proprietors supported the scheme. It was decided to have the necessary survey of the line made, and the result reported to an adjourned meeting in February.

**A Long Adit.**—According to the *Bauszeitung für Ungarn*, the longest tunnel in the world is a mining tunnel at Schemnitz, in Hungary. It is 10-27 miles long, and therefore one mile longer than the St. Gotthard. It is used for carrying off water from the workings. The height is 9 ft. 10 in., and breadth 5 ft. 3 in. It was commenced in 1782, the original cost being 7*l.* per foot run, and was completed in 1878, the final price being 22*l.* per foot. The total cost was nearly a million sterling, but a saving of 15,000*l.* a year is made by the absence of pumping machinery.

**Cardiff.**—Messrs. William Godwin & Son, Llugwardine Works, near Hereford, have just supplied, under the direction of Mr. F. R. Kempson, architect, Hereford, a pavement for the chancel of St. John's Church, Cardiff.

### The Royal Commission on Depression of Trade.

HE Report of the Royal Commission on the Depression of Trade is not in its main section a very strong or decisive document, and it is rendered still less so by the result, not uncommon in the case of commis-

sions of this kind, that the members of the Commission cannot sufficiently agree together as to the bearing of the evidence laid before them to enable them to join in one Report, and that a Minority Report is appended, signed by four of the members, differing in certain very important points from the conclusions of the majority, while one of the minority, Lord Dunraven, himself dissents from the dissenters to a certain extent.

Taking the Reports as published last Saturday in the *Birmingham Gazette* as correctly given (they are not, we believe, as yet available to the public in Blue-book form), the main distinction between the majority and the minority Reports is that the signatories to the latter regard the main Report as too optimistic and as not taking sufficiently into account the permanent character of some of the influences that are at work, adverse to the interests of labour. But the most important distinction in principle between the two Reports is that, while the majority are of the pure faith in regard to Free Trade, the minority distinctly suggest the policy of answering protection by protection. They avoid, it is true, absolutely suggesting this as a principle in so many words, and Lord Dunraven dissents even from the suggestion of it, which, as he very truly says, "is clearly indicated in certain portions of the Report"; but that is what it comes to.

The main Report is drawn up in a logical progression, giving facts as supposed to be ascertained; probable causes; suggested remedies. It is impossible to follow the document into all its ramifications, but we may take note of the principal heads of the conclusions arrived at. The Report is not unjustly characterised by the dissenting minority as too favourable in its conclusions and somewhat masking the gravity of the situation. It admits, however, the existence of a condition of trade and industry in this country "which may fairly be described as depressed," meaning by depression a "diminution or absence of profit with a corresponding diminution in employment for the labouring classes." Those who chiefly complain of diminution or absence of profit are the large

producers of goods and employers of labour; the Report entirely supports the view, which is pretty evident without any Commission, that the labouring classes are suffering not from any marked diminution in the rate of wages so much as from the want of full and regular employment and wages. "Those who are in the receipt of fixed salaries or who draw their incomes from fixed investments have apparently little to complain of"; one of those somewhat too self-evident propositions which meet us occasionally in the Report.

The chief features of the commercial situation are summed up thus:—

- (a) A very serious falling off in the exchangeable value of the produce of the soil;
- (b) An increased production of nearly all other classes of commodities;
- (c) A tendency in the supply of commodities to outrun the demand.
- (d) A consequent diminution in the profit obtainable by production. And
- (e) A similar diminution in the rate of interest on invested capital.

The diminution in the rate of profit obtainable from production, whether agricultural or manufacturing, has given rise to a widespread feeling of depression among all the producing classes."

Of these it is evident that the two first are the most important items of the summary, having a direct relation to one another in so far as the disposal of the products of manufacture within this realm is concerned. As the Report says in another section:—

"The purchasing power of a large portion of the community,—that, namely, which depends directly upon the productive capacity of the soil,—has been seriously crippled. Bad seasons and the competition of the produce of other soils which can be cultivated under more favourable conditions than our own, have reduced the quantity or the exchangeable value of the commodities which the agricultural classes have to offer for the products they desire. Meanwhile, a process of an exactly opposite kind has been going on in other branches of industry.

Most of those commodities, the production of which is independent of the seasons and of the natural qualities of the soil, have been produced in steadily-increasing quantities.

Machinery is being continually made more perfect, new processes which cheapen the cost of production are being continually introduced, and the quantity of this class of commodities which is annually placed upon the market is thus steadily increasing.

This tendency, which is, under ordinary circumstances, perfectly natural and usual, has been intensified in recent years owing to the stimulus given to production by the great demand for all manufactured goods which followed the war of 1870-71.

A demand which was only temporary, and which might have been satisfied in the course of a very short period, was treated as if it were of a permanent character; and manufacturers in this country and elsewhere enlarged their power of production accordingly, as if the demand could be expected to continue. This it might very possibly have done if it had not been checked by the falling off in the productive power of the soil above alluded to."

We are thus brought back to the old orthodox faith of the political economist, that "the soil is the ultimate source of wealth." Its present poverty in our country is partly due to causes beyond human control; how far its future improvement may be within human control is suggested by the author of the article in the current number of the *Edinburgh Review*, on "English Land, Law, and Labour":—

"If rents are to be permanently reduced, landlords must become their own agents. If increased production is to afford the remedy for agricultural collapse, scientific training is required by the tenant-farmer. If the soil is to be tilled by a peasant-proprietary, preparation must be made to educate them for the task. Thus, from every point of view, education becomes an indispensable condition in the future of agriculture. In England little provision is made to supply the want. Our manufacturers woke from their dreams of industrial supremacy to find that technical schools on the Continent had, in a few years, counterbalanced the advantages this country had gained from an early start. It is not impossible that our agriculturalists may, from the same cause, find themselves left behind in the race."

Considering the question of over-production in the abstract, the Report (which harps pretty constantly on this string) observes that if the aggregate quantity of commodities produced is on the increase, and is growing at a more rapid rate than the population, the depression in particular industries, or among particular producers, is no indication of a corresponding national loss. This certainly strikes us as a curious way of putting the matter, if the reference is to produce in manufactured goods, as from the context it appears to be. The old dictum about "the real worth of anything" surely holds good here: the production of manufactured goods for which there is not a market would seem to be a draining of the national resources rather than an addition to the national wealth. The remark seems the more unexpected as the Report fully admits the difficulty in finding a sufficient market, and is in fact largely occupied in suggesting the reasons for this restriction of the market, and the means to be adopted to revive and extend it. It is observed that the remarkable feature of the present situation is the length of time during which over-production has been carried on, after the stimulus received during a period of exceptional demand. But the statements in the Report itself seem to show that what has happened has not been so much a continued and systematic over-production (indeed no one, it may be said, overproduces systematically) as a continued process of closure of foreign markets by the combined influence of severe competition and foreign protective tariffs, of the influence of which our producers have only gradually had their eyes opened by the logic of facts:—"Our

trade with foreign countries is becoming less profitable in proportion as their markets are becoming more difficult of access owing to restrictive tariffs." This is very plainly put, and, on the face of it, appears certainly to count one to the arguments of the supporters of that vague ideal which is known as "fair trade." Seeing this *crux* of the question put forward in so plain a manner, we naturally looked for some definite expression of opinion in the portion of the Report devoted to remedies, as to the method of meeting this difficulty, but in vain. While the facts of the effect of foreign tariffs are admitted, the subject is to all appearance studiously shirked in the recommendations of the Report, and from a note of dissent by one of the Commissioners, Mr. Jamieson, we gather that this was from a disinclination to enter into the merits of the question of Free Trade *versus* Fair Trade. Now in so far as that the Commission are true to their Free Trade colours we are with them, but inasmuch as the effect of foreign protection is so plainly referred to as an adverse agency, it would seem as if the Commission hardly manifested the courage of their opinions in avoiding any further consideration of the subject, or any attempt to remove from the Free Trade policy the apparently damaging effect of their admissions. "This was looked for at their hand, and this was balked." It is on this point, as we have observed, that the minority Report has its chief difference with that of the majority. The minority consider that any industry contending against the insuperable difficulties "artificially created by the legislature of foreign States" must sooner or later fall into a condition of languor, capital and talent being gradually withdrawn from it. The minority Report, indeed, admits that it would be "an act of suicidal folly to attempt to counterwork these influences by a like system of enormous import duties"; but "a slightly preferential treatment of the food products of India and the Colonies over those of foreign nations would, if adopted as a permanent system, gradually but certainly direct the flow of food-growing capital and labour more towards our own dependencies and less towards the United States than heretofore." "Preferential treatment" is an admirable phrase, like "remuneration" in "Love's Labour's Lost," and the use of it shows the fear that the minority have of being numbered with the unbelievers; but, of course, it is only a round-about term for protection, and it is not surprising that Lord Dunraven should have added a special note to repudiate any share in it on his part. That foreign protection is an injury to our national pocket at present we hold to be undeniable; but, for nations as well as individuals, there are other interests besides the pocket, if one may still be permitted to say so. There can be, we hold, no possible question that Free Trade is for the good of the world generally; for the good of commerce, for the good of enterprise, for the good of that healthy life which is based on the principle "let the best man win"; only a large proportion of the world does not see it yet; does not see that the thing called "Fair Trade" is a mere arbitrary convention by which A agrees with B, "You rob me, and I will rob you, and we will each agree how much we will rob each other, so it will be all fair." It is to the credit of England to have been the first to see the fallacy and stupidity of this arrangement, and if we are temporarily losing by it in funds, we are at least taking an honourable lead in the right direction, which we can ill afford to drop, considering how lamentable things are behind in some less honourable things, such as the art of making war; nor do we know how soon we may have occasion to note the deadening effects of protection on national spirit and enterprise in the case of nations which are now filling their pockets temporarily at our expense. The faith in Free Trade is one to which the civilised world is certain to come round sooner or later; and though we should have liked to have seen the authors of the Report before us express themselves definitely on the subject, with a *Uberavimus animas meas*, we at all events feel grateful to them for sticking to their guns.

In connexion with this part of the subject, we may notice the curious little demonstration which Professor Bonamy Price, one of the majority, has made in regard to the limitation of hours of labour, and which has drawn down upon him the wrath of the *Pall Mall Gazette*. In reference to a paragraph in which it is observed that shorter hours of labour, however they may increase the cost of production, are compensated for by the other advantages they afford to the working classes, he says this is "specific repudiation of the great doctrine of Free Trade. Shorter hours of labour do not and cannot compensate to a nation for increased cost of production and diminished output. They tax the community with dearer goods in order to confer special advantages on the working man. They protect him, and that is a direct repudiation of Free Trade." Now, we are with this, in so far as it is opposed to the absurd principle which has been put forward occasionally at Trades' Union Congresses, and on which we have before commented, that the position of the industrial classes, commercially, could be benefited by doing less work and getting more hands to do it. But the idea of "Protection" in respect to this can only be sustained in the case of Government limitation of hours. Now, the majority Report distinctly repudiates any such suggestion. What it says is, that "it is for the country and the working man to consider whether the advantages of shorter hours compensate for the increased cost of production or diminished output. We believe that they do, and on social as well as economic grounds we should regret to see any curtailment of the leisure and freedom which the workman now enjoys." It may, perhaps, be said that these remarks are *ultra vires*, strictly speaking, of the Commission, which was not deputed to consider the social status of the working classes. But certainly the choice of the working man to limit his hours, though it may be carried so far as to be a mistake in his own interests, has nothing to do with "protection" in any sense, and the protest seems uncalled for in relation to its antecedents.

In the main, the suggestions for the amelioration of the present state of things, as made in the majority Report, are healthy and spirited in tone. They suggest (1) cheapening the cost of production in so far as it is consistent with the maintenance of sound quality and good workmanship. Of course, in reference to the matter touched on in the last paragraph, this negatives the idea of any further reduction of hours of work, in regard to which, in fact, the "working classes" have the advantage of many other workers in the community, whose labours extend through a greater period of the twenty-four hours than theirs, and have no specified limit. (2) Increased vigilance in the look out for new markets and in keeping our place therein. (3) Improved technical education; on which head all who know are agreed. (4) Diplomatic and consular assistance in regard to the wants and opportunities of foreign markets: in regard to which there is a salutary caution added, that while all general information of this kind should be looked out for and made public by consular representatives (which part the German consuls seem to be very actively taking), any direct interest of diplomatists or consul in the work of special firms should be entirely discontinued, lest the said officials should sink into the position of being "agents" in another and by no means desirable sense. (5) Statistics of internal trade, which are reported as very deficient. (6) In regard to railway and canal transport, it is suggested that greater facilities should be given for ascertaining the rates which the companies profess to charge, together with any modification of those rules which they make in favour of any individuals or classes; that the canal system should be further developed, and that no railway company should be allowed, either directly or indirectly, to control or own a canal; and that every facility should be afforded for the construction of light railways or tramways, for reducing the cost of transport. In a general way, however, we may observe that railways are regarded with a rather notable leniency by the Commission,

which almost shuts its eyes to the complaints as to the preferential rates for Continental merchandise, about which a good deal has been heard lately.

We are also struck with the exceedingly indulgent view taken as to the forcing up of wages by the action of the Trades' Unions. It is curious to read in one sentence that while the aggregate share in the wealth which falls to labour has increased, that falling to capital has diminished; "in other words, that while wages have risen profits have fallen"; and that "this is obviously a process which cannot be continued beyond a certain point"; and to read in the next sentence that the unfavourable elements in the existing condition of trade and industry cannot with any justice be attributed to the action of Trades' Unions. We shall be curious to see what is the nature of the evidence on which this conclusion is founded. We attach, of course, no moral blame to the efforts of the Trades' Unions to keep up wages. They were organised to do the best they could for the interests of their class; but that, in pushing this too far without regard to the state of the times, they have to a considerable extent checked the employment of capital in England and brought in foreign labour to their own detriment, seems undeniable; and it is to be regretted that this important question was apparently rather lightly dismissed by the Commission.

#### THE R.I.B.A. COMPETITION DRAWINGS AND DESIGNS.

THE exhibition of architectural students' work now open in the Conduit-street Galleries is one of the best, if not quite the best, that we can remember. The competition for the Owen Jones Studentship especially has brought together a number of sketches and studies which, both in quantity and quality, make a valuable addition to the usual collection, and the older competitions have mostly been well contested. The winner of the Owen Jones Studentship, Mr. Sydney Vacher, has submitted a large number of sketches of colour decoration, in all styles and periods, and collected from a great variety of sources, in all of which the colour is shown in its full strength, just as it really is or was intended to be, without taking account of accidental effects of light or time, sketches which are not and are not intended to be attractive in themselves, but scrappy, dirty, covered with notes, and altogether earnest, independent, and, to a student, delightful,—careless of everything but just the particular that was to be noted at the moment. Among the sketches are some of the studies of Italian diaper ornaments for the hook Mr. Vacher lately brought out, and a sketch for the decoration of the pulpit of St. Margaret's Church, Westminster, which was done under his direction; also some patterns of wall-papers, made by Messrs. Jeffrey from Mr. Vacher's designs.

The sketches and studies of Mr. Gerald Horsley, who takes the second place in the competition and a special prize, are such a treat to look at as one has not had since Mr. Barrett, competed for the Pugin Studentship two years ago. It is difficult to imagine a more perfect pen-and-ink sketch than that of the head of Augustus, or more beautiful pencil work than is shown in the drawings of the two Sibyls, and of the ambone from St. Miniato at Florence, and again in the almost conical carving of "Pharaoh" from the stalls at Amiens. The magnificent study of a portion of the celebrated retablo in Westminster Abbey, and the delicate drawing of a spray of red lilies, are enough to make most respectably good draughtsmen emigrate without delay. Mr. Horsley is also doing some practical work in the way of colour decoration, as witness the cartoons of some lunettes for the roof of Netley Church which are exhibited.

The studies of Mr. H. Wilson, submitted for this same prize, show very careful work, and an accurate colour-sense. They all seem to have been collected in London from pictures in the National Gallery and the exhibits at

South Kensington, supplemented by capital original designs.

Mr. Briggs has some very good and useful sketches from Pompeii.

The chief competitors for the Pugin Studentship exhibit work well up to the high average of excellence always now attained. Mr. Thomas Maclaren takes the studentship with what is certainly the best collection; many of his drawings and sketches are old acquaintances, some of which have taken other prizes, and many have already been illustrated in our pages, among which latter may be mentioned the design for "A Town Mansion," and a drawing of a bit of foliage from Melrose Abbey, which is quite the best of the pencil work there. The sketch of the great window of St. George's Chapel, at Windsor, has not been improved since we saw it last by the slight tinting that has been added. We think, too, that the very fine sketch of the tower of St. Mary's, Oxford, suffers from the crude greens of the shrubs at its base. The drawing of the pulpit at Siena Cathedral is a magnificent pencil study, but the best and most useful piece of work is the sheet containing the shaded and tinted elevation and details of the library door of the same building.

Mr. Arnold B. Mitchell's sketches are clever, ambitious, and plucky, and the system he has adopted of pencil drawings washed with a pencil-coloured tint, is probably a very rapid way of getting an effect which is certainly worth getting; but we cannot help feeling that the sketches are a trifle hard, and that too much time has been spent upon subjects that would be telling, and too little on real study. The best sketches are those of a sword-hilt in the Bargello at Florence, and a bright little general view of Siena.

Mr. E. P. Selby, who shares with Mr. Mitchell the honour of receiving medals of merit, has done some good work, of which some sketches of the marble paving of Siena Cathedral are probably the best.—Siena Cathedral figures unusually but deservedly frequently in this exhibition.

Mr. R. W. Paul, certificate of honour, shows work which tells of a rapid hand and practised eye, and which falls little behind that of more successful competitors in effective finish; his measured drawings of the tomb of William de la Marchia, Wells Cathedral, are particularly good. Mr. Frank Simon must have run the two last-named competitors rather close for their honours; his work is very artistic and good, and although the soft pencil and rougher paper he uses are not adapted to very delicate drawings, his sense of light and shade and his accuracy are notable.

Of the design prizes, the Tite Prize has this year brought out the best work and the largest number of competitors. The subject was "A Classical Church on an isolated Site." The design of Mr. Frank W. Simon, which takes the prize, shows a very considerable mastery of Classical planning and design; it is correct in style and very effective in its monumental, lofty, and graceful proportions and refined detail; the drawing, too, is delicate and pretty, and worthy of the design. Mr. John Keppie's design, which is placed second, shows great restraint and some originality in the treatment of the plan and elevations, and its weaknesses only become apparent in the perspective drawing, which shows the almost ugly effect of the irregular octagon dome and the quite ugly effect of the little towers at the west end. The detail is good and the style evidently familiar to the designer to some extent, but he probably omitted to try his effects in perspective until too late. Mr. W. Stirling, whose design is placed third, cannot be accused of being hum-drum or commonplace. Not content with a design in the freest of free Classic styles, such as is seen in some of the terra-cotta work of North Italy,—the west front of the Certosa at Pavia, for instance,—a design as bizarre as it is original and, in many respects, clever,—he has added the daring experiment of making his drawings in bright red. As a design seriously considered, though it looks reasonably well in elevation, it can, after all, only be put down as more than moderately successful if intended to

be executed in terra-cotta, when the extravagance of the carving and ornaments would serve to hide the imperfect joints. Of the other designs, that of "Unity" appears to us the best. It is severe, well proportioned, and appropriately decorated, but the drawing, at any rate where the figure is introduced, leaves something to be desired. "Lux" has made a reasonably successful study of Wren's London churches. He justifies his motto by introducing the very unclassical feature of coupled windows in the clearstory, thus flooding the interior with a rather unnecessary amount of "lux." "Fiat Lux" has introduced the novel arrangement of nave columns which support transverse arches instead of a longitudinal wall, so that the roof spans the whole width of the church, an arrangement which might lead to some novel artistic effects, and perhaps be less extravagant than it appears at first.

The competition for the Soane Medallion this year falls far behind that for the Tite prize, both in the number of competitors and in the excellence of most of their work. The medallion has been awarded to a careful study in that style to which it is difficult to give a name, since people have ceased to consider "Queen Anne" appropriate to any erection in red brick. Jacobean might describe most of its features, but will not do for all. Mr. Norman Shaw's building at the corner of St. James's-street is the very evident prototype of Mr. Francis E. Masey's study, and he certainly could not have chosen a finer design on which to work. His ranges of windows are effective, and so are the open arcades, but the turrets are too small in scale for effect, and the ingenious arrangement of entrances is very awkward. The plan is well balanced and convenient on the whole, but the corridors would be very dark. Mr. A. Whitehead, who takes second place, has a somewhat similar plan, but the corridors are better lighted, and the entrances are more convenient. The style is Classical, but the grouping is more adapted to a larger building and results in a too broken effect. The design would decidedly gain by the omission of the central turret and some of the spikes and urns with which it is ornamented. We should like to comment upon the design "Usui Civium," which we consider is architecturally a finer study than any of the pre-named work in this competition, but space falls us.

Of the three competitors for the Grissell Medal, Mr. Strong has fully earned his success by his careful calculations and adjustment of stresses, but if the scientific construction of a roof of 60 ft. span of wood necessitates so many joints and such a forest of timbers, we hope every such roof will, in future, be built of iron.

The competition for the Silver Medal has not collected quite so much good work as usual lately. Mr. James H. Cooke, who receives the medal for his drawings of Stokesay Castle, is evidently a practised draughtsman, and his drawings are only less beautiful than those of Mr. Frank Bellis, of Haddon Hall, who comes second, and only lost the first place, as was explained to the meeting on Monday, by omitting to measure some of the important stone jointing.

Mr. R. Elsey Smith has won the Essay Medal with a clearly-written account of the history of wall piers and buttresses, prefaced by an introduction dealing with the scientific theories connected with the subject, and accompanied by a portfolio of photographs and sketches illustrating it.

It was announced on Monday evening by the Hon. Secretary of the Institute that, in future, drawings which had obtained for their authors the Gold Medal of the Royal Academy or the Soane Medallion, or which had been executed by students during the compulsory tours connected with those prizes, would in future be excluded from consideration in making the award of the Pugin Travelling Studentship.

**Nineteenth Century Art Society.**—Wednesday, the 26th inst., has been appointed for the reception of works of art intended for the Spring Exhibition of this Society, at the Conduit-street Galleries.

ARCHITECTURE BY ADMINISTRATION.

HE architect is gradually assuming a new character. Long ago he ceased to be either a painter or a sculptor. Now he is in danger of altogether abrogating his claim to be considered an artist. He is becoming an administrator,—the director of other people's faculties,—and no more.

This change is partly due to the general movement in the world around us. But it is also due in part to an indolent yielding to unworthy solicitations. A modern building,—like a modern war vessel,—is a complex thing, and in proportion to its complexity the difficulty of designing and adjusting its multitudinous parts by a single mind increases. The advice of specialists in certain departments must be sought, and may be honourably obtained. No one will, for example, expect an architect to devise in detail a scheme of electric lighting. He must rely upon the aid of the electrical engineer, who should have due credit for his work. The architect must be content to receive directions for the necessary structural provision and preparation, and limit his share in the matter to the design of the visible fittings.

But this and similar necessities of modern practice have brought up a crowd of impetunate advisers, who would (and do) encroach upon the architect's peculiar province,—who will, in the expectation of supplying their manufactures, relieve him of his proper duties, calculate the strength of his girders and stanchions, and draw for him in elaborate detail the constructive portions of his works. The smith will suggest (to  $\frac{1}{2}$ -in. scale) ornamental ironwork; the plasterer will draw his strap-work and floral adjuncts, and only asks to have a diagram of the ceiling spaces to be filled, or even the size of the room; the firm who supplies the tiles or mosaic has a staff of young men who do nothing but provide "architects" with designs, and so on. From this prevailing condition of things two considerations arise.

First, that architecture so conducted degenerates into a mere manufacture. Buildings which are the reputed work of Mr. A. share with Mr. B.'s and Mr. C.'s certain characteristics, which are finally traced to Messrs. X. & Co. And the conclusion sooner or later is brought home to the public mind that A. and B. and C. are all impostors, using for their own emoluments and self-glorification the various artistic abilities of other people.

The second consideration is, that architecture by administration can be undertaken by administrators who are not even in name architects. Let our younger men look to it. Architecture is now sold at "the stores," and takes its place amongst other commodities dispensed by the universal provider.

This is a point which should be pressed upon young architects, who should be exhorted to design (in their own proper persons) everything that is ascribed to them.

It is possible that no one man will be able to design in all departments so well as he who restricts his attention to one. But there will be an ample compensation in the fact that a building designed throughout by one and the same person will be an original work, complete and congruous, and bearing the impress of a single mind.

Architecture so followed is an art. Pursued by the method to which we have alluded, and which threatens to become popular, it is a mere business, not of the most honourable kind, for it robs the actual designer of his credit, and gives honour where it is not due.

NOTES.

HERE seems to be a chance of finding a site for the re-edification of Temple Bar at last, and one that is eminently suitable for it, as was pointed out in the columns of the *Builder* nearly two years ago. According to the *Standard* of Monday last, the occupants of chambers on the south side and north side of Nos. 6 and 7, King's Bench Walk, Temple, respectively, have received notice from the

Benchers of the Inner Temple to give up their chambers in March. "The reason for this is that the outer walls of both these buildings, which are some of the oldest in the Temple, have been condemned as unsafe, and will consequently be pulled down. Advantage will at the same time be taken of this opportunity to widen the Whitefriars entrance to the Temple, which is at present inconveniently narrow, and a new and handsome gate will, it is said, replace the ancient wooden structure at present in use. It is expected that the alterations will be completed by October next." If the *Standard* had said "ramshackle" in lieu of "ancient" as the descriptive adjective of the existing gate, it would have been nearer the mark. It is an ordinary piece of joinery, and is probably not fifty years old. However, that by the way. There can be no doubt that this is the site for the re-erection of the old City gateway. It is within the City itself; the gateway would necessarily have to be put up with its eastern and western *façades* in the same relative positions as they formerly occupied, thus preserving the "orientation," so to speak; it would form a fine and appropriate entrance to the Temple from Whitefriars; and it would be well seen from New Bridge-street as the termination of the long *vista* westwards along Tudor-street and Temple-street, now widened for almost the entire length, one or two jutting buildings only remaining *in situ* temporarily, pending the development of the building estate on the Embankment. Re-erected on this site the "Bar" would remain identified in name as well as in fact with the Temple and its associations, while it would form an important architectural addition to this rapidly-improving part of the City, being in close vicinity to the civic and public buildings already erected and likely to be erected on the Embankment land. The new approaches to the Embankment from Fleet-street in continuation of Bouverie-street, Whitefriars-street, and Dorset-street are likely to do much for this hitherto somewhat benighted part of the City. We notice that Mr. James C. Powell, of the Whitefriars Glass Works, writes to the *Standard* unconsciously adopting and recommending the site which was proposed in our columns two years ago for the re-erection of the "Bar," if the stones "be still in existence." We believe they are, but we are not sure that they have been very tenderly cared for by their natural custodians, the Corporation of London.

THE meeting in furtherance of the French Railway Jubilee, held at the Cannon-street Hotel on Tuesday, left no doubt that the proposed International Railway Exhibition this year in Paris is likely to be conducted in such a way as to be a success, and that English engineers and railway authorities have done well to join hands with the French in furthering its success. It is unnecessary, however, for newspaper writers on the subject to take the complimentary tone some of them do, as to our possibly having a good deal to learn from the French as to railway work. We are behindhand in the matter of comfortable and roomy railway-carriages, though this defect has been a good deal made up lately; but in the matter of railway working, speed, and efficiency, our best railways are, we believe, at the head of the world; and there is no occasion for any unnecessary humility on this topic, at all events.

WITH a promptitude which deserves all praise, the *Railway Age* publishes full statistics of the mileage of new railways constructed in the United States during the year only just closed. We learn from the figures given, that 8,010 miles of new lines (reckoning main track only) were built in 1886, against 3,131 miles constructed in 1885, 3,825 miles in 1884, 6,741 miles in 1883, 11,568 miles in 1882, and 9,796 miles in 1881. The two last years showed the greatest activity in railway construction of any former year; but 1886 runs 1881 pretty closely, whilst 1871 (with 7,379 miles) follows close upon last year. Kansas leads the way with 1,520 miles, the greater portion of which was laid during the last six months of the year. Nebraska comes

next with 737 miles, and then follows Dakota with 678 miles, Minnesota with 587 miles, and Texas with 543 miles. The five States named make up a total of 4,065 miles of new railway, or more than half the mileage constructed in 1886. Assuming the average per mile of roadway to have been 20,000 dols. per mile, we obtain an annual expenditure for permanent way of 160,000,000 dols., or over thirty-two million pounds sterling; and to this must be added the capital spent in rolling stock and equipment.

THE recent case of *Simmons v. Kinsirinki*, which was an action for an infringement of the light to the plaintiff's buildings, and in which the jury found a verdict for the defendant, settled no legal point. It is certainly noteworthy, however, in one sense, for we are informed by the report of the trial that "scientific and other evidence was called in support of the plaintiff's case." Likewise, we are told that Mr. Joseph, an architect, and other expert witnesses, were examined on behalf of the defendant. The question for decision was whether there had been a substantial diminution of the light to the plaintiff's building. It is not to the credit of the profession of architects and surveyors that a number of gentlemen can be found to give diametrically opposite opinions upon a question as to which there should be very little doubt. It is natural that professional men should differ on the value of property, for this is a matter of comparative uncertainty. But a person of ordinary vision should be able to say whether a room is substantially deprived of light by a neighbouring building. We fear that the case shows that Professor Kerr's admirable work on the Consulting Architect requires wide and careful perusal.

THE undoubted success,—so far as it has gone,—of the new Agricultural Hall at Kensington makes it incumbent on the management to take care that visitors run no dangerous risks. But the staircases which lead to the gallery, with which the grand circle and some other parts of the building are in communication, appear likely to cause risk to limb, if not to life, in case of a panic. They are tortuous, and not very large,—large enough, perhaps, for the needs of an ordinary theatre, but insufficient for the vast numbers who visit Olympia, and have to use them. Even after an ordinary evening performance the crush is extreme, and were a panic to arise the result might be very serious. Staircases in such a place as this hall should be broad and as straight as possible, or else so numerous, if not of large size, that a full house may be able to be emptied with rapidity and with ease through a number of different exits.

A SAFE method of blasting (if the term can be correctly applied in this instance) in fiery mines has been suggested by Dr. Kosman. The system is described in a paper recently read by the inventor. It consists of bringing dilute sulphuric acid into contact with a fine zinc powder. A cartridge case of glass, 7 in. long and 1 in. in diameter, is divided into two parts, the volumes of the two divisions being as 1 to 4. The division is made by reducing the diameter of the glass cylindrical case to about one-third of an inch, and inserting a plug of cork, india-rubber, or asbestos. The larger division, which is closed at the bottom, having been filled with the dilute sulphuric acid, the cartridge is distributed to the miner for use. When the operator wishes to apply the cartridge he fills the smaller part of the glass cylinder with the zinc dust, and then forces a small metal rod through the zinc into the plug. In order to cause the cartridge to perform its work one or two smart blows are given to the metal rod or needle. This drives in the plug and breaks the glass, so that the acid runs into the part containing zinc-dust, and a rapid though not instantaneous evolution of hydrogen takes place, the expansive force being sufficient to break down the rock. The shot-hole is loaded and tamped in the ordinary way, but should the rock be porous or jointed it will

require to be clayed to prevent the escape of gas. Dr. Kosman gives the following particulars of working. A cartridge, 25 millimètres in diameter and 180 millimètres long,—about 90 cubic centimètres,—will contain 50 cubic centimètres of sulphuric acid and 12 grains of zinc dust, or 10 grains of metallic zinc. The latter will liberate 0.3 grains of hydrogen, or, by volume, 3.37 cubic centimètres. This volume of gas being confined to 90 cubic centimètres the resulting pressure will be approximately 37,000 atmospheres. The evolution of hydrogen is not thought to add to the danger owing to the rapid diffusion of that gas in atmospheric air. Particulars of the system may be found in the eighty-seventh volume of the "Transactions of the Institution of Civil Engineers," p. 41.

A FEW weeks ago we drew attention to Mr. Shilleto's translation of Pausanias; a book has since appeared, by Dr. Kalkmann, a "Privat docent" of the University of Berlin, which no student of Pausanias, even through the medium of a translation, can afford to neglect. In his "Pausanias der Perieget,"\* Dr. Kalkmann gives us a series of most interesting essays on the "sources" of Pausanias. Some of us are so used to regarding Pausanias as in himself the most final of "sources" that we may feel a little aggrieved to have to push our inquiries further back. It would not be easy, however, to over-estimate the importance of the line of inquiry that Dr. Kalkmann opens up. He himself regards his book as merely "path opening" (*bahn brechende*), but the "path" is one that every commentator is henceforth bound to follow. If Pausanias is to be used as evidence, we must convince ourselves that he is a credible witness,—that he is not a historian of the type that Lucian describes, who, "though he had never set foot outside Corinth or seen a battle, not so much as a painted fresco, yet begins his history of the Parthian war with the words, 'Ears are less trustworthy than eyes; I write therefore, what I have seen, not what I have heard'; and goes on to narrate how, 'from his seat in a high tree, he saw the Parthians hurling snakes from long poles against the enemy.'" How far Pausanias stands convicted of this, at that time, fashionable sort of mystification we leave it to Dr. Kalkmann to tell.

WITH reference to our remarks in the *Builder* for the 8th inst. (p. 77) with regard to the lion of St. Mark, Signor Boni writes in explanation that the framework of the lion was erected in 1815 to support the figure which returned from Paris in fragments, and that the iron nuts have in some places cracked the bronze plates of which the figure is composed. Signor Boni says that he has been accused by his countrymen of wishing to preserve monumental antiquities beyond the bounds of possibility, and that he feels no remorse in suggesting the substitution of a framework of copper for the present iron framing. He further explains that he does not propose to restore any missing portions of the figure, but only to modify or suppress such features as were added in 1815, and which falsify the symbolical value of the lion or alter its character. He proposes to remove the hooks between the lion's paws, which is of lead and dates from 1815; to take out the eyes, which were added in 1815 and are of white glass, and make the lion appear blind, and to replace them by crystal of an amber or ruby colour. The wings were, it appears, also the work of the year 1815, and are entirely different from the original design. Signor Boni acknowledges that it will be impossible to restore the original wings, all trace of them having been lost, but thinks it is possible to give the new wings a shape which will harmonise with the lines of the antique bronze; but how he proposes to carry this out he does not state. The capital of the column he proposes to retain in its present state, only substituting copper cramps for the present iron cramps.

\* Pausanias der Perieget. Untersuchungen über Seine Schriftstellerei und Seine Quellen. Von Dr. A. Kalkmann. Berlin: Reimer, 1886.

DR. SALOMON REINACH has done good service to archeology by the issue, in popular form, of his advice ("Conseils") to intending student travellers in Greece and Asia Minor. A noted epigraphist himself, his advice is primarily offered to inscription collectors, but much of it would well apply to the whole field of archeology. His most important piece of counsel is, "Bewell prepared before you start," and in the clearest and simplest way he details the essentials of mental equipment. Know precisely what is already known in the country you intend to visit, and thus avoid the waste of time involved in collecting materials already published. Dr. Reinach proceeds to explain carefully how a squeeze is taken, and to give directions for the sort of photograph that is desirable. He even gives hints as to the method of taking a topographical sketch. His book is thoroughly practical, and its principles applicable far beyond the limits of epigraphy. It is for want of some such advice as this that so little is done for science by the average educated traveller.

WE are very glad to find that at the Manchester Jubilee Exhibition an important place is to be given to original artistic work in "artisans' and women's industries." The Executive Committee have granted a sum of money to be spent in awards for the best original work in furniture, wall paper, carpet and calico designs, wrought-iron, wood carving, modelling in clay and terra cotta, brass-work, and embroidery. This should form a most interesting feature of the proposed exhibition.

SIGNOR RAGGFS statue of General Sir Arthur Kennedy, the late Governor of Hong Kong, which has been temporarily placed on the open ground opposite Shaftesbury Avenue, is said by the General's friends to be a very good likeness, and has at all events that individuality of expression which a good portrait likeness generally shows. The head is finely modelled. As to the rest of the statue, what can be made of military uniform in sculpture? It is better in bronze than in marble: that is all that can be said. It would be a great boon if any method were adopted of putting up memorial likenesses of eminent men in such a form as to get rid of the insuperable modern costume difficulty; say by treating them as a bust on the head of a "term," the shaft or plinth of which might be ornamented with small decorative bas-reliefs having some symbolical or historical reference to the subject of the monument. Nothing, we fear, will ever get over the artistic unsuitability of modern costume, military costume especially, for sculptresque treatment. The statue has been cast by Messrs. Young & Co., at the Eccleston Iron Works, and appears to be a very good piece of founder's work. It is ultimately to be erected at Hong Kong.

THE exhibition of landscapes in oil and water-colour, by Mr. MacWhirter, in illustration of "the land of Scott and Burns," now on view at the galleries of the Fine Art Society, in New Bond-street, is of much interest topographically, and includes some very effective works in the artist's broad though rather mannered style. Among others is a fine view of Neidpath Castle, recently referred to in our review of a work on Scottish Castellated Architecture. The scenes into which architecture comes, the views of Ayr and Dumfries, &c., are among the best of the series, and appear to combine topographical accuracy with artistic effect in a very well-balanced manner.

THE Metropolitan Board of Works have received forty-three applications for the post of Superintending Architect in response to their recent advertisement, eighteen of which are from architects or surveyors who applied before. Among the best known of those who previously applied, and who now apply for the second time, may be mentioned

Mr. J. Douglass Mathews, Mr. E. J. Tarver, Mr. R. Walker, and Mr. W. Woodward. Among the new applicants are Mr. T. Blashill, Mr. G. Corson, of Leeds, Mr. John Hebb, and Mr. A. Peebles. At the meeting of the Board on the 14th, it was moved and carried that the applications be referred to the Works Committee, with instructions to select and submit to the Board the names of not more than six of the candidates whom they thought most suitable to the office. Some of the best of the new applicants would have been ineligible on account of the limitation of age under the former advertisement, and the result shows that the Board have done wisely in withdrawing this limitation.

GOWER-STREET.

WERE it not for the new face which it has assumed within the past two years, Gower-street could claim to rank as one of the dullest, gloomiest thoroughfares in town. Within the memory of, doubtless, most of our readers it fully answered to the phrase which the Laureate applied, it is generally believed, to Harley-street. Looking at the then depressing vista of its blackened house-fronts, their monotonous elevations wholly unbroken or unrelieved, we have difficulty in realising the fact that less than sixty years ago the street was so free from smoke that grapes and wall-fruit would ripen in the open-air sun in the gardens at the rear. Lord Eldon once lived (1804-1815), being one of its earliest inhabitants, in Bedford-square, at the southern end of Gower-street. There is record that in the course of a case in court he took occasion to mention how the ever-increasing encroachment of London smoke had injured his fruit trees; just as Archbishop Howley, at Lambeth, found that his beloved garden was ruined by the kilns of the neighbouring pottery works.

An inspection of certain maps goes to show that Gower-street was planned, if not indeed inhabited, before the beginning of this century. As "Gore-street" at the lower end (in a map of 1799), it runs as far north as Pancras-street. But all the ground eastwards, and north of Montague House (British Museum) and Bedford House is shown as open fields with a diagonal hedgeway from Baltimore House (Russell-square) to Totten Hall. Again, from Baltimore House to the Brill (Somers Town) is marked "The Duke of Bedford's New Road." This for part of its length corresponds with the later Woburn-place. Between these two roads lies an enclosure—the Archery Ground, almost identical with what is now the site of Tavistock-square. Here the Toxophilite Society (a remnant of the old Finchbury Archers, 1781), established themselves in 1791 under a term of a lease granted by the Duke of Bedford. They remained until 1805, when they were compelled to retreat before a foe against whom their artillery could avail nothing to Highbury Barn. Hence they removed to Bayswater, and ultimately, in 1834, to their new quarters in Inner Circle, Regent's Park.

The open areas, of which we speak, was originally known as Long, and latterly as Southampton, Fields. It had been renowned in the seventeenth century, as Macanlay reminds us in his famous Chapter III., for peaches and snipes. It speedily acquired repute of a very diverse character. For there, according to a legend of the period illustrated by Macanlay, was fought that duel between two brothers which gave the name of the Field of Forty Footsteps to the place of their deadly encounter. Far into the eighteenth century Southampton-fields formed a favourite duelling-ground, and on Sundays were rendered hideous by the resort of patrons of the ring, with all the rascaldom that followed in their train.

Gower-street takes its name evidently from the second wife of John, fourth Duke and eighth

Earl of Bedford, who married Gertrude, eldest daughter of John, first Earl Gower. So plainly, indeed, has the genealogical history of the Russells been written in the nomenclature of the numerous thoroughfares with which Gower-street communicates, that it were worth while to illustrate under what circumstances these names were adopted. In traversing Gower-street we pass from the Bedford to the Grafton estates, being two of the great dual properties whose undivided existence forms a striking feature in the cadastral history of London. The district that is commonly called Bloomsbury was known to Stow as Lomsbury, a corruption probably of Blemunds, or Bleomunds, Bury. This and St. Giles were later sub-manors of the ancient manor of Ruggemere, which "in Domesday is described as a manor in Osnstun [hundred], belonging to Ralph, a canon of St. Paul's. It was assessed for two bides. It was worth thirty-five shillings (a year) . . . It was then, and had been, in the demesne of the canons of St. Paul's."† The name of Ruggemere yet attaches to a prebendal stall at St. Paul's. The mere lay in the slightly rising ground between Tyburn and Holborn. Its draining by a ditch or dyke is generally ascribed to one William Blemund, temp. John, and the course of his fosse should perhaps be identified with the bend of High and Broad streets, St. Giles, and the western end of High Holborn, which formed the highway before New Oxford-street was laid out. Some say that the manor-house stood where is now Bedford-place. We cannot here follow the history further back than to say that in the early part of the seventeenth century Henry Wriothesley, Earl of Southampton, bought the sub-manor for 600*l.*, his town-house being then in High Holborn, just west of the Bars. This was pulled down before 1657 (teste Howell). After the Restoration, Thomas, fourth Earl of Southampton, Lord Treasurer, built Bedford or Southampton House on what is now the northern side of Bloomsbury-square. Evelyn refers, under date 9th of February, 1665, to "a noble square or piazza, a little town," which his lordship was then building in Blomeshury. Mscanlay, too, on the authority of the Travels of the Grand Duke Cosmo, writes:—"Foreign princes were carried to see Bloomsbury-square, as one of the wonders of England."‡ Much of the eastern side, olim Seymour-row, is modern, and harmonises but ill with the others. Southampton House, eventually demolished in 1800, passed, together with the estate, to the Russells, on the marriage of Lady Rachel, née Wriothesley, second daughter and eventually heir of Thomas, fourth Earl of Southampton, to William Lord Russell (so often but erroneously called Lord William Russell), who, in Burnet's words, triumphed over death in Lincoln's Inn-fields on 21st July, 1683. Viscountess Russell was widow to Francis, Lord Vaughan, son of the Earl of Carbery. She died here in 1723. Their son succeeded 7th September, 1700, to his grandfather (who had been advanced Marquess of Tavistock and Duke of Bedford, 11th May, 1694) as second duke. In pursuance of our scheme, we should state that several members of the family were named Francis, and that Francis, second Lord Russell of Thornhaugh,§ inherited, 3rd of May, 1627, as fourth Earl of Bedford. The great John Russell of Henry VIII.'s day was elevated, 9th of March, 1539, Lord Russell of Cheneys, co. Buckingham, and obtained grants of Tavistock Abbey and Woburn Monastery, co. Bedford. He was advanced Earl of Bedford, 9th of January, 1550. Wriothesley, the second duke, had married 1695, Elizabeth, daughter and co-heir to John Holland of Streatham, and acquiring a considerable fortune by that union, was created, 13th of June, 1695, Baron Howland of Streatham, co. Surrey.¶ His nephew John, who succeeded, 23rd of October, 1742, as fourth duke, married, 11th of October, 1731, Diana, youngest daughter of Charles, Earl of Sunderland; and in 1737, Gertrude, eldest daughter of John, first Earl Gower. Francis, the son by this second marriage, married Lady Elizabeth Koppel, daughter of William, second Earl of

\* "The long unlovely street."—In Memoriam.  
 † This spelling in the old map, we may observe, is proof positive (if any were needed) of the incorrectness of the common Cockney pronunciation of the name of the street, with the same sound for the "ow" as in "how," "cow," &c. The old family name after which the street is called is a one-syllable word, pronounced Gore, as written in the 1799 map referred to.  
 ‡ Usually fixed in what is now the space between Woburn and Russell squares. But the bearings given by Southey in his "Commonplace Book" correspond with the now Drummond-crescent and the adjacent end of Drummond-street, beyond Euston-road. Moser, under date 16 June, 1800, says he saw that field just before it was destroyed for building purposes.

\* Compare with the local and personal names given in the text: one or two of the street names have been altered.  
 † The Rev. W. J. Loftie's "History of London," Edit. 1844.  
 ‡ History of England, cap. iii.  
 § Hence, Thornhaugh-mews. Thornhaugh-street is now Huntley-street.  
 ¶ Howland-street was the early home of the late Sergeant Ballantine.

Alhmarle, and left issue Francis\* and John, who succeeded in turn to the dukedom. John, sixth duke, married 21st of March, 1786, Georgiana Byng, second daughter of George, fourth Viscount Torrington; and for his second wife, on the 23rd of June, 1806, Georgiana, daughter of Alexander, fourth duke of Gordon.

So much of Gower-street as extends northwards of Francis-street was at one time known as Upper Gower-street and Gower-street North. At No. 15, Upper Gower-street lived and died (1834) a celebrated antiquary, Francis Douce. No. 65 Gower-street was the last London home of Jack Bannister, the actor, who in wit and simplicity seems to have been a second Gay. The house at the corner of Montague-place and Gower-street was used as a laboratory and repository by the singular recluse, Henry Cavendish. He devoted all his time to chemical experiments and research, being rarely seen out of doors except when going to or from Dean-street, Soho, where he kept his books, and would lodge a receipt for each volume he abstracted. An intimate of Banks and Davy, he was seldom known to entertain visitors, and even when he did, no other dish than a leg of mutton, one or more, ever suggested itself to him. In this house he died in 1810. At the northern end of Gower-street, where the road is blocked by one of the many barriers that still impede the traffic, are University College and the North London or University College Hospital. The latter was founded soon after the opening of the College, under Lord Brougham's presidency, and built after Alfred Ainger's design. The foundation of the College is generally attributed to Lord Brougham,—a scientific man amongst lawyers and a lawyer amongst scientific men,—though the exertions of Campbell, the poet, to the same end should not be forgotten. Its design,† by W. Wilkins, favourably compares with his later National Gallery in Trafalgar-square. The first stone was laid on Monday, April 30th, 1827, by the Duke of Sussex, under strong Whig auspices. The central portico, raised upon a lofty plinth and approached by flights of steps, has a fine effect.

The hall beneath the cupola constitutes a befitting resting-place for a priceless possession,—the original models of John Flaxman's chief works, which about ten years after his death were presented to the council by his sister-in-law, Miss Denman. Of these, as well as the not less interesting collection of Flaxman's sketches, we gave a full description some time ago.

The relaying of the roadway of Gower-street in recent times, partly with asphalt and partly with wood-paving, probably in an almost literal sense "paved the way" for the improvement and resuscitation of the street. In its former condition, with cobble paving of even unusually severe type, and with the rattle of vehicles was formidable, and, with the present development of traffic, the houses, had the old pavement remained, would have been almost uninhabitable for any sensitively-organised tenants. Following on this necessary alteration, great improvements were made some little time since in a number of the houses on the west side of the street, in regard to sanitary arrangements and additions necessary for modern ideas of comfort and decent living. The attempt made at the same time to give a more important appearance to the front of a good many of these houses, by framing the doorways with stone pilasters and architraves, has not been so successful; the additions thus made being, architecturally speaking, as ugly and badly-designed as they could well be; it would have cost no more to have made them agreeable and picturesque, had they been put into proper hands. Very recently some of the larger houses on the east side of the street have been taken in hand, and subjected to a thorough refitting internally, without any similar attempt at stone-casing the entrances, which, if it were to be done no better than on the west side, is certainly heter let alone. These more lately "revived" houses are excellent residences of their class, with a good deal of pleasing variety in the arrangement and planning of the principal rooms, and they have another attraction little suspected by the casual passer-by; for few who look at the long monotonous line of houses on this side of the street, would expect to find in their rear quite a plantation of

trees, some of them very fine ones. In the building alterations recently made, we are informed, the most religious care has been taken not in any way to injure these trees, which are a precious possession to the site.

#### A CLUSTER OF DECORATIVE ARTISTS.

BIRKENHULTZ—CARRAVAGGIO—FOLKEMA—PHILIP GALLE—JACQUINET—WENZEL JAMITZER—JANSSENS—PITTONI—VALCK—VISSCHER—WOERIOT.

We must commence by saying that the cluster of decorative artists whose work we propose to consider to-day, and whose names stand at the head of this article, are so grouped merely for our own convenience. They have no common country, no common period of work, and they produced designs which have nothing in common but, perhaps, excellence. We have lingered somewhat longer than we had intended over the work of the five artists we have specially considered, and for various reasons we

Fig. 1.

propose now to make a wide cast of our net. In some instances there are but few specimens of their work preserved,—at least, in the British Museum Collection. In some instances there is a good deal of very inferior work, relieved only at rare intervals by flashes of genius; and in others, again, there is an abundance of work, but little variety of style. We have, therefore, arranged their names in alphabetical order, and with our readers' permission will take them as they come.

Of Paulus Birkenhultz little is known save that he was at work in Germany about the year 1670. He worked like so many others for the jewellers, but his designs have mostly little merit. There is, however, one little panel in the midst of the pendants which cannot be passed over (fig. 1). To those who love the Renaissance and all its works without discrimination, the flapping of the bird's wings in the centre will seem a pretty incident; to those whose admiration is somewhat qualified and disturbed by such presence, it must seem a blot on the sculpture. But on this subject we have already spoken at sufficient length, and it will be unnecessary again to recur to it. "Barrin' the bird," however, the design is specially graceful, the main stem of the scroll splitting up the panel into six not too uniform subdivisions very pleasantly.

Fig. 2.

From Birkenhultz we go back more than two hundred and fifty years to Polidoro Caldara da Carravaggio, who was born in 1495. He was a disciple of Raffaele, and painted the friezes accompanying his master's work in the Vatican. His engraved decorative

work consists of a large series of designs for silver cups, which are remarkable for exquisite purity of form, and for the perfection of simplicity in the ornament put on them. One of these we will give an illustration of in our next.

The next name on our list, R. J. Folkema, probably worked at about the same time as Birkenhultz, or possibly even later. His work strikes one at first sight as mediocre, chiefly on account of a certain lack of fineness in engraving, and a want of freedom and firmness in the drawing of the curves; but it is not without merit. We should hardly, however, be justified in ranking him as a master of the art, but rather as a successful student. The want of freedom in his drawing suggests that a good deal of his detail was copied and applied rather than inspired, and the result is often ungainly: in one or two places he is, however, more successful. In fig. 2 we give the main structural lines of a really charming acanthus study, and in fig. 3 a more finished sketch of a fragment of the foliage, which, in spite of one or two obvious defects, is still not without a considerable amount of graceful feeling.

In the same rank with Folkema, we must (departing for the moment from our alphabetical arrangement) place Gerard Valk. He also seems to have been a not altogether unsuccessful student; but whereas Folkema mastered the art of construction of design, but lacked something of originality in his detail, Valk seems to have been quite successful in foliage detail, but to have missed the mark entirely with regard to general construction; fig. 4 is almost repulsive, with its uncouth and ungainly structural lines, but the acanthus-leaves are exceedingly well drawn and adapted to their places and purposes in and to which they are put.

Philip Galle is an artist of a very different order of merit. He was born at Haarlem in 1537, and afterwards became a print-seller at Antwerp. His name will not be entirely unknown to our readers, for some at least of his

Fig. 3.

Renaissance panels have been reproduced and serve as head or tail pieces in the illustrated magazines of the present day. But it speaks ill of the taste of those in whose hands the selection of designs for such objects rests, that they should have deliberately given prominence to Galle's worst work, and have passed by his best. For he worked in two very distinct styles. Although there is little to find fault with in the execution of his Renaissance panels, in design they are but a heterogeneous mass of ill-assorted and often unpleasing detail. But his best ornamental work is of a very different calibre, and it is difficult to realise that such good and such bad work can have come from the same hand. Of this second style we give an example in fig. 5; in it every canon of the art is observed with the greatest fidelity. First, as to its main structure. The curves are given off from the points above and below the little central medallion which does not enter into the design: from these points they flow with absolute freedom, adapting their volition without constraint to the form of the ellipse which has to carry them. There is not one inharmonious break or jar in their tangential flow. The longer scrolls from the bottom wind up to the right hand and the left, and meeting the shorter one from the top intertwine with them, and then fall back again; but there is no confusion, each has its own allotted space to fill, and each in due course fulfils the object for which it was created. And as the main structure is perfect in its way, so also is the detail in its way. The foliage is a very simple conventional form, a leaf with but few serrations, and only here and

\* Vide his statue, by Westmacott, in Russell-square.

† The northern wing was recently added, under the superintendence of Professor Hayter Lewis; but the buildings are yet uncompleted.

there a five or six petalled flower; but the whole surface is evenly covered, and there is no spot covered or uncovered which stands out above the rest with undue prominence.

From Folkema let us pass to one Jacquinet, a gunsmith, who ornamented the locks of the weapons he sold with pleasant devices. There is no extraordinary merit in them save one, but that one redeems every design he made from falling into commonplace: there is little compactness in their composition, the flowers are but slightly, if at all, conventionalised; there is not much originality in the detail, but,—and this is an important “but,”—the designs are in every instance perfectly adapted to the object they are intended to beautify. As in speech, action, its ornament, must be suited to the word; so in decoration the lines of which it is composed must be suited to the thing on which they are placed. It is Bourgnet’s “*ovales ronds*

It is difficult to decide to which to give the palm, the complicated outline or the elaborate detail which covers the surface. The latter can speak for itself, but the beauty of the outline demands some slight analysis. The beauty of an outline which is very much broken up depends on the beauty of the curve which is formed by joining the extremities of the most important of protuberances. Let us draw such a curve, starting from the topmost moulding, just underneath the pan which holds the candle-socket. It travels inwards past the second moulding till it reaches the little boss in the centre of the spheroid immediately below it; then it swells out, slightly touching the extremity of the wreath, touches the little bit of moulding which holds the little man’s head (which with the claws are but slight excrescences); still gradually swelling outwards it glides by the moulding underneath the arches

which is modelled to it, to be a thing of beauty also.

Our next illustration, fig. 6, is a fragment from one of the designs of a Flemish artist, Hendrik Janssens. Very few of them seem to have been preserved, but there is a singular grace and freedom in the curves of the fragment we have selected which seems to have been designed for some species of gold work.

In Battista Pittoni, born at Vicenza in 1585, and Claes Jansz Vischer, who flourished about 1640, we have two masters who worked almost exclusively on the revived classical models. The former produced endless variations on the acanthus scroll; the latter in addition to similar studies published a bookful of designs of festoons and fruit. These are not sufficiently interesting for reproduction, but we have reproduced one of the scrolls, and two of Pittoni’s. These are given in the separate plate of illus-

Fig. 4.

Fig. 6.

Fig. 5.

et curvds” principle over again; \* for harmonious effect the construction of the ornament must follow the construction of the thing ornamented. It is, perhaps, difficult to find an object that lends itself less to continuous and homogeneous design than a gun-lock, with its flint and steel, its hammer and spring, its bolts and its screws; but Jacquinet took it as he found it, embellished every part as it came under his hand with loving care, and, as we have said, produced at least some designs very pleasant to behold. There are a goodly number of these gun-lock designs evidently coming from an illustrated catalogue, and every one will bear its own witness to the truth of what we say.

The elaborate candlestick given on the separate plate of illustrations in this number comes from the hand of Wouzel Janitzer von Munch, sometimes called the Master of 1551. It is one of a considerable number of designs, most of which are for large and richly-embossed cups.

and figures, till, with bolder and bolder sweep, it passes the moulding beneath the medallions, and at length it meets the massive curves which form the base. We have drawn a beautiful curve. But why beautiful? We know not; perchance, by reason of its elaborate equation (which expression we might possibly, with some truth, hold to stand as the mathematical curve-tracing equivalent for the artistic suggestion of the infinite). But this we know, that one curve excels another curve in beauty; that an ellipse is more beautiful than a circle, a parabola than an ellipse, a hyperbola than a parabola, a catenary than all the others, and so on through all the mysteries of the tracing of curves to which no names can be given, so many legion are they. The bottom segment of the curve we have drawn has something of the spirit of a catenary about it; the upper segment runs into the lower at a perfect tangent to it, but is too short to indicate its ultimate destination. But the sum and substance of all this is that we hold it to be a line of great beauty, and the form of the candlestick

trations. It is needless again to enter upon the much-debated question of the artistic value and merit of this classical model; the general structure of the scroll is a fixed quantity, the only scope for the artist’s originality and individuality in the scroll itself being found in inventing new devices for the floral terminals and bud sockets; for the rest, the animals and children could be varied *ad libitum*, the designer’s liberty in this respect being absolutely unfettered and unconfined. With the elaborate sword-handle, also in the separate plate, one of a series designed by Pierre Woeriot, we close this article: the flowing lines of the guard are especially beautiful, as is also the treatment of the acanthus-leaves on the stem.

In this little cluster of decorative artists we have gathered only those whose work might justly serve as examples of merit of one kind or another. Even from the British Museum collection, which is the only one of its kind in England, but which from the nature of the case must necessarily be very incomplete, we would willingly have culled specimens of other

\* See our article on Jean Bourgnet, Jan. 1, 1887, p. 6.

masters; some of the many cups, for example, designed by Bernhard Zoo, about 1571, or of those which Hanns Christoff Loechin von Leutkirch published in 1594 in his "Buch mit xxvii. Stück"; or of the weaker designs for the same purpose by their contemporary Johann Stephens (1582); some of the ornaments for "argue-buzerie" from Pieter Schenck's collection, "tirées des premiers maîtres de l'Europe"; some of Daniel Mignon's gold work; but our series of articles would be mending, and we have still much ground to traverse before they are concluded. One eminent name our readers will have assuredly missed, De Bry; but we have reserved our next article for the study of the two artists who bore it.

#### THE TREATMENT OF SEWAGE.

In our previous article on this subject\* reference was made to the reports, only recently published in the Society of Arts Journal, of Dr. Tidy's paper on the subject read in the earlier part of last year. A reference to the opinions elicited in discussion on the same occasion, and also published in the Society's Journal, may be of interest as a supplement to the consideration of the subject.

The discussion was commenced by Lieut.-Col. A. S. Jones, V.C., who disposes of the sewage of Wrexham on his own farm, and is the author of the pamphlet published by Messrs. Spon, "Will a Sewage Farm Pay?" Dr. Tidy had said that the sewage mud accumulated on the surface of irrigated land, to which Colonel Jones replied that any farmer, or labourer even, could give the most positive and direct contradiction to that theory. He had applied large quantities of raw sewage, sludge and all, to fallow land every winter for fifteen years, and never found the pores of the soil clogged when it had been ploughed up for roots in the succeeding spring. Frost and heavy rain were also common hughears with indoor advocates of chemical precipitation, which the farmer knew how to combat without much loss of purification, as percolation goes on through the soil all the same under the sheet of ice, and it is quite unnecessary, as well as misual, to let the sewage run over frozen ground into a river.

Dr. Carpenter had seen the processes of sewage disposal in various forms and conditions, and he could say with the utmost satisfaction that the only arrangement which would fulfil all the requirements was the utilisation of the sewage by irrigation. The great point was not to let the land get water-logged or deprived of atmospheric air, and it must be broken up pretty often, so that the air would get in. He had seen cases where the sewage was allowed to go on the same plots for two or three days, or even two or three weeks, and then they wondered they could not get a crop. No sewage should go on to one plot for more than twelve hours, and then should be turned on to another, and the air must be allowed to get to the roots of the plants. Again, the land should never go beyond three years without being broken up, and it was the failure to do this which often led to difficulties. That was a fault on the part of the farmer, not of irrigation. Irrigation was the right thing, and it was even better to pump than to send the sewage into a river or the sea.

Apparently to strengthen his case, Dr. Tidy had said that "A precipitation scheme by itself has these two enormous advantages over irrigation, viz., its efficient working is totally independent of weather; and, if sufficiently large works be erected, any emergency of quantity can be met." This is contrary to all reason, and the facts of cases, unless special stress be laid upon the reservation that sufficiently large works be erected. With works of ordinary dimensions excessive quantities of sewage cannot be dealt with in tanks; and if tanks be made large enough to deal with these quantities in emergencies they become unnecessarily large for those of ordinary times. Dr. Tidy was attempting to show that with a tank system the separation of the hulk of the rainfall from the sewage need not be done, but Mr. Baldwin Latham said the first important point was that of separation; they were told that they were not to separate the rainfall from the sewage, and they were also told that in time of rain the sewers were flushed out, and the consequence was that at that time the sewage was much

fouler than at any other time. It seemed to him that that was the very strongest argument for separation. If as much rain as possible were kept out of the sewers the volume was considerably reduced; if it were not kept out, the average daily flow might be increased twenty to thirty times in one hour by a heavy shower; and instead of this being unimportant in chemical processes, it was far more important than in irrigation, because, to carry out such a process properly you wanted large tank space, and if in a limited time thirty times as much rain as the ordinary volume of sewage came down, as the tanks generally held only six hours' sewage, instead of having six hours for precipitation there would only be a few minutes, and consequently the sewage must go away in a polluted form.

As to the difficulty of disposing of the sewage to farmers Mr. Peregrine Birch said that in some parts of England the voluntary system had been found to be extremely useful; for instance, at Cheltenham, where precipitation tanks had been erected which did not efficiently perform their object, the Town Council had spent several thousand pounds in carrying the sewers further down the valley, and bought two farms of their own, and had made arrangements with the farmers on the route to take the sewage when they wanted it, and when they did not want it it was put upon the land belonging to the Corporation. They received from the farmers sums varying from 4s. to 15s. per acre for a dressing. When the farmers did not want the sewage the Corporation irrigated their own grass lands, and the result had been that instead of spending 6d., 9d., or 1s. per bead of the population on using the tanks ineffectually they had got out of the difficulty at the cost of 1½d. per head, paying off at the same time the cost of 300 acres of valuable land, so that at the end of forty or fifty years they would be possessed of a fine estate, instead of having a liability upon them to improperly deal with the sewage at a cost of 1s. or 9d. per head. The position taken up by Dr. Tidy was that precipitation, irrigation, and intermittent filtration had each its own advantages and disadvantages, which Dr. Percy Frankland said was a very safe position, and there was, no doubt, much truth in the statement; and that different processes were suitable to different places; but it should be clearly borne in mind what were the intrinsic capabilities of each process. People who had to select between the competing methods of purification ought to bear in mind what it was possible to accomplish by each process. There could be no doubt that sewage precipitation was adequate for some purposes, but it was an indisputable fact, which should never be lost sight of, that the best known processes of sewage precipitation could not accomplish such purification as it was possible to obtain by the best methods of irrigation and intermittent filtration. With regard to the precipitating material which the Metropolitan Board of Works were prepared to recommend for adoption, Dr. Dupré said that, in conjunction with Mr. Dibdin, he had made various experiments in the matter, and found that by using a larger quantity of precipitating material better results were not obtained. He thought very few people had any notion of the quantity of precipitating material necessary for the metropolitan sewage. One grain per gallon added to the London sewage represented ten tons of material per day; the total amount of material used in the A B C process was about five times that of the suspended matter in the sewage, or from 150 to 200 grains per gallon of London sewage per day, equal to 2,000 tons to be used daily, which came to 5,000 tons of pressed cake, chiefly formed of material which had been added. What was it added for? Not to produce any real benefit, because when this process was used the organic matter was 18·2 grains per gallon in the sewage, and 18·4 grains per gallon in the effluent. What was the object of adding 2,000 tons of material daily to sewage for the mere trouble of collecting it again and pressing it at a considerable expense? Professor Dewar took it that Dr. Dupré would admit now that the effluent ought to be oxidised, in order to make it anything like fit to be placed in a river. It was exceedingly surprising that there should be no limit to the amount of chemicals which could be used. It would seem that neither was there any particular substance which was better than another. The combination Dr. Dupré had selected, in conjunction with other

distinguished men, required explanation from a chemical point of view. He took it that the addition of lime and sulphate of iron gave rise to protoxide of iron, which withdrew a considerable amount of oxygen from the water. Subsequently he understood permanganate was to be added. He had not the slightest hesitation in stating that the samples of effluent that he had seen resulting from this process were the worst from any precipitation process whatever.

It is, therefore, plain that whether we regard the substance to be used, or the quantity, there is no agreement amongst chemists. Sir Robert Rawlinson pointed out, from his experience in this matter extending over thirty years, that to treat sewage by chemical deposition would not cost less than 1,000l. per annum for each million gallons per day. In some cases the cost would be double that. He thought that if there was any chance of dealing with sewage with the nearest result to profit, it was by irrigation, although neither this nor any other way of disposing of it could be looked upon as positively profitable. In some cases, where the land was in sufficient area,—where it was of an exceptionally good quality for sewage,—crude sewage might be put on the land without any previous tank process; and in cases where an area was less than 300 or 400 acres, expensive and permanent carriers of any kind were not required. Where the area was from 500 to 2,000 acres, then it might be necessary to construct certain leading, permanent carriers over the ground. A vast amount has been wasted by young engineers laying out small farms of 200 or 300 acres with costly permanent carriers, which had been an obstruction to the irrigation process. What was wanted in those cases was rough-and-ready carriers made with the plough or the spade. The crude sewage was to be taken to the highest point, and passed along contour lines gradually over the land. At certain sewage farms expensive depositing tanks had been made, but it was soon found that they became a nuisance.

The process of precipitating the sewage of the metropolis at the Barking outlet, and then carrying the residue down the Thames to the sea, was declared to be a monstrous proposition. Reasoning from small to great, about 10 tons of sludge per week are precipitated from the sewage of a population of 1,000. This quantity may be reduced by presses to 2 tons, or 104 tons of pressed sludge in one year from each thousand of the population. Taking the population of London at 4,000,000, there would be 40,000 tons of sludge per week, or 416,000 tons of compressed sludge per annum. If it cost 2s. per ton to produce it, the annual outlay would be 41,600l., besides the cost of the removal. To produce this sludge separate from the sewage, 165,000,000 gallons of sewage per day would have to be chemically treated, and each million gallons a day would cost 11,000l. per annum, or a total in one year of 1,650,000l. But if the sewage were raised by engine-power into a conduit which would convey it in the direction of Canvey Island or elsewhere, and if the conduit passed through an agricultural district, it could be disposed of on land, if the Board had power to purchase the land at its agricultural value for the purpose of letting it out for sewage irrigation, and so the crude sewage of the metropolis would be utilised between the present works and the sea, not only without any ruinous cost to the parties establishing the works, but with some chance of an income, and certainly not with the enormous loss which would have to be faced if the Board attempted to treat the sewage with chemicals. The Canvey Island scheme, with which Mr. Bailey-Denton's name is prominently associated, is based on the following particulars:—The population is assumed to be six millions; the quantity of sewage from the metropolis 200 million gallons daily; from the Lea Valley twenty millions, or a total of 220 million gallons per day.

The rateable value, including all places on the Lea south of Waltham, is set down at 32,162,864l. One penny in the pound raises 134,012l. The cost of the main conduit, with distributing conduits and appliances and the immediate formation of earthen basins to receive the solid portion of the sewage by settlement, and including also filtration beds to cleanse the liquid after its separation from the solid, and the purchase of the island (4,383 acres), and including compensations, would be 4,873,017l. The working and current

\* See p. 79, ante.

expenses would be 195,551. Three half-pence in the pound more than suffices to raise this amount.\*

"THE CONVERSION OF ENGLAND:"

A DRAMA WITH HISTORICAL COSTUMES.

The notices which appeared in anticipation of the performance of this play, stating that it had been in rehearsal for two years, were sufficient to excite the interest of any archaeologist, and although the statement proved to be an exaggeration of the fact that it had been performed two years ago, there was little room for disappointment.

The drama describes the mission of St. Augustine of Canterbury to Ethelbert, king of Kent, and the conversion of the Anglo-Saxons to Christianity; it is written by the Rev. R. H. Cresswell, whose name alone appears, the performers being announced as divers persons connected with the Church of St. Peter, Vauxhall, and the performance has taken place on Monday, Tuesday, and Wednesday evenings of this week, at the Boys' Parochial School, in Macaulay-road, Clapham. The tickets of admission had been eagerly secured, and the seats were all filled.

The drama is divided into ten scenes, each of which required elaborate setting, with the result that the intervals between them were long and the scenes themselves were so very short that the curtain seemed to fall almost before the scene had well begun; there was thus no time to make such careful notes of the scenery and costumes as they deserved, and, it is to be hoped, that the performers will allow themselves to be photographed in groups so as to preserve what has undoubtedly formed the subject of considerable study.

The first scene was the Forum of Rome, where the English children are sold as slaves, and gave Gregory the chance of making his three historical puns; but as we read that he was then a deacon, this may be held as an excuse for them. *Basilides*, the slave dealer, does business with *Theodora*, a Roman lady, who hands over her purchase to the Christians.

The second scene transports us to Heathen England, where Sebba, the priest of Woden, is officiating at an altar around which a troop of children dance various measures; their really bare legs and feet giving a very natural tone to the scene, and being a great relief from the meretricious effect of tights, though somewhat conducive to rheumatism. After the dance, Sebba tests the fate of a captive by mystic rites, which result in his condemnation, and Queen Bertha, who enters, pleads in vain for his life, she being a Christian.

In the third scene we find Augustine and his brethren of the Monastery of St. Andrew at Rome, seated at a table well supplied with food, of which they were apparently not hungry enough to partake. A messenger brings a letter from Gregory appointing Augustine to conduct the mission to England, and he accordingly chooses the four monks who are present,—Lawrence, Peter, Sergius, and Placidus,—to accompany him. The latter is the one laughable character in the piece, and, as the name suggests, should be the very opposite of a self-denying man; it was, however, taken by an actor so emancipated an aspect that one felt, all along, that he was regretting that he had left the food untouched.

The fourth scene is laid at the Monastery of St. Honorat, in the island of Lœnis, where the monks fall in with a Frankish count, whose gruesome accounts of England, which he has visited, go far to increase their despair, especially that of Placidus.

\* The letter of "Ferrometer," which we published last week (p. 132), conveys nothing to the point. Dr. Tidy did not refer to the area of land required for broad irrigation, as our correspondent supposed, but to the area required to set a river, as we pointed out; and this is, of course, very much less than that required for broad irrigation, about which "Ferrometer" gives some figures which we are not much concerned to dispute, although we may point out that he is wrong in saying that 30 gallons of sewage per individual per day is "the usual mean." Then, with regard to the effect of sewage passing through earth, the case of Edinburgh was not referred to, either by Dr. Tidy or by anybody who took part in the discussion of the subject. After a long examination of the facts of the case, the Rivers Commission reported that "the Edinburgh experience, therefore, must be quoted not as a successful example of sewage cleansed by irrigation, but rather as an instance of the largest produce raised by means of it from a limited area of land." Therefore, while we do not dispute our correspondent's statement that the effluent water of the Edinburgh sewage "contains 64.94 grains of foreign matter per gallon," yet we must say that it does not affect the question of the proper treatment of sewage.

The fifth scene brings matters to a worse pass, for the monks are attacked in a forest near Pont-de-Gé, and become separated; however, they manage to find one another, and then divide themselves into two parties, one to watch and sing psalms, and the other to sleep,—which, by the way, they do without previously saying their prayers.

The sixth scene is at the Palace of King Ethelbert at Canterbury, and is, in the matter of costume, the most ambitious of all. The simple dress of the king, without a mantle, was remarkable. A messenger brings word of the arrival of the monks, and the king takes counsel of his nobles whether they should be admitted to his presence,—a point strongly urged by the queen, but overruled by the nobles,—and the king decides that he will go and meet the monks instead.

The seventh scene is, therefore, on the Downs above Minster, in the Isle of Thanet, where the king, accompanied by his court, hears what the monks have to say. These enter, duly preceded by acolytes, who are not accounted for in the previous scenes and are presumably, recent converts. The monks stand behind Augustine, who is seated, and observes the effect of his appeal conveyed to the king by an interpreter. In doing so the actor committed the little forgetfulness of listening to the interpreter, whom he presumably could not understand, instead of only watching the face of the king. The pious fervour of this character was, however, beyond all praise, especially when he received the king's permission to convert his people, for which the queen comes forward to render heartfelt thanks.

In the eighth scene, in St. Martin's, Canterbury, the king is baptised and duly clothed in white, and a grand procession files out of the church, taxing the limits of the stage.

The ninth scene transports us to the porch of the cathedral at Arles, inside which Augustine is being consecrated Archbishop of Canterbury. In due time he issues forth, preceded by a crozier, and wearing the mitre, of loose material, indented along the centre, but not the pallium.

The tenth scene, laid near St. Augustine's oak, is a supplementary one, in which is represented the fact of the ultimate valuable co-operation of the British and Scotch churches in the conversion of the Anglo-Saxon races. Augustine's death is announced by his successor, Lawrence, one of his four companions.

This closed a performance which one would like to see repeated on a larger stage to a larger audience, if only as a means of archaeological instruction in a pleasant form.

SALT FOR REMOVING SNOW.

THE recent snow-storms have, as we have already observed, aroused the indignation of the British ratepayers, many of whom, especially in the metropolis, have been heaping contumely on the devoted head of all officialdom by means of letters to the *Times* and other journals. The use of salt for removing snow has occupied a prominent place in these outbursts, and has been awarded a full share of abuse. Under these circumstances it will be interesting to note what has been done in our sister capital of Paris, where the trouble from snow-storms is often greater than in London.

In the *Annales des Ponts et Chaussées* are given some particulars of the first efforts made by M. d'Ussé in 1850, to thaw the compressed snow caused by the passing of vehicles. During the winters of 1879-80 and 1880-81, nearly 200,000 l. was spent in the by no means successful efforts to remove the snow from the Parisian streets. At that time there was a heavy tax on salt, but in order that it might be used for the removal of snow this tax was remitted on the common kinds of salt, which would be unsuitable for culinary and table purposes. About 4,000 tons of salt were accordingly provided for last winter, and a regular service was organised for clearing away the snow before it became trodden down by pedestrians or compressed by the wheels of carts and carriages. This is an important point, as the ice formed by the compressed snow is much more difficult to get rid of than the virgin snow. The salt is scattered on the streets as soon as the snow begins to fall fast, about 1 dram per square foot for each 4-10ths of an inch of snow fallen being used, provided the temperature is not much

below freezing. The traffic, in place of causing the snow to stick to the ground, only helps to mix it and the salt together, producing a liquid that will not freeze at a temperature above 5° Fahr. In countries where the thermometer is apt to fall so low as this the system would be inadvisable. The cold liquid should be swept into the drains as soon as possible, but it is said to do no harm to asphalt-paved and wood-paved roads. On macadamised roads, however, it causes disintegration, and should not be used.

It is said that there is no method so cheap as this for the removal of snow. Steam has been tried but does not compare with it in the matter of cost. Formerly in Paris each centimètre, or 4-10ths of an inch, of snow that fell cost the city about 2,400 l. to remove it, but by the use of salt about two-thirds of this sum would be saved, the expense being only about 800 l. for the same result. With regard to the point, so much stressed has been laid on, in this country lately, the injurious effects of the "freezing mixture" on the boots of pedestrians and the hoofs of horses, it is claimed that the latter disadvantage can be obviated by greasing the inside of the hoof, and if the liquid be promptly swept into the drains, by sweeping-machines on the roads and "squeegees" on the pavements, the discomfort to pedestrians will be very small and of short duration.

Details of this method of removing snow by salt may be found in the eighty-seventh volume of the "Proceedings of the Institution of Civil Engineers," p. 47, *et seq.*, in which there is an abstract of a paper by Mr. Brahaud. It is said that possibly the system may not be confined to the clearing of streets of towns, but be extended to all paved roads, tramways, approaches to railway stations, and large factories. It might be also used for dealing with snow-drifts in railway cuttings, by spreading it in sufficient quantities and sweeping off thin layers. "The small cost of the system," it is said, "and the advantages to traffic are sufficient reasons for an early and wide extension of the use of salt for removing snow."

COMPETITIONS.

*Schools, Milverton.*—At a meeting of the School Board, on Monday last, to consider the competitive designs for the proposed new Board schools, it was decided to accept those of Mr. Geo. H. Cox, architect, Birmingham.

*Sewerage, Cleethorpes.*—An open competition was invited by the Cleethorpes Local Board amongst sanitary engineers for the best scheme of sewerage and sewer outfall for the district of Beacontorpe, which lies between Grimsby and Cleethorpes. The plans and report sent in by Mr. W. H. Radford, Assoc. M. Inst. C.E., of Nottingham, have been accepted as the best, and he will be appointed Engineer for the works. As the district is likely to increase considerably in population, pipe sewers of the largest sizes will be laid down. The sewage will be conveyed out to low-water mark by large iron pipes, and delivered on the ebb tide, which will take it straight out to sea. Storage accommodation is provided for the sewage during high tide, and flushing and ventilation arrangements are made.

MAP OF LONDON SHOWING THE BOUNDARIES OF SURVEYORS' DISTRICTS.

We publish this week the fourth and concluding section of this map.

Illustrations.

AMERICAN HOUSE ARCHITECTURE.

WE give, in one of our phototype plates this week, two characteristic examples of recent American domestic architecture,—a town house and a sea-side house, the first being the Art Club at Boston, designed by Mr. R. W. Emerson; the other, a sea-side house designed by Mr. Arthur Little. Each of these illustrates, in its way, the reactionary tendencies of modern American architecture. For a long time the great defect of American architecture was that not only did it attempt no originality, but it was tame and commonplace even in its reproduction from European

DESIGN FOR HOUSE IN CHICAGO.

HOUSE, CORNER OF OGDEN AVENUE AND ADAM STREET, CHICAGO.

Houses in Chicago.—Designed by the late Mr. S. G. Beaumont.

materials. A persuasion of this, coupled with the influence of one or two architects of genius (of whom the late Mr. Richardson was the chief), seems to have led, of late years, to strong resolution to be original, and even with that object to return to the first simple beginnings of architecture, and reduce houses to the roughest and most unworked materials and design, in the hope of, apparently, striking out from this new beginning into some original path. The "seashore cottage" illustrates this latter tendency. The architect appears to have studiously avoided everything like "architectural treatment," even putting unguaranteed tree poles to carry the balconies and overhanging eaves. This appears to us an absurd affectation of rusticity which is at variance with architectural principle and true good taste. In other respects the house is certainly picturesque, especially so the octagonal turret with its simple windows, which forms the outworks, so to speak, of the residence.

The Boston Art Club illustrates the manner in which some able American architects are endeavouring to develop hints from Romanesque forms of architecture into a style, or at least a manner of their own. The various details of this new American style seem still to require harmonising and refining, but there is force and picturesqueness in it, and it undoubtedly promises further possibilities of development.

The two illustrations are reproduced by the phototype process from photographs.

The sketches above given of houses recently erected in Chicago came into our hands while we were arranging the publication of the two photographs. We add them as marginal notes in further illustration of this move of American architecture in the direction of the rudely picturesque. Please to observe the random rustication of the basement portion (a "note" of much recent American house architecture), and the equally random, though effective, style of sketching. These houses were designed, oddly enough, by an architect (Mr. S. G. Beaumont) who went out from England, but appears to have contrived thoroughly to indoctrinate himself into the "new American" style. We regret to add that Mr. Beaumont,

who was formerly in the office of Messrs. Banks & Townsend, in London, died not long after he commenced practice in Chicago.

#### TANAGRA TERRA COTTAS.

The illustrations given are photographed from three of the reproductions of these charming little Greek toys, as they may be called, which are being made and offered to the public by Messrs. Bellman & Ivey.

Every one who has seen the numerous examples of these statuettes in the British Museum and at Berlin must have been charmed with the combined grace and natural simplicity of their pose and expression, and the very pleasing arrangement of the drapery in most of them. The copies are exceedingly good reproductions, and form very graceful household ornaments.

There is a great general similarity in the design and pose of many of these statuettes, though, as far as we have observed, all the examples in the British Museum differ in detail. What is not generally known, however, is that these figures show evidence of having been cast in moulds, and only partially touched up by hand afterwards. A good many replicas have been found; indeed, a German authority says they have been found "by the dozen"; but what strikes one is that there should be so much variety as there is, and so many different moulds made for figures which, after all, differ so little in character.

Mr. A. S. Murray writes from the British Museum,—“I can show you in some of our terra cotta here that the front of the figure has been pressed into a mould; you can see in the interior the marks of the fingers of the *keroplastes*, and you can see where he has joined on the clay that forms the back of the figure; the marks of his modelling-stick where he has roughly sketched in the folds of drapery which had to be carried round from the front are obvious enough. We have a mould of the front of a figure and several moulds of faces.”

The figures have apparently all been coloured; the colour is visible on the hair of nearly all of them, and in many parts of the drapery.

Messrs. Bellman & Ivey seem to have arrived at reproducing the effect of the statuettes as they are now, giving touches of colour in the same way, and leaving other parts clay colour. We should have thought it more reasonable to endeavour to reproduce them as they would have been when new, or else to omit the colour altogether, and give the form only; as the reproduction of the actual state has no archaic value in a copy; but it is possible they would have been less generally attractive than by the present treatment.

Part of the interest of these figures arises from their obviously realistic character, and the picture they give of the Greek lady as she looked and dressed. It may be observed that the dress-reforming ladies, who write letters in the papers urging the noble example of Greece in the freedom of woman's dress, are entirely contradicted in their assumptions by these heavily-draped figures, in the costume of which not a suggestion of the "dual skirt" is to be seen.

#### DESIGN FOR ASSIZE COURTS.

This design, by Mr. S. B. Russell, gained the Royal Academy Schools Prize for an original design for Law Courts for a small town. The plan is effectively arranged, and has good practical points about it: the witnesses' rooms are, however, inconveniently far from the courts.

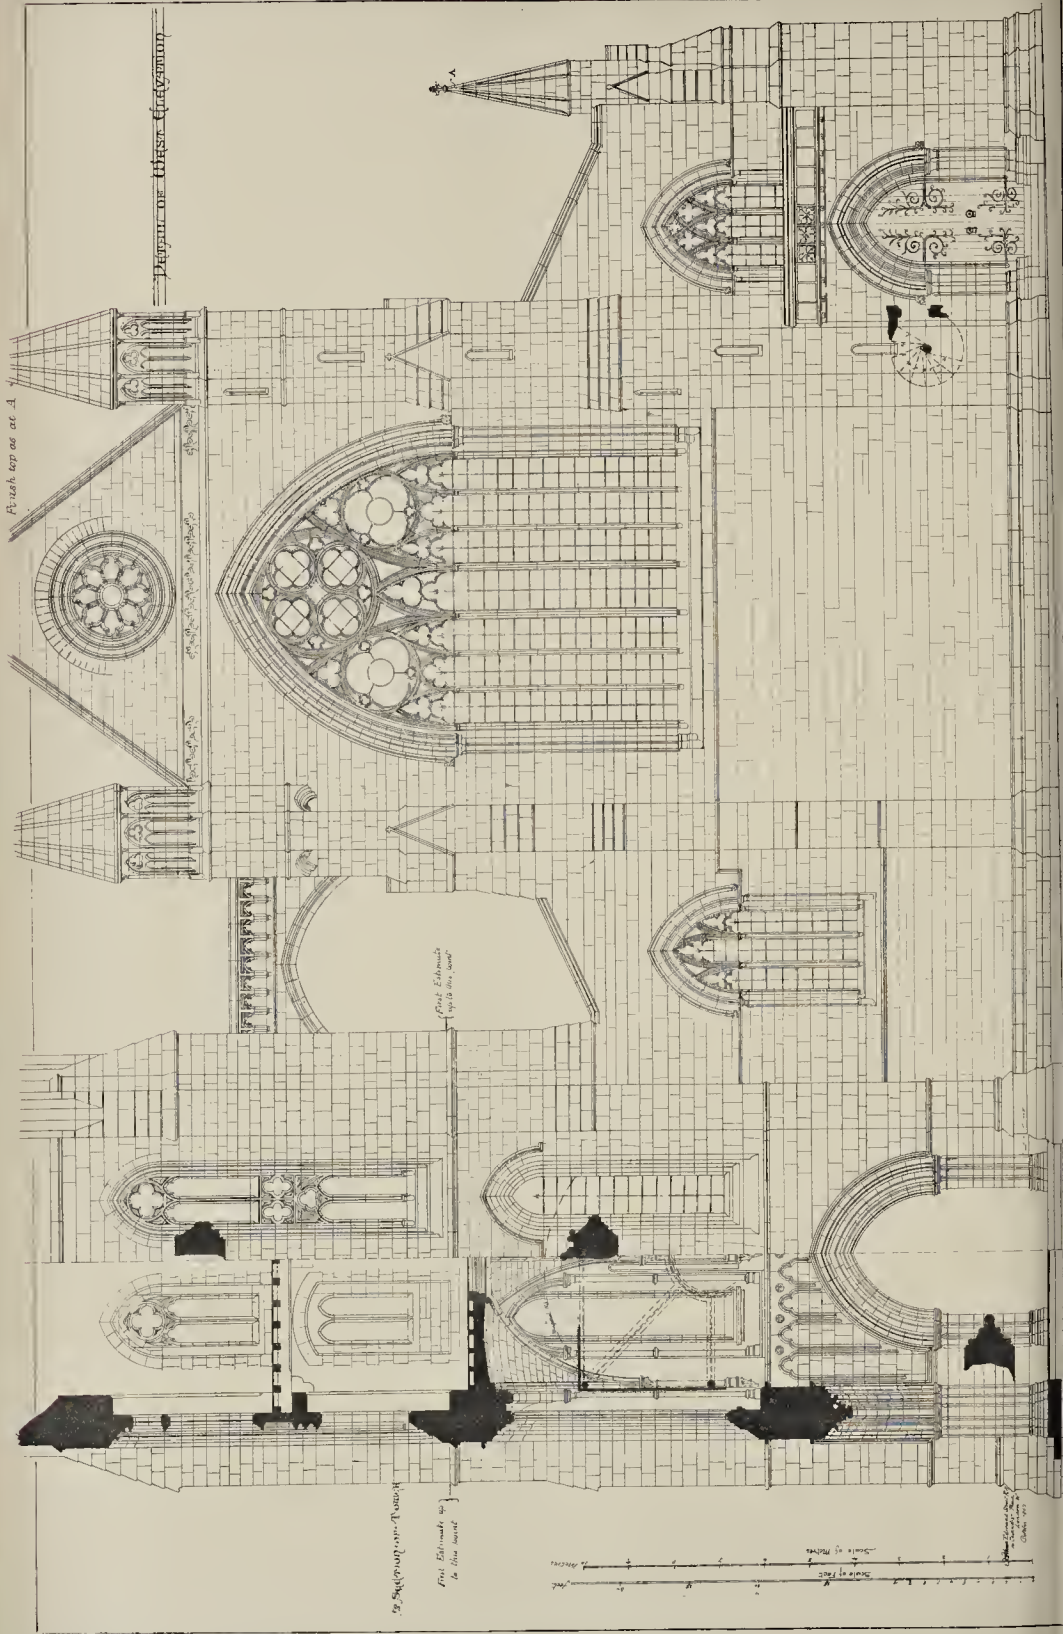

#### AMERICAN CHURCH, PARIS.

We give some more of the working drawings of this building, designed by the late G. E. Street and completed under the direction of his son, Mr. Arthur E. Street, believing that they will be of interest to a good many students and designers of modern Gothic church architecture.

**Northallerton Waterworks**—The Northallerton Urban Sanitary Authority have appointed Mr. A. M. Fowler, C.E., of Manchester, engineer for the preparation of a scheme for supplying the town with water. There were seventy-two applicants.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

AWARD OF STUDENTSHIPS, MEDALS, AND PRIZES.

The following is the report of the Council on Medals and Prizes, which was submitted to and adopted by the Special General Meeting on Monday evening last,—

*Owen Jones Travelling Studentship.*—Of the eight candidates of varying excellence who have entered for the Owen Jones Studentship this year,—the first year of its award,—Mr. Sydney Vacher has been awarded by the Council the first place. The work he has submitted shows that he has made a diligent study of colour decoration, and with this, as well as a natural love for and appreciation of colour which he seems to possess, he will be enabled to make good use of the opportunities afforded by this Studentship by his own and the general advantage. The Council have placed Mr. Gerald Horsley second, and they have awarded him the Special Prize offered in connexion with this year's Studentship by Mr. G. A. Audsley, namely, a copy of the magnificent work, entitled "The Ornamental Arts of Japan," as a recognition of the excellence of Mr. Horsley's numerous and beautiful drawings.

*Pugin Travelling Studentship.*—Ten candidates have this year submitted drawings for the Pugin Studentship, and the majority have attained a high standard of merit. Many of the pencil drawings especially show unusual clearness and delicacy of touch. The Council consider that the drawings and sketches submitted by Mr. Maclaren are the best, and they have awarded him the Studentship. The Council have placed Mr. Arnold B. Mitchell second, and Mr. E. H. Selby third, recommending that a Medal of Merit should be awarded to each by the Royal Institute. The fourth place has been fairly won by Mr. R. W. Paul, whom the Council recommend for a Certificate of Honour, and whose careful drawings are entirely of English subjects. Before concluding this portion of their Report the Council wish to direct the members' attention to the fact that Mr. Maclaren is a Royal Academy Gold Medallist and the holder of the Foreign Travelling Studentship of that body; while Mr. A. B. Mitchell is the Soane Medallist for last year. The best work which they have submitted for this, the Pugin Studentship, has been executed principally while fulfilling the conditions of travel attached to the prizes they had gained. The Council have consequently adopted a recommendation of the Medals and other Prizes Committee to the effect that, in future, there will be excluded from consideration in the Pugin Studentship all measured drawings and sketches which have obtained either the R.A. Cold Medal or the R.I.B.A. Soane Medallion, or which have been submitted as work done by the R.A. Cold Medallist or the R.I.B.A. Soane Medallist in fulfilment of the conditions of foreign travel attached to the two prizes referred to.

*The Godwin Bursary.*—The Council regret that no applications have been received this year for the Godwin Bursary, founded for the encouragement of the study of works of modern architecture abroad, and one of the requirements of which is that the candidate, who must be a British subject, should know at least one foreign language. The great importance of the subjects for which this Bursary was founded should in itself be sufficient to insure a good competition.

*The Tite Prize (value 30l.).*—The Council have awarded the Tite Prize, for which there are fourteen competitors, to the author of the design (a Classical Church) bearing the device X.P. They have placed the design bearing the device of a triangle in a circle second, and that bearing the motto, "St. Luke," third; and they recommend that the former be awarded a Medal of Merit, and the latter a Certificate of Honour. It is gratifying to the Council to be able to report that so many designs have been submitted for this competition, and that they are characterised by much excellence.

*The Grissell Gold Medal and Ten Guineas.*—Only three designs have been sent in for this Medal, offered annually for the encouragement of the study of Construction. The Council have awarded it to the author of the design bearing the motto "Interested," which is far in advance of the two others as regards a just appreciation of wood construction; and it is one in which the equalisation of strains and the

distribution of pressure appear to have been carefully studied. The sum of ten guineas to be awarded with the Medal is the gift of the Royal Institute, and the Medals and other Prizes Committee have advised the Council to recommend that this sum should be also awarded to the author of this design.

*The Soane Medallion and (under conditions) 50l.*—The Council recommend the award of the Soane Medallion to the author of the design (City Police Courts and Police Station) bearing the motto "Paulatim." Of the seven designs submitted it has the best plan, and its architectural character is good. The Council also recommend that the authors of the designs bearing the mottoes "Broadshire" and "Nene" be each awarded a Certificate of Honour for their architecture.

*The Institute Silver Medal and Ten Guineas (Measured Drawings).*—Five sets of measured drawings have been received, namely:—1. ("Foot-rule"), Stokesay-Castle; 2. ("Honoris"), Gate of Honour, Cambridge; 3. (Manners makyth Mann"), Haddon Hall; 4. ("Opus Amoris"), Gate of Honour, Cambridge; and 5. ("Spes mea"), Oakwell Hall, Bristol. The Council recommend the award of the Institute Silver Medal and Ten Guineas to the author of the drawings bearing the motto, "Foot-rule"; and the award of a Medal of Merit, with five guineas, to the author of the drawings bearing the motto, "Manners makyth Mann."

*The Institute Silver Medal and Twenty-five Guineas (Essays).*—Four essays have been submitted on the subject of "Attached Wall Piers, Pilasters, and Buttresses," bearing respectively the mottoes,—(1), "Expression"; (2), "Evolution"; (3), "Non enim tam auctores, &c."; and (4), "Palma non sine pulvere." Of these the Council recommend that the author of the essay bearing the motto "Evolution" should receive the Silver Medal and the sum of twenty-five guineas. They wish to add that the sub-committee who reported on the essays state in their report that in this essay the theory and construction of problems relating to the subject are well treated; the history of the development of wall-piers and buttresses is carefully traced; and the system of buttressing, both internal and external, has been fully considered.

The following is extracted from the minutes of the special general meeting on Monday evening last, Mr. Edward P. Anson, F.G.S., President, in the chair:—

*The Studentships.*—The Honorary Secretary announced that the Council had awarded the Owen Jones Travelling Studentship for the current year to Sydney Vacher, Associate, and the Special Prize offered in connexion with this Studentship by G. A. Audsley, Fellow, namely, a copy of the "Ornamental Arts of Japan," to Mr. Gerald Horsley, of 1, High-row, Kensington, W. Also that the Council had awarded the Pugin Travelling Studentship for the current year to Mr. Thomas Maclaren, of 27A, Old Bond-street, W. The Hon. Secretary further announced that the Council recommended the award of Medals of Merit to Mr. Arnold Bidlake Mitchell, of 36, Pembury-road, Clapton, E., and Mr. Edgar Harry Selby, whom they had placed second and third respectively; and a Certificate of Honour to Mr. Roland Wilmot Paul, whom they had placed fourth. Whereupon it was resolved that the recommendations be adopted.

*The Tite Prize (value 30l. and a certificate; subject, a Classical Church, to seat 700, without galleries, and on an isolated site).*—The Hon. secretary announced that the Council had, under the terms of the bequest, awarded the Tite Prize to the author of the design bearing the device X.P. [There were fourteen designs sent in.] The name and address of the successful candidate were found to be, Frank W. Simon, 5, Moston-terrace, Edinburg. The hon. secretary further announced that the Council recommended the award of a medal of merit to the author of the design bearing the device of a triangle in circle, and a certificate of honour to the author of the design bearing the motto "St. Luke." Whereupon, the recommendations having been considered, it was resolved that the same be approved and adopted. The names and addresses of these gentlemen were found to be:—John Keppie, 42, St. James-street, Hillhead, Glasgow; and William Stirling, 8, Upper Chadwell-street, E.C.

*The Grissell Gold Medal with Ten Guineas.* (Subject: A roof over a railway station, 100 ft.

by 60 ft., without floor supports; wood construction, without iron ties; central lantern light; height of walls, 40 ft.)—[Three designs submitted.] The Hon. Secretary announced that the Council had, under the terms of the bequest, awarded the Grissell Gold Medal to the author of the design bearing the motto "Interested"; and that they further recommended that the sum of ten guineas offered with the medal should also be awarded. Whereupon it was resolved that the recommendation be adopted. The name and address of this gentleman was found to be:—James Strong, 29, Queen-holdings, Dale-street, Liverpool.

*The Soane Medallion and Fifty Pounds* (Subject, City Police Courts and Police Station, for a provincial town).—The recommendations of the Council respecting the award of the Soane Medallion, and (subject to the usual conditions) the sum of 50l., were:—The Medallion, &c., to "Paulatim," a Certificate of Honour to "Broadshire," a Certificate of Honour to "Nene." [Seven designs submitted.] Whereupon it was resolved that the Soane Medallion, and (subject to the usual conditions) the sum of 50l. be awarded to the author of the design (No. 5) bearing the motto "Paulatim." The name and address of the successful candidate were found to be, Francis Edward Masey, 18, Gordon-street, Gordon-square, W.C. It was further resolved that the remaining recommendations in respect of Nos. 1 and 4 be adopted. The names and addresses of these gentlemen were found to be, Alfred Whitehead, 1, Olluda-place, Bagby-fields, Leeds; and Arthur Sykes, 16, Brnnswick-square, W.C.

*The Silver Medal and Ten Guineas—Drawings* (Measured Drawings of actual Buildings).—The recommendations of the Council respecting the award of the Institute Silver Medal and ten guineas (drawings) were:—The silver medal and 10l. 10s., "Foot-rule"; a medal of merit and 5l. 5s., "Manners makyth Mann." [Five designs submitted.] Whereupon it was resolved that the silver medal and ten guineas for measured drawings be awarded to the author of No. 1, bearing the motto, "Foot-rule," for drawings of Stokesay Castle. The name and address of the successful candidate were found to be James H. Cook, 12, St. George's-crescent, Liverpool. It was further resolved that the remaining recommendation in respect of No. 3, for drawings of Haddon Hall, be adopted. The name and address of the gentleman were found to be Frank Bellis, 6, Abbey-square, Chester.

*The Silver Medal and Twenty-five Guineas* (Essays: subject, Attached Wall Piers, Pilasters, and Buttresses).—The recommendation of the Council respecting the award of the silver medal and twenty-five guineas (essays) was, the silver medal and twenty-five guineas to "Evolution." [There were four competitors.] Whereupon it was resolved that the silver medal and twenty-five guineas be awarded to the author of the essay (No. 2) bearing the motto "Evolution." The name and address of the successful candidate were found to be, R. Elsey Smith, The Knoll, Upper Richmond-road, Putney.

The subjects for medals and other prizes, 1888, were then considered. These we will give next week.

ARTESIAN WATER SUPPLY IN LONDON.

The Commissioners of Sewers for the City of London, actuated by a spirit of resistance to the enhanced charge for water levied by the New River Company, have resolved on an experiment in well-boring. The increased levy on the City by the water company is simply due to the fact that the right is claimed to charge on the annual value, now defined under the Torrens Act to mean rateable value. As the value of property in the City goes up, the sum chargeable on the householder for his water-supply increases *pro rata*, the result being that in the case of large business premises, where little water is consumed, the price of the water actually drawn from the main is about equal to that of beer. The fate of the City, with a decreasing population and an increasing value, is that of consuming less water and paying more for it. Of course there is another side of the question, but this is the one which more especially engages the attention of the Commissioners, and it is on this that their action is founded. There is water in the chalk under the City, and the Commissioners intend seeking

for it with the immediate object of getting a supply for the Artisans' Dwellings which they have erected in Petticoat-square. At that spot a boring is to be made, and the cost is estimated at about 2,100*l.*, including engines, pumps, and buildings, and laying on the services for the supply of the dwellings. The rateable value of the premises to which the water is to be laid on is 2,25*l.* The New River Company make certain extra charges for water-closets, and it is stated that the present cost of the supply is about 100*l.* per annum. As the proposed artesian well will not be exactly what the name implies, but will require the aid of a pump worked by engine-power, it is not clear that the Commissioners will gain any immediate pecuniary advantage by their enterprise. But their object lies farther ahead, and they are going on in the avowed hope that the experiment will be "of considerable value in determining the mode of proceeding best calculated to advance the Commissioners' efforts towards providing the citizens with a cheaper supply of water."

The first thing is to get the water, and we will pass by for the present certain considerations as to what may best be done with it when obtained. Deep wells are not new things in the City, and of this the Commissioners are aware. There is a well of this kind at the Bank of England, sunk in 1851, and the Commissioners have been informed by the authorities of the Bank as to its character. It enters the chalk at a depth of about 230 feet from the surface, and descends into that stratum to a further depth of 100 ft. For several years the supply yielded by the well was good and plentiful, but more recently the supply has been less satisfactory, and the cause of the change has not been ascertained. On data furnished in respect of this and other wells the Commissioners expect to reach the chalk at a depth of between 200 and 300 ft. from the surface. The subject has been carefully gone into by Mr. J. Voce Moore, the Chairman of the Commission, who has collected a mass of information on the subject, which has materially assisted the Commissioners in deciding as to the course they shall pursue. Concerning the well sunk by Mr. De Keyser at his hotel at the eastern end of the Victoria Embankment, it appears that the flow of water is large, although the well is not so deep as that at the Bank of England, and the water itself is softer than that generally obtained from the chalk.

Few persons, perhaps, are aware of the extent of the supply drawn from the chalk in the metropolitan area, independently of the water companies. A single firm of engineers, Messrs. Tilley & Son, of Walbrook, have sunk or bored more than fifty wells into the chalk in London. These operations have extended over a long series of years, but one of the latest examples is that of a deep well just finished at the Grosvenor Hotel, where the yield amounts to about 30,000 gallons per day. It is said that where the consumption is not less than 10,000 gallons per day, it is cheaper to take water from a deep well than to take a supply from a company. For small works gas engines are generally employed to actuate the pumps. We have heard of a brewer at Chelsea who reckons that he saves 600*l.* per annum by having his supply from a well, the cost of which was only 1,000*l.* Most of the metropolitan workhouses have wells in the chalk, and the supply to the prisons is generally obtained in the same manner. Government offices, clubs, and public baths come into the same category. But the grand principle at stake is, that the water companies monopolise the right of selling water. Anybody may supply himself, but if he attempts anything more he will be entering on debatable ground, bristling with litigation. If it is possible to dislodge the companies from the position they claim, the City Commissioners will do it. But the hydro-geological facts are not altogether in favour of the Commissioners. Apparently there is no hope of finding the lower greensand under London, and the chalk itself is so compressed under the superincumbent strata that its efficiency as a water-bearing stratum is diminished. Another circumstance is that the level of the water in the chalk wells of London suffers a gradual decline. The Rivers Pollution Commission of 1853 in reporting on the domestic water-supply of Great Britain, expressed their opinion that "the strata beneath London would not be found to be an available source for any important part of the metropolitan water-supply." That chalk wells in the metropolis

are nevertheless useful is a matter of daily experience, and the City Commissioners can hardly fail to meet with some measure of success in the task they have undertaken.

#### THE UNITED ARTS CLUB.

THE inaugural dinner of the United Arts Club, which has been formed for the accommodation of architects, painters, sculptors, and engineers, was held at the Club-house, 27, Dover-street, Piccadilly, on Wednesday evening last. The President of the Club, Mr. E. P. Anson, President of the Royal Institute of British Architects, was in the chair, and he was supported by three of the Vice-Presidents (Mr. Lewis H. Isaacs, M.P., Professor Kerr, and Mr. Edmund Woodthorpe), as well as by several members of the committee and a representative body of the members at large, it having been deemed desirable to limit the number of guests rather than to hold the dinner off the club premises.

The Chairman having in felicitous and graceful terms proposed "The Health of the Queen," Mr. Lewis H. Isaacs, M.P., proposed "Success to the United Arts Club," in a very appropriate and well-turned speech. He spoke of the difficulty of election to the Athenaeum Club even by candidates of eminence and great attainments; and of the fulness to repletion of the Arts Club and the Hophart Club (the latter being for painters only). Upon these grounds he thought there was ample room for the United Arts Club, and that there were good reasons for congratulating the members on the good auspices under which they had succeeded in obtaining. The opportunities of social intercourse which the Club would afford between senior and junior members of the architectural profession, and between them and painters, sculptors, and architects, could not but be promotive of great good, and he felt warranted in believing that, if judiciously managed, the Club would grow in strength and usefulness. He therefore heartily wished "Success to the Club," and begged to couple with the toast the name of Mr. Robert Walker, who had been most active and zealous in promoting the successful starting of the Club. The toast was very heartily received.

Mr. Robert Walker, in replying, dwelt on the advantages which the Club was capable of offering to the members of the several professions for whom it was intended. Members meeting in common under its roof would get to know each other better, the asperities and misunderstandings incident to professional work would be softened down or explained away, and the disadvantages attendant upon the inevitably increasing tendency of the age towards specialism in the professions would, by means of free and pleasant intercourse between specialists in various walks of professional life, meet with a corrective. All would meet there on the broad ground of art, and the members would be pleasantly but wholesomely reminded that the profession of architecture, or of art or engineering, was a wider and grander thing than they might be sometimes apt to think it when their view was honed and limited by the work of their own offices or studios. Another way in which the Club might be of advantage to the professions would be to appoint, by-and-by, a competent standing committee to watch the progress of legislative and other proposals likely to in any way affect the interests of art or of the members of the artistic professions. In these and various other ways *esprit de corps* among professional men would be promoted.

Professor Kerr, in proposing the health of the President, alluded in graceful and well-merited terms to the professional and social fitness of Mr. P. Anson to be the President of the Club. Mr. H. R. Gough proposed "The Vice-Presidents," coupled with the name of Mr. Edmund Woodthorpe, who made a characteristically humorous reply.

Mr. H. L. Florence proposed the last toast, "The Honorary Secretary, Mr. A. L. L. Forrester," to whose untiring labours, he said, it was mainly due that the Club had been started on such a satisfactory basis.

Mr. Forrester briefly replied, and the formal part of the proceedings terminated.

We may add that the club-house, No. 27, Dover-street, is well adapted for the purpose,

and its proximity to the Royal Academy of Arts and the Royal Institute of British Architects will make it particularly convenient for members of those institutions. The Club will also be found to be of great advantage to gentlemen practising in the country who occasionally visit London. The premises contain dining-rooms, reading, writing, billiard, card, and smoking rooms, and are fitted with telephone and telegraphic tape, &c. The reading-room will be supplied with the usual papers and periodicals, including the professional journals, and it is proposed to form a reference library as soon as possible. Bedroom accommodation for the members has also been arranged for. Three hundred members have already been elected, and the committee propose to admit 200 more, without entrance-fee, at an annual subscription of three guineas for town, and two guineas for country members, after which the subscription will be raised.

We wish the Club every success.

#### A REVERSIBLE RIM-LOCK.

MR. JAMES HILL sends us a simple and very ingenious lock which he has contrived to act as either a left-hand or right-hand, left reverse or right reverse lock; the same lock can be used in all four positions, thus getting rid of all the difficulty about selecting and supplying right or left hand locks of this pattern. The four variations of "hands" are obtained, as may be understood on reference to the accompanying cut, by separating the body of the lock from the frame and by having latch and locking bolts the same size.

The illustration represents a left-hand lock, but it can be instantly converted to a right-hand by reversing the latch bolt (when out of the frame) and turning the lock right over. The "reverse bevels," for doors opening inwards, are obtained by simply turning the latch-bolt the reverse way round.

A lock which adapts itself to every door is a great boon to buyers at home, but must be a still greater boon to those abroad, because the "hands" are seldom known when requisitions are sent home: hence the doors have either to be hung to suit the locks, or the locks have to be fixed upside down!

The question of "hands" for locks has long been an international puzzle. On the Continent, in the colonies, and in America, what we term "lefts" are known as "rights"; and even at home the trade is constantly at variance in the matter of hands.

Mr. Hill's lock obviates all these difficulties. We have examined a specimen of the lock, which is perfectly simple in its working, and appears a really good and useful invention.

**The Last of the Kensington Exhibition Building.**—By order of the Royal Commission, the sale of the materials comprising the galleries, courts, annexes, and other structures lately used for the Colonial and Indian, Inventions, Health, and Fisheries Exhibitions at South Kensington was begun by public auction under the hammer of Messrs. Horne, Son, & Eversfield, within the Exhibition, on Wednesday last. The catalogue, which is very lengthy, comprises upwards of 823 lots. The chief items under notice on the first day were the Old London Street, and the Indian Palace, Durban Hall, and the Prince of Wales's Pavilion. The Old London Street was put up in eight lots. Mr. Humphreys, Knightsbridge, securing the entire block for a total sum of 160*l.* 15*s.* The brickwork forming the Indian Palace was sold to Mr. W. Linsley for 25*l.*, while the Durban Hall found a purchaser in Mr. Sharpe for 51*l.* The Indian or Prince of Wales's Pavilion fell to the bid of Mr. Martin for 30*l.*, and the Nats Tea-room was secured by Mr. Humphreys for the low figure of 8*l.* 10*s.*

A NEW METHOD OF STREET-PAVING.

OUR attention has been called to some improvements in street-paving which are the subject of a patent taken out by Mr. William White, of Abergavenny, well-known for his "Hygeian-Rock Building Composition," a material which is proposed to be used by the patentee for paving in lieu of asphalt, or in combination with granite, wood, or other materials in the manner hereafter explained. Or these materials may be used in conjunction with asphalt, the patent being applicable to the method rather than to the material used. The main object of the invention, which is applicable to footpath or roadway pavements, is to facilitate the laying-down and taking-up of the pavements, as well as to obtain a good foothold and to reduce cost. We cannot do better than quote the inventor's description of the mode of procedure:—

"I make a flat block of cement concrete, of a square, oblong, or other shape, and of any suitable dimensions. Through this block I form several apertures, larger on the one face than on the other, of a dovetailed shape. [The lower part of fig. 1

Fig. 1.

shows one of these blocks, with the conical apertures indicated by broken lines.] I then make a mould slightly smaller than, but similar in plan to, this block, and of a suitable depth. The concrete block is laid with the larger parts of the apertures uppermost, through which I pour into the mould, in a liquid state, the Hygeian Rock composition, or any kind of asphalt. The compound block, when set, can be removed from the mould, and the two parts will be firmly attached together. To provide a foothold, the upper surface of the mould can be ribbed, grooved, or otherwise [as shown in fig. 2,

Fig. 2.

which shows four of the said concrete blocks, with their covering of composition or asphalt, the one at the top right-hand corner showing granite chippings embedded in the surface], so that the imprint is left on the face of the pavement slab. On a good foundation, I lay a layer of sand or fine ashes, duly levelled. I place the slabs, bringing the concrete part of the blocks close together, but as the asphalt or composition part of each block is smaller in plan than the concrete part, a series of grooves is formed, into which I pour composition or asphalt, which binds them firmly together, producing perfectly impervious pavements. For footways I propose that the surface shall be ribbed or corrugated, and laid with a fall to the roadway, thus forming a series of small open drains to run the water into the gutter, thus keeping the pavement clear of water, &c., and giving a pleasant foothold. When it is necessary to take up and relay, or repairs to drains or pipes, &c., or to replace new slabs, the joint or groove can be cut out and easily removed. If required, the composition can be taken off, and the same slab can be replaced again. A combination may be made of wood and composition (see fig. 1); this also would be impervious. Pavements on this principle will only take hours to lay, whereas the present system takes days. The work can be done in sections, and the blocks prepared in the yard or workshop, and brought ready for laying, instead of making the street the workshop, and blocking the roadways. The blocks can be made any size, shape, or thickness; 14-in. concrete block faced with 3-in. composition would be sufficient for footways. Thicker ones would be required for roadways."

It should be added that the detached concrete blocks in the figures are laid on, but are not cemented or attached to, a firm and smooth

foundation-bed of concrete, such as is already used beneath asphalt and wood pavements of the ordinary type. The blocks are laid as shown, with butt-joints, but they are not cemented together, the asphalt or composition above, however, being continuous. The great merit of the invention seems to be that by its use a street could be re-paved in sections of a few yards in length night by night until completed, without interruption to the ordinary traffic. If the concrete blocks are evenly bedded, so as to prevent rupture of the connecting strips of asphalt or composition which are put in *in situ*, the pavement will remain impervious,—a very desirable thing both from constructive and sanitary considerations. Whether the new method of paving will answer all the expectations of its inventor (as we hope it may) experience of its use alone can show.

ARCHITECTURAL SOCIETIES.

**Birmingham Architectural Association.**—The fifth ordinary meeting of the current session was held at Queen's College on Tuesday evening last. The Vice-President (Mr. John Cotton) was in the chair. A paper was read by Mr. Whitworth Wallis on the "Streets, Shops, Houses, and Baths of Pompeii." The lecture was illustrated with some fine lantern views, and exhibited very clearly the characteristic peculiarities of Pompeian art and architecture. A vote of thanks, proposed by Mr. J. Cossins, accepted by Mr. Hanman, and supported by Messrs. J. Cotton, T. W. F. Newton, and Victor Scoulen (hon. secretary), was unanimously accorded to the lecturer for his able paper.

**Manchester Architectural Association.**—At the ordinary fortnightly meeting of this Association, held on the 11th inst., at the Diocesan Buildings, Mr. W. Parry in the chair, Mr. W. H. Littlewood, A.R.I.B.A., read a paper entitled "Recollections of a Tour in Italy," illustrated by photographs and water-colour sketches. The Cathedral of Milan, he said, is supposed to be the largest church in Europe after St. Peter's at Rome. It was commenced in 1386, and is not yet finished. An important competition is being contemplated at the present time for restoring some portions of it. The interior is grand by its simplicity and absence of ornament. In Venice, the most noteworthy place is the Piazza de San Marco, with the arcades surrounding it on three sides, and St. Mark's, with its towering campanile. The undulating floor of this building has often been under discussion, the late Mr. Street being under the impression that this was symbolical, and designed to represent the waves of the sea, but there can be little doubt that Signor Saccardo's theory is the correct one, viz., that the depressions arise from the settling down of the *débris* used in filling up the crypt, which formerly existed under the structure, the old piers having been left in, thereby preventing any settlement where they occur. The Loggiatta at the base of the Campanile is a fine piece of architecture, by Sansovino, and is now used as an auction-room and office for the sale of lottery tickets. After St. Mark's Square, perhaps the Piazzetta is the most important, flanked on the left by the Doge's Palace, and on the right by the Library, which forms a portion of the Royal Palace. In Rome, it might be noticed that what was characteristic in the costumes of the people was passing away. This is rapidly becoming the same all over Europe. St. Peter's takes precedence of all other churches in Europe, both in its architectural beauty\* and size, as will appear from the following dimensions (comparative lengths marked on the floor):—St. Peter's, 609 ft. in length; St. Paul's, London, 521 ft.; Milan Cathedral, 439 ft.; St. Paul's, Rome, 415 ft.; St. Sophia, Constantinople, 356 ft. Mr. Littlewood then described the principal features of the Vatican, Pantheon, Temple of Vesta, and the Colosseum, and concluded by detailing the chief objects of interest in Naples, giving a very interesting description of Pompeii.

**Edinburgh Architectural Association.**—At the last meeting of this Association, held in the Professional Hall, 20, George-street, the President, Mr. Hippolyte J. Blanc, occupied the chair. After the usual preliminary business was disposed of, a paper on "Ancient Medieval and Modern Locks and Keys" was read by Mr.

Harry W. Chubb, A.M.I.C.E. The interesting ethnological comparisons supplied by the discoveries of keys of similar shape and use in ages and countries far apart were first referred to. The paper then described the growth of the rudimentary lock, which was actuated by a sickle-shaped key, tracing its origin from the plain bar sliding in staples. Further development was stated to have resulted in the Egyptian lock, the sliding bar appearing in this lock, but in a hollow form, the means of retention when in its locked position being afforded by pins, which dropped into it from its staple when shot home. A lock of this kind is indicated on the wall sculptures of the Temple of Karnac, and is in use in Egypt at the present day. The wooden locks of the northern isles were shown to be analogous to the Egyptian locks. It is in the Roman locks that traces of the system of "warding" first appeared, combined also with the falling pins already alluded to. Seven varieties of Roman keys attached to finger-rings were exhibited in diagrams, and it was pointed out that in one of these the barrel was bored through from end to end, thus allowing accumulated dust to be pushed out. *Après* of this, it was curious to note that within recent years four patentees had applied for protection of the same idea in England. Padlocks were treated as forming a distinct branch, and being specially connected with travel, the English kinds had become widely distributed. The same mechanical arrangement that was used in the Roman padlock was seen at the present day in those of China. The absence of any distinctive Byzantine locks and keys was commented upon, and the gradual growth of ornament upon this form of metal was sketched from the beginning of the twelfth century, as it advanced through the various developments of the Pointed style. The various stages of this advance were illustrated by crayon drawings, in which all the details were artistically elaborated, together with those of the Transitional and Renaissance periods. Up to the commencement of the present century the only security attained was by complex systems of "warding," excepting the still well-known puzzle padlock, which was probably invented in the earlier part of the seventeenth century. The state of perfection of modern knowledge and practice in lock-making was briefly touched upon, special reference being made to locks not commonly known in England. A Chubb lock was exhibited, which showed that a variation of only the two-hundredth part of an inch in one of the steps of the key was sufficient to render the key useless. At the close of the paper a vote of thanks was awarded Mr. Chubb for his paper, and also to Mr. C. S. Wimbush for the drawings with which it was illustrated.

OBITUARY.

**Mr. George Bell, F.R.I.B.A.**—The death of Mr. George Bell, F.R.I.B.A., of Glasgow, was announced by the Secretary of the Royal Institute of British Architects at the special general meeting of that body on Monday evening last.

**Sir Francis Bolton, R.E.**—The death was recently announced of Col. Sir Francis Bolton, R.E. He was born in 1831. In 1868, in consideration of special military scientific service, he was given an unattached majority. He retired in 1881 with the rank of colonel. Sir Francis was the inventor of the system of telegraphic and visual signalling which was introduced into the Army and Navy in 1863. For these services and other improvements and inventions in regard to warlike material the Queen, in 1883, conferred upon him the honour of knighthood. Sir Francis, who was a civil engineer, founded, in 1870, the Society of Telegraph-Engineers and Electricians. Since 1871 he had been Water Examiner under the Metropolitan Water Act. His recent services in connexion with the South Kensington exhibitions will be fresh in the memory of the public, especially his direction of the illuminated fountains.

**Mr. Stephen Tucker, F.S.A., Somerset Herald,** died at his residence in the Albany, Piccadilly, on the 6th inst. Mr. Tucker, who was in the fifty-second year of his age, was the youngest son of the late Mr. Edward Tucker, of King's Nympston, Devon. Having previously held the office of Rouge Croix Pursuivant, he was appointed Somerset Herald in the year 1880 in succession to the late Mr. J. R. Planché.

\* We need hardly say that we entirely dissent from this opinion, which does not say much for Mr. Littlewood's judgment as a critic of "architectural beauty."—Ed.

## CEMENT TESTS.

SIR,—In your issue of the 8th inst. you give in "Notes" [p. 74] a summary of the results of the tests and examination of German cement made during the last year by the German Cement Makers' Association.

The information is of great value to the cement industry and to all interested in the subject in this country, but I am sure I am not singular when I say that we who are interested in the industry here feel a little jealous, not to say nettled, at having the quality of German cements put before us in such a lucid and clear manner, while the successes of our own manufacturers and the quality of the cement manufactured by them is more or less ignored.

This is, no doubt, the manufacturers' own fault, for, not having a trade association, they are unable to lay the result of tests before users and buyers here. I am, however, to a limited extent in a position to give such information as will place the English manufacturer on his proper footing, and I trust, therefore, you will find room in your columns for this letter.

The following is a short summary of results from my testing hooks for the year ending December 1886. It must, however, not be forgotten that many of the cements are sent to me for testing because, in some way or another, they have not complied with the terms of a specification, and may therefore be considered more or less damaged, and it would therefore be manifestly unfair to take the lowest results obtained as an indication of the quality of the manufacture of the country. The results given are from about 250 samples representing a bulk of, perhaps, one to two hundred thousand tons.

Fineness of grinding, taken on a sieve having 4,900 holes to the square inch. The sample having the greatest fineness left a residue of only 1 per cent., and 16 per cent. of the samples left less than 10 per cent. residue, while the coarsest left 29 per cent.

The time of setting varied from three-quarters of an hour to 24 hours; but only about 3 per cent. of the samples took more than 12 hours to set, the usual time being from 1 to 5 hours.

The greatest tensile strength shown by any sample on an average of five briquettes was:—

At seven days from gauging ..... 706 lb.  
At twenty-eight days from gauging... 850 lb.

And the highest individual briquette at twenty-eight days broke at 890 lb. Ignoring these cements that were absolutely damaged, the lowest results were:—

At seven days from gauging ..... 352 lb.  
At twenty-eight days from gauging... 399 lb.

The average strength of the whole being:—

At seven days from gauging ..... 468 lb.  
At twenty-eight days from gauging... 508 lb.

Comparing these with the German results, the German highest at twenty-eight days was only 702 lb., not equal to the English highest at seven days; and the lowest English at seven days is 30 lb. higher than the German lowest at twenty-eight days.

The results obtained with the sand test, i.e., briquettes gauged of one part cement to three of standard sand, was, at twenty-eight days from gauging, average of ten briquettes in each case:—

The highest ..... 806 lb.  
The lowest ..... 139 lb.  
Average of the whole ..... 231 lb.

While the highest individual briquette broke at 330 lb., as compared with the German highest 333 lb., and their lowest 94½ lb.

The cement in my testing room is all gauged in a machine which allows of the minimum amount of water being used, and which greatly expedites the process, but it is rammed into the moulds by hand, the moulds being formed in nests of five, and the strain is applied to the briquette when being tested at the uniform rate of 100 lb. per fifteen seconds, i.e., 400 lb. per minute.

With respect to the matter of adulteration, which it seems our neighbours think it necessary to allude to, I should like to say that I have never yet met with an adulterated sample of English cement.

HENRY FAIR, M. Inst. C.E.

4, Great Queen-street, Westminster,  
January 11, 1887.

**Tunbridge Wells.**—It is proposed to build a campanile and form a reading-room to St. Augustine's Church, Tunbridge Wells. Mr. Brett A. Elphicke, architect, is preparing the design.

## TAXATION OF CHIMNEYS AND SMOKE PURIFICATION.

SIR,—A few years ago a paragraph in the newspapers gave an account of a new system of smoke purification which had been adopted at a factory in one of the North of England manufacturing towns. The method of treatment was to conduct the smoke into a chamber, where revolving paddle-wheels dipping slightly under the surface of water in a tank threw up a constant cloud of spray, which washed all the impurities out of the smoke, the spent air from the furnace then passing up the flue in the usual manner. The report affirmed that the purification was entirely successful, did not cost much, and hinted at a saleable product from the "lamp black" washed out of the smoke. Reports of new ventures of this kind are apt to be optimistic, but assuming a fair measure of success in this attempt to deal with the smoke nuisance, we might reasonably have expected to have heard more about it. Possibly it was nobody's business to make the matter known, and no special economy to manufacturers generally to adopt the system. The general advantage of a purer atmosphere does not count much with the average smoke-producer, as against his personal trouble and expense in preventing impurities. Hitherto the attempt to secure purer air in towns has taken the shape of an appeal to the smoke-producer to reduce his coal output by "smoke-consuming" grates and furnaces which give the greatest possible heat with the smallest amount of smoke. This has not been successful. The smoke nuisance is worse than ever. The great increase of the "block" system of houses, both for residences and offices, all over London, is one reason for increased smoke. The domestic fire is not smokeless. The tall "model" dwellings and "mansions," or "chambers," where every two or three rooms are a separate household, usually mean about three times the number of fires and smoky chimneys to the same superficial space as compared with the smaller houses of former years. Practically very little, if anything, can be done by means of improved fireplaces to prevent smoke. There remains the alternative to wash the smoke, as has been suggested above. Smoke purification is now much more practicable than formerly. The very increase of block dwellings that has caused an increase in the smoke nuisance makes smoke purification comparatively easy. The roofs are mostly flat, and their numerous chimneys are close together. Some hundreds of chimneys could easily be conducted into one central smoke-chamber on the roof and purified. In the same way those streets of houses all wall to wall, and exactly the same height, would be treated. In the case of the factory referred to it was found that the purifying paddle-wheels could be made to regulate the draught at the furnace. In applying the purifier to domestic blocks and hotels, therefore, its good effects would be useful in preventing smoke in the rooms as well as smuts in the streets.

The next question that arises is how are people to be made to purify their smoke? To secure the public benefit of a cleanly atmosphere it is out of place to try and get it indirectly by a bribe of a smaller bill for coals. The public, as represented by the authorities, have no concern with the amount, large or small, of any one's coal account. They are concerned with civic comfort and cleanliness. It is not the creation of smoke in a fireplace, but its liberation into the air, that has to be taken notice of. The best notice to take of it is simply to tax every smoky chimney; that is, every chimney, domestic or manufacturing, that simply conducts the smoke from the fire and delivers it into the air without purification. Some standard of purity must be determined upon. To do this, as well as for the general purposes of legislation on the subject, a number of experiments must be made to ascertain the conditions under which a general smoke purification is reasonably possible. Perhaps this initial work may have to be done by some unofficial body, such as the National Health Society. It might even be worth while for some enterprising landlord or "Dwellings Company" to do it as an inducement to tenants. They could then tempt tenants with the offer of "splendid roof gardens and skittle grounds; no smoke; special facilities for children's playgrounds; and the cleanly drying of clothes." In any case it must be demonstrated that a general

purification of smoke is fairly practicable. Then tax every smoky chimney and grant exemption to all who purify their smoke up to a required standard. The tax should be heavy enough to make purification and consequent exemption the preferable alternative. The sum need not be much per fireplace or chimney to secure this. The result would likely be the gradual adoption of purification by all hotels, Dwellings Companies, and large owners of house property in general, with great advantage to the cleanliness of city life.

D. McE.

## "SANITARY INSTITUTE OF GREAT BRITAIN EXAMINATIONS."

SIR,—I think your correspondent, "J. A. A.," in your issue of the 8th inst. [p. 100], attaches altogether too much value to the certificates, or "diplomas," of the Sanitary Institute of Great Britain when he imagines that local authorities, in the choice of a surveyor, would be likely to be influenced by the candidate being possessed of one, or otherwise. There are probably few local authorities in the country who know anything about that body, if they have as much as heard of its existence; and when they find that a certificate of "competency to perform the duties of a local surveyor" is awarded, as "J. A. A." so aptly remarks, to "any young man who possesses, as evidenced solely by his answers to a given number of questions, a fair knowledge of municipal law and sanitary engineering, as extracted from books, . . . notwithstanding the absence of proof, or, may be, with proof to the contrary, of even a day's experience in the actual work of a surveyor's office," and that "he may be unable to use a level or theodolite, make a survey, or get out a drawing, may never have seen a sewer laid, nor appreciate the importance of 'girt' in mortar"; in fact, in office parlance, not know how to draw to a straight line; utterly ignorant of the preparation of specifications, estimates, and reports, measuring-up and valuation of works; maintenance of highways, keeping accounts; and the every-day routine of a surveyor's office, saying nothing of such things as arbitrations and provisional orders,—local authorities are not likely to treat such certificates with much consideration; and the bare fact that of about 1,000 Borough and Local Board Surveyors in England and Wales, not more than about a dozen possess the certificate of the Sanitary Institute speaks for the little importance with which they are regarded by the profession.

A person otherwise competent to act as local surveyor would have little difficulty in satisfactorily answering the few comparatively simple questions prescribed by the Sanitary Institute, while, on the other hand, a person holding their certificate, if not otherwise qualified, would be quite incompetent to undertake the duties of an office.

That the granting of such certificates is likely to be productive of some mischief, however, there can be little doubt, as the way in which they are so readily obtainable cannot but tend to facilitate the admission to public offices of incompetent persons, who do not hesitate, whenever a vacancy occurs, to become competitors along with legitimate candidates, a many of us are already painfully aware, and with whom, on account of their being in a position to accept appointments at low salaries, men who have received a professional training frequently cannot compete. Nor is it to be expected that gentlemen who have been regularly articulated in the offices of civil engineers and gone through the whole course of a professional training, would submit to the anomaly of being technically examined by an amateur society.

It would be not a little interesting to know what are "the obligations which the profession owe to the Sanitary Institute," the constitution of whose Examining Board is, in the opinion of your correspondent, "a sufficient indication of the high-class nature of the examinations," and when the Sanitary Institute became "a semi-official body of great repute." "J. A. A." must have overlooked the fact that voluntary examinations are held periodically by the Association of Municipal and Sanitary Engineers and Surveyors, whose Committee of Examiners are exclusively professional men, holding some of the most important public appointments in the kingdom, and who

are themselves authorities on municipal and sanitary engineering.

ROBERT S. SCOTT, C.E.  
*Ventnor Club, Isle of Wight,*  
 12th January, 1887.

Sir,—May I plead, through the medium of the *Builder*, that the suggestion of "J. A. A." in your issue of the 8th inst. be not adopted by the Board of Examiners. On p. 18 of the handbook issued by the Council under the heading of "Objects of the Institute, Rules, &c.," we read the following:—"To examine and to grant certificates of competence to local surveyors and inspectors of nuisances, and to persons desirous of becoming such, or of obtaining the certificate." From this, I think, it is quite clear that the certificate is intended not only to be used in an official capacity, but also in private practice, as in the event of a sanitary engineer wishing to obtain the certificate, and succeeding, he would then be designated as "Certificated by the Sanitary Institute of Great Britain," as provided in their rules above referred to. Surely this would be an advantage in private practice.

I have been in a surveyor's office for some years, and hope some day to gain the Local Surveyor's Certificate; but my plea is that any man working hard in qualifying himself to pass the examiners may still be able to obtain the Certificate without regard to his present position. I would respectfully suggest in answer to "J. A. A.'s" objections that when the *red-voice* examination is taking place, a level might be at hand, and the candidates questioned upon it; the practical experience of the examiners would soon be satisfied as to whether or not he had ever used one. The candidate might also be called upon to produce drawings of sections he had taken, and of surveys he had made and plotted.

HISTORIC CITY BUILDINGS.

Sir,—Those of your readers who are interested in the preservation of memorials of demolished buildings having historical associations may be glad to know that, as architect for the new warehouses on the former site of St. Matthew's Church, Friday-street, Chapside, I have placed the following inscription upon one of the pilasters:—

"The site of these buildings was formerly occupied by the Parish Church of St. Matthew, Friday-day-street, founded before the year 1322, destroyed by the Fire of London, 1666; rebuilt by Sir Christopher Wren, and taken down in 1885, when the parish was united with that of St. Vedast, Foster-lane."

I may also add that, as architect for the six warehouses occupying the larger portion of the former site of St. Paul's School in St. Paul's Churchyard, I am arranging for the erection of a small tablet, in the centre feature, bearing the following inscription:—

"On this site, A.D. 1512 to A.D. 1884, stood St. Paul's School, founded by Dr. John Colest, Dean of St. Paul's."  
 DELISSA JOSEPH.

CLASS OF MASONRY, CITY AND GUILDS TECHNICAL INSTITUTE.

Sir,—As the large class of masonry will soon be engaged on exercises requiring some amount of knowledge in descriptive geometry, I advise students who intend to join the class, as well as the present members, to study, in the "Student's Column" of the *Builder*, year 1885, the following figures:—175, 165 (Sept. 19, Oct. 2); 71, 12, 18, 14, 15, 16, 17, 18, 19 (Feb. 28); 30, 31, 32, 33 (March 14); 36, 37, 38, 39, 40 (March 21); 96, 102 (June 13); 105, 107 (June 20); 123 (July 18).

The two first figures are examples of the general method for finding the intersection of any two surfaces. It may be summed up as follows:—"There are certain surfaces, the intersections of which are known, such as planes, spheres, cones, &c., under certain conditions. These must be mastered by the mason as his multiplication table. Then, to find the intersection of two surfaces, we cut them by a third, the intersections of which with each of the two surfaces given are readily known. The points where these intersections meet belong to the intersection of the two surfaces given."

The above is the method of finding intersections of surfaces, on which the whole art of masonry rests; all the other figures indicated are applications of this method to special cases.

The next meeting of the large class of masonry will take place, Tuesday, the 25th inst. in the Examination Hall on the upper floor of the City and Guilds of London Central Institute, South Kensington.

LAWRENCE HARVEY,  
 Director of the Class of Masonry.

COLONIAL.

Sir,—I should be very much obliged if any reader of the *Builder* could give me any information about Colonial architects' associations. Are there such associations? If so have they any office here to which I could write for information?

ARCHITECT'S ASSISTANT.

"MASONS' WAGES."

Sir,—Although reluctant to answer the question of your correspondent "A. B." in your last [p. 132], I feel it a duty to state, in the interest of our trade and the men so unmercifully dealt with in this case, that such was a fact. Such information will, I am sure, be received by your readers with astonishment and disgust, when so many of our fellow men are at this moment begging for employment. It is heart-rending, I can assure you, sir, to those in the position of engaging our skilled and unskilled workmen to hear the pitiable truths related of suffering and want occasioned by this lack of work, the earnest desire and endeavour of men to obtain even the means of existence. What must we think of this cruel demand made by the enemy of our trade, our independence, and our very livelihood at such a time as this? God forbid that any injustice should be used by employers at this critical period of depression towards our working-classes. But, I ask, how many hundreds free from the lash of the Society Union would and are eager at this very moment to supply the void occasioned through the black-halling of these men, whose only fault was their fortunate and happy lot of being able to provide the means of sustenance for their wives and families?

A. B. & C.

CHURCH-BUILDING NEWS.

Burley.—The parish church of St. John the Baptist, Burley, Hants, was reopened on Christmas Day, after enlargement. Built fifty years ago, it is described by the *Hampshire Independent* as a bad example of the debased church architecture and faulty work then so prevalent. As originally built, it consisted of a nave only, no chancel, no vestry, no accommodation for a choir, no arrangement for warming the building. Moreover, it was in a very dilapidated condition when the present vicar entered upon his duties last Easter. The vicar at once moved in the matter, and the following works were found to be necessary:—1, the erection of a chancel to comprise choir sanctuary, and of a small south transept for harmonium organ; 2, a vestry; 3, new porch in the door to the north; 4, an efficient heating apparatus; 5, partial re-flooring with tiles, and entire re-seating; and 6, general repairs of the structure. Mr. Butterfield was consulted, and under his supervision these works have been carried out, at a cost of about 1,500l.

Cannes.—The *Morning Post* of the 29th ult. contains a letter from a correspondent at Cannes describing the Memorial Church there. He writes:—"High up among the trees which cover the heights of California, and overlook the Isle of St. Marguerite, is to be seen an unfinished column which stands in front of the villa in which the Duke of Albany breathed his last. When finished, this is to be crowned by the figure of St. George; and a little lower down, by the road which leads to the large hotel (California), a church spire, not yet completed, calls the attention of the traveller to one of the most perfect specimens of English Church architecture in France. It is the Memorial Church which is being erected among the English villas which circle around the winding road, and are hidden among the trees and gardens of the English retreat. The church is practically complete, except for the internal fittings, and Mr. William Conradi, an old pupil of Sir Gilbert Scott, and Mr. Blomfield's deputy, having ascertained what my intentions were, gave me permission to enter, and acted as my *cicerone*. The church is from the designs of Mr. A. W. Blomfield, and every portion of the interior ornamental work is sent out from England, and has been executed under his personal supervision. The builder is Mr. George Russell, of Cannes, and the stone employed is from the neighbourhood of Grasse, and, for the first time, this stone has been polished, and used for purposes of ornamentation as well as for the rougher work of building."

Dingley.—The little Church of All Saints, Dingley, has recently been reopened after what the *Northampton Herald* describes as "complete restoration" of the exterior and interior. The amount of the contract for the restoration was between 2,000l. and 3,000l., and the expense has been generously borne by Lord and Lady Downe, the rector (Rev. H. B. Upcher), and others. The work was entrusted to Messrs. Cornish & Gaynor, of North Walsham, and it has been carried out under the superintendence of Mr. J. Bell. The high-backed pews have been superseded by modern chairs of unvarnished beech, which stand on a floor composed of pitch-

pine blocks, and the aisles are relaid with stone. New hases have been added to the pillars, which have been pieced and restored. The walls have received a new coat of plaster, and new braces to the principals of the beams have been put in, and new rafters where required. The chancel is paved with Dorsetshire stone, and the Griffin Chapel on the right of this with oak blocks. The chancel and chapel roofs are quite new, the former being a copy of the original design, and the latter being panelled. Half of the chapel will in future be used as a vestry, and will be partitioned off by means of curtains. Externally, the porch has been restored, and new roofs of Colley-Weston slates put on both chancel and chapel. The walls have been pointed where required, and a channel dug round the chancel and nave (which are below the adjoining soil) in order to prevent damp.

Holme-next-the-Sea.—The restoration of the chancel of St. Mary's Church has just been completed through the exertions of the vicar and churchwardens, assisted by Mrs. Nelson, senior, who has been most energetic in getting up concerts and other entertainments in aid of the funds. Mr. Le Strange, the patron of the living, has subscribed very liberally. It is proposed to re-seat and complete the restoration of the nave in the spring, which was left unfinished about two years ago for the want of money. The works in the chancel have been carried out by Mr. Ducker, of Lynn, under the direction of Mr. Wm. Adams, architect, of King's Lynn.

Irechester.—At the annual meeting of the Architectural Society for the Archdeaconries of Northampton and Oakham, held recently, plans for the restoration of Irechester Church, prepared by Mr. Pearson, were laid before the committee and approved. It is stated that the restoration "is to be carried out in a thorough manner." The chancel will be restored by Lord and Lady Wantage.

London.—At Christ Church, Lancaster Gate, a new baptistery, the gift of a member of the congregation, has been formed under one end of the south gallery, by adding an extra granite shaft. The stone capitals have been removed, and new carved ones substituted, with angels on the inside portion. These support the moulded stone ribs above, which terminate in a carved boss in the centre. The roof-pannels are fitted with emblems in Venetian glass mosaic, representing various Christian symbols, and on the back wall is a panel of Christ blessing little children, in glass mosaic, with gold ground. The mosaics have been executed in Venice, by Dr. Salvati. In the centre of the baptistery stands the font, which is of alabaster and marble. The lower step is of Purbeck marble. Above this is a base of rouge royal, which supports a model base of Ippelen. The centre is of grey Devon, and is surrounded with green marble shafts. These support a bowl, which is in light alabaster, of octagonal form, with carved cornice on top. The panels are inlaid in marble, in floral and geometrical designs,—the rose, lily, passion-flower, vine, and wheat being all represented. The basin is of polished Carrara marble. On two sides a metal screen, picked out in gold, is fixed, and the floor enclosing the lower step is in ceramic mosaic. The work has been designed and carried out by Messrs. Underwood & Sons, Duke-street, Grosvenor-square, who have also made the new pulpit, which is the gift of Lady Brabazon, and is composed entirely of alabaster and marble, highly polished. It is of hexagonal form, with winding stairs.

Northampton.—The structural alterations to the interior of the Church of the Holy Sepulchre are now completed. An organ-chamber, choir-vestry, and an enlarged clergy-vestry have been added to the church. The additional buildings have been carried out in precisely the same style as former renovations, and are strictly in keeping with the other portions of the church. The plans for the alterations were prepared by Mr. Townsend, the diocesan surveyor, and have been carried out by Mr. Reynolds, builder and contractor, of Margaret-street. The tender for the vestry and organ-chamber was 375l., but this amount does not represent the whole of the outlay on the interior. Mr. R. Lee Bevan, of Brixworth, has intimated his intention to place a stained-glass window in the church to the memory of his deceased wife.

Petrockstow (North Devon).—On Christmas Eve a memorial reared was unveiled in the parish church of St. Petrock. It has been executed by Mr. Harry Hems, of Exeter, from a design by Mr. Horace L. Field, architect,

London. It is of oak. The five main panels are filled with carved figures.  
**Ruddington.**—There is a scheme on foot for building a new church in Ruddington, on the site of the present inconvenient structure. Nearly 4,000*l.* have already been subscribed, and plans are being prepared.

**The Student's Column.**

**FIELD WORK AND INSTRUMENTS.—IV.**  
*Surveying Instruments.*  
 III.—THE BOX SEXTANT (continued).

**T**HE mathematical proof given upon the plate showing figs. 1 to 5 of our last article (see pages 134, 135, ante) will be seen to depend chiefly upon the facts stated at the commencement of that article, and upon the principles enunciated in Euclid, that the exterior angle of a triangle is equal to the two interior and opposite angles, also that when two straight lines cut one another, the opposite angles contained by those lines are equal. Thus, we prove that the angle, A E B, is double the angle, A F B. Now, if the mirror at A be placed parallel to the mirror at B, the angle M A F will equal the angle A F B, and, therefore, the angle A E B will be double the angle M A F. Hence, if the vernier stand at zero upon the plate shown in fig. 3, when the mirrors are parallel to one another, the angle at E will be double the angle over which the revolving mirror will travel. Fig. 1 supposes a case in which this angle is 52½ degrees, and hence the vernier in fig. 3 reads 105 degrees. The angle thus indicated in fig. 3 is not exactly vertically over that in fig. 1, but is made to depend upon it, the graduated silver arc being fixed in the most convenient position upon the top plate for recording the angles. A small magnifying glass is attached, as shown in fig. 3, which glass can be raised or lowered to suit the eye-sight, enabling the subdivisions upon the vernier to be clearly defined. The surveyor selects the line which comes on his left hand when about to take an angle between two given directions, or to set out an angle in a required direction, and holds the instrument in his right hand by the box which has been screwed on to its underside after lowering the darkening glasses by means of the side levers as described in our last article. He then observes a pole marked D in figure 1 through the unsilvered portion of the glass marked B, and with his left hand he turns the milled screw R until the pole marked C upon his right hand is reflected from the mirror at A to the silvered portion of the mirror at B. When these two poles appear in line one over the other in the glass B, as shown in fig. 2, the desired angle is obtained and read off the upper plate; or, when the angle is given, the surveyor directs his assistant to move the pole C right or left as required until set out to the given angle, as will be proved by the coincidence of the poles in the glass at B. To observe the pole D the instrument is moved slowly by the right hand until its face is in the plane passing through the eye and the two objects between which the angular distance is being taken. When, therefore, altitudes are to be observed, the instrument is held in a vertical plane; when horizontal or oblique angles are to be measured it is held in a horizontal or oblique plane. Unless the objects lie in the same horizontal or vertical plane its use for surveying purposes, where horizontal or vertical angles are alone required, can only be approximate. To ensure accuracy in the position in which the instrument is held the same precaution as to the use of double poles or ranging rods in a line, is necessary to be observed, as was explained in our article upon the optical square. This will be clear upon reference to figure 10. The adjustments of the mirror are effected by the key marked K in fig. 3, which, for safety, is screwed into the top plate, as shown in section in fig. 4. These adjustments are usually made by the manufacturer, and when once effected seldom need repetition, but may be tested by the surveyor in the following manner. As shown in fig. 6 a distant object is observed with the vernier set to zero. If the sun be that object then the reflected image of the lower part of the sun will or can be made to appear vertically in line with the upper part of the sun by means of the key K slowly turning the bar L in the side of the instrument fig. 1, which acts upon the spring

connection shown in fig. 2. By this means the two mirrors are placed horizontally parallel; then by turning the instrument on its side and repeating the operation, but this time placing the key K in the spindle marked N in the top plate (fig. 3), the mirrors can be set also vertically parallel. With constant use the mirrors will after some time get very dirty. The best way to clean them is by the use of a small light brush.  
 The parallelism of the line of the sight in the telescope to the plane of the instrument is tested by placing the index glass so as to produce the apparent coincidence of two distinct objects whose directions make an angle of 90 degrees or thereabouts, and observing whether any slight motion of the plane of the telescope about an axis traversing the object seen by reflection disturbs the apparent coincidence. If the adjustment of the telescope is correct, no such disturbing influence should appear. We have mentioned this adjustment of the telescope to complete the subject, but as in ordinary land surveying the telescope is dispensed with, its accuracy when supplied by reliable makers can be trusted, and it is only necessary for the surveyor to test the adjustments described by fig. 6. For further explanation we must refer our readers to the notes upon the plates shown in our last article (pages 134 and 135).

IV.—THE LINE RANGER.

This instrument, the use of which is explained in our illustration, enables the surveyor to find

**NOTE**

**THIS INSTRUMENT IS USED AS A LINE RANGER FOR DETERMINING THE POSITION OF ANY INTERMEDIATE POINT**

an intermediate station upon a given base line, and is useful where great accuracy in the determination of any required point in a line is essential.

**The Paving, Lighting, and Cleansing of the City.**—The accounts of the Commissioners of Sewers for the last year have just been issued. The cost of paving the streets was 28,987*l.*; lighting, 13,422*l.*; cleansing and watering, 39,685*l.*; sanitary works, 3,070*l.*; legal and parliamentary expenses, 2,361*l.*; contractors and artificers, 4,749*l.*; stoneyard, 4,972*l.*; collectors' commission, 5,705*l.*; officers' salaries, 9,347*l.* The Commission paid during the year, for interest on moneys borrowed, 64,824*l.*; and to the School Board for London, 138,263*l.*—*City Press.*

**Books.**

**Vauban; Montalensbert; Carnot; Engineers' Studies.** By E. M. LLOYD, Major R.F. London: Chapman & Hall, 1887.

**T**HIS is a very interesting handbook of the lives of three eminent military engineers, preceded by an introduction giving a brief sketch or outline of the general history of fortification, the growing power of artillery, and the modifications of construction to which its employment and improvement gave rise. In the course of this the author notes the prevalence in the sixteenth century of what may be called the "draughtsman engineer," which the thing became a kind of fashionable profession, and, as a contemporary critic observed,—"Sundry persons being able to make the draught or portraiture of a thing, give themselves to the making of plates of fortresses without number, not understanding or knowing how to prosecute or to discourse from the foundations of the matter with lively reasons"; a kind of thing, that has happened in other professions time and again. It is curious to find that about this time, or at the beginning of the seventeenth century, the work of making the lines of approach to a besieged town was almost purely a matter of money, being contracted for and paid for in proportion to the danger and probable loss of life. Heuss's "Hexham recommends the besieged to use their cannon freely against the approaches, for then the enemy must either raise the siege or it will cost them dear, because no men will undertake this work but such as will be soundly paid for it."

The life and character of Vauban are graphically sketched; and whatever moralists may think of the business in which he was engaged, and the merits of the combatants he worked for, there was no doubt that he both thoroughly understood his business, and was ready to expose life and limb in its prosecution, without regard to his own safety or comfort. Indeed, it seems to have been thought necessary at last to endeavour to keep some kind of control over him, and keep him out of danger, as too valuable a possession to be lost.

Vauban's special merit, besides his close attention to details of an attack, was that "he was the first engineer who considered fortresses collectively as units in a general scheme of defence." The special principles of attack and defence favoured by the three men who are the chief subjects of the book are clearly stated, and the volume closes with a short essay on "modern forts," showing how the modern adoption of "extended order" in the line of men in battle has also, under the influence of modern long-range fire, been adopted in fortification. The book, we presume, is addressed to the general rather than the military reader, and of interest in this light as giving, under the guise of a biographical treatise, a good deal of information as to the nature of the problem of fortification and attack in past and present times.

**How I managed my Estate.** London: George Bell & Sons, 1886.

This very pleasant and readable little book containing many suggestions and much good sense, is a reprint, we perceive, from the *St. James's Gazette*. The author's practical claims to be listened to on the subject are set forth in the first paragraph. He gave 14,000*l.* for an estate in Sussex; farmed and managed the lands almost entirely himself; sold a thousand pounds' worth of timber; spent about 5,500*l.* on improving houses and land; and, within fifteen years, parted with the place which he had "made too grand for him," for 27,000*l.*—the whole transaction leaving him 9,500*l.* richer in money, as well as in a great deal of pleasant experience and country knowledge. The experience of any one who has made such a practical success must be worth having. The heads under which this experience is given are "Choice of an Estate," "Underwoods," "Timber," "Building and Quarrying," "Making Grounds," "Farming and Shooting," &c. In the chapter on "Building and Quarrying," however, the author does not explain to us why newly-faced walls should have involved a new roof, or why a new roof involved "new walls right through the middle of the house is order to support it." This is the sort of nonsense that gets written in daily papers by people who think it clever to laugh at the architect who told them it would only cost so much

and then do without him and find themselves running into all kinds of expense which he might have shown them how to avoid. Some shrewd remarks about labour occur in this chapter. The London workmen, who received 8s. a day seemed, he says, to have a certain standard of their own as to the amount of work which might be turned out, and "the country masons who received half that sum, and when alone did twice the work, seemed under some tacit compulsion not to do more than their fellows did, so long as they worked with them, so that 18s. a square of walling before the London men came, cost about 3l. during their stay, though it fell again to the lower rate as soon as the country workmen laboured by themselves." This is telling, but, we suspect, exaggerated. A device by which he saved 300l., the writer tells us, was that of having the dams of a series of fishponds puddled by horses instead of men; "I found that one heavy horse would do the work of ten or twelve men, and a great deal better, the weight of his hoof being vastly more powerful than the stroke of the usual puddling-rod." All horses, however, may not be equally manageable in this way. "One man may bring a horse to the clay, but twenty cannot make him puddle"; and, query, does it improve the horse to be paddling about in wet, stiff clay for many hours together?

We are interested to notice in the chapter on watering grounds, that the author, in laying out his lawn, applied the practice of the Greek architects, as discovered by Mr. Penrose (to whose work he refers), laying out the lawn with an almost imperceptible rise in the centre, and which was much more satisfactory to the eye (as we can well believe) than a perfectly level turf.

*The Conversion of English Timber (Timber Trade Handbooks, No. 1).* London: Timber Trades' Journal Office.

A VERY useful little treatise on the methods of cutting up and clearing timber for use, on things to be sought and things to be avoided. Young architects would do wisely to possess themselves of it; they will get a good many practical hints in a small compass.

*Model Dwelling-Houses. With a Description of the Model Tenement erected within the Ground of the International Exhibition, Edinburgh, 1886.* By SIR JAMES GOWANS, Architect, Lord Dean of Guild of the City of Edinburgh. Edinburgh: T. A. Constable & Co.

THIS is mainly a description of a block of "flat" tenements erected in the grounds of the Edinburgh Exhibition by the joint and gratuitous efforts of architects, engineers, manufacturers, and artificers. The idea was a good one, and has been well carried out. The author prefaces his description by a few remarks on the history of the typical Scottish flatted tenements, and some not undeserved strictures on their insanitary condition. His object is to show that they may be improved in plan and construction, and be at once healthy and remunerative, and such as should, he thinks, be built in the suburbs of large towns, for the accommodation of the working classes. The plan is very convenient and complete, and the construction quite in accord with the latest lights on the subject. We find little or nothing to criticize, except, perhaps, the extreme smallness of the third bedroom, which has a cubic capacity of only 567 ft. It would be in all probability occupied by more than one person, and even if they were children, and although there is a fireplace in the room, it is not enough for a "model" dwelling.

In the case before us the building is only two stories in height, and has light and air on all sides. It would have been more generally useful if Sir James Gowans had shown by plans and diagrams how the lofty street tenement with its narrow frontage could be brought into something like a sanitary condition, and to this task we hope he will on a future occasion address himself. As at present built, "the central staircase, with no well in the centre, surrounded on all sides by rooms, lighted by side windows, reminds one more of a vault than anything else." The high fen duty is of course the root of the evil, and one which is not likely, we fear, to be soon destroyed. From the peculiar circumstances attending the erection of the block of buildings illustrated, its cost cannot be given, and although cost is of the essence of the problem, Sir James Gowans does not touch upon it. The book is

an interesting record of a practical experiment in tenement building; it is well written, illustrated, and printed.

*Horticultural Buildings: Their Construction, Heating, Interior Fittings, &c. With Remarks on some of the Principles Involved, and their Applications.* With 123 Illustrations. By F. A. FAWKES. New edition. London: Swan, Sonnenschein, Le Bas, & Lowry.

THE author of this useful little book covers an astonishing amount of ground, ranging from astronomy and solar physics to the Metropolitan Building Act, and the familiar analysis of a rod of brickwork. Much of the information has been collected from well-known sources, but much is original, and based upon personal experience, and all is useful. The author recommends the old-fashioned panty glazing for horticultural buildings, and the old-fashioned system of heating with hot water at low pressure, and this after reviewing all modern substitutes for both. We find ourselves in accord with almost all his views, and especially agree with him that architects have too much neglected the design of the class of structures of which he treats, and that therefore the purely horticultural interest has prevailed over what he aptly calls the horto-architectural, — a new word, for which we thank him. He writes with enthusiasm, as all authors worthy of the name should write, and endeavours to press home the high importance of his subject by the following amazing syllogism:—"Contact with, and a proper contemplation of, God's works has a refining influence on mankind. A greenhouse enables both contact and contemplation to be intensified. Therefore, a person cannot but be ennobled who thoroughly appreciates and properly uses a greenhouse. Upon social, hygienic, moral, and even religious grounds, horticultural buildings may justly claim advantages of a solid and superior character!"

We cannot agree that the summer-house which is figured at p. 100, and looks like a carman's shelter, is all that the author claims for it on the score of beauty, and prefer the "usual rustic thatched" affair, insects notwithstanding. But, horto-architecture apart, we can honestly recommend this little book for its practical wisdom and vast store of useful information.

*The Art of Architectural Modelling in Paper.* By T. A. RICHARDSON, Architect. London: Crosby Lockwood & Co.

THE very book for the amateur modeller of architectural subjects, containing wise cautions as to the true principles of the art, and warnings against the temptations which beset the inexperienced modeller to give his work the character of a mere toy. We are not sure the author goes quite far enough in this direction, and doubt whether the trees made of gummed twigs covered with moss, and flower-heads of cork, burned to give the appearance of rich mould, and diversified with moss and bits of scarlet paper, do not verge on the toy-like. The architectural subjects selected for illustration and experiment are simple and suitable, and the instructions are conveyed with clearness and precision.

*Practical House Decoration: A Guide to the Art of Ornamental Painting, &c. With some Remarks upon the Nature and Properties of Pigments.* By JAMES WILLIAM FACEY. London: Crosby Lockwood & Co.

THIS is evidently written by one who has some acquaintance with the practical side of the subject, and only falls short of the desirable standard on the side of art. The illustrations show how not to do it, and are anything but satisfactory. If it be true, as the author says of fig. 8, that arrangements of the kind are often "adopted in the quaint mansions which are so rapidly increasing in the fashionable quarters of the metropolis," all we can say is we are sorry for it. The example of "ecclesiastical ornament" given is grotesque, and the "grotesque" simply shocking. The book is not to be recommended as a guide in matters of design; but it may be consulted on practical questions; although we take exception to the directions for the preparation of "ivory white" with burnt sienna,—yellow ochre being, in our opinion, by far the more suitable pigment, and, indeed, the only suitable one.

*Constructive Geometry of Plane Curves.* With numerous Examples. By T. H. EAGLES, M.A., London: Macmillan & Co.

WITH so vast an accumulation of text-books on geometry, it might be supposed that within the ordinary bonnds of study nothing new remains to be placed before the student, but the author of this work is amply justified, both by his matter and method, for adding one more to the number. Perhaps in no subject more than in geometry has evolution been harder at work during recent years, and, as a natural consequence, the text-books of our earlier days have to be discarded for their newer rivals. We now demand more conciseness in our analytical work and a better adaptation to practical purposes of our geometrical methods. The main feature of this volume is the systematic treatment and actual delineation from given data of some of the more important straight-line figures, together with various plane curves, as the circle, parabola, ellipse, hyperbola, and all the useful miscellaneous curves, such as the cycloid, catenary, tractory, &c. As a compendium of the subject it will be found of considerable value to the scientific draughtsman, and to the candidates for honours at South Kensington it should be almost indispensable. The extensive use of graphic methods in the present day has greatly tended to popularise the use of such books, but some of them unfortunately presuppose a distinctly mathematical education, and have consequently a chilling effect upon the ordinary mind. In the present work the construction of the problems is as clearly elucidated as in any of the simple introductory text-books to practical geometry, while the proof follows for those who desire to master it. The concluding chapter upon the graphic solution of equations will be found both useful and interesting, as showing the possibilities of the method when applied to ordinary requirements.

RECENT PATENTS.

ABSTRACTS OF SPECIFICATIONS.

2,070, Cowsls or Caps. J. Watson.

THE cowsls made in accordance with this invention are constructed with two or more concentric cylinders. The two cylinders are both supported by and fixed to an annular plate, the plate being supported by the flue to which it is applied, and the central opening in the annular plate is made to fit that of the flue. Vertical plates divide the cylinders, and the inner cylinder has a number of perforations to permit the rising air from the flue to gain access to the annular spaces between the cylinders. Where necessary, the cylinders are stayed and strengthened, and are finished off with a suitable ornamental cover.

2,199, Closet-Basin Joints. W. H. Tylor and W. B. H. Drayson.

THIS improved joint is applicable to all sorts of metallic sanitary jointing, and to water connexions. The kind of joints in general use for such purposes are usually made by cementing the lower or outlet part of the basin into the socket or outlet box. This, however, is unsatisfactory, as the cement is liable to become disintegrated and loose. A self-adjusting split-ring is therefore used in this invention, and rings of india-rubber or other compressible material are used to make the joint tight and compact.

2,309, Mixing Concrete. H. Faija.

ACCORDING to this invention, in place of passing the materials in a continuous manner to the mixing vessel, they are fed in separate and distinct portions, and are taken up by rotary stirrers, so arranged as to give the maximum of mixing. A compound movement of these stirrers effects a thorough admixture of the materials.

4,224, Ornamenting Panels, &c. A. E. Ryles.

THE process which is the subject of this invention somewhat resembles the process of marbling paper. Into a shallow trough is put water in which is dissolved size, glue, or glycerine. On this is dropped or sprayed the colours that are to appear on the ornamental object. These colours spread out in views and shades; when they are too thick they may be thinned by blowing on them, or if this is insufficient the thick parts may be touched with a brush holding a little turpentine, and then with a feather or light stick. The surface to be ornamented is prepared with a suitable ground colour, and then placed face downwards on the liquid. It is then taken off and dried, when the surface may be flattened with pounded pumice and varnished, and afterwards polished with rotten stone. Several dippings and dryings may be arranged if necessary.

2,310, Pigments. D. Swan.

THE object of this invention is to utilise a by-product of galvanising,—proto-chloride of iron. The solution of this substance is mixed with carbonates, and when air is forced into the mixture

It will form a chloride of a yellow or red colour, which is the pigment.

14,434, Decorating Wood. G. Howard. By this invention, a pattern is cut out of a polished wooden block by means of a sand blast; then the interstices are filled with suitable adhesive stopping, previously coloured as required, the whole surface showing the natural colour of the wood on a ground the colour of the filling. It has been smoothed over. The most delicate and intricate patterns may be reproduced.

NEW APPLICATIONS FOR PATENTS.

Jan. 7.-235, S. Shields, Laying or Fixing Wood-block Floors.-267, J. Gamble, Warming and Ventilating Dwelling-rooms, &c.-268, Cebury and Lamm, Drain Traps.

Jan. 8.-291, E. Phillips, Automatically Sharpening Saws.-296, Francis and Carey, Combined Latch and Bolt for Doors.-315, G. Hardingham, Iron Cement.-325, A. Boulton, Adjustment of Saw Blades in Saw Mills.

Jan. 10.-366, T. Sterne, Ventilating Rooms or Buildings.-375, E. Sycers, Sash Fastener Securers.-383, A. Beaubais, junior, Automatic Bolt for Double Doors.

Jan. 11.-414, T. Whalley, Water-closets.-424, W. White, Roads and Pavements.-437, J. Thompson, Ventilators and Chimney Cows.-440, G. Butler, Window Sash Fasteners.-442, J. and S. Stott, Rendering Buildings Fireproof and Water-proof.-456, Underwood and Dobie, Door Locks.

Jan. 12.-480, J. Buckle, Flushing Syphon for Water Closets, Cisterns, &c. Jan. 13.-538, J. Mitchell, Joiner's Bench, Stop, and Cramp combined.-547, J. Wilesmith, junior, Ornamenting Wooden Panels, &c.-577, P. Justice, Manufacture of Cement.

PROVISIONAL SPECIFICATIONS ACCEPTED.

14,680, H. Perry, Machine for Sizing and Varnishing Paperhangings.-15,233, C. Perrot and Others, Making Tile-Grates with the Tile-frames in one Piece with the Front.-15,815, George Martie, Hold-fast for Pipes, &c.-16,284, H. Bassett, Window-sash Fastener.-16,452, F. Crittal, Open Stoves for Warming and Ventilating.-16,525, C. Brasier, Door-locks.-16,637, E. Milson, Mantel-board.-16,705, A. Clarke Chimney Caps and Ventilators.-16,911, J. Hunter, Signboards.-14,755, T. Dewsbury, Ventilator.-16,007, J. Deddon, Fastenings for Window-sashes.-16,437, T. Malling, Fuel-supplying Apparatus for Fire-grates.-16,480, W. Joy, Manufacture of Portland Cement, &c.-16,752, J. Honeyman, Ventilators.-16,809, E. Hughes, Circular Saw Benches.

COMPLETE SPECIFICATIONS ACCEPTED.

Open to Opposition for Two Months.

2,630, B. Mills, Electrical Indicators.-3,520, F. Biggs, Locks and Latches.-7,455, J. Kaye, Automatically Latching and Bolting Doors.-1,852, H. Owens, Secure-locking Casement Stays.-4,603, J. Rawlings, Bench Plugs and Cams for Cabinet-makers, &c.-12,333, J. Weatherhead, Making Cowl-heads for Ventilators.-13,730, R. Crane, Water-supply System.

RECENT SALES OF PROPERTY.

ESTATE EXCHANGE REPORT.

Table with columns for property address, area, and price. Includes entries for Lambeth-230 and 232, Kensal New Town-1 to 7, Clapton-85, Holland Park-41, West Ham, Mergerly Park-road, Peckham, and Chester Square.

MEETINGS.

Monday, January 24. Royal Academy of Arts (Lectures in Sculpture).-Mr. A. S. Murray on "Greek Sculptures Expressive of the Emotions: before Pheidias." 8 p.m. Society of Arts (Contar Lectures).-Dr. Thudichum on "The Diseases of Plants, with special regard to Agriculture and Forestry." 1. 8 p.m. Leeds and Yorkshire Architectural Society.-Sketch Club Exhibition. Tuesday, January 25. Institution of Civil Engineers.-8 p.m. Manchester Architectural Association.-Mr. Phytian on "Mr. Ruskin's Writings on Architecture." 7.30 p.m.

Wednesday, January 26. Society of Arts.-Mr. J. Traill Taylor on "Photographic Lenses." 8 p.m. Thursday, January 27. Royal Academy of Arts (Lectures in Sculpture).-Mr. A. S. Murray on "Greek Sculptures Expressive of the Emotions: etout the time of Pheidias." 8 p.m. National Society for Preserving the Memorials of the Dead.-1) The Rev. W. J. Loftie, F.S.A., on "Epitaphs." 2) Mrs. Danvers Taylor on the "Fetichion Monuments in Stanford-le-Hope Church, Essex," and on the "Tyrell Monuments, in Downham Church, Essex." 4 p.m. Society of Telegraphic Engineers and Electricians.-Professor Silvanus P. Thomson on "Telephonic Investigations." 8 p.m. St. Paul's Ecclesiastical Society.-Annual Dinner (First Avenue Hotel, 7 p.m.).

Miscellaneous.

Lectures on Sculpture and Architecture at the Royal Academy.-The following lectures are announced:-In Sculpture: by Mr. A. S. Murray, Keeper of the Greek and Roman Antiquities in the British Museum: -Jan. 24, "Greek Sculptures expressive of the Emotions: before Pheidias"; Jan. 27, Ditto, "about the time of Pheidias"; Jan. 31, Ditto, "after Pheidias." By Professor C. T. Newton: -Feb. 9, "Archaic Greek and Italian Terra-cottas"; Feb. 15, "Terra-cottas of the final period of Greek art"; Feb. 24, "Terra-cottas of the Roman Period." In Architecture: -By Professor J. H. Middleton: -Feb. 7, "Methods of Decoration, as applied to Greek Architecture"; Feb. 11, Ditto, "as applied to Roman Architecture"; Feb. 14, Ditto, "as applied to Medieval English." By Mr. G. Aitchison, A.R.A.: -Feb. 28, "Doorways"; March 3, "Windows"; March 7, "Balustrades." The Stables of "Olympia." -With reference to the mention made by us a fortnight ago [p. 90] of the opening of the National Agricultural Hall, Kensington, we are asked to mention that the stables of "Olympia," both as regards the stalls and centro promenade, are entirely paved with Candy & Co.'s vitrified Devon buff paving bricks.

The New Exchange Station, Liverpool. Referring to our notice last week (p. 132, ante) of the opening of a portion of the New Exchange Station, Liverpool, erected from the designs of Mr. H. Shelmerdine, we are asked to mention that the floors of the hotel and of the cab-approach in connexion therewith have been laid with Mr. R. L. Lowe's patent wood block flooring and pavement respectively.

The Russian Petroleum Industry.-During the last few months several cargoes of Russian petroleum have arrived in Europe, the oil being said to be equal in quality to the American "water-white," whilst at present six steamers are in course of construction in this country for the purpose of carrying on this trade. Every autumn the producers at Baku now hold a conference in order to consider what steps should be taken for improving the industry, especially as regards transport, it being their determination to respond to every demand of the European market, and it will be of interest to watch the competition now in progress between the Russians and Americans. Since 1876 the number of petroleum wells in the Caspian has increased by 300, whilst the annual production of raw oil has risen from 30 million to 875 million gallons. There are in Russia now 136 refineries, which yield annually 125 million gallons of oil. The cisterns for raw oil are capable of containing 60 million gallons, and the iron reservoirs at Tschjornji, Gorodk, 20 million gallons of refined oil. On the Russian railways there are 1,000 reservoirs, capable of holding 3,000 gallons each. The number of steamers engaged in conveying the oil on the Caspian Sea is thirty, with a tonnage ranging from 250 to 1,000 tons. There are, besides, a number of smaller steamers and sailing vessels engaged in this traffic.

The Archbishop of York and the Churchwardens of St. Mary's, Beverley.-A somewhat acrimonious dispute has been going on for some little time between the Archbishop of York and the Churchwardens of St. Mary's, Beverley, in reference to the seats in the church. The Vicar and Churchwardens having determined that all appropriation should be abolished, copies to that effect were put up in the church. Notices of the notice, with an explanatory letter, were sent by the Warden to His Grace, who, however, instead of giving the step his approval, told them in reply that by law "their duty was to assign the seats to the parishioners according to their degree"; that, therefore, their notice was "quite illegal," and he must "request and direct that it be withdrawn and

cancelled." The Churchwardens, in reply say:—"If the Warden are wrong in their view of the law, it is important that their error should be corrected; but if, on the contrary, your Grace's statement of law is wrong, and your claims illegal, it is much more important that error and illegality should be shown." Between the two statements, viz. your Grace's, 'The law is quite clear. The churchwardens are the officers of the bishop of the diocese, and their duty is to assign seats in the church to the parishioners according to their degree,' and the Warden's, viz. 'The churchwardens are not the officers of the ordinary, but of the parish and Vicar, being appointed by them respectively.' 'The body of every parish church belongs of common right to all the parishioners, and this right cannot lawfully be defeated by any permanent appropriation of particular places' ('Report of House of Lords Committee, 1885,' p. 181) lies the gist of this unfortunate disagreement and scandal. As to which is the true one the Warden have no shadow of doubt. The Vicar seems to have yielded to the Archbishop, but the Churchwardens are obdurate, and seem to challenge the ordinal of legal proceedings.

East India Teak.-Messrs. C. Leary & Co.'s "Annual Circular on Ship-building, Furniture, and other Hard Woods" gives the following statistics for the last three years:-

Table with columns for year (1886, 1885, 1884) and categories (Imports, Deliveries, Stock, Dec. 31). Values are in thousands of tons.

The present stock of timber is composed of 7,866 loads of Moulmein, 2,264 loads of Rangoon, 2,789 loads Bangkok, and 19 loads of other sorts. The course of the market has been favourable throughout the year; the visible demand, and the accumulation of large stocks in this, as in all the other markets of the United Kingdom, having had a very serious influence on values. The depression eventually became so pronounced that importers decided about June, to make large concessions in price, in order that their stocks, then in course of increase by further supplies, afloat and loading, should not assume unmanageable proportions. This policy has enabled them to effect extensive sales, and seeing that the quantity now afloat is only 5,395 tons, as compared with 17,180 tons at the beginning of 1886, and the additional tonnage now under charter is only 11,329 tons, against 16,015 tons at the same date last year, we may fairly expect an improving market. Cargo quotations for Burmah wood have declined from about 13s. at the opening of the year, to from 10s. to 10s. 10s. its close, Siam wood standing at about 30s. per load less.

The Projected Nicaragua Canal.-A report which was recently read at Washington by the Senate Committee relating to the B. incorporating the Nicaragua Canal has been received with general approval, and has revived public interest in the scheme. According to the report the canal can be constructed for about one-fourth of the estimated cost of the Panama Canal. Various estimates have been submitted varying from 75,000,000 (15,000,000) to 150,000,000 (30,000,000). The Bill restricts the tolls to a maximum of 10 dollars fifty cents per ton. It is calculated that the net income from the canal, when completed, will amount to 12,000,000 (2,400,000) per cent. on the highest estimated cost. The canal, if executed, will in all probability be ultimately connected by a through railroad with the United States.

The Sahara Lake Scheme.-The old proposal for making the Desert of Sahara an inland lake appears to be again on the tapis in France, M. de Lesseps having dwelt on it at recent meeting of the Academy of Science. It is, however, now proposed, instead of effecting the cutting of the ridge on the Atlantic side, previously, to sink artesian wells along the Tunis border on the Sahara and then to form cities, so that by the time the desert had been converted into a lake there would be a population ready to trade upon it. Various other engineering works are then also contemplated. According to M. de Lesseps, this plan has found much support among engineers and others interested in the scheme. It is, however, maintained by some that the scheme is useless, as the lake will be dried up again, and that railways would answer the purpose in view far better.

**Liverpool Engineering Society.**—The annual fortnightly meeting of this Society was held at the Royal Institution, Colquitt-street, Liverpool, on the 12th inst.; Mr. J. J. Webster, f. inst. C.E., President, in the chair. A paper by Mr. R. W. Brightmore, M.Sc., entitled "The Flow of Water," was read by the author. The author commenced by pointing out that the present theory of hydrodynamics is only applicable to one form of motion of water, and that the least prevalent in nature from an engineering point of view. After explaining under what circumstances this was the case, and, on the other hand, the conditions of motion to which it did not apply, he went on to describe the motion of water under three conditions which most commonly present themselves to the engineer,—viz., the motion of water in streams, in pipes, and the motion of ships in water. With regard to the first of these three, the theory was of but little use, and empirical laws of various degrees of complexity had been proposed, of which he mentioned the one of easiest application, and giving results probably as accurate as the others. In describing the motion of water in pipes, he pointed out that when the velocity was slow enough the motion came under the present theory, but after attaining a certain critical velocity, depending *ceteris paribus* inversely on the size of the pipe, the motion became sinuous, and an empirical law had been found to express the flow under these conditions. This law, owing to the more restricted conditions under which the flow took place, was of a more definite nature than in the case of streams.

**Fire at New Cross.**—Messrs. Clark, Bunnell, & Co., Limited, ask us to mention that the fire that took place at their New Cross Works on Sunday morning last was confined solely to that section of the building occupied by the foundry, and that beyond the stoppage of that portion the works are proceeding as usual.

**The Tin-Plate Trade.**—Messrs. Arthur Bird & Co., in their January circular, say—"The course of the trade for the first six months [of 1886] at least was somewhat uneventful, the over-production which we dwell upon in our last Report, and demonstrated by figures, effectually preventing remunerative prices from being obtained by makers. While, therefore, exports and consumption continued to increase, notwithstanding a shrinkage of prices all round in general trade, values steadily declined until they reached a point when several works were compelled to cease operations. The majority of the manufacturers were then forced to demand from their men a reduction in wages, and in a good many instances succeeded in obtaining certain concessions. These, however, were by no means general, and several large makers, failing any satisfactory arrangements with their workmen, have during the last two months closed their works altogether until better trade and more remunerative prices may enable them to re-start, with a prospect of being able to keep their men and themselves regularly and profitably employed. The course of last year's trading may be gauged very closely by the fact that while the exports in 1886 show an increase over those of 1885 of about 37,000 tons, or nearly 12 per cent., the price of coles has fallen from 11s. to 12s. 9d., a decrease of nearly 10 per cent. The prospects of the trade in 1887 are now what we would particularly call attention to, and to form any reliable estimate of future prices we must look closely at the present productive power. This is still perfectly able to supply the present visible requirements of those markets of the world which are exclusively our own, though we always hope that progress and development, aided by a long continued range of moderate prices, may so stimulate consumption as to ultimately benefit the producer. With the opening of the year 1887 one most important feature has shown itself which is not at all unlikely to have a very serious effect upon the values of tinplates. We allude to the somewhat sudden rise in the prices of nearly all the materials used in their manufacture, and, more especially, of hematite pig-iron, as affecting the price of steel. The advance already amounts to about 10 per cent. without any corresponding improvement in tinplates, and should this rise continue,—and in the opinion of those best qualified to form a correct judgment market appearances favour this view,—prices must advance in proportion, quite irrespective of the relation of demand to supply."

**Carbonic Acid in the Ground.**—The amount of carbonic acid in the ground has been lately shown by Professor Wollny (we learn from *Naturforscher*) to depend, on the one hand, on the factors of decomposition of organic substances (heat, moisture, porosity), as affected by the physical nature of the ground and its covering; on the other hand, on the resistance which the ground presents, according to its mechanical state, to the escape of the gas. Ground-air seems to have most carbonic acid when the ground is at a slope of about 20 deg. Slopes facing south have most carbonic acid; those facing north least, though the difference is not great, as the two principal factors, heat and moisture, largely counteract each other. In drought, ground facing north has more carbonic acid. With equal quantities of organic matter there is more carbonic acid, the more finely granular the ground; and such ground hinders movement of the gas downwards as well as into the atmosphere. The air in ground shaded by living plants has considerably less carbonic acid than that in the bare ground, and in the latter it has less (in dry years, not in wet), than in ground covered by dead parts of plants.—*Nature*.

**Building on the Clock House Estate, Clapham Common.**—The Clock House Estate, on the east side of Clapham Common, is at present the scene of active building operations. The estate, which occupies about twenty acres, and which for many years was the residence of the late Mr. J. Kemp-Welch, was, with the mansion, sold about two years since for upwards of 50,000l., with the view of its being laid out for building purposes. A few months since the materials of the mansion were disposed of, and the building having been cleared away, the estate has been laid out for building upon. It has a frontage to Clapham Common nearly 600 ft. long, its south boundary being Cavendish-road. Three new roads have been formed through the estate, running parallel with Cavendish-road, eastward, and already several new houses have been erected facing these various roads, and also in Cavendish-road, whilst fronting the main road, overlooking the common, several residences are in course of erection. The area of the estate will admit of the erection of about 400 houses of the "villa" class.

**Registration of Plumbers.**—A few days since, plumbers from Folkestone, Salisbury, Cardiff, Colchester, Leeds, and various districts of London, attended at the City and Guilds Technical Institute, Finsbury, to undergo practical examination in order to qualify themselves for registration. The examination included pipe-bending, joint-making, the formation of roof-gutters, cisterns, &c. After practical examinations in these branches, the candidates were required to answer questions prepared by the Board of Examiners, and directed to testing the candidates' knowledge of materials, construction, and sanitation. The Examiners in attendance included Mr. George Shaw, Chairman of the Registration Committee, and Messrs. Nurse, Gilbert, Timas, Webb, Smeaton, R. J. Syne, and Ashdown, nominated representatives of the United Operative Plumbers' Association and of the Plumbing Trade of London. The candidates on this occasion were chiefly journeymen.

**New Reservoir for Wallasey.**—The increase in the population of this rising suburb of Liverpool has necessitated a greater supply of water; and with that view, some time ago, the Local Board of Wallasey decided to construct a new reservoir in the upper portion of New Brighton. After competition, the works were entrusted to Mr. J. Etheridge, contractor, Manchester. A few days since the water was turned on by the Chairman of the Gas and Water Committee (Mr. John Joyce). These works were designed by Mr. H. Ashton Hill, the Gas and Water Engineer to the Local Board. During the luncheon the contractor presented the Chairman of the Water Committee (Mr. J. Joyce) with a gold key, the facsimile of that used in turning on the water.—*Liverpool Journal of Commerce*.

**Raffety, Thornton, & Co. (Limited).**—We are informed that the directors of Messrs. Raffety, Thornton, & Co. ### Mechanics of the Girder.

THE majority of English bridges were erected at a time when there was but little theory to guide the engineer; the principle of leverage and a simple application of the parallelogram of forces were all he had to direct him in proportioning his material, and it is doubtful, even if the more complete methods of the present day had been available, whether he would have been able to find the time requisite for their use. Accordingly, with such precautions as were deemed necessary to "keep on the safe side," approximate formulæ founded upon very limited experiments were considered to be amply sufficient. Now, however, that we have time to look around us, a "learned" education is a *sine qua non* for an engineer, and he finds ready to his hand the investigations of mathematicians into the structures for whose practical design he is responsible. Applying the general principles of the mathematician to specific cases, the engineer occasionally presents us with an elaborate record of his research, and such a work is that before us,\* by J. D. Crehore, a recently deceased United States engineer.

Commencing with a simple examination into the action of pressures and forces in a plane, he proceeds to an enunciation of the principle of moments, and shows the application of it to the external forces upon beams and girders variously loaded and supported. The descriptions are accompanied by a concise table of the formulæ for the moments at any section, which must be resisted by the internal forces of the beam; numerical examples illustrate each case, and every care is taken to so arrange the matter that the elucidation of the subject shall be continuous with the explanation of the principles. The most modern terminology is not adopted, but the meaning is nevertheless perfectly clear. With regard to the strains in framed or built girders, the author truly remarks that the published results of trustworthy experiments for determining the ultimate resistance of materials to shearing, are very meagre; those recorded by Rankine and Stoney are given in a table, and show considerable variations. The conditions of experiments

are frequently such as do not arise in practice, e.g., in punching a hole through a wrought-iron plate or bar we have a true shearing force, but the support afforded by the surrounding material makes the result useless as an indication of the shearing strength for structural purposes. A large number of diagrams typical of framed trusses for roofs and bridges are given, and their corresponding formulæ, either by the method of moments, or that of shearing forces, or both combined. We are then presented with the mode of estimating the moment of resistance offered by the cohesion of the particles of the material composing a rectangular beam, followed by the moments of resistance of the internal forces of a girder with continuous web, and various hollow and solid forms. As the investigations assume throughout a knowledge of trigonometry and the integral and differential calculus, the use of this book will, no doubt, be limited, but many young engineers who have not yet rusted up will hail it as a very thorough and complete work upon an important subject, leaving no part to guess-work but having everything, so far as may be, mathematically demonstrated. The plane of the neutral axis is generally considered to pass through the centre of gravity of a section under all conditions of strain, although the author confines this position, and we think rightly so, to cases where the elastic limit is not surpassed. He then gives us a very complete table of the ultimate resistance to compression, tension, and cross-breaking, together with the modulus of elasticity, of various materials. This is most useful for reference as a compact summary of all the best known and most important experiments. In the next chapter, which is a long one, the deflections of all the various forms are rigorously deduced from the equation of the elastic curve, and it is then shown that for open girders of the same central height, same length, and of uniform strength, the total deflection is nearly in the inverse ratio of the areas of the figures of the girders.

In connexion with the theoretical dimensions of oak beams for supporting given loads, attention is called to one of the causes for the popular opinion that theory and practice are sometimes at variance. "In order to simplify the work of calculation the equations which determine the dimensions do not pretend to take into account all the conditions affecting the sufficiency of the beam for its purpose, and hence the theory is not complete until the modifying conditions are introduced." The different modes of producing camber, and their effects upon trussed beams, are briefly discussed. The strength of pillars, including all cases of thrust is next considered by rational

formulæ compared with the empirical formulæ of Hodgkinson, Gordon, and Rankine, and afterwards with experiments of Hodgkinson, Lovett, &c., but although these are very carefully collated, they only serve to show that we are still very much in the dark as to the true theory of the strength of pillars. The United States Government have a special testing-machine in the Arsenal at Watertown, Mass., and it is hoped that they will shortly contribute a set of values for the constants to be used in formulæ more in agreement with the capabilities of the actual members of the structures than any values hitherto determined. The next chapter of the book deals with the proportions and weights of all the members of a bridge excepting the girders proper, and following this the stresses are determined in various girders, together with their weight and the effect of wind-pressure. The effect of varying the number of bays or panels is followed out in the calculations to present a tabular view of the comparative advantages and disadvantages, and, owing to the mass of calculations, the method appears rather more cumbersome than it really is, considering the value of the results. The author then gives a copy of the general specification for iron bridges issued in 1879, by the New York, Lake Erie, and Western Railroad Companies, containing much useful information for designers. We have only space for a few extracts:—

"The following modes of construction shall preferably be employed:—Spans up to 17 ft., rolled beams; 17 ft. to 40 ft., riveted plate girders; 40 ft. to 75 ft., riveted lattice girders; over 75 ft., pin-connected trusses. In calculating strains, the length of span shall be understood to be the distance between the centres of end pins for trusses, and between centres of bearing-plates for all beams and girders. . . . Variations in temperature to the extent of 150 degrees shall be provided for. . . . All parts of the structures shall be so proportioned that the maximum strains produced shall in no case cause a greater tension in pounds per square inch than the following:—On lateral bracing, 15,000; on solid rolled beams used as cross floor beams and stringers, and on bottom chords and main diagonals, 10,000; on counter rods and long verticals, on bottom flange of riveted cross girders net section, and on bottom flange of riveted longitudinal plate girders over 20 ft. long, net section, 8,000; on bottom flange of riveted longitudinal plate girders under 20 ft. long, net section, 7,000; on floor beam hangers, and other similar members liable to sudden loading, 6,000. . . . In beams and girders, compression shall be limited as follows:—In rolled beams used as cross floor beams and stringers, 10,000; in riveted plate girders used as cross floor beams, gross section, and in riveted longitudinal plate girders, over 20 ft. long, gross section, 6,000; in riveted longitudinal plate girders under 20 ft. long, gross section, 5,000. . . . The rivets and bolts connecting all parts of the girders must be so spaced that the shearing strain per square inch shall not exceed 6,000 lb., nor the pressure upon the bearing surface exceed 12,000 lb. per square inch of the projected semi-intrados

\* Mechanics of the Girder: a Treatise on Bridges and Roofs, in which the necessary and sufficient Weight of the Structure is calculated, not assumed; and the Number of Panels and Height of Girder that render the Bridge Weight least, for a given Span, Live Load, and Wind-pressure are determined. By John Davenport Crehore, C.E. New York: John Wiley & Sons. London: Trübner & Co. 1886.

(diameter by thickness of piece) of the rivet or bolt hole. Pins shall be so proportioned that the shearing strain shall not exceed 7,500 lb. per square inch, nor the crushing strain upon the projected area of the semi-intrados of any member connected to the pin be greater than 12,000 lb. per square inch, nor the bending-strain exceed 15,000 lb. per square inch when the centres of bearings of the strained members are taken as the points of application of the strains. . . . The compression flanges of beams and girders shall be stayed against transverse crippling when their length is more than thirty times their width. The unsupported width of any plate subjected to compression shall never exceed thirty times its thickness. . . . The iron in the web-plates shall not have a shearing strain greater than 4,000 lb. per square inch, and no web-plate shall be less than  $\frac{1}{4}$  in. in thickness. . . . When the least thickness of the web is less than one-eighth of the depth of a girder, the web shall be stiffened at intervals not over twice the depth of the girder. The pitch of rivets in all classes of work shall never exceed 6 in., nor sixteen times the thinnest outside plate, nor be less than three diameters of the rivets. . . . The rivets used will generally be  $\frac{3}{4}$  in. and  $\frac{1}{2}$  in. diameter. The distance between the edge of any piece and the centre of a rivet-hole must never be less than  $\frac{1}{4}$  in., except for bars less than 2 $\frac{1}{2}$  in. wide; when practicable it shall be at least two diameters of rivets. When plates more than 12 in. wide are used in the flanges of plate or lattice girders, an extra line of rivets, with a pitch of not over 9 in., shall be driven along each edge to draw the plates together and prevent the entrance of water. . . . The pins shall be turned straight and smooth, and shall fit the pin-holes within one-fiftieth of an inch. . . . All bed-plates must be of such dimensions that the greatest pressure upon the masonry shall not exceed 250 lb. per square inch. All bridges over 50 ft. span shall have at one end nests of turned friction-rollers formed of wrought iron, running between plated surfaces. The rollers shall not be less than 2 in. diameter, and shall be so proportioned that the pressure per lineal inch of rollers shall not exceed the product of the square root of the diameter of the roller in inches multiplied by 500 lb. Bridges less than 50 ft. span will be secured at one end to the masonry, and the other end shall be free to move by sliding upon plated surfaces. . . . In riveted work all surfaces coming in contact shall be painted before being riveted together."

In chapter x. we have a section of 100 pages devoted to a practical illustration of the author's method in working out all details of a Brunel girder bridge, consisting of two equal parabolic double-bow girders, with top and bottom chords of same curvature. It was the intention of the author to carry out similarly an example in each of the twelve classes of girders which he delineates; but his death in 1884 left the work unfinished, and we have at present only one other example worked out, viz., the parabolic bowstring girder, of double triangular system, with which the book closes; the method of working is, however, fully set forth in the earlier pages, and we are promised the completion of the remaining examples by Professor John N. Stockwell, who has supervised the passage of Mr. Crehore's MS. through the press. The "method of moments" in this form is not much in favour among bridge designers in England, but possibly its use may become more extended when it is seen how applicable it is to the investigation of the economics of construction, and no one has more fully exemplified this than the author of the present work.

#### SPECIFICATIONS FOR PRACTICAL ARCHITECTURE.\*

It is so seldom that an architect addresses himself to serious literary work that we are most reluctant to discourage such attempts by a too rigorous criticism. Still, there are cases in which plain-speaking is a duty, and the work before us presents such a case. The original edition of Alfred Bartholomew's "Specifications for Practical Architecture" was published in 1839. It met with an immediate and deserved success, was re-issued in the following year, and republished with revisions in 1846. It was the first attempt to reduce the art of specification writing to a system, and was prefaced by an essay on the history of the art of building. Its author possessed all the necessary

\* Specifications for Practical Architecture: a Guide to the Architect, Engineer, Surveyor, and Builder, &c. Upon the basis of the work by Alfred Bartholomew. Thoroughly revised, corrected, and greatly added to. By Frederick Rogers, Architect. London: Crosby Lockwood & Co. 1889.

qualifications for the task, a wide experience of practical building, a true feeling for art, a vast store of archaeological and antiquarian learning, and a literary style of singular clearness and force. This once popular text-book has been for many years out of print, and it was a happy thought to revive and revise it for modern use.

The preface matter which forms the first part of the original work should have been reprinted intact for its historical interest, or omitted as no longer applicable to the present state of the art; or, if modified and modernised, should have been so printed as to leave the variations readily distinguishable. The editor has, however, taken a different view. He has mutilated the original text,—omitting about one half,—and he has not brought the remainder to date. The author's remarks on the Elizabethan and other impure styles have been cut out, either because the editor does not share the expressed objections to those styles, or because a change in the public taste has sanctioned their use. It may be fairly inferred that the editor endorses what remains of this preface essay. But will he seriously maintain that in this our day "our only endeavour is to copy at second-hand some ancient work in bad, improper materials"; that architects "are not sufficiently acquainted with the principle of the truss"; that we "expend our means in concealing chimney-shafts" (shades of Norman Shaw & followers!); that architecture has scarcely received from mechanical science "one machine for facilitating, improving, and rendering more exact the operation of building"; and, finally, does he really believe that even our public institutions become "in the first year of their existence masses of creaking ruins," filling every mind with "one humiliating feeling of disgust"? If he does not believe that this is a fair picture of the art as now practised, why does he publish it and hold up the profession, of which he is himself a member, to the scorn of the Philistines?

But, to come to the specifications themselves, which form the second part of the book. They have been reduced in number from fifty-four to twenty-seven, and with this we have no fault to find. They might have been still further reduced with advantage if only those retained had shown something of that "thorough and careful revision" which the editor claims to have exercised. Of the new systems of building, to which reference is made in the preface, we see little or nothing. As to the "greater attention given to hygienic matters," rendering certain additions to the text necessary, let us take this portion of the work for examination.

Chapter xvii. is a specification for a mansion, and here, at least, the subject of drainage may be expected to be fully gone into. We note in passing that all reference to a damp-course is omitted; but that is a trifle. Under the marginal note "Drainage," we are referred back to p. 77. This is a specification for a small dwelling-house" (of the fourth rate in the original edition), and does not look a very promising beginning of an important subject. At p. 77 this is what we find:—"Drainage, &c. To lay to a fall of 1 $\frac{1}{2}$  in. in 10 ft., 6-in. socket-jointed earthenware soil drain-pipes, and 4-in. branch drains from the rain-water-pipes, with proper Y and other junctions, bends, and diminishing pipes, trapped to all outlets, as shown on plan of drains."

It is not necessary for us to enlarge upon the scantiness and imperfection of this description. Let us try again. For the sinks we are referred to p. 81, and there the waste is properly described as being carried through the wall and discharging over a gully. Under "Butler's sink" we find, however, this instruction "Line the butler's sink . . . with bell-trap and connexion with the drains."

What sort of connexion? At p. 390, the last example in the book, it is stated casually in a note that rain-water pipes and wastes are not to be connected direct with the drains. It is the business of a specification to show how much work is to be done, and it is provided for in the earlier examples as follows:—

"To put to the sink in the scullery a 2-inch strong lead waste to lead into the drains."

"Put stacks of rain-water pipes from flats of projection (sic) bays and carried into drains."

"To put from the sink to the drains a 2-inch strong lead waste-pipe, &c."

We can find no reference whatever to the customary intercepting traps, the fresh-air inlets, the split pipes, the inspection pits at changes of direction, the flushing-tank at head of drains, nor to any of the points to which every architect now attends in the performance of this portion of his work.

We are almost afraid to call attention to these omissions lest the "Sanitary Engineer," for whom amongst others the book is written "as a guide," and who is now usurping the architect's position, should bring it before his clients as an indication of the manner in which the architect of to-day deals with this important part of his duty.

It would be an endless task to criticise in detail these model specifications. They teem with inaccuracies of all sorts. Precept and example are in perpetual conflict. The use of ganged brickwork is condemned and enjoined throughout, and all sorts of separate subjects are jumbled together. Pieces of carelessness, such as the provision of wash-out closet-pans with three-quarter inch service-pipes; and such antique injunctions as "put to internal doors wood mouldings to resemble architraves" are met with. Such paragraphs as this appear: "Put to all the windows Portland stone sills . . . and to all the other windows" &c. &c.; whilst the typographical errors—"damp corner" for damp course, "period" for per rod, "cubit" for cubic,—are incredibly numerous. Two words which should be banished from all scientific specifications are sprinkled thickly over the pages, viz., "proper" and "patent"; everything is to be "proper" or "properly done,"—which is not by any means specific; and "patent" is used as though there were in every case two articles, one patented and the other not,—patent lines, patent fasteners, patent w.c. apparatus, patent everything. The contractor for the fourth-rate dwelling-house is given the alternative of copper or zinc nails for the slating! Vagueness is carried in some instances to an extent which runs very closely to the amateur quantity surveyor's celebrated "No. 1 bay window complete."

We have, however, no heart to pursue further the distasteful task. A book on specifications has still to be written, and possibly the editor has all the necessary practical knowledge and literary qualifications, if he would only give himself the requisite trouble. But he should substitute the pen for the scissors, and for the long wail over the ignorance and back-sliding of his professional brethren,—which is as inaccurate as it is irrelevant and unseemly,—a carefully-written description of the various building processes as now pursued. He may then produce an edition "based on" Bartholomew's book which shall be really useful to the student, and we promise it in advance a welcome in proportion to its deserts.

#### NOTES.

THE Works Committee of the Metropolitan Board of Works have selected from the candidates for the post of Superintending Architect the following six names for further consideration:—Mr. A. Peebles, Mr. Rowland Plunbe, Mr. H. Gundry, Mr. T. Blashill, Mr. P. Gordon Smith, and Mr. E. J. Tarver. The Committee intend to recommend that the election be proceeded with on Friday next, the 4th of February. It may be remarked that the first four candidates on the list are all District Surveyors under the Board, and Mr. Gordon Smith is Architect to the Local Government Board, so that Mr. Tarver is the only one of the six selected who is a non-official architect. From among these six candidates the Board will be able to make a good selection for the post; but we cannot help expressing surprise at their ignoring the claims of their present Acting Superintending Architect, who seems to have been passed over for some reasons not apparent on the surface.

Since this was written we find that Mr. Williams has given notice that, when the recommendation of the Committee comes before the Board, he will move:—

"That the voting on the six selected candidates for the office of Superintending Architect be by ballot, and that the ballot be taken by each member of the Board writing one name of a candidate on a piece of paper, and so continuing until one of the candidates has a majority of the votes, and that at each count of the votes the name of the candidate who has the least number be struck out of the list."

FROM Mr. Westgarth we have received a pamphlet consisting mainly of a reprint of two papers contributed by him to the Journal of the London Chamber of Commerce. The object of the papers is to show briefly how the "appreciation" or rise in the standard value of gold has had an influence in temporarily reducing profits, for a concise explanation of which rather difficult subject we refer the reader to Mr. Westgarth's pamphlet,\* which puts the matter very clearly for the intelligence of the non-economic reader, though perhaps Mr. Westgarth does not bring forward quite prominently enough the necessarily temporary character of the influence and the almost certainty of a compensating re-action of the balance sooner or later in an opposite direction. The second portion of the pamphlet is devoted to a suggestion for the employment of labour in work for which the profit is to be obtained by "natural increment" (which phrase Mr. Westgarth prefers to "unearned increment"), in plainer language by holding on to the property till its rise in value in the natural course of things affords an adequate return for the outlay. Mr. Westgarth draws attention to the fact that outlay has already been incurred on this principle, in the Birmingham Municipal improvements and in some of the schemes of the Metropolitan Board of Works. As a matter of fact, it has often been tacitly acted upon; but the author wishes to suggest that this is a means of employing labour and putting out capital in an ultimately remunerative manner, which is destined to be much more largely and systematically employed than it has been. As a practical illustration to his paper, he cites the Houndsditch area as one where extensive improvements and rebuilding might be carried out to the employment of many hands, with the certainty of a large return eventually, from its contiguity to the increasingly overcrowded "city," and the same principle would apply to other sites which might be named. The difficulty is, perhaps, to find capitalists who can afford to wait long enough for their money.

WE append a ground plan of so much of the hall of the Hebrew Dramatic Club in Spitalfields as will serve once more to point the moral of such disasters as that which occurred a few nights ago to a panic-stricken crowd. The case is all the more noteworthy in that the defective planning which contributed to the disaster could easily have been obviated. The \* shown on the plan indicates the spot where the two streams of persons,—one coming from the body of the hall, and the other down the stairs from the gallery,—impinged and became jammed together. The stairs from the gallery could easily have been carried down in a straight line over the space marked "Office," instead of being turned at right angles, and with "winders" too. The vestibule is apparently wide enough to take both streams of people had they been both passing in the same direction, even without any barrier or partition wall to divide them, as would be preferable, and as is required by the Metropolitan Board of Works in buildings over which it has control. Too much attention cannot be paid to the planning of the exits of all buildings where large numbers of people assemble. Former disasters have shown that exits which might be sufficient when used by an audience of intelligent, self-controlled people (we doubt whether large audiences of such

are often brought together) are totally inadequate when there is a helter-skelter rush of panic-stricken people upon them. That the large hall in Spitalfields should not be under

the control of the Metropolitan Board of Works, while every little first-floor room of an ordinary public-house, if used as a concert-room, is under their jurisdiction, is one of those anomalies which are so abundant in the details of London "government."

THE circumstance that the funds raised by means of the Coal and Wine Dues have been almost exclusively devoted to the carrying out of public improvements within the metropolis itself seems to give good ground to the contributing outlying districts for desiring some alteration in the mode of administering these funds. The Acton Local Board has secured the support of most of the suburban authorities to a petition which, though not seeking the total and unconditional abolition of these dues, urges the application, in their administration, of the principle that representation and payment should go together. And there is no doubt that if the outlying districts were properly represented in this respect, the benefits derivable from these revenues would be extended, in a fair and equitable measure, to all parts of the contributing area. It is asked, for example, why should the inhabitants of districts as far west as Kingston-on-Thames and Staines be called upon to contribute by these dues funds for the construction of the proposed tunnel underneath the Thames in the east end of London? A carefully-prepared Bill, conceding to the outlying districts the principle of representation in regard to these dues, and the extension of their benefits to the whole of the contributing area would take away a great deal from the arguments of those who would totally abolish them.

MANY of our readers will have heard with great regret of the early and unexpected death of Mr. Alfred Newman, the worker in wrought iron, whose atelier, carried on under the firm of A. Newman & Co., has exhibited a remarkable progression since its comparatively recent establishment. Mr. Newman united in an unusual degree the qualities of business capacity and artistic taste; he thoroughly understood the principles of the treatment of wrought-iron work, and took the greatest interest in the adequate carrying out of designs entrusted to him; going into every detail, and often making valuable suggestions for the improvement in detail of designs entrusted to him for execution, especially in regard to facility of working, and appropriateness to the capacities of the material employed. His work was formerly carried on in some rooms in Marlborough-mews, whence he had not long since removed to the rooms in Archer-street, which had already become well-known to architects and others

interested in the production of wrought-iron design, and which presented to the visitor an interesting combination of artistic detail and practical workmanship. Several of Mr. Newman's works have been illustrated in our pages from time to time. Mr. Newman had been employed on among other things the great wrought-iron lamp standards for Eaton Hall, for the Marquis of Westminster; he had also carried out a good many wrought-iron signs for various premises in London, notably the large one which forms such a conspicuous object at the angle of Mr. Norman Shaw's picturesque building at the end of Pall-mall. Another characteristic work which we illustrated was the grille, with the spider in the centre, made for the entrance door of a house in Prince's-gate. Mr. Newman's loan exhibition of wrought iron work, ancient and modern, in some rooms in Bond-street a year or two ago, and his Saturday expositions on the subject to artisans, attracted much attention; and his forge in the grounds of the Health Exhibition was one of the centres of interest there. Only two or three weeks before his death we took part in a consultation with him and his chief artisan at the rooms in Archer-street, on the carrying out of a design of peculiar type; and he was then full of energy and interest in his work. Mr. Newman was quite a young man, and his death has terminated unexpectedly a career highly creditable to him, as that of one who put his whole heart and ability into everything he undertook.

DEVERTING to the mention made by us last week as to the opportunity which now presents itself for the re-erection of Temple Bar on a site which, as was pointed out in our column nearly two years ago, is a peculiarly appropriate one, viz., at the eastern entrance to the Temple precinct, we are glad to see that Mr. G. Gilbert Scott has written to the *Standard* in support of the suggestion. We have received a letter from Mr. J. R. Morgan, the Secretary of the Temple Bar Reconstruction Committee, stating that the remains, though no very great care has been taken of them, are in a better condition than might have been supposed, and approving of the idea of seeing the monument re-erected on the site proposed. Mr. Morgan states that the committee have been given to understand that, though the Corporation are indifferent as to the re-erection of Temple Bar, the stones will be presented to any one finding a site and the cost of erection.

THE last two numbers (35 and 36) of *Der Baumeister's Denkmäler des Klassischen Alterthums*, a publication the more noteworthy of whose issues we have drawn attention to from time to time, contains an article on Pergamos of special popular interest. It is not every one who can consult, still fewer who can possess, the magnificent work which the Prussian Government have published on the recent excavations. Now, at the cost of a few shillings, any one can obtain a reliable account of the whole proceedings, and what is even more desirable, a series of plates, which are in most cases very respectable reproductions of the now famous marbles. The great frieze of the altar is by now in part known to every one interested in art; photographs of it have, however, been dear and scarce. As to the smaller frieze, known as the "Telephos frieze," it is practically almost unknown. It is less well preserved, and of far less sensational interest, but in connexion with the history of art it is quite as important. The reason of its comparative obscurity is, no doubt, the fact that even at Berlin the original is not yet exposed to public view, though the courteous directors are always willing to show it to the professional visitor. We are glad to find that in the *Denkmäler* three of the slabs are figured, and in the text the interesting but little known myth of Telephos is fully discussed. The old and incorrect restoration of the great altar is unhappily given, but the editor states in a note that he is aware of the recent correction. This correction appears in a general view of the whole Acropolis.

\* To be had from F. C. Mathieson & Son, Bartholomew House, E.C.

WE recently called attention to the discovery of the statue of a running girl in the excavations at the Villa Spithover. The statue is just published, front and side views, in a fine prototype in the *Bulletino della Commissione Archeologica Comunale di Roma* (iii., 11), and turns out to be of even more interest than was expected. The statue has lost the head, arms, and lower part of both legs, but enough remains to show a curious and very close correspondence with a passage of Pausanias. Speaking of the races run by the maidens at Elis, in honour of Hera and in memory of the contest for Hippodameia, he says, "They all run with their hair loose down their back, and they wear a short tunic to below the knee, and the right shoulder is bare to the breast." All these characteristics appear with singular exactness in the Spithover torso, so that there can scarcely be a doubt that we have a votive statue set up by a victorious maiden. She was represented as *actually running*, not as just about to start, like the Vatican running girl. The style of the new statue is of the fine period, and the drapery is of singular freedom and grace, drapery that it was possible to run in, a singular delight in these days, when part, at least, of "the human dress is forged iron."

THE current issue of the *Board of Trade Journal* contains the following extract from a report on the water and sewer works at Warsaw, made by Mr. H. Grant, H.M. Consul in that city:—"The works undertaken in 1882 by Mr. W. H. Lindley for providing this city with a daily supply of 600,000 cubic feet of well-filtered water and with sewers measuring 58,000 ft. in length, at a cost of 350,000l. sterling, will be completed next spring, when it is expected they will be further extended, as the above supply of water will only suffice for about half the present population of Warsaw (420,000), and the same may be said of the sewers." The following articles required for the works have been supplied from England:—Stoneware invert lining, stoneware pipes, fire bricks, steam engines and boilers, cocks, and sluice-valves. The field is now open for water and sewer fittings, taps, water-closets, syphons, gullies (street and yard); also stoneware pipes and specials for house drainage (4 in. 6 in. and 8 in. diameter), stoneware gullies, &c. Lead piping will also be required, but it is doubtful whether British makers could compete in this.

WE have before referred to investigations as to the use of galvanised iron for water-pipes, and we have now another report on this subject from a German source, which is quoted in the current volume of the Proceedings of the Institution of Civil Engineers. At the 26th annual meeting of the German Gas and Waterworks Engineers, held at Eisenach, Dr. Bunte presented the report of a committee that had been appointed to inquire into the suitability of galvanised iron for water-pipes. As a result of numerous experiments made, it appeared that in the case of new pipes the water invariably took up zinc; but notwithstanding this, was in no way injurious to health. After some discussion the meeting unanimously decided the "employment of galvanised wrought-iron pipes for water supply occasions no injury to health."

MR. ACLAND'S letter in the *Times* of the 21st inst. demands the consideration of the powers that be. He pointed out the difficulties which exist in the obtaining of Government publications, such as reports of Select Committees and Royal Commissions. Not only is their price high, but their form is very inconvenient, indexes and tables of reference are often published long after the evidence or the report appears. Except by very special application and at the expenditure of some trouble, it is not possible to obtain these publications. It is clear that reports and similar documents should be published at a reasonable price in a convenient form so that they should be not only published in the sense of being printed but should be issued in such a manner that any one interested in the subject of which they

treast should be able to obtain them without difficulty and at a reasonable price.

THE next thing to abolishing distance by making new railways is to utilise more completely those that are made, and to get the very utmost of them by international connexion, which at once impresses upon the system a necessity for saving every moment. By so doing the Iberian Peninsular Company has succeeded in saving seventeen hours in the journey between Lisbon and London, and twelve hours between Madrid and London. Fifty-one hours' run between the Spanish and English capital is pretty good work, and no one can complain of thirty-six hours from Lisbon. There is no change of carriage between Lisbon and Calais, the difference of gauge being got over by the simple means of slinging the body on another set of wheels, and so easy is this arrangement, that it is a wonder that it has not been resorted to before. The South American trade will benefit by this new route more than all others, and when we remember the horrors of the Bay of Biscay, we may well imagine that a fair overland traffic to Gibraltar and the Mediterranean may spring up, bringing Lisbon in the regular highway of traffic. It is to be hoped, too, that the parcel post between England and Spain may be put on a proper basis; for hitherto we have been one of the few nations that have been bereft of that privilege.

WE have received from Messrs. W. Cooke & Co., of Leeds, a number of samples of their "Golden Lustre Silk Paperbangings," which are, in fact, wall-papers of the usual types of design, but made, by a special process, with a surface having a silk-like lustre, and with something also of the richer texture of silk, as compared with ordinary paper. We are not, we confess, liable to be moved to any great enthusiasm about improvements in wall-papers, having a deeply-seated conviction that wall-papers are at the best an evil which it is for the time necessary to be subject to, because no other more sanitary and equally economical method of giving a decorative surface to the interior of a room has been devised. Apart from this general principle, however, we admire the effect and lustre of these papers, which may afford a new item in decorative effect, at a moderate cost.

A PROJECT is on foot to provide a new parish church for Hornsey. The Rev. James Jeakes, rector, has offered a site in Church Yard for an edifice to receive 1,200 persons. An amount of 4,000l. is already promised, under certain conditions, to the building fund. The existing church, rebuilt in 1832, is conspicuous for its ivy-clad tower, that dates from the fifteenth century. In the graveyard are buried Rogers, the poet, who once lived at Stoke Newington; and a daughter of Tom Moore, who for awhile occupied a cottage at the foot of Muswell, or rather Mousewell, hill. The surrounding woods are remains of the ancient manor and park of Haringhee or Haringay, that were reserved for the chase by the bishops of London. In the bishops' palace Henry VII., on his accession, was offered homage by the citizens of London. Hornsey Wood together with the later Wood House or tavern, and its lake, near to the Stuce House, a favourite resort for cockney anglers of the last generation, is now represented by Finsbury Park. The park covers 115 acres of the Finsbury division of Ossulston Hundred.

SOME old houses by the entrance into Fleadis-court, Fetter-lane, are about to be demolished. That to the left hand is a traditional home of Dryden, who is said, when living here, to have opened a quarrel, in verse, with his neighbour, Otway, across the street. This house bears a tablet to the memory of "glorious John!" It is remarkable for the two lions' heads above its side piers. The house on the right hand of one entering the court is notorious for the murder there (1767) by Mrs. Brownrigg of her apprentice Mary Clifford. They who are curious in such matters may see the cellar-

grating through which the victim's screams were heard. Here was formerly one of the fishing-tackle shops for which Fetter-lane was at one time renowned.

AT their recent annual general court the Honourable Artillery Company of London resolved to commemorate the Queen's Jubilee concurrently with the 350th anniversary of their own-embodiment. The commemoration will consist of the addition of a new wing to the Armoury House, by Bunhill fields, together with a spacious drill-hall and riding-school, to cover an area of 65 ft. by 108 ft. The ground they now hold, being part of the prebendal manor of Finsbury (more correctly, Holywell), was originally leased to them in 1641, under name of the New Artillery Garden. This regiment is singular in its absolute emancipation from anything in the form of Parliamentary control. The members of the infantry battalion are commonly regarded as modern representatives of the City Trained Bands. But they quite repudiate an honour which more strictly appertains to the City of London Militia, whose headquarters adjoin to their own. There are records to show that in 1796 the Court of Assistants resisted,—and for some months with success,—the use of their ground by the London Militia, who had been enrolled, or rather, reorganised, in the previous year. The Company, distinguished as "Honourable" in 1685, claim status and governance in virtue of certain royal warrants granted and confirmed to them by our several sovereigns, from a date when "regular" forces were not. In the year 1537 King Henry VIII. gave them a charter of incorporation, with the style of the "Fraternity or Guild of St. George." Their muster-rolls comprise an unusually long list of highly eminent personages. In 1770 John Wilkes was elected as a "general." Alderman Beckford, Monk, Milton, Prince Rupert, the Duke of Monmouth, and Sir Christopher Wren, were also members of the corps. It is this Company who are represented as firm upon the "No Popery" rioters in Broad-street (on the 7th of June, 1780, Walpole's "fat day"), in F. Wheatley's fine drawing, after an etching by J. Mox. Some of our readers are perhaps familiar with Picket's large-size aquatint, after E. Dayes, of the inspection a Finsbury by the Earl of Harrington, on the 22nd of September, 1803, wherein the artillerymen are shown as drawing their cannon with ropes. The Jubilee festivities will be attended by delegates from the Artillery Company of Boston, U.S., founded there in 1731 by an emigrant member of the Company in London.

THE Baths Committee of Bath, not satisfied with Mr. Penrose's report, have now called on Mr. Waterhouse to report both as to the stability of the new building and the steps taken to keep the Roman bath remains unobstructed. On the latter part of the matter Mr. Waterhouse does not differ much from Mr. Penrose; he considers that City Architect has steered a fair course between archaeology and practical requirements. This may be fairly said, perhaps, though it strikes us that both reports were (unconsciously, no doubt) drawn up rather in the terms of an advocate of the City Architect than of a judicial critic. Mr. Waterhouse is against the idea of making a vaulted basement for the specific purpose of enclosing the Roman remains, on the ground that it will spoil the new room above by taking away from their height, and that the Roman remains will get very little light in that way. He is emphatic, however, in saying that every means should be taken to facilitate inspection of the Roman remains, and to isolate them completely would have been the most effectual way of doing this. Part of the mischief was done before the fight began about it; and the matter seems unfortunately to have been argued out by two parties, each holding rather exaggerated views in opposition to the other side. The archaeologists are no doubt somewhat neglectful, in their zeal, of the practical requirements of the modern bath-

while the City Architect and his allies seem actuated a good deal by a spirit of opposition and a determination not to take anybody's advice if it does not agree with their own opinion. Mr. Davis has not done all the damage to the remains that he is charged with; but he might have done still less if he had given his efforts to that object.

A CORRESPONDENT sends us a delightful specimen of "Instructions to Competing Architects" for a competition for a proposed cemetery at Fareham, Hants. No premiums are offered, and each competitor is to send a statement for what commission on the outlay he will do the work of planning and superintendence; so that apparently the "job" goes to the lowest bidder. Do the Fareham Local Board imagine they will get the services of any competent professional man in response to such an advertisement?

#### ON GREEK SCULPTURE AS EXPRESSIVE OF THE EMOTIONS.

ROYAL ACADEMY OF ARTS.

MR. A. S. MURRAY, Keeper of the Greek and Roman Antiquities in the British Museum, delivered the first of a series of three lectures on this subject, on Monday evening, to the students of the Royal Academy. He commenced by saying that it was a matter of common belief that Greek sculpture was singularly defective in expressing the emotions. Without stopping to contest the accuracy of the belief, which was partially shown to be ill-founded by such groups as the Laokoon, its origin and prevalence might, perhaps, be accounted for by the fact that our knowledge of the ancient Greeks had come down to us more through their literature than their art. It was usual with most people when they saw a piece of Greek sculpture to be content with the thought that it was Greek; that it had come down to them from a nation whose art they had been taught to admire; that it was strangely attractive to them by its costume, its attitudes, its lines, its modelling of form. They rarely set themselves to interpret it; it was enough that it was Greek. Their ideal was the Parthenon. They did not trouble to think much about the older sculptors who worked out the beginnings of the art and launched it on its prosperous voyage; nor did they mind overmuch the later sculptors, whom new impulses drove beyond the severe limits of the Parthenon. Worst of all, the remains of Greek sculpture were but a fragment of the whole, and that fragment we viewed only in such aspects as suited us. While it was true of the literature of the ancient Greeks that it was one of measured dignity and reserve, yet that was not the whole truth. The plays of Aristophanes were an obvious exception; and if the vast number of comedies which we knew now only from fragments had met with a better fate, we should have had more than enough of evidence as to the faculty of the Greeks for observing and characterising emotions of one kind or another. He did not know whether it was meant for blame or praise,—possibly sometimes the one and sometimes the other,—when it was asserted of Greek sculptors that they were defective in expressing the emotions as compared with the sculptors of modern or comparatively modern times. If it were meant for blame, the blame could not be just, even if it were true. A fair comparison would be between the Greeks and their predecessors, the sculptors of Egypt and Assyria, because the Greeks had many opportunities of learning from them or of profiting by their mistakes. It would be a fair comparison also from the fact that in both those nations sculpture had long flourished, if not with the same freedom as in Greece, yet with ample encouragement. In Egypt it was an art which ministered to the deepest thoughts and most sacred hopes of the people. In innumerable instances it was called upon to furnish forth a true presentment of famous deeds and famous men. But if inquiry were made as to what the Egyptians had done in that matter of expression, and if their works were contrasted with those of the Greeks, the advantage would be found to be on the side of the Greeks. Even in Assyria, where the sculptor was free to deal with forms and incidents of daily life, and to reproduce them in a manner likely to please and gratify the common tastes

of the day, we found extremely little in the way of representation in sculpture of the human emotions. As a rule, the Assyrian sculptor preferred action, and passed over the passions or emotions out of which it had arisen. The lecturer next proceeded to define what he meant by the phrase "expression of the emotions." No doubt, he said, there were certain emotions which were habitually expressed by certain actions. For instance, fear was expressed by opening wide the eyes and mouth, by the beating of the heart, the paleness of the skin, and, as fear increased to terror, by the hair standing on end and by the limbs losing their power. And this was true of savages as of educated persons. At the same time, the degree of intensity with which those actions were evoked might differ widely in differently-constituted men, or even in the same men under different circumstances. As an example of this, the lecturer quoted the beautiful scene in the *Odyssey* where Nausicaia and her maidens, while playing at ball on an open field, were startled by the sudden appearance of Ulysses, stripped by shipwreck of every rag of clothing he had possessed. The maids screamed and ran in horror, but the Princess Nausicaia awaited calmly to hear the story of the poor castaway. Homer, it would be allowed, was no bad observer of the different ways of expressing emotion in different classes of people. In reference to the scene referred to, there could, the lecturer supposed, be no question that the princess experienced the same emotion of surprise and fear as did her maids; she only revealed it in a different manner. He had not noticed that that different manner of expressing emotion in different classes of persons had been dealt with by Darwin and Herbert Spencer in their inquiries on that general subject. From their point of view it was held to gather as much evidence as possible from the average of mankind, if not from savages and others below the average, and thus establish the link between man and the lower animals. Besides, their object was to show that certain emotions, when they were produced at all, were manifested in the like manner in all persons; whereas the artist, in reproducing a particular incident, might treat it as the cause of strong emotion, or the reverse, according as he conceived the character of the persons whom it affected. He might make a child moved with terror while a grown-up person beside it remained perfectly calm. He might take his model from the market-place, where the slightest incident produced overdone emotion, or he might go to the other extreme, and find types of persons who had steeled themselves in presence of causes which produced emotion in others. The lecturer's argument was that in Greece there were sculptors who took both directions, but that naturally the latter sculptors chose the better types to work upon. That might appear to be a confession that the best sculptors of Greece avoided the expression of emotion; but he (the lecturer) had still to consider whether, by selecting a type of man steeled against the direct expression of emotion, and placing him in circumstances which would greatly move a different person, one might not equally convey the powerful, though not emotional, effect on him. It might be asked, did the Greek sculptors, like their contemporaries the dramatic poets, recognise the need of any contrast or foil to their tragic or serious compositions? and, in recognising that need, did they produce other statues or compositions intended to express emotions among beings of a lower nature? One would think that they must have occasionally experienced, after the strain of a more or less tragic composition, the same necessity of a spontaneous outburst of common nature in which they might give plastic form to their observation of scenes or incidents in daily life. We could easily understand how works of that kind were allowed to perish along with the multitude of satiric and comic plays which in later times no one cared to preserve. But a difficulty arose here, for whereas we had a record of the existence of the comedies, we had little or no record of works of the kind here contemplated being executed by the sculptors of the great age. We might fancy that Polykleitos, a sculptor renowned for the severity and dignity of his style, must have relaxed those qualities when he made a group of two boys playing at knuckle-bones. Or we might reinforce the argument by appealing to the story of the painter Zeuxis having died of a fit of

laughter at the figure of an old crone which he had himself painted. But, after all, the conclusion appeared to be inevitable that the vast proportion of sculptors in the best age dealt with subjects of a grave and serious turn, where emotion was naturally made evident by repression rather than by expression. In time there arose a new and separate class of artists who addressed themselves gradually, and at length specially, to a lighter kind of work, just as the strictly comic poets of Greece might be said to have arisen to produce the fun and drollery which their tragic brethren could not always command, the result being that the tragic poets were soon banished altogether from the stage, the comic poets reigning in their stead. Much of this lighter kind of work, displaying the keenest observation of the emotions, had survived to our day, and examples of it would be mentioned later on in dealing with the later stages of sculpture, for it was part of the lecturer's argument that the steady progress of Greek sculpture from its early times was accompanied by a progress in the expression of the emotions. The lecturer here quoted Lucian's description of a painting by Apelles, which represented "Calumny":—

"On the right sits a man with long ears, like those of Midas, holding out his hand towards the figure representing Calumny, who approaches him. Beside him stand two women, in whom Ignorance and Suspicion are personified. On the opposite side is Calumny herself, a woman of surpassing beauty; but here she is burning with anger and agitation, like one who cannot repress her rage and indignation. In her left hand is a flaming torch; with her right she drags along by the hair a boy, who stretches his hands to Heaven and calls the gods to witness. Then comes a man, pale and thin, with the cadaverous look of one wasted by long disease. That is Envy, and next appear two more women, pressing, decking, and adorning Calumny; they are called Cunning and Deceit. Behind them follows, poorly clad in black and tattered garments, the figure of a woman, Penitence by name, who weeps and looks back, ashamed, to Truth, who follows her."

Except for the figure of *Penitence* and that of the boy imploring Heaven, both of which were emotional enough, the picture of Apelles would remind us rather of the "Pilgrim's Progress," or, more appropriately to the present question, it would recall a little-known book, the "Characters of Theophrastus." Theophrastus would be more or less a contemporary of the painter Apelles, and would represent the general taste of the times for the observation of character—a taste which, though it perhaps never died out in any nation, yet had its times of ebb and flow. Strictly speaking, it might be said that the representation of character and of emotion were different things; and, what was at present more to the point, it might be said that the representation of both the one and the other in painting or in literature could not have more than a remote bearing on ancient sculpture. But he (the lecturer) was not so sure of that, for whatever was being done by contemporaries eminent in literature or in painting was done also, in their own way, by the sculptors. Why not, then, it might be asked, let Greek sculpture speak for itself? Unfortunately, Greek sculpture had been rendered dumb to a large extent by the loss and destruction of its greatest and noblest works. Passing on to notice the difference between the expression of character and that of emotion, the lecturer observed that the permanent character of a man was frequently revealed more strongly under emotion than otherwise. For that reason it was often difficult, in reading ancient descriptions of works of art, to make out how much or how little of the quality of emotion had been employed by the artist to help out his expression of character. Parrhasius, we were told by Pliny, painted a picture of the Athenian democracy in which he showed it to be variable of temper, angry, unjust, inconstant, and at the same time inexorable, clement, compassionate, self-glorious, proud, humble, fierce, slippery: in fact, "everything by turns and nothing long." We had to suppose that the Athenian *demos* was here represented by a single figure; but how so curious a complication of character could have been depicted in it was beyond comprehension, unless we assumed that his face was so conceived and so painted as to show a capacity for each and all of the various moods and emotions which had been mentioned. The remains of Greek sculpture which we now possessed afforded no large number of instances of emotional expression, except in minor or in later branches of the art. A well-known piece of sculpture mentioned by Homer ("Iliad," xxiv., 613) was the figure of Niobe out on the rock on Mount Siplyos. According to the poet, she had been turned into stone by the gods, and

there for ever sat brooding over her woes. Travellers found there still a figure cut into the rock, which, at a distance, had a resemblance to a woman. It was a figure of about 16 ft. in height, but the workmanship was too rude to give any evidence of a sculptor's talent; yet it might well be the Niobe of Homer. He need not have known how rudely it was cut; but it was certain that he believed the figure to be a woman expressing in her attitude the deep emotion of a mother who had lost at a moment her six brave sons and six fair daughters. Keeping still to Homer ("Iliad," xviii., 590) the lecturer instanced the chorus sculptured by Dædalus for Aridne in Crete, representing youths and maidens as they danced hand-in-hand round in a semicircle in joyous spirits. It was not supposed that these emotions were expressed by the sculptor with the precision of modern art, or with the accuracy of the poet in observing them. Greek sculpture was then in its infancy; but the mere fact of attempting such a subject was evidence at least of its desire to render emotions. One of the oldest existing works of Greek sculpture, the frieze of a temple which stood at Assos in the Troad, was now to be seen in the Louvre, with the exception of some pieces found on the spot recently by an American expedition. The relief was very low, and in many places very carefully executed. On one slab Herakles was shown wrestling with the sea-god Nereus, to the astonishment of the sea-nymphs, who dreaded the consequences to their friend Nereus. Their manner of expressing astonishment and fear was to extend their hands with the palms wide open, to run away and yet to be unable not to look back. In conclusion, the lecturer instanced one of three surviving metopes from a temple at Selinus in Sicily, in which the subject represented is Perseus cutting off the head of the Gorgon Medusa, the sculptures of the Harpy Tomb, some slabs of the Phigaleian frieze, the sculptures of the Temple of Zeus at Olympia, and a bust of one of the fourteen statues lately found on the Acropolis at Athens, to the north-west of the Erechtheion, as each and all affording clear evidence, more or less pronounced in character, of successful efforts made by early Greek sculptors to express the emotions.

Mr. Murray's second lecture was delivered on Thursday evening last, and dealt with Greek sculptures of about the time of Pheidias. He commenced by asking his hearers to bear in mind the significant fact that though Pheidias was the first to introduce true largeness and dignity into sculpture, yet in respect of those two qualities of style he had been preceded by others in the sister art of painting, and in particular by the painter Polygnotus. If then, we might gather from the records of that painter any conspicuous evidence of an inclination towards expressing human emotions, it would not be unreasonable to hear that evidence in mind as an indication of the atmosphere in which Pheidias was brought up. He did not mean to argue that Pheidias was obliged to follow out every line of observation indicated by the great painter. On the contrary, it was likely enough, from all that was known of him, that he rather set himself to confine within narrower bounds the freedom of expression which the painter had indulged in. Sculpture had a different function from painting in those days. It was more in the service of religion, and thus, even if it were known that Pheidias had in every instance severely repressed emotion in his figures, we should only be free to conclude that the occasion required so much,—not that he refused to recognise expression of the emotions as a legitimate channel of sculpture. As a matter of fact, we could not believe that his practice excluded a recognition of that view which we read ancient accounts of the impression made on spectators by his great statue of Zeus at Olympia. Of course, for a statue to make an impression was not exactly the same thing as to convey an expression. But it was worth observing that an artist, whether he were sculptor, painter, or poet, who produced a figure or a scene that moved us deeply, and yet was not itself moved, must possess the true creative faculty of anticipating our emotions,—must have himself gone through those very emotions in working out his conception. Returning to the painter Polygnotus, the lecturer said that the description had survived of two of his great paintings at Delphi, the one representing the taking of Troy, the other a visit of Ulysses to the Lower World, and

what he saw there. In the former picture there must have been extremely little of emotion, as, indeed, might be expected considering that the subject was one in which emotion had passed over into action more or less violent, according to the general law laid down by Mr. Herbert Spencer, and accepted by Mr. Darwin, that "feeling passing a certain pitch habitually vents itself in bodily action." But in the picture of the visit to Hades all that was changed. There, action had ceased to be of any avail,—so much so, that Achilles would rather have been a day-labourer on earth than a prince in the Shades. There was, however, a compensating scope for emotion. Having described this picture, in which, he said, there must have been abundance of emotion expressed, the lecturer glanced at the poetry of Greece during the century that immediately preceded Pheidias, which, fragmentary as it deploredly was, contained much to convince us of the strength and force with which the emotions were expressed. Homer was then, and for long afterwards, the great school-book of the Greeks. It was because of him in particular that Plato wished all poets to be banished from his republic; and one of the strongest arguments for that purpose which he put into the mouth of Socrates was founded on those very Homeric passages where emotion was most strongly expressed. Socrates, though he had been trained from his childhood to love and revere Homer, thought it wrong that the sorrow and tears of great men should be exhibited. The blame of Socrates extended to Pindar and Æschylus, the actual poets of the time of which the lecturer was speaking. But we ought to take notice of the fact that the strong objections which Socrates urged against the poets in the matter of expressing the emotions were not held out by him as applying equally to the sculptors. Socrates had himself been trained as a sculptor, and might be presumed to have been familiar with the various characteristics of the art which he had abandoned for the pursuit of philosophy. He was acquainted, also, with painters and painting. What, then, were we to say of his silence in regard to these arts on the subject of expressing the emotions, so objectionable to him in the poets? In the first place it was Plato who made the objections, and not necessarily Socrates, though the words were put into his mouth. In the second place, it had always been a cause of surprise that a thinker like Plato, who combined the perfection of literary art with the most intricate problems, should have passed over with so extremely little notice the great works of sculpture in the Athens of his day. There was no proof that he had any eye for them at all, and we could readily suppose that in avoiding criticism of them in reference to the emotions he was guided by the desire of not exposing himself to successful rejoinders. In any case his silence was not to be construed as proof that in his estimation the sculptors were altogether free from the charge which he had levelled at the poets. It was not, of course, possible for sculpture to go nearly the same length in that matter as a narrative poem like the Iliad. Sculpture was from its nature more organic, and had the forms and energy of actual life, and as such it appealed so vividly to the imagination that we could not allow any vagueness or inexactness of detail, any compensating here for what was left out there, such as there might be in some kinds of painting and of poetry. In sculpture, therefore, if there was to be emotion, it should be spread throughout the whole figure, or, in the case of a group, it should be diffused through the whole organism. It should be, so to speak, like the colouring matter of a plant, and should give the whole tone of the figure or group. The lecturer then called the attention of his audience to a slab from the west frieze of the Parthenon, which represented the youth of Athens starting and preparing to start on their ride to the Acropolis on such occasions there were always some too eager and some too slow. The young horseman on the slab in question was of the former class. He was placed at a point in the frieze where his impatience was easily intelligible, for just before him the great body of the cavalcade was heaving away at a gallop. He knew that there were some behind who had not yet mounted, and he had thrown himself round on his horse's back to urge them to make haste, which he had the more reason to do since

just before him there stood one of the marshals of the procession, looking round attentively if not anxiously. On his head had been attached a metal wreath, now lost, and the usual explanation was that his left hand was raised in the act of placing the wreath on his head. He (Mr. Murray) could not agree with that explanation. The figure seemed rather to have thrown up his left hand in the act of urging forward his companions. Eagerness was marked in the whole movement of his body. The throwing up of the arm was so completely part of that movement, and was so truly the very climax of the action, that the mere suggestion of its being due to the act of placing a wreath on the head was repugnant to the whole sentiment of the figure. The whole figure, including the face, was a noble expression of a fine emotion, and the more one realised the circumstances in which the youth was placed the more readily would that be seen. In Greek sculpture it was often difficult, if not impossible (and at the best it was always laborious) to realise the circumstances that were in an artist's mind and that were familiar enough to his contemporaries. Yet there were times when nothing was more necessary. We could do without it, or rather we had to do without it, in judging, for example, of one of the metopes of the Parthenon, which represented a Lapith suffering severe pain from the grasp which a Centaur has made a his throat. We knew the savage nature of the Centaurs, and we were told that the Lapiths were of a race, endowed with simple and noble natures, whose primitive function it was to subdue the more brutal elements of the world, represented by the Centaurs. It was essential, therefore, for the sculptor to give the Lapiths simple and noble forms, though in the particular metope referred to he had not succeeded to anything like the degree of his success in some of the others. But why, it might be asked, were the Lapiths always young in these metopes of the Parthenon, and in Greek sculpture generally of the good time, while the Centaurs were long-bearded and old? Apparently the intention of the artist was to bring out the contrast of a new race subduing and supplanting an older race. To the ordinary fancy of the Greeks it must have appeared at times that some of the Lapiths must have been old and some of the Centaurs young. Had the sculptors allowed their imagination the same licence the result would have been that they would have left us a record of what had been done by the Centaurs and Lapiths, or of what was believed to have been done by them; but they would not have told us how it was done. Therein lay the function of the artist, as Aristotle rightly observed, to tell how things were done, and not what things were done. As the lecturer had been led by these considerations away from the subject of emotion, he would go a step further, and call attention to what seemed to him to be a curious difference of style in the sculptures of the Parthenon metopes. In another metope which represents practically the same subject as the one before referred to, the Lapith and Centaur were massed together so as to present as large and as broad a surface to the light as possible, the shadow playing principally round the outer contours of the group. But such was not the case with the other metopes. There each limb had its true projection, its own light and shadow, and so far, it must be allowed that the sculptor was in the right, considering their position on the Parthenon, exposed as they were to the full light of day. We may further suppose him to be right because it was in following out that principle that those other metopes were sculptured which had won the greatest praise. Still, there was a strong source of attraction in the other method which admitted of a softening and toning down of the action. It exposed to the light large surfaces which a gentle hand might modulate with sunny pleasure in its ups and downs. It was high relief in a true sense, whereas the opposed principle was more nearly sculpture in the round. Having thus noticed some examples of the metopes and frieze of the Parthenon, the lecturer proceeded to discuss in detail the extent to which the groups of the pediments would serve the purpose of illustrating the expression of the emotions in sculpture. Was there any method or principle in allotting the sculptured decorations of the Parthenon which would enable one to forecast from an emotional point of view, the characters of the sculptures of the two pediments? H

believed there was. Having described the rizee, the metopes, and the pediment groups, he lecturer said that they presented a series of opportunities for the expression of emotion. Among the sculptors older a little than Pheidias, notice had been handed down of Pythagoras, and a statue which he made of Philoctetes offering so badly from the wound in his foot that the spectators could not but feel the pain of it. It seemed strange to find a group of boys playing at knuckle-bones among the works by Polykleitos, the contemporary and rival of Pheidias. Obviously enough, such a subject could be treated so as to express strong or even violent emotion, as in the remains of a marble group in the British Museum, executed in Roman times, where the one boy was so far carried away as to bite the arm of the other. We might make it for certain that that was not the view of the subject chosen by Polykleitos, who was never in search of strongly-expressed emotion. The lecturer concluded with a notice of the works of another fellow-pupil and contemporary of Pheidias,—Myron,—whose well-known work, the "Discobolus," or disk thrower, did not express so much emotion in the face as might be expected, though it was a question whether we were justified in looking for any strong expression in the face in those instances where emotion was venting itself in action, as Mr. Herbert Spencer put it. Mention was also made of Myron's statue of Ladas, the celebrated runner, who was represented in the attitude of leaning forward to the goal; of that statue, a Greek epigram said that the sculptor had stamped the whole figure with expectancy of winning the Olympian crown. According to the writer of that epigram, then, the statue of Ladas was an instance of emotion forcibly expressed throughout the whole figure.

[Mr. Murray's third and concluding lecture of this course, to be delivered on Monday evening next, will deal with the works of sculptors subsequent to Pheidias.]

GLoucestershire.

With the exception of Tewkesbury and the cathedral cities of Gloucester and Bristol, this county may be said to be comparatively unknown to architects. Perhaps the fact of its being surrounded by rich districts,—Oxfordshire, Wilts, and Somerset,—may account for this to some extent. Nevertheless, there is much interesting work, both ecclesiastical and domestic. So much has been written about Tewkesbury, that it would seem difficult to say anything new. The chapel on the north side of the transept is interesting, however, as being in a somewhat similar position as what is known as the Elder Lady Chapel at Bristol Cathedral. At Bristol, it adjoins the east wall of the transept, and is approached from it, and also from the north aisle of the choir. At Tewkesbury, the chapel was built along the north side, the length of the nave coinciding with the breadth of the transept, and the chancel extending beyond it eastward. The nave has been destroyed, though the traces against the transept wall show it to have been of four bays. The chancel arch is double with a central column,—an unusual feature. This still remains. Both examples retain their wall arcading, the carving at Tewkesbury being much coarser in character than the beautiful spandrels at Bristol, so well known for their grotesques. Some colour remains at Tewkesbury, the spandrels having had a groundwork of blue and red.

The fine apsidal choir, with its radiating chapels, is seen to advantage from the private gardens on the north-east side (see lithograph plate), and the marks of the Lady Chapel eastward are still visible.

Amongst the wealth of shrines and tombs possessed by this abbey is one of late character, ascribed to Abbot Coates, in the south ambulatory of the choir, having a rich segmental band of vine-leaves, with dragons in the spandrels. The abbot's tomb of the fourteenth century, on the south side of the south choir aisle, is chiefly remarkable for the immense heavy-looking finial that surmounts it. Here, again, a comparison may be made with Bristol, where, in the sacristy,—also of fourteenth-century date,—the finials to the arcading and the spandrels have the same heavy appearance, and approach to coarseness,—a defect which cannot be charged against the Tewkesbury work.

From Tewkesbury it is three miles to Deerhurst, where is to be seen an interesting series of caps, which show the gradual development of the Early English foliage from the Norman cushion form. South-west of the church is a fine old timbered house, known as Abbot's Court, and adjoining which is the Saxon Chapel recently discovered.

a fine old manor-house, built round two courtyards, with a fine bay-window and many interesting internal details.

Standing in a lonely valley at the back of the Cotswold, on the Roman road, is Northleach. The church here is probably the finest parish church in the county, excepting perhaps, Cirencester. It is of Perpendicular date throughout,

Deerhurst  
Abbot's Court & Saxon Chapel.

*Spencer  
1851.*

Across the country, at Stow-in-the-Wold, is a good church, finely situated on a hill, and visible for many miles. The early church of the thirteenth century has been destroyed, with the exception of the lower portion of the tower, and upon this has been raised a simple but very elegant Perpendicular superstructure of two stages, crowned by an embattled pannelled

and is remarkable for the curious treatment of its western tower, the fine parvise porch, elaborately decorated with canopied niches and figure-work. Inside is some stained glass, the remains of a fine reredos in the south aisle, good sedilia, and a font of the same date as the church. Both Northleach and Cirencester possess very good stone pulpits, the former

Stow-in-the-Wold.

*Spencer  
1851.*

parapet and angle pinnacles. Note the triangular stair lights. The tower is, as is often the case with early work, in an unusual position here, at the east end of the south aisle. The rest of the church is mainly Decorated, with later additions.

Near Stow is Icomb, or Iecomh, well worth a visit, for its perfect Early English church and

more nearly approaching the type found in Somersetshire. In the Cirencester example the sides are pierced above the floor-level. Cirencester is rich in screen-work, the chancel screen having an excellent cresting of birds, and the parclose screen, known as the "Jesus Chapel," in St. Mary's Chapel, should not be overlooked.

The New Drainage Works at the Houses of Parliament.—Sectional Perspective View of the Pneumatic Ejector Chamber.

No architectural visitor in Gloucestershire should pass over the fine old church at Berkeley, with its well-proportioned arcade, its stone rood-screen, and the mortuary chapel of the Berkeleys on the south side of the chancel, which, owing to the exigencies of the site, is not a rectangle, the south wall canting north-east,

Chichester  
crossing, rood screen.

making it narrower at the east end than at the west. The chapel has its own stone screen dividing it into nave and chancel, and a curious arrangement of squints allows the chapel altar to be seen from the nave of the church, whilst another gives a view of the high altar from the chapel. The tomb of James, eleventh Lord Berkeley, is rich in figure sculpture; amongst them a good St. George and the Dragon. Outside, on one of the pinnacles, is the same saint, elaborately worked amongst the crockets, and

in richness of effect reminding one of the appearance of the work at Rosslyn, near Edinburgh.

In various parts of the country are to be found fine examples of Domestic work: Southam House, near Cheltenham; Icomb Place, Berkeley Castle, Wanswell Court, Iron Acton, Little Sodbury (with a fine hall and oriel), and last but not least, Thornbury Castle, are all worthy of close inspection.

**Surveyors' District Map**—If we may judge by letters that have reached us, the Map of London, showing the boundaries of the Surveyors' districts, which we issued with the first four numbers of the present volume, is likely to prove as useful to architects and builders as we hoped would be the case. The Publisher has now made arrangements for mounting the sheets on strainers or rollers, for convenience of reference, as to which particulars will be found in our advertisement columns.

**Death of Sir Joseph Whitworth**—Mechanical science has sustained a great loss by the death of Sir Joseph Whitworth (which occurred at Monte Carlo), but, as we need hardly say, it has gained greatly by his life's work.

THE NEW DRAINAGE WORKS AT THE HOUSES OF PARLIAMENT.

ON Tuesday last we were enabled to inspect the new drainage works at the Houses of Parliament, which, however, are only completed in detail for a portion of the buildings, leaving the remainder of the work to be done in future recesses. But, as will be seen by the following particulars, for which we are mainly indebted to a pamphlet issued by the engineer of the works, Mr. Isaac Shone, the main part of the work has been done, and the source of the evil smells which have been so noticeable until lately within the building and its precincts has been removed.

It appears that in 1839 Sir Charles Barry laid down, under the middle of the Houses of Parliament, from north to south, a large, nearly flat-bottomed brick sewer, which discharged into a similarly constructed sewer in Abingdon-street, near the Victoria Tower. This sewer, owing to its bad form, excessive size, little fall, and absence of any means for flushing it, accumulated a large amount of sewage deposit, the gaseous emanations from which continually polluted the air of the Palace. In 1846 the smells from the Palace sewer were so bad that Sir Charles Barry consulted Mr. John Phillips,

E.E., who was then the Chief Surveyor to the Westminster Commissioners of Sewers, with a view to its improvement. Mr. Phillips, after examining the sewer, recommended that a narrow, deeply-curved invert, with a reversed fall, should be substituted for the old invert, and that it should be continued northward, across the Speaker's Green, into the outlet of a sewer in Bridge-street, which latter he found to be about 5 ft. lower than the sewer in Abingdon-street. Sir Charles Barry not only adopted and carried out these recommendations, but the increased depth enabled him to construct two main branch drains from near the lower end of the new portion of the sewer, for draining the east and west sides of the Palace at a much lower level than they were originally. By the better gradient thus obtained, and by the narrow and deeply-curved invert put in, the sewer, as altered, supplemented with ample flushing power, became self-cleansing, and it continued in this improved condition for a quarter of a century,—until twelve or thirteen years ago. At that time,—about 1873,—the Metropolitan Low Level Sewer, 7 ft. 9 in. in diameter, was put down through Westminster, and the Palace sewer was connected with it, its bottom at the junction being about 21 in. above the bottom of the Metropolitan Low Level Sewer. Ever since this work was done there has been daily, in dry weather, from 3 ft. 6 in. to 4 ft. in depth of sewage flowing on the bottom of the Metropolitan Low Level Sewer, and this created a constant head of sewage against the Palace sewer outlet, converting it into a creek for a length of about 200 ft., containing from 1 ft. 9 in. to 2 ft. 3 in. in depth of nearly stagnant sewage, which was always present upon the bottom of the Palace sewer. But, besides this, in wet weather the Metropolitan sewer was not only always filled with sewage water, but sometimes this water has risen to 10 ft. above the crown of the metropolitan sewer, or 13 ft. above Ordnance datum. During wet weather, therefore, the Palace sewer and its main branch drains have been filled with sewage and rain-water, which could not be discharged until the flood-water contained in the Metropolitan Low Level Sewer had subsided, by being cleared out by the pumps at Abbey Mills, Bow, and by running it off through the sluices at Blackfriars and elsewhere into the Thames. Hence, for twelve or thirteen years past the Palace sewer, as well as its main branch drains, have been periodically converted into a series of sewage reservoirs; and from these the sewage water, as it accumulated and filled them, pressed out the foul gases contained within them, up the various contributing drains into the Palace. This discharge of sewage-gas into the Palace has been going on more particularly at night-time, during the Sessions of Parliament, when the gas has been burning throughout the Palace, and when the waste hot-water and steam from the warming and ventilating appliances of the Palace were discharged into the drains and sewers, and fermented the sewage lying therein. In the early part of 1886 a Committee was appointed, Sir Henry E. Roscoe, F.R.S., being the chairman. One of the members of this Committee, Mr. L. H. Isaacs, fortunately had a thorough practical knowledge of the subject upon which they were asked to report. He deemed it desirable personally to examine the interior of the main sewer under the Palace, from the Victoria Tower to the point of discharge at the Speaker's Green; and, having regard to the state of the main sewer, this was a disagreeable, not to say courageous, work to undertake. At the termination of his subterranean survey he presented himself as a witness, and deposed to the state of things which he found to exist beneath the Palace. Subsequently, he repeated his examination of the main sewer, and deposed a second time to what he had seen. Mr. John Phillips, who had had a large practical experience as a sanitary engineer, and who had advised Sir Charles Barry as to the improvements which were effected in the drainage of the Palace about 1848, as already mentioned, was also asked to give evidence before the Committee. With that object Mr. Phillips made examinations of the sewer, and of some of the branch drains, under the Palace, and endorsed the views of Mr. Isaacs in regard to the faulty character of the same. He subsequently, from his special knowledge of the circumstances connected with the drainage arrangements both inside and outside the Palace, submitted to the Committee a plan for again improving the main sewerage arrange-

ments of the Palace, and rendering them perfectly independent of the metropolitan low-level sewer as a means of discharge by gravitation. This plan was supported by Major Hector Tulloch, R.E., Local Government Board Inspector, who had previously reported to the President of the Local Government Board upon the defects of the drainage of the Houses of Parliament. The Committee, after due consideration of the subject in all its bearings, recommended Parliament that the plan, as proposed by Mr. Phillips, on the Shone Hydro-Pneumatic System, should be adopted; and their recommendations have been substantially carried into effect.

On the preceding page is a sectional perspective view of the pneumatic ejector station, looking from the base of the Clock Tower in the direction of Westminster Bridge. Fig. 1 on the smaller diagram is a cross-section of the 1839 sewer, showing, by black colour, the invert

Fig. 1.

Fig. 2.

waterway necessary to pass through it the maximum quantity of sewage obtaining at the Palace when Parliament is in Session. The original sewer had a gradient of 1 in 923 only, but by the alteration suggested by Mr. Phillips in 1846 it was increased in 1848 to 1 in 315.

The new works, briefly described, consist (1) in improving the gradients of the main sewer and its principal tributaries; (2) in reducing the sizes of the sewers,—the main sewer, for example, from 10 ft. 6 in. high by 3 ft. wide, to one of 12 in. in diameter, as illustrated, by fig. 2; this latter figure also shows the waterway on the invert of the new main sewer, with its improved gradient, when that sewer is charged with the maximum quantity of sewage which obtains during the Parliamentary session. The chief tributary is reduced from 24 in. high by 15 in. wide, and laid at an average gradient of 1 in 372, to a pipe sewer of 9 in. in diameter, laid at a gradient of 1 in 309; (3) in providing superior flushing appliances (Shone's automatic hydraulic flushing ejectors) for the sewers, at a considerably reduced expenditure of water; (4) in providing an improved method of ventilating the main sewers; (5) in forming proper connexions between the drains and the main sewers, and giving facilities for inspection at the junctions; (6) in severing absolutely the large tunnel-like connexion between the Palace sewer and the metropolitan low-level sewer by means of a dam of brickwork shown in the sectional perspective view; in dispensing with the big cumbersome penstocks and flap-valve arrangements connected therewith, and substituting therefor a small 12-inch iron sewer, with sluice and reflux valve; (7) in providing, in case of need, improved automatic arrangements for permitting the palace sewage and rainfall to flow into the metropolitan low-level sewer by gravitation, on the principle heretofore adopted, independently altogether of the ejector system, but without the possibility of the foul gases from the metropolitan low-level sewer getting into the palace sewer; (8) in preventing the hot water and steam from the boilers, &c., from passing into the drains and sewers, and providing a separate and independent outlet for same into the Thames; (9) in providing means whereby the sewage and rainfall proceeding from the Houses of Parliament shall flow uninterruptedly therefrom both in dry and wet weather, irrespective of the height at which the metropolitan low-level sewer is discharging sewage, or sewage and rainfall in combination. This latter desideratum is effected by means of Shone's pneumatic sewage ejectors, which are fixed in a chamber (the interior of which is shown in the view) under the Speaker's Green, near the Clock Tower. These ejectors are placed below the level of the Houses of Parliament main sewer, so that the sewage and rainfall flows to and into them by gravitation.

There are three ejectors, one of 500 and two of 350 gallons capacity. They can be worked separately or unitedly, just as the flow of sewage or rainfall is small or large.

The compressed air required by the ejectors to expel the sewage and rainfall is supplied by air-compressors, driven by Atkinson's patent differential gas engines. There are four of these (of 4-horse power each) situated in the basement of the palace, about 650 ft. from the ejector station. The minimum and maximum quantities of sewage, and sewage and rainfall together, it is now difficult to estimate; but as one of Kaiser's patent counters is attached to each ejector, a practically accurate record can be kept of the quantities that will be received and ejected from time to time. When one engine and one ejector are insufficient, during periods of extraordinarily excessive rainfall, there is a float within the sewage manhole, adjacent to the ejector-chamber, which will rise and fall with the sewage and rainfall, and which will actuate one of Mr. Julius Sax's automatic electrical tidal water gauges. This apparatus is fixed within the ejector-chamber, and a duplicate of it is also fixed in the gas-engine room, both being very effectively operated simultaneously by the float. These instruments have faces resembling ordinary clocks, and the hands on them denote the exact level, in inches, of the water in the sewage manholes, from which the ejectors are supplied. The moment one engine is overcome the electrical apparatus rings a bell within the ejector-chamber, and in the gas-engine room, at one and the same instant, and then the attendant will set a second gas engine to work; but if the sewage continues to rise in the sewage manhole, notwithstanding the setting to work of a second engine, the electrical apparatus will continue to indicate such increased height, and the attendant will then put a third, and, if necessary, the fourth gas engine to work.

The works were divided into three contracts, the general contract (No. 1) being let to Messrs. John Mowlem & Co., of Westminster; and the special contracts (No. 2), embracing the supplying and fixing of the pneumatic and hydraulic ejectors, to Messrs. Hughes & Lancaster, Chester; and (No. 3) for the supply and erection of the gas-engine air-compressors, to the British Gas-Engine and Engineering Company, Queen Victoria-street, London. The cost of these special works has been about 11,000*l.*, but other works in connexion with them have been done by Messrs. Perry & Co., contractors, under the direction of Mr. John Taylor, of the Office of Works. The plumbing work has been done by Messrs. Dent & Hellyer. The whole of the work has been carried out under the general supervision of Mr. T. J. Jones, the Clerk of Works at the House of Commons.

Illustrations.

"SPRING TIME": DECORATIVE DESIGN.

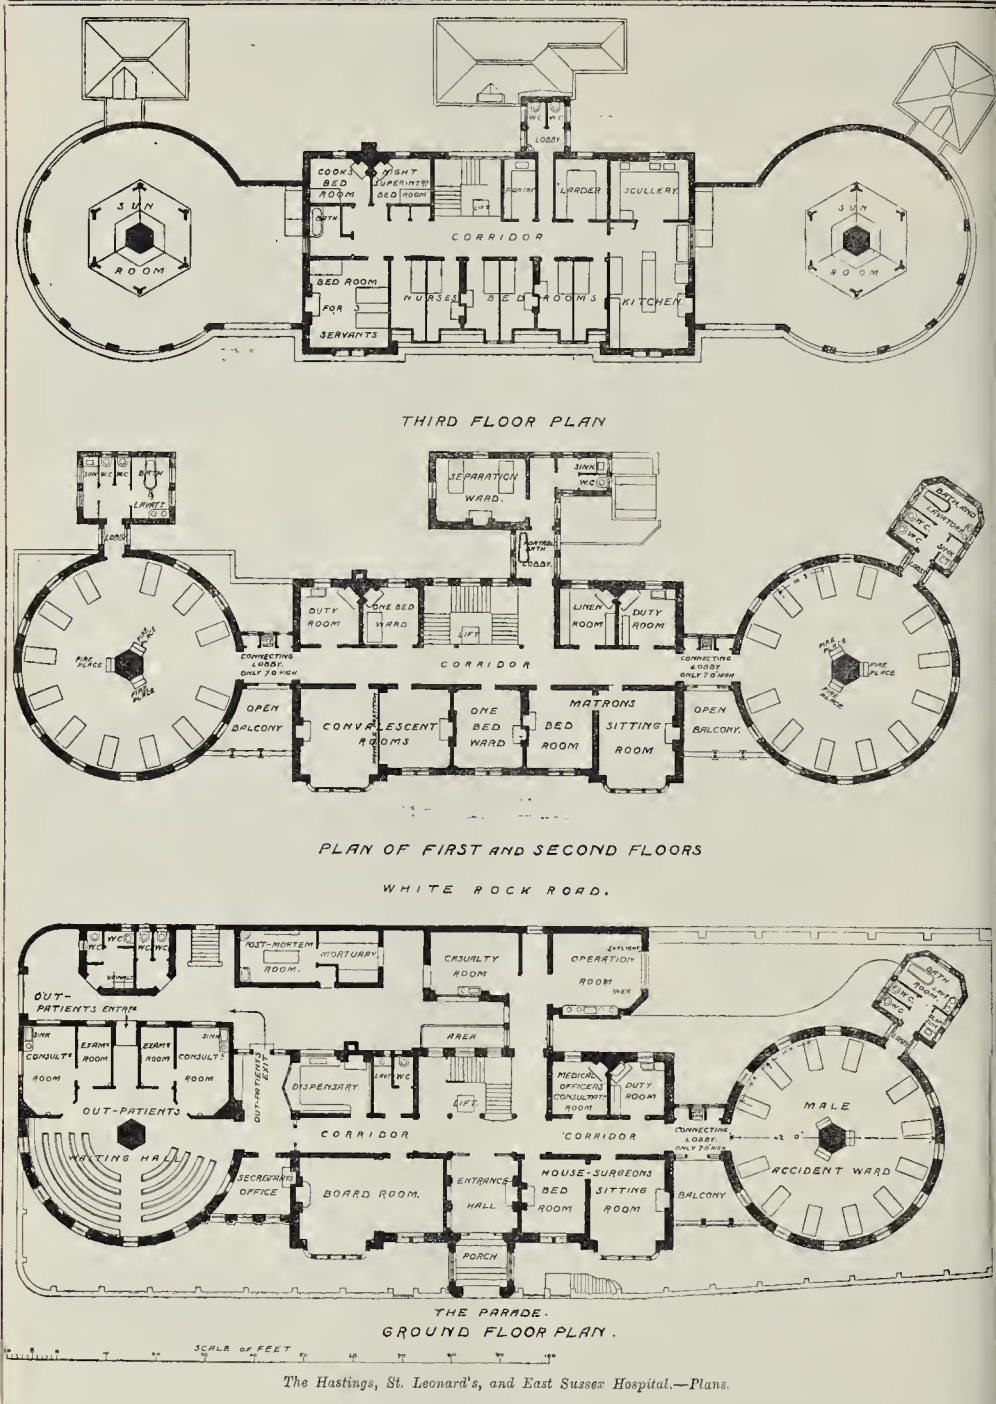

THIS design is the one which obtained the prize for decorative design in the Royal Academy Students' Competition for 1886, as mentioned by us at the time the designs were publicly exhibited. It was one of the few which fulfilled the proper requirements of mural decoration, being composed in one plane, and in a light key, and without any attempt at effects proper only to oil painting and easel pictures. The designer is Mr. Herbert J. Draper.

We may add that this is the design which was referred to by the President of the Royal Academy in his address to the students, when he congratulated them that, for the first time, the Academy had been able to commission one of the students' designs for execution. It will probably be executed in a London Hospital.

HASTINGS, ST. LEONARD'S, AND EAST SUSSEX HOSPITAL.

In December, 1884, we illustrated the designs for this hospital which had been prepared by Messrs. Young & Hall, and which had obtained the approval and sanction of the committee. The committee, however, failed to obtain the necessary funds, and the whole matter remained in abeyance.

In the early part of last year it was decided to considerably modify the original scheme for the new hospital, and plans on a much-reduced

The Hastings, St. Leonard's, and East Sussex Hospital.—Plans.

scale were accordingly prepared by the architects, Messrs. Young & Hall. Two schemes were submitted for the approval of the committee,—one having wards of the usual form, the other having wards of a circular form, a system which owes its origin to the eminent surgeon, Professor John Marshall, F.R.S.

Several members of the committee and of the medical staff having visited the Miller Memorial Hospital at Greenwich, which (the

first hospital with circular wards erected in this country) had recently been completed from the design of Messrs. Young & Hall, the circular system was, after much discussion, finally adopted, and the designs from which the present hospital is being erected were definitively approved.

The building is planned to accommodate sixty-eight patients in five circular wards of twelve patients each, four wards of one bed

each, and two separation wards of two beds each.

The central portion contains the general administration offices, with rooms for the resident medical officer, matron, nurses, and servants. The kitchen is placed on the top floor, and will be fitted with a complete gas-cooking apparatus by Messrs. James Slater & Co.

The wards are connected to the administrative department by means of corridors which are

Ingram House, Fenchurch-street.

only 8 ft. high, so constructed as to allow a free current of air to pass over them, and these lead to a broad balcony, so arranged that the patients can be wheeled out into it in their beds.

The mortuary and post-mortem room are placed on the ground floor, isolated from the hospital.

The building is constructed of red brickwork, and all dressings are of Portland stone.

Mr. H. L. Holloway obtained the contract in competition with eleven other builders, and is carrying out the work.

**THE COLIGNY MONUMENT, PARIS.**

The marble statue of the Admiral Gaspard de Coligny, of which we give an illustration this week, is intended to adorn the monument which is soon to be erected at Paris by public subscription. It is the work of M. Crank, one of the most eminent disciples of Pradier, and the author, among other works, of the winged Victory, which stands in the Square des Arts et M&etiers.

The monument is to be placed in front of the apse of the "Temple d'Oratoire" of the Louvre, and will therefore face the Rue de Rivoli, from which it will be separated by a small garden surrounded by an ornamental grille. It has a large pedestal in the form of a cenotaph, surmounted by two allegorical figures in marble seated on the extrados of a pediment. That on the right, symbolising "La Patrie," is grouped with a crown, bearing an inscription commemorative of the siege of St. Quentin, where the gallant warrior distinguished himself. The figure on the left represents Religion. Near it is engraved the ill-omened date of St. Bartholomew. Between these two figures an open Bible, sculptured in bas-relief on the base of the statue, recalls the source whence Coligny drew his patriotic valour and Christian faith.

The whole sculptural group is relieved against an architectural composition consisting of an order of Corinthian columns supporting an entablature, above which will be engraved the arms of the Coligny family.

The three figures carved by M. Crank, and which are still detained in the D&ep&ot des Marbres de l'Etat,\* are each 3 metres in height. The whole monument will be about 10 metres high by 7 wide.

We may add that the Committee, which includes all the leading persons of the "monde reform&e" of Paris, and is presided over by the Marquis de Jaucourt, has already raised in France and in the Protestant countries of Europe, and principally in England, a sum sufficient to warrant their commencing the work, as soon as the Municipality of Paris shall have officially approved it.

**WEST CROYDON CONGREGATIONAL CHURCH.**

This church is situated at the junction of the London and Campbell roads, Croydon. It is designed in the Early Decorated style of Gothic, arranged on plan with narrow aisles, nave with central passage and double transepts, and a small gallery at the west end. The tower, with the spire, rises to the height of about 150 ft. Vestries are provided at the rear for minister and deacons, as also a church-parlour. The organ-chamber is at the south side of the apse, and opens towards it, as well as to the church; it contains an instrument by Messrs. Hill & Sons, which cost about 1,200*l.* At the north side of the apse is the pulpit, which was the gift of the Misses Peacock, of Thornton Heath, and was executed by Mr. Sansom from designs by the architect. Externally the church is faced with Kentish rag, in drop-coursed work, finished with a fine joint. The dressings, mouldings, windows, &c., are in Monks' Park stone, from the quarries of Mr. Sanson at Bath. The interior walls are lined with Parleigh Down stone, relieved with bands of blue Bath, from the same quarries; the columns supporting the roof trusses are in similar stone, while the clustered columns to

\* Strangers passing through Paris who wish to see the statue of the Coligny monument should ask permission from M. le Pasteur Bersier, Boulevard Pasteur, 216.

the nave arches supporting the clearstory are in brown Portland. The fittings throughout are in pitch pine.

The following gifts have been made to the church:—A stained-glass triplet window at the west end, by Mrs. Peacock, executed by Mr. Frampton; and the clock and chimes, by Mr. J. Spencer Balfour, J.P., the work of Messrs. Gill & Co.

All the carving was executed by Mr. Sansom; Messrs. Vaughan & Brown did the gasfitting, and Mr. Boulting the warming. The ventilation of the building is by inlets built into walls, and the vitiated air is extracted by one of Boyle's ventilators. The work was carried out by Mr. James Holloway, from the designs and under the superintendence of the architect, Mr. W. D. Church. The foreman was Mr. Jones, and the clerk of works, Mr. Laurence. The cost of the building, exclusive of the pulpit, stained-glass windows, organ, and bells, was about 10,500*l.*

**INGRAM HOUSE, FENCHURCH-STREET.**

This building occupies the sites of four different premises that were acquired for its erection, except so much of the frontage as was taken for the widening of Fenchurch-street. It consists of three shops of moderate size, each having its basement, and of very extensive suites of offices and store-rooms occupying seven stories, and extending along the whole of the east side of Ingram-court. There is a sub-basement for storage, and a half-basement above it, lighted from Ingram-court. The principal entrance has a lobby panelled in teak, leading to the entrance passage and the staircase, which gives access to the offices. The floors of these parts are laid with mosaic pavement in ornamental patterns, by Messrs. Diespecker. The walls throughout the passage and staircase are covered with scagliola, by Messrs. Bellman & Ivey, the dado being of a very rich red, the capping of dark green, and the wall surface is of yellow. The staircase is of Cliff-wood stone. The windows of the staircase are of stained glass, by Messrs. Powell, of Whitefriars.

The building being designed with very large rooms on the ground and upper floors, which could be afterwards divided to suit tenants, considerable use was made of iron in columns and girders and fireproof floors, supplied by Mr. Archibald D. Dawney, of London Bridge House. The skylights are by Messrs. Marshall & Hatch.

The construction was so arranged that certain fireplaces were provided on the second and third floors in places where they could not be supported upon walls or piers on the lower stories. Strong rolled iron girders in sets of three were provided, as shown on the ground and first floor plans, the flanges being 4½ in. wide, to take the fronts and backs of the flues, while the flues themselves ran up between the girders. Provision was made on the first floor for building similar fireplaces afterwards if necessary, and this has been done as regards the back part of the building.

The plans throughout show the building as it was erected, leaving as much as possible to be determined by the requirements of the tenants. Certain modifications were actually made, but none that affect the principles of the arrangement.

The parts of the plan marked A show how it was necessary to slope off a small portion of the building in order to prevent a dispute about light with an adjoining owner.

The front elevation is of red Danfrices stone, with pilasters on first and second floors in dark Shap polished granite. The carving is by Messrs. Farmer & Brindley. The fronts to the shops were added when the shops were let, so as to accord with the views of the tenants. The front in Ingram-court is faced with Candy's terra-cotta bricks, which are of a warm white colour, and of very close texture.

The premises were built for Mr. C. J. Knowles, from the designs of Mr. Thos. Blashill, architect, the contractor being Mr. Edward Conder. Mr. Chas. Watkins was the clerk of works. The cost was about 16,000l.

*Houses at Chicago.*—In referring to the sketches published last week (p. 148) we have unwittingly done the injustice to their architect, Mr. S. G. Beaumont, of consigning him to a premature grave. The information which we understood to refer to the architect of the houses, viz., that he was educated in a London office and died shortly after going out to Chicago, referred, Mr. Townsend tells us, to the draughtsman, Mr. G. W. Tait, who made the sketches, and whose signature is appended to them.

#### BRITISH ARCHAEOLOGICAL ASSOCIATION.

At the meeting on Wednesday, the 19th, Mr. W. De Gray Birch, F.S.A., in the chair, reference was made to the death of Lord Idlesleigh, one of the vice-presidents of the Association. The Rev. Scott Surtees exhibited a large collection of fragments of Roman pottery and brick found at Pountneys Bridge, Dinsdale, on the River Tees. Mr. Loftus Brock, F.S.A., exhibited Roman pottery of various kinds found at Vinovia (Bincchester) during the recent excavations there. Mr. Roope exhibited a fine ancient Mexican howl, similar in style to some others shown on a previous occasion. Mr. Irvine forwarded sketches of Roman graves, formed of tiles of large size, made for this use, of peculiar pattern, one tile being sufficient to form the end of each compartment. Each tile bears a legionary stamp. A paper was then read on the "Early Sculptured Crosses and Stones of the Isle of Man," by Mr. Romilly Allen, F.S.A. (Scot.). These crosses are worked in the local slate of the island, and are found in considerable numbers, the earliest being a pillar stone at Santon, having an inscription in Roman capitals, AVI MONUMENTI; but the inscriptions are almost entirely Scandinavian, with runes. The forms are not unlike those of the early crosses of Scotland, Ireland, and Wales, but the ornamental patterns more frequently cover the whole of the shaft, without being divided into panels. The symbolism of the figures was dwelt upon, and it was stated that only a single representation of the Crucifixion has yet been found. The story of Sigurd and Tafna is shown on one of the crosses. The paper was illustrated by a fine collection of photographs and rubbings of the monuments described. A paper was then read on Roman Chieftain, by Mr. C. Roach Smith, F.S.A. The whole of the inscriptions found in the city were described.

#### THE ARCHITECTURAL ASSOCIATION. PROFESSOR CORFIELD ON "HOUSE SANITATION."

The seventh meeting of this Association for the present session was held at 9, Conduit-street on the 21st inst., Mr. J. A. Gotch (President) in the chair.

The following new members were elected, viz., Messrs. J. K. Wilson, G. W. Burrell, T. W. C. Woolf, S. Tugwell, S. Walker, and G. C. Taylor.

A letter from Mr. Thos. Blashill was read, referring to the forthcoming Italian excursion, and recommending those who intended to take part in it to study beforehand the information in regard to the different places they were likely to visit.

Professor Corfield then gave a lecture on "House Sanitation." He began by asking his hearers to suppose they were inspecting a house in regard to its sanitary arrangements. In his opinion, the proper place to commence with would be the roof. Going on the roof, they should look to see if there were any ventilating-pipes, their size, and the materials they were made of. Such pipes should be of the same size as the pipes they were intended to ventilate, and in the next place they should be above all the parts of the building, with the single exception of the chimneys. But they should not be in any way sheltered or protected by any building or wall, nor be against a wall or side of a chimney, for when the wind blew against the wall or chimney, the air in front of the wall or chimney, and over the top of the ventilating-pipe, would be under pressure, and would descend the ventilating-pipes, reversing their currents, for they were intended as outlets for the air of the soil and waste pipes and house drains, and if what should be the outlets were so constructed that air could blow in at them instead of being drawn out, then the insects in the front areas or back yards of houses would become outlets, and prove a great nuisance. A great variety of cowls had been made and used for crowning these pipes, with the idea of helping the extraction of the air. As to the utility or otherwise of cowls, he would not speak too positively, because a committee of the Sanitary Institute had been at work for some time on the question, had made an exhaustive report, and would shortly give the world the results of a series of experiments. He did not know what those experiments would prove, but he believed he might safely say that it was unnecessary, in almost any position, that there should be a cowl at the top of any soil-pipe. The only thing requisite was to have a few wires across the top of the pipe, and some holes or slits a little way down the side. The wires would prevent anything getting into the pipes, such as birds, which were fond of building their nests where there was a bend a little way down. The holes or slits would be of great use in allowing the air to blow through on the occurrence of heavy snowstorms, especially when the snow froze together as it fell, blocking the tops of the pipes. On the roof, too, they must look for the way in which the rain-water was got rid of. That was best done by pipes, front and back, carried down outside the house, and made to discharge in the area or yard below, either above a gully grating, or below the grating into a ventilated space above a trap. Rain-water pipes were, however, frequently carried down inside the house. It was not an uncommon thing to find builders, and even architects, who would not allow the pipes to go down the front of the house, so that the rain-water pipes were either embedded or encased in the walls, or carried down inside, often passing through the bed and sitting rooms into a drain in the basement. The pipes so improperly placed were frequently faulty in their jointing, and were, besides, liable to rapid decay, and especially when they were imperfectly trapped at the foot, they were mere channels for the admission of foul air into the dwelling. If trapped at the foot, and then connected with the drain, it made little difference, because, even with water in the trap, they were apt to become very foul. In the intervals of storm or rainfall, the foul air from the drains passed, in accordance with the law of diffusion of gases, through the water in the trap, filling the rain-water pipe with foul air, and nearly as foul as if no trap existed at all. He had frequently known cases of illness to persons sleeping in bedrooms the windows of which looked out behind parapets immediately over the rain-water gutters, often at the very point

where the rain-water pipe went down to the drain, and that even where the down-pipe was provided with a trap at its foot. Great mischief, too, was often caused in cases where, to avoid taking the pipe down the front of the house, the rain-water was carried in an open gutter or trough through the top part of the dwelling, either to a down-pipe in the centre of the house or to a pipe at the back of the house. These troughs or gutters were at one time very commonly carried through the house in this way, either just below the ceiling of the top story, under the attic floors, or in the space between the top ceiling and the roof covering. Sometimes the heads of the internal down-pipes for rain-water were placed under the bedroom windows. He had known many instances of illness arising through foul air engendered in such rain-water gutters, into which leaves, soot, and dirt were washed. Rain-water pipes were not unfrequently, but very mistakenly, made to serve also as soil-pipes. The heads of such pipes were necessarily (being used for carrying off the rain-water) often close to windows, so that much of the foul air emanating from them entered the open windows, and was inhaled by the occupants of the rooms. The first thing to look at inside the dwelling, either in the roof or in the attics, would be the cistern. The material of which it was made should be noticed, for a good deal both of truth and nonsense had been said on this subject. The common material for a cistern was lead, not in the way in which our ancestors used it, but as a lining to a wooden cistern. Now lead was not nearly so mischievous a thing for cisterns and pipes as it was commonly made out to be. Very few waters would attack lead, though soft water, and rain water especially, would do so. The effect of an ordinary town water on lead was practically inappreciable, and even in the case of Glasgow, where a most necessary change was made some years ago from the polluted water of the Clyde to the pure and soft water of Loch Katrine, there was no outbreak of lead-poisoning. Galvanised iron was now fast replacing lead as a material for cisterns, and a very admirable material it was, though there were certain waters which would dissolve zinc (and galvanised iron was simply iron dipped in zinc), the salts of which were poisonous. It was important to observe whether the cistern was clear, and capable of being easily kept in that condition, being of no importance to the health of a house as the waste or overflow pipe of the drinking-water cistern. That pipe need invariably be connected directly with the drains, and in that case the foul air, containing possibly the poison of one or more specific diseases, would get into the cistern. Even should the foul air not contain such poison, it would contain foul, putrescent, organic matter, suspended or else in a gaseous state, which the drinking-water would readily absorb. He had seen, in many old houses, the "standing wastes," as they were termed, of drinking-water cisterns connected directly with their drains, soil-pipes, and traps of water-closets. He was afraid that in many old houses that highly pernicious arrangement still existed unsuspected. Such waste or overflow pipes ought, of course, to be entirely dis severed from all connexion with drains, soil, or waste pipes. There were several ways of disconnecting them, but they should never be carried directly over a foul gully. A very common but very inefficient device was to put a siphon trap on the waste-pipe, or make a bend on it before it entered the drain, but such a trap did not always remain full of water, and even if it did it would not prevent the admission of foul air to the cistern by absorption and diffusion, in the way previously mentioned. The lecturer proceeded to give several examples of the extraordinary attempts on the part of plumbers which did not understand the true principles of sanitary science to remedy these defects. Denning next with a housemaid's sink, the lecturer stated that its position should be against an external wall, with a window capable of affording ample ventilation. The commonest form was the wood sink, lined with lead, but the best material was white glazed stoneware, which could be kept perfectly clean and sweet, whereas oily matter adhered to lead, and rendered it difficult to keep clean. The waste-pipe of the sink was frequently wrongly connected with some part of the soil-pipe. In order to prevent the ingress of foul air a P-trap, or what was incorrectly termed

siphon-trap (for if it would siphon out it would be a trap) should be used. The waste-pipes from such sinks should always end in the open air over the trap of a gully, or into the side of the inlet of one, or over an open pipe head. The waste-pipe of an up-stairs sink should either be carried through the external wall and discharged into an open pipe head or taken down and disconnected at the foot, being at the same time carried up through the roof full bore or ventilation. The bell-trap was often used for such sinks, the waste-pipe being connected with the soil-pipe. A more improper or highly dangerous arrangement could not be conceived, or when the bell was taken off there was no trap, and the pipe would, of course, ventilate itself into the house. Where a series of waste-pipes or closets discharged into the same down-pipe there was great danger of some of the traps becoming siphoned out and unsealed unless the main pipes and the branch pipes as well were efficiently ventilated. This was shown by a series of demonstrations made in face of the audience by the lecturer. Every pipe down which foul water went should be as small as possible, so that it might be self-cleansing. The waste-pipe of a bath should be trapped and disconnected in very much the same manner as the waste-pipe of a sink. The waste-pipes of sinks, although disconnected from drains or discharging over open gullies, should also be trapped immediately under the sink. If not they would become, and especially at night, inlets for outside air, which would be more or less tainted by the impurities which would necessarily adhere to the inside of the pipe. The up-stairs water-closet should be against an external wall, with a window opening into the air. Water-closets are often placed in improper positions, such as in the very centre of the house or under the stairs, and very often no attempt was made to ventilate them or they were very imperfectly ventilated into a shaft going up through the dwelling, into which rooms were also ventilated. Such things as this should be done away with, and the closets put against the outside walls. The soil-pipe into which the water-closet discharged should be outside the house, for, however perfect such pipes were at first, they did not remain so for ever. The best material was strong lead pipe with properly soldered joints, which could be made stronger than the pipe itself, thus giving much less chance of leakage than iron pipes having what might be called mixed joints. The soil-pipe carried down outside the house should be taken into a 6-in. drain, passing into a trap with an air inlet above the water-line. The soil-pipe might be connected with the drain at its foot, with the view of being the outlet ventilator, and be disconnected from it by a disconnecting trap, in which case the drain would have to be separately ventilated by an outlet-pipe carried up above the roof. If soil-pipes were not ventilated they would ventilate themselves sooner or later, for the sulphuretted hydrogen and other gases arising from sewers would act upon the lead in such a way as to eat holes into it and thus make their escape. The lecturer here exhibited a piece of piping showing hundreds of little holes eaten into the lead in this way. The soil-pipes inside houses were often placed in almost inconceivable positions, sometimes horizontally under floors, or placed in walls, covered over and plastered, so that nobody knew where they were until some one was taken ill, and on examination a soil-pipe, riddled with holes, was found, perhaps, in the wall immediately behind the bed-head. In all upstairs water-closets the traps should be part of the soil-pipe, and not part of the closet apparatus itself, as it was in so many earthenware closets. The reason why he condemned such closets was that if, for instance, there was an earthenware basin with an earthenware trap all in one piece, the weak point would be the joint between the trap and the soil-pipe, which would be a joint between two different materials, and necessarily more or less weak. Therefore, for up-stairs closets, discharging into lead soil-pipes, there should be lead traps soldered. In that case, if the apparatus got shifted in the least, the joint that would go would be the one between the apparatus and the trap, or, in other words, the one above the trap, and not the one between the trap and the soil-pipe, as would be the case in the event of a settlement of one of the combined earthenware closets and traps to which he had referred. To protect the ceilings below the floor in case of overflow of the basin or leakage of a valve,

it was usual to put a lead tray, called a "safe,"—a word the most inapplicable of any in the language to the contrivance as commonly constructed. The waste-pipe of the safe-tray should be carried direct through the external walls, and made to discharge into the open air; it should be provided with a little brass flapper to prevent draughts. The apparatus most commonly used in old houses was the pan-closet, which could not be too strongly condemned. It was a curious thing, and one not generally known, that long prior to its introduction the valve-closet had been invented and brought to a considerable degree of perfection by Alexander Cummings in 1776, the main difference between his closet and that now in use being that in his the valve was really a slide to let the water out. That closet was patented in 1776, an improvement being made upon it by the well-known Bramah, who made it more workable, though he did not improve it in principle. Practically in the form in which Bramah had left it it had been used ever since. The valve-closet had great advantages, one of which was that it held a large quantity of water in the basin, but as originally devised it had certain disadvantages that had not yet been quite got over. The first of these was that it was supplied with water only at one part of the basin. Valve-closets were now made with flushing rims, which, however, necessitated a large supply of water, and larger pipes. The next thing was the overflow-pipe from the basin, which might get siphoned out in the following manner. Below the valve was the valve-box, and below that the trap. When a large volume of water was discharged from the basin, it went into the valve-box, and through the trap. That partly exhausted the air in the valve-box, so that when the valve was shut, the water drained out, leaving the valve-box in a state of partial vacuum, and thus the overflow-pipe became untrapped. The difficulty was got over in several ways, one of which was to ventilate the valve-box by a pipe carried through the external wall. Again, if the overflow were opposite the handle and passed into the valve-box opposite the valve, when the handle was pulled up some of the contents of the basin were shot into the outlet of the overflow-pipe. The result was that the overflow-pipe and the little trap at the bottom got very foul, so that the proper side for the overflow-pipe valve was the left-hand side, because when the valve was opened it closed against the overflow-pipe and prevented anything getting into it. The valve-closet was for long displaced by the pan-closet on account of the cheapness of the latter, and possibly because of its being well advertised at the commencement. The first disadvantage of the pan-closet was the conical shape of the basin, and it had a large iron receptacle beneath it called the "container," which got very foul, for it was a veritable "container" of filth; so that every time the handle was pulled the foul air was forced up into the house. That evil was only very partially cured by having a ventilating pipe, carried up outside from the "container." The evils of the pan-closet were intensified when such an apparatus was fixed over an old-fashioned D-trap, which was in reality a miniature cesspool, and could never be thoroughly flushed out. The water-closet on the ground-floor was often necessarily placed in such a position that it required a separate soil-pipe, which was more often than not left unventilated. All water-closets should invariably be supplied from cisterns which did not supply taps. It was of no use to say that drinking water or water for culinary purposes was only to be drawn from one particular tap. Practically every tap must necessarily be looked upon as a tap for supplying drinking-water, for servants and others would replenish water bottles and jugs at the nearest tap, any injunctions to the contrary notwithstanding. Therefore, draw-off taps should under no circumstances be supplied from the cistern that directly served the water-closet. The best thing was to have a separate cistern to supply the water-closet, and the only other way of meeting the difficulty was to have water-waste preventing or intercepting cisterns between the main cisterns and the closets. Closets in basements were commonly hopper or "wash-out" closets. The ordinary long conical hopper was a very bad form of basin, but what was known as the "short hopper" was a great improvement. This was not a regular cone, being more vertical at the back

than in the front, and having also a flushing-rim. The traps should be simple bends, either P or S traps, and in the case of basement-closets should be stoneware traps cemented to stoneware drains. A disadvantage of hopper closets was that they held no water in the basin, only in the trap. That had been partly got over without employing complicated apparatus by the invention of the "wash-out closet," which retained a small quantity of water in the basin, and in which the outlet was at the side or in front of the basin, there being a weir over which the water and the other contents of the basin had to go to make their way into and through the trap. Various forms of this type of closet had become favourites, and especially the pedestal closets. The disadvantage of the wash-out closets which he had seen was that the weir, before referred to, was apt to become fouled, and no amount of flushing would keep it clean. Unless the handle of such a closet was well pulled the basin got extremely foul, so that on the whole the small short hopper was a superior apparatus to the various forms of "wash-out" closets.\* The "plug" closet had an outlet at the side, closed by a solid plunger, but this form had the disadvantage that one could not see the outlet, which was apt to get clogged with paper and other adherent matter. In connexion with scullery sinks, fat-traps were, as a rule, quite unnecessary, and all that need be said about them was that the waste-pipe should be disconnected from them. In inspecting the basement of a house, bell-traps would frequently be found in the floor. These were exceedingly mischievous and dangerous. There should be no traps in the basement of a dwelling connecting with the drains; and if there must be gullies there, they should be made to discharge outside the house, and entirely disconnected from the drain. As to the drains themselves, it should be seen whether the soil-pipes were ventilated, and so on; and if there were inspection chambers, it was an easy matter to examine them. Brick drains under houses were highly improper drains; they would not hold water, and rats made their way through them into the dwellings. Wherever rats went, the foul air followed, and thus the existence of rats in a house was always a very suspicious circumstance. The best way to test the water tightness of a drain was to block it at the lower end, filling it with water to the upper end, marking the level, and allowing the water to stand for half an hour or longer. If the water did not remain at the same height the drain was not, of course, water-tight. A good test of the efficiency of traps, &c., was by blowing in smoke, which, if it escaped in various parts of the house, showed that the traps were not efficient. A third plan was to discharge a specially-made rocket into the drain, thus causing an immense amount of smoke from any leaks that might exist. Drains should be water-tight and smoke-tight, but the better test was to be water-tight. In the case of new drains, they should be tested after being filled in as well as before. Cast-iron pipes coated with Angus Smith's solution were now largely used for drains. These iron drains had the advantage over those of stoneware of only having a joint every 6 ft. Stoneware drains, however, were made of a material which was absolutely unalterable, which water and acids would not touch, and they were smooth inside. No doubt an iron pipe could be made gas and water tight now, but what authority was there to show that it would be so in ten years' time? He answered, "none"; iron was a perishable material, rusted by moist air, and affected by acids. Even when said to be coated with a preservative solution, could they be sure of its being protected everywhere? Only the other day he saw a Barfield iron pipe eaten through and through merely by drinking-water. It was, therefore, a wrong principle to use a material known to be perishable, instead of a material like stoneware, which was practically unalterable. The method most in favour for jointing iron pipes was to caulk the

\* We cannot agree with Professor Corfield here. No doubt some forms of wash-out closet require a large flush of water to ensure clearing everything over the weir, and some of the waste-preventing cisterns now made are too small for safety in regard to any closet of this type. But the type of pedestal closet in which the water is driven forward across the basin to the weir through a series of pierced openings, so as to come with considerable force, appears to us as perfect a sanitary closet as can be made. Other types of "wash-out" basins we have found work very well with a large flush, and all forms of closet ought to be liberally supplied with water, if only to ensure proper carriage to the drain.—Ed.

**A House of Straw.**—It is stated that at the forthcoming American Exhibition, which is to be opened on May 2nd at Earls Court, Kensington, will be a house of straw, now being made in Philadelphia. This house is an American suburban villa, "two-and-a-half stories high," and covering a space of 42 ft. by 50 ft. It is built entirely of materials manufactured from straw, foundations, timber, flooring, sheathing, roofing—everything, in fact, including the chimneys, the material being fireproof as well as waterproof. The inside finish will be in imitation rosewood, mahogany, walnut, maple, ash, ebony, and other fine woods, the straw lumber taking perfectly the surface and colour of any desired wood.

**Timber-Drying.**—We have already described Mr. Philip Parsons's "Common-sense" Patent Drying-kiln. We hear that Mr. John T. Chappell, the well-known builder and contractor, is erecting at his works, Thames Bank Wharf, Pimlico, two large drying-rooms, each 43 ft. long, on the "Common-sense" system.

The Student's Column.

FIELD WORK AND INSTRUMENTS.—V.

Surveying Instruments.

V.—THE CROSS STAFF.

THE cross staff consists in its simplest form of a rod, having a spike at its lower end for fixing into the ground, and two pairs of sights attached at right angles to one another at its upper end. Sometimes these sights are made with hinged joints to fold down, and at other times two fine grooves are sawn at right angles to one another, through a block of wood, which forms the head of the instrument.

Fig. 1 shows a cross staff head with brass fittings. The rod which connects it to the ground is set up, and fixed plumb over the point at which the right angles are required to be set out. The head consists of an octagonal brass box having slots in four of its sides, two of each being in line with one another through the centre of the instrument, and so cut that a broad opening comes horizontally exactly opposite a small circular opening, the latter serving as an eye-piece. In the centre of each of the broad openings shown below A and above D in fig. 1, are fixed wires or horse-hairs, which are intended to range the eye in adjusting the instrument over the rod upon the main line, and to act as a guide in setting out the cross line. Narrow openings with a small circular hole at top and bottom are provided opposite one another in each of the four remaining sides of the octagon, as shown between A and D in fig. 1. On the top of the cross staff head is shown a compass box, which can be revolved round by the hand, while the lower octagonal portion remains fixed. By means of this compass the magnetic meridian can be obtained with reference to any required direction. This is accomplished by setting the points on the compass box, marked north and south, as near as possible in the direction of the line under observation, and allowing the needle to float freely on its centre; then when the needle is at rest the angle which the magnetic meridian makes with the given line can be read off the graduated ring, which is marked round the edge of the compass box. By means of a small catch or trigger in the side of the box, situated in the rim where the word "compass" is marked in our illustration, the needle can be thrown off its bearing when not in use.

The cross staff is sometimes constructed in a circular form instead of the octagonal shape shown in fig. 1, and may be fitted with a rack and vernier, in addition to the compass box,

as shown in the accompanying cut. When this is done, the upper portion is made to revolve upon the centre of the box over a graduated circle fixed upon the circumference of the instrument, so that when great accuracy is not of importance, any angle may be thus set out approximately.

The accuracy of an ordinary cross staff may be tested as shown in figs. 2 and 3, where A, B, C, D, represents an enlarged sectional plan of the instrument shown in fig. 1. Having set up the cross staff vertically over the point E by means of the rod, which is fixed plumb in the ground, the eye is applied to the small opening at A, and ranged by the vertical hair or wire in the broad slot at C, the pole H is fixed at any convenient distance in the direction of the line of sight A C. Then, without moving the cross staff, the eye is applied at the small opening at B, and ranged by the vertical hair or wire in the broad slot at D, the pole F is fixed in the ground in the direction of the line of

sight, B D, which should be at right angles to the direction A C. Having done this, we next turn the cross staff round a quarter of a circle, so that when half-reversed, the position indicated by the letters on fig. 2 take the position shown in fig. 3. If when the line of sight A C points towards F, and the line of sight D B points towards H, the poles F and H, as set out in fig. 2, still remain, when viewed in fig. 3 in the lines of sight A C and D B respectively, the instrument is correct. If not, it must be returned to the makers for adjustment.

The cross staff is used for setting off perpendiculars from a base line that are too long to be approximately estimated by the usual tape or offset rod measurements, also for laying-out streets and building lots, and for setting out lines of cross-sections at right angles to a longitudinal direction, preparatory to taking levels. In the latter case the instrument compares itself as being sufficiently simple for a sharp intelligent chainman to be trusted to assist the surveyor in setting out his transverse sections, whereas an optical square or box sextant could only be used for this purpose either by the surveyor himself or a competent assistant.

VI.—THE PRISMATIC COMPASS.

The prismatic compass is shown in fig. 4 open ready for use, consisting of a glass-covered box containing a magnetic needle, which turns upon an agate centre. The needle is either attached to a card, as shown, or to a light graduated silver ring, which revolves with it. The ring or card has its outer edge graduated into degrees and half degrees, sometimes subdivided into 20 min. or thirds of a degree. That known as Major Hutchinson's pattern constitutes the Woolwich and Sandhurst instrument, and consists usually of a box about 2½ in. diameter. When packed in a leather sling case it is very portable, and largely used in military surveying.

A magnifying prism, situated between A and B in fig. 4, is attached to one side of the box, and made to slide up and down in a groove, so as to obtain a proper focus for reading the divisions distinctly upon the circle underneath. Upon the opposite side is attached a vane having a fine thread marked C down its centre. This vane is equal in height to the diameter of the box, and has a hinged joint so as to turn down flat upon the glass, or upon the fixed cover plate over the glass. This cover is indicated in fig. 4 by only a portion of the card being seen. When turned down, this vane lifts the card off its bearing, and the needle ceases to act. When turned up, as shown in fig. 4, the needle is free to turn, and the instrument must be held horizontally so that the card may play freely on its centre; otherwise the results obtained will not be accurate. The sliding framework by which the prism at B can be raised or lowered for arranging the focus, is also connected by a hinged joint so as to fold back, and be easily packed in the case when not in use. In order to show bearings in degrees to the east of north the card is graduated from the south, reading west, as shown in fig. 5. The numbers also are inverted upon the card, so that they may be refracted in an upright position through the prism of glass while viewing the direction required. The vibrations of the compass card when playing freely, can be checked by gently pressing a small spring, not shown in the illustration, but generally placed in the side of the box under the sight vane C, and below the level of the floating card. When the compass is held over a station point or any selected point in a line, and an object is viewed through the hole and slit in the prism at B, the instrument is turned horizontally by the hand until the fine thread in the vane at C bisects the point under observation. When the card is at rest, the number of degrees indicated in the line of sight is read through the prism. If, under certain circumstances, an increased amount of light should be found necessary in order to read the figures correctly, the card can be clamped while at rest, and the instrument tilted up a little above or below the horizontal, until there is sufficient light upon the card to see the divisions distinctly.

**Tanagra Terra-Cotta Reproductions.**—Messrs. Bellman & Ivey wish us to say that they are not the makers of these, which are made by Mr. R. Lechner, of Vienna, whose sole London agents they are.

PRISMATIC COMPASS

— HUTCHINSON'S PATTERN —

FIGURE 4

$$360^{\circ} - 337^{\circ} = 23^{\circ}$$

MAGNETIC MERIDIAN—THE PRISMATIC COMPASS IS HELD IN THE DIRECTION OF A GIVEN LINE, THE BEARING OF WHICH IS REQUIRED—THE INSTRUMENT IS THEN TURNED HORIZONTALLY IN THE HAND UNTIL THE VERTICAL SIGHT VANE AT C, WHEN VIEWED AT B, COMES IN THE DIRECTION OF THE GIVEN LINE. THE FLOATING CARD IS ALLOWED TO SETTLE, AND IS THEN MAINTAINED AT REST BY PRESSING THE SPRING STOP THROUGH THE PRISM OF GLASS AT B—AS SHOWN UPON THE PLAN OF THE FLOATING CARD, THE ZERO OR 360° CORRESPONDS WITH THE SOUTH POLE IN THE MAGNETIC MERIDIAN, 90° IS MARKED ON THE WEST SIDE, 270° ON THE EAST SIDE, AND 180° DENOTES THE NORTH; HENCE IN READING THE CARD AT A, THE DIRECTION OF THE MAGNETIC NORTH, WILL LIE TO THE LEFT HAND SIDE OF THE SURVEYOR, WHEN THE ANGLE READ, IS LESS THAN 180°, AND TO THE RIGHT HAND SIDE OF THE SURVEYOR, WHEN THE ANGLE READ, EXCEEDS 180°—THE EXACT DIRECTION OF THE MAGNETIC MERIDIAN, WILL BE IN A LINE, MAKING AN ANGLE WITH THE GIVEN LINE; AT THE POINT OF VISION, EQUAL TO THE NUMBER OF DEGREES READ UPON THE CARD, WHEN THIS ANGLE IS LESS THAN 180°, BUT IF THIS RESULT EXCEEDS 180°, THE ANGLE OF DEVIATION, AT THE POINT OF VISION IS EQUAL TO THE DIFFERENCE BETWEEN 360° AND THE NUMBER OF DEGREES READ UPON THE CARD.

## MEETINGS.

SATURDAY, JANUARY 29.

*St. Paul's Ecclesiastical Society.*—Annual Meeting. 2.30 p.m.

MONDAY, JANUARY 31.

*Royal Institute of British Architects.*—Mr. William Simpson, F.R.C.S., on "Med. Architecture: Notes made in Persia and other Countries." 8 p.m.

*Royal Academy of Arts (Lectures in Sculpture).*—Mr. A. S. Murray on "Greek Sculptures—Expressive of the Emotions: after *Phidias*." 8 p.m.  
*Society of Arts (Junior Lectures).*—Dr. Thudichum on "The Diseases of Plants, with special regard to Agriculture and Forestry." 11. 8 p.m.

TUESDAY, FEBRUARY 1.

*Society of Arts (Applied Art Section).*—Opening address on "The Present Condition of Applied Art in England, and the Education of the Art Workman. By Mr. T. Armstrong, Director of the Art Division, Science and Art Department." 8 p.m.

*Institute of Builders.*—Third Ordinary General Meeting, to receive report of Council, &c. 3.30 p.m.

*Institution of Civil Engineers.*—Discussion on Mr. W. J. Dibdin's and Mr. W. Sando Crisp's papers on "Sewage Sludge and its Disposal." 8 p.m.

*Society of Biblical Archaeology.*—Rev. C. J. Ball on "The Metrical Structure of Zephaniah." 8 p.m.  
*Birmingham Architectural Association.*—Discussion, to be opened by Mr. Heuman, on "Stonework at Terra-Cotta." 7.30 p.m.

WEDNESDAY, FEBRUARY 2.

*Civil and Mechanical Engineers' Society.*—Mr. W. Lee Beardon on "House Drainage." 7 p.m.

*Society of Arts.*—Dr. Alfred Carpenter on "Sewage Irrigation." 8 p.m.

*British Archaeological Association.*—(1) Mr. W. de Gray Birch, F.S.A., on "The Domes in England and the Rebuilding of London by King Alfred." (2) Mr. J. T. Irvine on "Companion Plate, Peterborough Cathedral." 8 p.m.

*Builders' Foremen and Clerks of Works' Institution.*—Ordinary Meeting. 8.30 p.m.

THURSDAY, JANUARY 3.

*Institution of Mechanical Engineers.*—Fortieth Annual General Meeting. 7.30 p.m.

*Royal Archaeological Institute.*—Mr. Albert Hartshorne, F.S.A., on "Blythborough Church." 4 p.m.

*Edinburgh Architectural Association.*—Mr. John Kinross, on "The Jesuit Churches of Italy." 8 p.m.

FRIDAY, FEBRUARY 4.

*Architectural Association.*—Discussion on Professor Corfield's lecture on "House Sanitation." 7.30 p.m.

*Royal Institution.*—Mr. Edwin Froehfeld, F.R.S.A., on "Some Unpublished Records of the City of London." 8 p.m.

*Institution of Mechanical Engineers.*—Fortieth Annual General Meeting (continued). 7.30 p.m.

*Institution of Civil Engineers (Students' Meeting).*—Mr. John Goodman, on "Recent Researches in Friction." 7.30 p.m.

SATURDAY, FEBRUARY 5.

*Architectural Association.*—Visit to a new Church at Wimbleson. 3 p.m. (See advertisement.)

*Association of Public Sanitary Inspectors.*—Fourth Annual Dinner. 6 p.m.

## Miscellaneous.

**The Sixth International Congress of Hygiene and Demography.**—A considerable progress appears to have been made by the organising committee of the sixth international congress of Hygiene and Population Statistics, to be held this year at Vienna. The financial prospects of the congress are satisfactory, close upon 15,000 florins (1,500*l.*) having either been promised or received from public bodies, whilst it is expected that private persons will subscribe with equal liberality. Amongst the subjects coming on for discussion the following may be mentioned as proceeding from English members of the congress. Professor Frankland proposes to read a paper on the utilisation of sewage and the purification of rivers; Mr. Whymper one on the hygiene of factories and legislation for the protection of workmen; and Dr. S. Murphy one on international regulations for epidemics. An important paper, dealing with the most material changes of the European population during the last thousand years, will be read by Dr. Von Inama-Sternegg, of Vienna. During the congress an exhibition of objects relating to the purposes of the congress will be held; but only exhibits possessing novelty and acknowledged merit are to be admitted.

**The Association of Municipal and Sanitary Engineers and Surveyors** notices (as will be seen by an advertisement in another column) that the third examination of candidates for the offices of municipal and local board engineers and surveyors will be held at the Institution of Civil Engineers, Great George-street, S.W., on Friday and Saturday, the 22nd and 23rd of April next.

**William Edgcombe Rendle & Co. (Limited).**—Attention may be drawn to the prospectus of this new company, which has been formed for the purpose of purchasing as a going concern, and further extending, the well-known business of Messrs. Wm. Edgcombe Rendle & Co., Government and general contractors for glazing and other works.

**Hellhoffite versus Nitro-glycerine and Powder.**

—Some blasting experiments have recently been carried out in St. Petersburg with the new explosive, called "hellhoffite," invented by Messrs. Hellhoff & Gruson, as against nitro-glycerine and powder, which are somewhat interesting. Hellhoffite consists of a solution of an organic nitro-combination (naphthalene, phenol, benzine, and some similar substances) in nitric acid; but, for the experiments in question, bi-nitro-benzene, a solid, non-explosive, and slightly-combustible substance, had been used in the manufacture of the hellhoffite. At the first experiments glass bottles, with a capacity of 20 cubic cm. each, were filled with 20 grammes of each explosive and corked, a tube, filled with fulminate of mercury, being inserted through the cork, in the end of which was attached a slow-burning fuse. The bottles were then placed on conical blocks of lead, having a height of 60 mm. and a diameter of 35 mm. at the top, and 45 mm. at the base. On exploding the bottle filled with nitro-glycerine, the block of lead was compressed to about one-fourth of its height, whilst its diameter increased to 55 mm. The surface had the appearance of having been hammered with a very worn hammer. The hellhoffite had, however, far greater effect. The top of the cone was completely rent to pieces, bits of lead, 50 mm. long, and 20 mm. thick, being torn off and thrown a distance of several yards, whilst only the lower half of the block held together, but being quite unrecognisable. At the second experiment, the bottles were filled with 25 grammes of each explosive gunpowder, nitro-glycerine, and hellhoffite, and placed in holes bored in logs of fir of equal dimensions. On exploding the powder the log was splintered into four almost equal portions, as if it had been severed with an axe, the pieces being thrown to a distance of from 10 ft. to 18 ft., whilst on exploding the nitro-glycerine the log was splintered into a far greater number of pieces. The hellhoffite was, however, considerably more destructive, the log in which this explosive was deposited being rent into very small fragments. The advantages of hellhoffite, as compared with nitro-glycerine are,—1, that when exploded with fulminate of mercury its force is greater than that of the latter; 2, that it may be stored and transported without the slightest risk through being handled, as it cannot be made to explode by being shaken or struck, and does not ignite even under a naked flame. On the other hand, it has the following disadvantages:—1, it is a fluid; 2, the rapid evaporation of the nitric acid necessitates its being kept in hermetically sealed vessels; 3, on being mixed with water hellhoffite loses its explosive properties, and cannot, therefore, be used for submarine blasting as easily as nitro-glycerine or dynamite.

**The Architectural Court at the Manchester Exhibition.**—We would direct attention to the advertisement on our first page respecting the architectural court at the forthcoming Manchester Exhibition. The object, as has already been mentioned in our columns, is to get together a representative collection, illustrative of the progress of architecture during her Majesty's reign. The authorities of the Exhibition have confided this task to the Manchester Society of Architects, who are associating with themselves representatives of various architectural societies in the Kingdom. We are informed that the space allotted to the architectural court is already more than applied for.

**Lectures at the Royal Academy.**—Referring to the paragraph in our last (p. 168), giving dates and subjects of forthcoming lectures at the Royal Academy, we regret very much to hear from Professor Newton that the state of his health has obliged him to withdraw from his engagement to lecture to the students this session.

**Septicæral Monuments of Essex.**—A work on the "Ancient Septicæral Monuments of Essex," by Mr. F. Chancellor, is announced to be published by subscription. The book will contain illustrations, drawn to scale, of about 150 plates of monuments to members of various families in Essex, in parish churches and other places in the county.

**Concrete-work for Harbours,** which formed the subject of discussion at the Institution of Civil Engineers in November last, has just been issued by the Institution as a thick pamphlet, illustrated by seven plates and numerous wood-cuts.

**The Berlin Museum of Hygiene.**

—The Health Exhibition which was held at Berlin in 1883 has led to the establishment of a permanent Museum of Hygiene. The impulse to its foundation was given by Herr von Gossler, Prussian Minister of Education, who was ably seconded in his efforts by Professor Koch, the "Father of the Bacilli," as Berlin wit has dubbed him. The principal objects shown at the Berlin Exhibition formed the basis of the museum; numerous exhibits, the best of their several special branches, having been gradually added to it, so that the establishment now forms a unique exhibition. The objects are displayed in thirty-four well-lighted rooms, each of which contains complete departments. There are, in the first place, numerous examples of life-saving apparatus for use both on land and sea, as well as models, those objects forming a conspicuous feature of the late Exhibition. One room is specially devoted to models of workmen's dwellings; another to models of machinery used in spinning, weaving, agriculture, and other industries, provided with guards against accident, as well as of other protective apparatus in workshops. Four rooms are full of models of the various systems adopted for heating and ventilating of private dwellings and public establishments, as well as those relating to water-supply and sewerage. Another room contains hospital and ambulance appliances. An important room is that in which the various articles of food are displayed by the side of adulterations. The Exhibition is a most instructive one, although some departments,—for instance, public baths and washing establishments, in which Germany is behind other countries,—are not well represented. The electric light also makes but a poor show, the lighting department being chiefly confined to gas and petroleum.

**Historical Treasures in the Upsala Cathedral.**

—The Cathedral of Upsala, in Sweden, one of the oldest in Northern Europe, possesses some historical treasures of great artistic interest and value. Among them is a chalice of pure gold, with paten of the same metal, weighing 125 oz., covered with pearls, emeralds, sapphires, topazes, rubies, turquoises, and amethysts. On the foot is the following inscription:—"Hans Hviitt de Hallis hunc calicem fabricavit est, 1541. Taken at Prague, 1648; presented to Upsala Cathedral by Queen Christina." It is valued at 2,000*l.* There is also another chalice of gilt silver, richly covered with precious stones, brought by Charles XII. from Poland. On the foot is a Polish inscription, and the date 1655. Besides these treasures, the cathedral possesses the crown, sceptre, and orb of King John III., all of gold, and set with precious stones, recovered from this monarch's grave in 1833. The crown alone weighs 36 ounces. It also possesses the crown and sceptre of Queen Catharina Jagellonica, recovered from her coffin; a cross of gilt silver, weighing 17 lb., presented in 1160 by Pope Alexander III., to the first Archbishop of Upsala, Stephanns, in the foot of which is a splinter of the Holy Cross. Further Archbishop Arimbald's shrine of absolution, of enamelled copper, a beautiful piece of Byzantine workmanship; a heavy neck-chain of gold, recovered from the grave of Duke Gustavus of Saxony in 1767; two crosses and one ring of gold, found in 1815 in the grave of Sten Sture (Lord Protector of Sweden in the fifteenth century). The archbishop's staff still in use in the cathedral is believed to have been presented by Pope Urban VII. to Archbishop Jöris Bengtsson Oxenstjerna.

**Drainage of Codnor, near Derby.**

—A Local Government inquiry was held at Codnor on the 20th inst. by Major-General C. Phipps Carey, R.E., into an application made by the Basford Union Rural Sanitary Authority for power to borrow the sum of 4,000*l.* for proposed sewerage works at Codnor. The system known as intermittent downward filtration will be adopted. Mr. John Parker, C.E., of Nottingham, is the engineer appointed by the Sanitary Authority to design and execute the works.

**The International Statistical Institute.**

The first general meeting of this body, founded in London at the Jubilee-meeting of the Statistical Society in 1855, was to have taken place at Rome in September last, but owing to the prevalence of cholera was postponed until the present year. It is now definitely decided that it shall be held at Rome from the 12th to the 16th of April next.

The Surveyors and Auctioneers' Clerks' Provident Association on.—The annual report and balance-sheet of this Association, which has its registered office at the Auction Mart, Tokenhouse-yard, E.C., and of which Mr. Daniel Watney is the President, has been issued. The financial statement shows that the Association is in a sound financial position; the capital amount standing to the credit of each object being, in every case, larger than in the previous year. Five members have joined during the year, and none have become disqualified. Only one member has made a claim on the Sick Fund during the past year. The distribution of the members is as follows:—sick fund, 25; life assurance fund, 23 (including one member's wife); superannuation fund, 9; benevolent fund, 7. The committee have had several applications for grants from the benevolent fund from members of the profession not being members of the Association; but on investigation it did not appear that the circumstances of the applicants were such as came under the regulations framed by the committee, and no grants have been made. The annual meeting will be held at the Auction Mart, on Saturday, February 12th, at 3 p.m.

Liverpool Engineering Society.—The usual fortnightly meeting of this society was held at the Royal Institution, Colquitt-street, Liverpool, on Wednesday evening last, Mr. John J. Webster, M.Inst. C.E., President, in the chair. A paper was read by Mr. Charles H. Darbishire, M.Inst. C.E., on "The Ventilation of Sewers." After calling attention to the great disregard that had been generally paid to sanitary matters until recent years, the drainage system of the Houses of Parliament was referred to as an example of the awful state of affairs that could be devised and allowed to remain under the very chambers wherein were enacted the various Public Health Acts and other sanitary laws. The various gases which were usually found in sewer air were then detailed, and a careful description of Doulton's automatic flushing arrangement was given, illustrated by a working model. The systems of ventilation in vogue in various towns were compared, the conclusion arrived at being that the only safe, reliable, and universal system of ventilation was the simple one of as many openings as possible to the sewer. When, owing to faultiness of construction, or to improper matter being allowed to enter, any particular section of the sewer emitted foul gas and effluvia, if the sewer could not be rectified, or the improper matter excluded, special means, depending upon the circumstances of the case and the situation must be adopted to draw off the excess gas to where it could escape without injury to the public health or offence to the senses.

St. Paul's Ecclesiastical Society.—In the eighth annual report of this Society, to be presented at the meeting this Saturday, the 29th inst., the Council congratulate the members upon the proceedings of the past year, and say that the general interest manifested, and the very large attendances at the out-door meetings, testify to the continued usefulness and popularity of the Society. During the year, nine meetings have been held at the Chapter House, and papers have been read by Mr. J. T. Micklethwaite, Mr. J. P. Seddon, Mr. Charles Browne, Mr. G. H. Birch, Mr. Hugh Stannus, Mr. Joseph Grimshire, Mr. Somers Clarke, and Mr. Veargitt W. Maughan. Afternoon visits were made to St. Paul's Cathedral, the Charterhouse, the Church of St. Bartholomew the Great, to West Ham, to Hatfield, to Ongar, to Greensted, to St. Mary Cray, and to St. Paul's Cray. A day was spent in Ely. Part I. of the second volume of the Transactions has been issued during the year, and Part II. is in preparation. The balance-sheet shows that the finances of the Society are in a satisfactory condition. There are now 331 members on the register. Seventeen members have been elected during the year, and fifteen have resigned.

Exeter Cathedral.—A local paper says that the Dean and Chapter have decided to commence the erection of the cloister and library on the south side of the nave of the cathedral at once. The architect for the work is Mr. J. L. Pearson, R.A., of London, and the execution of the work is entrusted to Messrs. Luscombe and Son, of Exeter, who executed the work of restoration of the cathedral. The demolition of the old verger's house to make way for the first section of the cloister and library has commenced.

PRICES CURRENT OF MATERIALS.

Table with columns: Material Name, Unit, Price (s. d.), Price (s. d.). Includes items like Greenheart, B.G., Teak, E.I., Sequoia, U.S., Birch, Elm, Fir, Dantsic, Oak, Canada, Pine, Canada red, Lath, Dantsic, St. Petersburg, Wainscot, Bigs, Deals, Finland, Riga, St. Petersburg, 1st yellow, Swedick, White Sea, Canada, Pine, 1st, Mahogany, Honduras, Maple, Bird's-eye, Bose, Rio, Bahia.

TIMBER (continued). Table with columns: Material Name, Unit, Price (s. d.), Price (s. d.). Includes items like Box, Turkey, Satin, St. Domingo, Porto Rico, Walnut, Italian.

METALS. Table with columns: Material Name, Unit, Price (s. d.), Price (s. d.). Includes items like Lead, Pig, Spanish, English, common brands, Sheet, English, Silesian, special, Ordinary brands.

OILS. Table with columns: Material Name, Unit, Price (s. d.), Price (s. d.). Includes items like Linseed, Coconut, Ceylon, Palm, Lagos, Bappeded, English pale, Cottonseed, refined, Lubricating, U.S., refined, Turbentine, American, in casks, Stockholm, Archangel.

Epitome of Advertisements in this Number.

COMPETITIONS.

Table with columns: Nature of Work, By whom required, Premium, Designated to be delivered, Page. Includes Re-Seating Chapel and New Schools.

CONTRACTS.

Table with columns: Nature of Work, or Materials, By whom required, Architect, Surveyor, or Engineer, Tenders to be delivered, Page. Includes Making-up and Paving Roads, Town-Hall and Offices, Hall for Working Men's Club, Works and Materials, Granite Curb, Timber, Lamp Columns, Works and Materials, Rectification of Shaft, Repairing Footpaths, Miscellaneous Repairs, Sewerage Works and Carbolic Disinfectants, Watering and Cleansing Roads, Hospital for Infectious Diseases, Brick and Pipe Sewers, Construction of Sewer, Steel Dock Gates and Quays, School Desks, New School, Smethwick.

PUBLIC APPOINTMENTS.

Table with columns: Nature of Appointment, By whom Advertised, Salary, Applications to be in, Page. Includes Clerk of Works.

TENDERS.

Table with columns: Tender Name, Amount. Includes COSHAM (near Portsmouth), GEORGE and DRAGON INN, J. Biden, H. Jones, J. Crockerell, Burbridge, Leaver, Cosham, D. W. Lewis, W. R. & C. Light, J. Cross, T. Quick, J. Collings, W. Learmouth, J. H. Corrie, T. P. Hall, C. Dye, London-road, Kingston, Portsmouth, DEPTFORD, J. Heast.

Table with columns: Tender Name, Amount. Includes COLCHESTER, Messrs. Goby & Sons, Bull-road, Mr. J. W. Start, architect, Colchester; LONDON, For the laying-down of new granite carriage-ways and York-stone footways, the construction of a pipe sewer, and the execution of other works for the purposes of the Tower-hill and Postern-row Improvement, for the Metropolitan Board of Works.

LONDON.—For re-building printing office for Mr. George Stevens, 87, Commercial-road, E. Mr. Joseph Harris, architect, Bow:—  
 Huckle ..... £1,163 0 0  
 Croft ..... 1,068 0 0  
 Calman ..... 1,043 0 0  
 Russell (accepted) ..... 1,027 0 0

LONDON.—For alterations to the Queen's Head Public House, Piccadilly, for Mr. Stewart, Mr. H. I. Newton, architect, Queen Anne's Gate, Westminster:—  
 Dixon & Jones ..... £585 0 0  
 Burman & Sons ..... 359 0 0  
 Jackson & Todd ..... 230 0 0  
 John Anley (accepted) ..... 237 0 0

Feather's Work.  
 Davidson ..... £55 10 0  
 Helling ..... 50 0 0  
 Heath ..... 47 0 0  
 Sanders & Sons (accepted) ..... 46 10 0

LONDON.—For alterations and additions to premises in Whitfield-place, W., for the Borough of Marylebone Medical Club, Mr. Arthur W. Saville, architect, Strand. Quantities supplied:—

W. Downs ..... £84 0 0  
 J. Heath ..... 659 0 0  
 J. Adams ..... 443 0 0  
 J. Anley ..... 638 0 0  
 Ward & Lambie ..... 637 0 0  
 W. Royal ..... 623 0 0  
 Spencer & Co. (accepted) ..... 600 0 0  
 Treweeke ..... 685 0 0  
 \* As amended, £430 previously tendered in error.

LONDON.—For shop fittings at 133, Tottenham-court-road, for Messrs. J. H. Deakin & Co. Mr. Arthur W. Saville, architect, Strand:—  
 W. Royal ..... £165 0 0

PORTSMOUTH.—For extension of drainage, &c., at the Kingston Cemetery, Portsea, for the Portsea Island Burial Board, Mr. James W. Strand, surveyor, Portsea. Quantities supplied:—

\* Victoria-road, Southsea. The others of Portsmouth and Southsea.  
 † Accepted for estimate A.

RAMSGATE.—For the erection of two houses at Ramsgate, for Mr. J. B. Hodgson, Mr. Alfred R. Pile, architect, Bloomsbury-square:—  
 Wehl ..... £769 0 0  
 Wood ..... 585 0 0  
 Bowman ..... 583 0 0  
 Martin ..... 544 0 0  
 May ..... 518 0 0

SOUTHSEA.—For additions to "Wealey House," Victoria-grove, for Mr. J. W. Gardner, Messrs. James W. and John W. Strand, architects. Quantities supplied:—

H. Jones ..... £397 0 0  
 W. Wood ..... 311 4 5  
 T. P. Hall ..... 330 0 0  
 J. Croad ..... 317 0 0  
 D. W. Lewis ..... 315 0 0  
 J. Crockerell ..... 312 0 0  
 W. & J. Briggs ..... 293 0 0  
 J. H. Corke ..... 290 0 0  
 J. Rogers ..... 243 0 0  
 Leamouth\* (accepted) ..... 225 0 0  
 \* Emworth-road, Kingston, Portsmouth. The others of Portsmouth and Southsea.

SWINDON.—For erecting house and shop in Regent-street, New Swindon, for Mr. J. E. Baker. Mr. William Drew, architect, Swindon:—  
 Wiltshire, Swindon (accepted) ..... £370 0 0

SPECIAL NOTICE.—Lists of Tenders frequently reach us too late for insertion. They should be delivered at our office, 46, Catherine-street, W.C., not later than Four p.m. on THURSDAYS.

TO CORRESPONDENTS.  
 Registered Telegraphic Address, "THE BUILDER, LONDON."

E. H. H. (if the words "each cement" are on specification the contractor is bound to put a larger light in each, and knows that as well as you do. If the words were "each window" there might be ground for difference of opinion, but the fair construction would be in your favour even then).—H. E. P.—W. P. (no such question could be fairly answered without an inspection of the work on the spot. We do not undertake to write on disputes between owners and builders).—"Demons Bump" (the first part of our last answer applies to this case. Opinion cannot be given, to be worth anything, without inspection on the spot).—J. T.—W. C. A. Co.—F. M. (not to an unlimited depth, certainly. In a long frost the thickness of ice would go on increasing to some extent, probably only very slightly after the first few days; as after a certain point the ice itself becomes a protection from cold to the water under it, which is also receiving a comparative amount of warmth from the earth).—A. B. (we will consider your letter with a view to inserting some portion of it in next week).—C. P. A. (does not comply with our conditions).—W. T. H. (should have sent amount).—F. W. (see answer to C. F. A.).

All statements of facts, lists of tenders, &c., must be accompanied by the name and address of the sender, not necessarily for publication. We are compelled to decline printing out books and giving addresses.  
 Note.—The responsibility of signed articles, and papers read at public meetings, rests, of course, with the authors.  
 We cannot undertake to return rejected communications.  
 Note.—Communications (beyond news items) which have been duplicated for other journals, are NOT RECEIVED.  
 All communications regarding literary and artistic matters should be addressed to THE EDITOR; all communications relating to advertisements and other exclusively business matters should be addressed to THE PUBLISHER, and not to the Editor.

**FIRE BRICKS.**

E. BOWEN, Fire Brick Manufacturer, STOURBRIDGE. Manufacturer of Best Standard Fire Bricks, and Cement Fire Clay, Gas Retorts, Muffles, &c. Fire Bricks and Blocks for the Highest class of Iron Blast Furnaces, Puddling, and Steel Furnaces, Pottery, Bottle, and Flint Glass Furnaces, Roasting and Melting Furnaces, Chemical Works, Coke Ovens, &c. Boiler Setting Blocks, Fine Covers, Locomotive Bricks, Tug-boilers, Steel Runners, Gate Blocks.  
 Special Lists and Shapes made to Engineers' Drawings. Prices quoted to any Port or Railway Station.  
 London Agents:—  
 R. CULL & SON, Pancration-buildings, E.C. Stores.—Railway Arches, Corner of London-street and Bradly-street, near Bethnal Green Station.

**GLAZED BRICKS.**

OATES & GREEN, HALIFAX. GLAZED BRICKS (White and Coloured), Special Salt Glazed Bricks, Sanitary Tiles, Glazed Earthenware Slabs, Cattle, Sheep, and Pig troughs, Horse Mangers, Patent Automatic Pouch Clasp, Patent Flush Tank, Channelling for Stables and Yards, Salt Glazed Bricks for Stables, Sewers, &c. Ventilating Bricks, Patent Ventilating Gullies and Traps, Garden Edging, Patent Chimney Vents and Cures for Down Draughts, Patent Drain Clearing Rods, Six Prize Medals, Copies of Testimonials sent free of charge.  
 London Agents:—  
 R. CULL & SON, Pancration-buildings, E.C. Stores.—Railway Arches, Corner of London-street and Bradly-street, near Bethnal Green Station.

**BLUE BRICKS.**

THE KETLEY BRICK COMPANY, Manufacturers of Staffordshire Blue Bricks, KINGSWINFORD, near Dudley, Staffordshire. E. CULL & SON, Pancration-buildings, E.C. Stores.—Railway Arches, Corner of London-street and Bradly-street, near Bethnal Green Station.

**DRAIN PIPES.**

Blue, Cement, Bricks, Slates, Laths, Hair, Sand, Plaster, Stable Taving Bricks, Coping, Channel Bricks, Blue and Red Edges, Red Plain Tiles and Pan Tiles, Closet Pans and Traps, Drain Pipes, Bench, Junctions, &c. all sizes. Chimney-Pots, Red and White Fire Bricks, Lumps, Tiles, Fire Clay. PRICES on APPLICATION.  
 R. CULL & SON'S Stores, Railway Arches, Corner of London-street and Bradly-st., near Bethnal Green Station, Chief Offices.—72, Palmerston-buildings, Old Broad-street, E.C.

**MAP OF LONDON,**

SHOWING BOUNDARIES OF SURVEYORS' DISTRICTS. The four Sheets, into which the Map is divided (issued with the numbers of January 1st, 8th, 15th, and 22nd), if sent to the Office direct, or through any Newsagent, can be Mounted on the following Terms, viz.:—  
 On Cloth (Rollers) and varnished, 3s. 6d. | On Cloth (Strainer) and varnished, 5s. 6d.  
 N.B.—In the case of "Strainers," if packed for rail or carrier, 1s. 3d. extra.

Best Bath Stone. CORSHAM DOWN, } SUMMER DRIED. FARLEIGH DOWN, }  
 BOX GROUND, COMBE DOWN. WESTWOOD GROUND. RANDELL, SAUNDERS, & CO., LD., CORSHAM, WILTS.

Bath Stone. BEST QUALITY OF ALL KINDS. PICTOR & SONS, BOX, WILTS. [ADVT.]

Doubling Freestone. The stone from these quarries is known as the "Weather Bed," and is of a very crystalline nature, and undoubtedly one of the most durable stones in England.

THE CHELVYNCH STONE. THE BRAMBLEDITCH STONE. Is of the same crystalline nature as the Cheelvynch Stone, but finer in texture, and more suitable for fine-moulded work.

HAM HILL STONE. Greater facilities have been provided for working these quarries, and the stone can be supplied in large quantities at short notice. Prices, and every information given, on application to CHARLES TRASK & SONS, Norton-sub-Hamdon, near Ilminster, Somerset. London Agent—Mr. E. WILLIAMS, 16, Craven-street, Strand, W.C. [ADVT.]

Doubling Free Stone For prices, &c., address S. & J. STAPLE, HAM HILL STONE, Quarry Owners, Stone and Lime Merchants, Stoke-under-Ham, (Ground or Lump), Ilminster. [ADVT.]

Asphalte.—The Soysseal and Metallo Lava Asphalte Company (Mr. H. Glenn), Office, 33, Poultry, E.C.—The best and cheapest materials for damp courses, railway arches, warehouse floors, flat roofs, stables, cow-sheds, and milk-rooms, granaries, lun-rooms, and terraces. [ADVT.]

Asphalte. Soysseal Patent Metallo Lava, and White Asphalte. M. STODART & CO. Office: No. 90, Cannon-street, E.C. [ADVT.]

Ladders for Sale or Hire. One 102-round, Two 90-round Ladders and other Lengths. Apply to JOHN BATCHELOR, 66, Hammersmith-road, West Kensington. Close to Addison-road Station. [ADVT.]

**NOTICE.**—THE BANNER SANITATION CO. beg to give Notice that having sold over 10,000 BANNER'S PATENT VENTILATORS, also a proportionate number of other Sanitary Appliances, and wishing to keep pace with the times, they have decided to reduce the prices of their goods from 25 per cent. to 40 per cent., thus offering to the public the best appliances at the lowest prices.

**BANNER VENTILATORS.**

The Strongest Exhaust Ventilators for all Buildings, Public Halls, Churches, Billiard-Rooms, &c. HIGHEST PRIZES at all the most important EXHIBITIONS. Gold Medal, Health Exhibition, 1884.

For further Particulars and Revised Prices, apply to **BANNER SANITATION COMPANY,** Wesssex House, Northumberland Avenue, Charing Cross, London, W.C.

### Mountain-Building.

**EXCEEDINGLY** few works have been written exclusively on the theory of mountain-building, and no monograph, so far as we are aware, had appeared in the English language before the publication of the work

now before us.\* The author being both a civil engineer and an architect has incorporated a few observations which apparently came under his notice in professional practice, in illustration of some of the points of his work, and it is our intention to speak firstly of these and then pass on to the purely scientific part of the book.

In considering what effect a local change of temperature would have on the earth's crust, he points out the results of expansion on external objects, such as chimneys, kilns, metal-work, rails, bridges, roofs, girders, and masonry. He observes that a vessel formed of such a ductile material as lead, if repeatedly heated and cooled, permanently increases in size with every such operation. "In laying small sheets of lead or zinc the metal must be free to move or it will quickly rupture by changes of temperature. Hence in all good roof-work, if of lead or zinc, soldered joints are rigidly excluded. Notwithstanding all these precautions, one has only to examine an old lead roof to find it covered with ridges and puckers. These ridges arise from the accumulated small superficial expansions which imperceptibly affect the lead, but the low tensile strength and ductility of the metal will not allow it to regain its form by contraction."

The distortion, however, occurs in a more perfect manner in vessels lined with lead, for the metal in such cases has very little play. "Who has not noticed the ridges on an old bath lined with lead?" To further illustrate this portion of his subject, the author made several experiments by heating sheets of lead and observing the permanent results. Four good ink-photo plates are given to show the effects of superficial expansion on these. One of them is a fac-simile of a hutter's pantry sink, where a ridge is shown to have been formed by the contractions and expansions produced by the ordinary alternations of hot and cold water.

\* The Origin of Mountain Ranges considered Experimentally, Structurally, Dynamically, and in Relation to their Geological History. By T. Mellard Reade, C.E., F.G.S., F.R.I.B.A., &c. London: Taylor & Francis, 1898.

With regard to the effects of expansion by heat on brickwork, he observes (p. 12) that "Any practical man, who has had experience of setting of boilers, the building of chimneys, or the erection of kilns, knows that the effect of such heat as they are subjected to is very destructive of the structure. It arises from two causes,—first, the unequal expansion of the heated interior compared with the cooler exterior; and, second, the low tensile strength of brickwork. The heated interior brickwork expanding, ruptures the exterior, which expands less. This effect does not follow from one operation, but through repeated heatings and coolings. At every heating the brickwork is moved, but in a way imperceptible to the eye, and it does not recover its original dimensions on cooling. The accumulated results of these internal movements soon, however, become sensible by rifts in the brickwork. To counteract these destructive forces, it is usual to bind the brickwork together with iron rods or hoops, which, having a high tensile strength, hold the work more firmly together."

The author, in addition, quotes the opinion of Herr Eckhartz in the *Builder* of March 17, 1883, p. 362, wherein he dwells upon the use of iron-hooping, and remarks that its object and result are not, strictly speaking, the prevention of extension, but rather the attaining, in the outer brickwork, of a uniform distribution of the tension, and the prevention of its concentration at certain points.

The effects of expansion by heat are also exemplified by the well-known fact that a line of hot-water pipes for heating a building requires considerable play, even though never rising above a temperature of 212° Fahr., and has to be fitted in places with expansion-joints, otherwise the pipes would fracture, or the ordinary joints leak. The expansion of railway metals by the heat of the sun is also considered, as well as the huckling of plates on the sides of a series of girder bridges. With reference to the latter, the author states that some of them have domed up from  $\frac{1}{2}$  in. to  $\frac{3}{4}$  in. in plates 1 ft. 8 in. wide. The effect is quite striking, and he is satisfied that it is mainly the result of changes of temperature, as in every case it is the south side exposed to the mid-day sun which is mostly acted upon.

A series of experiments on the effect of heat in expanding different kinds of building and other stones were conducted by the author, and the results given in detail, together with their co-efficients of expansion. These trials were in most cases made with dressed hars of stone about 15 in. long, but of various scantlings, best suited to the material. The ends were dressed square. Each stone was tested several times, and the mean of the observations taken as the correct result.

Summing up, we find the mean co-efficients of expansion of various rocks, as determined by the author's experiments, to be as follows:—

|                 |                     |
|-----------------|---------------------|
| Sandstones..... | $\frac{1}{178,825}$ |
| Marbles .....   | $\frac{1}{184,797}$ |
| Slates .....    | $\frac{1}{193,827}$ |
| Granites.....   | $\frac{1}{203,322}$ |

These results do not in most cases greatly differ from those of Mr. Adie in the *Trans. Royal Society, Edinburgh*, vol. xiii, p. 366. The author also refers to the well-known experiments on American building stones under Col. Totten, the object of which was to ascertain the cause of the fissuring of the joints of coping-stones in certain buildings, it having been found impossible to keep the joints perfect for more than a few weeks. The conclusion arrived at was that the fractures were due to ordinary changes of temperature.

Passing on to the purely geological portion of the work, we observe that the author firmly believes that the earth is solid throughout, and that although heat increases with the depth in the crust of the earth, and that a depth would eventually be reached at which any known rocks would be melted if they were at the surface, yet they are prevented from melting by reason of the pressure of the superincumbent rocks. He further believes that upon any sufficient release of the pressure, portions of such underlying rocks would assume a molten state, and that, therefore, the material below a certain depth, although being actually solid, may be described as being in a *potentially liquid* condition. When in that condition, they act as a plastic mass, and differ in their relative strengths in resisting the superincumbent pressure, so that, on contraction, the subsidence that must follow causes strains which, although occasionally are met by the strata merely bending, are oftener eased by sudden snaps producing faults. The nearest parallel to this state of things, he observes, is that of the walls of a building on a foundation of differing degrees of solidity, under which circumstances the building will very soon tear itself to pieces.

Up to this point, we have refrained from offering any criticism of the work. One has only to read it through to be convinced of the great amount of care and thought the author has bestowed upon it. But there are, nevertheless, many points that, in our opinion, materially affect the bases of some of his hypotheses. We entirely agree with the author as to the solidity of the earth, and the absence of a fluid stratum beneath the crust, as we think that, on the whole, this is the condition which most readily accords with the known facts of

geology, on this particular line of research. We are also prepared to believe in the plasticity of the potentially liquid mass and in the portion of the crust for some distance above it. It would also be idle for us to dispute that local changes in temperature, due to thick sedimentation in certain areas, cause a corresponding rise in the isotherms under those areas, the result of which would be expansion of the rocks so affected. The author's arguments on these heads are in many instances both novel and conclusive, and on this portion of his work we cannot too highly compliment him.

But we cannot agree that the effect of this sedimentation, and the consequent rising of the isotherms, and attendant results, are such as to be great factors in producing the phenomena of the elevation of mountain ranges. It may have a *little* to do with it, but we think that the principal effect of such thick sedimentation is to cause the slow movements of large continental areas. Besides, there are areas where the sedimentation has been of very great thickness, and where no mountain ranges have resulted from this loading. If the author's theory is the correct one, we cannot account for this. Looking at the matter from another point of view, we might say that unless a considerable thickness of rock were in existence before mountain chains were formed, there would have been nothing for them to have been made out of. We do not think, therefore, that any theory need be formulated to account for the connexion between mountain ranges and thick sedimentation.

We are pleased to see that the author does not attribute the corrugation of the earth's surface to the contraction of the nucleus (p. 125).

Speaking generally, it appears to us that he has not laid sufficient stress on the effects of the subsidence of large ocean bottoms, and the great weight of water thus accumulating on those portions of the crust immediately subjacent. Take, for example, the Pacific Ocean, the greater part of which has been formed in recent geological times by the subsidence of the land which now forms its bottom. Concurrently, volcanoes and mountain ranges appeared all round its shores from Cape Horn, through Chili, Peru, Central America, the Rockies, Aleutian Is, Japan, and so on, until New Zealand and even the land of the Antarctic continent are reached. Surely this is not without its significance, in dealing with the hypotheses connected with mountain-making. We cannot think that the deposition of the sediment,—however thick,—forming the mountain ranges referred to, has had such a stupendous effect, in the elevation of those mountain ranges and adjacent land, as to cause the subsidence of the land which is now the bottom of so great a part of the Pacific.

Again, we should like to have seen more notice taken of the action of extra-terrestrial bodies on the earth. We allude, of course, to the attraction of the sun, moon, &c. In our opinion, the silent forces which are capable of producing tides, the precession of the equinoxes, nutation, and changes in the obliquity of the ecliptic, have had a very considerable share in the formation of mountain ranges. We must not forget, either, the high probability of the instability of the earth's axis, changes of the earth's centre of gravity, or, indeed, the significance of the connexion between the periodicity of earthquakes (and attendant phenomena) and lunar attraction, as has recently been advanced and reported in our columns. All these things and more have had their share of work in twisting and corrugating the earth's surface.

We would not by such criticisms desire to convey to the minds of our readers that the work is not up to the mark. It must be remembered that the author has attacked a most difficult subject, and one about which it is quite impossible, in the present state of our knowledge, to dogmatise, as he himself, of course, admits. The work marks a distinct advance of, and is a valuable contribution to, physical geology, and must take its rank accordingly; for, whatever the value of the hypotheses he has brought forward, they are

interspersed with a large number of facts, which future writers will not fail to take advantage of in some way or another. Enough has been said to show that there is much in it of interest to our readers, especially in connexion with the effect of heat on various building materials. The work is well and very profusely illustrated by ink-photos.

#### ACADEMIC QUARRELS.

**T**HE incidents which would seem to have marked the recent elections to fill the gaps in the ranks of the Royal Academy are curiously calculated to prove how history repeats itself. Little as is actually known of a transaction which is usually conducted amidst the most dignified secrecy, enough has transpired to show that the causes of friction between the President and his brother Academicians closely resemble a very similar disagreement which occurred a century ago among the members of the then only recently-formed institution. At that time as now, the difference would seem to have turned on a purely personal source of irritation, and as is sometimes apt to occur on these occasions the friends of the "outs" would seem to have expressed themselves warmly respecting the backers of the "ins." Such quarrels are, of course, no novelty to those familiar with elections, of whatever description, but when they break the dignified ease and calm of academic life they smack almost of sacrilege. There is an air of staid respectability surrounding all academies, but especially our own Royal Academy, which is, strictly speaking, the sole existing Academy in our country. The divinity which hedges the governing body whose deliberations are held at Burlington House has, however, once again been rudely broken in upon, and in the causes of the difference the opponents of the Academy, who of late have been expressing themselves somewhat warmly, will, it is to be feared, have found fresh grounds for their attacks. In the quarrel in which Sir Joshua Reynolds was only with difficulty induced to withdraw his resignation the disagreement turned, it may be remembered, on the refusal of the Academicians to raise from the rank of Associate Reynolds's friend, the architect Bonomi, whom the President very rightly considered would admirably fill the then vacant chair of Lecturer on Perspective. But the clique which supported Fuseli manoeuvred with such apparent animus against their chief and his nominee that the President resigned. He returned to office, it is true, but a few months later he delivered the last of his long series of discourses, the collected edition of which is to this day presented to each medal student of the Academy. Fortunately, it is rarely that Academic quarrels reach such a pitch of acrimony as to result in open warfare, but it may be safely said that no election of members passes without a considerable display of personal friendship and animosity between the too-often conflicting "sets" into which every body of men belonging to one profession seem inevitably divided. Potter hates potter, a Greek proverb tells us, and united in their aims as Associates and Academicians may be, they are no less subject than other mortals to human influence, not to say weaknesses. Some of the most deeply-rooted failings of humanity would seem to be exhibited in the causes which dictate such quarrels as spring up among brother academicians, and to which academies at all times have owed the absence from among their number of some of the greatest names in literature, art, and science. Even the French Academy, the model of all such institutions, is not free from this defect.

The story of the forty-first *fauteuil* of the Académie Française has been brilliantly related by M. Houssaye, and the fact that that imaginary throne of honour has been occupied by some of the most eminent names in French literature,—Pascal, Molière, Diderot, Rousseau, Beaumarchais, Descartes, Béranger, Balzac, Théophile Gautier, Dumas, Georges Sand, among others less familiar to English readers,—is a point which certainly "scores" for the

opponents of academic exclusiveness. This spirit and the bickerings it never fails to rouse are the chief origin of the quarrels which seem to be inseparable from academic life. In the case of our own Royal Academy, it is to be regretted, for the sake of our national art, that such disputes tend to prove the assertions of those who urge that the Academicians are more interested in the promotion of their own personal interests than in carrying out the aims laid down in the famous "instrument" granted them by George III. "for the purpose of cultivating and improving the arts."

The arguments in favour of and against the influence of academies have often been brought forward. That influence has been accused of fossilising into nerveless tradition the living bones of free inspiration. Nothing, in fact, is easier than to criticise academic institutions, and the errors into which they fall. Whenever the controversy is revived,—and it would seem to enjoy a perennial vitality,—it seems too frequently forgotten that the real aim of an academy, whether it be connected with the arts, with literature, or with science, is not, and never can be, to satisfy the various personal sympathies and antipathies of the public, however intelligent that public may be. When, two centuries ago, Richelieu founded the famous French Academy, his intention was to form a high court of letters, to give, as Mr. Matthew Arnold has said, the tone to literature, and that tone a high tone. An academy, in fact, to carry out its true aim should be a sovereign organ of opinion, an authority which in addition should practically influence the current of public opinion. All readers of Mr. Matthew Arnold know with what brilliancy that master stylist has regretted the absence of such a standard in the literature of our own country, which individually has enriched the world with so many creations of pure genius. The arguments in favour of an academy of letters tell far more powerfully in behalf of the arts. It is on the point whether the Royal Academy represents this high standard, that should turn, and turn solely, the criticisms addressed to the Burlington House authorities. Does that body in its exhibitions show its encouragement of the highest work, not necessarily in the productions of its own members, who are privileged, but with the creations of the "outsiders" whose names (in smaller type) are admitted to a place beside their own in the pages of the familiar blue-paper covered catalogue. Unless these conditions be fulfilled the Academy must submit to the attacks to which it is yearly subjected, and its members must expect the recurrence of constant internal dissensions. It is singular how obstinately the Burlington House authorities seem to place themselves in the power of their enemies. Each year, as May comes round and "the Academy" is opened, the rejected ones are able to draw attention to exhibited works which no stretch of kindness can argue are up to the standard of merit which the Academy should uphold. The injurious effects of this are incalculable. In a past when the Academy was the one of the two or three exhibitions in which the English artists could show their year's work, the conditions of admission were different; but now, when certain streets in the West-End seem exclusively devoted to fine-art galleries, Burlington House could afford, without cruelty, to reject even a larger number of works than at present is the case, and the exhibition would then present a severe standard of English art, by which the public taste might be influenced, and the level of general "journeyman work" raised. It is because within the Academy itself there are members who hold these views that once again a quarrel has broken out between the representatives of the typical "Academic" traditions and the younger enthusiasts who would see the institution to which they belong boldly carrying out the aims for which their charter was originally granted.

**The Proposed Liverpool Cathedral.**—Sir A. B. Walker has signified his intention of giving 10,000*l.* to the building fund of the Liverpool Cathedral.

NOTES.

R. J. OLDRID SCOTT and Mr. Seddon have prepared a memorial for presentation to the Committee of the Liverpool Cathedral, to which they ask for the signatures of all architects who feel interested in the matter, desiring that the designs submitted in competition should be exhibited in London "for the purpose of eliciting the best skilled and widest public opinion on them." This is a compliment which Mr. Ewan Christian will no doubt appreciate equally with ourselves, the implication being that they have not received such "opinion" so far. Nevertheless, we are quite in the mind that it would be a matter of interest to have the designs exhibited in London, though it must not be forgotten that they have already received considerable general publicity through the illustrations in this and other journals, one of our contemporaries, indeed, having been so eager in the good cause as to produce them from our plates, failing other means. It cannot be said, therefore, that "this thing was done in a corner." Inasmuch, however, as the obvious intent is to re-open the discussion as to the selection of the designs, we hold that the proposition would have come better from persons outside the ranks of the architectural profession, who, we must plainly say, are a great deal too fond of endeavouring (of course in the interest of art) to upset competitions which have been fairly decided. *Aut rest*, we imagine the "most skilled public opinion" really means that of the "church party," who want to stereotype church architecture on the Medieval model; or, perhaps, Lord Grimthorpe is to write an article on the designs. In that case all concerned would be certain of amusement, if not of instruction.

ON the 28th ult. Baron de Worms received a deputation of Lancashire and Cheshire trade representatives on the subject of the proposed Government legislation on railway charges. The deputation wished to impress their views upon the Board of Trade as to the injustice involved in the principle apparently guiding the railway companies in fixing their rates, their own opinion being that the charge was often out of proportion to the service rendered. Judging from the Baron's reply, he was in entire sympathy with the traders, for he fully endorsed their views; and the Bill about to be introduced in the House of Lords will, doubtless, be quite as comprehensive as Mr. Mundella's. He expressed his belief that satisfactory remedies for their grievances would be found in the measure, and stated that the Government were prepared to give the fullest consideration to any suggestions. A notable defect in last year's Railway Bill was the absence of any practical clauses for the regulation and more efficient management of canals, Mr. Mundella admitting, after its introduction, that he had come to the conclusion that in this respect he had failed to make any satisfactory provision. It has been stated in the House of Commons that there are thirty-nine canals, with an aggregate length of 1,436 miles, under the direct control of the railway companies, several others being also in their hands to a great extent. Recent events connected with canals communicating with the Thames and the Severn, go to show that it is very probable that the fact of railway part ownership prevents the public from deriving that benefit from them which they are calculated to afford. The Great Western Company deny that the inefficiency of these waterways is due to any action of theirs (though it may be said, in passing, that the complaint is of inaction), and it is still an open question; but this, and other cases of a similar nature, will doubtless come under discussion when the matter is again before Parliament, and this particular question should receive more prominence in the forthcoming measure than it has done in former ones.

WE observe that one of our contemporaries has been commenting upon the line of frontage laid down by the Superintending Architect of the Metropolitan Board of Works

in what is known as the Brixton-rise and Trent-road case, and the question of the legality of his certificate has been brought before the House of Commons, — when the Chairman of the Board stated that the Board had no powers to interfere in the matter; and we are inclined to think that the Chairman's reply was in accordance with the law upon the subject, as also with recently-reported cases. The Superintending Architect is appointed by the 25 and 26 Vict., c. 102, as a statutory officer to define lines of frontage, and in this character the Metropolitan Board of Works have no power to interfere with his decision, which is final, and cannot be impeached in any way.

IT is a reassuring thing for English travellers and intending residents abroad, when they see the authorities of a city actively bestirring themselves to remedy their sanitary defects; and it is seldom that we meet with such determined efforts to improve the public health as are now being made in Florence. The city has recently been the scene of some serious aspersions on the score of health; and although a one-time resident defended her with more zeal than discretion, his figures were soon pulled to pieces, as proving too much. There can be no doubt that Florence, while fairly free from great epidemics, is not nearly as healthy as she ought to be. Few cities, either at home or abroad, are more carefully swept and garnished; and even in the slums around the Ghetto, such as Pelliceria or Calimari (where the cholera alarm took place last June), the smells are not unbearable, nor are the accumulations allowed to become too marked. The chief difficulties are the length and intricacy of the sewers, the cesspools, and the drinking-water. Everybody knows, and Florentines best of all, that if their fair city gets a bad name, they might as well efface themselves from off the earth. Neither Raffaele, Michelangelo, nor Donatello will attract visitors, if it is known that the drains are all wrong; and the Syndic and his followers are acting sensibly in acknowledging the evil, and resolutely bending to its cure. The Hygienic Society is doing its best, not only theoretically but practically, to inquire minutely into the conditions of typhoid; and the inquiry naturally brings to light many hitherto unsuspected errors of sanitation. Even now, the wells are being examined, the sewers flushed, and publicity given to all hotels, pensions, and lodgings, where proper drinking-water is supplied. This is especially necessary, in view of the enormous crowds which may shortly be expected to assemble at the opening of the new facade of the Duomo.

APART altogether from the question as to a cause of the death, at Chiswick, of the girls Wilkes, and the serious illness of the mother and other members of the family, which cannot possibly be known till the analysis of the food is completed, a deplorable case of over-crowding is presented. The mother and the six children slept huddled in a bedroom measuring 9 ft. by 8 ft. There were three unoccupied bedrooms besides, one of them containing an uncovered bed, in the house. It is a case, however, which only the closest watchfulness on the part of the sanitary officer would find out, as the general accommodation, so far as outward appearances are concerned, was ample for the family. It is reported that the sanitary condition of the house is distinctly bad; the atmosphere of the house was so stiflingly impure that an experienced ex-nurse only remained in it, under great trial, to wash the insensible children. It is rather surprising to find this sad sanitary condition of things in Chiswick, which only quite recently made a house-to-house inspection. But it seems the Local Board have not fully recognised the importance of the necessary corollary to this action, — effective steps to require the remedying of all sanitary defects. Inspection is of no use unless it be promptly followed by remedial action.

EVEN if Londoners had not daily before their eyes the smoothness and the almost perfection with which the Fire Brigade turns out for action, Captain Shaw's report and the

statistics embodied in it would make us feel assured thereof. The year 1886 showed a list of 2,149 cases of actual alarm in which more or less serious damages resulted, not to mention false alarms or chimney fires. And when we come to think of the extensive area over which the little army (only 539 altogether) is liable to be called at any moment, night or day, it is simply marvellous with what success the great demon is kept under. At the same time, we cannot disguise from ourselves that both the number and the size of the London fires have been increasing at an alarming rate the last few years, though it is true that 1885 exceeded even 1886. Another serious matter is the lamentable loss of life, which is undeniably on the increase. This seems to point to some defects in the life-saving apparatus.

THE delegates of the Edinburgh Free Library Committee, after having examined the several sites considered eligible for the central library, have recommended the site on the west side of George IV. Bridge, immediately to the south of the Highland Society's rooms, and opposite to the Sheriff Court Buildings. The estimated cost of the site is 11,000*l.* The recommendation was submitted to a full meeting of the Library Committee, and it was unanimously adopted, and the site in question fixed upon. The superficial area of the proposed site is stated to be ample for the requirements, affording an available floor space of 1,950 ft., which is capable of accommodating 150,000 volumes. The foundations of the new building will be upon the low level of the Cowgate, and will necessitate the removal of several old buildings in that street. The principal entrance will be from the high level of the bridge, having an elevation of three stories, beneath which will be other three stories. A report is to be given by an architect as to the best manner of constructing the proposed building, and it is probable that designs will be called for by an open competition.

AT a meeting of the Edinburgh Town Council on Tuesday last, it was agreed to ask the Executive Committee of the International Exhibition to remove all the buildings from the West Meadows at an early period. It was reported that fifty-five competitive plans had been received for the new Municipal Buildings, and arrangements were made for selecting those which are entitled to the awards. The successful plans are afterwards to be exhibited at the Council Chambers for the benefit of the public. This appears to us to be putting the cart before the horse. The real use of exhibiting competition drawings is to get general criticism and public opinion; to exhibit them after the award is made is to lose all the advantage of that.

WE mentioned a few weeks back that a series of plinths, bearing sculptors' signatures, of the school of Aphrodisias, had been discovered in the Sette Sale. We are glad to learn from the last issue of the *Buletino della Commissione Archeologica* that one of the statues belonging to a signed plinth has been successfully reconstructed. The statue represents Poseidon life size. The head is finely worked, and in excellent preservation. The body, with portions of both arms and legs, has been put together. The feet still adhere to the plinth, which is covered with a series of curved lines to indicate the sea. The right arm seems to have leaned on the trident. The inscription is clear, and can easily be restored: —

“ΦΛ(αοβίος) Χρυσάρι(ς) (Ἰάφρο)δεισ(αυς)  
(ἱπο)ίει.”

This gives us a clear instance of the type of the god Poseidon at a definite date, and hence a fixed standpoint for the dating of many other unsigned statues.

IN our number of the 27th of December, 1884, we described the new buildings for Hatchett's Hotel and "White Horse Cellars," at the corner of Dover-street, Piccadilly, which were opened on Monday, the 19th of January

following. On the 26th of January last (1887) the premises were put up for sale by auction, under order of the Court of Chancery. The sale at the Auction Mart realised 65,000*l.*, the purchaser being, it is reported, Mr. R. Pratti, of No. 45, formerly the Ship, Charing-cross. The ground plot contains about 4,550 superficial feet, excluding the vaults beneath the pavements. This freehold site was sold for 70,000*l.* about four years since. The land-tax having been since redeemed, the existing premises were erected at a cost exceeding 32,000*l.* What Limmer's, in Conduit-street, used to be to patrons of the ring and the turf, so was Abraham Hatchett's hostelry to the high-class gentlemen of the road. It served, in fact, for head-quarters of the mail coaches that travelled into the West of England. Hazlitt says that the finest sight in the metropolis is the setting off of the mails from Piccadilly,—a scene depicted in Rosenberg's print, after J. Pollard, of 1823. In Holcroft's yet popular play, "The Road to Ruin," will be found Goldfinch's rattling account of the wedding coach he had just ordered at Hatchett's. That "all-flash" equipage, could it be reproduced to-day, with its striped panels, fringed hammer-cloth, and green and white curtains festooned, and team of grays, would form a startling feature of the view whose pristine glories a recent revival has partially restored. Some relics of the former house are preserved here; amongst them an oaken drain-pipe, the smoke-jack, and game roasting-hook, the toasting contrivance, and the sign-board bearing the first proprietor's name.

A PARAGRAPH in the *Standard* of the 31st ultimo records the death of the Marquess de Foulon, architect, at the ripe age of ninety-two. He was the son (or nephew) of that Foulon who in the French Revolution told,—or was believed to have told,—the famishing populace to "eat hay." They set upon him in his carriage in the streets of Paris, murdered him in the presence of his wife, stuffed his mouth full of hay, and hanged him on the next lamp-post. We have heard the son recount the facts, while denying the assigned cause. He was, and used to be, a young man, the pupil of Nash, and used to meet at his house, among the society of that day, Brummel, the elder Pugin, Mathews, and the Prince Regent. He was full of anecdote, and recounted, with frank speech and much genuine humour, the sayings and doings of the jovial spirits of that practical joking age. He tried his fortune in America, and built more than one theatre in New York, but returned to this country partly through lack of employment and partly through dislike of the Yankee of the period. At seventy years of age he was employed in the Works Department of one of the Government offices. He had all the vivacity of a young man,—stood the whole day at his drawing-board, and walked to and from his work daily. He was a perfect gentleman, and had something of the grand manner about him, and although he never obtruded his affairs or his history on his companions, he would, upon a little encouragement, be communicative, and was on such occasions extremely interesting. As a water-colour artist he had considerable skill, although his work was of a kind now obsolete,—purely conventional, and having but little resemblance to nature. We hope that a full memoir of him will be forthcoming, for so long and varied a professional career cannot but be worth relating by those who have time and materials for the task.

IT appears that the Royal Academy, under the recent pressure of public opinion in favour of "reform," has voted, by a majority, for a scheme by which 100 privileged "outsiders" are to be selected, whose works will have priority of choice in hanging, after those of R.A.'s and Associates, of course. This appears to us a very clumsy expedient, merely creating another privileged class, and leaving painters of genius who have not been brought under notice in making the selection still the probability of having their works turned out for inferior but privileged ones. The question to be settled by the Academy is this: do they intend their exhibition to represent contem-

porary art at large, or do they intend it for an Academicians' Exhibition? In the former case, there is too large a proportion of their own work; in the latter, too large a proportion of outsiders. It is neither one thing nor another. What is really wanted is that a good many Academicians should paint better than they do, or else give up claiming space for exhibiting. The former condition they cannot comply with, and the latter would be too much perhaps for human nature. But we do not think the privileged-hundred idea will work.

A PORTABLE smoke-hox and fan for driving smoke for fumigation, testing of drains, &c., produced by Messrs. Baird, Thompson, & Co. under the uncouth sobriquet of the "Grahtrix," appears to be an acquisition in the practical application of smoke tests. The portion of the apparatus containing the motor windlass and fan fits inside the smoke-hox, and can be taken out and put in the reverse way, the whole then forming a closed hox with lid and handles, 17 in. by 8½ in. by 12 in., and such as one man can carry. The propelling of the smoke is done, by the working model we have examined, very efficiently.

THE collection of "Italian, French, and Spanish pictures" at the Goupil Gallery includes, among its best items, two or more works by an English painter, Mr. Fulleylove, which have been seen in London exhibitions before, but are well worth seeing again. Among the pictures which come properly under the description of the exhibition are some brilliant works by Benjamin Constant, and some of the light, hard, but very clever pictures of T. Benliure. Of these, "Selling Pardons" (41) is perhaps the best, and contains some brilliant painting of architectural detail. The "Spanish Flower Market" (18) is one of those paintings which represent the unreal effect of a brilliant sunlight which yet seems to cast no shadows,—a falsity which is unpleasant to the eye.

WE are glad to learn, from a letter in the *Times* of the 31st ult., that Mr. W. Colnett, the recent proprietor of the old Cook Tavern, immortalised by the Poet Laureate in his "Waterproof's Lyrical Monologue," has had all the old fittings, "including the celebrated chimney-piece, with the carved oak overmantel," and the panelling seats and tables, refitted in a room at 22, Fleet-street; so that the associations of the old room are not dispersed and lost entirely.

WHAT can be the meaning of this advertisement in the *Church Times*?

TO the CLERGY, and Others interested in Church Restoration and Rebuilding.—PLANS and advice free of charge, by an experienced and successful Architect. Highest testimonials. Distance no object.—Apply to Messrs. B.— & Co.

We suppress the address. What do Messrs. B.— & Co., or the architect they "keep," expect to get by this? Clergymen are usually pretty wide awake as to the capacities of the architects they employ. Surely in vain the net is spread in the sight of any bird, more particularly of a clerical bird. However, the *Church Times* is not a "trade journal," and that may account for odd things getting into it.

AMONG the various ways proposed of celebrating the Jubilee of our most gracious Sovereign, one of the oddest at first sight is that proposed by Mr. Mark H. Judge at a meeting of the Paddington Vestry on the 25th ult. We may give it in the form of the resolution proposed:—

"That in the opinion of this Committee, the Dust-collecting and other trades, which are carried on in connexion with the Canal basin between Warwick-crescent and Praed-street, besides being a continual menace to the health of the parish, are, during the summer months, a serious danger to the inmates of St. Mary's Hospital, and a source of annoyance to the Great Western Railway Terminus, which is so often visited by Her Majesty the Queen and the Ministers of the Crown; and that the Committee, therefore, considers that no better memorial of the Victorian Jubilee could be devised in Paddington than for the vestry to purchase the

canal basin and adjacent property in order that this long-standing nuisance may be abolished, and the site suitably utilised for residential and other purposes."

The other proposals, which were all referred to a Special Committee, were,—a Town-hall; a Recreation Ground; a Public Library and Museum; and an "Imperial Institute" (!). These are more showy projects, no doubt, than the dust (or anti-dust) scheme; but it may be doubted whether the latter is not the most useful and beneficial of all. Dust being "matter in the wrong place," if all the matter of every kind that is in the wrong place could be removed during the year, it would indeed be a year of jubilee.

#### LETTER FROM PARIS.

M. FOURQIAN, a young architect who in 1883 displayed much activity and taste in the organisation of the Amsterdam Exhibition, has been charged by the Committee for the French Railway Jubilee Exhibition to instal in the Bois de Vincennes, on the lawn Daumesnil, the International Railway Exhibition of which we spoke in our last. Though the City of Paris has given the committee every facility and has liberally granted them a large slice of one of our most frequented promenades as a site, the principle of the Exposition has been unfavourably discussed and has aroused a kind of tacit opposition. Thus, the six great French railway companies, in spite of protestations and of the favourable report of the new Minister of Public Works, persist in refusing to associate themselves with the scheme, which they declare to be contrary to historic truth and against the interests of the Great Exhibition of 1889.

This latter and larger project may be considered to have entered definitely into its active period. On the Champs de Mars the work for the foundation of the piers is being arduously carried on, and it is hoped that the foundations will be entirely finished by the 1st of May. Some figures may give an idea of the extent of the work. The general levelling of the ground and construction of drainage has been estimated at 780,000 francs. The cost of the Palace des Beaux Arts is taken at 6,205,725 francs. The gallery for various exhibitions and the annexes count for 5,900,179 francs, and the machinery pavilion is estimated at 6,496,228 francs.

Various modifications are being introduced in the architectural portion of the constructions. Thus, the principal gallery, by M. Bouvard, will have a monumental entry, surmounted by a dome, opposite to the Trocadero. The galleries designed by M. Formigé also present each of them a dome; and the machine gallery by M. Dutert, which will terminate externally in semicircles, will present at its two extremities enormous gables, the decorative effect of which will be ungraceful enough.

The Colonies Exhibition will occupy, on the esplanade of the Invalides, a surface of 11,000 mètres. Another space of the same extent will be reserved for the countries of the Protectorate. Lastly, the banks of the Seine will furnish a good position for the annex services of the colonies, where will be picturesquely grouped the multiform and many-coloured products of Eastern and tropical localities, illustrating boats, fishing, habitations, &c. Along the river also, on the Quai d'Orsay, will be installed the large bazars reserved for agricultural produce and food products.

As to the Eiffel tower, which one must still talk about because so much talk is made about it, its intended position has been again modified by being moved back to the extent of the width of one of the great piers which are to carry it. This unhappy tower was the occasion of a popular disturbance the other day, on the ground that three-fourths of the workmen engaged for it were foreigners. On inquiry, the number of actual foreigners was reduced to seven Belgians; and no one could complain of this, as the construction is really a private enterprise of M. Eiffel's. Nevertheless, there were loud protestations, and a numerous crowd repaired to the Hôtel de Ville to protest and demand work, as in the bad days of the *année terrible*. M. Alaphand dissipated the popular wrath by promising new and important works as soon as the weather became milder.

It may be mentioned, in connexion with this subject, that there is talk of organising on the Champ de Mars a section of "Economic sociale ouvrière," showing what has been done in

France since 1789 to improve the position of the artisan, and what is contemplated in the future.

The private exhibitions usual at this time of year have been inaugurated by that of the "Garde Artistique et Littéraire," in the Rue Volney. It contains important works by a good many artists of repute, and portraiture especially is very honourably represented by MM. Bonnat, Aimé Morot, Hennep, and Delannay. M. Cazin exhibits a landscape of great power and originality; M. Rollé's "Tauxem au Pâturage" is a magnificent study; and we may mention also the works of MM. Jules Lefebvre, Barillot, Carols Duran, and Contois. The exhibition of the rival club, the "Mirlitons," will take place shortly.

Special mention may be made of an exhibition of water-colours in the Galerie Georges Petit, the work of a young artist, M. Tsché, who gives evidence of remarkable originality and power. The collection contains impressions of Eastern scenes, painted with much truth, and some powerful original compositions, in which allegory and realism are successfully combined. The decorative feeling of the young painter has had the most free play in the work which he has executed at Chénonceaux, the mansion of M. Pelouse, a commission in which his talents were allowed full scope, and which shows him to be an artist with a future before him.

We referred before to a dispute between M. Marquette, the sculptor commissioned to complete the statue of Étienne Marcel, and the Messrs. Thibaut, the well-known founders. The upshot of the affair (in which the artist had the bad taste to invoke the aid of the Parisian press while the committee of experts was still sitting) was that, although the committee decided that the statue had been cast in one piece (which was what the sculptor denied), MM. Thibaut, by way of putting an end to discussion, requested to cast it again at their own cost. The actual merit of the work is left for the jury of the 1889 Exhibition to determine, as the founders are to keep it as the chief feature of their show-room until that period.

The Municipal Council have recently increased the budget of the Beaux Arts department by 100,000 francs for the undertaking of some new and important work. Independently of the decoration of the salons of the Hôtel de Ville, which is to be commenced soon, there is the question of the restoration of the magnificent Gobelin tapestries, the value of which is estimated at two million francs, and which are decaying in a cellar of the Pavillon de Flore. It is thought that the Municipality may purchase, as a museum for these and other objects, the Hôtel de Sens, the former habitation of the Archbishops of Paris, and which is now on sale. All the "Amis des Monuments Parisiens" join in hoping that the Government will thus save from almost certain destruction this ancient and interesting relic of the past.

In speaking last month of the future of the Musée Guimet, we forgot to mention another museum which is to be erected not far from that, on the Avenue de Trocadéro; a museum which the Duchesse de Galliera has generously given to the city. M. Guinain is the architect entrusted with the work, the cost of which is estimated at about three million francs.

The inauguration of the new Hôtel des Postes is at last announced for next month; so, at least, the Ministry promised the other day to the delegates from the Municipal Government. If this is adhered to, the ugly sheds will, it is to be hoped, be removed from the Place de Carrousel, and there will only remain there, for some time at least, a sufficiently enormous metallic construction which is erected really by way of an experiment. This, which is intended to serve the Public Library at Fort de France, is in the form of a square with angle partitions; the whole construction is of iron, partition walls, landings, tables, &c. The cost is about 100,000 francs.

Among current artistic news may be mentioned first two competitions opened, one for the erection of a monument to Sergeant Bobillot (killed at Tonkin), the other for the construction of a Hôtel de Ville at Vincennes. The first is open to sculptors and architects equally, the latter to architects who satisfy the jury that their designs can be carried out for 450,000 francs. We shall have occasion to refer to this competition again.

A fine statue of Denis Papin is to be erected in the Court of the Conservatoire des Arts et

Métiers; the sculptor is M. Aimé Millet. The work will soon have for a pendant the statue of the celebrated chemist Leblanc. During the month the statue of Louis Blanc, by M. Delhomme, will be unveiled on the Place Monge. Lastly, M. Margnet de Vasselot has nearly completed the model for the statue of Henri Martin, the bronze of which is to be erected at St. Quentin, the birth-place of the historian. The same artist is working at a bust in marble of General Boulanger, which the old comrades of the Minister of War wish to present to the Ecole Militaire of St. Cyr.

At the Ecole des Beaux Arts the work of the pupils is in full activity. The architectural section is proceeding to the classification of the sketches for the Achille Leclère competition, the subject of which was "An Establishment for the Exhibition of Horticultural Products." The decision will be made known on the 12th of March. The examination for the Diploma of Architecture has been completed, and it is to be conferred on MM. Devienne and Laffolye, pupils of M. Coquery; M. Leidentrost, pupil of M. Guinain and Questel; M. Kraff, pupil of M. Pascal; MM. L. Roy, Coetz, and Hardion, pupils of M. Vandremere; MM. Bomier and Handucœur, pupils of MM. Moyaux and André; M. Manahäfer, pupil of M. André; M. Brémont, pupil of M. Guinain; MM. Barbary and Majon, pupils of M. Guadet; and M. Étève, pupil of M. Douillard.

For the Godehœuf competition, for which the subject was "a design for an electric lamp standard," out of sixty-nine designs sent in, the jury presided over by M. Questel has given "premières médailles" to M. Paquier, pupil of M. Guadet; M. Tourmaine, pupil of M. André, and M. Raphael, pupil of M. Raulin; two "secondes médailles" to MM. Weissmerger and Defays, pupils of M. André; and twenty-three honourable mentions.

January has unhappily left us a longer list than usual of mortalities in the artist world. We have lost M. Bartet, the engineer, M. Alphonse's right-hand man, and most active assistant in the embellishment of Paris, of whom we have made mention on various occasions. He was an "aspiré d'élite," admirably gifted, and with a great faculty for work. He had the charge of the new crematory appliances at Père Lachaise, and had been commissioned to work with M. Alphonse on the 1889 Exhibition. He was still young, and it is to be feared he succumbed to the pressure of overwork.

Art has suffered a great loss in the death of Ferdinand Gaillard, one of the modern masters of the burin, who has died when in the maturity of his talent and reputation. He obtained the Prix de Rome in 1856, and received medals in 1867, 1869, 1872, and 1876, since which latter date he has been Chevalier of the Legion of Honour.

Two other artists of great talent are deceased after a long life of work. The celebrated glass-painter, Maréchal de Metz, is dead at the age of eighty-six, at Bar-le-Duc, where he had retired since the war. He received medals at the Salons of 1840, '41, '42, and '50, and was officer of the Legion of Honour since the date of the last Exhibition. The *doyen* of French sculptors, Daumas, has also died at the age of eighty-six. He was the oldest and one of the best known pupils of David d'Angers. His first exhibition work was in 1833. He was author of the "Cavalier Romain" statue on the Pont de Jena. He received a decoration in 1808, and medals in the Salons of 1843, '45, and '48.

Lastly has disappeared from the world of art Joseph Michel Anne Le Lonfaché, formerly pupil and then assistant of Duban, successively treasurer and then "censeur" of the Société Centrale des Architectes. M. Le Lonfaché was also member of the jury of the Ecole des Beaux Arts and Chevalier of the Legion of Honour. He built a number of private houses at Paris, and may be in some degree regarded as the creator of the Parisian house as adapted to the requirements and tastes of modern life. He was eighty-three years old at the time of his death, but had up to the last shown all his usual energy in the work of the Annual Congress of Architects, at which he assiduously attended the meetings, visits, and excursions. M. Questel and M. Hermant pronounced at his funeral some eloquent words in recognition of the merit of their old professional brother, whose death had left such a void in the Société Centrale.

#### THE TWO DE BRYs.

SOME of our readers who have followed us in our studies of the old masters of the art of decoration will, doubtless, feel some relief when they light upon the heading to this article, in the fact that at last we have come to two artists whose name and whose works are, to a certain extent, known to them. With the exception of two or three of the more famous of the German masters,—Israel von Meckenen, Aldegrevier, and Altdorfer, and possibly, though in a less degree, Béham and Virgil Solis,—in the numerous crowd of artists who lived by designing, there is hardly another, save the De Brys, father and son, over whom the cloud of oblivion does not rest; but that it does, as a fact, envelope them undeservedly we think that we have by this time established conclusively. Some of the work of the De Brys, however, must be familiar to many through the medium of the many illustrated magazines whose editors have dipped slightly, and all too superficially, into the treasure-house of the past for decorative friezes and tail-pieces. Both father and son were very prolific workers in a style, among others, admirably suited for these objects. But even in their case the difficulty of accurately apportioning to each his proper work meets us, and even so astute a student as Nagler has been compelled to give up his task in despair. This difficulty arises in the first place on account of the father and son having the same name, and using almost identical monograms; and in the second place, on account of their having worked a good deal together; so that "I.D.B. fec." now stands for the father, now for the son, and now for both together. Even when for the sake of the father, we are not free from trouble, for another son, John Israel, appears on the scene as the younger John Theodore's assistant. But John Israel De Bry does not appear to have done any original work, and he may be at once dismissed, leaving the two Theodores to be jointly studied.

The father, Theodore, otherwise Derick, which has been Englished into Dirk, De Bry was born at Liege in 1528; he afterwards resided in Frankfort, as a print and book seller, where he died in 1598. As an engraver he modelled himself on Hans Sebald Béham; whether he did more than this, whether he actually copied, worked with, or worked for Béham is a difficult matter to determine. One of his plates of processions seems to us to be a sort of "Homage à Béham," for on the awning of a cart forming part of it is engraved the Little Master's monogram H.S.B. with a coat of arms below it. The impression in the British Museum is printed on satin, as if it had been designed and published to commemorate some special incident in Béham's life. There are a great number of these processions, for the most part 7 in. or 8 in. in length by rather more than 1 in. in height. He seems to have taken the greatest delight in devising them; they are all crowded with admirably-drawn figures, and are all executed with the greatest skill and precision. One series is especially noteworthy; it bears the title "The Procession for the Funeral of Sir Philip Sydney, invented by Thomas Lant, gent., and graven in copper by Derick or Theodore de Brie, in the City of London, 1578, in thirty-four plates." These processions are outside the scope of our present study; they are interesting, however, to us as being the known work of the elder De Bry, and so furnish us with some clue towards the determination of the authorship of some of the less known decorative work. The engraving of the dolphin friezes is clearly from the same hand; there are four or five of them each containing, but not in consecutive design, five dolphins and children; a sketch of one of these groups is given in fig. 1; the endowment of the dolphin with acanthus fins and tail is especially curious. The child, however, is entirely realistic, and they may be regarded as whimsical fantasies rather than serious efforts at ornament.

But of ornament pure and simple the elder De Bry designed a considerable amount, and we think that there are certain fairly clear signs by which it can be distinguished from the ornament which is known to be by his son; that is to say, if we omit taking any note of the assistance which the son rendered to his father. The execution is as fine and careful as it is in the Processions, and the design is as closely packed on the surface of the object ornamented as are the figures in the crowds. We shall see when we come to the examination of the son's

work an absence of any attempt at compression, the subjects being chosen for the most part to allow of a greater freedom and play for the curves, and almost as a necessary consequence of this, a very much coarser execution. Figs. 2 to 5 are characteristic of the old De Bry's manner, and may be taken as typical of nearly all his work; the style is almost invariably Renaissance, which, if not very original, is at least graceful. The two designs, figs. 2 and 3, probably come from the series "Des pendants de cleffs pour les femmes, propre pour les argentiers"; fig. 4 is one of two isolated designs for bracelets. With regard to fig. 5 we confess to having some besitation in admitting it to be the work of either of the De Brys. It is, however, classed among his works in the British Museum collections,—a fact which must, of course, carry much weight. The elder De Bry is also known to have designed some "manches de couteaus avec les feremens de la gaine (the ironwork of the sheath), de plusieurs sortes, fort profitable pour les argentiers ou autres artisans." The work, both in detail and in general execution, almost exactly resembles the knife-handles of Michel Le Blond, more especially the series from which the fig. 8 of our issue of Jan. 15 last is taken, the quaint outlines of both being absolutely identical, though the ornament is different. Le Blond, it will be remembered, was born in Frankfort in 1580, and probably had begun to work there before the elder De Bry died. If therefore the two sets of plates are correctly assigned to their respective authors,—as to which we still have our doubts,—the resemblances are so strong as to indicate a close artistic relationship between the two men, such as the apprenticeship of the young Le Blond to Derick De Bry.

The large circular panel (fig. 6), though it is generally attributed to the father, seems to us clearly to have been the joint production of the two De Brys. The entire execution is as fine as the Processions, and the whole plate was probably engraved by the father. The compactness of the surrounding ornament in its main structure, and the neatness with which its main features split up the surface, suggest that the conception of the design was also the father's. But the subordinate details, the hunches of flowers and fruits, the dogs and the rabbits, the caterpillars and the butterflies, have no counterpart in any of the designs which may without doubt be attributed to the father, but are almost identical with the details which frequently figure in (or rather disfigure) the son's acknowledged work. It appears to us, therefore, that though the father engraved the whole plate, the son was employed to devise the minor details of the ornament which, though they are subordinated to its main structure, go far to mar the beauty of the whole conception. That conception, as we have said, is very charming, and to it may be attributed the popularity of the engraving, which is, perhaps, the best known of all the works of the Frankfort printseller.

Fig. 7.

Passing now to the work of John Theodore Do Bry, the son, who was born at Liege in 1561,

Fig. 1.

Fig. 3.

Fig. 2.

Fig. 5.

Fig. 4.

Fig. 8.

Fig. 9.

Fig. 10.

we must first notice his "New Artistic Alphabet, ornamented with beautiful figures, the meaning of which adapts itself to the letters, artistically engraved on copper by De Bry, also described by entertaining Latin and German verses." From this alphabet comes the initial letter S (fig. 7): S stands for Solomon, and the verse attached to the letter is as follows (translated into very blank verse):—

"Solomon, also, the wise man,  
Full of great gifts and good deeds,  
Trusting alone on God;  
He built to his honour a temple,  
Therein was God's name praised,  
And it covered the king with glory,  
For whatever is done for God's honour  
Shall endure everlastingly."

Each letter of the alphabet stands for some person famous in Scripture or history, beginning, as in duty bound, with A for Adam, the chief features in the ornament being supposed to

series of gymnastic evolutions, men fishing, bunches of flowers hanging about everywhere, varied by bunches of pears, and apples, and gourds (which will at once be recognised as coming from the same hand as the hanging fruits in the ornamental border of the circular panel which we have already criticised in fig. 6); tassels and tortoiseshells, helmets, spears, and armour of all kinds; in one Moses giving the law; in one a man in an impossibly awkward position cutting off poppyheads (presumably Trajan, though somehow or other he has found his way into the letter G); in another a centurion drinking to "love and war," and in yet another a fisherman holding grapes in one hand and catching a mullet with a hook and line in the other, while his naked spouse with less purpose in view even, dangles fruits into space; and everywhere Cupids put in just to fill up odd corners. Mongrel,

Israel De Brie, "fratres Germanos, cives Francofortien."

Figures 8 and 9 are two of a series of friezes probably executed by the younger De Bry at a much later period of his life. We have attributed them to the son on our own authority; no reference to them is made in Nagler's list, unless they are the "Grotis [grotesques] pour orfèvre et autre artisien" which he attributes to the father. But, as there is no possibility of doubt that they are not the work of a De Bry, so it seems to us there is no possibility of doubt that they are not the work of old Derick. The hand which crowded seven or eight square inches with fifty or sixty carefully-drawn figures, or which filled the little bracelet and "pendants de clefs" with minute Renaissance designs, could never have forgotten the minuteness of its cunning, nor would it even have voluntarily relinquished it. These friezes, which are about

Fig. 6

adapt themselves suitably to the character of the person, whose merits or demerits the poet sings in his simple verses; though it must be confessed that the connexion between Solomon in all his glory and the acanthus-tailed angel who forms part of the structure of the letter S is a little difficult to follow: though, of course, she may be a glorified Queen of Sheba. The letters themselves are about eight inches high by five broad, and can only be described as poor in the extreme; very few of them, indeed, have any sign of properly conventionalised ornament; the fragment of acanthus scroll at the bottom of the S, and forming the angel's tail, is almost the only attempt at it. The figures themselves are ill drawn, and the details are badly conceived and promiscuously put together: they are of all sorts and kinds; birds, beasts, and fishes, reptiles and insects, Cupids balancing themselves in all manner of impossible situations, ladies with wings going through a whole

impossible, contortionate, disproportionate, without a spark or germ of beauty from A to Z, and withal lacking the true humour of a genuine grotesque, this alphabet is still not without its interest, as telling of the simple things which pleased the minds of simple Frankfort folk towards the close of the sixteenth century; and it has a further interest too, for us, illustrating the remarkable progress in the art of decoration, which study can bring about in a man's work. The remarkable step from bad to good which the younger De Bry took, and which our remaining illustrations witness to.

It is not very clear whether the brother John Israel did not assist in the contriving of this remarkable production; he certainly did in another, which, from its title, is doubtless conceived in a similar style,—“Alphabeta et Characteres, jam inde a creato mundo ad nostra usq. tempora,” by John Theodore and John

9 in. by 3 in., came, on the face of them, from another workman; and though they differ from the alphabet as light from darkness, it is not impossible but that they should be examples of the mature powers which in their infancy had only produced work worthy of infants. In these friezes there is but little to criticise adversely; the birds do not obtrude themselves too prominently in fig. 8, and in fig. 9, they form a not illegitimate part of the design, and are treated almost heraldically. If there is a weakness at all, it is in a certain lack of homogeneity in the main structure of the design. Although it is with a certain sense of relief that we miss the great scroll of the acanthus rolling its length along, in at one end of the frieze and out at the other, yet we also notice with a certain sense of pain the absence of any well-defined lines of construction. They are there, it is true, but they are out of proportion with and lost behind the

foliage and flowers, which are of considerable size, and this gives at first sight a patchy appearance to the whole which is distinctly unpleasant. On closer study, however, we cannot fail to be struck by the beauty of the foliage and floral devices. They are as original and beautiful as those of Israeluh von Meckelen, though they only resemble them in the faintest degree. Wherever we look we are met by some form which is entirely new to us, and which has clearly been worked out and elaborated in accordance with the best traditions of decorative art. The conventional form of the seed-pod of a papilionaceous plant strikes us as especially beautiful and original. Nor do we remember coming across it in the work of any other designer before or since. Every one of the series (there are at least ten of them, and possibly more, though they are not all in the British Museum collection) will well repay careful examination. As we did in the case of Von Meckelen, in our issue of the 5th of December, 1885, we have extracted in fig. 10, from the remainder of the series, some specially noticeable forms with which we close our short sketch of these two men, who, if they are not in all things worthy of a place in the first rank of designers, are at least remarkable men, worthy of attention and study at the hands of those who follow the arts in these modern days.

#### ON GREEK SCULPTURE AS EXPRESSIVE OF THE EMOTIONS.

-ROYAL ACADEMY OF ARTS.

Mr. A. S. Murray, of the British Museum, delivered the third and concluding lecture of this series\* to the students of the Royal Academy on Monday evening. He said that the history of Greek sculpture in respect of style divided itself into three periods,—an archaic period, in which the tendency was towards technical skill in rendering the human figures with reference to its movements and costume; a second period, when the human figure was conceived and rendered in a large, broad, ideal manner; and a third period, when technical skill, with innumerable new resources, again obtained the ascendancy. If it were needful to define those three stages more strictly, one way of doing so would be to test each of them by its manner of dealing with the expression of the emotions. In the archaic stage the human figure, in its movements and costume, was paramount; its emotions, and the soul within it, were known and recognised, but they were not identified closely with the body; they were chiefly shown as impelling it to this or that action. In the ideal stage a grand effort was made to reconcile, as Hegel said, the inner with the outer life of man,—his emotions and his thoughts with his bodily form. The effect was altogether noble; but obviously the tendency could not rest at the simple reconciliation of soul and body which we found in the works of Pheidias, where emotion was expressed only so far as it was consistent with the highest conceivable type of form. The next stage was to particularise more the several elements of the body and the several elements of the soul resident in it, always, however, developing them both simultaneously, and never incurring the reproach which had been levelled at Christian art,—the reproach of treating the passions and emotions irrespectively of, and often with intentional indifference towards the form or beauty of the human figure in which they were displayed. The present lecture had to do with the last stage, when the Greek sculptors set themselves to particularise the emotions, and to find such types of the human figure as could best be made to express emotion and yet remain beautiful. It was a natural step from Pheidias, with his figures alike ideal in body and soul, yielding to passion or feeling only as such beings might yield. It was a step that led ultimately to the Laokoon group and the sculptures of Pergamon. But it was necessary to go back to the first masters of the school, Skopas and Praxiteles, and see the kind of beginning it made. For us, Skopas was represented by certain sculptures in relief from the Mausoleum, in particular those slabs found at Halicarnassus by Mr. Newton. A comparison of those slabs with the same subject as represented on the friezes of Phigaleia and of the Nike temple

\* For reports of the first and second lectures see last week's *Builder*, p. 175.

at Athens would show that the Mausoleum figures had a marked individuality. They were particularised in their forms; each had its own identity. They were more likeliving sympathetic beings than any other figures in older art. But the standard of beauty was still rigorously enforced as a necessary accompaniment to the expression of feeling. The lecturer did not claim for those figures a pronounced show of passion or feeling, but he contended that certainly some of them did clearly express emotion, and that their forms were so conceived as to be able to convey emotion and yet remain beautiful. For instance, there were bearded men as well as youths among the Greeks there fighting against Amazons, and it might as well have happened to a bearded man to have been struck down by an Amazon as it had happened on one of these slabs to a youth who still eagerly tried to defend himself. But the emotion which was appropriate to the fine form of the youth would have been disagreeable in an older man; it would have touched us with pain. It was almost an art in itself to find the right type of figure for the emotion which it was desired to express. Skopas himself might not have had any hand in those particular sculptures, but there was one figure from another frieze of the Mausoleum with which it was difficult to dissociate him. It was a figure of a charioteer bending forward in the race. The reason for assigning it to Skopas was that among the few fragments that had as yet been recovered from his sculptures at Tegea, was a head which closely resembled the head of the charioteer referred to, both in style and in type. It was a type of being to whom the eager straining forward in a race was perfectly natural, and not the source of confusion or perturbation. The eyes, which were naturally deep in the sockets, were pressed forward and rounded. The cheek was kept flat, showing the strong line of the jaw and the cheek-bone, as was usual in the expression of anxiety, where the muscles strained forward and produced that somewhat hard look. The throat had become strongly marked through the upward movement of the face, by which movement also the hair had slipped a little down on the ear, the charioteer being too absorbed in the race to notice it. This was made all the more noticeable by the fineness of the ear itself and the precision with which its relation to the cheek was indicated. The lips were parted in eagerness. Belonging to the school of Skopas or of Praxiteles was the statue of Demeter from Knidos. The type of the figure was that of a young mother, "a Greek Madonna," as she had been called, whose sorrows and whose joys were of a saintly character. Her feelings at the untimely loss of her daughter Persephone must not do violence to her physical beauty, and yet they must be expressed. It was thus a question with the sculptor of reconciling her physical beauty with her emotions, keeping both unimpaired. The head was turned sideways a little, as if in some uncertainty as to the direction in which she should look for the coming again of her daughter. The sockets of the eyes, though fairly deep, were relieved of some part of their shadow by the brows being rounded off and not allowed to impend over the eyes. Why the forehead was so unusually high seemed to pass explanation. The eyeballs were rounded and penetrating. The muscles of the face worked forwards towards the profile, as in all cases of sorrow, the effect being that the breadth of the face when seen in front was considerably narrowed, or, in other words, the expressive part of the face was circumscribed within the narrowest possible limits, and thereby intensified. But the cheeks did not lose their softness; they were not flattened at the sides, showing the jaw and cheekbones. That had been achieved by taking as a model one of those typical women who carried much of the aspect of ripe maidenhood on into a fairly advanced matronship, who, in fact, reminded us of Madonnas, and who combined both the spiritual and the sensual life. The mouth would be too small for a figure of the older ideal order of Pheidias, though it suited perfectly the type of figure under consideration. The lecturer next referred to the head of the statue of Hermes by Praxiteles, found at Olympia and still remaining there. The statue was of marble, and represented the god holding on his left arm a younger brother, the infant god Dionysos. Hermes was looking down and answering the infant's look of childish curiosity with a smile of kindness. The corners of the mouth were

drawn back as if he were restraining the smile from becoming a laugh, confirmation of this being afforded by the lips being parted, though the teeth were shown to be closed. The smile was not enough to broaden the face in front, as happened in the expression of mirth, yet it did sensibly broaden it. The right cheek was pushed back distinctly, and the effect was heightened by the otherwise strong and firm line of the jaw being interrupted through the lowering or bending forward of the head, an action induced by the feeling of kindness and tenderness, and one which contributed to the expression of an emotion. The eyes were turned inwards a little, as in looking with curiosity at a near object. The pupils, instead of standing vertically to the face, sloped forward in the upper part. That might not be possible in nature, but it was not uncommon in Greek sculpture where a face was looking downwards. In the present instance, the object of the sculptor was to express the full and kindly gaze of Hermes. It appeared to the lecturer that that position of the eye, filling up the socket more than was usual, and destroying the mass of shadow that would otherwise be there, helped materially to brighten the face, and to contribute to the expression of tender regard on the part of a strong man for a weak child. In the Farnese Hermes the same type of face was to be seen, but worked into an expression of actual pain or anguish, under the later influence of Rome, when for a time it seemed as if art, in its pursuit of sentiment and emotion, would abandon that old and true principle which insisted on a special type of physical beauty for special types of emotion. Having spoken of the statues of satyrs by Praxiteles, and of his statue of Eros, the lecturer said that an effective example of the expression of grief by sculpture was to be seen in a marble figure, of life size, found a few years ago not far from Athens. It had been a monument above a tomb, and represented a female figure seated in an attitude of grief, her head resting on her right hand, the elbow on the thigh, the left hand lying helplessly in her lap, and the feet crossed. That statue had been assigned to the age of Skopas and Praxiteles, but it must have been at the beginning of their age that it was sculptured, if not even a little further back towards Phidias. The forms were of a larger mould than had usually been associated with Skopas and Praxiteles, and there was a roughness and want of finish about the work which was unusual in their time. The figure was not penetrated with vitality, as were those on the Mausoleum frieze. She was not a personification of grief in general, but of grief as it affected a particular class of womanhood which she in her person placed before us. The sculptor appeared to have carefully avoided any very strong expression, such as would have driven us to think of some particular person and her sorrows. In Athens might be seen hundreds of funeral monuments sculptured with figures in relief, which were intended to soothe the survivors by appearing to share in their sadness and sorrow. As a rule there was no approach to violent emotion in those reliefs. Of the expression of such emotions as rage, the lecturer did not remember any noticeable instances in Greek sculpture, though there were several striking examples on the painted vases. While between the time of Praxiteles and the Laokoon group there had been growing up a desire on the part of sculptors of expressing strong emotion in the faces of their figures, that desire was accompanied by a considerable disregard of the principle which in the good times had insisted on powerful emotions being confined, as far as possible, to beings of a lower nature placed in subordinate positions in the design. The rule seemed to have been that a figure, ugly or repulsive in its form or expression, was not itself a fit subject for the higher arts. But in approaching the period of the Laokoon group, not only did strong emotions find expression in the faces of exalted persons, such as deities and heroes, but there was a large accession to the list of beings of a lower nature in whom the expression of violence of feeling or of passion was regarded as appropriate. The well-known figure in Rome of a dying gladiator, a Gaul in the very act of dying from a deep wound in his side, was a case in point. Anguish was expressed in every feature, and pain in all his limbs. Again, the *Amendola* sarcophagus, as it was called, was a very mine of sorrowful expression, with its series of reliefs representing com-

bats between Roman soldiers and Gauls. Among the figures of the Gauls, but only among them, the pain of mortal wounds, the fury of deadly combat, and despair at the sight of a descending blow from which there was no escape, were forcibly rendered; while among the women of the Gaulish camp it would seem that every attitude capable of expressing dismay, sorrow, and grief had been brought into use by the sculptor. The lecturer next proceeded to refer to the Laokoon group, an objectionable element in which, as it seemed to him, was that the punishment was being inflicted by hateful and loathsome creatures against whom there was no credit in struggling, if, indeed, there was any time given to struggle. Be that as it might, the three sculptors who combined their talents on the marble group conceived Laokoon as making a last effort of physical strength accompanied by an expression of the deepest pain and agony. The central figure was that of a priest of noble birth and of a fine form, yet with an expression on his face that could not be regarded as other than ugly and repulsive. Such a combination of beauty of bodily form with repulsiveness on the face seemed to the lecturer to be a mistake. No doubt the face was one which in time of repose would look equally noble with the bodily forms, but even that consideration did not remove the objection to it. The lecturer said he could only see one explanation of it, and that was that the group had been sculptured under the influence of what was called the Pergamon school, which revelled in representing battles of gods against giants having legs formed of serpents, or battles between Greeks and Gauls. A great many of these Pergamon sculptures were now in Berlin, where they constituted a long series of figures in pretty high relief and on a colossal scale of proportions. They were much admired in Germany, where force and rude vigour are more admired in art than need be. But admiration of the Pergamon sculptures was not at all confined to Germany. They appealed to every one who cared for a skilful handling of the human form with a sound knowledge of it in detail, and with a strong appreciation of its beauty. These sculptures showed invention, also, in abundance, but that was the point where they seemed to go wrong. The invention was not of a good kind. A recent writer in Germany had said it down that the business of an artist was to represent scenes and objects which the imagination of ordinary people was unable to recall or reproduce. That, said the lecturer, seemed to be a good description of an equally ordinary artist. One could understand the admiration of that writer for the sculptures of Pergamon, because, with their excellent qualities they combined a very ordinary faculty of invention. Nevertheless, it was a fertile faculty, and supplied us with much to look at. Side-by-side with the love of seeing strong emotions expressed in beings of a lower order there grew up also in later sculpture a love for the expression of the gentler feelings which distinguished persons of finer natures. Groups representing such sweet brotherly affection as existed between Orestes and Pylades, or Orestes and Elektra; or motherly tenderness, as between Merope and her son,—these were the subjects which Pasiteles and his followers delighted in for three successive generations. That was the last phase of Greek sculpture proper, and it was gratifying to observe that in it the old rule had re-asserted itself,—that whatever feelings were to be expressed, a special type of physical beauty must be found to convey them. No doubt the range of feelings expressed in the works of Pasiteles and his school was very limited. It included for the most part only such as could be reconciled with, and were most natural to, youthful forms advancing towards manhood and womanhood. In general that was the age of sentiment, and among persons of that age it was often difficult to say whether it was the sentiment they expressed or their physical beauty which ennobled them the most, so completely were those qualities reconciled in them. Pasiteles was a sculptor of many accomplishments, and he was a close student of the works of the old Greek masters in his art. Old records bore testimony to the carefulness and elaborateness of his preliminary studies, and to his having modelled directly from nature. That testimony was confirmed by such works as were known to have been executed by his school; unfortunately, we had nothing from his own hand. The sculptures of his school derived their pose and structure in the main

from an archaic Greek type. But the sentiment which pervaded them, the sensitiveness of skin and flesh, the delight evinced in observing the minutest formations of bone, as at the knees and feet, the softening down of outlines where they were apt to be harsh in nature, and the general placidity of forms which accompanied the severe and almost rigid structure of the limbs,—these characteristics were at variance with the sculpture of archaic Greece as we generally understood it, and we might credit their introduction into sculpture by Pasiteles and his school. In his concluding remarks, Mr. Murray said he had been anxious not to appear as a special pleader for the expression of emotion in Greek sculpture, because, though that had been the subject treated of in these lectures, it would have been equally allowable to have declared, in the manner of the famous chapter on snakes in Iceland, that there was no such thing as expression in the sculpture of the Greeks. The facts, however, did not justify such a view; what they did justify him in doing was to admit that there had always been a certain measure of constraint in the expression of the emotions by the Greek sculptors, but at the same time to claim that notwithstanding that, the desire of such expression was always present as a guiding factor in their conceptions.

#### ROYAL INSTITUTE OF BRITISH ARCHITECTS.

The fifth ordinary meeting of this Institute for the present session was held on Monday last, Mr. Thomas Worthington (Vice-President) in the chair.

##### Obituary.

The Secretary (Mr. W. H. White) announced the decease of Mr. R. C. Hussey, formerly a Vice-President, and who had retired a short time ago from the membership of the Institute. He added that a memoir of Mr. Hussey, communicated by Mr. Rickman, would appear in the forthcoming Journal of Proceedings. Mr. Thomas M. Rickman was a pupil of Mr. Hussey, who had been a partner with Mr. Rickman's father, the Rickman of the Gothic revival.

Mr. Joseph Jennings said that he had known Mr. Hussey as a young man, and produced two architectural etchings of his executed in 1827 and 1828. Mr. Hussey was the youngest of a clever family, but he was for a long time inviolated, which was the reason for his retirement both from the profession and from membership of the Institute.

Mr. J. Macvicar Anderson (Hon. Sec.) announced the receipt of a large number of donations to the library.

##### The New Street at Charing Cross.

Mr. Macvicar Anderson further said that in connexion with the new street recently formed by the Metropolitan Board of Works from Charing-cross to Tottenham Court-road, a suggestion for its improvement had been made by the standing Art Committee of the Institute, and submitted to the Council and adopted by them. It was intended now to submit it to the Metropolitan Board. Any one who had taken the trouble to examine the street recently formed, especially at the part adjacent to the National Gallery, would see that the line adopted was a peculiarly ugly one, so much so that the marvel was how it had entered into the brain of any one to adopt such a line. It would further be observed that the plot of ground which existed north of Hemming's-row, and on which a public-house now stood, was proposed to be left for a small triangular plot of buildings. The Council intended to ask the Metropolitan Board to be kind enough to hold their hand for a short time in regard to dealing with this plot, until they had considered the suggestion about to be submitted by them. That consisted (1) of amending the line of street which had been adopted, along the eastern frontage of the National Gallery, making an architectural line parallel with what would be, he hoped, the architectural *façade* of the building to the east facing St. Martin's Church; (2) that the triangular plot, instead of being left as a group of unworthy houses standing on the north side of one of our most important national monuments, should be embraced in the site of the National Gallery, so that that building might have not only a southern frontage to

Trafalgar-square, but an eastern architectural *façade* opposite St. Martin's Church, and a northern *façade*, finished probably with a circular termination facing the new street. Those suggestions the Council thought well worthy of consideration, and they would be sent within the next few days to the Metropolitan Board of Works, accompanied with a strong letter of recommendation.

##### Jubilee Exhibition at Adelaide.

Mr. Anderson further referred to the Jubilee Exhibition to be held this year in Adelaide. The Fine Art Committee appointed for this Exhibition, and consisting of Sir Frederick Leighton, Sir J. D. Linton, and Sir John Gilbert, proposed to send out a limited number of drawings by leading English architects. They, however, regretted that the allotted space was small, but suggested that, in addition to the drawings, photographs should be sent of buildings executed by living architects. The Council of the Institute hoped that this invitation would be liberally responded to. They proposed to send 100 photographs of representative buildings, and the only condition was that the photographs should be of executed buildings, and not be taken from drawings. The expense of forwarding these photographs to Adelaide would be defrayed by the Institute.

##### The Liverpool Cathedral Designs.

Mr. J. P. Seddon remarked that next morning most of the Fellows would receive an invitation from Mr. John Scott and himself with regard to the proposed memorial to the Liverpool Competition Committee that they should, before coming to a decision on so important a subject, permit the drawings to be exhibited in London. This was a matter of national importance, and he believed that such a memorial could not but be acceded to. He would, therefore, be glad if the Council thought fit in any way to second the proposition.

##### Presentation of Medals and Prizes.

Mr. Anderson said that the next business was to present the Godwin Medal for the year 1886, but before that was done he might be permitted to explain that the successful competitor, Mr. W. T. Oldrieve, had carried out the necessary obligations, completing his tour and submitting his report to the Council, who had awarded him the money prize of 40l.

Mr. Oldrieve not being able to attend the meeting personally, Mr. Hugh MacLachlan received the Medal from the Chairman on his behalf.

Mr. Anderson then said that the Pugin Student for 1886 was Mr. H. D. Walton who undertook to make a tour in parts of Worcestershire and Shropshire, following the lines of railway that pass through Tewkesbury, Hereford, Ludlow, and other places of equal interest; and selecting such examples of domestic architecture as seemed most suitable. Those who had visited the exhibition of Mr. Walton's drawings in the Arbitration-room of the Institute had an opportunity of judging how he had fulfilled his obligations. The Chairman then presented the Pugin Medal to Mr. Walton.

Mr. Henry Thomas Hare then came forward to receive the Ashpitel Prize for 1886. Mr. Anderson explained that this was a prize of books to the value of about 10l., awarded by the Council to the candidate who, in the opinion of the Board of Examiners, distinguished himself most in any one of the examinations held during the year. The number of candidates who passed the obligatory examination, in the three held during last year at Leeds and London, was thirty-nine, and Mr. Hare was considered to have excelled beyond all the others.

Mr. Anderson added that before leaving the subject of prizes, it was not altogether inappropriate that Mr. Worthington should preside upon the occasion when a paper was to be read on "Mind Architecture," he having at the age of sixteen or seventeen submitted an essay upon the manufacture of bricks, which gained the Silver Medal of the Institute. In those days there were not so many prizes offered as at the present time, and the credit of gaining one was, therefore, all the greater.

##### The New Superintending Architect.

Professor Kerr.—I think we ought not to lose the opportunity of saying a complimentary word with regard to the selection of our Fellow and friend, Mr. Thomas Bashill, to a very dis-

tinguished appointment. There were many others amongst the candidates whom we might have cordially congratulated, but the fortune of war has gone in Mr. Blashill's favour. Those of us who know Mr. Blashill, and we almost all know him personally, will all be able to congratulate him on his appointment, and, not only so, but to congratulate the Metropolitan Board of Works upon having appointed him. Mr. Blashill is a sound practical man, and I think we ought to be gratified to give utterance to this feeling, as a testimony of our appreciation of him. We know him as a thoroughly practical man, who has been well trained in business, as a man of genial manners and good-natured conduct, and he has especially distinguished himself recently by promoting those happy excursions into Italy, which I hope will soon make their mark.

Mr. Charles Barry.—It gives me the greatest pleasure to second the proposition of Mr. Kerr. Had he not mentioned it, I intended myself to have suggested it to the meeting, knowing the great cordiality with which it would be received.

#### Portrait of Mr. Ewan Christian, Past-President.

With reference to the portrait of Mr. Ewan Christian, past-President, Mr. Charles Barry, Treasurer to the Subscription Fund, observed that from want of funds he was not yet able to accept the generous offer of Mr. Oules, R.A., to paint the portrait for the Institute at considerably under his ordinary charge. He needed about 150*l.* to complete the sum required, and could not doubt that it would be speedily provided by the members of the Institute.

#### Election of New Members.

The following gentlemen were then, without ballot, admitted as Honorary Corresponding Members, viz.—The Conte Giuseppe Sacconi, Architect, Member of the Superior Council of Fine Arts, Ministry of Public Instruction, Rome; Signor Michele Ruggiero, Director of Monuments and Excavations for the Kingdom of Italy, Member of the Royal Academy of Naples; and Signor Giovan Battista Filippo Basile, Professor of Architecture at the University of Palermo, Member of the Academy of St. Luke, Rome.

The following members were elected by ballot, viz.—As Fellows: Mr. C. H. Samson, Taunton; Mr. T. H. Sapsford, City Architect, Sydney, New South Wales; Mr. Edward John May (Associate), Hart-street, Bloomsbury; Mr. H. Hall (Associate), Southampton-street, Bloomsbury; Mr. Hugh Stannus (Associate and Ashpitel Prizeman), Larkhall Rise, Clapham; Mr. Thomas William Aldwinckle, East India-avenue, Leadenhall-street; Mr. John Butler, Redcliffe-gardens, South Kensington; and Mr. Fred. Bath (Associate), Salisbury. As Associates: Mr. W. A. Gelder, Savile-street, Hail; Mr. A. B. Mitchell (Soane Medallist, 1885), Pembury-road, Clapton; Mr. A. Hayes, Clyde-street, Chelsea; Mr. S. Perks, Wandsworth Common; Mr. G. E. T. Lawrence, Ealing Common; and Mr. Henry Thomas Hare (Ashpitel Prizeman), Regent's Park-villas, Gloucester Gate.

The following Hon. Associates were elected by acclamation:—Professor G. Baldwin Brown, M.A., F.S.A. (Scot.), the University of Edinburgh; Mr. Edwin Lawrence, LL.B., B.A., Assoc. Inst. C.E., King's Ride, Ascot; and Major-General Richard Clement Moody, Fairfield, Lyme Regis.

#### Mud Architecture.

Mr. William Simpson, R.I., F.R.G.S. (Hon. Associate), next read a paper entitled "Mud Architecture: Notes made in Persia and other Countries." We give an abstract of the paper, and some notes of the discussion thereon, on another page.

**Messrs. Perry & Co.'s Government Works Unemployed Relief Fund.**—The committee of this fund have met weekly for the past ten weeks to distribute the balance of 43*l.* remaining from the fund of last winter. We are informed that they have relieved forty-two most deserving cases, and the funds getting low, they appealed to the men employed on these works, with the result that 19*l.* 7*s.* 8*d.* was subscribed in a fortnight, with the promise to continue the subscriptions for four weeks longer if necessary.

## Illustrations.

### "A CLASSICAL CHURCH."

**WE** give this week the design by Mr. F. W. Simon, which obtained this year the Tite prize at the Institute of Architects. The Tite prize was founded, as most of our readers are aware, by the late Sir William Tite, for the encouragement of the study of Italian architecture, at the time when the Italian style was apparently entirely succumbing to the inroads of modern Gothic. Times have changed since then. The author has chosen a square type of plan, with a large central area, as the type specially suited for modern worship, in which we concur with him.

The design is a successful treatment of recognised and orthodox features in the Italian Renaissance style, the introduction of the headed two-light windows, with a dividing shaft, being a reminiscence of the earlier Renaissance manner, which breaks the coldness of the prevalent type of detail very agreeably, but which Sir W. Tite probably would not have approved. From our point of view, on the other hand, it is a pity to see such poor and worn-out features as the festoons and urns reproduced once more. Cannot the aspirants for the Tite Prize exercise themselves in attempting to improve upon and develop the details of the style a little? There is plenty of room for it.

### "THE BRAZEN SERPENT."

#### SCULPTURE.

WE give illustrations of the two sketches in clay of this subject, which obtained the first and second prizes respectively, the former being by Mr. W. H. Totterdale Venner, the latter by Mr. George J. Frampton. We commented on the designs at the time of the exhibition of the students' drawings.

### MORTUARY BUILDINGS AND FIRE-ENGINE STATION, HORNSEY.

WE illustrate this week two sets of buildings, viz., mortuary buildings and fire-brigade station, which have been recently erected by the Hornsey Local Board, and the business-like manner in which they have been designed and carried out speaks well for the care that the Board is taking in providing for the ever-increasing wants of the large and important area under their control, comprising as it does the districts of Hornsey, Highgate, Crouch End, Stroud Green, Fortis Green, and Muswell Hill.

The site of the mortuary is on a short private road, out of the High-street, Hornsey, and in the arrangement of the plan the greatest care has been taken to ensure that the buildings and premises generally shall be isolated, nonobtrusive, and, as far as possible, concealed from the public view.

The mortuary buildings are in four distinct blocks, the first comprising coroner's court, witnesses' rooms, and caretaker's rooms; the second, two mortuary chambers, with viewing lobby and shell-store; the third, a *post-mortem* room and laboratory; and the fourth, disinfecting rooms and offices in connexion with same.

The coroner's court is a spacious well-lighted and ventilated room, about 27 ft. by 18 ft., fitted with benches for the jury, and a raised platform for the coroner, and with waiting-room for witnesses adjoining.

The caretaker's rooms comprise two bedrooms, kitchen, and scullery, bath-room, &c.

The mortuary building consists of two chambers, each containing three slate slabs on iron standards, one chamber being reserved for those who have died from infectious diseases.

The chambers are separated by a viewing lobby which has a small window and blind opposite each mortuary slab. From this lobby the jurors, or others interested, can view the bodies without entering the chambers. This lobby is also provided with an exit door, so that the jurors after their inspection may pass along the open passage in rear, and return by the side entrance into the court, as indicated by the arrows on the plan. On the outside of each chamber is a glazed closet or press, in which are hung the clothes of the deceased, as a means of identification.

The walls of the mortuary are lined with

white glazed bricks, and all internal angles are formed of hollow bricks, to prevent the accumulation of dust.

The floor is of Granolithic concrete, and the ceiling of iron joists and concrete, finished in Keene's cement.

A small room is provided adjoining the mortuary for an ambulance-shed and shell-store.

The *post-mortem* room and laboratory adjoining are lighted and ventilated from the roof, and lined with white glazed bricks, and contain the usual fittings and appliances.

This building is kept entirely distinct from the others, in compliance with section 143, Public Health Act.

The disinfecting-room contains a Lyon's patent disinfecting apparatus, manufactured by Messrs. Manlove, Alliott, & Fryer, of Nottingham. The infected clothing is brought in a covered van (kept for this sole purpose) into the disinfecting-room, and the infected articles are placed direct into the disinfecting-chamber, which consists of an oval cylinder 5 ft. long, with door at each end, and in which works our runners a galvanised-iron wire cage; the steam-tight doors being closed, steam is injected into the cylinder from a vertical boiler adjoining, at a pressure of 25 lb. to the square inch, and the articles, after remaining a sufficient time in the chamber, are withdrawn through the door at the opposite end of the cylinder into a second room, which is fitted with a copper, and other appliances for washing and cleansing, and from thence are returned to the owners,—a separate van being kept for this purpose.

Adjoining the disinfecting-rooms is a destructor, for destroying all articles which it is necessary so to treat.

The fire-engine station is situate in the Tottenham-lane, Hornsey, and being in a more prominent position than the mortuary, more attention has been given to the external appearance; the stock brick fronts being relieved by red-brick quoins, moulded cornices, and pediments, and terra-cotta enriched string courses.

Accommodation is provided on the ground-floor for two fire-engines, the large doors to engine-rooms opening automatically. On the upper floors are chambers for resident firemen, and in the rear of the main building are stables, and also a large depot for the scavenging and watering appliances of the Board. At the side of the fire-engine house is a shed for housing the steam-roller. These works have been designed and carried out by Mr. T. de Courcy Meade, A.M.I.C.E., the Surveyor and Engineer to the Board.

The mortuary buildings were erected by Mr. Wm. Tongue, of Plumstead, and the fire-brigade station by Mr. J. W. Dixon, of Highgate.

### ELECTION OF A DISTRICT SURVEYOR.

At the meeting of the Metropolitan Board of Works on the 25th ult., the election of a District Surveyor for the District of Charlton, Lee, and Kidbrooke, in the room of the late Mr. James Collis, was proceeded with. There were thirty-eight candidates, but for voting purposes these were reduced to thirty-five, three out of the total number of candidates not being present,\* in accordance with the requirements of the Board. The results of the preliminary voting on these thirty-five candidates, to reduce the number to six, were as follow:—Edmeston, J. S., 38 votes; Hardcastle, W. J., 32 votes; Lovegrove, H., 32 votes; Saunders, M. L., 38 votes; Stock, H. W., 37 votes; and Woodthorpe, E., jun., 31 votes. The subsequent voting, which was taken by ballot, was as hereunder:—

|                     | Second | Third | Fourth | Final |
|---------------------|--------|-------|--------|-------|
|                     | Vote.  | Vote. | Vote.  | Vote. |
| Edmeston.....       | 20     | 25    | 26     | 34    |
| Hardcastle.....     | 7      | 4     | —      | —     |
| Lovegrove.....      | 10     | 11    | 11     | —     |
| Saunders.....       | 10     | 10    | 14     | 17    |
| Stock.....          | 5      | 4     | —      | —     |
| Woodthorpe, E. Jun. | 2      | —     | —      | —     |

Mr. Edmeston was therefore declared to be the successful candidate, and thanked the Board for his election.

**Ingram House, Fenchurch-street.**—Mr. N. Maurice, of West Green-road, Tottenham, writes to say that he supplied the stoves, grates, fireplaces, tile-hearths, &c., for this building, as well as the marble columns and pilasters to shops.

\* One of the absentees, Mr. W. Hilton Nash, wishes us to state that he was unavoidably absent.

## MUD ARCHITECTURE IN PERSIA AND OTHER COUNTRIES.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

At the meeting of the Royal Institute of British Architects on Monday evening last, Mr. William Simpson, F.R.G.S., of the *Illustrated London News*, read a paper on "Mud Architecture," being notes made in Persia and other countries.

The author explained that his paper treated of mud when used directly in building, as well as when formed into bricks and dried in the sun. His information was collected in the winter of 1884-85, when he was attached as a special artist to the Afghan Boundary Commission. Starting from Resht, on the Caspian, he travelled to Sarrahs and Kuhsan by way of Persia. The winter was spent at Bala Murghab, and the return journey was made *via* Meshed, Shahrud, Astrabad, and Keneri Gez, on the Caspian. Throughout the whole of this district mud is, to this day, the principal material used in building; buildings of burned brick are rare, and the ruins of such still more so. Where old towns or cities stood, all that now remain are mounds. In Persia he came across one or two examples of mud architecture, which served to show to what perfection the process might be carried, and the use that was made of glazed pottery in embellishing this class of building.

Pursuing his journey eastward, about 100 miles from the Persian capital Tehran, Lasgrid was reached. Here is a very remarkable specimen of mud building, in the form of a village erected on a circular mound of mud raised some 30 ft. above the surrounding level. There is but one entrance to this block of buildings, capable of admitting only one person at a time. This village is probably the remains of the stronghold of a town, and the object of this peculiar mode of construction is to provide a refuge inaccessible to the Turkoman horsemen, the ruthless raiders of Central Asia, and the Eastern frontiers of Persia. As they were unable to besiege a place, rapidity of movement was necessary to the success of a swoop upon a village, and the chief object of the inhabitants was to put themselves as rapidly as possible into a safe retreat.

Near Mazinan are the remains of two towns now deserted and in ruins. One of these, he stated, was similar to that at Lasgrid, but only 20 ft. in height, and had now become a quarry, from which mud was extracted for other buildings. Here he found a small room, 15 ft. by 10 ft., which was a great surprise to him, and which showed what it was possible to do with this material. The walls were perfectly square, and at right angles, and had been finished off with a layer of *gutch* or gypsum, which had been run into delicate mouldings and stamped, whilst wet, with a raised pattern.

Two miles south of Nishapur, a large town of mud houses, and mud walls, he found a large square mound, and traces of the mud walls of an ancient town. At Meshed, the capital of Khorassan, is the tomb of Iman Reza, the eighth Iman, who died in 818 A.D. This is inaccessible to any but the faithful, but the author obtained a good view from a neighbouring house. The dome over the tomb and the tips of the minarets are of copper thickly gilt, and the interior was described to him as being richly decorated with gold, silver, alabaster, marble, precious stones, and beautiful tiles. On the road from Meshed to Sarrahs he passed through a desolate country where are the remains of mud villages and walls in various stages of ruin. At Sarrahs, the Persian town or New Sarrahs, built as a fort for the accommodation of troops, the walls and houses are entirely of mud. At Old Sarrahs, on the right hand of the river Tejed, though no doubt a very ancient, and probably in former times a large, place, he found only a square mound, each side of which was about 300 ft. The top of the mound was covered with fire-burned bricks, the remains of substantial buildings. About a mile to the north-west of New Sarrahs are the remains of a burned-brick tomb, decorated with beautiful plaster ornament, which seemed satisfactory evidence that similar results had been obtained in the plaster ornamentation of mud buildings, in which it was known that plaster had been employed for finishing. From Sarrahs to Kuhsan, a distance of 140 miles, the country once fertile and populous is a desert, in which are slight traces of the ancient water-courses. From Kuhsan, the author crossed over the ancient Badghiz to

the Khushk Valley, in the centre of which is a large mound with ruined towers of burned brick on its summit, and ruins of mud walls at its base. So recently as 100 years ago this valley was well peopled. At Kara Tappah Kurd, and Kala-i-Maur, he found mounds, apparently square on plan, and on the latter the remains of a burned-brick fort.

Near the junction of the Khushk and the Murghah rivers stands Ak Tappah, or the "White Mound," by far the largest mound seen by the author. Roughly speaking, it is triangular in form, the longest dimension being about 300 yards, the greatest width 100 yards, with a total height of about 100 ft. With the exception of a modern mud parapet, this was found to be a bare hill. On both banks of the river for a considerable distance south of Ak Tappah he found a succession of mounds, many of them probably of great age, indicating where prosperous towns have stood in this once fruitful valley. The whole distance of about twenty miles from Penjeh to Meruchak is covered with similar ruins. Among nearly all the mounds examined, the author found innumerable fragments of pottery, the remains of the beautiful glazed tiles with which it was no doubt customary to decorate the most important mud buildings, such as mosques, tombs, &c.

He managed to pick up a few details of the manner of construction of mud buildings in Persia and India. In good houses, the foundations often 3 ft. or 4 ft. deep, are formed of rough uncut stones or burned bricks. Walls are from 2 ft. to 4 ft. in thickness,—thickness of wall ensuring coolness in the house. The mud is built in layers, 2 ft. or 3 ft. in depth, it being necessary to allow one layer to dry before another is put on. The upper parts of the walls are sometimes formed of sun-dried bricks, and are occasionally built "hollow." A mixture of mud and chopped straw, called *kahgill*, is applied as a coating on the outside of walls to preserve them from the weather. In Indian villages the mud houses stand on a *chabutra*, or raised platform, which is washed at regular intervals with a mixture of mud and cow-dung. In India flat roofs covered with mud are common; but in Persia, wherever wood is scarce, the roof is carried on arches or domes of mud bricks, laid in *gutch* or gypsum.

The author's interest in the mud buildings of Persia arose from their similarity to the Afghan villages with which he had become familiar in 1878-79. An Afghan village is surrounded by four walls with a tower at each corner, and an entrance gate at one side; and he found the same arrangement and mode of construction to exist on the whole route followed by him from the Caspian to near the banks of the Indus. He considered that this similarity found in methods of building, although in such a primitive material as mud, should give greater confidence to those interested in tracing a connexion between the arts of Persia and those of India. He noticed on the Heri Rud, and at other places near, some rock-cut caves, which he believes to be clear evidence of the spread of Buddhism from India towards Central Asia, and possibly further westwards. The mud crenellated walls, with towers at the corners, and occasionally at intervening points, seen by the author in Central Asia in ruins, and in course of construction at the present moment in Persia, are the exact counterpart of the walls shown on the Assyrian sculptures in the British Museum, which it is known were built of mud. Such walls have existed in Mesopotamia for thousands of years, and the identification includes a long period of time and covers a large geographical space.

His examination of these mud buildings has led the author to think that the idea of the arch, for the invention of which the Romans have been credited, is all but co-eval with mud building, and that its invention, as is shown by Egyptian remains, is lost in the past. The dado also, he considered, was only a direct evolution from the simple mud wall of primitive times, which required protection along its base. Our investigations into the origin of architectural forms have, he stated, up to now been almost exclusively confined to early wooden construction, to the exclusion of the more primitive method of building in mud. The oldest civilisations that we know of were in Egypt and Mesopotamia,—two countries where mud building has existed from the earliest times, and is the mode of building still employed. The author had himself sketched

the mud houses discovered by Dr. Schliemann at Hisarlik in Greece, and quoted Miss Yule's description of the present method of building "cob" walls in Attica.

As far back as the year 385 B.C., the year in which Agesipolis took Mantinea, mud walls were used for defensive purposes, and were usually found more effective than walls of stone. The author thought that translators of Greek works had used the word "brick" when "crude brick" would have been a more faithful rendering; hence the extent to which mud was used by the ancient Greeks has not been quite understood. The late explorations at Olympia revealed at one spot some data upon which a theory has been based, which, if correct, will add much to the importance of mud in relation to architecture in the past. The discovery has led to the suggestion that the cella walls of temples were sometimes built of sun-dried bricks, a suggestion on which the author did not venture to pronounce a judgment of his own.

In many parts of the world "wattle-and-dab," is to be found, and the author was indebted to an article in the *Quarterly Review* for the knowledge that in at least one part of England mud is a building material. The writer of the article came to the conclusion that the city Cain built was of "cob"; and that the tower of Babel was principally formed of the same material. The importance of this subject was illustrated by references to it in early mythology. A divine origin was generally given by the primitive religions to whatever was of high value to man; architecture, or building, on this account, was supposed to be derived from the Deity, and Sanchoniathon, as well as Berossus, gives a mythic origin to sun-dried bricks, and to building houses with mud. A similar expression of idea is found in the Shah Nameh of Firdusi, where Jemshid is said to be the first teacher.

In the discussion which followed, Mr. Alexander Finn, H.B.M. Consul at Resht, in Persia, said that he had been in Persia for eleven years, and while out on shooting excursions he had often put up in villages the houses of which were entirely constructed of mud. In fact, it would be said that north of the Elhurz range, which ran through the north part of Persia, every village was built of wattle and mud, and every village to the south of mud without any wattle. Indeed, he did not know of a single town in Persia not built of mud, with the exception of some of the principal buildings, which were constructed of stone or kiln-dried bricks. He was sorry that he could not quite agree with one of Mr. Simpson's remarks about the dado. This, he believed, was not intended to protect the walls from the men's backs, for during all his sojourn in the East, he could not remember once seeing an Oriental with his back touching the wall. The dado was intended rather to protect the lower part of the wall from damp. The floors being made of the same muddy material as the walls were apt to become dusty, so that each time they were swept the watering-pot had to be used. These mud walls, generally speaking, did not last very long, and the moment a house was deserted, or left for any reason, it seemed to begin to tumble down. In the plain of Verameen could be seen the walls of an old city called Erig still standing, though nothing whatever of the town remained.

Professor Kerr proposed a vote of thanks to Mr. Simpson for an exceedingly appropriate, useful, and learned paper. The subject might be of more interest to them than Mr. Simpson would suppose, because they, as architects, fully appreciated what he had called mud building, only they did not like to use the word "mud." Indeed, he almost wished Mr. Simpson had not used the word. For himself, he should prefer to call it "earth-concrete." He merely suggested the term, and he would tell them why. There was a certain dignity,—and he spoke advisedly,—of building involved, which dignity had been the theme of Mr. Simpson's discourse throughout, but which was not indicated by the manner of the application of the term "mud." Might not he put it historically in this way,—first, they had "earth-concrete"; secondly, soft brick; thirdly, hard brick; and fourthly, lime-concrete, stone not being involved here at all? These four materials looked at historically constituted a complete series of scientific building materials, and if Mr. Simpson would only consent to abandon the use of the word "mud," and adopt another more dignified term, the series was one which might be studied with

considerable interest and profit. He had ventured to apply the term "earth-concrete" quite on the spur of the moment, because they had reverted at last to the same form in their lime-concrete. He would suggest that the vault had probably its origin in the use of "earth-concrete," but not the arch. The arch, he believed, was proved by the remains of Egypt and Mesopotamia to have proceeded originally from the contact of two stones laid at an angle, and meeting together at the top, where the abutment at each end was sufficient to maintain them in position. They could follow the introduction of the arch as a stone feature from the beginning to the end, but they were not able to trace the origin of the vault to its very commencement, and he was therefore disposed, on the spur of the moment, to accept Mr. Simpson's suggestion that it had its origin in the use of "earth-concrete." With respect to unburned bricks there was a singular illustration of it in the legend of the building of the Tower of Babel.

Mr. Hugh Leonard seconded the resolution. Having been a good deal in India, and having seen many mud buildings, he could appreciate the learned and scientific paper they had listened to that evening. He did not like to object to the use of the word "mud," as the poor natives of India made much of it, and the darning of the floor was really a modification of what the servants in this country did when using a white mixture to clean steps and floors. He happened to have a brick he had brought from the most perfect part of the Great Wall of China, which was there composed of sun-burned bricks, covered with parapets of burned bricks, and with a terrace of tile between them. Other portions of the Wall, which were built of stone, were by no means so strong as the parts constructed of sun-burned bricks.

The Chairman (Mr. Thomas Worthington, Vice-President) said that not the least interesting part of Mr. Simpson's communication was the exceedingly fine series of drawings exhibited on the wall. Mr. Anderson had made a personal reference to him (the Chairman), and to an essay he wrote in early life. He little thought when he received the medal from Earl de Grey, in the old rooms of the Institute in Grosvenor-street, that forty years afterwards he should occupy the chair on an occasion of this kind. He could remember that the researches necessary to produce a work consisting of some 200 quarto pages were very lengthy. He came across a great deal of mud architecture at the time, and sometimes found himself very much stuck in the mud. Indeed, the *Athenæum* of that day stated that he had exhausted the subject from the days of the Deluge down to the middle of the nineteenth century.

The vote of thanks was then put, and carried by acclamation. Mr. Simpson, in replying, expressed his satisfaction at the manner in which the paper had been received. He was afraid Professor Kerr's recommendation had come too late. He (the speaker) would have no objection to changing the title, though he preferred the one he had adopted. Professor Kerr's title might be a little more scientific, but his own, he believed, would be better understood.

The Chairman announced that the next meeting would take place on the 14th inst., when a paper entitled "Notes made during Tours in Greece, 1881 and 1884," would be read by Professor T. Hayter Lewis, F.S.A., Past Vice-President.

**Hygienic Exhibition at Warsaw.**—Arrangements have been made for holding this year a hygienic exhibition at Warsaw. The exhibition will be divided into five groups, comprising, respectively, the hygiene of food, of dress, of dwellings, of schools, workshops, and hospitals, and, finally, statistics and meteorology. The opening is fixed for May 15th, the closing for July 1st.

**The Cheap Application of Electricity.**—The *Journal Officiel* contains a decree of the French Minister of Education appointing a Commission charged with considering a prize of 50,000 francs to the inventor of a cheap application of electricity to heating and lighting, chemical action, mechanical power, transmission of telegrams, or the treatment of the sick. The chairman of the Commission is M. H. Bertrand, Permanent Secretary of the Paris Academy of Sciences.

#### NATIONAL ASSOCIATION OF MASTER BUILDERS OF GREAT BRITAIN.

This Association held its half-yearly meeting on the 25th ult., at the George Hotel, Nottingham. Mr. W. H. Cowlin, of Bristol, presided, and representatives from London, Bristol, Bradford, Bolton, Birmingham, Manchester, Liverpool, Derby, Hull, Walsall, Lincoln, and Nottingham, were present.

The report and accounts for the past half-year were adopted and passed, and

The following gentlemen were appointed officers and Council for the ensuing year:—*President:* Mr. Robert Neill, jun., Manchester; *Vice-Presidents:* Mr. J. H. Colla, London, and Mr. Robert Dennett, Nottingham. *Hon. Vice-Presidents:* Mr. Stanley G. Bird, London, and Mr. W. H. Cowlin, Bristol. *Hon. Treasurer:* Mr. J. C. White, Liverpool. *Hon. Auditor:* Mr. Jos. Stevenson Jones, Liverpool.

The following gentlemen were appointed to serve on the Committee:—Birmingham, Mr. John Bowen and Mr. W. Sapote; Bolton, Mr. Joseph Henry Marsden; Bradford, Mr. William Monson and Mr. John E. Bealand; Bristol, Mr. A. Krass; Edinburgh, Mr. Thomas Bonnar; Hull, Mr. R. Bevers; Lancaster, Mr. William Huddington; Leeds, Mr. C. Tomlinson; Lincoln, Mr. William Henry Close; Liverpool, Mr. James Bronly and Mr. James Pendleton; London, Mr. Thomas Rider; Manchester, Mr. William Southern and Mr. William Browne; Northampton, Mr. W. H. Smith; Nottingham, Mr. Enoch Hind; St. Helens, Mr. R. Belshor; Wigan, Mr. Charles B. Holmes; Wolverhampton, Mr. G. Higham; and the Presidents of the Local Associations as Members of the Council, *ex officio*.

In the evening the representatives of the various Associations were entertained at dinner by the President of the Nottingham Association.

It was resolved to hold the next meeting of the Association in Glasgow.

#### THE INSTITUTE OF BUILDERS.

The annual general meeting of this Institute was held at the Offices, 31 and 32, Bedford-street, Strand, on Tuesday last, Mr. George Dnr, J.P., in the chair. The secretary, Mr. Richard S. Houshaw, read the report, from which we extract the following passages:—

"The Council, in presenting their Third Annual Report, are pleased to be able to state that during the past year the number of members has been increased by twenty-eight, making a total of seventy-one. They also have to announce that Mr. Robert Mitchell, President of the Melbourne Builders' Association, has been elected an honorary member, but they regret to have to record the death of Mr. George Eban.

The advisability of the admission to the Institute of Associates was discussed at the commencement of the year, but it was considered by the Council that the time had not arrived for the extension of the Institute in that direction. The matter is, however, to be again brought forward at an early date.

The question of the 'Non-acceptance of the Lowest Tender,' in limited or select competitions, was referred to the Institute by the Council of the Central Association of Master Builders of London, and the matter has been left to two members of the Council to draft a resolution to be presented to the Royal Institute of British Architects, calling the attention of that body to the subject.

Two Amendment Bills to the Employers' Liability Act (1880), having been introduced into the House of Commons, they were referred to a Select Committee of the House for consideration and report. Evidence was given by the President and Mr. W. H. Cowlin as to the working of the Act, especially with the object of showing the necessity for retaining the clause compelling notice of accident to be given to the employer within a reasonable time of its occurrence, and having the meanings clearly defined of the words 'employer,' 'contractor,' and 'sub-contractor.' The Select Committee have since reported to the House in favour, generally, of the proposed Amendments, and as the Act expires with the present year the Government have announced their intention of introducing a new Bill.

The Metropolitan Board of Works introduced a 'Water-wood' Bill (calculated to effect the storing of timber by builders, &c.), but the former did not reach a second reading, and the latter was withdrawn.

The Council saw no reason to object to the new By-laws as to Concrete Buildings introduced by the same body. It is generally understood that a 'Sanitary Registration of Buildings Bill' will be brought before Parliament next session, rendering it obligatory on the part of the 'owner, lessee, sub-lessee, or occupier' in towns of over 50,000 inhabitants, to deposit with a 'Registration Authority' a certificate that the sanitary condition of any building, occupied or intended to be occupied, is satisfactory. The Council are watching this Bill closely, and will consider their duty to oppose any such measure unless very considerably modified as to the manner in which its provisions are proposed to be carried out.

As the members are doubtless aware, a Benevolent Fund has for several years been in existence in connection with the late Builders' Society; this has now been transferred to the Institute in the names of Messrs. George Pincknett, Stanley George Bird, and Frederick John Favon, trustees, and is invested in New Three per Cent. Consolidated Annuities. . . .

Mr. Benjamin Hansen having resigned his trusteeship of the funds of the Institute, Mr. John Howard Colla was appointed to fill the vacancy thus occasioned.

The Council, being desirous of establishing a library in connection with the Institute have the pleasure to announce that a special fund has been started for that purpose. The Council, after due consideration, have decided that a course of papers on subjects of interest to the building trade shall be read at the Institute. . . .

In accordance with the Articles of Association, the President, Mr. Stanley G. Bird; one of the Vice-Presidents, Mr. George Burt; the Treasurer, Mr. George Pincknett; one of the Auditors, Mr. Herbert H. Bartlett; and the members of the Council, Mr. Woodman Hill, Mr. W. S. Horner, Mr. Robert Neill, jun., and Mr. Joseph Rendall, retire, but are eligible for re-election.

The Chairman, in moving the adoption of the report, said he was pleased to be able to say that a standing committee on Practice had been appointed by the Royal Institute of British Architects, who had under their consideration the Conditions of Contract.

The motion for the adoption of the report having been agreed to

Mr. J. Howard Colla was elected President for the ensuing year; Mr. H. T. Ashby as Vice-President; and Mr. Woodman Hill, Mr. W. S. Horner, Mr. R. Neill, jun., and Mr. Joseph Rendall were re-elected on the Council. Mr. G. Pincknett, J.P., and Mr. H. H. Bartlett were re-elected as treasurer and auditor respectively. Mr. Stanley G. Bird was elected a member of the Council, in the place of Mr. H. T. Ashby, after having filled the office of President for two years, for which service he was accorded a very cordial vote of thanks.

#### ELECTION OF SUPERINTENDING ARCHITECT:

##### METROPOLITAN BOARD OF WORKS.

At the meeting of the Metropolitan Board of Works on the 25th ult., Mr. George Edwards (Deputy Chairman) moved the adoption of a report of the Works and General Purposes Committee, submitting the names of the following six candidates for the office of superintending architect, and recommending that the Board do proceed to elect one of them to fill the vacant office.—Mr. T. Blashill, Mr. H. Gundry, Mr. A. Peebles, Mr. R. Plumbe, Mr. P. G. Smith, and Mr. E. J. Tarver.

After it had been decided, on the motion of Mr. Williams, to take the voting by ballot,

The Chairman of the Board (Sir James McGarel-Hogg) read a paper detailing the duties of the office as follows:—"To be Superintending Architect of Metropolitan Buildings, and to be Architect and Superintending Architect of work to the Board, at a salary of £500l. per annum, payable quarterly. To perform all the duties, statutory or otherwise, of the above-mentioned offices, and such other duties as have hitherto been performed by the Board's architects, and also to perform all such duties as the Board may from time to time direct. To be removable at the Board's pleasure. And the Board authorises the persons appointed to exercise the powers of entering and inspecting, and all other powers exercisable by Architects of the Board, and by virtue of the 21st Section of the Metropolitan Management and Building Amendment Act, 1878, or otherwise, under any statute or bye-laws."

The voting was then proceeded with, and a very tedious business it was. The following is a record of it:—

|                       | First Vote. | Second Vote. | Third Vote. | Fourth Vote. |
|-----------------------|-------------|--------------|-------------|--------------|
| Blashill, T. . . . .  | 14          | 17           | 20          | 27           |
| Gundry, H. . . . .    | 3           | 20           | 22          | 25           |
| Peebles, R. . . . .   | 19          | 20           | 10          | —            |
| Plumbe, R. . . . .    | 13          | 12           | 10          | —            |
| Smith, P. G. . . . .  | 4           | 3            | —           | —            |
| Tarver, E. J. . . . . | 0           | —            | —           | —            |

Mr. Blashill was therefore declared to be duly elected, and on the motion of Mr. Edwards the common seal was ordered to be affixed to the deed of appointment.

Mr. Blashill, addressing the Board, said,—Sir James Hogg and Gentlemen,—I beg to thank you most heartily and sincerely for the honour you have done me in electing me to this highly important office. No one can understand better than I do how it is that my majority is so narrow. It was because my good friend against me was so well worthy of the appointment. I hope that under the circumstances I shall so perform the duties of my office as to give

\* This was not the way in which the recommendation was put on the Board's agenda paper, owing to the quantity of which we were last week beguiled into announcing that the election would take place till Feb. 4.

satisfaction to every member of the Board. I am now about to enter on a most honourable office, and I hope I shall be able to carry it out with great cordiality with all the other officials of the Board of whatever degree.

[Mr. Thomas Blasbill, it may be mentioned, was a pupil of Mr. T. E. Knightley. He has been for twenty-five years in practice, and for the last ten years a district surveyor. He was elected an Associate of the Royal Institute of British Architects in 1866, and a Fellow in 1877. He is also a Fellow of the Surveyors' Institution, and some years ago he was President of the Architectural Association, in whose work he has continued to take a very active interest. We cordially re-echo the congratulations which were given utterance to at the Institute of Architects on Monday evening last, and which are reported in another column.]

#### THE USE OF MORTAR DURING FROST.

SOME time ago the police authorities of Berlin issued an order forbidding the construction of brickwork, should the temperature fall to or below 2° R. (26° Fahr.). This order being based on the supposition that mortar freezes at that temperature, and does not set, Herr Krause, architect, of Stropp, sent a communication to the *Baugewerke-Zeitung*, in which he publishes his experiences, which by no means seem to bear out the necessity for issuing the order. We give a résumé of Herr Krause's remarks, as well as of the opinions of some other German architects upon the matter. Herr Krause states that in the winter of 1856 he was compelled to erect a small building during a very sharp frost, the temperature being down to from 4° to 5° R. (23° to 14° Fahr.). As bricks and sand were frozen, his workmen had great trouble in properly setting the bricks, the mortar freezing under their hands. It would have been too expensive to warm all the materials previously. He, therefore, had the lime slaked in small quantities, mixed the mortar hot, and had the brickwork liberally pointed. He fully expected to find the mortar perished in the spring; but he was greatly mistaken, for the work was as firm as if it had stood for several years. In 1880 he had to take the same building down, when the mortar was found so firm that the bricks broke, and could be cleaned only with difficulty. Herr Krause subsequently had outer pointing done at several degrees of frost, and always found that, if lime mortar had been subjected to frost for about ten days, it had set as firmly as mortar made in the summer in as many months. The architect in question says that, if it freezes, and the frost continues for some time, it is much firmer than when applied in the height of the summer. It is different when a sudden thaw sets in after a sharp frost. Herr Krause had executed, during an alteration, a wall 10 metres high and 3 metres wide, with three windows placed over each other, and joined to an old brick wall, when suddenly a thaw set in. The wall settled about 6 centimetres, and bulged out, so that he had great trouble in preventing it from collapsing. A sudden frost, however, made it firm again. After twenty years the wall is as good as ever, and there are no cracks. In that case, however, he had omitted to use unslaked lime, employing only hot water. The bricks had been stored in a heated room. Herr Krause has come to the conclusion that continued frost has the contrary effect upon mortar to what is generally supposed. Herr A. Klemm, architect, of Stuttgart, expresses the same opinion in a communication which he sends to the *Deutsche Bauzeitung*, in which he says that in the winter of 1848-9 the works required for altering and fitting up the Prussian House of Deputies had to be carried out during a most severe frost. Notwithstanding this fact, the brickwork, executed with freshly-slaked hydraulic lime, was found to be so firm in 1867, when alterations had to be made, that in some portions wedges had to be used in breaking it up. Herr Klemm adds that in his country (Württemberg) it is the general opinion that frost not only does not injure the brickwork, nor the plastering, but it improves its quality. The frost, however, should continue for some time. Herr Klemm expresses surprise that doubts could be entertained on the subject. A Berlin firm of builders, Herren Ende & Böckmann, writing on the same subject to the *Deutsche Bauzeitung*, state that, in the autumn of 1864, they had orders to erect a warehouse

near Unter den Linden during the winter. They were at first indisposed to undertake such work in that season; but circumstances demanded speed, and building operations were continued during the frost. They fully expected to find the brickwork faulty in places when the spring came, and had made up their minds that they would have to replace some of it. They were agreeably surprised to find the brickwork perfectly sound; in fact, it seemed to have set exceptionally well. Since that time, the above Berlin firm of builders have not hesitated to continue bricklayers' work as long as they could; that is to say, as long as the water did not freeze on the bricks or the mortar in the pans. It should be added that the lime mortar used at Berlin is said to be of exceptionally good quality.

#### ARCHITECTURAL SOCIETIES.

*Birmingham Architectural Association.*—The members of this association made a visit on Saturday afternoon last to the new Conservative Club, Temple-row, Birmingham. The building is erected in the Roman Renaissance style, and has every convenience and comfort of a modern club. Messrs. Osborn & Reading, the architects to the club, met the members and kindly conducted them over the new premises. Messrs. Barnsley & Sons, of Birmingham, are the builders.—The sixth ordinary meeting of the current session was held at Queen's College on Tuesday evening last. Mr. E. F. Tihley was nominated for membership. A paper was read by Mr. W. Henman on "Terra Cotta and Stone." A discussion ensued in which Messrs. H. Clerc, John Cotton, E. Wood, W. H. Bidlake, and Victor Scruton (Hon. Secretary), took part. A vote of thanks, proposed by Mr. H. Clerc and seconded by Mr. W. H. Kendrick, was unanimously accorded to Mr. Henman for the very able manner in which he had set forth the respective merits of the two materials. After a response from Mr. Henman the meeting terminated.

*Manchester Architectural Association.*—At the ordinary fortnightly meeting, held at the Diocesan Buildings, on the 25th ult., Mr. L. Booth in the chair, Mr. J. E. Phythian read a paper on "Mr. Ruskin's Writings on Architecture," in which he said criticism in England was pre-eminently associated with three names, John Ruskin, Matthew Arnold, and P. G. Hamerton. The last two writers were by many people considered safer guides than Mr. Ruskin; but, without entering into comparisons of that kind, it might be noticed that Mr. Ruskin's criticisms covered a much wider range of subjects than did those of the other two. He never seemed contented to consider any branch of art or life detached from the rest, but strove to bring all into what he considered their relation with each other. It was not to the erection of large public buildings we were to look for establishing a school of architecture, but through our domestic buildings, Gothic architecture had developed from the burgher's house, and without the domestic architecture of the Middle Ages the glories of the minster would have been impossible. Every profession was dependent on its clients, and a demand for noble architecture was much to be desired to-day. Mr. Phythian then referred to Mr. Ruskin's definition of architecture, which, he said, was generally considered too narrow. Mr. Ruskin drew a sharp line between building and architecture, and relegated to the former much that was usually included in the latter. It was no use disputing over definitions, but assuredly this was true, the greater the part that sculpture and painting played in architecture, the higher was the position it took as a fine art. Soundness of construction and beauty of proportion were essentials, but sculpture and painting were the crowning glory, and although they were not wedded in every building, yet no great school of architecture could exist if the architects were not masters in both arts. Mr. Phythian then discussed "The Seven Lamps of Architecture" and the "Stones of Venice," dealing at length with Mr. Ruskin's preference for Gothic, which preference, he said, arose from, amongst other things, the greater opportunities which that style gave for developing the higher intellectual power of the workman. Classical architecture was satisfied with a narrower perfection. Messrs. Colley, Hodgson, Mee, Hewitt, and the Chairman took part in the discussion which followed.

#### THE ACCIDENT AT ISLINGTON WORKHOUSE.

SIR,—I have read with some surprise a report in the *Times* of remarks made by the Coroner for Central Middlesex on the gallery which lately fell, with fatal results, at Islington Workhouse. That officer is reported to have said at the inquest,—“Such a case does not come under the Building Act. It was erected in a private room. Any one could have a gallery erected in his private house without having it inspected by a surveyor.”

Supposing this to be correctly reported,—and if it be incorrect, the report uncontradicted is equally likely to mislead,—it is worth while to point out that a workhouse is a public building, and that every part of it, including galleries, is to be constructed as the District Surveyor may approve, and, in the event of disagreement, as the Metropolitan Board may direct; and that the builder (in this instance a foreman) consequently was bound to give notice, and his employers are culpably negligent in not having given directions that notice should be given. As the gallery appears to have been movable and taken down and rebuilt within six months, it is to be hoped that the District Surveyor will see it to be his duty to proceed against the builder in question, not for the sake of pressing hard upon a poor fellow who has the consciousness of a grievous calamity upon him, but as a public warning that notice must be given in all such cases.

#### A DISTRICT SURVEYOR OF TEN YEARS' STANDING.

#### "SANITARY INSTITUTE OF GREAT BRITAIN EXAMINATIONS."

SIR,—I have read with interest the correspondence of the 8th, 22nd, and 29th ult. There is one matter touched upon by "W. H. Colbran," which I think it well to emphasise, and that is the amount of the fee payable upon entrance for examination. I certainly think that five guineas is excessive, and specially so, considering it is paid whether a candidate passes or not.

The fee charged by the Royal Institute of British Architects to candidates for the examination for the District Surveyorships in London, or the Building Surveyorships under Local Authorities, is two guineas. The Association of Municipal and Sanitary Engineers and Surveyors' examination fee is three guineas; and, judging from the papers set, these are far superior to those held by the Sanitary Institute.

Some time ago I addressed the secretary upon what, in my opinion,—and, I doubt not, in that of many others,—is an excessive fee, and the advisability of consideration by the Council of lowering the same. It would certainly interest many intending applicants to know whether anything is likely to be done in this direction. F. T. R.

#### A NEW SAFETY MINING CARTRIDGE.

SIR,—This invention, described in your issue of January 22nd, 1887, p. 142, appears to be based upon erroneous chemical data.

The inventor claims (see *Gluckauf*, No. 16, 1886) that in a cartridge 180 mm. long and 25 mm. diameter, whose cubical contents are 90 cm<sup>3</sup>, the production of hydrogen from 12 grammes of zinc will be 3.37 m<sup>3</sup> and the pressure 37,000 atmospheres.

According to formula  $Zn + H_2SO_4 = H_2 + ZnSO_4$ , 65.2 grammes of zinc will produce 2 grammes 22.32 litres of hydrogen. 12 grammes of dust will contain about 10 grammes of zinc, and the volume of hydrogen produced will be 3.425 litres. If this volume be compressed into a space of 90 cm<sup>3</sup>, the pressure will be 38, and not 37,000 atmospheres.

It is somewhat extraordinary that the description of this invention and the above-named inaccuracy has appeared in many English and foreign papers without correction. J. MALTON BROWN.

#### "MASONS' WAGES."\*

SIR,—As one of the delegates appointed by the Masons of London to investigate the system of working, and wages paid to the masons employed at the restoration of Buckingham Palace I send you the following facts for publication in your next issue.

It was reported to one of our London Lodges, that the masons working at the above job was receiving one penny per hour under the current rate and also that they were working 24 hours per day overtime, it was decided to send a deputation to Messrs. Pery & Co. the contractors to ask them if they would stop the overtime, so that more of the masons who were out of work might be employed, and also if they would discontinue paying at this reduced rate, as we did not consider it just to the

BUT CAN ALSO BE USED  
FOR THE CROSS STAFF.

employers who had done the Government work before they received the contract, and who had paid the full wages to the masons employed for the different Government jobs, we saw one of the Firm who told us that he was not aware that the masons were working overtime, but he would enquire into the matter and if he could he would put a stop to it, for he did not agree with men working overtime. We then went into the question of wages, and he told us that the men employed were on the staff, and were old and infirm men, who were more than the price they were paying them, this we know to be wrong, for the Foreman had given men (who were not Old and infirm) work, and had told them that they was not paying the full wages, he said if such was the case they had not set the men on at the yard and he seposed the Clerk of Works had done so, and he could not do anything in it, so we left him and then proceeded to the Palace to see the Clerk of Works, and after waiting an hour we saw him come in from Buckingham Palace Road, and ran after him but he would not deign to see us, although he did not know what we had come about he referred us to Messrs. Pery & Co we told him we had seen this Firm, but that they could not do anything in the case and that we had come to consult him, but he said he would not have anything to say to us and kept walking away, so the London Lodges Committee decided to send a deputation to the first Commissioner of works, we was unable to see that Gentleman, but was received by Mr. Primrose, his Secretary, and Mr. Taylor, Surveyor, who received us with every respect, and, after explaining our mission they promised that the affair should be investigated and if the overtime could be stoped it should be done, and I received a letter the next day from Mr. Primrose, to say that overtime would be discontinued on that job we then went into the Question of wages, but they were unable to do anything in that, for they said that although the contractors was paid a price for the work that would enable them to pay men the proper wages, never the less if the Contractors got the work done to the Satisfaction of the Surveyor and only paid the men 2d. per hour they could not interfere but of course it would be more profit for the contractor, and they also told us that in some cases were extra skilled labour was required, they (the Government) paid extra wages for the work

done to the contractors, but weather they paid the man or men anything extra, they could not say; and if they did not, this again would be extra profit. With regard to the Clerk of Works putting on men, Mr. Taylor said that he had nothing to do with that, nor yet with what wages they should receive, but he said that he would find out weather the Clerk of Works had put men on or not. We thought it would be advisable to see Messrs. Pery & Co, again, which we did the following day. At first we was refused an interview, but after sending in word to the effect that we had been to whitehall, we was admitted, and after telling him what Mr. Primrose and Mr. Taylor had said about his having a price for his work that would enable him to pay proper wages he said that was his business but with regard to the men working on this job he had nothing to add to what he had already said, but when he employed masons at any of his other jobs he always paid the full amount.

One of the delegates reported to the particular Lodge, that first found out what was going on at Buckingham Palace, and the members thought they was quite rs able to judge who was old and infirm men, as Messrs Pery & Co was and therefore acted in what they thought was just to the employers who had done the work for the Government before Messrs Pery & Co got the Contract and also to the Members of Our Noble Society, who when they got Old and infirm like A. B. C. they have a fund that pays them so much a week and so prevents them from having that dread of what the employers will do to them.

Secy London Lodges Committee

O. S. M.

\* \* \* We give the above, spelling and all, as the "Noble Society's" statement on their side of the dispute, leaving our readers to form their own judgment as to the social and economic aspect of the affair.

"How to Ensure Healthy Homes"—This was the subject of an able lecture recently delivered by Professor Henry Robinson, C.E., at Swanage, a place which, judging from an official report recently mentioned in our columns, would seem to be in some need of the instruction which Professor Robinson is so well able to give.

FIELD WORK AND INSTRUMENTS.—VI.  
*Surveying Instruments.*

VI.—THE PRISMATIC COMPASS (continued).

THE reading upon the card described in our last article gives the magnetic azimuth of the object observed. The term "azimuth" is used to express the horizontal angle by which the direction of a vertical plane passing through a station point and a given object, deviates to the right of another vertical plane, which passes through the given station and the north pole. When magnetic azimuth is specified, the angular deviation is reckoned from the magnetic meridian instead of the true meridian. The plane in which the needle remains at rest is called the magnetic meridian. As the magnetic poles which attract the magnet do not correspond with the poles of the earth, it is plain that the needle cannot point due north and south except in those countries where the true and magnetic meridians coincide. The deviation between these two directions is different in different places, and continually varying in the same place. The circle which divides the eastern and western hemispheres is called the astronomical meridian, because, when the sun appears to the south part of it, it is then meridian, or mid-day. At midday the sun has attained its greatest altitude for that day, and as the sun is never at this altitude at two places east or west of one another at the same time, each of these places has its own meridian, and these pass through different degrees of the Equator.

The circle or horizon is divided into thirty-two parts, each subtending an angle at the centre of  $11\frac{1}{4}$  degrees. The four cardinal points are termed north, south, east, and west. The intermediate points will be best remembered by attending to those in one quadrant, say, from north to east, and afterwards repeating the whole. They are as follows,—N, N by

E. N. N. E., N. E. by N., N. E., N. E. by E., E. N. E., E. by N. E. From a map published at the Admiralty, under the superintendence of Capt. F. J. Evans, F.R.S., in the year 1880, it appears that in the eastern hemisphere there is little or no variation on a line drawn through St. Petersburg, passing west of Moscow and east of the Black Sea, thence proceeding by the south-west coast of India through the territory of Western Australia. To the east of this neutral line the variation increases eastwards, being in the year 1880 about 3° E. at Calcutta, 8° E. at Melbourne, 13° E. at Tobolsk, in the north of Asia, but afterwards decreases further east to zero between Canton and Amoy, upon the south-east coast of China, the curve of no variation running between Formosa and the Philippine Islands, passing through the North Pacific Ocean, the east coast of Asia, and the north-east of Siberia. To the west of the neutral line in the eastern hemisphere the variation increases westwards, being 15° W. between the islands of Majorca and Minorca, 19° W. at Cape St. Vincent, and 20° W. at Sierra Leone. In Iceland the amounts vary from 34° W. upon the south-east coast, to 42° W. upon the north-west coast. In Cape Town the variation is about 30° W.

At the present time upon the east coast of Ireland, and in the North Channel, the variation of the needle will amount to about 22° W. Upon the west coast of Wales, the east coast of the Isle of Man, and the centre of Scotland, 21° W. On a line drawn through Lancashire, Glamorganshire, Devonshire, and Cornwall, 20° W. On a line drawn through the East Riding of Yorkshire, Nottingham, Gloucester, and Dorsetshire, 19° W. On a line through Norfolk, Suffolk, Surrey, and Sussex, 18° W., being 17° 50' at London.

In the western hemisphere in the year 1880, there was little or no variation upon a line drawn through the west coast of Hudson's Bay, the east coast of Lake Superior in North America, the west coast of Lake Erie, between Canada and the United States, thence passing through Washington and Charleston, Puerto Rico among the West Indian islands, and between Barbadoes and Trinidad, to the north-east coast of South America, crossing that continent to the South Atlantic Ocean at San Paulo. To the west of this neutral line the magnetic curves increase eastward in variation being 10° E. at the Fiji Islands, decreasing thence towards zero at a point in the mid-Pacific Ocean. It increases also to 23° E. to Vancouver's Island, decreasing to a line of no variation along the China coast. To the east of this line in the western hemisphere the magnetic curves increase westward in variation, being 13° W. at Montreal and at Pernambuco. Jamaica, at the present time, is about 3° E.

These angles of deviation from the true or astronomical meridian are continually varying. At Greenwich, in the year 1576, the magnetic variation was 11° 15' E.; and between 1657-62 there was no variation. In 1820 it was about 24° 11' W. The needle is also subject to diurnal fluctuations, the north end being drawn most to the west at about 2 p.m., and most to the east during the night or early morning. The amounts, however, are inconsiderable, except when magnetic storms occur, which produce great disturbances.

In fig. 5 of the illustration given in our article last week, two positions of the needle are indicated, one direction reading 34° and the other 337°. The difference between these two azimuths would express the angle taken in the direction of the hands of a watch, which the objects viewed, would subtend at the point of vision. An azimuth exceeding 180° denotes that the direction of the object to which it is measured lies to the left of the direction from which azimuths are usually measured. For practical purposes a surveyor may express these two directions as being in one case 34° E., and in the other case 23° W., of the magnetic meridian, the excess of 360°, above the angle read, being taken when that angle is greater than 180°.

The prismatic compass is generally made as shown in figure 4 of our illustration last week, to be held in the hand for sake of portability, but it can also be made of larger diameter with an uncovered glass top, as shown in fig. 3 of the annexed illustration, and constructed to fit on to a hall and socket stand, the details of which will be clear upon reference to figs. 1 and 2. Fig. 2 shows the parts which are fixed together in fig. 1. When the prismatic compass is thus

set up, horizontal angles can be measured from the magnetic meridian upon level ground with sufficient accuracy for filling in the minor portions of a survey. It should be borne in

Sometimes a mirror, marked K in fig. 3, is supplied with a prismatic compass, and is intended for the purpose of reflecting objects above or below the level of the observer. The mirror can be placed with its face upwards or downwards, and can be removed at pleasure. It is made to slide up and down with sufficient friction to remain at any part of the back of the vane C that may be required.

VII.—THE COMPASS CLINOMETER.

Figs. 4 to 6 illustrate a combined prismatic compass and clinometer, the former to record horizontal angles, the latter to record vertical angles. Fig. 4 shows a plan of the additional arrangements which are fitted on to the underside of the prismatic compass for this purpose, so that when the prismatic compass shown in fig. 3 is turned over, its side elevation will be as indicated in fig. 5. The sight-vane C being turned down upon the box in the direction indicated by the arrow upon the dotted line in fig. 5, the compass card is thrown off its bearing. A short sight-vane marked E, equal in height to the depth of the box, is raised at right angles as shown. When not in use as a clinometer the sight-vane E folds back outside the box, and when thus folded back upon the edge of the box, it clamps the clinometer card D in the same way as the folding down of the sight-vane C clamps the compass card A. The same prism, marked B, is available for reading both the compass card and the clinometer card, the prism being made to turn upon a pivot, half way round in one direction, and is provided with a stop in the other direction to enable the surveyor to place it at right angles to the box in the positions shown by full and dotted lines in figure 5. When taking vertical angles the instrument is held between the thumb and the first and third fingers in the position shown in fig. 6, the second finger being placed upon a button marked F, which presses a spring, by which the swing of the clinometer card is regulated. This card, D, is provided with an attached lead weight marked H in fig. 7, and is graduated as shown from zero upon a horizontal line to 90° at the top and bottom of the card. The figures upon the card are reversed so as to be read by the prism in the same manner as the figures upon the compass card. Either hand is selected according to the light. In fig. 6 the face of the clinometer is to the right. It is recommended that in taking vertical angles the line of sight should be directed at first upon some object in the same vertical plane, either above or below that which it is desired to observe, and the card brought to rest by the employment of the regulating button, F. When perfectly steady gently raise or lower the sight-vane E, until the central hair or wire cuts the line of sight ranging between the eye and the point observed. In order to change the instrument into a prismatic compass it is only necessary to fold down the sight-vane E, to turn the prism B to the reverse side of the box, and to raise the sight-vane C. This combination of compass clinometer has been patented by Lieut.-Colonel O'Grady Haley.

RECENT PATENTS.

ABSTRACTS OF SPECIFICATIONS.

1,126, Cements. C. D. Alison.

The cement which is the subject of this patent is claimed to be waterproof and fireproof, and is particularly applicable for internal decorations and as a lining for kilns and such-like purposes. The principal ingredient is a non-diatomaceous silicious earth, found in a natural condition in the West of England, and which the inventor calls siesine.

2,419, Fixing Door Handles. J. Hicken.

According to this invention the square spindle is screw-threaded in the ordinary way. One handle is permanently fixed to the spindle, and the other is fitted with two small projecting buttons or studs. When a disc with slots is forced against these projections they engage the spindle and handle, being afterwards further secured by a screw on the outer edge.

2,727, Fire Stoves, Ashpans, &c. A. W. Woodhead.

This invention consists in simply rolling or bending the mouldings used in place of casting them. For corners and bends a special method of bending and rounding is devised by means of a block curved to the radius required with the pinch or head cut thereon. A roller with a similar configuration is then used with it.

4,103, Setting Saws. R. Elliott.

The appliance which is the subject of this invention acts by setting the teeth of a saw at different

mind that the presence of iron, whether in the shape of heavy keys or of an iron chain lying along the ground or the vicinity of an iron bridge, may exercise an influence over the observed bearings to a very important extent.

angles to the blade by striking them with a peculiar tool, which is divided at its lower end into a number of parts corresponding in length to the pitch of the teeth, and out away alternately to right and left angles. Or a metallic disc cut away in a similar manner is used.

12,857, Securing Screws, or Nails, to Brackets, &c. H. Munslow.

This invention consists in utilising an ordinary wooden screw or an ordinary nail in manufacturing brackets, cup-hooks, hat and coat hooks, and such like articles, especially where one screw or nail will support the article. The nail or screw is either fastened to the article by a die which spreads the head a little, or by a washer and riveting.

11,983, Locks and Latches. F. T. Davies.

The bolt or catch of these locks and latches is of a peculiar pear-shaped form, and the mechanism is ingeniously adapted for throwing back this latch by a movement of the door-knobs, while the key locks the action with but very few parts, and in a very simple manner.

11,555, Attachment to Shafts, Tools, and Picks. T. Brown.

The insertion of a double wedge in the handle or shaft of the tool, and the affixing of a peculiarly-formed shield over the top of the said shaft, are the chief features of this invention.

MEETINGS.

THURSDAY, FEBRUARY 5.

Association of Public Sanitary Inspectors.—Fourth annual dinner, Guildhall Tavern. 6 p.m.

MONDAY, FEBRUARY 7.

Royal Academy of Arts (Lectures in Architecture).—Professor J. H. Middleton on "Methods of Decoration as applied to Greek Architecture." 8 p.m.

Society of Engineers.—The President, Professor Henry Robinson, will deliver his inaugural address. 7.30 p.m.

Society of Arts (Cantor Lectures).—Dr. J. H. W. Thudichum on "The Diseases of Plants, with special regard to Agriculture and Forestry." 11l. 8 p.m.

Surveyors' Institution.—Mr. T. A. Dickson on "Artificial Manures." 8 p.m.

Clerks of Works' Association.—Mr. R. Wheeler on "Stonefield Slating." 8 p.m.

Liverpool Architectural Society.—Mr. G. H. Morton on "Colour." 7 p.m.

Leeds and Yorkshire Architectural Society.—Mr. E. H. Jacob, M.D., on "Architectural Treatment of the Organ." 8 p.m.

TUESDAY, FEBRUARY 8.

Institution of Civil Engineers.—Further discussion on Mr. W. J. Dibb's and Mr. W. Santo Cimp's papers on "Sewage Sludge and its Disposal." 8 p.m.

Manchester Architectural Association.—Paper by Mr. Stelfox. 7.30 p.m.

WEDNESDAY, FEBRUARY 9.

York Architectural Association.—Mr. T. Stockton Worthington on "Decoration." 7.45 p.m.

THURSDAY, FEBRUARY 10.

London Institution.—Professor Silvanus Thompson on "Electric Bells." 7.6 p.m.

Society of Telegraph-Engineers and Electricians.—8 p.m.

FRIDAY, FEBRUARY 11.

Royal Academy of Arts (Lectures in Architecture).—Professor J. H. Middleton on "Methods of Decoration as applied to Roman Architecture." 8 p.m.

Society of Arts (Indian Section).—Dr. Watt, C.I.E., on "The Economical Condition of India." 8 p.m.

Draft Historical and Antiquarian Society.—Mr. J. Lester, M.A., on "Gleanings from Old Halifax Life." 7.30 p.m.

SATURDAY, FEBRUARY 12.

Architectural Association.—Visit to Church at Wimbledon. 3 p.m. (Postponed from Feb. 5. See advertisement.)

Surveyors' and Auctioneers' Clerks' President Association.—Annual Meeting, Auction Mart. 3 p.m.

Edinburgh Architectural Association.—Visit to Magdalen Chapel and High-street clozse.

"A Reversible Rim Lock."—Referring to our notice a fortnight ago (Builder, January 22, p. 162) of the new reversible rim lock introduced by Mr. James Hill, we would correct a slip of the pen which occurred in the last line but one of the second paragraph, where, for "inwards," the word "outwards" should be substituted.

Miscellaneous.

Handicraft Instruction.—A valuable series of lectures in handicrafts is being delivered weekly to School Board masters, at the Guilds Institute, in the theory and practice of carpentry and joinery, so as to enable them to teach these crafts to their pupils. The lessons are alternatively devoted to theory and practice. Professor Unwin was invited to lecture to the Board School masters on the scientific knowledge connected with carpentry; and, in doing so, presented to his hearers a model of didactic style more important to them than even the subject treated. The lesson which was given last Saturday was purely practical. In front of the professor's desk in the large lecture-hall of the Guilds Institute was placed a carpenter's bench; and, instead of a learned professor, an intelligent, practical carpenter, Mr. Robertson, instructed the class. At first sight, there does not seem to be much to be said about the use of a saw and a plane; and most people would think themselves capable of using both without any teaching. Yet, there is a right and a wrong way of handling tools; there is also, what is even more important, a methodical system of working which leads safely to a satisfactory result, whereas a haphazard system, or, rather, the absence of a system, is the fruitful cause of bad work. After the lecture, the members of the class went down to the workshop to practice what had been explained to them.

Sanitary Registration of Buildings Bill. A special meeting of the Council of the Sanitary Assurance Association was held on Monday last for the final revision of the above Bill before presentation to the House of Commons, Sir Joseph Fayer, K.C.S.I., F.R.S., in the chair. The new measure was adopted by the Council, and in the absence from England, of Dr. Ferquharson, M.P., it was decided to ask Mr. C. C. Leachin, M.P., to take charge of the Bill in the House of Commons. The Bill, as introduced in 1886, consisted of ten sections, and it will be remembered, made the sanitary registration of all buildings compulsory in towns of 50,000 inhabitants and upwards. The new Bill consists of seventeen sections, and is to apply to all towns or districts of 2,000 inhabitants, but it is only to be compulsory in the case of schools, colleges, hospitals, asylums, hotels, and lodging-houses. An important feature of the new Bill is that the local authorities will have to keep a sanitary register in which any building certified in accordance with the proposed Act may be registered, so that a stranger visiting any district would be able to ascertain at the office of the Local Authority whether any particular house was or was not certified as in a satisfactory sanitary condition. By the provisions of the new Bill, all persons entitled to certify must first obtain a licence from the Local Government Board, and examining Boards are to be appointed. Persons entitled to sign certificates are to be designated "Licentiates in Sanitary Practice."

Birmingham Students of the Institution of Civil Engineers.—The Association of Birmingham Students of the Institution of Civil Engineers held their first Meeting at the Colonnade Hotel, Birmingham, on the 27th ult., to hear a paper read by Mr. R. Peirce, Stud. Inst. C.E., upon the "Kidderminster Sewerage and Water Supply." Mr. E. Pritchard, M. Inst. C.E., the President, was in the chair. Mr. R. Peirce, in his paper, gave a very interesting description of the past and present sanitary condition of the town of Kidderminster, upon which had been expended in 1874 over 100,000l. in the construction of sewerage and water-works.

London and County Banking Company (Limited).—The report and balance-sheet of this company, for the half-year ending Dec. 31st, which are published in extenso on our last page of advertisements this week, show that, after paying interest to customers and all charges, making provision for bad and doubtful debts, and allowing 37,000l. odd for rebate on bills not due, the net profits amount to 215,870l. 19s. 10d. The directors, at the meeting held on the 3rd inst., recommended a dividend of ten per cent. for the half-year, making twenty per cent. for the year 1886. This was adopted.

The Court of Common Council on Thursday decided to place in the Guildhall a bust of the late Earl of Ellesleigh.

Nineteenth Century Art Society.—Saturday, the 12th inst., has been appointed for the Private View of the Spring Exhibition of this Society, at the Conduit-street Galleries, and the Exhibition will open to the public on Monday, the 14th instant.

### Art at the Society of Arts.

THE elaborate paper read by Mr. T. Armstrong at the Society of Arts on the 1st of this month, on "The Condition of Applied Art in England, and the Education of the Art Workman," marks,

if not a new departure in principle, the formation of a new section for the special promotion and consideration of the class of subjects which are called "artistic" in the now usually understood sense of the word. For, in spite of the treatment of such subjects, from time to time, in some of the series of "Cantor Lectures," the Society of Arts has more generally been occupied with subjects which belong rather to what would now be called "Science," and which are Arts only in the sense of the word, glanced at in Mr. Armstrong's paper, which was prevalent in the last century, when, as the lecturer reminded his audience, the only absolute *artiste*, in common parlance, was the chemist, who laboured at *le grand art*; others were "artists in tapestry," "artists in metal-work," &c.; while in the present day the word "art" is supposed to apply only to painting, engraving, etching, drawing, and sculpture.

This consideration of nomenclature bears directly on an important point in the lecture in question, one of the objects of which was to urge that the "art-workman," as he is usually called, should be more distinctly and generally recognised as an "artist," and honoured as such in company with those who at present specially enjoy the title by common consent. One reason urged in favour of this view by the lecturer was, that if better recognition were accorded by Society to the art-workman, there would be much more probability of persuading men of original power and earnestness to devote their efforts to decorative and applied art. Many of the art-workmen, Mr. Armstrong tells us, who come to the training school at South Kensington to receive such instruction in design as will better qualify them for carrying on the handicraft they have already worked at, and propose to devote themselves to, "are strongly moved to give up their trades on leaving us after a period of two years, and take to the painting of pictures and the modelling of busts"; and Mr. Armstrong, as a painter, naturally in some sort sympathises with them, though regretting the course they adopt, of which the result must often be to produce mediocre sculptors and painters in place

of good decorative workmen. He adds:—"I have a firm conviction that much could be done to keep them in the trades to which they belonged if they could receive the consideration in their respective callings which is given to the painter of a picture which is exhibited."

Up to a certain point this is perfectly true, and we are more particularly with Mr. Armstrong in his suggestion that the actual designer and executor of decorative or applied art should receive credit by name for his work, and not be suppressed by the dealer who sells his productions: a view which we have frequently urged. But it would not do to encourage the idea that the best carpet design, for instance, can ever rank as an intellectual effort with a work of genius in painting or sculpture. The latter includes not only design and execution, but the expression of thought and feeling, which is beyond the power of applied art. All that can be properly demanded is that the occupation of making common things so as to impart beauty and interest to them should be recognised as a noble and dignified calling, and as something quite above a mere mechanical trade. There is a certain move in this direction in popular opinion, though a very limited one. The further development of it, perhaps, rests in some degree with the art-workers themselves. Let those who are conscious of special ability remain in their calling and raise it, rather than mistakenly seek to raise themselves by quitting it,—an old story, illustrated in many departments of modern life.

A great part of Mr. Armstrong's paper was taken up with remarks on the Cantor Lectures, on a nearly similar subject, given by Mr. Burges twenty-three years before. Burges summed up then the hindrances to future progress as follows:—

- (1) A want of distinctive architecture, which is fatal to art generally.
- (2) The want of a good costume, which is fatal to colour.
- (3) The want of sufficient teaching of the figure, which is fatal to art in detail."

The second subject Burges gave up, as beyond our own control, and only to be left to Providence; but he recommended the increase of Government schools of design, and the multiplication of local museums.

Both these recommendations have been to a great extent carried out, and it appears from Mr. Armstrong's paper that a great amount of annual work is done in connexion with the Government schools of design, as last spring more than 800,000 drawings and models were sent up for inspection, being an increase on the previous year of about 38,000, and it is even suggested that the increase in the numbers is progressing so fast that it may soon be neces-

sary to localise the examinations, instead of having the whole sent up to London. Yet Mr. Armstrong repeats Mr. Burges's former complaint, that "the artisan has not taken so much advantage of the schools of design as he might have done."

"It is true that in many,—I may say most,—towns in the United Kingdom, there are hardly any trades depending on the arts of design; but there are no towns in which the building trade is not represented, and those belonging to it, including house-painters, might certainly be convinced that the teaching to be had in art-schools and art-classes would make them better workmen, and would open the way to promotion. Until there is some such conviction, the mass of working men will not be persuaded to attend school in the evening, after a day spent in hard manual labour, for mere love of knowledge or skill in the abstract. They must be shown that the probable gains of the self-denial required for this will rapidly lead to higher wages and greater consideration."

This is a perfectly reasonable statement of the matter from the point of view of the artisan, and it is to be feared that these higher wages and this greater consideration do not at present await him in return for any knowledge of design and drawing which he may add to his handicraft attainments. If his employer has any consciousness that his work is of more value for being better designed, the public have not. We are speaking now not so much of things which are generally recognised as work with a specially artistic object, such as stained glass, but of things made for use, but which will bear artistic treatment (as almost everything made for use will, except, perhaps, a dynamo). Endeavour to get, in a London shop, such a thing as a gold or silver watch-guard artistically designed. There is not such a thing to be had, except by furnishing the design and giving a special order. We heard, the other day, of an intending purchaser wishing for something with a little character and design in it, instead of the curb-chain patterns usually made for watch-guards, whereupon he was shown a chain made of mimic horse-shoes, and on expressing his opinion freely on this piece of vulgarity, met with the response (in an injured tone) "Well, you wanted a fancy pattern, and this is one!" Occasionally in shops where a little more knowledge exists you will be told, "Yes, we quite understand what you want, and we can get it made for you; but it is useless to keep anything of the kind, as there is no sale for it." Our experience in this respect exactly tallies with what was stated by Mr. Hunter Donaldson in the discussion on Mr. Armstrong's paper: he was in the show-room of a man who obtained a gold medal at the Paris Exhibition of 1878, and seeing some inferior work there, he spoke to him about it, and received the reply that "it was

no use making superior articles, for the public would not buy them." That is the really most serious bar to progress. There is a certain improvement in public taste, and a great improvement of late years in design, in regard to such things as furniture, textiles, and wall-papers, and in regard to these a kind of standard of taste has been established to a certain extent, and people who have no real artistic culture have acquired a general knowledge as to what kind of thing they ought to get, though few of them can give a reason for their choice beyond the fact that these things are in fashion. When it comes to any class of article in which an artistic fashion has not yet been established, they are as much at sea as ever. The study of jewellers' windows and cases is enough to show the depths in which we still are in this respect. It is not too much to say that it is rare to find anything among their wares which a person of sensitive artistic tastes would care to purchase.

It is the demand, then, for better work that is first wanted; but meantime, is the artistic establishment at South Kensington, with its 800,000 subjects sent up yearly, really in the path to do all the good claimed for it? We doubt it. Who are the students who send up all these things, to begin with? A great many of them, we imagine, are amateurs, especially ladies, who wish to amuse themselves with a little art and to have the gratification of showing a prize or two. The system of training in "the Department" is supposed to be a very rigid one, compelling the pupil to go through a regular course, from first elements; but Mr. Armstrong, who ought to know, seems to admit that these rules are tacitly relaxed, as in cases where the student has already acquired some power of drawing they may very well be. But this admission seems to indicate that there is a considerable amateur contingent who do not come to the schools for any serious work. Then, as to the standard of work shown in the premiated and annually exhibited students' works: is that altogether satisfactory as representing "the best work of the country during the year?" The life studies are usually good; the oil paintings poor; the decorative design is often good; the architecture nearly always bad. Mr. Armstrong took the position that architecture was the central art, and the architect the central artist, who should control everything. Accepting this position, how does it come about that the architectural element in the annual exhibitions of premiated drawings is so defective that none of the drawings to which prizes are given would have any chance of such a distinction at the Institute of Architects or the Architectural Association? Not long since we were asked to print an essay on architecture sent by a correspondent who stated that he was a certificated teacher under the Department. The first page of it disclosed an entire ignorance of all that had been brought forward on the subject of the lighting of Greek temples during the last quarter of a century, the writer simply re-stating the old "hypæthral" theory. It is impossible to suppose, under these circumstances, that the art teaching of the Department is all that it should be. We are glad to learn that Mr. Armstrong accepts the view which we have repeatedly urged, that prizes given for highly-finished and stippled drawings from casts, do not conduce towards rapid or real progress in figure drawing. But the conversion of the authorities on this point is certainly of very recent date, if we may judge from what we have seen at the exhibitions of students' drawings.

Mr. Walter Crane's contribution to the discussion was a rather curious one. He said the Art Department carried the students carefully "through all the grades," and it was not their fault if there were not more inventive artists, but he in the same breath condemned "the system under which we were forced to live." Every child began to draw, and would naturally begin to draw the figure, as the most interesting subject, but "all that was crushed out of him, and he was set to draw corners and angles, and rounds and squares, which had absolutely no meaning to his mind, and his invention was

never set to work." We should have certainly supposed that this was an indictment against the South Kensington system; we believe it was meant so, only Mr. Crane was too polite to say so on the occasion in question. Then Mr. Crane referred to the case of an artist who was asked why he did not do something worthy of himself, and replied, "My dear fellow, I have eight children"; and the speaker said that "in a properly-constituted society he would have had no anxiety about his children." We should certainly like very much to know what is, in Mr. Crane's mind, the idea of this "properly-constituted society" in which an artist is to be placed above or apart from the ordinary responsibilities of life. We fear it is only to be found in Utopia.

We have read Mr. Armstrong's summary of the situation with much interest, but it does not lead to any very definite conclusions. What we gather from it is that the art-teaching machinery of the Art Department, even if it were more perfect than we think it is, would not avail in itself to produce first-class artists in applied art, unless there were so strong and intelligent a demand for better work on the part of the public that a definite and tangible reward was before the craftsman who would give his extra time and labour towards obtaining a knowledge of and training in design. This public demand we cannot create or compel; we can only protest and preach, in the hope of leavening the public taste in time. The most tangible point in the paper is the suggestion that a better class of artists would be induced to give themselves to decorative and applied arts if the value and importance of these branches of art were more generally recognised. Here, again, we cannot force public opinion, and something rests with the art-worker himself. Let him show that he respects and values his art by giving his best mind to it, not by trying to quit it for some branch of art supposed to be higher, and for which he has less qualification, and he will command respect for it and for himself in turn, from the outside public, who will learn to consider more seriously what may be the value of an occupation to which a man of abilities and high character is content to devote his life. But this respect for the decorative worker will not be brought about by self-glorifying speeches about "jumping on architects," such as a well-known decorative artist had the bad taste to indulge in at the meeting in question. That is not the way to do it.

#### HOUSE AGENTS.

EN are accustomed to speak of the "red tapeism" of Government officials, but it is more than equalled by that of house-agents. For there are probably no class of business men who are more tied and bound by various useless and troublesome customs than are house-agents. The functions of house-agents as intermediaries between vendors and purchasers, or lessors and lessees of houses, are capable of being so considerable a convenience that it is a matter of surprise that house-agents do not more thoroughly grasp their position. As a matter of fact, in a very large number of cases the house-agent is solely of use as an advertising medium, and business between the parties to the bargain would be carried through more quickly and more satisfactorily after they have been brought together, could the house-agent be eliminated from the proceedings. After the would-be hirer has, through a house-agent's list, been put in possession of the salient facts in regard to a house, the remaining work when transacted through the agent is necessarily prolonged at an expense to both parties. In many cases also the agent, so far from facilitating a bargain, rather hampers it from being consummated, because one of the leading ideas of house-agents is to keep up prices in a locality. Of course, in the long run, it is an impossibility to prevent rents or premiums from descending if the supply of houses is overdone or the demand slackening, but while this is in progress many are the bargains which are lost. A house-

agent will positively declare that his client will not take less than 300l. premium for a lease. He thinks the intending assignee of the lease may be worked up to take the premium, and meanwhile the latter, choked off by the firm tone of the house-agent, takes another house, when all the time the actual lessor would have been willing to take a smaller premium. This happens over and over again, the lessor in the result being out of pocket by the agent's tactics. It may be said that in some cases the agent succeeds in obtaining a better bargain for his client, but unless he is thoroughly acquainted with all his client's views and his whole position there can be no question that the disadvantages of this idea of the house-agent's are more numerous than the advantages. Again, a house-agent throws every obstacle in the way of any personal communication between the interested parties. Not content with having brought them into communication, he tries to play the part of a diplomatist. If the hirer or buyer asks a question about the sanitary state of a house, he gets no information but the very vaguest. He is told an inspection by a surveyor will be permitted, and so on, when the owner of the house can give all information of a *prima facie* kind which the hirer wishes. One of the maxims of his trade is also to keep his client in the dark as to his proceedings. He is very reluctant to give information as to the number and nature of the demands for the property; the consequence being that the owner has much difficulty in thoroughly grasping his position and the probabilities in regard to the disposal of his property. If there have been few or no inquiries, he will endeavour to make out that they have been of a very encouraging nature and that he has great hopes of soon letting or selling the property, while he knows all the time that there is no substantial prospect of a bargain. In truth, the house-agent will not realise that his primary function is merely to bring two parties together, and that any other work should only be done as an exception and not as a rule, and only when fully authorised by the client, and fully informed of his wishes and position. If this principle were acted on, a very large amount of trouble and annoyance would be saved to the householding community in general, and when agency work was undertaken it would be satisfactorily carried out. Again, the house-agent is fond of trying to take the place of a solicitor by drawing up agreements, or of charging a comparatively exorbitant fee for an agreement, the form of which can be bought for sixpence at any law-stationer's. He will declare that it is an invariable custom for such and such a thing to be done as, for example, that the owner of a furnished house always pays the water-rates, when it is merely a practice of a few house-agents in some particular locality, who, for some reason best known to themselves, choose to try and keep it alive. There is also another curious and illogical custom among house-agents, namely, that when a valuation of fixtures or furniture is made, they will not state the value they have placed on particular items. This is often a cause of much inconvenience when furniture is taken over, because the buyer, not being aware of the value at which he takes the various pieces of furniture, is unable to know what price he should obtain for any part or piece when he wishes to dispose of it. But unless a special arrangement is made with the house-agent to state the value of each item in his inventory he absolutely refuses to do so, and even when such an arrangement is proposed he will, if possible, refuse to agree to it. We are convinced that by this red-tapeism and want of flexibility, and desire to keep all the things in their own hands, house-agents do much to drive away business from their offices. It causes persons to advertise in papers, to give information to builders and decorators, and to try to find hirers or purchasers by what we may term illegitimate means. The public, as a whole, regard house-agents with suspicion and with dissatisfaction. A franker and less pretentious manner of carrying on business, a willingness to promote personal communication between parties, and a

more complete mastery of the client's position when agency work has to be done, a determination to give no countenances to trifling and absurd customs, and to study as much as possible the wants and wishes of the public, would place the business of house-agents on a sounder and more satisfactory footing.

## NOTES.

**T**HE appeal made by Major Flood Page and Sir George Grove in the *Times* of Wednesday, on behalf of the Crystal Palace, will not come as a surprise to any who have observed the indications for some years past that the Palace is in the wane of its career. We are not disposed to dispute any of its claims made by Major Page in regard to the part which the Crystal Palace has played as a centre of recreation for London. All that he says about it in this respect is justified. For ordinary recreation for the masses it has been, according to the season, a summer park or a winter garden, the immense size of the building making it an unequalled promenade in bad weather, with a certain degree of higher recreation in the shape of its really fine collection of casts. The architectural courts, we fear, have never been of interest to the masses, while by the more learned they have long been regarded as somewhat gewgaw productions, not up to the present archaeological standard. The fireworks have always been very good; the picture exhibitions nearly always very bad. In regard to music alone the Palace has taken the highest artistic standard; the fame of the Saturday concerts is European; the Handel festivals, despite the unsuitability of the building, have been among the most glorious memories in the lives of many lovers of music. It is difficult to know how these could be replaced. But the falling off in attendance at the Saturday concerts is easily accounted for by the present multiplication of high-class concerts in London, and more easy of access. Major Page's appeal is curiously illogical in pleading for the Palace as "the most popular resort" of the people, in face of the fact that the falling off in the attendance, and consequently in the receipts, is what has rendered the appeal necessary. The suggestion that dwellers in London should continue to take season-tickets to the same extent as formerly, to keep up a place in which they have lost their interest, is even more unfortunate. The one logical appeal in the letter, financially, is to the debenture-holders, to forego part of their lawful interest rather than run the risk of greater and more permanent loss. The prophecy of the fall in value of house property at Sydenham if the Palace ceases to exist we do not think much of. The Palaces made the neighbourhood, no doubt, but it is now a well-laid-out and "desirable" suburb, and may hold its own as such with other outlying residential neighbourhoods. But we imagine that the big structure has pretty well played its part. "Temporary" is marked on its whole character and appearance; it has had, on the whole, a fairly long lease of life for an erection of that nature, and we have long considered that its demolition was an event not far off. It would be a grand thing, no doubt, to erect a more permanent people's palace on the site around which so many associations cluster, but this could only be done as a national affair and by a Government subsidy. Our impression is that in a few years people will be living in red brick houses in "Crystal-Palace Gardens" and "Handel Avenue."

**I**N view of the expected railway legislation in this country, considerable interest is taken in the Inter-State Commerce Bill of the United States, which attempts to remedy the evils arising from the bad management and reckless competition of some of their lines. The chief point aimed at is the abolition of "discrimination," as the Americans significantly describe the preferential rate system, but our own railway authorities seem to think that in

drawing a strict line as to equal mileage rates the Congress is making a mistake that will be self-evident directly the new rules are put into operation. Mr. Grison, of the Great Western, who, when interviewed upon the subject a week or two ago, said that this legislation would have to be modified if not entirely reversed, has devoted a considerable portion of his work on English and foreign railway rates to this branch of the subject. He adduces many arguments to show that equal mileage rates would sometimes act unfairly, and quotes a New Zealand correspondent of the *Economist*, who declares that many trades are much hampered by their Government tariff, which does not admit of differential rates. Another English railway official, writing from Cleveland, Ohio, says that the American managers consider that a little experience of the proposed legislation will teach Congress to let them alone in future. Always hearing in mind the great difference between the conditions of our lines and those of other countries,—which make it difficult to institute comparisons, and which our railway champions always make a great point of,—it will be instructive and interesting to watch the result.

**E**XPERIENCE seems to have proved indubitably that the Model By-laws of the Local Government Board with respect to buildings, upon which the by-laws of Local Authorities generally are based, are, in many instances, ambiguous in their language, and in others, where they are explicit enough, unnecessarily stringent. The correspondence which has taken place between the Local Government Board and a Local Board in the western suburbs clearly shows this to be the case in regard to such important points as the thickness of dividing walls of smoke-flues and of chimneys when they come back-to-hack in domestic buildings; also the excavation of cellars or basements in old properties, the covering over of areas at the back of business premises, and the distances separating buildings which should require parapets erected on their external walls. The Local Board in question was placed in a dilemma because the present surveyor was disposed to uphold what was generally regarded as a more stringent interpretation of the by-laws than his predecessor put upon them. The present officer insisted upon a thickness of 9 in. for the dividing walls of smoke flues and 18 in. for those of chimneys back to hack. An appeal was made to the Local Government Board for an authoritative interpretation of certain by-laws, and it has sanctioned an alteration now making it clear that only half the thickness just mentioned, in each case, is required. A vexed point with the Local Authority and the builders has thus been for the present settled.

**T**HE Local Government Board has conceded one important point sought, in adding to its model by-law relating to cellars, "that where a cellar is within one-third of the area of the site of the building it shall not be deemed a story," and, consequently, the requirements as to additional thickness of walls in the upper story do not apply. But the Central Authority has refused to assent to the proposal to allow the back areas of buildings, which at present must have an aggregate open space of 200 square feet, to be covered in. Many domestic buildings are transformed into business premises, and it seems hardly necessary for sanitary or other purposes to restrict owners or builders from erecting extensions or warehouses upon these open spaces in the rear. With regard to parapets on external walls, the Central Authority has fixed 10 ft. as the limit of distance between each house instead of 15 ft. as formerly. But it seems ridiculous to fix any limit of distance when these Model By-laws do not prohibit owners or builders from putting windows in their gable-walls, which would thus present a very vulnerable point with regard to the spread of fire. There are many other points in these by-laws which are destined to be materially altered, not by the tinkering emendations of the Local Govern-

ment Board, but under the operation of a comprehensive Act of Municipal Reform.

**A**N experiment appears likely to be soon tried of some importance in the purchase of the railways by the Swedish Government. Of the 4,284 miles at present constructed in that country, 1,483 already belong to the State, leaving 2,841 to private companies; and this railway interest of late years, just as it has in other countries, has been very much depressed, the principal traffic being of a heavy nature, and not able to bear the expense of a long rate. The private lines would be very happy of themselves to make a reduction; but the shareholders naturally feel that they could not do this, with the competition of the State lines. The result of the inquiry into the question is that the Government is advised to buy up the private lines, if they can be had at a price which would not be unreasonable. Once that is done, the rates can be adjusted as is thought proper for the circumstances and the locality.

**C**OLDBATH FIELDS PRISON and its site of 8½ acres are, like to the neighbouring House of Detention, offered for sale. The prison, whose cells have received 1,800 male prisoners at a time, is now being shorn of its portable fittings. The big clock, and chapel and office furniture, for instance, are destined for removal to the new convict settlement at Dover; the records, extending over nearly 100 years, to the Stationery Office. The tread-wheel machinery will be reconstructed at Pentonville. The vast wheel-shed stands on the north-eastern side of the main building, having been set up there to replace a still larger one, on the south-western side, that was burned some years ago. The four tread-wheels, clogged one into the other, and connected with the adjacent flour-mill, accommodated 350 men working together, each in his own box or compartment. To that number might be added the one "off" man for each three at labour, taking his five minutes' rest on a stool every quarter of an hour in turn with his own party. Three of the angles formed by the five radiating arms of the principal building are railed off for exercise-grounds. These, now turfed and gravelled, were until lately, like to those at Newgate, paved. On either side of the southern main gallery, with its five floors of cells, stand certain portions of the older prison, including the original chapel, since appropriated to the Roman Catholic inmates. These earlier portions (1794) are easily to be distinguished by their excellent red-brick masonry, dressed with Portland stone, and the vaulted roofs of the "solitary" cells. These cells were some of the first of their kind, and were originally unwarmed. The modern building that towers from within over the entrance-gates on Mount Pleasant is the chapel and offices, the latter being upon the ground floor.

**A** MOVEMENT has been set on foot to raise a fund wherewith to erect a monument to the great Marquis of Montrose over his grave in St. Giles's Cathedral, Edinburgh. A committee has been formed, including, amongst others, the Duke of Montrose, the Marquis of Lothian, the Marquis of Breadalbane, Lord Napier and Ettrick, the Lord Justice-General, and Sir William Fettes Douglas, P.R.S.A. A circular has been issued inviting subscriptions and stating that "attention has lately been directed to the fact that there is no monument or even commemorative tablet over the grave of the Marquis of Montrose in the Cathedral Church of St. Giles. On the restoration of the monarchy the scattered remains of the 'Great Marquis' were reverently collected, and after lying in state at Holyrood they were interred at St. Giles's by order of Charles II., with all the ceremonial of a State funeral, on May 11, 1661. They were buried behind the tomb of the Earl of Athole, in what is now known as the Montrose Aisle. A monument over the grave was contemplated at the time, but never executed, and this omission it is now proposed to repair." The monument will contain a figure of the Marquis, and, if funds admit, the window beside it will be filled with appropriate

designs. The estimated sum for carrying out these requirements is 1,500*l.* Towards that sum subscriptions have been received to the amount of about 1,000*l.* The subscription list contains the names of the Duke of Montrose, 150*l.*; the Marquis of Breadalbane, 25*l.*; and the Marchioness, 25*l.*; the Duke of Hamilton, 50*l.*; the Earl of Powis, 50*l.*; T. Graham Murray, 50*l.*; &c.

IN regard to the new Free Library at Edinburgh the following suggestions have been made, viz., that the building shall have a frontage of 98 ft. towards George IV. Bridge and 87 ft. towards the Cowgate, leaving a space of 30 ft. to the rear for light and air. That the lowest flat be appropriated for electric dynamos and the necessary machinery for lighting. That the second flat be utilised as workrooms for binding, &c., and sanitary accommodation. The third flat to be used as a newspaper room. The fourth flat, being that on the level of the bridge, to be the lending library. The floor above to be the magazine department, with a separate room for ladies; and the uppermost flat to be a reference room. The idea of the Committee is that a handsome and suitable building can be erected for 25,000*l.* or 30,000*l.*, and that the balance of Mr. Carnegie's gift of 50,000*l.*, after payment of the value of the site estimated at 11,000*l.*, be devoted to the purchase of books and the starting of the library. It is expected that the operations connected with the clearing of the site will be commenced shortly after Whit Sunday, and that the plans will be thrown open to competition.

THE archaic sculptures recently found in the Acropolis have excited abundant interest. The fragments of archaic vase-paintings, of no less importance to the history of art, are only just beginning to be known about. In the last issue of "Εφημερίς Αρχαιολογική" (iii., 3), Dr. Studniczka publishes a few of the most interesting. Of these, one represents the birth of Athene from the brain of Zeus, and is by far the earliest bit of work we have embodying this scene. The goddess springs full-armed from the head of the god; she carries an enormous shield on the left arm, and, from the attitude of the left, must have been swinging her spear. Behind Zeus appear the uplifted hands of the birth goddess, Eilithuia, perhaps the most primitively-drawn hands ancient art has left us, but full of vigorous expression. It is still possible that further fragments of a composition which, in its entirety would settle some interesting problems, may be found. With it Dr. Studniczka publishes another archaic Athene of later date, beautifully drawn, somewhat in the style of Amasis, and also the fragment of a dedicated pinax, with part of the dedication still legible. Together with these may be studied with advantage an archaic bas-relief, published in the same number, representing a very early type of the worship of Athene. The goddess is standing unarmed except for her helmet, her right hand uplifted and her left holding back her drapery. The head, hand, and drapery are, in spite of their extreme stiffness, of the greatest possible delicacy. The waist is of quite unnatural smallness. The goddess in those early days was not, as later, the patroness of the Rational Dress Society. Two full-grown figures are approaching to worship, and with them they bring two tiny children, also a sow for sacrifice. The relief is the earliest of its class as yet known, and is specially interesting because of the analogy of the women types,—goddess and mortal,—to the large figures in the round which have been found in such numbers in the Acropolis excavations.

IT seems hard that an inscription of such great interest as that now published by Dr. Kabbadias should have been found last year, on the 16th of July, and only now, after seven months, be accessible to the educated public. Since the Delos excavations, the name of Archermos of Chios, who "first gave wings to Nike," and the praise of whose works exceeded even that of the Chian wine, has had

an actual substantial interest denied to his shadowy contemporaries. It is true that since the inscribed plinth and the figure of Nike have been brought from the local museum at Myconos to Athens, doubt has been thrown on their supposed connexion; but this only makes the inscribed column published in facsimile by Dr. Kabbadias of greater interest. The inscription written in the fittings of the fragment runs as follows:—

"... (Α)ρχερμος ἰποίησεν ἡ χι(αυ)  
... (ἀνά) θεκεν Αθηνάι πολιόχο(ι)."

Of course, theory will be rife as to the statue that once stood on the column, and Dr. Kabbadias thinks it may possibly be a curious female figure of non-Attic type recently discovered. This awaits confirmation.

ON the evening of Friday of last week Professor Baldwin Brown lectured to the members of the Edinburgh Philosophical Institution on "Art and Nature," in place of Mr. Holman Hunt, who is indisposed. He said that a faithful transcript of nature might, in painting, be both beautiful and interesting, but in sculpture would be so tasteless as soon to become intolerable. It was not nature, pure and simple, of which we desired a literal transcript, but only of that side of nature which had beauty or interest, or sympathetic charms. The principle of "Truth to nature" had actually been taken up and made the watchword of a school of novelists and painters who dwelt with revolting minuteness of detail on all those aspects of nature from which in actual life we were glad to divert our eyes. This latest development of naturalism in art, which had its chosen home in Paris, was, at any rate, of value in showing that it was no true touchstone of art to inquire simply whether or not it adhered closely to nature. The true arbiter of art was not nature, but mind.

THE Dudley Gallery Art Society seems to have followed the lead of the Institute of British Artists in restricting (vertically) its hanging space and draping the upper portion of the walls. The effect is good, and the exhibition does not suffer. The exhibition is strongest in landscapes, and contains some fine works by Mr. Goodwin and some very good architectural subjects by Mr. Hubert Medlicott, as well as some good landscapes bearing names we are not so familiar with.

WE received the intimation, just too late for our last issue, that Mr. Waterhouse has been appointed assessor in the matter of the Edinburgh Municipal Building Competition. The appointment of Mr. Waterhouse in such cases seems to be becoming almost a foregone conclusion now, but we cannot suggest that any better man could be found.

THE advertisement of the competition for the Imperial Institute, which appeared in our columns last week, inviting architects who wished to compete to send in their names, stating what public buildings they had carried out, is a foolish sort of business. The architects of public buildings that are worth anything are well known, and might just as well have been selected at once; and it is a very lame conclusion that those who have not had such an opportunity hitherto are necessarily of inferior capacity to those who have. It is rumoured that some candidates intend to send in a list of some public buildings which they have not designed, as a claim, at all events, better than that of having perpetrated them.

Lectures at the Royal Academy.—In lieu of the three lectures which were announced to be given by Professor Newton on "Terracottas" (see pp. 168, 204, ante), arrangements have been made for two lectures by Professor Middleton on "Early Medieval Sculpture," to be given on Feb. 21 and Feb. 25, and for one lecture by Mr. R. S. Poole, Keeper of the Coins at the British Museum, on "Medals." The date fixed for this lecture is Wednesday, March 9th.

#### THE "SUPERINTENDING ARCHITECT" AND HIS POWERS.

IN regard to the Brixton-rise and Trent-road case, to which we referred last week, Mr. Broadhurst addressed a question in the House of Commons to the Chairman of the Board on Thursday week with regard to the powers of the Superintending Architect with respect to the general lines of the buildings in the metropolis. The Chairman, in replying, stated that the Board have no control over the Architect with reference to his decisions as to general lines of buildings, and that he was not aware that the Board proposed to initiate any legislation this Session with a view to an alteration of the existing law. The exceptional powers possessed by the Superintending Architect in this respect were confirmed by an Act of Parliament passed in 1862, and they have been exercised with almost universal approval up to the present time. The Lord Chancellor (Earl Selborne), in the course of giving judgment in the House of Lords in the case of *Spackman v. The Plumstead District Board*, speaking of the Superintending Architect, said,—“He is a statutory officer, who the makers of the same statute which constitutes the Metropolitan Board of Works, and gives their powers, think is a proper officer to take part in the execution of those powers. He must be a man of intelligence and a man of position. I think that all this presumption is against the idea that when upon himself, and not upon his employers, a duty is imposed by the Legislature he would discharge that duty partially for the purpose of pleasing his employers.”

And the Lord Chancellor further remarked,—“If there is a row of houses . . . built in a regular mathematical line . . . the fact is already determined, and there is no room for a judgment. But if the buildings are irregular, if one house projects beyond another, or one block of houses projects beyond others, or if there is anything breaking the line, then in the nature of the case there is need of a judgment. And what better than that of the Architect of the Board, an expert in matters of this description, can he conceive? Is it *a priori* so plain as to alter what otherwise would be the proper construction of the statute, that a Justice of the Peace is a better and more competent judge of these matters than an architect?”

On the same occasion, Lord Watson remarked,—“That one tribunal is preferable to another is no reason whatever for disregarding the words of the statute, and when the Courts are of opinion that the Legislature has chosen the worst of the two tribunals, it is an opinion which I can only say does not exist in my own mind. I am by no means satisfied that a decision by a gentleman in the position of the Superintending Architect of the Metropolitan Board of Works is likely to be less favourable to the interests of all parties concerned, or is less likely to attain the ends of justice than a series of decisions by a number of district magistrates. I concur in all the observations which have been made by the Lord Chancellor on this part of the case.” Similar opinions were expressed by the Law Lords in giving judgment in the *De Venning* case (*Barlow v. The Vestry of Kensington*).

Mr. Broadhurst does not state precisely what alteration he desires should be made in the existing law with regard to lines of frontage, but it may be reasonably assumed from the manner in which his question is framed that he desires to transfer the duty of deciding general lines of buildings from the Superintending Architect to the Metropolitan Board of Works. If this is his intention it is not at all likely that he will be supported by public opinion. At present the power of deciding general lines of buildings is in the hands of an independent officer, whose decision on matters of fact is practically without appeal, and to transfer this power to a heterogeneous body of fifty or sixty members with widely different capacities and interests would open the door to endless confusion, and invite suggestions of favoritism and corruption. The decisions would be probably left in the hands of one or two members of the Board who make a trade of these matters, and no fairness or consistency could be hoped for from such a tribunal.

The Work of some Unknown Designers.—Want of space obliges us to postpone this paper till next week, rather than divide it.

ENGINEERING AND ARCHITECTURE:  
IN RELATION TO SANITARY SCIENCE.

This was the subject of a paper read before the Parkes Museum and Sanitary Institute two or three weeks since by Mr. M. Ogle Tarbotton, M. Inst. C.E., Borough Engineer of Nottingham. Captain Douglas Galton, F.R.S., was in the chair. Want of space compelled us to defer noticing it earlier; but as both the paper and the discussion on it are of considerable importance, and the discussion has not hitherto been reported at all, we give them now, as containing matter of permanent value.

Mr. Tarbotton, in the course of his paper, said:—

Engineering and architecture take an important status in the operations which are necessary for the practical application of sanitary measures. It is difficult to say where, in many branches, the former ends and the latter commences. There is, in the details of sanitary work, such a necessary fusion of the two, that any one entrusted with the execution of health works, should have special teaching and experience in both engineering and architectural construction and practice. Architects have lived and maintained their powerful influence in all ages.

At the present day it is well known that in buildings, commercial and monumental, the architect seeks the assistance of the theoretical and practical engineer; for it would be impossible, in these times, for an architect to obtain in his education, or acquire by his experience, or even sustain in his mind, a correct and practicable knowledge of many of those constructive and mechanical problems which are involved in the raising of a monster edifice, as it would be for an engineer to design a Westminster Abbey or a Rheims Cathedral.

Until within the last forty years the sanitation of dwellings was very little understood by architects, and ventilation and drainage were looked upon with comparative indifference. Since the great inquiry into the health of towns conducted by the Royal Commission issued in 1843 by Sir Robert Peel, considerable advances have been made in sanitary science, not only in England but in most parts of the Continent, and those who knew the state of Paris or Berlin thirty years ago and are intimate with those cities now, can testify to the radical change for the better sanitary works have produced in external appearance, in public health, in decreased mortality, and in advanced prosperity. The result of the Royal Commission was the passing of the Metropolitan Commission of Sewers Act in 1847, and the first Public Health Act in 1848. Since that time many sanitary Acts have been passed by Parliament, the Public Health Acts have been extended and consolidated, and numerous collateral Acts of great value, such as the Artisans' and Labourers' Dwellings Acts, have been brought into existence.

Concurrently with the aforesaid legislation the principles of water supply, sewerage, house drainage, ventilation, &c., have been deeply studied and carried into effect by both engineers and architects; the latter are now, as a rule, giving very much more personal attention to hygienic matters, and architectural students are making them part of their professional education.

Architects are now enabled to specify, with increased confidence, the materials and character of the work required to be used for the various sanitary appointments, not only of an ordinary dwelling-house, but of the most palatial edifice; also for the, sometimes, complicated appointments of asylums, gaols, workhouses, barracks, and other large buildings.

The publications issued by the Local Government Board, and by professional societies and private practitioners, give most valuable information as to the best means of carrying out ventilation, heating, drainage, water supply, and the like, for public and private buildings, the abatement of nuisances under the Nuisance Removal Acts, the formation of street surfaces and external pavements for various purposes, and for floors for men and the so designated, inferior animals, all of which, with many others, are distinctly sanitary work.

The branches of engineering are exceedingly numerous, and it would be impossible to collate many of them with architecture. It is generally understood that the practical separation of the two divisions of constructive science and art took place about 300 years ago, when the Dutch

commenced their large works of land reclamation. Then a body of hydraulic engineers sprang up, and these were strengthened afterwards by the engineers of canals and railways in various parts of Europe. Subsequent enterprises caused a further combination, and thus was established the now recognised distinct body called Civil Engineers.

It is with the sanitary engineer, however, that this Institute is mostly engaged, and a few words may be said as to the difficult and contested problems he has to encounter.

When sanitary work is carried out in a proper spirit, and on correct bases, the practice of it increases in interest, in proportion to its recognised results. It is allied with the physician, the chemist, the architect, and the geologist; and the engineer must, in addition to considerable constructive knowledge, possess more than the rudiments of that technical knowledge which belongs to the above professions.

The greater fields of labour for the sanitary engineer are those of water supply, sewerage, and drainage. On the subject of water supply, Great Britain may be considered to be fortunately situated, when compared with many Continental areas, and no district in this land of ours need be destitute of a supply, derived from a healthy and continuous source, if proper and thoughtfully-devised means be adopted to acquire it.

Water, in nature, is never absolutely pure, that is, having the qualifications of distilled aquafaction, and need not be; but the great object is to secure immunity from carbonaceous and nitrogenous impurities, and to avoid sources where there is the slightest possibility of organic contaminations, especially when water is and should be mostly consumed *Asperes* (or prandium) *vis uera*. The relative qualifications of hard and soft water have always had a prominent position in pathological debate, but the subject has many surroundings. It is impossible in some districts to obtain soft water, and in the chalk beds and in the Keuper beds of the New Red Sandstone formation, and some others, the water is invariably hard, varying from 20 to 60 degrees and more. The chalk waters can, however, be reduced from their initial to a comparatively low permanent hardness, by simple chemical processes. Water derived from the igneous and aqueous and some of the metamorphic rocks, and from a great part of the carboniferous system, is usually soft, and this class of water is to be found in Wales and Cornwall, on the Yorkshire and Lancashire moors, in the great lakes of England, and in the lochs of Scotland, also in most parts of Ireland. For potable purposes, the public taste is decidedly in favour of hard water. Such water is usually bright, pleasant to the palate, and refreshing, whilst soft and puer water is insipid, tasteless, and gives no feeling of exhilaration. It has been contended that soft water causes imperfect development, and that hard water is essential to the formation of tissue in the human frame. It has also been shown that in towns where the hardness exceeds 10 degrees, the death-rate is much lower than in those supplied with softer water. In manufacturing districts the softer waters, i.e., those from 2 degrees to 5 degrees, are all important, but perhaps the most palatable and useful waters for all purposes are those derived from the Bunter beds of the New Red Sandstone, when the hardness is, initially, about 6 degrees, and infrequently exceeds 12 degrees or 14 degrees, except where the gathering reservoirs are washed out, at which time the supply therefrom should be abandoned.

This country is so full of well-executed water-works, and of literature bearing thereupon, that the sanitary engineer, having a fundamental knowledge of geology, meteorology, and hydraulics, should never fail in bringing to a successful issue a system of public water-supply in any part of this country. The rock-cut temples of India and the well-known aqueducts of Rome express in the strongest physical language our ancestral demonstration of the value of a pure atmosphere and an unpolluted water.

On the subject of water-supply to our large communities, a few words may be said on the real value of water and the modus of its distribution. At one period, not especially recent to some I am now addressing, the water-supply, by defective mains, services, and fittings, particularly the latter, was most extravagant, or, rather, wasteful. In many towns the consumption reached so high as 40 to 50 gallons per

head per diem, and no thought appeared to be bestowed upon the proper and economical distribution of one of the most, if not the most, valuable elements of existence.

By the agency of engineers of the last thirty to fifty years a great change has been effected in most of our great towns, large towns mainly, but not excluding many subordinate districts, the most careful measures have been designed to secure freedom from wanton and needless expenditure of water. The public, I fear, do not, in any class of life, recognise properly the expense of obtaining and delivering water, excepting when the cost is expressed in terms of rates, and when these are applied for, there is, of course, pronounced and popular discontent evolved from either absolute ignorance or imperfect experience in the management of communistic undertakings.

As to the influence on the rates of a town, where water is suffered to be improperly used, or, in other words, wasted, the public little knew what a differential advantage would ensue if a cautious and sensible use of water were maintained. Of course, the consumption in cities and water districts varies much, and the greatest variation occurs in manufacturing towns; but a community can, apart from manufacturing supplies, be well served by a provision of from 12 to 14 gallons per head per day; that is, if proper fittings be employed, and a proper supervision thereof be regularly exercised.

These latter remarks are applicable to the subject of town and general public sewerage, which, in some respects is more complicated than that of water supply. The Government Blue Books and the Reports of the several Royal Commissions on Sewage and the Pollution of Rivers, which have, *in se*, much greater value than the public are in the habit of attaching to them in ordinary municipal life and conversation, with many other professional publications, give, in the aggregate, much information on the modern plans of urban sewerage; but, perhaps, the best practical information is to be gathered from a personal examination and study of the sewerage works in the metropolis, and in several of the larger towns of the kingdom. In these places the most precise care and study have been given to the numberless details which surround the construction of a system of town sewerage, and those details are now fairly well formulated and established.

After making provision for the drainage of the subsoil to a sufficient depth, to allow the basements and lower floors of the buildings and houses to be freed from water and damp, the points then to be considered are the lines and gradients of the outfall (having reference to the ultimate disposition of the sewage), the volume of sewage to be provided for, the amount of rainfall to be dealt with, the size and materials of the outfall and internal sewers, the modes of ventilation and flushing, and the methods of forming junctions and means of access, so that the whole system may be under most immediate control. The house-drain connections with the public sewers should receive more attention than has hitherto been given to them, if the subsequent internal house drainage is to be made beyond suspicion of danger. The above being satisfactorily arranged, the collected refuse will have to be disposed of, and the *modus operandi* will have to be determined upon. Here commences the sewage difficulty, but one which has been greatly mitigated, by past and late experience. The cardinal principles of any system of appropriation must be non-contamination of the atmosphere, non-pollution of any river or stream, and the recovery from the discarded and disorganised fabrics of nature, of all the powers of compensation that can be extracted from a pre-acknowledged nuisance. By an almost general consensus, it appears that the safest and cleanest, and, in the end, most economical method of extracting the compensation referred to, from town refuse, is to restore it to the soil from whence it came, and this is done in the form of land-irrigation, or, in other words, the application of effete organic matter, in a soluble form, to the resuscitation of vegetable life, and the subsequent sustentation of animal life and human existence greatly depends upon the consumption of vegetable substance. The success of this process is now so almost uniformly established that most towns, large and small, cities of great magnitude, and hamlets of the humblest size, are resorting to irrigation, sometimes called land filtration; and compelled so

to do to dissolve their sewage difficulties, and to recoup to some extent the great cost which attends the extinguishment of a gigantic and inevitable social nuisance. Other processes have been tried, with results more or less good, but in many cases they have been abandoned in favour of irrigation. It would be absurd to declare that no chemical process is capable of deodorising and disinfecting sewage, and rendering it innocuous, but the cost is great, the results are not satisfactory, and it is totally unremunerative.

Towns vary much in the character, volume, and value of their sewage, and to lay down a rigid and absolute rule would be preposterous; but in the majority of cases irrigation is found to be the natural, safest, and most rational. In some few places the sewage may be cast into the sea, distant from the shore, with impunity; but in the majority of cases where the physical configuration of the country is favourable, where the land is light, porous, and well drained, where the population is extensive and the markets or farms are near for the sale or use of vegetable produce, and where, most importantly, the management is competent, irrigation and sewage farming should not involve a loss to any community greater than it can reasonably bear, considering the objects of the undertaking. We hear that in King Solomon's time the sewage from the Temple was used for the fertilisation of the market gardens in the Valley of the Kidron, and the latest and largest similar work, of modern times, is the utilisation of the sewage of Berlin, on about 1,500 acres of sandy land, north and south of the city and many miles away, the extreme distance of the farms being nearly twenty miles.

With regard to house drainage, great advancing movements and works have taken place during the last few years, and the public appear to be more fairly aroused to the importance of having their dwellings absolutely secure from the influences of sewer gas and bad air. The great point, clearly, is to have the principles of drainage properly taught to and understood by all classes of the people; and, secondly, to secure thoughtful and honest work in carrying out the necessary operations. This is an important branch of a sanitary engineer's labours, and sometimes a very tedious one, but it must be remembered it is quite as important in a sanitary sense as the larger works of public sewerage.

The solid and miscellaneous refuse should be collected and carried outside, and buried, or consigned to the flames of a destructor, which can, and should, rapidly and effectually annihilate them. This process has the merit of cleanliness and common sense, is coming into popular use, and its prototype is described in the earliest records of human sanitary teachings, and especially in those of the city of Jerusalem, from whence it appears that all matter, effete and deleterious to health, was consigned to the fires of *Hésva*, or the "Furnace of Hell."

Another sphere of work for the sanitary engineer, is to be found in the superintendence, if not in the designing, of houses, hospitals (general and epidemic), barracks, and such-like buildings. In this branch of labour the technique of construction must be thoroughly understood, combined with the nature of materials and the most economic methods of employing them, aération, and ventilation, warming and lighting, cubical capacity in relation to all classes of occupation, width of streets and internal areas in reference to light and air, and the manifold minor concomitants of a structural and sanitary character. Without such knowledge no sanitary engineer can raise a building of integrity, or advise upon the defects of those which may unfortunately exist. Some architectural art culture is also desirable, for no building at the present time, of any social pretensions, dare raise its head without some legitimate accentuation.

In the discussion which followed,

Sir Robert Rawlinson said that Mr. Tarbotton, whom he was proud to call his personal friend, had told them that engineering and architecture ought to be allied. He agreed with him; and Mr. Tarbotton was a capital example of the alliance. He was himself both an able architect and an able engineer. He had designed and put over the Trent one of the most beautiful bridges in England; and as for sanitary arrangements, he (Sir Robert) knew no engineer who had done better work, or had executed works

and devised means more perfectly than his friend. The paper was so wide and so discursive that he would not attempt, even briefly, to follow it. But Mr. Tarbotton had touched on a subject which was of very great interest to London at this moment, namely, the question of sewage treatment,—whether it was to be treated in one way or in another. He hoped he might be pardoned for bringing in a subject outside the paper, but which was one of general interest at the present moment, namely, the best, cheapest, and most beneficial method of dealing with the sewage of London. They knew that it had been taken by the Metropolitan Board of Works down to Barking and Crossness, and they knew it had been poured in a crude state into the river, they having been told by Parliament to carry out the main sewerage work in such a manner as to prevent the river being polluted. The Board was now proceeding, he believed, to continue the establishments at those points, shirking altogether the question of irrigation, and persisting in treating the sewage with chemicals in some infinitesimal quantity, and then, it was said, the residuary sludge was to be taken out in hopper-barges and deposited in the sea. Speaking as an engineer, he ventured to say that that was the most hopeless, helpless, and extravagant and costly method that could be devised. Mr. Tarbotton was too modest to tell them what he had done; but he had most successfully carried out sewage irrigation on a grand scale in Nottingham, where he was Consulting Engineer. In Berlin, sewage was being applied to the land, and only that week he had received two volumes from the engineer-in-chief at Paris, M. Dorand Clay, showing that in that city the sewage was being extended to the land. In England they rather prided themselves in setting examples than in following them, and he was heartily sorry that in such great works as the disposal of the metropolitan sewage they were not leading rather than lagging behind; because he held that the entire sewage of the metropolis could be taken down through the intervening agricultural districts from the present outlets to the sea, and such arrangements might be made that in a very few years the greater part of that sewage would be taken voluntarily by the landowners on either side of the conduits to produce those crops which we knew a proper application of sewage would produce. The conduits should have an outlet for winter discharges to Canvey Island or to the sea, when the sewage might not be applicable to the land. As to the so-called movable-pit system adopted in some towns in England, Mr. Tarbotton had said that it was only a slight advance upon the asphalt system. His (Sir Robert's) opinion was that it was a very long advance backwards, and was in some respects worse than the asphalt system. It was, in fact, a most detestable practice. There were those who poured ridicule upon the water-carriage system, because, they said, it was a wasteful system, but that was not the teaching of experience. What did water-carriage mean? It meant that whatever the volume, whatever the weight, whatever the magnitude in volume of the sewage, make conduits for it to flow along and we should not require either horses or other motive power, as the sewage by means of water could be carried to any point, there to be disposed of as might be best advisable.

Mr. E. C. Robins, F.S.A., said they were much indebted to Sir Robert Rawlinson for the lucid way he had put the matter before them. He thought it was quite clear that there were a sufficient number of lands irrigated by sewage to prove that it was not an impossible or impracticable method, and it was the one method which seemed to have realised some return for the money expended upon it. The subject of Mr. Tarbotton's paper was most interesting, and, as an architect, he was very glad to have heard it, and to reciprocate Mr. Tarbotton's idea as regards the association of architects and engineers. It would be foolish for an architect not to take advantage of the services of an engineer as to a subject with which he was more particularly informed. On the other hand, he thought that engineers might sometimes benefit by the advice of an architect, more especially on the fine art side of construction and house sanitation.

Mr. Scott Moncrieff thought the Institute was very much indebted to Mr. Tarbotton for the valuable paper which had been read, and also for the very valuable remarks made by Sir Robert Rawlinson. He endorsed the remarks

made by Sir Robert, and thought his views were of exceeding value. He did not think it was at all likely that sewage, as an available manurial agent, would remain long in the defective position in which it stood in relation to the practical work of farming.

Mr. William White, F.S.A., said that the chief interest in the paper to him was the attention it called to the amalgamation of the architect with the engineer. This was a question raised many years ago and continued down to the present time,—the question of the division and concentration of labour. The question was whether an architect ought to be essentially an architect, or whether he should also carry on his works with reference to those great and wonderful structural engineering works, of which there were so many at the present day. The point of interest raised by Mr. Tarbotton was rather with reference to the association of the essentially sanitary arrangements of a dwelling with the architect and not so much so the association with the engineer in the structural work, for he thought, on that point, there could be very little question. There was quite enough in architecture to take a man's whole attention, as there was in engineering for an engineer. That an architect ought to be versed in the proper sanitary arrangements for buildings he erected was incontrovertible. If an architect had not learned the sanitary principles which ought to be carried out in a house, there was no question whatever that he ought to call in for his own assistance the sanitary engineer, who had devoted his life and energies to that especial branch of the profession.

A vote of thanks was then unanimously passed to

Mr. Tarbotton, who, in reply, said he wished it to be distinctly understood that he did not mean that engineering and architecture could be absolutely fused, but on sanitary questions there might be more fusion than there was at the present time. Mr. White referred to that point very properly and very strongly, and he quite agreed in his views. In the course of his experience of a third of a century he had found that up to the present time architects did not understand anything about drainage.\*

#### HOUSE DRAINAGE.

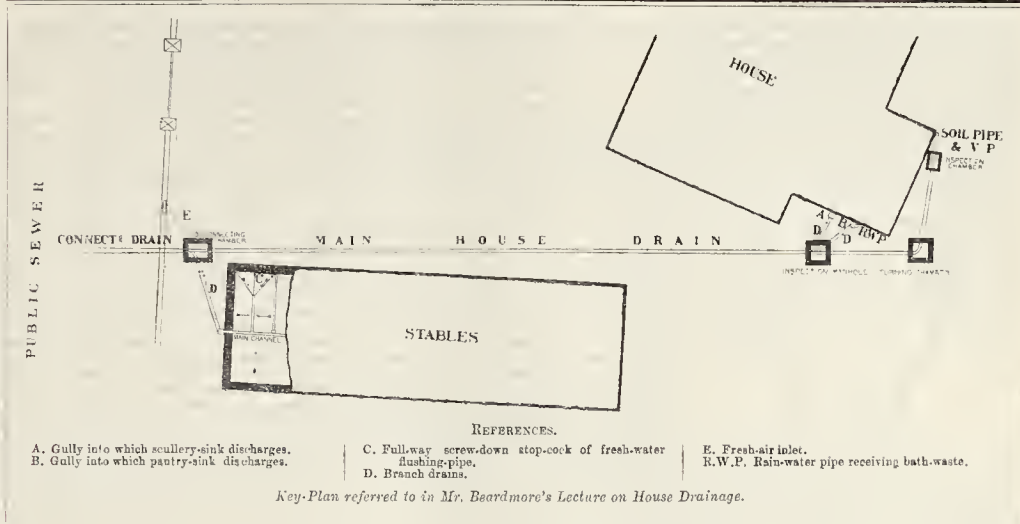

CIVIL AND MECHANICAL ENGINEERS' SOCIETY.

At the meeting of this Society on the 2nd inst., the President, Mr. E. H. G. Brewster, A.M.I.C.E., in the chair,

Mr. W. Lee Beardmore, A.M.I.C.E., gave a lecture on house drainage. Dealing first with a country-house, such a one as might be situated in the position shown by the accompanying key-plan,† he pointed out that it was unnecessary in such a case to carry any part of the house-drain beneath the house. The main house-drain in such a case might be carried along as shown in the plan, it being quite cut off from the public sewer by a disconnecting manhole, which should be placed at from 60 ft. to 70 ft. from the house whenever possible. The sewage of the house in the case shown by the key-plan would be carried from the channels in the disconnecting manhole or chamber by means of a short length of drain (which he preferred to call the "connecting drain"\*) into the sewer, which in this case is taken to be at the left-hand of the diagram, though it is not shown thereon. Of course the upper end of the connecting drain, just after it leaves the disconnecting chamber, must be trapped with a trap of the form shown in fig. 1, the upper socket receiving an inspection-pipe, passing upwards to the disconnecting manhole, above the outlet into the trap. This inspection pipe is provided with a cap, so that in case of any stoppage in the connecting drain (i.e., between the disconnecting manhole and the sewer), the cap,—which is, like the trap itself, of stone-ware—could be easily removed and the drain inspected or cleared by rods, &c. The cap should,

\* Mr. Tarbotton is certainly putting this statement in far too general and sweeping terms. Had he said that "a good many architects did not," we fear we must have left the statement unchallenged. But to make the statement roundly imply that Mr. Tarbotton's experience has not been fortunate.—Ed.

† It should be mentioned that the key-plan is intended more as a lecture diagram, illustrating the principal points touched upon, than as a representation of a complete plan of drainage. As Mr. Beardmore pointed out, there are appliances not shown, which would have to be discharged through a branch drain into an inspection chamber.

however, be sealed with neat cement, in order to prevent the passage of foul gases into the disconnecting manhole or chamber. The trap shown in fig. 1 was pointed out as a good form of

Fig. 1.

trap, inasmuch as, while it gives an ample amount of seal, its contour is such as to lend itself to the easy passage of the sewage. The trap shown in fig. 2, on the contrary, was

Fig. 2.

instanced as a bad form of trap, owing to its uneasy bends and angularity offering resistance to the flow. For the like reasons, figs. 3 and 4 were pointed out as good and had forms of gully-traps respectively. Fig. 3 shows a gully-trap which was designed by Mr. Rogers Field and is manufactured by Messrs. Bailey & Co., of Fulham. The connecting drain should be 6 in. in diameter, but the siphon trap itself should only be 4 in. in diameter, and the inspection arm terminating with the cap should also be 4 in. in diameter. The outlet of the connecting drain into the sewer might be provided with a hinged flap, which would open to allow of the passage of sewage, and might exclude rats, though it would not exclude sewer-gas from the drain, which could only be done by the siphon trap in the disconnecting manhole before referred to. The main house-drain itself need rarely be more than 4 in. in diameter. If it and the siphon-trap were much larger they would seldom or never get flushed full-bore by the sewage of an ordinary house,—in short, they would never get flushed as they needed to be if they were to be kept sweet and clean. If the main house-drain were going to be carried outside the house, the lecturer advised the use of glazed stoneware pipes. If however, the house-drain had to be carried under the house, as was generally the case in London, he recommended

the use of iron pipes. He thought that the objections which had been lately urged against the use of iron drain-pipes were not conclusive. Cast iron, it was true, was liable to rust, but the extent to which liability would operate against the use of iron for drain-pipes had been, he thought, very much over-estimated. If coated with Dr. Angus Smith's solution they would be protected from rust for a very long time. Being in 8 ft. or 9 ft. lengths (as compared with stoneware pipes, which were only 2 ft. long), the joints in a given length of iron drain would be something less than one-third the number of those in the same length of stoneware drain. The iron pipes should be socket and spigot pipes, with the joints well caulked with tow

Fig. 4.

Fig. 3.

and run in with blue lead, which should also be caulked home. Iron pipes thus jointed would successfully resist much greater strains than were ever likely to come upon them when used for drainage purposes, even in case of settlements in the ground. Stoneware pipes, even for work outside the house, should be chosen with a thorough glaze inside and outside, should be free from hurr and flaws, and should be true in outline and shape. The joints should be made with neat cement. The soil-pipe should be of the same diameter throughout as the house-drain, and should, wherever possible, form the head or extreme limit of the house-drain as shown in the key-plan. It should be carried up full bore as a ventilating-pipe, 3 ft.

or 4 ft. above the eaves of the house and above any dormer windows. By having the soil-pipe at the head of the house-drain a thorough current of air from the fresh-air inlet into the disconnecting manhole, along the house-drain, and up the soil-pipe, would be better maintained than if the soil-pipe went up at some intermediate point of the house-drainage system. The soil-pipe should, of course, be external to the building, and should be of heavy iron pipes, with the joints made in the same way as prescribed for the iron house-drain. Lead soil-pipes outside a house were open to the objection that a ladder placed against them by a gardener or horse-painter would dirt them, and so cause them to lose their true cylindrical form,—an evil much to be deprecated in the interests of the self-cleansing capacity of the

Fig. 5.

pipe. Where the air inlet-pipe to the disconnecting chamber was placed, as it sometimes necessarily would be in towns, in the near vicinity of a house, a tale flap might be placed over the aperture so as to close against the emission of foul air, whether momentarily caused by a rush of water down the soil-pipe and house-drain, or by the down-blow of occasional gusts of wind. The fall of a main house-drain of 4 in. diameter should never be less than 1 in 30; a 6-in. drain should have a fall of not less than 1 in 40; and if it were ever necessary to have a 9-in. house-drain (which he did not believe) the fall should be not less than 1 in 60. Mr. Beardmore then went on to describe other details as to the disconnection of water-closets, baths, lavatories, and sinks. Baths should discharge through a round-sectioned P or O-trap, leading to and discharging into an open rain-water-pipe-head, the pipe being carried down above the water-level in a gully-trap, such as that shown in fig. 3.

Scully and butler's sink wastes should discharge over open gullies of the same kind, and should be trapped, otherwise the waste-pipe would act as a kind of Tobin's tube for the admission of air, mingled with foul gases caused by the greasy deposit always found in such pipes. The trap shown in fig. 5 was a very good one for a butler's sink or for a lavatory; but for a scullery sink, discharging over an open gully, he preferred Jennings's improved hell-trap (a section of which is shown in fig. 6), owing to

Fig. 6.

the readiness with which it could be cleansed. The removal of the disc in this trap, it would be observed, did not destroy the seal. The housemaid's slop-sink was generally a very objectionable thing, and it was always better, in his opinion, to treat it as a w.c. The best form of water-closet he believed to be the valve-closet, but it should not be provided with that readily-siphoned appliance, an overflow-pipe. He advocated the adoption of Mr. Rogers Field's valve-closet, in which provision was made for allowing the overflow, if any, to run over the top of the basin into a lead safe or tray, whence it could be conducted out through the wall by a pipe like the warning-pipe of a cistern, but provided with a brass flap to prevent up-draughts. That pipe should be made to discharge into the open air, so that the overflow might be observed. The drainage of the stables should be made to discharge over a gully-trap, which in its turn should discharge through a branch drain, over the straight, open channel in the disconnecting manhole, whenever possible. Mr. Beardmore advised the use of iron channels such as those made by Messrs. Cottam & Co., especially the "Claremont" pattern. The branch channels could be readily flushed from water-pipes carried from the heads of the stalls to the tops of the channels, while the main channel could be flushed similarly, but by a larger pipe at the end furthest from the gully. Mr. Beardmore also referred to the evils resulting from the redundant size of house-drains insisted upon by some local authorities, and, in conclusion, urged architects to plan their buildings in full view of and with all consideration for the best and most workable disposition of the drainage and sanitary arrangements generally, instead of planning their buildings first and then considering the sanitary arrangements, sticking a water-closet in one corner, a lavatory in another, and a urinal in another, wherever a nook otherwise difficult of utilisation could be found. Such a method of planning could never be productive of satisfactory results. Another golden rule in house sanitation was to have as few sanitary fittings and appliances as possible. The water-closets should be placed, whenever they could be, at the angle of a building, so as to be situated against two external walls, and each closet should, in fact, form a small room, with ample light and ventilation. A well-ventilated lobby or ante-room (which might also serve as a lavatory) should whenever possible be interposed between the closet and the house.

[So much interest was taken in the subject of the paper that a special meeting for its discussion was held on Wednesday evening last.]

**Sunday Art Exhibition.**—The exhibition of the Institute of Painters in Oil Colours, at the Piccadilly Galleries, will be open to the members of the Sunday Society next Sunday, and on Sunday, February 20th, the public will be admitted by tickets. These tickets will be ready for issue on Monday next, and they will be sent free to those who make written application, and send a stamped and addressed envelope for reply, to the Honorary Secretary, 8, Park-place-villas, W.

## LECTURES ON ARCHITECTURE AT THE ROYAL ACADEMY.

### METHODS OF DECORATION AS APPLIED TO GREEK BUILDINGS.

ON Monday evening last Mr. J. H. Middleton, M.A., Slade Professor of Fine Art in the University of Cambridge, lectured to the students of the Royal Academy on "Methods of Decoration as applied to Greek Architecture." Having given a brief though graphic outline of Greek history, in the course of which he showed how strongly Oriental and especially Phœnician influences had tinged the early art of Greece, he went on to speak of and to describe the Palace of Tiryns, from the remains of which we had learned a very great deal as to the early use of different branches of art as applied to the decoration of buildings. As far as could be judged from the evidence of the building itself and its forms of ornament, the palace belonged to the earliest period of Hellenic development, —to the time when a Greek chief had succeeded to the wealth and magnificence which had been founded by one of the Oriental invaders. Though there was distinct evidence to show that the powerful rulers who inhabited Mycenæ and Tiryns belonged to an earlier age than that described in the Homeric poems, yet the buildings, the decorations, the arms, and the gold jewelry found there all assisted us to understand the meaning of much in both the Iliad and the Odyssey which before was obscure and indistinct. Before proceeding to describe the various modes of decoration used in the palace, the lecturer observed that in early times Greek art was almost purely decorative. Painting, sculpture, and metal-work were not employed for the production of objects such as enamel pictures and statues, which were simply intended to be beautiful works of art; but all the various arts were devoted to the enrichment of walls, columns, or roofs, or else, on a smaller scale, to the production of magnificent armor and personal jewelry. Such limitation of the scope of early art did not, however, act upon it in a degrading or in any sense in an injurious manner; on the contrary, the strong recognition by the early Greeks and their Oriental predecessors of the restrictions imposed on their art by the truest canons of decorative treatment, led to a simplicity of treatment and a certain reserve of power and knowledge which resulted in magnificent decorative effects. Passing on to speak of the examples of architectural decoration which were supplied by the remains of the Tirynthian palace, Professor Middleton referred first of all to the floors, which were partly of concrete and partly of mosaic, the open courts of the palace being carefully paved with a thick bed of concrete, which in places where there was exceptional traffic had its surface studded with a sort of mosaic formed of water-worn pebbles set closely together, this being clearly the first beginning of the art of mosaic-work. The other method of floor decoration at Tiryns was no less interesting. Inside the rooms and passages the concrete had been floated with cement to a fine surface, on which, while yet soft, simple designs of squares and wavy lines were scratched, and the whole was then coloured blue and red,—the lines or bands one colour, and the main ground another. From the fact that the colouring matter had sunk some perceptible distance into the body of the cement the pigment must have been applied while the cement was quite fresh,—a real example of true fresco in its simplest form. As to the decorative treatment of walls and other surfaces by means of metal linings, traces existed which showed that some of the walls were at least in part lined with thin plates of bronze, beaten into reliefs and thickly gilt. These bronze linings were nailed on to wooden boarding, with which the wall surface was first of all covered. Doors were covered with bronze plates in a similar manner, the method of treatment being probably not unlike that to be seen in the bronze gates of Salmeser II., from Balawat, now in the British Museum. What the form of the bronze linings on the wooden columns might have been was shown by a red marble shaft and capital which belonged to the doorway of the so-called Tomb of Agamemnon at Mycenæ. That beautiful piece of sculpture (which, by the way, was illustrated in all the hooks worn way up and called a "base") was richly decorated with

delicate surface reliefs of chevron and lozenge bands, clearly copied from a metal original, as rows of nail-heads were carved in the marble. Thus the apparently mythical splendour of the Palace of Alcimons described in the Odyssey (vii., 84), the brazen walls, the doors of gold, and lintels of silver, were not the mere offspring of the poet's fancy. Another sumptuous form of decoration in the Homeric palace of Alcimons had its prototype at Tiryns, namely, the *θηρική σκηνή*. A fragment was found in the great hall of a richly-carved alabaster frieze, covered with delicate ornaments and rosettes and spirals cut in relief, and thickly studded with jewel-like pieces of deep blue glass or paste, carefully cut and fitted. Lastly, the Tirynthian palace was richly decorated with mural paintings. With the exception of a stone plinth about 2 ft. 6 in. high, the walls of the house were built of sun-dried clay bricks. The whole surface was covered with fine hard stucco, which formed a very perfect protection against the weather, and both inside and outside the stucco was decorated with paintings. The wall-paintings of the Palace of Tiryns were of special interest, as being the only examples of the kind that had yet been found. Sufficient fragments had been preserved to show that a great variety of designs were used, belonging to two quite distinct classes of art. Though very simple in treatment, and not minutely finished, the paintings showed a very keen sense of the true principles of decorative art, and also by their freedom of line, and strong decisive touch, bore witness to a very remarkable technical skill and thorough training of hand and eye. The pigments were applied before the stucco was dry; in other words, true fresco was used, not distemper or encaustic painting, both of which were chiefly used by the later Greeks. Not only had the colours sunk into the stucco to an appreciable depth, but in some places the bristles of the brush had left their impression in the stucco. The pigments used were such as would have stood the contact with fresh lime. The native style of art was not limited to mere patterns; figures of animals and men were also introduced, and some very curious examples of these occurred on the painted pottery. There was a special charm about this early art, which was in some respects of even greater interest than that of later and more highly-developed periods. While there was less demand for mechanical perfection, there was more individual freedom allowed to each workman, and thus his work must have been more interesting to him. In the early pottery, for instance, what was most striking about it was its endless variety of form, evidently changing with the mood and individuality of each potter, and full of the most easy grace and multifarious flowing lines. It showed extreme fertility of invention, and the utmost freedom of touch in the manipulation of the revolving mass of plastic clay. The whole style was in great contrast to that of the very beautiful Greek vases of the fifth century, in which the individuality of the potter was carefully suppressed. In these later vases one fixed model had to be followed, from which very little deviation was allowed, and so the result was that there was something rather rigid in their highly-finished beauty, their polished surface, and their extreme perfection of workmanship. Again, the sculptured ornaments on the Greek buildings of the best period also suffered very seriously from the demand that the Greeks made for perfection in design and execution. Towards the end of the fifth century, after long ages of development, the Greeks had arrived at what they considered was the perfectly appropriate ornament for certain parts of a building. One fixed pattern was to enrich the main members of the cornice, others were exactly the right ones for the capitals, and so on, so that even at the most highly-developed period of Greek art there was an undeniable dullness in much of their ornament; for however beautiful a thing was, its beauty could not stand constant and precise repetition. Freshness and spontaneity were absolutely essential elements in the production of works of the highest æsthetic value. On the whole, the earliest Greek art belonged to one of the greatest periods of decorative skill that the world had ever seen, produced by a combination of wealth in the precious metals, and unsparing labour, with the true sense of the fit methods to be employed and the limits to be observed in the use of sculpture, painting, and metal work.

THE ASSOCIATION OF PUBLIC  
SANITARY INSPECTORS.

## ANNUAL DINNER.

The fourth annual dinner of this Association was held at the Guildhall Tavern on Saturday evening last, the President, Mr. Edwin Chadwick, C.B., in the chair, supported by a large number of well-known sanitarians.

The Chairman, in proposing the health of the Queen, the Prince of Wales, and the rest of the Royal Family, said it was matter for congratulation that in the fifty eventful years of the Queen's reign so much had been attempted and so much achieved in the special subject of the health of nations. It might be claimed that in these fifty years the science of sanitation had been founded, and that the Queen was herself one of the first to recognise its principles in the advancement of the health, the strength, the duration of life, and the happiness of her subjects. More than a quarter of a century ago he stated that if all her Majesty's subjects were to bestow the care that by the Queen's directions was bestowed on her own cottages, every third year would be a jubilee, in which there would be no sickness and death.

Dr. John C. Peters, of New York, proposed "The Army, Navy, and Reserve Forces," which was coupled with the names of Sir Andrew Clarke, R.E., Capt. Douglas Galton, R.E., and Major Lamorock Flower.

Sir Andrew Clarke, in replying, bore testimony to the great results that had been achieved for the Army as well as for the civilian population by the labours of Mr. Chadwick, instancing the case of Fort William, on the Hooghly, formerly one of the deadliest of military stations, but now, by the observance of sanitary laws, one of the healthiest.

Captain Douglas Galton and Major Flower also replied, the former gentleman remarking that he looked upon the sanitary inspectors as the very backbone of sanitary administration.

Sir Robert Rawlinson, in proposing "The Association of Public Sanitary Inspectors," said that their President might be said to have laid the foundation of modern sanitary science. He (Sir Robert) had been brought to London and educated in sanitary work under Mr. Chadwick's supervision. And there were other men who had done a great deal for the promotion of sanitary science, notably Lord Fortescue, Captain Douglas Galton, and Mr. George Godwin, the late editor of the *Builder*. No one had done more to help on the work of sanitary reform, especially in house accommodation, than Mr. Godwin, whose labours in the cause had been persistent, well-directed, and emphatically successful. In the course of further remarks Sir Robert Rawlinson insisted upon the necessity of making sanitary inspectors and other health officers to a great extent independent of those who, as things at present stood, were able to bring undue and improper influences to bear against the efficient performance of important public duties. With the toast was coupled the name of Mr. Edwin Chadwick, C.B.

Mr. Chadwick, in replying, said that sanitary science was now so far advanced in certainty that if it were duly represented for the people by a superior and competent State organisation, say by a Minister of Health, that authority might within limits direct, and the sanitary engineer might undertake to effect, large definite reductions of death-rates, and (setting aside the consideration of human pain and misery) might do so as a contractor at a charge for works simply for the saving of money by the reduction of the insurance charges for preventable sickness and mortality. Thus, the present reduced annual death-rate for the metropolis might be stated at 19 in 1,000. He concluded that the sanitary engineer might undertake its reduction to 5 in 1,000, and that he might undertake to do so at a cost greatly below the existing insurance charges for sickness, loss of work, and death. These conclusions he based on that which had been done for the common lodging-houses,—old buildings once the seats of pestilence, now cleared of them by very rudimentary sanitary measures,—also on what had been done in blocks of buildings in the metropolis,—also in old urban districts, such as Salisbury, where the death-rate was as high as 40 in a thousand, and, since sanitation, had been reduced to 16 in a thousand,—in Dover, once 28 in a thousand, now about 14; Rugby, once 24 in a thousand, now under 12; Croydon, once 23, now 10 to 15; Matlock, once 18, now 9. These figures were

subject to fluctuations above or below. But the working examples of reductions of death-rates by more than a third were sufficiently numerous to warrant the undertaking of the reduction of the death-rate of metropolis by at least one-third.

Dr. B. W. Richardson, in proposing "The Houses of Parliament," coupled with the names of Earl Fortescue and Sir Guyer Hunter, referred in eloquent words to the labours of Earl Fortescue as one of the pioneers of modern sanitary reform.

Lord Fortescue and Sir Guyer Hunter replied,—the former speaker mentioning some interesting reminiscences of sanitary administration forty years ago, and Sir Guyer Hunter referring to the improved and improving sanitary condition of India.

Mr. W. E. H. Lecky, the historian, in an eloquent speech, proposed "The Executive." He said that whatever might be said of the eighteenth century, it could not be said to be distinguished for the prevalence of sanitary knowledge. Sanitary science, as we now understood it, was a thing of later growth, although one great sanitary reformer had appeared before the eighteenth century, and his name was The Great Fire of London, who undoubtedly did good in destroying plague-spots, whatever harm he might have done in addition. The end of the eighteenth century witnessed the work of another great sanitary reformer, John Howard, whose labours amidst the horrors of gaol fever were so remarkable. But it was not until the nineteenth century had dawned that it was seen how much could be done by legislation and voluntary effort to improve the health and to ameliorate the social and moral condition of the people; and when the history of the nineteenth century came to be written, among the many notable figures which the historian would have to trace, one of the most notable would be that of the distinguished founder of modern sanitation, Mr. Edwin Chadwick.

With the toast was coupled the name of Mr. G. B. Jerram, Chairman of the Council, and Mr. S. C. Legg, the Honorary Secretary, who briefly replied, Mr. Jerram mentioning circumstances which gave additional point to Sir Robert Rawlinson's remarks as to the necessity of protecting health officers from unfair treatment because they honestly and fearlessly discharged their duties.

Among the other toasts were "Colonial and Local Government," proposed by Dr. Mouat, of the Local Government Board, who gave an interesting account of what (stimulated by the writings and reports of Mr. Chadwick) he had done to improve the sanitary condition of Fort William more than thirty years ago. The toast was replied to by Sir Saul Samuel and Dr. T. O. Duddield.

## SOCIETY OF ENGINEERS.

The first ordinary meeting for the present year of the members of the Society of Engineers was held on Monday evening, February 7, at the Town-hall, Westminster. The chair was first occupied by the retiring President, Mr. Perry F. Nurse, who presented the premiums of books awarded for papers read during the past year. These were—the Bessemer Premium, to Mr. Percy Tarbutt, for his paper on "Liquid Fuel"; the President's Premium, to Mr. G. B. Jerram, for his paper on "River Pollution caused by Sewage Disposal"; and a Society's Premium to Mr. E. S. Bellasis, for his paper on "The Roorkee Hydraulic Experiments."

The death of Sir Joseph Whitworth, an hon. member of the Society, was announced, and a resolution passed offering to Lady Whitworth the condolence of the Society.

The retiring President then introduced the President for 1887, Professor Henry Robinson, who proceeded to deliver his inaugural address. He dwelt at some length on the essential conditions that had to be observed in preparing and training a young man for the engineering profession. Many youths are sent almost direct from school into workshops; whilst, on the other hand, many pursue their theoretical studies apart from opportunities of observing the practical application of their knowledge. In the former case, the youth may become a skilful mechanic, but will lack breadth of knowledge. In the latter, the youth acquires a higher proficiency in pure science than may be required for actual engineering work, and is wanting in the heaven of practical

knowledge. The brain and the muscles, or the mind and the hands, should work together. He urged the necessity for State aid towards higher technical education which a Royal Commission in 1872 had recommended for the endowment of colleges like King's College and University College, London, and others in great industrial centres. Various other matters were touched upon in the address, which also included a strong expression of opinion as to the necessity for such a modification of existing legislation as would bring the letting or selling of houses under more stringent control as regards health. It was pointed out that it was an offence, by Act of Parliament, to sell food which was unfit for consumption, and which was a danger to health. In like manner it should be made an offence to sell or let a house when in an insanitary condition, it being equally dangerous to health.

At the conclusion of the address, a cordial vote of thanks to Professor Robinson was proposed and unanimously passed.

## ARCHITECTURAL SOCIETIES.

*Leicester Society of Architects.*—The fourteenth annual meeting of this society was held on the 25th ult., when the following officers were appointed:—President, Mr. J. B. Everard; Honorary Secretary, Mr. W. Jackson; Council, Messrs. J. Goddard, R. J. Goodacre, J. Tait, and S. Harrison. On the 2nd inst. the society held a *conversazione* at the County Assembly-rooms, Leicester, which was attended by about 500 guests, including the Mayor of Leicester and members of the Town Council, the presidents and secretaries of several provincial societies of architects. There was a good display of artistic objects lent by Messrs. Wardle, of Leek; Messrs. Trollope & Sons, Mr. Staynes, of Leicester; the Worcester Porcelain Works, Messrs. Minton, Messrs. Copelands, and Messrs. Wedgwoods. The Venice and Murano Glass Company sent two cases containing candelabra, vases, glasses, and other articles. On the wall of the reception-room was a collection of water-colour drawings, the work of Sir Edwin Landseer, George Morland, Sir John Gilbert, Birket Foster, and other well-known artists. Two side rooms were converted, one into an Early English room, and the other into an Oriental room. The English room contained tapestry from Mr. Heaton, of London, furniture, pictures, and other objects. The Oriental room was fitted up by Messrs. Elgood Brothers with drapery, grotesque lamps, Japanese art work, and Persian carpets lent by Messrs. Pare & Arthur and Messrs. Hampton & Sons. On the 3rd inst. the President, Mr. Everard, entertained at luncheon about fifty guests, including visitors, exhibitors, and members of the Society.

*Liverpool Architectural Society.*—The sixth ordinary meeting of the Liverpool Architectural Society, was held at the Society's rooms on Monday, the 7th inst., the President (Mr. S. E. Grayson, F.R.I.B.A.) in the chair. Mr. C. Aldridge called attention to a circular letter, signed by Mr. J. Oldrid Scott and Mr. John P. Seddon, which has been sent round to all the Fellows of the Royal Institute of British Architects, inviting them to sign a memorial to the Liverpool Cathedral Committee. Mr. Aldridge stated that it was easy, reading between the lines of this memorial, to see that it was an attempt to set aside Mr. Christian's very able report, and to reopen the whole question, and pointed out to the meeting that to do this would be a most improper course, as it would entirely weaken confidence in the report of a professional assessor; it was also tantamount to saying that the people of Liverpool, with the assistance of Mr. Christian, were not competent to form a correct opinion as to the suitability of the design for the proposed cathedral. Mr. Aldridge did not know how this memorial would be received by the Liverpool Cathedral Committee, but he had a very strong idea that it would be ordered "to lie on the table." Mr. G. E. Grayson, the President, and Mr. W. Farslow, emphatically endorsed the opinions expressed by Mr. Aldridge, which were evidently approved of by the meeting. Mr. J. H. Cook was congratulated upon having been awarded the Silver Medal of the R.I.B.A. and 10l. 10s. for his measured drawings of Stokesay Castle. Mr. G. H. Morton, jun., read a suggestive paper on "Colour," chiefly in regard to decoration, at the close of which he remarked that harmony of

colour arose from the equal presence of the three primary colours: "the scientific fact that natural solar light caused three principal colour sensations, all of which must be equally excited or the eye got wearied, must not be neglected." In the report sent to us the "primary colours" are not named; we presume, Mr. Morton, that there are differences of opinion on the subject.

*Manchester Architectural Association.*—On Tuesday evening last an interesting paper was read before the members of this Association by Mr. H. E. Stelfox, on the origin and development of wrought iron flooring in France. The paper was illustrated by a number of diagrams showing various kinds of flooring in use in that country. The President of the Association, Mr. L. Booth, F.R.I.B.A., occupied the chair, and at the close of the meeting a hearty vote of thanks was accorded to Mr. Stelfox.

#### DRAWINGS FOR THE ROYAL ACADEMY.

As on former occasions, we shall be glad to photograph beforehand any drawings of importance that are intended for the Architectural Room at the Royal Academy, for ultimate publication in our pages, and to deliver the drawings at the Royal Academy on the day appointed for reception.

In connexion with this subject we may draw attention to the manner in which we are now enabled to reproduce architectural water-colour drawings by the Phototype process, of which an example is given in the perspective view of a design for an Art Museum in the present number. The process is equally available for reproductions from photographs of the actual building, and an example of this method of illustrating contemporary architecture will be found in the plate in our issue of January 22 of this year, showing the "Boston Art Club" and "a Sea-shore Cottage." These are from photographs taken from the buildings, and the reproductions, it will be seen, are as sharp and clear as the photographs themselves.

The Phototype method, under present arrangements, is not available for any other architectural journal.

### Illustrations.

#### DESIGN FOR AN ART MUSEUM FOR GENEVA.

**T**HIS design, which obtained the second premium in a limited competition, is by Herr Alexander Koch, a German architect, formerly of Zurich and now resident in England. We append the plans of the ground-floor and first-floor, or rather (from the way the plan is drawn) of mezzanine and first floor, as the roof of the colonnade seems to be shown on what is described on the plans sent to us as "erdgeschoss." It should be observed that from the rise of the level of the proposed site, from front to back, the first floor has an entrance from the ground level at the back.

The design is a good example of a type of modern architecture much more admired in Germany than in England, and which is, no doubt, open to the charge of being cold and formal in feeling, but it is a dignified and stately design of its kind. It is reproduced by phototype from the author's monochrome drawing.

MESSRS. SAMPSON LOW, MARSTON, SEARLE, & RIVINGTON'S NEW PREMISES, FETTER LANE, FLEET STREET.

We this week give an illustration of a new block of offices and warehouses in course of erection in Fetter-lane, between Fleet-street and the Record Office, for Messrs. Sampson Low, Marston, Searle, & Rivington, the well-known publishers. The premises have a frontage of 80 ft. and a depth of 70 ft. The elevation, which is of Portland stone, and Wilcox's ivory white bricks, will make a considerable improvement in Fetter-lane, as the building occupies a site which has been vacant for some time.

The works are being carried out by Messrs.

UPPER FLOOR.  
1. Vestibule. 2. Galleries. 3. Gallery (committee room &c.).

GROUND FLOOR.  
1. Vestibule. 2. Galleries. 3. Doorkeeper. 4. Porter. 5. Caretaker's rooms.

Plan of Design for School of Art.—A. Koch, Architect.

Patman & Fotheringham, contractors, of Theobald's-road, from the designs and under the superintendence of the architect, Mr. W. Seckham Witherington.

#### DESIGN FOR A PROPOSED PEOPLE'S PALACE,

BY THE LATE E. W. GODWIN AND JOHN P. SEDDON.

The accompanying drawing of a building that was proposed to be built some time since on the Savoy site on the Victoria Embankment in London, now occupied by the Medical Examination Hall, was prepared by the late Mr. E. W. Godwin and Mr. John P. Seddon, as joint architects.

The elevation of the river-side façade, which we now give, was the actual handiwork of Mr. Godwin, and, as such, is an interesting example of this style of drawing, of which he was a master. Its breadth, clearness, and brilliancy speak for themselves, and we can recommend our student readers to study it carefully for those most essential qualities of draughtsmanship. No plan of the building is extant.

The prospectus of the scheme which was issued at the time gives the following particulars with regard to the proposed structure, as "a handsome building to be called the Savoy Palace," upon the site of rather more than half an acre, on the Victoria Embankment, facing the river Thames on the west side of Waterloo Bridge, and belonging to the Duchy of Lancaster. The basement, ground, and first floors were to be devoted to a central hall, gallery, &c., for periodical exhibitions of modern art, manufactures, pictures, &c., and the upper portion of the building for residential chambers and club-rooms, the lowest of which residences would have been on the second floor of the building, level with and approached by a high-level bridge across Savoy-street, through the Duchy House, in Lancaster-place, Strand, for which the necessary permission had been obtained.

#### WARMINSTER CHURCH.

This is an interesting church, retaining, in spite of the incongruous work of the last century, and the destruction of many ancient details, ample evidence of the beauty and fine proportions of the original building.

Early in the last century the whole of the nave was taken down and reconstructed in a bastard Classical style, galleries being erected at the west end, and in the aisles, the walls of which were raised to make room for them. It does not appear that any alteration beyond this was made in the exterior of the church, except that some enormous buttresses were added to strengthen the aisle walls, to receive their additional height and the weight of the galleries. It had long been intended to reseal the building, and make it in other respects better fitted than it can now be said to be for the services of the church. Plans were made ten years ago by Mr. Street for rebuilding and enlarging the nave and aisles, and re-arranging and restoring the eastern part, but they were never carried out, and what is now being done, as well as what is proposed to complete the work, is on different lines, and of entirely different character.

The work now proceeding is the restoration and re-arrangement of the eastern portion.

As to the nave and aisles, Mr. Blomfield reported that as they now stand they are substantial, and in good repair, and with the galleries accommodate a large number of people.

On the other hand, the style of architecture is not only bad of its kind, but is utterly out of harmony with anything in the old parts of the church, while the proportion adopted though in itself lofty and imposing, overpowers the rest of the building, and dwarfs the tower.

He recommended, therefore, that they should either be left precisely as they now stand, without any alteration whatever, or that the nave should be entirely pulled down, leaving only the old aisle walls, and that the nave should be reconstructed on a scale, and in a style indicated by remains which still exist; the necessity of providing seats to make up for those lost in the galleries, being met by adding two bays to the length of the church.

It was decided to adopt the latter of these two alternatives, and Mr. Blomfield's designs were approved.

It is hoped that the reconstruction of the nave may be undertaken as soon as the present work is complete. Mr. W. Strong, of Warminster, is the contractor, and Mr. J. Simpson is clerk of the works.

SKETCHES IN THE ISLE OF WIGHT.

To the architectural student in town the Isle of Wight offers a holiday resort the quietness and beauty of which is refreshing after the bustle and worry of London work. It is full, too, of historic interest; traces of the Romans remain in the villas at Carishrooke and at Morton, and there are good examples of different periods scattered about. The sketch of Carishrooke village is taken from the slopes leading to the ruins of the celebrated old castle,—with which Celts, Saxons, Romans, and Normans may all have had something to do. It is a pity that the place is not better preserved; for instance, that portion of the building which had in all likelihood been used as a great hall by the Lord of the Island (perhaps Baldwin de Redvers, 1135) is cut in two horizontally, the lower portion being occupied as a store-room for the militia. The outer walls and gateway were built in the reign of Elizabeth, the letters "E. R. 1598" are cut on the outer gateway. The moat has long been dry, and the portcullis gone, but the original wooden gates remain, although much patched up.

Carishrooke Church, said to be founded 1064, has been partially restored; it is beautifully situated, surrounded by a fine old churchyard, adjoining the "Priory Farm House," the site of the priory attached to the old church. There are a few monuments and a pulpit, dated 1628. The tower contains eight bells. There is some fine bold carving on the pinnacles, and the view from the tower is magnificent. There are some curious stones in the churchyard: a slab over the grave of a farrier has the following lines:—

"My sledge and hammer lie reclined,  
My bellows, too, have lost their wind;  
My fire's extinct, my forge decay'd,  
My vice all in the dust is laid;  
My coal is spent, my iron gone,  
My last nail's driven, my work is done."

A long time ago some one caused to be planted over his grave, in this place, a tree instead of a tombstone; its spreading branches form an excellent shade, and is certainly a much more beautiful object than many of the monuments we meet with.

Godshill Church is situated on the top of a hill overlooking the beautiful village of the same name. The view from the churchyard is well worth the trouble of walking to see it. The church is of Norman origin, and is cruciform on plan: note on the gable of the south transept the old Sanctus Bell. There are some fine monuments in this church, and a picture is pointed out as the original "Daniel in the Lions' Den," by Rubens. It was purchased by Sir Richard Worsley about 100 years ago for 1,500*l.*, and presented to the church. There is a legend current to the effect that the site of this church was originally selected at the bottom of the hill, but as all the walls and materials built and used in the day-time were promptly moved in the night by supernatural beings to the top of the hill, the builders, to save themselves any more bother, were at last glad to commence operations where indicated.

Arreton Church. The sketch shows the porch noticed by the Rev. Legh Richmond, in his "Dairyman's Daughter." He writes:—"Looking upwards as I drew near the porch, I observed a dial on the wall. The sun's declining rays directed the shadow to the evening hour. As I passed underneath this simple but solemn monitor, I was reminded of the lapse of time, the uncertainty of life, and the sure approach of eternity." The tower has four bells, about 200 years old. The chancel was restored in 1863.

J. ELSLEY INGLIS.

FAIRFAX HOUSE, PUTNEY.

We give a sketch and some details of this interesting old house, long a conspicuous object in the High-street of Putney, and which we greatly regret is to be demolished shortly.

**Ingram House.**—Mr. Blashill writes to say that the stone used in this building, illustrated by us a fortnight ago, should have been described as "Red Corsehill," not "Dumfriess," which does not particularise the stone, though Corsehill is in Dumfriesshire.

Fairfax House.

Fairfax House.—Details of Staircase.

ARCHITECTURAL ASSOCIATION.  
DISCUSSION ON "HOUSE SANITATION."

The eighth meeting of this Association for the present session was held on the 4th inst. at 9, Conduit-street, Mr. J. A. Gotch (President) in the chair.

The following new members were elected, viz., Messrs. H. Somerfield, W. Taylor, and M. F. Cavanagh.

The President.—Gentlemen, I think we shall all feel that it is a matter for congratulation that one of our oldest members, Mr. Thomas Blashill, has been elected Superintending Architect to the Metropolitan Board of Works (applause).

It was announced from the chair that the Coates Prize had been awarded to Mr. Grainger, of Nottingham.

The meeting then proceeded to the discussion of the lecture on House Sanitation,\* given at the previous meeting by Professor Corfield, who was unable to attend on the present occasion.

Mr. John Slater, B.A., said that the subject was such a large one, and contained in itself so many points deserving of attention, that when he was asked to open the discussion, he rather rashly concluded he would find a number of matters that had been omitted by Professor Corfield. On reading the report of his lecture he found, on the contrary, that the subject had been exhaustively dealt with, and he was then rather sorry that he had consented to open the discussion. Perhaps the newest discovery made of late years, with regard to traps, was as to the way in which they got misapplied. He believed Mr. Hellyer was almost the first to make experiments showing how this occurred, and to detail it at considerable length in the last edition of his book on plumbing. Professor Corfield had not attempted to explain how the unwhomping took place. It did so in two ways, either by absolute momentum through the rush of water itself, carrying the whole of the contents of the trap right away down the pipe; the other way being when the trap was connected by a branch with another down-pipe. If a considerable quantity of water filled the main soil pipe, it created a partial vacuum in the branch pipe, during the continuance of which the pressure of the atmosphere on the top point of the trap became greater than the pressure on the other side, forcing some of the water in the trap down the branch into the main duct. This was the reason why it was so important to ventilate traps and branch-pipes as well as soil-pipes. With regard to water-closets, his own experience was not so strongly against what were termed the "wash-out" closets, as that of Professor Corfield; but everything depended, with a wash-out closet, upon there being a thoroughly good supply of water. He quite agreed that a good valve-closet was the best form of closet that could be employed anywhere, but it was a very much more expensive form than the wash-out closet, and he would prefer to have a good wash-out closet with a sufficient head of water even to the best form of "improved hopper." There was no doubt that the regulations of some of the water companies of London and elsewhere, as to the size of the feeding cisterns to water-closets, were very ridiculous, two gallons being quite insufficient to give a good flush. If flush-out closets were used, care should be taken that the water went in directly opposite the out-go, and not obliquely. At one time it seemed to be the fashion for builders of houses to advertise the position of the water-closets by wretched little windows; while if there was a place where light and air was wanted, it was the water-closet. The windows should always be large, and where plenty of room existed, it was well to have a small cross-ventilated lobby between the water-closet and other parts of the house. He always had the water-closet seat made without a flap, with the seat itself hinged, so that if anything went wrong with the apparatus, the seat could be lifted at once. In small houses, too, where a housemaid's slop-sink was not provided, it was well to have the hinged seat raised before the slops were thrown down. With respect to the sanitary condition of houses, in many cases where smells were observable in an upper room, the fault lay not with the plumber, but rather with the plasterer. The partition between the water-closet and a bedroom would often be found to be of lath and plaster, sometimes not even carried beneath

the skirting. As a rule, the water-closet was colder than the other rooms of the dwelling, and it was, therefore, necessary to have the plaster carried down to the sill of the partition, so as to prevent bad smells from finding their way into the rooms. He hoped the time had gone by for any of them to allow such abominations as the D-trap to be used. It was often difficult to apply the proper remedies for putting old houses into a sanitary condition, but one thing at least should be attempted. If a water-closet was found in a situation which rendered it difficult to be made sanitary, some other place should be found for it which would always be better than bringing air-ducts into all sorts of places. Everybody knew that it was very much better that the drain-pipes should not go under the basement of a house, but in London terrace-houses it was next to impossible to avoid this. He would not go into the vexed question of earthenware versus iron pipes, but he believed by a little re-adjustment of the plan of a terrace the necessity for carrying pipes under the basements might be obviated. He was alluding to what were called joint-drains for several houses. If the drainage was put down in such a manner that the stoppage of one drain might close a number, it would not do; but by having inspection-chambers at the junction of each house-drain, with what might be called a supplementary drain running along the backs, with an inspection-chamber at the junction, it would be an easy matter to clear them. It was necessary to look to the testing of the drains, for no one who had not had experience of the extraordinary things builders and their workmen were in the habit of doing, would believe what monstrosities could be perpetrated by the plumber, the bricklayer, and all sorts of people; and they must not even expect to have things done correctly by the man who styled himself a "Sanitary Engineer." He had not a word to say against many of the sanitarians, but the mere fact of a lot of plumbers dubbing themselves "Sanitary Engineers" would not mend matters much. Good drainage was not the one thing to make a house sanitary, for stuffy rooms would make a dwelling unhealthy. The great desideratum was to provide an amount of ventilation which would not cause draughts, and that was a difficult thing to do. Tobin's tubes and all sorts of contrivances would not always do it, and the best way was really to introduce fresh air through the stove, especially in the winter-time. A house, too, could never be sanitary unless care was taken to have an impermeable stratum of concrete, or something of the sort, in the basement, otherwise the atmosphere of the house being warmer than the outer air would draw up the foul air from the soil beneath. With regard to the whole subject of sanitation it might be said that if people cared to spend the money they could have perfectly sanitary houses. The great difficulty was with the small houses of London and other towns, and until the Legislature, therefore, took up the question and made it a punishable offence to build a lot of houses that were mere fever-traps very little that architects could do would be of any avail.

Mr. W. Scott Moncrieff remarked that Professor Corfield was such an able authority upon this subject, that he would have been somewhat diffident in acting the part of a critic, had not reference been made to one or two matters in which he had special experience, and as to which he was somewhat inclined to differ with the Professor. No exception could be taken to his general remarks on the subject of sanitation. On the subject of water-closets, however, the Professor had approached a subject capable of more discussion, because the immediate disposal of fecal matter was one on which a great deal of ingenuity had been expended. As to the vexed question of water-closets, he was much inclined to agree with Professor Corfield and Mr. Slater that, after all, the somewhat complicated but really complete apparatus known as the valve-closet was the best that could be used for all situations. If there was any objection as to its liability to get out of order, that could be got over by making it all the stronger. One of the defects of the valve-closet,—and it had several, which would not be tolerated in the practice of the ordinary mechanical engineer,—was the absence of a gland and stuffing-box, so that the apparatus had practically been found fault with, not because there was any inherent objection to it, but because the connexion of the valve spindle

was defective. Turning to the question of iron versus stoneware pipes for drainage, he could not endorse Professor Corfield's condemnation of iron pipes. On the contrary, he believed that cast-iron would ultimately be found to be the only material available for meeting the tests which in future the public and sanitarians would demand in a modern system of house-drainage. There was a general feeling in favour of earthenware pipes because the surface was clear, because the material *per se* was durable in itself, and it was not subject to be acted upon by oxidation. That might be the case, but the important question was,—Which of the two materials, cast iron or earthenware, was the better, all things being taken into consideration? The glaze of earthenware was sufficient of itself to hide defects in the pipes, and it not infrequently happened that a pipe made by the best makers gave way under a slight collision or pressure, revealing the fact that the pipe was really not homogeneous, but practically dependent on the glaze for its existence at all. In the laying of cast-iron drains his experience was that sewage had the effect of preventing any oxidation whatever, a slightly greasy coating, similar to that found in stoneware pipes remaining on the inner surface of the pipe, so that after a time the same sort of action ensued in both kinds of pipes. This action was quite positive as regards oxidation, and he had been unable to find in an ordinary house-drain any oxidation from the inside outwards. As regards oxidation from the outside inwards, the engineer should be guided by the experience of the water companies; in laying their pipes in a very wet clay soil, and especially if any oxide of iron was present there would be a somewhat rapid decay from the outside of the pipe inwards. That would approach the point of destructive corrosion, and should be avoided by having the pipe laid in cement concrete or by some other means, as there were several ways of protecting a pipe besides Dr. Angus Smith's composition. But when they came to the question of testing drains the cast-iron pipe had really got it all its own way. If a pressure of 10 lb. on the square inch was generally applied to the man-hole covers as well as to the drains themselves, as it very well could be, what an important effect it would have on the health of the community! It would mean, in fact, that all defective drainage would be done away with at a single blow. Now that the water test had come in he believed that in a short time something of the sort would be generally demanded, and if it were applied to the drains themselves he failed to see why it should not also be applied to the manholes and the manhole covers. He looked to the wholesale introduction of some system in which the test demanded would be enormously greater than those in use at present in order to overcome the weak points in our sanitary system.

Mr. S. Stevens Hellyer said that notwithstanding all that had been done to bring home to the London household the importance of putting his drains in order, only a few houses here and there had been properly sanitized, and the amount of sewage which could be found today in pan-closets, traps, soil-pipes, drains, and cesspools in the houses of the metropolis would be sufficient to fill a 9-in. pipe drain from London to Cologne, that home of scents. Eighteen loads of sewage had been taken out of only one house last week by his workmen, where it had been accumulating for half a century, and he thought they would agree with him, now that all kinds of domestic matters were being aired in public, the metropolis ought not to be averted with the excreta of centuries. It would be possible to so reconstruct the plumbing, drainage, and sewerage of London that not a vestige of sewage matter would be found within its area twenty-four hours after it had been excreted. A house to be properly sanitized ought to rid itself of anything and everything passed into its water-closets, sinks, &c., within the space of ten minutes, while every foot of its drains, soil and waste pipes should have its air changed at least every hour. Mr. Hellyer here showed an experiment demonstrating the non-advisability of employing traps of too large a diameter. Good sanitation, he contended, depended upon water, and that ran through the whole scale of plumbing and drainage. He also exhibited a piece of 3-in. soil-pipe, cut out of a stack into which three closets discharged, and which closets had been used six days in the week for six years, by a large number of clerks

\* See *Builder*, p. 1395, ante.

and workmen, averaging about eighty, and which was yet perfectly clean and uncorroded on its inner face. But, however, good the plumbing-work and fittings, if the supply of water was limited, unwholesome water-closets would be the result. It was quite possible to do the plumbing and drainage work of a house in such a way as not to find in the whole system, after a use of five years, sufficient unpleasant matter to cover a half-crown piece. He agreed with what Mr. Scott Moncrieff had said about the valve-closet, in which there was not only a large area of water, as in the wash-out closet, but also a great depth of water. As to cowl, he was quite content with open pipes, under certain conditions, but he liked the wire top to be made of a balloon shape. At the same time, when the air from a down-draught in such pipes would be likely to enter the house through the doors or windows, he would prefer to employ a cowl to reduce the blow-down as much as possible. With regard to the question of iron *versus* stoneware pipes, the great point, in his opinion, was the reliability of the men who were employed to put in the drains. If he could depend on the bricklayer, he would be quite content with an earthenware drain. And here he would say that he thought that a bricklayer who did drainwork ought to be registered as well as the plumber. As to the alleged liability of iron drain-pipes to oxidation he had lately examined one which had been properly coated with Dr. Angus Smith's solution. On opening this drain and inserting a scrubbing-brush a little slime was washed out, but otherwise it appeared to be as good as when laid down five years ago. With a grease-trap for the scullery sink and three gallons of water to flush a good form of water-closet, and with other good sanitary appliances, properly-laid drains would keep free from stoppage, and would be as wholesome ten or fifteen years afterwards as they were after the first three months' usage.

Mr. W. Lee Beardmore, C.E., next made some observations, but his views on the subject will be found in the report, which we give on another page, of his lecture last week before the members of the Civil and Mechanical Engineers' Society.

Mr. E. C. Robins proposed a vote of thanks to the specialists who had kindly lent drawings and specimens to illustrate the subject. He had not had the pleasure of hearing Prof. Corfield's lecture, but had read with much interest the report of it which had appeared in the *Builder*, and which had given him a clear idea of what had been said. The question of siphonage had been dealt with exhaustively by Dr. Reuk, of Munich, in a series of experiments, the results of which he (the speaker) had given in a paper read before the Sanitary Institute. He had not used iron pipes for drainage because the ordinary workmen were not accustomed to that kind of work, but he never laid pipe drains through houses without seeing that they were buried in cement concrete. He never permitted a drain to be closed up without its being tested, and, as young men, they could not do better than look after these matters personally, as the word of the builder or of his workmen, or even of the clerk of works, was not sufficient, curious examples of which he gave.

Mr. John Smeaton remarked that he could not quite agree with the note of the Editor of the *Builder* appended to Prof. Corfield's lecture. As a sanitarian, he (the speaker) considered the wash-out closet one of the worst that had been invented. The bottoms of such closets got foul in course of time, and the apparatus became coated with deposit.\* The best kind of closet, to his mind, was a good valve or hopper closet, but in order to prevent the possibility of leakage of the water in the basin, the joint of the latter should be up almost as high as the top of the out-go of the trap.

Mr. Leonard Stokes seconded the vote of thanks moved by Mr. Robins, which was passed, and the meeting separated.

**Surveyors' District Map.**—It has come to our knowledge that there are one or two slight "errors of omission" in the map we recently issued. Those of our subscribers who intend to preserve it should send the sheets to the Publisher, who will have them corrected, as has already been done with those sent to him for mounting.

\* We can only repeat that this is contrary to our experience, provided that there is a sufficient flush of water, properly applied.—E.S.

THE WELSCHACH INCANDESCENT GAS LIGHT.

We give an illustration of this light, which produces, by the agency of gas, a steady white light of great brilliancy in proportion to the amount of gas burned. The system, the invention of Dr. Carl Auer von Welschach, of Vienna, consists in placing within the flame of a special form of atmospheric or Bunsen burner a mantle or hood of cotton net or webbing which has been previously steeped in a solution containing oxides of the elements Zirconium, Lanthanum, and some other bodies. The moment that a prepared mantle is ignited it burns away with the smoky flame characteristic of burning cotton, but it leaves behind it a residual skeleton composed of the incombustible oxides contained in the impregnating solution, and this skeleton, while preserving its woven or reticulated character, becomes, under the influence of the Bunsen flame, powerfully incandescent, and emits a purely white and intensely brilliant light, so closely resembling that of

incandescence electric lamps as to be easily mistaken for it. It is, however, rather whiter than the incandescence electric light. The mantles so employed last from 800 to 2,000 hours, according to the situations in which they are placed, and they can be renewed at a small cost. The patentees claim that while a standard Argand gas-burner as certified by the Board of Trade, and consuming 5 ft. of gas per hour, gives an illumination equal to sixteen standard candles, or 32 candles per cubic foot of gas per hour, the Welschach burner produces a purer light (with less heat and no smoke) of twenty candles, with 2½ ft. of gas per hour, showing an efficiency of eight candles per cubic foot of gas consumed. The Welschach lamps can be screwed on to all the ordinary gas fittings, and require no special apparatus for varying the pressure or the quality of the gas, and, as the gas consumed is employed solely to heat the light-giving mantle, it need possess no illuminating property in itself, and therefore gas of poor illuminating quality may with advantage be employed under

the Welschach system, and with a corresponding saving of cost. We give the figures as to relative cost on the authority of the Company. The light itself we have examined carefully, and consider it a most efficient and agreeable form of artificial light.

CASE UNDER THE METROPOLIS LOCAL MANAGEMENT ACT.

At the Woolwich Police Court, before Mr. Marsham, George Viney, of 13, Keenwood-street, Woolwich, builder, was summoned by the Metropolitan Board of Works for that he did, at Graydon-street, in the parish of Plumstead, unlawfully form and lay out a certain road, passage, or way for building, as a street of a less width than 40 ft., contrary to 18 and 19 Vic., cap. 120; and 25 and 26 Vic., c. 102, and by-law.

Mr. Thomas Burton, solicitor, appeared for the Board; and the defendant appeared in person.

Mr. Burton, in opening the case, stated that the defendant had erected several houses in the above street, and by so doing he had reduced the width to 25 ft. 9 in. He had been repeatedly cautioned by the district surveyor that he was not complying with the law, but he had persisted in going on, and the buildings were now finished and occupied.

Mr. Millwood, surveyor, and Mr. Conder, district surveyor, having been called in support of the above facts, Mr. Marsham said he should fine the defendant 40s. and costs.

LIGHT AND AIR CASE.

CARTER v. SPICER.

In the Queen's Bench Division, before the Lord Chief Justice and a special jury, Dr. Geo. Roe Carter, the lessee and occupier of No. 119, Anerley-road, Norwood, sued John Spicer, the owner of the fee simple of premises adjoining, to obtain an injunction restraining the defendant from proceeding with building operations, which the plaintiff contended obstructed certain ancient lights in his house; also for an order compelling the defendant to remove the shop already erected to such an extent as was necessary to secure to the plaintiff the enjoyment of his ancient lights; and for damages in respect thereof.

The defendant denied that the lights in question were ancient, and contended that his new erection had in no way interfered with the access of light to the plaintiff's premises. The walls of the two shops in question were originally 14 ft. high, but proceedings were taken by the Metropolitan Board of Works, under 25 and 26 Vic., cap. 102, sec. 75, and they were reduced to within a height of 6 ft. from the ground.

Mr. Finlay, Q.C., and Mr. Colt appeared for the plaintiff; and Sir Henry James, Q.C., Mr. Murphy, Q.C., and Mr. Upjohn represented the defendant.

The Plaintiff stated he was the lessee of the house in question for a term of twenty-one years, seven years of which had to run, and complained that the light in his drawing and dining rooms has been obstructed, which seriously interfered with the enjoyment of those rooms. The defendant's case was that there had been no sensible diminution of light in the room. It appeared that the premises with which the defendant was dealing were originally private houses, but were now converted into shops, one of which had been opened for some time as an ironmonger's. An interim injunction had been obtained in the Chancery Division, pending the trial of this action, which was proceeded with in this division in order that it might be taken before a jury.

The plaintiff's case having been concluded, Mr. Murphy addressed the Court on behalf of the defendant, and at the end of his speech the jury stopped the case, stating that the plaintiff had not made out his case.

His Lordship gave judgment for the defendant, with costs, and certified for a special jury, and the expenses of a view.

**Rosemount School, Aberdeen.**—This large new public school, erected by the Aberdeen School Board for mixed pupils, on a site at the corner of Esslemont-avenue and Rosemount-place, is to be opened for scholars on Monday next, February 14. The buildings, which are from designs by Mr. James Souttar, A.R.I.B.A., accommodate 860 children, and have cost 7,500l. The external walls are of white Aberdeenshire granite, except the rustic portions at the base, which are of dark blue granite. The main features of the erection (which is to be followed as a model for future new schools) are its square formation, the various class-rooms, &c., surrounding a central hall and staircase; the mechanical process of ventilation; and the piazzas obtained as covered recreation places on the south side of the buildings by the declivity of the site. The open playgrounds are in some parts concreted and in others gravelled, so as to allow of football being played.

## LIVERPOOL CATHEDRAL MEMORIAL.

SIR.—At the suggestion of the Committee on Competitions of the Royal Institute of British Architects, the proposed memorial, which has received about 300 signatures, will be modified, and will be in the following form:—

"To the Liverpool Cathedral Committee.

"We, the undersigned, as architects, considering the national importance of this great undertaking, upon which much depends affecting the future of church architecture throughout the kingdom, venture to request that you will allow the designs to be exhibited in London."

Should any architect who has already signed the memorial object to this modification, or should any others desire to have their names added to it, they are requested to communicate with us.

31, Spring gardens, S. W. J. OLDRID SCOTT.  
1, Queen Anne's gate, S. W. J. P. SEDDON.  
February 10th, 1887.

SIR.—I should like to be allowed to say a few words upon the letter from Messrs. Scott & Seddon, referred to so properly in your last.

Some time back I declined to sign the circular from the "Competitions Special Committee," pledging me to the principle of an architectural assessor; and I did so on this ground, namely, that, though fully sympathising with the idea, I felt that in the absence of any provision to ensure, as far as possible, that the assessor should be a man of broad views, the remedy might easily be worse than the disease; and I said that, personally, I would rather trust myself to a committee than to a man of one style,—a sort of architectural Cyclops, if I might so designate him without offence,—who could see no good existing in one direction.

If the letter above referred to does not fully justify my objection, I am at a loss to know what would.

No. 2, Arundel-square.

GEORGE McDONELL.

## FIRE STATION, TOTENHAM LANE, HORNSEY.

SIR.—As some of my friends have written regretting that the plans of this Fire Station were not illustrated last week with the elevation, I should like to explain that the ground-floor is an open space wholly devoted to the engines and fire-extinguishing gear, the first and second stories being used for residential purposes.

The only feature of interest on the plan is the automatic system of opening the large circular-headed folding-doors, to which the arrangement designed by Mr. J. Sexton Simonds, the second officer of the Metropolitan Fire Brigade, was applied, and is found to answer admirably.

T. DE COURCY MEADE.

\* \* \* We are asked to state that the glazed bricks used for the masonry buildings were made by Messrs. Edward Brooke & Sons, of Fieldhouse Works, Huddersfield.

## "MASONS' WAGES."

SIR.—As a mason who has worked in London many years, both as a foreman and at the banker, I was somewhat startled when I read the letter from a brother chip which you inserted in last week's issue of your journal.

I have not a word to say about the orthography or composition of the letter as a literary production, but I am surprised at your correspondent's want of information respecting the amount of wages paid to masons and other workmen on Government works in the Metropolis. It does not matter who the contractor for the work may be, it is their general rule to employ those only who are willing to take considerably less than the current rate of wages. At the Houses of Parliament there are or were a few masons who get the full rate of 3s. per hour, but the men required for this work have to be highly skilled workmen; hence an exception is made there to the general rule.

W. T. KEMP.

SIR.—Permit me, through your paper, to request the members of the London Lodges Committee (your correspondent, A. Robins, being secretary) to seek to bring about a better feeling between the employer and the employed, rather than try to create trouble with Government officials and Messrs. Perry & Co.

It is a well-known fact that many of the employers of masons have not, for some time past, paid a fixed rate of wages, but have paid their men according to merit; therefore the attack on Messrs. Perry & Co. at the present time is unjust.

If the members of the above-named committee (backed up, no doubt, by the members of their Society) have the interests of their fellow-masons at heart, they would be much better employed in trying to induce the master-builders of London to cease having stone worked at the quarries. I know of cases where builders have taken contracts, and then sub-letting the masonry to a sub-contracting mason, and the latter has again let it to be worked at the quarries. This is manifestly unfair to the masons of London.

If questions of this kind were fairly laid before the employers, I am satisfied it would bring better results than creating strife about wages.

G. C. W.

## The Student's Column.

## FIELD WORK AND INSTRUMENTS.—VII.

## Surveying Instruments.

## VII.—THE CLINOMETER (continued).

THE form of clinometer most generally used is that known as the clinometer rule, which consists of two flat arms hinged together at the centre in a manner about to be described, and fixed so as to open and fold like an ordinary foot-rule, the arms being made broad enough to contain certain tables, which are referred to in our diagram as tables A, B, and C. One of these tables is placed upon the front face and the other two upon the back of the rule. They are intended for use in the application of the instrument to vertical and horizontal measurements. Upon the edges of the rule, inches are also marked subdivided into eighths and tenths.

When the instrument is open it is seen that the head of the rule consists of two metal sliding pieces jointed, so as to turn accurately on the centre D. Each of these sliding pieces has a scale engraved upon it, both scales being, as shown in our illustration, on the same side of the rule, and placed so that when the instrument is closed, the arrow marked A upon the inner scale points to zero upon the outer scale, and the arrow marked B upon the outer scale points to zero upon the inner scale. One of these scales expresses the angular amount of opening between the arms in terms of the degrees of a quadrant, while the other scale registers the inclination as a rise or fall of a certain number of inches per yard run of horizontal distance. Spirit levels are also fixed in the edges of each arm, enabling the observer to place either arm horizontal when using the instrument in a vertical direction. To the inner side of one arm upon the same edge as one of the spirit levels is attached an ordinary magnetic compass, contained in a box, which is constructed to turn to a horizontal plane when observations are being made vertically, and to fold back into recesses marked E and F when the instrument is closed. The needle is set free to revolve by a small stop-lever fitted into the side of the compass-box, and should always be lifted off its centre when not in use. To each end of the other arm of the rule are attached eight-vanes, consisting of metal plate, hinged so as to fold down flush upon its edge when they are not in use, as indicated by the curved dotted lines in the diagram. Each eight-vane has a small circular hole drilled at G, and a larger circular opening at H. The openings at H each contain a glass disc, upon which lines crossed at right angles accurately mark the centre, and guide the eye both vertically and in a direction parallel to the edge of the rule.

When raised, they serve as sights to view objects situated either above or below the level of the eye, in the manner explained by the direction of the arrows upon the diagram, marked as lines of sights when looking up or looking down. These lines of sight are parallel to one another and to the face of the rule, but are not co-incident, as it will be observed upon reference to the end view marked K that the hole at G is not in the centre of the plate. This is because the two eight-vanes are not of the same width: that at the end of the rule being as wide as the edge of the rule, while that at the head of the rule is reduced by the thickness of the outside sliding plate. In each eight-vane the small hole G serves as an eye-piece, and the diaphragm H gives the direction of sight when viewed from the opposite eight-vane: hence the positions of G and H are alternate, by being above H in the one, and below H in the other vane. With the use of the instrument vertically we are enabled approximately to measure heights by the application of table A, while horizontal distances for certain angles of elevation or depression up to 45 degrees can be calculated by the application of Table C. With the use of the instrument horizontally, lateral distances can be approximately ascertained by the application of table B, and with the aid of the compass set parallel to the face of the rule the relative bearing of two defined distant points may be taken. The tables marked A, B, and C depend upon the

fact that when either the base or perpendicular of any right-angled triangle is known, and one of the remaining angles of that triangle can be measured, then the unknown length of either the perpendicular or base can be mathematically obtained. When using the instrument vertically the spirit bubble upon the inner edge of the lower arm is first set by the hand, and then maintained in as level a position as possible. The eight-vanes are raised and the upper arm lifted, until the cross line at H, when viewed at G in the opposite eight-vane, is either at the top of the object to be observed, or until it bisects any point upon that object which can be sufficiently localised to make a calculation reliable.

Then the arrow-head upon each one of the metal sliding pieces marked A and B respectively, will point to the angle and inclination to be read off the other sliding piece. As an example, suppose from a tower 120 ft. high that you can see an object through the sights when one scale reads 26°, and the other scale 18 in. per yard, with the instrument set as shown in the diagram; the upper arm then bears an inclination to the lower arm of the rule equal to a rise of 1 in 2, so that in this case the base would be about double the perpendicular height, and the object is found to be approximately 240 ft. distant. An inclination of 1 in 2 is more accurately expressed by an angle of 26° 34', but the instrument only registers degrees. Referring to table C, an amount of 2'05 is given as the amount of run horizontal per unit of vertical measurement for an angle of elevation or depression equal to 26°.

Applying this ratio to the case under consideration, we find 2'05 × 120 = 246 ft. to be the distance of the tower from the object observed. Next, so as to compare the use of table A with table C, let us suppose the angle observed to be 30° and the tower to be at a horizontal distance of 100 units of length from the given object, we find upon applying the figures given in table A that the height of the tower would be 57.7 units of length; then if the height of the tower be known to be 57.7 units of length, and the distance of the tower from the object viewed be required, we find upon applying the figures given in Table C opposite 30° that the horizontal distance would equal 57.7 × 1.73 = 99.82, or practically 100 units of lengths, as was assumed when applying Table A. If the angle observed be 45° then the height of the tower and the distance of the object from the tower are seen upon reference to Tables A and C to be equal to one another. By the use of Table B lateral or transverse distances can be arrived at when the instrument is held with its face horizontal. When so placed the sights are arranged to be in a line with one extreme, say the left hand of the object, and the arm containing the sights is kept turned towards this point while the other arm is moved out horizontally under its edge in a line with the right hand of the object, the head of the rule being placed as near as possible by the eye opposite the centre of the distance to be calculated, after the shortest or perpendicular distance between this point and the surveyor has been measured. The result gives the transverse thickness of an object parallel to the line LN and perpendicular to the direction of DM produced. If the angle LDN be 45° and the arms DL and DN measure each 6 inches, DM will, upon plotting these lengths and directions to a large scale, be found to measure 5.54 inches and LM 2.29 inches. If DM be produced so as to measure 100 units of length, then a line parallel to LN, subtending an angle of 45° at the head of the rule, gives 100 multiplied by 2.29, multiplied by 2, (because LN = 2LM), and, divided by 5.54, as the number of

units of length required, i.e.,  $100 \times \frac{2.29 \times 2}{5.54} =$

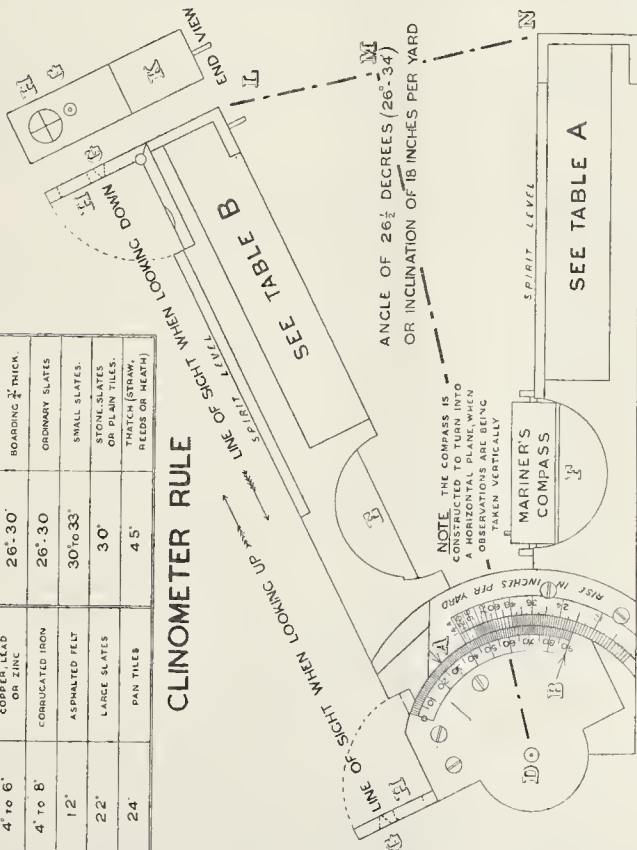

$\frac{45800}{5.54} = 82.8$ , as stated in Table B. From this

we can determine the transverse or lateral dimension at any greater horizontal distance. An object 100 ft. from an observer, subtending an angle of 45°, would be 4 × 82.8 = 331.2 ft. in width.

Independent of the tables the rough inclination of mountain slopes and the dip of strata in a shaft may be determined by the clinometer. The instrument can also be used for setting out the pitch of roofs or to check their inclinations according to the table given in the left hand at the top of our diagram. Having laid the under edge of the lower arm upon the slope to be measured, the upper arm is raised vertically

| PITCH OF ROOFS                                      |                                                     |
|-----------------------------------------------------|-----------------------------------------------------|
| MINIMUM INCLINATION OF SLOPE OF ROOF TO THE HORIZON | MINIMUM INCLINATION OF SLOPE OF ROOF TO THE HORIZON |
| 4° to 6'                                            | 26° 30'                                             |
| 4' to 8'                                            | 26° 30'                                             |
| 12'                                                 | 30° to 33'                                          |
| 22'                                                 | 30°                                                 |
| 24'                                                 | 45°                                                 |

TABLE B

**NOTE** SCALES OF INCHES DIVIDED IN EIGHTHS AND TENTHS, ARE ALSO MARKED UPON THE EDGES OF THE CLINOMETER RULE.

**TABLE A** GIVES THE DEPARTURE FROM THE HORIZONTAL, EQUAL TO THE AMOUNT OF RISE OR FALL PER 100 OF RUN HORIZONTAL FOR CERTAIN ANGLES UP TO 85° WHEN THE INSTRUMENT IS USED VERTICALLY AS IN THE FIGURE.

**TABLE B** GIVES THE TRANSVERSE THICKNESS OF AN OBJECT, MEASURED PERPENDICULAR TO THE LINE JOINING THE EYE WITH THE CENTRE OF THE OBJECT, WHEN THE NEAREST DISTANCE OF THE OBJECT IS 100. — BY PLACING THE FACE OF THE INSTRUMENT HORIZONTAL, & THE FACE OF THE COMPASS PARALLEL TO IT, THE RELATIVE BEARINGS AS WELL AS THE DISTANCE BETWEEN TWO OBJECTS CAN BE OBTAINED.

**TABLE C** SHOWS CERTAIN ANGLES OF ELEVATION OR DEPRESSION, WHICH GIVE UNITY OF VERTICAL MEASUREMENT PER AMOUNT OF RUN HORIZONTAL.

until the bubble of the spirit level on its top edge appears in the centre of its run. The angle or inclination of the slope required is then found to be registered upon the scales at the head of the instrument.

### Books.

*Safe Railway Working: A Treatise on Railway Accidents, their Cause and Prevention.* By CLEMENT E. STRETTON. London: Crosby Lockwood & Co. 1887.

THOSE of the large public of railway travellers who wish to enlighten their generally deplorable ignorance in regard to the working of the railway system on which they travel, and the means which are taken to guard against accident, have now a favourable opportunity of doing so by the publication of this small and inexpensive book, by a competent professional man, and written and illustrated in such a manner as to be intelligible to non-professional readers. The making of railway roads, the system of signalling, the various forms of brakes, the new inventions for automatic coupling, &c., are gone into and illustrated by numerous diagrams, and with as little of technical phraseology as possible. Those who wish to acquire a little general and reliable knowledge on a subject which ought to be of some practical interest to most of us, cannot do better than purchase Mr. Stretton's book. It is a matter of constant surprise to us that the public generally can allow themselves to remain so ignorant of everything in connexion with the working of our great travelling system as they commonly are. If they took a little trouble to understand what was being done on a railway, they would not only find it a subject of considerable interest, but they would be saved some of the nervousness which many ignorant travellers allow themselves to give way to at any derangement of the traffic, without having the slightest knowledge as to whether there is ground for any apprehension beyond that of a delay.

Those who inquired into the system would probably find their respect for railway companies a good deal increased. They would have their eyes opened to the nature of the complicated precautionary machinery which is in daily and hourly operation to provide for their safety. It must be added, *per contra*, that Mr. Stretton's book takes note of some anomalies in the signal system which ought to be done away with as soon as possible. We are surprised to find, according to Mr. Stretton's statement, that the system of signalling by lights is still not uniform on all the railways; that a white light on the Great Northern is "danger," while on other lines it is "all right"; that a green light, originally employed as "caution," is in some quarters employed merely to indicate the back of a signal-lamp; that on some railways a purple light is "all-right," and on others it is a "danger" light. There must be a very limited employment of the purple light; we never remember to have seen one. The most serious item in this indictment is that a great railway like the Great Northern should read its lights the opposite way to that almost universal on other railways, on all of which, as far as we know, a white light is "all-right." Considering the number and increasing frequency of junctions of communication between different railway systems, and the running of the trains of one company over the lines of another, it seems a most imperative matter that the same colour signals should be universally adopted, instead of giving the driver the additional chance of mistakes by his having to read a light for one meaning on one line of railway and for another meaning on another line. A Bill ought to be brought forward without delay for compelling the adoption of one system over the whole country. If this were done, it would be a question whether the red light had not better give way to some other light, say purple, for "danger." It is curious that red and green should have been originally selected on our railways for "danger" and "caution," these being the two colours in regard to which there is more colour-blindness than in regard to any other two. At present, as Mr. Stretton observes, "caution" signals are practically abrogated, as on the block system the line is either "clear" or "not clear," and there is no middle course. Green, therefore, may be got rid of, and purple and white for "danger" and

"all right" respectively, would probably be the best and most distinctive colours for universal adoption.

We hope this subject will receive the early attention of Parliament, and along with it should be passed a measure for making a uniform code of bell signals compulsory also. At present, the code of signals by the number of strokes on a bell is different on different railways, so that a signalman at a junction-box may have to use one code of signals in one direction and another in the opposite direction. It seems really monstrous that such an additional difficulty and source of mistake in signalling should be allowed to continue anywhere. It is not so much the fault of the separate companies, each of which may consider it has a good reason in favour of its own code for simplicity and clearness; it is the want of a general regulation from a central authority; a want which ought to be supplied without delay.

The chapter on "railway servants and the law" is a rather painful one to read, showing as it does in how many cases a railway servant who is doing his work to the best of his ability is made a scapegoat for an accident which arose from the defect of the system or of some higher powers. Engine-drivers especially seem to have been liable to this unfair treatment. Of course, the responsibilities of engine-driving are so great that any proved carelessness should be visited severely; but, in fact, it is the rarest thing to find a driver really responsible for an accident, and in the main we believe that no set of men do their work better and more carefully than locomotive engine-drivers.

*A Practical Treatise on Land and Engineering Surveying, Levelling, Estimating, Quantities, &c.* By H. S. MERRITT. Fourth edition, revised and corrected with Appendix by GEORGE W. USILL, A.M. Inst. C.E., M.S.A., &c. London: E. & F. N. Spon.

If land surveying could be taught by books, which we doubt, this book can teach it; for it takes up every point and deals competently with all. But a month's work in the field is worth all the books that ever were written, and will teach more of the practical details in an infinitely more pleasant way.

A useful chapter on contouring,—not always found in such works,—is given; and the illustrations deal with every kind of problem likely to be encountered by the surveyor in practice. The author does not believe that the Ordnance Maps will drive the civil professional surveyor from the field, and recommends special surveys for lines of railway, &c., in preference to the published maps, as not only being more trustworthy, but more economical.

It is somewhat naively stated that the English yard was "settled" at the length of Henry I.'s arm, which reminds one somewhat of Diedrich Knickerbocker's measure of weight. It has, in fact, been often settled, and finally fixed and legalised by the 5th Geo. IV., c. 74, which declares that "the pendulum vibrating seconds of mean time in the latitude of London in a vacuum at the level of the sea is 39.1393 inches of the standard, and that the yard shall be in the proportion of 36 to 39.1393.

The history of the standard measures of Great Britain, their destruction by fire in 1834, their restitution in 1876, is full of interest, and a résumé of it would not have been out of place in a scientific work, dealing about all things with the science of measurement.

*The Gas Engine.* By DUGALD CLERK. London: Longmans, Green, & Co. 1886.

THE author of this work is the inventor of one of the best known types of gas-engine, and has been engaged in the manufacture of these motors for some years. He is, therefore, necessarily in a position to speak with authority on the practical aspect of the question he has made the subject of his work. Mr. Clerk has, however, gone further than this, for he has applied himself to the more abstruse aspects of the case, and has carried his researches so far as to enable him to claim no mean position amongst the students of physical science. If we add to these qualifications for the task he has undertaken a facility for expressing himself in clear and forcible language, it will be evident that the work under notice can hardly fail to reach a high standard.

There is one pitfall that must have beset Mr. Clerk's path in his career of authorship. As the inventor of a special type of gas-

engine, it might have been expected that he would have devoted undue space to the merits of his own system, and to the demerits of those of his rivals. This snare he has well avoided, and there is no evidence in the book, either when the author's own or his rivals' schemes are under discussion, that he has a child of his own appealing to him with that fervour which only in an inventor's breast finds an echo.

Mr. Clerk opens with a historical chapter, dating from the very earliest days of gas-engine invention, which, it will surprise many to learn, extend back for over 200 years. In that era, however, the gas was of a very different kind to that now used, being generated by the explosion of gunpowder,—a means by which Hnyghens proposed to obtain motive power in 1680. The effort was, of course, unsuccessful, as were the experiments of Papin, who shortly after followed in the same track. A truer form of gas-engine was introduced by Robert Steele, who patented his device in 1734. The bottom of the motor was heated by fire, and some spirits of turpentine being injected, the gas thus obtained was used for explosion in the motive cylinder. The next gas-engine (Browne's, of 1823), worked by vacuum, the flame being condensed by an injection of water. This motor was placed in a boat, which was run on the Thames. Other engines followed, but the origin of the modern gas-engine has been so well thrashed out in the law courts within the last few years, that it is, perhaps, unnecessary to say more on this subject.

In the second chapter on "The Gas Engine Method" the author points out the advantage this motor has over the steam-engine, inasmuch as the fuel (gas) heats the working fluid (atmospheric air) in the motive cylinder in place of the operation being performed in a separate vessel. We are not quite clear whether the author means to infer that the products of the exploding gas play no part beyond heating the air. If so, it is hardly in accordance with the generally-accepted opinion. The very obvious advantages of gas-engines over hot-air engines are next dealt upon. The temperature usual in a gas-engine cylinder, the author tells us, is 1,600° C.; whilst the temperature of molten cast-iron flowing from a cupola is about 1,200° C. Of course, the metal of the engine cylinder is preserved from injury by the water jacket, but the price paid for this immunity from fusion of the iron is about one-half of the whole heat of combustion. The slight conductivity of air for heat prevents what would otherwise be a far more serious loss.

The chapter on "Gas Engines Classified" gives a brief abstract of the leading elements of various types; after which the book proceeds to treat of the "Thermodynamics of the Gas Engine." The labours of Professor R. Schöttler and Dr. A. Witz are referred to, and the general principles which govern the action of gas-engines, in common with other heat-engines, are briefly and plainly set forth. Efficiency formulæ are worked out, and illustrated by means of diagrams, practical examples being given. "The Causes of Loss in the Gas Engine" supply a suggestive chapter, after which "Combustion and Explosion" form the subject of a useful section of the work. The descriptions which follow of gas-engines of different types with details of various parts constitute the main body of the book. It is an impartial and lucid composition, aided by diagrams of all the chief forms of gas-engine, including some of the earlier types. The Otto engine occupies, as by right it should, the chief attention of the author, who gives full credit to the ingenuity and talent of his fellow worker and rival. He is not chary, however, in giving the results of his own labours; whilst the Robson, the Stockport, and Atkinson's engine are illustrated and described. A dissertation on the theoretical action of the gases in the modern gas-engine, and a chapter entitled "The Future of the Gas Engine," together with a brief appendix, completes the work. The book may confidently be recommended to any one wishing to obtain a knowledge of the theoretical and practical aspect of what is often described as "the coming motor." It is not often one meets with a work that contains so much good material in the same compass.

*Studies in Russia.* By AUGUSTUS J. C. HARE. London: Smith, Elder, & Co.

THE criticism which most readers would pass on this book is made by the author himself in his preface, where he quotes the Russian

proverb,—"A foreigner must spend two years in our country before he can judge of it." As Mr. Hare spent but one summer there, and his knowledge of the language,—acquired in long, dreary journeys by Russian railways,—was but superficial, the "studies" are not of great value. It is true that a trained traveller like Mr. Hare sees a vast deal more than an ordinary tourist. He observes as well as sees, and practice has taught him how to present his observations to the reader in an acceptable fashion. The scissors, moreover, have supplemented the pen; and, from Richard Chancellor and George Turberville,—forgotten authors of the sixteenth century,—down to Kohl, de Custine, Haxthausen, and Wallace, with whose names we are more familiar,—there have been gathered passages which bear upon pretty well every Russian matter. The author was, unfortunately, unable to sketch many places or public buildings,—the use of the pencil at once making him an object of suspicion to the obtuse officials, who were rarely able to read the permits with which Mr. Hare had provided himself. Altogether, therefore, the book cannot claim a place beside some of its predecessors, though the failure must not be ascribed to any lack of industry on the part of the author, but simply to the circumstances which surrounded him.

From an architect's point of view, Russia is a barren land. The towns are almost as deficient in beauty as the country around them. In the capital the wide streets suggest desolation rather than grandeur. The shops are mean, and the palaces, "built of hard brick covered with worse stucco," look paltry and puerile. "Human hands built Rome," says the poet Mikewicz, "divine hands created Venice, but he who sees St. Petersburg may say,—This town is the work of the devil." Probably the epithet which Mr. Hare applies to the archway at the end of the *Grand Mostoi*,—the epithet "aimless,"—is that which best characterises Russian architecture, unless we recognise size alone as the aim to be secured. The *Cathedral of St. Isaac* has, indeed, some few pretensions to grandeur. "Its pillars are glorious granite monoliths from Finland, hurried there for centuries amidst the swamps, and the golden screen, decorated with huge columns of malachite, is a very striking feature." The building rests, like most of the city, upon very insecure foundations, and the piles upon which it rests already show signs of decay, though the present structure was completed only in 1858. Novogorod and Moscow are much more interesting than St. Petersburg. Both the two former have their Kremlin, or citadel, of high antiquity, and their many-mingled monasteries, which look picturesque against the sky. But from Novogorod the grandeur is departed, and in Moscow is side by side with squalid misery. There is a quaint picturesque about the Cathedral of St. Sophia, Novogorod, which Mr. Hare's sketch reproduces, but the bulbous gilt domes which ornament its roof are rather meaningless. Not so the crosses which there and everywhere else rise supreme. It will be noticed that they have crescents at their base, and for this reason:—"The Tartars, who were masters of Russia for 200 years, had changed the churches into mosques and fixed the crescent upon them. When the Grand Duke Ivan Vassilivitch drove out the Tartars and restored the churches, he left the crescents, but planted the cross upon them in sign of victory, and Russia has since continued the practice."

We must add that Mr. Hare has provided his book with a good index, so that it is really useful for purposes of reference.

RECENT PATENTS.

ABSTRACTS OF SPECIFICATIONS.

2,967, Improvements in Levels. J. J. Hicks and C. T. Light.  
According to this invention, a chamber of a disc shape, either circular or square, is half filled with coloured fluid or spirit, and the circle around it graduated, so that the level of the fluid will indicate at both ends against the scale, or the chamber may be nearly filled, and the bubble of air which will be formed at the periphery of the disc will travel round in the same proportion to the change of level.  
3,006, Water-taps. H. Watson.  
This invention consists in altering the construction so that the tap can be readily attended to when leakage occurs. The tap is made in two parts placed horizontally, the joining being made water-tight by a gland, stuffing-box, or other suitable means. The valve spindle and working parts are also placed horizontally to prevent the sediment or

grit from resting on the valve, and for greater convenience in getting at the working parts in case of the same being out of order.

3,217, Sewage and Cement. J. B. Hannay.  
The object of this invention is to treat sewage so as to render the water innocuous, and at the same time to form a cement similar to Portland. The precipitate of the sewage is dried and burned in a reverberatory furnace. Lime and clay are mixed in at an early stage in the operation, and when thoroughly burned, the material, it is claimed, forms a valuable cement.

11,524, Fences, Stalls, Tables, &c. T. S. Winter.

This invention relates to a convertible contrivance for use in fields, &c. It is made in wood, somewhat similar to an ordinary rail fence, but provided with hinges, which allow of one part lying out horizontally and being supported by legs opening wider. This form may be used in drying hay and other agricultural work with great advantage.

15,948, Alarums for Doors. N. J. Bushy.  
This invention consists in an arrangement of striking mechanism actuated by pulling a knob in the ordinary manner, but designed to give an extra sound and with certainty, and also to obviate loosening or slackening of wires and cranks.

15,684, Improved Vices. C. J. Hermann.  
This invention relates particularly to bench vices and it is claimed for the improvements that the jaws can be drawn further apart and the object sustained in the vice is securely held at all positions of the jaws. The vice itself is fixed upon a turntable, and it is movable to many positions, in each of which it may be rigidly fixed.

15,257, Stained Glass. O. Lossing.  
According to this invention, cut and coloured pieces of glass are placed according to the pattern desired, and while heated to a proper temperature joined and covered by cement of colourless and transparent cement. Sometimes two sides of transparent glass are used to enclose the picture. No "leads" are required, and though the coloured glass may be small and thin the picture may be made very strong.

NEW APPLICATIONS FOR PATENTS.

Jan. 28.—1,348, J. Cornell, Latches for Locks, &c.—1,362, J. Macintyre and Others, Kitchen Ranges.—1,364, W. Farrell, Gauge for obtaining Lines, Angles, &c., in working Mouldings on Stone.—1,414, W. Barnes and Others, Paint Brushes, &c.

Jan. 29.—1,448, J. Bidder, Chimney Cowl or Ventilator.—1,457, E. Tonks, Sash Fasteners.

Jan. 31.—1,471, J. Moore, Nails.—1,480, C. Stroud, Guttering for Roofs, &c.—1,488, G. White, Fixing Lines to Window-sashes without removing the Sash from Frame.—1,493, J. and J. Wilson, Cowl for Smoky Chimneys.—1,508, G. Hookham and W. Tonks, Lines for Window-sashes, &c.

Feb. 1.—1,532, T. Woodriddle and T. Jones, Forming Floors.—1,577, J. Guest, Ladders and Steps.—1,598, H. Lake, Preventing Damage by overflow of the Leakage of water to the Contents of Warehouses or other Buildings.

Feb. 2.—1,636, M. Stansfield, Counterbalancing Sliding Windows or Sashes.—1,663, G. and T. Claughton, Wooden Pins and Dowels.—1,688, D. Sorfeet, Automatic Draught Preventer for Doors.

Feb. 3.—1,708, H. Roberts and T. Osborne, Automatic Siphon Flushing Cisterns.—1,730, J. Gibson and W. Glasgow, Closing the Space underneath Doors when Shut.—1,738, W. Reynolds, Substitute for Stained Glass.—1,740, J. Gets, Forming Water-tight Joints for Doors and Windows.—1,754, E. Purdon and H. Walters, Door Closer.—1,758, J. Harrington, Sash Fasteners.

PROVISIONAL SPECIFICATIONS ACCEPTED.

3,369, J. Denny, Embossed and Geometrical Tiles, Mosaics, &c.—15,446, C. Steer and J. Stubbs, Norfolk Latches.—16,498, E. Court, Johnson's Spokeshafts.—16,945, C. Swindell, Stone Grates and Fireplaces.—209, R. Worrall, Preparation of Distemper.—424, W. White, Roads and Pavements, and Paving Blocks for same.—442, J. & S. Stott, Rendering Buildings Fire-proof and Waterproof.—559, J. Murphy, Fireproof Construction.—743, E. Dive, Ventilating Apparatus.—80, D. Balsey, Fixing Mouldings and other Woodwork.—138, W. Blessey, Ornamentation of Tiles, &c.—357, J. Gregson, Ha-gers, Nails, and Holdfasts for Rain water Pipes, &c.—414, T. Whalley, Water-closets.—684, F. Benekenstorff & C. Jungst, Roofing Tiles.—1,039, C. Schlickeysen, Moulding Bricks, Tiles, &c.

COMPLETE SPECIFICATIONS ACCEPTED.

Open to Opposition for Two Months.  
3,449, C. Davis, Roofing Tiles.—3,508, Crompton & Kyle, Electric Light Fittings.—3,597, J. Lawson, Self-acting Water-closets.—4,245, J. Brerley, Combined Wood and Earthenware Floors.—4,332, G. Couch, Ridge Hip, and Wall Tiles.—4,577, A. Harding, Air Extractors and Chimney Cows.—4,610, J. Bloomfield, Buildings.—4,646, J. Danby, Metallic Buildings.—4,660, A. Cross, Sash Fasteners.—6,565, Beau & Gaines, Closing and Preventing the Slamming of Doors.—16,926, E. Bron-

son, Compound for Coating and Finishing Walls.—1,672, E. Edwards, Releasing the Bolts of Doors from a Distance.—3,044, C. Kite, Ventilators.—3,424, M. Macleod, Laying Pavements of Wood, Tiles, Concrete, &c.—3,450, G. Newman, Pneumatic Door springs and Checks.—4,572, D. Cottier, Imitation Stone, Marble, Terra Cotta, &c.—25, E. Banner, Testing Pipes, Drains, and Sewers.—115, W. Thompson, Portable Houses.

MEETINGS.

SATURDAY, FEBRUARY 12.  
*Architectural Association*.—Visit to Church at Wimbledon, 3 p.m. (Postponed from Feb. 5. See advertisement.)  
*Surveyors and Auctioneers' Clerks' Provident Association*.—Annual Meeting, Auction Mart, 3 p.m.  
*Edinburgh Architectural Association*.—Visit to Magdalen Chapel and the High-street closes.

MONDAY, FEBRUARY 14.  
*Royal Institute of British Architects*.—Professor T. Hayter Lewis, F.R.A., on "Notes made during Tour in Greece, 1881 and 1884" 8 p.m.  
*Royal Academy of Arts (Lectures in Architecture)*.—Professor J. H. Middleton on "Methods of Decoration as applied to Medieval English Architecture." 8 p.m.  
*Society of Arts (Lectures)*.—Mr. W. Y. Dent, F.C.S., on "Building Materials." I, 8 p.m.  
*London Institution*.—Mr. W. B. Richmond, on "The Future for Art." 5 p.m.  
*Society of Antiquaries of Scotland (Edinburgh)*.—8 p.m.

TUESDAY, FEBRUARY 15.  
*Institution of Civil Engineers*.—(1) Further discussion on Mr. W. J. Dibdin's and Mr. W. Santo Grimm's papers on "Sewage Sludge and its Disposal." (2) Mr. W. Willcocks on "Irrigation in Lower Egypt." 8 p.m.  
*Society of Arts (Foreign and Colonial Section)*.—Mr. Allan Ransome on "Some of our Colonial Woods." 8 p.m.  
*Birmingham Architectural Association*.—Mr. Whitworth Wallie on "Pompeii." 7.30 p.m.  
*Statistical Society*.—Ordinary Meeting. 7.45 p.m.

WEDNESDAY, FEBRUARY 16.  
*Society of Arts*.—Mr. Henry H. Cunyghane on "Uses, Objects, and Methods of Technical Education in Elementary Schools." 8 p.m.  
*British Archaeological Association*.—(1) Rev. L. H. Lloyd on "The Parochial Registers of Wing, Bucks." (2) Mr. J. T. Irvine on "The Communion Plate, Peterborough Cathedral." 8 p.m.  
*Civil and Mechanical Engineers' Society*.—Mr. David Gravel on "Reservoir Dams." 7 p.m.  
*Royal Meteorological Society*.—Ordinary Meeting. 7 p.m.  
*Builders' Foremen and Clerks of Works' Institution*.—Ordinary Meeting. 8.30 p.m.

THURSDAY, FEBRUARY 17.  
*Society for the Encouragement of the Fine Arts*.—Mr. G. A. Rogers on "The History of Wood-carving." 8 p.m.  
*London Institution*.—Professor Silvanus Thompson on "Electric Bells." II, 6 p.m.  
*Parke's Museum of Hygiene*.—Mr. Chas. E. Cassal on "Food Adulteration and Analysis." 5 p.m.  
*Edinburgh Architectural Association*.—Ballie Russell on "The Work of the Architect in Relation to Health and Longevity." 8 p.m.

FRIDAY, FEBRUARY 18.  
*Architectural Association*.—Mr. Walter Crane on "The Architecture of Art." 7.3 p.m.  
*Institution of Civil Engineers (Students' Meeting)*.—Mr. G. A. Becks on "Diving; the Apparatus used, and the Work carried out under Water." 7.3 p.m.

SATURDAY, FEBRUARY 19.  
*Builders' Foremen and Clerks of Works' Institution*.—Annual Dinner (Holborn Restaurant). 6.30 p.m.

The Surplus Lands of the Metropolitan Board of Works.—At the meeting of the Board on the 4th inst., Mr. T. G. Fardell moved: "That it is desirable that all the Board's surplus lands should, in the first instance, be offered for sale by public auction." He believed that better prices would be got in the majority of cases if the lands were put up to auction instead of being sold by tender. Mr. W. A. Lindsay seconded. After some discussion, the question was referred to the Works Committee for consideration.

**REDHILL.**—For repairs, &c., at Wesleyan Chapel, Redhill. Mr. F. Boreham, architect:—  
 G. Room ..... £204 0 0  
 Steneman & Sons ..... 197 0 0

 FOUR Lines (about THIRTY words) or under ..... 2s. 6d.  
 Each additional line (about ten words) ..... 0s. 6d.  
 PREPAYMENT IS ABSOLUTELY NECESSARY.

\* Stamps must not be sent, but all small sums should be sent by Cash, in Registered Letter or by Money Order, payable at the Post-office, Covent garden, W.C. to DOUGLAS FOURDRINER, Publisher, Addressed to No. 48, Catherine-street, W.C.

Advertisements for the current week's issue must reach the office before THREE O'CLOCK p.m. on THURSDAY.  
 The Publisher cannot be responsible for DRAWINGS, TESTIMONIALS, &c. left at the Office in reply to Advertisements, and strongly recommends that the latter COPIES ONLY should be sent.

PERSONS Advertising in "The Builder," may have Replies addressed to the Office, 48, Catherine-street, Covent Garden, W.C. Free of charge. Letters will be forwarded if addressed in envelopes are sent, together with sufficient stamps to cover the postage.

AN EDITION Printed on THIN PAPER, for FOREIGN CIRCULATION, is issued every week.

FIRE BRICKS.

**E. BOWEN, Fire-Brick Manufacturer, STOURBRIDGE.**  
 Manufacturer of Best Stourbridge Fire Bricks, and Cement Fire Clay, Gas Reborts, Mullins, &c. Fire Bricks and Blocks for the Highest Heat, for Locomotives, Furnaces, Forges, Rolling, Puddling, and Steel Furnaces, Pottery, Bottle, and Flint Glass Furnaces, Boiling and Retorting Furnaces, Chimney Flues, Coke Ovens, &c. Boiler Setting Blocks, Flue Covers, Locomotive Bricks, Tapered Steel Runners, Grade Backs.  
 Special sizes and shapes made to Engineers' Drawings. Prices quoted as per Port or Railway Station.

**R. CULL & SON, Palmerston-buildings, E.C.**  
 Stores—Railway Arches, Corner of London-street and Brady-street, near Bethnal Green Station.

GLAZED BRICKS.

**OATES & GREEN, HALIFAX.**  
 GLAZED BRICKS (White and Coloured), Special Salt Glazed Bricks, Salitary Tiles, Colored Earthenware Tiles, Cattle Sheds, and Pig Troughs, Horse Mangers, Patent Automatic Trough Closets, Patent Flush Tanks, Channelling for Stables and Yards, Salt Glazed Bricks for Stables, Sewers, &c. Ventilating Bricks, Patent Ventilating Gallies and Traps, Garden Edging, Patent Chimney Pots and Curbs for Down Draughts, Patent Drain Cleaning Rods.  
 Six Prize Medals. Copies of Testimonials sent if required.  
 London Agents—

**R. CULL & SON, Palmerston-building, E.C.**  
 Stores—Railway Arches, Corner of London-street and Brady-street, near Bethnal Green Station.

BLUE BRICKS.

**THE KETLEY BRICK COMPANY, Manufacturers of Staffordshire Blue Bricks, KINGS-WINFORD, near Dudley, Staffordshire.**  
 London Agents—

**R. CULL & SON, Palmerston-buildings, E.C.**  
 Stores—Railway Arches, Corner of London-street and Brady-street, near Bethnal Green Station.

DRAIN PIPES.

Lime Cement Bricks, Flates, Laths, Hair, Sand, Plaster, Stable Paving Bricks, Wall Copings, Channel Bricks, Blue and Red Ridges, Red Plain Tiles and Flat Tiles, Closet Pans and Traps, Drain Pipes, Bends, Junctions, &c. all sizes, Chimney Pots, Red and White, Fire Bricks, Lamps, Tiles, Fire Clay. PRICES and SPECIFICATIONS at R. CULL & SON'S Stores, Railway Arches, Corner of London-street and Brady-st., near Bethnal Green Station, Chief Office—72, Palmerston-buildings, Old Broad-street, E.C.

TERMS OF SUBSCRIPTION.

"THE BUILDER" is supplied direct from the Office to residents in any part of the United Kingdom at the rate of 12s. per annum in advance. To all parts of Europe, America, Australia, and New Zealand, 20s. per annum. To India, China, Ceylon, &c. 25s. per annum. Remittances payable to DOUGLAS FOURDRINER, Publisher, No. 48, Catherine-street, W.C.

**Best Bath Stone.**  
**CORSHAM DOWN, } SUMMER DRIED.**  
**FARLIGH DOWN, }**

**BOX GROUND, COMBE DOWN.**  
**WESTWOOD GROUND.**

Doubling Freestone.

**THE CHELYNCH STONE.**  
**THE BRAMBLEDITCH STONE.**  
 The stone from these quarries is known as the "Wether Bed," and is of a very crystalline nature, and undoubtedly one of the most durable stones in England. It is of the same crystalline nature as the Chelynch Stone, but finer in texture, and more suitable for fireproof work.

**HAM HILL STONE.**  
 Greater facilities have been provided for working these quarries, and the stone can be supplied in large quantities at short notice.

Prices, and every information given, on application to CHARLES TRASK & SONS, Norton-sub-Hamdon, near Ilminster, Somerset. London Agent—Mr. E. WILLIAMS, 16, Craven-street, Strand, W.C. [ADVT.]

Doubling Free Stone

For prices, &c., address S. & J. STAPLE, Quarry Owners, Stone and Lime Merchants, Stoke - under - Ham, (Ground or Lamp), Ilminster. [ADVT.]

Asphalte.—The Seyssel and Metallo Lava

Asphalte Company (Mr. H. Glenn), Office, 38, Poultry, E.C.—The best and cheapest materials for damp courses, railway arches, warehouse floors, flat roofs, stables, cow-sheds, and milk-rooms, granaries, tun-rooms, and terraces. [ADVT.]

Asphalte.

Seyssel, Patent Metallo Lava, and White Asphalte.  
**M. STODART & CO.**  
 Office:  
 No. 90, Cannon-street, E.C. [ADVT.]

Map of London,

SHOWING BOUNDARIES OF SURVEYORS' DISTRICTS.

The four Sheets, into which the Map is divided (issued with the numbers of January 1st, 8th, 15th, and 22nd), if sent to the Office direct, or through any Newsagent, can be

MOUNTED ON THE FOLLOWING TERMS, VIZ. :—

On Cloth (Rollers) and varnished, 3s. 6d. | On Cloth (Strainer) and varnished, 5s. 6d.  
 N.B.—In the case of "Strainers" if packed for rail or carrier, 1s. 3d. extra.

**NOTICE.**—THE BANNER SANITATION CO. beg to give Notice that having sold over 10,000 BANNER'S PATENT VENTILATORS, also a proportionate number of other Sanitary Appliances, and wishing to keep pace with the times, they have decided to reduce the prices of their goods from 25 per cent. to 40 per cent., thus offering to the public the best appliances at the lowest prices.

BANNER VENTILATORS.

The Strongest Exhaust Ventilators for all Buildings, Public Halls, Churches, Billiard-Rooms, &c.

HIGHEST PRIZES at all the most Important EXHIBITIONS.

Gold Medal. Health Exhibition, 1884.

### Elasticity and the Strength of Materials.

CONSIDERABLE amount of information upon elasticity is scattered through the periodicals of this and other countries, and a few books have been wholly devoted to it, but we have

now before us the first great attempt of recent years to give a comprehensive view of the subject and its relation to the strength of materials.\* Not only does elasticity cover all the principal phenomena of the latter: it would, if fully understood, enable us to form a much clearer conception of the ultimate constitution of matter, and is therefore of the utmost importance to men of science generally. In this volume of nearly 1,000 pages we have Dr. Todhunter's first instalment of the history of the theory, bringing us up to the year 1850, and we are indebted to Professor Pearson for a large amount of additional matter, together with a revision of the whole. In collating the work of writers of various ages and countries there is, of course, a difficulty in deciding upon and adopting a uniform terminology, but we think this has been successfully accomplished, and the present work will, as a standard of reference, go far to confirm its usage. There is so much confusion in ordinary text-books at the present day as to the use of the terms "stress" and "strain" that it is interesting to note the terminology here adopted. The word *strain* is retained, as first suggested by Rankine, for the purely geometrical consideration of distortion; *stress* is reserved for the dynamic aspect of distortion, as first accurately defined by Saint-Venant. Thus the stress across an elementary plane is the resultant of the actions, whether attractive or repulsive, which the molecules situated on one side of the plane exercise upon the molecules upon the other side, when the direction of these actions traverses the plane. "Tension" and "compression" are not used; in place of them the word *traction* is used, being positive or negative, for a *stretch* or *squeeze*, and indicating the external effort as against stress, the molecular resistance. *Shear* is used for the stress aspect of the current use of that term, while *slide* is adopted for the strain aspect. The book abounds with copious extracts in the original language of the

various writers whose opinions and theories are quoted, in order that no misunderstanding may arise where important statements are involved, and these add much to its value as a standard work. With so distinguished an author and so discriminating an editor its mathematical excellence is beyond our praise; as it is the last so it is the best history of a subject which is essentially mathematical in its nature; but we shall confine our notice to the practical side of the subject, as being of more immediate interest to our readers.

Commencing about 250 years ago with Galilei, whose problems of the resistance of beams gave a foundation for the theories of elasticity, although he believed the fibres were themselves inextensible, and passing over Sir Wm. Petty, who attributed sexual characteristics to atoms, we find in the hypothesis of Hooke (1678) the first hint of the modern conception of elasticity. "*Ut tensio sic vis*" was the law he laid down for springs and elastic bodies, and although his theory was tainted with the vague and unsatisfactory notions of his day, the experimental law was of the greatest importance, and gave rise to the Mariotte-Leibnitz theory that extensible fibres resisted as their extension. Mariotte considered that half of the fibres of a bent beam were extended and the others compressed; Varignon thought the neutral surface coincided with the fibres farthest from the extended side; Jas. Bernoulli, who solved the problem of the elastic curve, thought that the force required upon the end of a beam to cause its fracture would be the same wherever the "axis of equilibrium" might be, and he, therefore, considered the position indifferent. Newton (1717) argued that the cohesive and dispersive phenomena of matter were due to attraction and repulsion among the particles, not that attraction was a cause, but only,—the same as was gravity,—"a general law of nature, the truth appearing by phenomena, while the cause was yet undiscovered." A few years after, Musschenbroek made experiments, principally with wood, to ascertain these *vires internæ*, holding that without our needing a metaphysical hypothesis as to their cause, we may determine them in each case by experiment. Billfinger (1729) rejects the theories of Mariotte and Bernoulli, and holds that until the laws of compression are formulated the position of the neutral line must be found by experiment. The majority of early writers took but scant notice of compression, and even at the present day much remains to be done. A great difficulty in the way of progress during the seventeenth and eighteenth centuries was "the union of those theological and metaphysical tendencies of the time which so checked the true or experimental

basis of physical research." J. Riccati (1750) approaches the modern conception of the conservation of energy; he says the *forma viva* spent in producing a deformation remains in the strained body in the form of *forma mortua* or, in modern language, the mechanical work stored up in a state of strain must be equivalent to the energy spent in producing that strain; but the chief value of his writings lies in his method and his desire to explain the elastic property of bodies upon a purely dynamical theory. Euler (1759) applied his mathematical powers to the investigation of the elastic curve and the bending of columns with other important matters. He assumed that the moment of the forces of elasticity at any point is inversely proportional to the radius of curvature, the proof of which we do not get until we reach Poisson. Lagrange (1770) continued the study of columns, and asserted that a truly cylindrical column was more efficient than one of similar weight with an entasis, such as Vitruvius and other architects had recommended; but Hodgkinson afterwards refuted this by means of careful experiments on columns of cast iron. Coulomb (1773) places the neutral line at the middle of the transverse section of a rectangular beam, the sum of the forces of extension being equal to the sum of the forces of compression across any section. He introduced (1784) his theory of torsion, which by means of a suspended filament has afforded such an exceedingly delicate means of measuring small forces. He also formed an important conception of cohesion as applied to "les corps formés de molécules agglutinées," such as a masonry pillar, and others; he held that the difference in the cohesion of the same material in different states depends upon its capacity for receiving set-slide (*glissement*): if its parts cannot slide on each other it is brittle; if they can, it is ductile or malleable. The eighteenth century is brought to a close with an account of Girard's treatise on elasticity, which, besides a historical review, contains an exhaustive account of all that was known upon the subject at that time; speaking of it the author says,—"The whole book forms at once a most characteristic picture of the state of mathematical knowledge on the subject of elasticity at the time, and marks the arrival of an epoch when science was to free itself from the tendency to introduce theologico-metaphysical theory in the place of the physical axiom deduced from the results of organised experience."

In the opening of the nineteenth century the subject seems to have attracted attention in England, and, although from his superior attainments as a mathematician we can understand that Dr. Todhunter could not tolerate the want of such knowledge in any man pro-

\* A History of the Theory of Elasticity and of the Strength of Materials, from Galilei to the present Time. By the late Isaac Todhunter, D.Sc., F.R.S. Edited and completed for the Syndics of the University Press by Karl Pearson, M.A., Professor of Applied Mathematics, University College, London. Vol. I. Galilei to Saint-Venant, 1639-1850. Cambridge: University Press. 1886.

fessing to be a leader in science, we were not prepared for such a sweeping condemnation as the learned doctor passes upon all our "fathers" in the science of building. Young, Robison, Gregory, Barlow, Tredgold, each comes in for a portion of the discredit which is finally summed up in the following paragraph:—"It is difficult to picture the remarkable scientific ignorance of practical men in England in the first quarter of this century. One can only trust that there may be a closer union of practice and theory in our own day." No doubt the practical men would be more reliable if they had more theory to guide them; but are the theorists without blame? Have not mathematicians devoted much labour to questions of little practical value, neglecting many others for the solution of which the world of constructors is waiting? And have not the practical questions they have touched been too often left involved in obscure mathematical language?

Young (1807) originated the modulus of elasticity: it was then a modulus of length, but, as now known, is one of weight. He added but little to the subject under review. "Without making any very definite statements, he would appear to ascribe the properties of cohesion and elasticity to the existence of the ultimate material particles in an ethereal medium, which, in some fashion, produces between them apparent forces." He appears, however, to have been among the first who laid marked stress on the distinction between lateral adhesion and direct cohesion; he was also the first to state the general theorem of resilience. Belli (1814) remarks that two opinions have been held as to molecular force: "Newton and his followers maintained that molecular force was quite distinct from the force of gravity or universal attraction; whilst, more recently, Laplace had suggested that it was only a modification of gravity." He opposes the latter view, relying upon the argument furnished by the fact that a drop of water will remain in equilibrium hanging from a horizontal surface, where the attraction of the drop on its lowest particle must be strong enough to overcome the attraction of the whole earth. Binet (1814) has the credit of first discovering the fundamental principle that spiral springs act chiefly by torsion. Biot (1816) attributes the elastic properties of bodies to their molecular construction and to forces between these molecules. G. Rennie (1817) made several experiments on the strength of materials, particularly cast iron, and gave some facts of practical experience for mathematicians to work upon. P. Barlow (1817) assumed that the sum of the moments of the tensions of the extended fibres about the neutral point of any section must be equal to the sum of the moments of the compressed fibres; Hodgkinson objected to this, and Barlow afterwards (1837) accepted Coulomb's principle. Tredgold (1822) calls down the full wrath of our author on account of his rejection of fluxions as a necessary branch of study, "Such is the scientific capacity of the man whose works remained for years the standard text-books of English engineers!" Hodgkinson (1822) adds some important deductions from his experiments on cast iron, among which we find that "the *moduli* for extension and compression are not exactly equal, hence the neutral line does not exactly pass through the centres of gravity of the sections; the difference, however, is so small that it does so very approximately." He proved experimentally that a cast-iron girder should have unequal flanges in the ratio of the tensile and compressive resistance of the metal, while for wrought iron the ratio being practically equal, the flanges should be equal. The author adds, "We have referred thus at length to Hodgkinson's second paper (1831) because it suggests several points which have not received full treatment at the hands of the mathematician. Notably the difference in character between cast and malleable iron, the range of imperfect elasticity, and the shape of the beam of the greatest absolute strength, are all points which seem capable of mathematical treatment with advantage to both theory and practice. The mathematician can-

not fail to be struck with the *very small* portion of the phenomena presented by a material subjected to continuously-increasing strain, which is covered by the current theory of elasticity." The decade from 1820 to 1830 shows a remarkable progress in the theory of elasticity; during this period the theory was definitely established, and its broad outline completed. "It is entirely to French scientists that we owe this great contribution to a wider knowledge of the physical universe, and however we may regard the relative merits of Navier, Poisson, and Cauchy, there cannot be the least doubt as to their dividing between them the entire merit of the discovery."

Navier (1821) gave for the first time the general equations of equilibrium and motion which must hold at every point of the interior of a body, as well as those which must hold at every point of the surface. He also considered many practical questions, as the limits of safety for various kinds of stress, the equilibrium of masses of earth, arches, continuous beams, &c. During this period we have also the contributions of a lady, Mlle. Sophie Germain, the pupil and friend of the great mathematician Lagrange, who invented the calculus of variations. She was herself no mean mathematician, and succeeded in finally establishing the equation for the normal vibrations of a plate. Laplace (1825), in his celebrated "*Mécanique Céleste*," says, with reference to forces which are sensible only at imperceptible distances—"Dans ma théorie de l'action capillaire, j'ai ramené à de semblables forces les effets de la capillarité. Tous les phénomènes terrestres dépendent de ce genre de forces, comme les phénomènes célestes dépendent de la gravitation universelle. Leur considération me paraît devoir être maintenant le principal objet de la philosophie mathématique." He devotes some space to the investigation of the attraction of one sphere on another, but does not much help the present subject. In the *Memoirs* by Savart (1819-40) we have some very interesting matter relating to elasticity founded upon original experiments. Although he deals principally with elastic vibrations as regards their relationship to the theory of sound, yet valuable hints may be derived therefrom upon the structure of elastic bodies, and a wide field is opened out for the verification of his results by mathematical processes. Lagerhjelm (1827), a Swedish physicist, showed that within the limits of elasticity all kinds of iron,—hard, soft, or brittle,—possessed the same degree of elasticity, *i.e.*, the modulus of elasticity was identical, notwithstanding that the limit of elasticity itself was greater for the harder irons. According to Lagerhjelm, the breaking-weight increases with the limit of elasticity, and is nearly proportional to it; also, "if a beam or wire be subject to tension, which produces a permanent extension, its limit of elasticity is increased, and, in proportion to its diameter, it possesses a greater absolute strength." The same writer shows that a permanent set produces an increase of volume. Poisson (1814-28), as a great master of analysis, is dealt with very fully, particularly section 6 of his "*Mémoire sur l'équilibre et le mouvement des corps élastiques*," which is the first investigation of the problem of the elastic plate from the general equations of elasticity, and which gave rise to much controversy; section 7 is devoted to the application of the formulæ. In his *Memoir* of the general equations of equilibrium, &c. (1829), he refers to *caloric* as supplying a repulsive force, in addition to the attractive force which may be supposed to arise from the action of particles of matter on each other. His writings are of the greatest value in elucidating the general subject of elasticity, and many of the most important problems are due to his initiative. Contemporary with Poisson was another celebrated elastician, Cauchy, whose attention was directed to the subject by being appointed one of the Commissioners to examine the memoir sent to the Paris Academy by Navier. His theory included the six stress-components which have to be considered at any point, the stress ellipsoid, &c., and he originated what is

known as Cauchy's Theorem. At this time no advance was made in the science of elasticity by the transition from the consideration of the forces upon a molecule exerted by its neighbours, to the consideration of the stress upon a small plane at a point. He was invited by the Academy to write a treatise on Molecular Mechanics, but this was never accomplished, his literary work consisting principally of detached memoirs published in the "*Comptes Rendus*." Cauchy observes that a disturbing element is introduced into the equations if we consider a homogeneous body as built up of a system of molecules and each molecule as in itself a system of atoms. The experiments on wires in connexion with the Geneva suspension bridge (1824) cause the remark that "they bring out various physical facts which are too often omitted in the theoretical consideration of traction problems, and for which no comprehensive mathematical theory has yet been propounded." In Rondelet's "*L'Art de Bâtir*" (1830) we have mention of some of the first recorded experiments on adhesion, but they are confined to mortar and plaster, and were made in 1787. He found that when two stones were united by mortar the separation occurred in the middle of the thickness of the joint, and not following the surfaces; whereas with plaster the contrary took place. We are told that this preponderance of adhesion over cohesion in mortar compares with that of glue in Bevan's experiments, but the figures quoted (Art. 374) hardly bear out this statement.

Weber (1830) first drew attention to the importance of considering the influence of temperature on stress, and made some interesting experiments on wires under traction. In 1835 he discovered the remarkable phenomenon now known as elastic after-strain or "Weber effect"; to explain this "he supposes the ultimate particles of the body to have three axes, and the angles made by these axes with the central distances of adjacent particles to be capable of variation; the complete equilibrium for any applied load denotes a certain relative position of these axes for neighbouring particles, but this position can be attained only after a long interval of time." About this period the contraction at point of fracture received some attention, and owing to the increasing number of practical experiments under various conditions, together with the minute attention bestowed upon them, many physical problems were propounded which mathematicians have not yet fully elucidated. Vicat (1830) pointed out the omission of *shear* and *slide* from the ordinary theory then current in practical books; they had, however, been the subject of investigation by various experimenters. He also insists upon the distinction which must be drawn between instantaneous and permanent loads. His experiments on compression confirm the modern theory that rupture by pressure is produced by lateral extension. Those on short beams of non-fibrous material built in at one end, show that when the rupture takes place at a built-in end the surface of fracture is always curved in certain definite ways, which are *très prononcés* for a short beam, but cease to be appreciable when the length becomes considerable. Ampère (1832) appears to have been the first to clearly distinguish between particles, molecules, and atoms: a particle is an infinitely small portion of a body which still retains the nature of the body: the molecule is essentially solid, and cannot be broken by mechanical force, only by chemical force; with regard to atoms, the only statement that can be made with certainty is that they are absolutely indivisible. "Molecules as a whole can vibrate: from this arise the phenomena of sound; their atoms can also vibrate: from this arise the phenomena of heat and light." Belli (1832) argues against the attributing of cohesion to gravitating force, and recounts the three current hypotheses of the nature of matter, *viz.*: Bodies are formed of minute extended particles separated by distances not much greater than their diameters (Newton); Molecular distances are incomparably greater than molecular diameters (Laplace); Bodies do not consist of discontinuous

molecules in a vacuum, hut of discontinuous vacua in a continuous matter (Bernoulli and Euler). Belli himself concludes that in every disposition of matter it would be necessary to suppose bodies to have "una enorme rarità di tessuto e una enorme densità della materia, se vi vuole che la coesione possa dipendere dalla gravitazione." Piola (1833-6) applies the mathematical methods of Lagrange and Poisson, and analyses the theory of elasticity, but he does not appear to advance the subject to any extent. Gerstner (1833) in a series of careful experiments on pianoforte wires, made the important discovery that the elastic strain even after the beginning of set remains proportional to the load, and that when such a wire is reloaded no further set occurs until the previous load has been exceeded. Baudrimont (1835) pointed out that, owing to the "worked state" of wires, their elastic character was very peculiar, and that such material did not present uniformity in its elastic constants. The Transactions of the Inst. C.E. for 1836 contain a paper by Tredgold on tension, where he shows the importance of making the load exactly axial with the bar in all structures. Avogadro (1837) gives a good account of the state of mathematical and physical knowledge at that time, hut contributes no original work. Brix (1837) tested French and German iron in comparison, and carefully noted the results; he found that the strain after the beginning of set consisted of two parts,—a purely elastic part following Hooke's law, and a set for which he could discover no law; he also proved that a given load will only produce a definite amount of set, however long maintained. His tabulated results showed clearly the position of the yield-point, hut he appears not to have noticed its existence. He observed that rolling and wire-drawing produce a change in the elastic conditions of the surfaces. Duhamel (1835) contributes some problems upon thermo-elasticity. Lehanc (1839) notices an important practical point, that long wires have a less breaking load than short ones of the same diameter, because there is greater probability of small flaws occurring. Hodgkinson's experiments on cast-iron (1840) naturally receive some attention, but although they were more exhaustive than any preceding them, and were of great practical value, our author is unable to find any mathematical theory upon them beyond a modification of Euler's theory for columns. It appears to be very desirable that mathematical and technical experts should be associated in carrying out such experiments, in order that the physical results may be noted in such steps as will ensure their mathematical value. Theory must be founded on practice, but practice can only make progress when theory lends her aid. Poncelet (1839), to whom we owe the introduction into practical mechanics of the principle of energy, gave courses of lectures wherein several points relating to elasticity were first treated. They were published in various editions, known generally as the "Mécanique industrielle." Among other things he described the *résistance vive d'élasticité*, or work done in deforming a bar up to its elastic limit, and represented graphically by the use of curves the result of several experiments. He was the first to give "an accurate graphical representation of the traction-stretch relation for bars subjected to terminal tractive load." He also went very fully into the question of resilience, and was instrumental in advancing the general theory.

In 1826 a small band of French military engineers in the Russian service, of whom Lamé and Clapeyron were the chief, was formed into a Commission for investigating the subject of the most suitable iron for suspension bridges, and to their labours are due many interesting facts and theories. The want of isotropy in iron bars, the properties of the state of ease, the conditions of the yield-point, Lamé's stress ellipsoid, and the existence of principal tractions, are among the points established. Considerable space is devoted to an account of Lamé's mathematical work, but this does not appear to be directly based upon physical axioms, and is of purely theoretical interest.

The chief feature of the decade 1830-40 is thus seen to be a richness of physical results which gave a broad basis for a reciprocal development of theory.

In the next decade we find a remarkable activity in all branches of research. "On the technical side it is no longer suspension-bridges, hut practical railway needs, which call forth not only innumerable experiments on iron, but corresponding developments of theory. . . . The technical papers of the period abound with material suggesting profitable lines of mathematical or physical investigation."

Hausmann (1840) notes that after rupture has taken place in a bar of wrought iron at the section of stricture, the stricture ends of the bar were found to be strongly magnetised when tested upon iron filings. Masson (1841) attempted to set up a relation between the elasticity of a substance and its atomic weight, hut the experiments were not very conclusive. Brewster, relating his researches on the polarising effect of strain upon glass and other bodies, suggested that models of arches should be made of glass, and so the stress in different parts of the arch rendered visible by exposure to polarised light, though we are not aware that this proposal was ever carried out. Neuman (1841) starting from Brewster's researches develops a theory for the analysis of strain by means of its double-refracting influence on light: his chief object was to determine the fringes produced by a given strain; but naturally the converse problem is of more importance. He also compares the effect of temperature with that of load in producing a change of density. One great difficulty that English engineers,—and not engineers alone,—have laboured under has been a very imperfect knowledge of the labours of scientific men of other countries, and only within quite recent years has any practical step been taken to remedy this; we refer to the copious extracts from foreign periodicals and hooks now found in every volume of the Transactions of the Inst. C.E. These place engineers in the present day *en rapport* with their co-workers abroad, and are of inestimable value. This difficulty was fully appreciated by Moseley, who, in his "Mechanical Principles of Engineering and Architecture" (1843), reproduced much of what was useful in the writings of Poncelet and others. Stokes (1849) contributed some important papers upon the vibratory motion of elastic solids, and a mathematical analysis of experiments on the effect of moving loads upon railway bridges. Wertheim (1842) experimented upon all the principal metals to determine the stretch-modulus, limit of elasticity, electro-elastic and magneto-elastic properties of bodies. The true elastic limit is considered to be "the stretch at which stress ceases to be proportional to strain," but he measured it as "the stretch at which set commences" and these are not necessarily the same. His contributions to physical elasticity are, however, among the most important of the period. Person (1848) considered that the work done in separating the molecules of a substance mechanically ought to be related to the heat required to separate them by fusion, but we fail to see any analogy between his exhaustive experiments on the vibrational constants of elasticity, and the temperature effect; according to the author, his experiments "conclusively prove that either isotropy possesses two constants, or that wires possess a cylindrical arrangement of elasticity, *i.e.*, are *aeolotropic*."

In 1849 we have the Report of the Commissioners on the Application of Iron to Railway Structures, containing the opinion of nearly all the leading British engineers of that day, and a detailed account of experiments upon the effect of continuous and intermittent loads, of long-continued impacts, of moving loads, &c., carried out upon a large scale and with every regard for accuracy. This Report caused a great activity in the discussion of the general subject of molecular mechanics, and the practical use of wrought and cast iron, and is, of course, well known to all practical men; it is, in fact, the "corner stone" of their structural work in iron, but it may not be out

of place to recapitulate a few of the conclusions arrived at. The dead load on girders should not be more than one-third to one-fifth the breaking load; travelling load, causing vibrations, should not be more than one-third to one-tenth of the breaking load, the majority being in favour of one-sixth. According to the evidence of nearly all the practical men, a girder was supposed to be deflected less by a load moving at a high velocity than by the same load at rest; Hawkshaw, P. Barlow, and R. Stephenson, however, held the contrary view, which we now know to be the correct one. Some interesting evidence was given as to the change of molecular structure in iron by long-continued vibrations, tough and fibrous metal being reduced to a crystalline and brittle state, but, on the whole, this change appears to be brought about from repeated *transverse* impulse, and to be absent in the case of *longitudinal* impulses only. Homersham Cox (1848) ingeniously applied some well-known elementary principles to formulate the elastic equations, and obtained close approximations in a very simple manner. Hodgkinson's experiments covered a very wide field. In addition to his better-known work, he tested bricks and building stones; he found that sandstone failed in crushing by the formation of a wedge fracture as in cast-iron, while limestone formed perpendicular cracks and splinters. The change of shape in the cross section of a solid rectangular wrought-iron bar under transverse stress must have presented itself to many experimenters, but it is first noted and figured in Clark's "Tuhular Bridges," where it resembles "the elastic figure obtained from Saint-Venant's theory of flexure." According to Clark, if a bar he put under initial transverse stress, by heating hot and straightening cold, the deflection is decreased, and the bar gains in absolute strength, although from theoretical considerations it seems very doubtful whether the absolute strength of a body (its limit of cohesion) can be increased in this way, and further experiments are needed.

A most important remark by the author upon the criterion of strength for permanent structures is contained in the following sentence:—"It cannot be too often reiterated that the theoretically best form of a section for a beam to be loaded only below the elastic limit by no means necessarily coincides with the section of beam of greatest strength." All the investigations of physicists and mathematicians into stress-strain relations tend to substantiate this opinion, yet, with the exception of Box, we can call to mind no popular writer of the present day who gives any heed to it in fixing the limit of safe load in structures. Fairbairn, in experimenting upon iron plates for ship-building (1850) found a very slight difference between the absolute strength of plate and bar iron, also between the strength of a plate torn through or across the fibres. As now made, the material shows very decided differences. We need not on that account impeach the accuracy of the experiments, which were doubtless correct for the material employed, but in utilising the results we must be guided by the present circumstances of manufacture. Haughton (1846-54) incidentally adds to the theory of elasticity, but is principally concerned with establishing the laws of the undulatory theory of light. Jellott (1850), employing Lagrange's method, investigated the equations for an elastic solid, the solid being regarded as an aggregate of molecules, and considered the hypotheses of both independent and modified action. Clerk-Maxwell (1850), among other interesting problems, follows up Brewster's suggestion of determining the nature of a strain in an elastic solid by means of the colour-fringes exhibited by polarised light, and furnishes a graphical solution of the problem.

The closing chapter is specially devoted to the researches of Saint-Venant before 1850. This renowned elastician "had a keen appreciation of practical needs combined with a wide theoretical grasp of which it would be hard to discover another example in the history of our subject." Although many valuable discoveries had been made, they were not current

in the practical world, being either misunderstood or ignored, and "to restate theory in its true place, to make the theory of elasticity of practical value, has been the life-work of Saint-Venant." He died only so recently as January, 1886, and the major part of his work will come under review in the second volume of this History. Prior to 1850, however, we owe to him the best definition of stress across an elementary plane, the true criterion of the strength of a body, the correction of the Bernoulli-Eulerian theory of flexure by the consideration of slide, and that of torsion by the discovery of the distortion of the primitively plane section. Note B in the Appendix by Professor Pearson, upon terminology and notation, will repay careful perusal before reading the History; the remainder of the Appendix, with its diagrams, will be better appreciated after tracing the gradual development of the theory, and many suggestive remarks will be found to give food for reflection until the appearance of the next volume. A word of praise is due to the very complete index prepared by Mr. Beare; the entries appear to have been made with judgment, and really form a concise summary under each head.

Although our notice of this work has extended to some length, we have given but a faint idea of the mass of information it contains, and particularly of the detailed mathematical investigations which are inserted and discussed throughout, and we have not even referred to the great controversies respecting multi- and vari-constancy, uni-constant and bi-constant isotropy, &c., as these, although of the very essence of the subject, are of interest only to the specialist in elasticity. Naturally the book will prove somewhat heavy reading to the ordinary practical man; but no scientific library will be complete without it, and any engineer or architect aspiring to deal with the forces of nature in an intelligent manner will do well to possess himself of it.

#### NOTES.

**I**T will be remembered that nearly a year ago the House of Commons rejected a vote of 50,000*l.* for the maintenance of the London parks, on the ground that London ought to maintain its own parks other than those designated "royal parks"; these include Hyde, St. James's, Regent's, and the Green Parks. But in addition to these "royal parks" Her Majesty's Office of Works has hitherto had under its control Victoria, Battersea, and Kennington Parks, and it was urged that the expense of the maintenance of these should be borne by the ratepayers of the metropolis, and should not be a charge on the national exchequer. As we said at the time, there can be no question as to the abstract justice of this proposition, and we now learn that as a consequence of the rejection of last year's vote the Government has introduced a Bill by which it is proposed to transfer the custody and maintenance of the three parks last named to the Metropolitan Board of Works (we presume) their "successors, administrators, or assigns." The opinion we have before expressed that the Metropolitan Board has its hands sufficiently full, and more than sufficiently full, is a growing one, but seeing that the Board has created and has under its control Finsbury Park and Southwark Park, and that it has charge of such open spaces as Hampstead Heath, Blackheath, Clapham Common, Peckham Rye, and Wormwood Scrubs, we think there will at any rate be no harm done by the transfer of the parks in question to the control of the Board as the local authority of the metropolis for the time being. The question came up for discussion at the meeting of the Board on the 11th inst., when an important communication was received from the Government, enclosing a statement of liabilities and assets which are to be taken over by the Board with the parks. A very heavy liability (nearly 200,000*l.*) rests on Battersea Park, but this may possibly be

eventually covered, in great part at least, by the ground-rents of land on the margin of the park, although it appears that some doubt has been thrown on the validity of the title to this property. The Board seems to be proceeding cautiously in the matter, and Sir James McGarel-Hogg has taken steps to oppose the second reading of the Bill pending the further consideration of the matter by the Board.

**T**HE same Bill proposes to transfer to the Board, with all obligations and assets, the control and maintenance of Westminster Bridge, the gardens adjoining the Bethnal Green Museum, and the embankment wall at Grosvenor-road, adjoining the Board's Embankment at Chelsea. With regard to these, as well as with reference to the parks, members and officers of the Board do not hesitate to express the opinion that the particulars of liabilities and assets furnished by the Government are insufficient. The Board is only doing its duty to the ratepayers by being chary of buying a "pig in a poke" or of accepting a gift in the nature of a white elephant. One of the members of the Board, we may note, spoke disparagingly of Westminster Bridge, which he characterised as "a very fragile structure."

**W**ITH regard to the new street from Charing-cross to Tottenham Court-road, which will shortly be completed and opened, two recommendations concerning it have been made by the Works and General Purposes Committee of the Metropolitan Board of Works for consideration at the Board meeting which will be held a few hours after these lines are published. The first recommendation is "That the name 'Charing-cross-road, W.C.' be applied to the new thoroughfare now in course of formation by the Board between Charing-cross and Tottenham Court-road." We cannot say that we think this suggestion any happier than the Board's original proposal to designate the new street from Bloomsbury to Piccadilly-circus "Piccadilly-road," for which the name "Shaftesbury-avenue" was ultimately adopted. Even supposing that the new street came right down to Charing-cross (which it does not), Charing-cross would be at only one end of the new line of thoroughfare. We were the first to suggest that the name of the great philanthropist should be associated with the street from Bloomsbury to Piccadilly, and we had the satisfaction of seeing our suggestion adopted. We now venture to make another suggestion, and that is, that the new street from Tottenham Court-road to Charing-cross should be named "Nelson-avenue, W.C." The connexion of the new street with "Trafalgar-square" will say something for this, but the strongest argument in favour of our suggestion is that the name of one who is generally regarded as the greatest naval commander England has ever seen is not given to any important street in London. "Nelson-avenue" would be popular, and no one could confound it with the three "Nelson-streets" which exist in other and remoter parts of the metropolis.

**T**HE other recommendation of the Committee has reference to the improvement of the line of frontage of the new street, especially in the immediate vicinity of the National Gallery. It will be remembered that at a recent meeting of the Royal Institute of British Architects, it was announced (see *Builder*, p. 215, ante) that, acting on a suggestion of the standing Art Committee, the Council had decided to memorialise the Board with a view to getting a better line than that which the new street now presents at its southern end. The memorial was duly sent to the Board, and referred to the Works Committee for consideration. The Committee now report recommending:—

"That the Royal Institute of British Architects be informed, in reply to their letter relative to the Board's new street from Charing Cross, that a line upon which is practically the same as that suggested by them; and that, as regards their proposal that the National Gallery shall be extended across Hemming's-row, this is a matter for the considera-

tion of Her Majesty's Office of Works, &c., and not of this Board."

We venture to hope that, 'twixt Board of Works and Office of Works, not only will the opportunity of securing architectural effect at the flank-end of the National Gallery be duly secured now, but that it will be taken advantage of at no very distant date.

**I**N all the many changes of public opinion scarcely anything more marked can be found than that which has reference to public spaces in towns. Thirty years ago it never occurred to philanthropic society that the regulation parks were not sufficient for the general wants; indeed, it never occurred to the people themselves what a valuable addition a few more would be to their health and pleasure. As to the commons, they were nobody's business to take care of; and if a greedy Lord of the Manor did sometimes encroach upon the rights of the parishioners, a little grumbling, or occasionally a little pulling down, took place, and nothing more was heard of the thing. But now-a-days open spaces are not only craved for, but are jealously searched for; and should some old suburban mansion, which has not been heard of since the days of Pepsy, emerge from its seclusion, and be announced for sale, it is immediately pounced upon as an open space, and if there be a bit of park land and some good trees, it is sought to secure them for the public. It is only by watching these events that we can at all realise the vast absorption that is going on around us from day to day,—an absorption that will in fifty years' time make an open space of Leith Hill, and a park of the whole range of the South Downs. Last year was very successful in this particular form of legislation, and during this year, so far as we know at present, we are to have two new parks, both in quarters where they will be highly appreciated. Ravenscourt Park, Hammersmith, is familiar to tens of thousands who daily pass it by rail. The house we may dismiss, but the 32 acres are certainly very charming, and so is the avenue that leads to them from the high road. Clissold Park, Stoke Newington, is still better from a scenic point of view, for it has water,—albeit it is but the New River,—and some very lovely timber; and as it is understood that the Ecclesiastical Commissioners have power to sell, and are willing to do so for 95,000*l.*, it would be a sin if the serried rows of terraces and streets, which are even now beating at the door, should be allowed to enforce an entrance. Scarcely a week but brings some complaint through the press that some historical house is for sale, so that there need be no fear that the speculative builder will be able to make a bargain round the corner. On the whole, the community is to be congratulated that so healthy a spirit is abroad.

**A** USEFUL little Bill has been introduced into Parliament, which if passed will be known as the "Quarry Fencing Act, 1887." The title explains the object of this piece of legislation. It is to oblige every owner of a quarry, whether being worked or disused, to keep it safely fenced. The term quarry is to include every pit or opening made for the purpose of getting stone, slate, lime, chalk, clay, gravel, or sand. There are far too many of these places now wholly unprotected, or fenced in so fragile a manner that the so-called protection is almost worse than none, being a mere trap. We are inclined to think that in addition to a substantial fence there should be near every quarry a notice-board conspicuously placed, having the word "quarry" on it in legible letters, so that persons approaching it, either riding or driving, might be warned of its existence before getting very close to it.

**T**HERE is no bond of federation to heat the iron rail, and we are heartily glad to see that West Australia, which has been too long out in the cold, is preparing to ally herself with her fellow colonies in a very practical and substantial manner. It is proposed by an English syndicate to make a line of 700 miles in length, from Perth to Eucla, on the land grant

system, and it is believed that this offer will be accepted by the Government. As Eucla is a considerable distance inland, this line would, of course, not do very much towards bringing the colony a connexion; but it happens that this same place is only some 400 miles from Port Augusta, in South Australia; and the same syndicate has, therefore, made a similar proposal to the South Australian Government. There seems some uncertainty as to the character of the country about Eucla, but a large area between it and Perth, which was said to be waterless and good for nothing, has already been examined, and proved to be just the contrary, so that very little fear is entertained as to the remainder. Should this scheme be carried out in its entirety, a continuous railway will exist throughout the entire southern half of Australia, and it will be possible to run a through train from Perth to Adelaide, Melbourne, Sydney, and Brisbane, a journey which will take from five to six days. Partly in dependence upon this large undertaking, a land syndicate is already issuing proposals to deal with West Australian land on an extensive scale.

TWO or three days hence some old landmarks will have disappeared from Clerkenwell. Spa Fields Chapel, in Exmouth-street, and the Countess of Huntingdon's house adjoining thereto, have just been pulled down.\* Their site is appropriated for the new Church of the Good Shepherd, to be built after Mr. J. D. Sedding's designs, for which an appeal is now before the public. The Metropolitan Board of Works' project for what are known as the Clerkenwell-road to Islington Improvements have involved the diversion from its hitherto uses, perhaps the ultimate extinction, of a relic of the several spring-heads which formerly fed the River of Wells, and gave so rural a character to this once favourite quarter of the town. The inner block of Coldbath-square is in the wreckers' hands. Here, behind Nos. 25 and 26, on the north-eastern side, and boarded over to protect it awhile from the falling debris, lies Nell Gwynne's hath. Having until very recently continued to serve their converted purpose, the frigid chalybeate waters, rising not far from the Fleet's course, were at one time sufficiently famous to give names to various thoroughfares and alleys in the immediate vicinity. Their specific virtues were first announced to the world by Mr. Walter Baynes, of the Middle Temple, who owned the property. His advertisement in the *Post Bag* informed his patrons that the best route thither for carriages lay through the notorious Hockley-in-the-Hole, at foot of Ray, or Rag, street. In or about 1697 he built, on what was then the open ground of Sir John Oldcastle's field, the three-gabled bath-house whereof a view is preserved to us in the little print published by A. Bengo in 1812.

THE demolitions we speak of in the foregoing paragraph will, in all likelihood, be followed by the destruction of the Clerkenwell House of Detention, which, together with its site of about two acres, is now offered for sale. This prison was erected in 1845-47, to replace the "New Prison," which had been rebuilt in 1774-5, near to the Old Bridewell, by William Moseley, architect. The original plan consisted of four arms radiating from a common centre. To these a fifth floor was subsequently added, with two more blocks along the south-eastern and north-eastern sides. The total accommodation is for 1,000 prisoners, male and female, under remand or awaiting trial. One can plainly see from within (as also from Corporation-row) the breach that was made in the back of the outer wall, opposite to the northern exercising-ground, at the attempt to rescue the Fenian prisoners, Burke and Casey, on December 13th, 1867. The signal was given by a woman from a house in Corporation-row, which overlooks the lofty boundary-wall. But some rumour of the attack had reached the governor's ears, and Burke and Casey were not amongst the exercising party at the time. Certain movable fittings have been despatched

to Holloway, Norwich, Liverpool, and elsewhere. The most interesting feature of the prison is the two-storied entrance-lodge by the main gates in St. James's-walk. This, we were told, is part of the original watch-house or lock-up. It contains an upper small apartment, now occupied as a bedroom, wherein Jack Sheppard was once confined before trial. If this be so, it may possibly form the scene of one of his celebrated exploits of prison-breaking.

THE habit of holding exhibitions of the sketches of this or that painter has one especial interest among others, that it sometimes serves to show more satisfying artistic qualities than are to be found in the same painter's more complete and larger works. Now Mr. E. H. Fahey is, in the oil paintings by which he is best known, one of the most mannered of contemporary artists, but in the series of small water-colour sketches from the Norfolk Broads, now on view at the rooms of the Fine Art Society, though this pervading manner is apparent enough, it is certainly not so pronounced or so mechanical in quality as in the finished works of the same artist; and there is more of the variety and individuality which comes of direct transcript from nature. The scenes are well chosen to convey an idea of the characteristic features of that very peculiar landscape (or waterscape). Among incidents which belong specially to the district are the immense boat-load of "Marsh Hay" (No. 9), and "The Winning Boat" (20), coming down one reach of the zig-zag river or canal, while the sails of the other yachts are seen across the land pursuing the opposite direction on another reach of the stream. The whole collection is of great topographical interest, and exhibits much refined and delicate work of its kind, though it cannot be said to belong to the highest order of landscape painting.

ONE must be thankful for small mercies when Government Departments deal with anything of an artistic nature. It would, therefore, be captious to complain of the tasteless colouring and bits of weak and meaningless design to be seen in some of the recently introduced postage stamps. It is a great gain that the insipid lilac which pervaded the last set appears only in two or three of this one. The twopenny stamp is distinctly good, and so is the colouring of some of the others, notably the bright red of the halfpenny, especially on a considerable field of white, but the zigzag margin line of the latter is nothing short of ridiculous. As to the unaltered penny stamp, no amount of getting accustomed to it will prevent our giving an occasional regretful thought to its old brick-red predecessor.

A WOULD-BE witty evening journal makes wondrous merry over its original discoveries,—by the aid of Professor Middleton's lectures,—in the domain of architecture. These discoveries are that the dado is no modern invention, but "was in fashion nearly two thousand years ago," and that the Romans were "jerry builders," to the extent of venerating some of their massive walls with thin slabs of marble. Would our esteemed contemporary be surprised to hear that the origin of the dado may be referred at least to the date of the erection of the ancient palaces of Assyria, and that a good proportion of the Roman "jerry buildings" in question have been "substantial and lasting" enough to stand "nearly two thousand years"? It is true that much of the marble was but a casing, and has disappeared, but that is a fact which few persons who had ever seen such a building would be disposed to doubt, even if there were no Slade Professor to give them the information.

**Iron, Hardware, and Metal Trades' Pension Society.**—The thirty-first annual ball of this charity was held at Willis' Rooms, on the 10th inst., under the presidency of Mr. D. W. M'Innes, of the Carron Company, who was assisted by numerous stewards representing the various branches of the trades throughout the kingdom. The attendance numbered 300 persons.

#### ON THE WORK OF SOME UNKNOWN DESIGNERS.

FROM the known we must plunge our readers hack once more into the region of the unknown. We present them to-day with a series of sketches of designs, all of great excellence and some of the rarest beauty, the names of whose authors are not only wrapped in oblivion, but the object of whose existence can only be the subject of conjecture. With regard to all the works which we have hitherto examined the purpose for which they were created has been sufficiently clear. We have seen how some designs were made expressly for tradesmen's catalogues, and how these artistic catalogues were issued by jewellers, goldsmiths, locksmiths, and gunsmiths alike, in a kind of friendly rivalry, each striving to raise his own wares to the highest pitch of artistic excellence. Then, again, we have seen how a goldsmith would publish a book of ornament pure and simple, with no mercenary object in view, but merely from a desire to improve the standard of work in his own craft by instilling first principles into apprentices; and yet, again, there have been books published by artists who were not craftsmen themselves containing suggestions for those who were. In our next article we shall deal with some of the numerous books of grotesques which were published for the amusement of the world at large of the sixteenth and seventeenth centuries. But the engravings which we have now before us owe their existence to something higher than a mere sordid desire to attract purchasers; they were designed and executed out of the purest love for the art, and are invested with the charm which is inherent to all labours of love. They are simply decorative engravings, and stand on a par with those other engravings of Scriptural, historical, and fancy subjects with which the art life of three or four centuries ago was enriched. All the specimens which we have seen of the ornamental work of this period seem to have been published simply as engravings, and do not appear even to have been incorporated in books, either on friezes or tailpieces. It is just possible that some of them may have been intended as name-plates; for example, the quasi-heraldic device (fig. 3) or the V (fig. 4); but even this is doubtful, and there is nothing left for us but to imagine that they were designed for the love of the art of designing, and for the love of that art alone. The first two illustrations (figs. 1 and 2) which we give are photographic reproductions, and show both the actual size of the original plates and the style and manner in which they were engraved. The remainder of our illustrations are reproductions of sketches in which the style of the engraving is lost, but in which the design itself is preserved with great fidelity.

Apart from the very great beauty of these two engravings, the point to which we specially desire to call attention in connexion with them is the lesson they teach with regard to the shading and embossing of ornament generally. We need not recur to what has already been said as to the necessity, in criticising any design on paper, of first ascertaining whether we are looking at the actual design in the condition in which it is intended to remain, or whether we have only a drawing or representation of the design as it will appear when it comes hereafter to be wrought in wood, stone, or metal, or in the softer fabrics. The designs which we have now before us are clearly not intended to represent the effect of any carved or wrought work, but are simply the ornamentation for the small surfaces on which they are graven; for although the leaves are shaded, yet the flatness of the surface is not destroyed, and the appearance of actual embossing is nowhere given to them. They will serve us, therefore, as excellent examples of the due limits which should be set to shading in decoration.

In dealing with this question it will be necessary, however, to bear in mind some of the first principles of the art. In the first place, let us imagine a surface which has to be relieved of its monotonous uniformity by means of ornaments placed upon it. The simplest possible form in which this can be done is by the use of lines of uniform thickness arranged in some graceful form: a good example of this style will be seen in one of Michel Le Blond's knife-handles (fig. 8 in our issue of January 15 last). A more elaborate, but equally severe, style is based on the use of lines of varying thickness, as in the patterns known by the names of arabesques: of this style the panels by Gentsch

\* See *Builder*, November 29, 1886.

JANIE

and the tablet by Brentel (figs. 10, 11, and 12 in our issue of January 15 last) are as fine examples as could be found. The third style is less severe than the two preceding ones; its characteristic is the adaptation of the lines of ornament to some form suggested by nature—the process, in fact, which we call conventionalising; in this style the lines used are not only of varying thickness, but take the form of leaves and flowers. Referring still to our issue of January 15, Le Blond's small circular panel (fig. 19) will serve as a good example of this method. But, so far, we have got nothing beyond a flat ornament on a flat surface; and the question which then presents itself is, have we in these three styles, with any modification or amplification of them which can be devised, exhausted the resources of decorative art? Is the whole field of ornament quite covered? Will the next step take us across the line and plunge us at once into the domain of representative art? Experience shows us that there are still resources left untried, that the field is but half explored, that there remains on that side of the line which belongs to decorative art an abundance of space for the invention of another class of ornament of a peculiar fascination and grace, though of a much less severe character than even the third of the classes already mentioned. In this class not only is the form of natural objects conventionalised, but also their structure and appearance. How is this done? Now it is absolutely necessary that one further point should be clearly understood. If any one thinks that, say, a dessert-plate is a good or convenient place on which to have painted a lily or a rose, let him have as many such dessert-plates as he is pleased to pay for, by all means; if another should think, as many a very few years ago seem to have thought, that a wall-paper is a fitting place on which to have painted bunches of flowers tied up in nosegays with beautiful streamers, or the semblance of a trellis up and on which many plants of ivy grow and cling, let him by all manner of means cover his drawing-room walls, and ceiling too for that matter, with the nosegays, and his dining-room with the trellis and the ivy; but if either of our imaginary friends does thus think, let him, in Heaven's name, have his roses and lilies, or his nosegays and ivy, painted with at least a moderate degree of accuracy. We will not be exacting, we will ask only for moderate accuracy, but if he will not meet us to this extent let him not, if we declare him to be one without taste, to be one without a shadow of an idea of the meaning and function of decoration, turn round upon us with the exclamation that we who have severely criticised his dessert-service and his wall-papers are enthusiasts for principles which have no separate existence from our own brain, or (as some who are old enough art-critics to know better have said) that we are mere harmless devotees of line for line's sake.

The answer to the question how the structure and general appearance of a natural object is to be conventionalised, as well as its form, seems to depend on the further inquiry, how its structure and appearance are conveyed to the eye? Obviously by means of lines and shadows: the lines we have already dealt with, the shadows alone remain to be considered; these must also be treated in a conventional manner. The method of doing this must depend on the materials used. For work in colour the old mural painters show us how this can be most effectively done: instead of letting the colours gradually deepen from light to dark, they adopted the plan of using three or four distinct shades of the colour, and laying them on separately one on the top of the other, allowed each shade to terminate abruptly in a hard line. Almost any piece of early illuminating will furnish an example of this method, and one or two capital letters in which the stems are treated in this way are to be found in Owen Jones's "Grammar of Ornament" (plate lxxi.—Illuminated MSS.—notably the letter N there given). This method, easy enough with colour, is, of course, inapplicable to engraving, but the best way of dealing in a conventional manner with shading in black and white ornament is to be seen in the two facsimiles given in figs. 1 and 2: practically only the deepest shadows are indicated, the curvature of the foliage being obtained by a very few curved lines springing from the structural base of the object, and shortening as they extend outwards. In this simple way the actual curvature of the leaf is indicated, but without any approach being

made to an accurate representation of the real lights and shadows which play upon the leaf in nature: the similitude of an actual plant twined over the surface is nowhere aimed at, but the surface itself on which the ornament is placed is preserved, and is as present to the eye as it was before the ornament was put upon it, though its harsh and unpleasing monotony is broken up with graceful forms.

In an earlier article we have said that most of the engravings which we have sketched to-day might be attributed to a school which might fittingly be called "The School of Gentsch." The two plates undoubtedly his which we gave in our issue of January 15th, are the only ones which bear any known monogram. Those which we give to-day vary considerably in style, and are many of them inferior to his plates, but there is a strong family likeness between them all in the manner in which they are executed, and there can be little doubt that the same influences which impelled his hand impelled also those of the designers of most of the others. Such influences are, within certain limits, eminently local and co-eval. His two charming arabesques, which we have already referred to, point to him either as the master whose spirit the others, the now nameless ones, caught; or as the most successful exponent of the spirit in which they also worked. The small plate which bears a capital V (fig. 4) is in much the same style, and may have come from his hand, unless it be by the same designer as fig. 5. The monogram on this plate is usually read A. S., but this is probably a topsy-turvy reading of V. S. or S. V.; if this be so, the V-plate might also be attributed to the same man with safety, and the monogram could then appear to be S. V. If this should not be correct, the V. S. must not be confounded with the monogram of Virgilius Solis, between whose work (to be noticed in a subsequent article) and this plate there is nothing in common. The V does not give the impression of forming part of an alphabet, though it might, as we have said, possibly be the initial for a hook-plate; it certainly looks as though it were the initial of the inventor's name.

The remainder of the sketches will appeal to our readers without any special comment on our part.

The last illustration of to-day's article, the lovely scroll, fig. 6, stands by itself apart from the series of engravings we have just been dealing with, both in style and in method of execution. It is probably of very much earlier date, but its authorship is absolutely unknown. To our mind, it is one of the most beautiful pieces of decorative art that we have ever seen; in fitness and firmness of drawing, in implicit obedience to every canon of the art, it stands alone among its lovely companions in the British Museum collection, the loveliest of them all; nor is there any other plate which gives us the slightest clue to its history or origin. We must leave it as it stands to appeal to our readers, as we think it should, as the most perfect and beautiful expression of all that is good in one of the most beautiful of the arts.

The following sketch is one of the series of cups designed by Carravaggio, which we refer to in our issue of January 22, and of which we promised our readers a reproduction in a subsequent article.

**Lifts.**—Messrs. Archibald Smith & Stevens have been instructed to supply one of their improved hydraulic lifts for Messrs. Lloyds, Barmett, & Bosanquet's new bank in Lombard-street. This lift will run through the entire height of the building.

#### THE METROPOLITAN BOARD OF WORKS AND LONDON THEATRES.

The Bill introduced by the Metropolitan Board of Works for the further regulation of theatres provides that the Board shall every year cause an inspection to be made of all licensed theatres and music-halls, with the exception of such of the latter as contain a superficial area for the accommodation of the public of less than 500 ft., and if the result of such survey is satisfactory the Board shall grant a certificate to the person by whom such theatre or music-hall is kept open.

Certificates under the Act shall be granted not later than the 1st of July in each year, and the Board may, with the approval of the Home Secretary, fix a charge for the same. In the case of the Board refusing to grant a certificate, the person aggrieved may appeal to the Secretary of State.

No alterations may be made in the structure of any theatre or music-hall without the consent of the Board, and penalties are provided for any infringement of the Act.

Any premises kept open as a theatre or music-hall after the Board has refused to grant a certificate, or a certificate has been cancelled, shall be deemed to be unlicensed, and shall be liable to the penalties attaching thereto.

The Board may serve notice upon the manager of any theatre or music-hall requiring him to comply with any regulations the Board may make with regard to appliances for the extinction of fire, the keeping of the gangways and staircases free from seats, persons standing, and all other form of obstruction, and the provision of oil lamps and candles in theatres and music-halls, and the exit corridors therefrom for use in the event of the extinction of gas.

The Bill was brought in by Sir James M'Garel Hogg, Mr. Tatton Egerton, and Mr. R. G. Webster, and the second reading is fixed for the 9th of March.

The Bill was framed before the occurrence of the lamentable disaster in Spitalfields, and it is possible that if it had been framed since that event it might have been of a more stringent character. It will be seen at once that as the Bill now stands it will be inoperative as regards the Hebrew Dramatic Club and similar establishments, notwithstanding the Home Secretary's declaration to the contrary in answer to a question by Mr. Isaacson in the House of Commons on the 10th instant, the operation of the Act being confined to licensed premises. The dual control of the Lord Chamberlain and the Metropolitan Board of Works in the case of theatres, and of the Justices and the Board in the case of music-halls, will be continued. The inconvenience of this condition of affairs has been repeatedly pointed out, and calls for a remedy. The simplest plan of dealing with all places of public entertainment would be to make the inspecting authority the licensing authority also, and this might be done by transferring the licensing power from the Lord Chamberlain and the Justices to the Metropolitan Board of Works or the new Municipality for London.

#### LECTURES ON ARCHITECTURE AT THE ROYAL ACADEMY.

METHODS OF DECORATION AS APPLIED TO ROMAN BUILDINGS.

On the 11th inst. Professor J. H. Middleton, of Cambridge, delivered his second lecture of the present course\* to the students of the Royal Academy, taking as his subject, "Roman Houses and their Decoration." In his prefatory remarks he pointed out that subsequently to the early "feudal" period of Greece, there was no age of anything like equal splendour in the decoration of houses until we came to the early years of the Roman Empire. In the most flourishing period of Greek art, architectural splendour was devoted to sacred purposes. Throughout the Republican period of Ancient Rome the same was the case, and as late as the days of Julius Cæsar anything like magnificence in a private house was viewed with extreme jealousy by the Roman people. But fifty years later all was changed. Augustus encouraged the use of marbles, and the erection of splendid buildings of every kind, and in his reign the house of almost every rich

\* For an abstract of the first lecture, on "Methods of Decoration as applied to Greek Buildings," see last week's *Builder*, p. 248.

century began to be decorated in the most costly and elaborate way. One of the characteristics of the houses in Rome itself, beyond those in other parts of the Roman domain, was the magnificent way in which the walls of the rooms and courts were lined with costly foreign marbles and porphyries, of rich and varied colour, brought from countless quarries in Northern Africa, Arabia, Greece, Asia Minor, and other far-distant portions of the Roman Empire. Great skill was shown by the Roman marble-masons in the way they cut and polished not only slabs and columns, but even delicate mouldings in the very hard red porphyry of Egypt, and the green porphyry of Sparta, which a modern marble-mason would declare to be unworkable. The skill of the Romans in this respect appeared to have been derived from Egypt, where the use of the tubular drill set with jewels, such as rubies or corundum, was known as far back as 4,000 years B.C. Marks of such drills, and of saws set with similar jewels, were still to be seen on the hard granites and porphyries used in Rome. By the use of the saws such refractory materials as those referred to were cut with comparative rapidity into slabs of wonderful thinness and evenness. The Romans were always seeking to make the greatest possible display at a given cost, and veneers of the porphyries were found having only a thickness of  $\frac{1}{8}$  in. There was no known example extant of a Roman room with its decorative marble lining still complete, but the broken fragments which had been found, aided by the impressions of the marble-work on its cement backing, helped us to make out the usual scheme adopted, which, supposing marble to have covered the whole wall, seemed to have had a strong general resemblance to the designs of the wood panellings which were used by Wren, and his pupils and followers in the first half of the last century. There was a dado, with a moulded skirting below it; the skirting was 12 in. or 14 in. high, while the capping of the dado was 3 ft. or 4 ft. above the floor. At the ceiling line there was a deep cornice, the intermediate wall-space being divided into panels. Marbles of various colours were used to strengthen the effect of each line and moulding. Great pains were taken to polish the whole marble surface to the highest possible degree, so that the effect of one of these rooms, with its strong contrasts of vivid colours and reflective brilliancy of surface, must have been more magnificent than artistic. In some cases the marble linings were used in a less simple way, series of columns, free or engaged, being ranged along the walls, the intermediate spaces being broken by semi-circular niches filled with statues. Having described the way in which the marble linings were affixed to the walls by means of iron or bronze hooked clamps, the lecturer passed on to speak of mosaics, which were largely used for Roman houses, not only for floors, but also for the decoration of walls, vaults, and ceilings. Probably no mosaic now to be seen in Rome dated from an earlier time than the middle or end of the first century B.C. The earliest were those in the Regia, in the so-called house of Livia on the Palatine, and the fragments in the *cella* of the Temple of Castor. These were very different in style from the later mosaics of which so many examples still existed. Simple geometrical designs were used, with scarcely any variety of colour, the pattern being grey on a white ground. The tesserae were smaller and much more neatly fitted than in the later mosaics. Indeed, as time went on, both the design and the execution of Roman mosaics became steadily coarser, while richer and more varied materials came to be used, until in the reign of Severus, at the end of the second century, mosaics in Rome had become large, gaudy, and devoid of any artistic quality. As the art of the mosaicist declined, and became feebly pictorial,—marble would no longer supply sufficient varieties of colour, and so tesserae of brilliant glass were introduced, at first mixed with the marble, and then by themselves. These sparkling jewel-like mosaics were mainly used for the decoration of walls and vaults, but sometimes even columns were encrusted with them, producing a startling splendour of effect, such as no other method could surpass. Stucco reliefs were also used by the Romans for the decoration of walls and ceilings. The best of these were by far the most artistic among the methods of decoration used in Rome, the more especially as the finest examples had nothing whatever that was Roman

in their design or treatment, but were really pure Greek work, such as would not have disgraced the school of Praxiteles or Scopas. Some of the best of the stucco reliefs in question were made thus:—Four or five coats of stucco were applied to the brick facing of the wall after it had received its usual studding of metal plugs. The first coat was made of coarse *pozzalana* and lime; the next coating was compounded with finely-sifted *pozzalana*; the third coat was of pounded marble; the fourth was of marble in finer particles; and the finishing coat consisted of pure white marble-dust mingled with lime and a little size or fig-tree sap. This set slowly to a surface as hard as marble, and almost like ivory in colour and texture. But before the final coat had set, a sketch in outline of the design was incised with a pointed tool upon the soft surface; the artist then mixed some of the marble-dust stucco into a plastic mass, and applied it in lumps on to the level surface within the sketched outlines. Then rapidly, before it had time to harden, he moulded the work into shape with his fingers and thumb, assisted by a few modelling tools. Very little after-touching seemed to have been needed. The decision and rapidity with which the work was necessarily executed resulted in imparting to these reliefs a vigour and life such as could perhaps never have been given by the slow chiselling of a hard substance. It would be difficult to find any other examples of art which showed so strongly a combined high training of hand and eye. Rapid as must have been the execution of these reliefs, the modelling of the nude showed a very complete knowledge of human anatomy. When they had set hard, the reliefs were coloured, gilt, and silvered, not coarsely all over, but with much skill, so as to increase their decorative effect without vulgarising the figures by any attempt at realistic colouring. Professor Middleton devoted the remainder of his lecture to the subject of mural painting. He said that in Imperial times wall-painting seemed to have been left to an inferior class of house-decorators, who, though possessed in some cases of very remarkable technical skill, were not original artists of a high class. We found constant repetitions of the same composition, so closely followed as to show that the wall-painter was not in the habit of producing designs of his own. Moreover, we found a certain equality of merits and defects in the paintings of quite humble houses and Imperial palaces, which would not be the case if it had been the custom for the famous artists of the time to produce wall-pictures. In most cases the great manual skill of the painter was shown rather in the way in which he produced rich and striking effects at a small expenditure of labour than in any serious and carefully-studied excellence either of drawing or finish. In the main, the mural paintings of ancient Rome had the merits and the defects of theatrical scene-painting: they were to be regarded as part of the whole scheme of decoration in each room, and not, as a rule, to be examined for their own sake. Information as to the technical methods of painting used by the Romans was to be found in Vitruvius. The processes used were very varied, and included tempera medium, varnish medium, fresco *humo*, and encaustic. These were severally described by the lecturer, who referred in conclusion to the Pompeiian wall-paintings.

#### METHODS OF DECORATION USED IN ENGLAND DURING THE THIRTEENTH CENTURY.

THIS was the subject of Professor Middleton's third lecture, delivered on Monday evening last. He observed that much had been said and written about the Renaissance of art in Mediæval Italy, but he wished to say something about the very interesting but much neglected subject of the Renaissance in England,—a movement which, on the whole, began earlier than in Italy, was quite independent of it, and during its earlier and most flourishing period produced works of art in many branches, sculpture, painting, and metal-work, which on the whole were superior to anything that the Italian artists of the same time were able to produce. To that statement there was one reservation, and that was with regard to the Pisan sculptor Niccola, who in 1260 carved the great Baptistery pulpit. That wonderful genius, born out of his due time, was a quite exceptional person in Italy, and it was not till some years after the end of the thirteenth

century that any of his pupils showed knowledge or skill at all equal to that of their master. Niccola's son Giovanni was far inferior, both in sense of beauty and power of plastic simplicity of design, to our English sculptor William Torelli, the London goldsmith, who modelled and cast the beautiful effigies of Henry III. and Queen Eleanor, which still existed in the Confessor's Chapel at Westminster. That wonderful period of English art, during which the artists of England were unrivalled in the world, began with the early part of Henry III.'s long reign of fifty-six years (1216–1272), and lasted in full glory till the beginning of the following century. After that its development was checked, owing to a series of causes, among which the most obvious were the Black Death, which devastated the country more than once during the fourteenth century, and the disturbances and preoccupations of mind which resulted from the Wars of the Roses. Apart from its interest as the birth-time of the new life of art, the thirteenth century was a very momentous one in England, no less than in Italy, for it marked the transition from the old system of feudalism to the modern one of individual rights and liberties. A striking feature of the period was the growth of the various art and trade guilds, which had very important effects both in art and politics. In matters of art the formation of the guilds led to the creation of a superior class of artists, and by degrees took such branches as painting, sculpture, and metal-work out of the hands of the monks, who had previously to some extent monopolised them. The secularising of the artist was a distinct gain, and helped the world to free itself from the dull hieratic formalism of Byzantine tradition, which had for so long prevented any progress towards the growth of a really living art in any branch of work. Any study of the beauties of the human form had hitherto been forbidden to the monkish artist as a snare of the Evil One and a lapse towards the errors of paganism. The secular artist soon threw off such deadening influences, and though for some centuries he continued to work under the influence and mainly in the service of the Christian faith, yet he could not be prevented from pressing sensual beauty,—the true scope of art,—into the service of his nevertheless purely religious painting and sculpture. In another way the art-guilds were of service to the interests of art; they provided for the careful training and long probation of large classes of art-apprentices, and their governing councils were very strict in keeping their members up to a high standard of excellence, both in workmanship and materials used. The painters' guilds, for example, fined the master-painters if their drawing was judged to be faulty, or if they used inferior materials,—such as impure gold or silver leaf, bad flesh-tints, or second-rate azure, and for any carelessness shown in allowing "knots" to show through paintings on panel. One of the chief causes of this brilliant, though brief, period of England's supremacy in art was the enthusiastic way in which Henry III. devoted an unsparing amount, both of time and money, to the production of works of art of all kinds. In all parts of England new palaces were built, and covered with sumptuous paintings. The chief among the many artistic glories of Henry III.'s reign were the creation of the magnificent royal Palace of Westminster, the rebuilding of the greater part of Westminster Abbey Church, and the making of the wonderful gold shrine for the body of Edward the Confessor, the mere inventory of which, by its list of gold reliefs, gold statues set on and around the shrine, and the great sapphires, rubies, antique gems, and other precious stones which studded every part of it, reminded one of a story out of the "Arabian Nights." Of the gold shrine nothing but its imagination-dazzling catalogue now remained. Westminster Abbey, on the other hand, being so well known to his audience, Professor Middleton said he would select for description some of the mural decorations from the Royal Palace at Westminster, some notion of whose splendour might be gleaned from a few fragments saved from the fire in 1834, aided by the very interesting series of accounts which were now preserved in the Record Office, and also by some careful copies by Stothard (lent by the Society of Antiquaries) of the few paintings that survived till the present century in one of the great halls of the palace. No mere painting, how-

ever beautiful, could have had the rich decorative effect of the walls of the palace; the very exceptional splendour of the work was produced by a combination of painting and relief, which was practised in England at that period in a much more complete and skilful manner than was ever done in Italy. The walls of the chief halls were lined inside with fine ashlar stonework, over which a very carefully-prepared coat of thin plaster was laid: a fine mixture of gypsum and size, with in some cases a proportion of whitelead, which set with a hard smooth surface, very like the beautiful stucco which was used by the Greeks and Romans, and quite unlike the soft, spongy, rubbishy stuff which was now used for the internal plastering of houses. When the thin layer of plaster was dry, the outlines of the picture were lightly sketched in with a fine brush in red or brown, or else with red chalk. The next step was to apply the ornament in relief, such as diaper backgrounds, rich patterns on the dresses of the figures, crowns, sceptres, hrooches, and other ornaments, and especially the main lines of the gables, arches, and other parts of the various buildings which formed the background of many of the pictures. All this ornament in relief was formed by applying a fresh skin or thin layer of the finest stucco in the proper spaces, and by stamping it while soft with very minutely-cut wooden dies or stamps, executed with the delicacy of a cameo or engraved gem. The detail of this ornament was in many places so minute in its richness of design that the full beauty of the pattern could only be made out by a very close inspection. When the stamped reliefs had set hard they were covered usually with thick gold or silver leaf, and then further decoration was added by painting in transparent oil-colours (especially in crimson lake) over the gleaming gold surface of the reliefs. The gold leaf used was very much thicker than modern gold leaf, and was proportionately costly, while the cost of the wall-paintings was materially added to, owing to the necessity of drying the oil-colours with braziers of charcoal, for "driers" were not then known. For this reason, it was only in portions of the pictures that oil-colours were used, the other parts being in tempera. The artists were usually paid a fixed sum for their labour and skill, all materials being found, and very commonly, hoard and lodging in part of the royal palace. The usual pay of an artisan in Henry III.'s reign was what would now be equal to about 3s. 6d. a day, with hoard and lodging, or 5s. per day without. The painter was paid at a higher rate. The usual wage for skilful but not distinguished artists was from 6s. to 7s. a day, and that was what the majority of Henry III.'s painters received. A more distinguished artist, like William of Westminster, a Benedictine monk, was paid about 30s. a day; and the architect of Westminster Abbey, Edward Fitz-Otho, had special favour shown to him, besides being paid a very liberal salary. He had a set of rooms in the Palace, and the king granted him a lead pipe the size of a quill to carry water to his rooms from the Palace conduit, — a remarkable favour at a time when it was very rare for secular houses to have water laid on to them, though the richer monasteries were usually well supplied. In conclusion, the lecturer described the Palace of Westminster (the general arrangement of which, he said, was well shown in a drawing\* by Mr. H. W. Brewer) and its decorations, and said a few words as to the decorations and artistic objects of the sanctuaries of many thirteenth-century churches, which must, in some cases, have looked rather like museums of valuable curiosities.

**Failures in the Building Trade.** — According to *Kemp's Mercantile Gazette* the number of failures in England and Wales gazetted during the week ending Saturday, February 12th, was 111. The number in the corresponding week of last week was 85, showing an increase of 26, being a net increase in 1887, to date, of 58. We regret to notice that, on the same authority, the number of failures in the building trades during the week was 17, as against five and nine in the corresponding weeks of 1886 and 1885 respectively.

\* The drawing exhibited by the lecturer was the original of the illustration entitled "Westminster in the Time of Henry VIII." which appeared in the *Builder* for Nov. 15, 1884.

## Illustrations.

### SKETCHES IN FRANCE.

#### AN OLD HOUSE AT ROUEN.

 IN a small garden just off the Rue Jean d'Arc stands the tower of St. André, and behind this tower, hidden up in a corner, is the front merely of a house which once stood in the Rue Grosse Horloge. Who will venture to say how many modern works have owed some portion of their design to this small building? What a familiar feature is the window in the gable! Be that as it may, there is much that is suggestive in the whole front, and it was a happy thought on the part of its owner thus to preserve it, when circumstances compelled its demolition where it originally stood. It is constructed entirely of wood, and either time has dealt very leniently with it, or it has undergone a most judicious restoration, for the appearance is rather that of a house just built, than of one nearly three centuries old.

#### CHURCH OF NOTRE DAME DE L'ÉPINE, NEAR CHALONS-SUR-MARNE.

The church of Notre Dame de l'Épine, near Chalons-sur-Marne, which has been declared a "monument historique," possesses two open spires of great beauty,—quite a rarity in this part of France. It is said to have been designed by an English architect, and Ferrusson compares it to St. Mary Redcliff. The plan is that of a Latin cross, with nave and choir of nearly equal length, and with boldly projecting transepts,—this latter being certainly an English feature. The church is groined throughout, and the aisle is continued round the apse, which is formed in three cant. The flying buttresses surrounding the choir are sculptured with most comical and amusing grotesques, thoroughly French in their detail, as indeed is the whole building, notwithstanding its English origin. The windows, however, more nearly approach the English Late Decorated in their tracery and general form than any French example, but examination of the mouldings and other details unmistakably proclaim a foreign workmanship; and the curious western porch, surmounted by a great Crucifixion in full relief, is unlike anything to be met with on this side of the Channel. The tower differs slightly in design, the southern being larger and more important than that on the north, which latter has recently been rebuilt. For many years this tower was used as a telegraph station, the spire having been taken down to accommodate it to this novel purpose. Happily, better days have dawned; all signs of posts and signals have vanished, and the church, now in its restored condition, presents a striking contrast to the miserable hamlet in which it stands.

#### DESIGN FOR A SUBURBAN CHURCH.

This design, prepared by Messrs. Thos. Garratt, of London, and J. C. Carter, of Cardiff, in competition for a large church in the suburbs, where economy was an important condition, shows an attempt to gain effect in the simplest possible manner. It was intended to be built of grey stocks, with red brick dressings, and a sparing use of stone in the windows, strings, &c.

The nave and chancel being of the same width, a large arch is thrown across the transepts in continuation of the nave arcade.

A hoarded barrel roof is carried through the nave and chancel at the same height, the former having principals showing, whilst the latter is panelled out with longitudinal and transverse ribs, and a simple wooden vault formed over the crossing.

Externally the nave clearstory is arcaded. The chancel has its clearstory arcaded internally, arranged in connexion with the five-light window at the east end, below which there is space for a large reredos.

The clergy and choir vestries are placed on the north side of the chancel, and an organ-chamber and porch on the south side, the latter to be used as an exit supplementary to the large western porch. The baptistery is at the west end, near the entrance.

The choir seats are arranged so that communicants could return to their seats by the passage behind them.

There is seating accommodation for 831, to

which, on special occasions, chairs could be added to a considerable number.

THOS. GARRATT.

#### NEW OFFICES, LEEDS.

THESE buildings are being erected for the *Yorkshire Post*, a well-known Conservative daily in the north, for the accommodation of the advertising department. The large room on the ground-floor will be fitted up in the most finished style, with furniture from the architect's designs. The walls, and probably the ceilings, will be lined with Burmantoffs' valence in colours. The whole of the front externally is of Ruabon red bricks, with terracotta dressings. The architects are Messrs. Chorley & Connon, Leeds, and the contractors Messrs. Franks & Evans, of the same town, Messrs. Wilcock & Co. having supplied the terracotta. The building shown in the view and plan forms only the street front to extensive premises behind, in which are accommodated the printing, editorial, and other departments, all of which have been carried out from the designs of the same architects.

#### LANTERN TOWER, PERSHORE.

THIS tower is a remarkably fine example of early fourteenth-century work. It consists of two stages, built on the original Norman arches, the lower stage being open to the church, and the upper forming the belfry. The late Sir G. G. Scott inserted a ringing-gallery in the lantern (omitted in the drawing), which is approached from the upper passage. There is a notable absence of ornament, the ball flowers on the two external strings and on the hand of panels of the lantern inside being the only carving in the work. The upper portions of the pinnacles are restorations. This drawing was one of those for which a certificate of honour was awarded in connexion with the Page's studentship this year.

#### BASINGSTOKE BOARD SCHOOLS.

The foundation stones of these schools were laid in November last by the Chairman of the Board (Mr. G. Dunn) and Major May, the Mayor of the Town.

The schools are planned in three departments,—the boys and girls in one building, and the infants in another. They accommodate respectively 900 and 400; total, 1,300. The site is over one acre in extent, and occupies an elevated position, with frontages on three sides to roads. The boys' and girls' schools have each a central hall, with class-rooms opening out of it for sixty children. The infants have all their rooms on one floor, and the sexes are divided equally. The playgrounds are spacious, and with a sunny aspect, with sheds on one side. The schools are built of red local brick, with flint facings above the plumb line. The roofs are tiled. The large school will be heated by hot water, and ventilated on an improved system,—a shaft for this purpose being provided 70 ft. high. The infant school will have open fires. The architect is Mr. Charles Bell, F.R.I.B.A., of Dashwood House, London; the builder, Mr. Goodall, of Basingstoke; and the clerk of works, Mr. G. W. Bery. The contract is 10,351l., and it is expected the works will be completed in the autumn.

**Surveyors' and Auctioneers' Clerks' Provident Association.**—The third annual meeting of this Association was held on Saturday last at the registered office, the Auction Mart, Tokenhouse-yard, Mr. G. Haines (Messrs. H. Haines & Son) presiding. The report and financial statement (to which reference was made in the *Builder* three weeks ago, p. 205) for the past year were agreed to and adopted, and the officers re-elected for the current year. The chairman said it was a matter for congratulation that the Association was in a successful position, financially, though he regretted the number of members was not considerably larger. He hoped all interested would do their best to extend the usefulness of the Association, which was established for the objects of granting allowances to members in sickness, life assurance, and superannuation. A vote of thanks to the annual subscribers was passed, and also to the chairman for presiding.

THE EDINBURGH MUNICIPAL BUILDINGS COMPETITION.

The exhibition of the designs sent in to this competition was opened on Monday, but we defer a detailed notice of them until next week. The designs will remain on view for three weeks longer.

The Edinburgh papers state that Mr. Waterhouse has provisionally approved of the six designs bearing the following mottoes, viz.—“Edina Classica” (estimated cost 98,000L.), “Fortuna” (125,000L.), “In my Defence” (102,000L.), “Light and Air” (75,000L.), “Nineteenth Century” (120,000L.), and “Ora et Labora” (280,000L.). It will be seen that there is a wide margin of cost between the estimated cost of the last-named design and the one marked “Light and Air.”

The Scotsman gives the following list of the other designs submitted, with the estimated cost of each, viz.—“Fiat,” 125,000L.; “Kathleen Mavourneen,” 130,000L.; “N.D.I.V.” 120,000L.; “Rathhaus,” 170,000L.; “Virtus in Ardis,” 98,011L.; “Olympus,” 150,564L. 6s.; “Am Freiceadan Dubh,” 127,500L.; “Iona,” 100,000L.; “Line upon Line,” 102,000L.; “Crevecoeur,” 66,000L.; “Golden Star,” 135,000L., including 4,000L. for statuary; “Waverley,” 110,000L.; “St. Giles” (1) 170,000L., “Quien Sabe,” 151,000L.; “Si Monumentum Requirit,” 140,000L.; “Excipere Laboravi,” 132,800L.; “Fors,” 128,000L.; “Scotia,” 120,000L.; “Municipalis,” 165,000L.; “The Heart of Midlothian,” 80,000L.; “Dora,” 160,000L.; “St. Giles” (2), 190,000L.; “Ravensraig,” 90,268L.; “Res Publica,” 116,560L.; “Fors,” 178,000L.; “Rex,” 112,000L.; “Finis Coronat Opus,” 137,258L.; “Tanma,” 150,000L.; “Civis,” 141,618L.; “Edina, Scotia’s Darling Seat,” 149,245L.; “Waverley,” 112,200L.; “Edina,” 79,580L.; “Baronia,” 80,000L.; “City Cross,” 126,400L.; “Tannahill,” 135,700L.; “Warriston” (1), 115,000L.; “Aihinis,” 118,000L.; “Dignity and Simplicity,” 135,000L.; “St. Andrew,” 120,741L.; “In My Defence,” 161,352L.; “Warriston” (2), 120,000L.; “Orion,” 150,000L.; “Experience,” 150,000L.; “Rob Roy,” 145,791L.; “For Queen and Country,” 150,000L.; “Heriot,” 121,537L.; “Jubilate,” 95,000L.; “Omega,” in cypher, 130,000L.; “Quadrangle,” 82,000L.

The Scotsman of Thursday says it is understood that Mr. Waterhouse, R.A., has given his decision, and that the Lord Provost on Wednesday received the assessor’s report. The Sub-Committee on the Plans, as also the Lord Provost’s Committee and the Town Council were to meet on Thursday, when it was expected that the contents of the report would be communicated to them. “Light and Air,” “Edina Classica,” “Nineteenth Century,” and “Fortuna” were generally spoken of as the likely designs to which the awards would be given.

By the courtesy of the Editor of the Scotsman, we learn by telegraph (just as we go to press) that the following are Mr. Waterhouse’s awards:—

- First, “Edina Classica,” author, Leeming, Westminster.
- Second, “Nineteenth Century,” author, Stark, Vincent-street, Glasgow.
- Third, “In My Defence,” (with heraldic device), author, Simpson & Allen, Strand.

Birmingham Architectural Association.

The seventh ordinary meeting of the current session was held at Queen’s College on Tuesday evening, February 15th. The Vice-President, Mr. John Cotton, was in the chair. Mr. E. F. Tibley was elected a member of the Association. Mr. E. Westwood was nominated for membership. A paper was read by Mr. E. R. Taylor (Head Master of the School of Art), entitled “Servants of Architecture.” The lecturer pointed out the necessity of all architectural students studying the art of modelling in clay in addition to the various branches of freehand drawing. A hearty vote of thanks was proposed by Mr. W. Donbleday, and supported by Messrs. W. H. Bidlake, T. Timmins, J. Cotton, and Victor Scrpton (Hon. Sec.). After a response from Mr. Taylor the meeting terminated.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

The sixth ordinary meeting of this Institute for the present session was held on Monday evening last, Mr. Alfred Waterhouse, R.A. (Vice-President), in the chair, in the absence of the President in Italy.

Obituary.

Mr. W. H. White (Secretary) announced the death of Mr. T. H. Sapsford, the City Architect of Sydney, New South Wales. Mr. Sapsford was only elected a Fellow at the last meeting of the Institute, and the letter announcing his decease was received two days after the notice of election had been posted.

The Royal Gold Medal.

The Chairman.—This being the meeting at which the proposal by the Council as to the Royal Gold Medal is announced, I will call upon the Hon. Secretary to read by-law 76, which affects the question.

Mr. Macvicar Anderson (Hon. Secretary) read the by-law.

The Chairman.—In accordance with that by-law, I beg to announce that the Council propose that the name of Mr. Ewan Christian, past-President, be submitted to her Majesty as that of a fitting recipient of this year’s Royal Gold Medal. (Applause.)

A Member.—Mr. President, I do not know whether I am out of order, but I cannot help expressing my feeling that a very worthy man has been passed over.

The Chairman.—I am afraid you are out of order. We cannot discuss the question to-night.

In reference to a complaint made that Mr. Ewan Christian had been prematurely mentioned in a Liverpool paper as the Council’s intended nominee for the Medal,

The Chairman remarked that the subject had been discussed at the Council that afternoon, and deep regret had been expressed by every member present that such a thing should have occurred.

Mr. H. Dawson considered that something more than a mere expression of regret was called for. This was a betrayal of trust quite unworthy of any gentleman.

Mr. Macvicar Anderson took the same view as Mr. Dawson, but the difficulty was to find the individual who ought to be censured.

Mr. Ralph Nevill thought that would make it all the easier to pass an expression of censure.

The Chairman added that a considerable amount of indignation was expressed at the Council meeting, and he did not believe the thing would occur again.

The matter then dropped.

The Imperial Institute.

Mr. Macvicar Anderson, the hon. secretary, next read a communication from Sir Frederick Abel, on behalf of the Prince of Wales, inviting the co-operation and subscriptions of the members in favour of the Imperial Institute. The Council had, therefore, ordered the communication to be read before the members, and to be published in the Journal of Proceedings.

The Liverpool Cathedral Designs.

A Member drew attention to the statement in the public press as to a certain memorial which had been circulated among some members of the profession in regard to the Liverpool Cathedral competition. It was desirable that it should be stated officially whether the Institute had put its hand to this thing or not, because it seemed a very dangerous precedent.

The Chairman replied that the committee in question had not yet reported to the Council on the subject. But that the Council had had the question forced upon its consideration, was evident from the fact that they had passed a resolution which would now be read.

Mr. Macvicar Anderson.—The resolution that the Chairman has referred to, which was passed this afternoon by the Council, is as follows:—

“Resolved, that a letter be addressed to the Builder and certain other newspapers, stating that the modified circular referring to the Liverpool Cathedral competition, which appeared in their last week’s issue, has in no sense been approved by the Council or the Competitions Committee of the Royal Institute of British Architects; and further, the Council feel very strongly that nothing should be done, by exhibition or otherwise, to upset an

\* The letter referred to, as well as one on behalf of the Competitions Committee of the Institute, will be found on p. 301 of this number.

award conscientiously arrived at by a professional assessor.”

Mr. Macvicar Anderson added that it was his opinion that the circular was one which should not have been issued. He threw it in the waste-paper basket when he received it, on the broad ground that the Liverpool Competition had been conducted in accordance with the recommendation that the Royal Institute of British Architects had promulgated, that no competition should be conducted without a professional assessor being appointed. He thought that for any members of the Institute to take such action as had been taken by the memorialists was simply an effort to make the Institute eat its own words.

Professor Kerr said he had signed the memorial merely because it seemed a courteous and business-like request to those in charge of this important national competition to allow the drawings to be exhibited in London.

Mr. J. P. Seddon remarked that he was rather in a difficulty because he had been out of town, and had not been able to see Mr. Scott, who had, however, written to say that he had modified the thing. He (Mr. Seddon) had not sent it until it had appeared in print,\* therefore he was rather in a difficulty as to making any explanation of the matter. He was ready, however, to support everything he had said in connexion with it.

Mr. Henry Currey, as the chairman of the Competitions Committee, said that the amended memorial had not been submitted to the committee.

Mr. Seddon added that he would not let the memorial go in until it had been again sent to the members who had signed it, giving any one liberty to withdraw. For his own part, he thought the whole action of the Competitions Committee most undesirable for the profession (laughter). Therefore, he maintained what he had done, but would withdraw it until each member who signed it knew exactly what he had signed for.

The Chairman said the members must be obliged to Mr. Currey and Mr. Seddon for their explanations, and they would at the same time feel that the Council had expressed itself strongly and fully in the matter.

Notes on Greek Architecture.

Professor T. Hayter Lewis, F.S.A., then read a paper entitled “Notes made during Tours in Greece, 1881 and 1884.” The Professor, after referring to his first visit to Greece in 1842, described what he saw there in 1881 and 1884. As the greater part of what had been uncovered had been admirably illustrated by the Society of Dilettanti and the Greek and German archaeologists, the Professor restricted himself to a general description, supplementing this with details of any of the remains which are more specially interesting by means of diagram drawings. He said that at Menidi, near Athens, is a remarkable circular tomb, of the bee-hive form so well known in Western Europe, 27 ft. in diameter and 23 ft. high. The courses of stone are built, not radiating, but having horizontal beds, as have all the other buildings of the same type known to the Professor. The most remarkable feature of this tomb is the peculiar construction of the masonry over the entrance doorway, which closely resembles that employed by the builders of the king’s chamber of the Great Pyramid. The Professor confessed that he did not quite understand the principle on which these successive lintels were erected, but thought that the intention may have been that, if the top one were broken, its two pieces would tilt down and be stopped by the next lintel, and, if that were broken, by the next one, the stonework above being wedged together into a solid mass as it followed the lintel. Two drawings of tombs, found in the old Athenian cemetery,—the Cerameicus,—were then referred to, and a third tomb, built of rough stones, having just the appearance of a dolmen, was more particularly described. The tomb contains two chambers, side by side, with a third cross-wise at the end. The total size is 9 ft. by 6 ft. Few discoveries of importance, as compared with those at Eleusis and other places, have been made at Athens; and, as such there are would probably shortly be described by Mr. Penrose, the Professor passed on to describe the group of buildings at Eleusis. The building first referred from the village is the little temple of Diana Propylea. This measures

\* See Builder, p. 268, ante.

about 24 ft. by 16 ft. internally, and only the foundations and pavement now remain. Its dimensions confirm the theory of proportions so ably worked out by Mr. Watkias Lloyd for Professor Cockerell. Beyond this temple is the Propylæum, built entirely of Pentelic marble, nearly as a copy of the centre part of that at Athens. Beyond this, again, is the gateway, called the inner vestibule, which gives access to the remains of the Temple of Ceres. There are scarcely any ancient descriptions of this building, owing to the dread entertained of incurring the anger of the deity by revealing any of its secrets. It is about 170 ft. square, exclusive of the portico. It was built on the side of a steep hill, and, quite exceptionally, the angles, not the sides, of the building, face the four cardinal points of the compass. The date of the erection and the architect of the temple are matters of doubt. The portico, which may be considered apart from the main building, is there can be little doubt, purely Greek in design and execution. The Professor thought it might be possible to reconcile the conflicting statements as to the architect of the *cella*, and that so celebrated an architect as Ictinus might have given the design, as consulting architect; the execution of the work itself being placed in the hands of Corebus and Metagenes. The late Mr. Fergusson supposed that the centre part of the building was originally left quite open, without the row of columns shown on the Professor's plan; and produced a most ingenious restoration, based on the meagre statements which we have from ancient writers. The Professor thought that this restoration must be accepted as the nearest yet suggested to the original design; but we were still left in doubt as to the mode of covering the central portion. All translators agree that Xenocles of Cholarus roofed, or domed, or arched, or completed in some way, the top; each employing a different word, and arriving at different results, according to his interpretation of the word *σπαιον*. The question is how was the work done? It might have been, the Professor thought, that the central portion had originally been left open, as suggested by Mr. Fergusson, and that Xenocles afterwards covered over the open space in a manner similar to that employed in the Egyptian halls, but with sloping instead of flat roofs. But in attempting to discover the reason for the glowing descriptions of this temple, given by various ancient authors, the Professor was led to suspect that this cell might not be Greek at all, but a rebuilding by the Romans: a suspicion supported by historical references and by Mr. Penrose, who describes the columns as being late Roman. The result, then, of all these excavations appears to be that the original form of this temple is still as much a mystery as the Eleusinian mysteries themselves, for the celebration of which the building was designed. After passing Corinth, Mycenæ, Argos, and Tiryns, the Professor had visited Epidaurus, and he described the Theatre and, later on, the Tholos, when describing that at Olympia. The theatre is of gigantic proportions, and is especially interesting in that it is purely Greek throughout. Its general plan is the ordinary Greek one, but with some peculiarities as to orchestra and stage. Usually the orchestra was much lower than either the front seats or the stage, so that there was a high podium before the seats, and a high proscenium to the stage. At Epidaurus, however, the whole is level, with the singular exception of a wide trench or surface drain passing half round the orchestra in front of the seats. Nearly all the seats remain, but are a good deal misplaced, owing to the giving way of the ground under. The Professor could find no traces of the great masts or other supports that must have been used if the theatre had ever been covered by a velarium; nor of any covered gallery or portico, though remains of an enclosing wall were shown on his plan. It is quite clear, he stated, that there must have been some such protection, yet in the shape of a high wall the echo would, he thought, be very great. There may, perhaps, have been a high curtain or velum to prevent the actors' voices being carried away by a high wind. He had examined the seats to see if they sloped at different angles as they receded from the position occupied by the actor, and found that such is the case to a limited extent in this theatre, as also in one or two other Greek theatres referred to. But he had been unsuccessful in endeavouring to find any

acoustic vases disposed between the seats in the manner described by Mr. Gordon Hills, who cites various authors to show that such vases, or the cavities containing them, have actually been found in several Greek theatres. The Temple at Bassæ, built in a commanding position, is in ruins, but some of the columns are erect, and are carefully watched by the Athenian Archaeological Society. The external columns were Doric, the internal Ionic, with one solitary column in the centre Corinthian. The architect was Ictinus, and the date of the building therefore was circa 440 B.C., i.e., some forty years before Callimachus, who, according to Vitruvius, invented the Corinthian order. The temple runs north and south, not east and west, as is usual; and there is the unusual feature of a side entrance. The internal columns are not detached as elsewhere, but are united by buttresses to the walls. Surely Ictinus was too good an architect, the Professor remarked, to do this without a reason! If so, what was his special reason? It could not have been the support of cross-beams of marble, as usual in flat ceilings, as there was nothing out of the common way to support. Pausanias, in describing this example, says,—"A temple of Apollo, the roof of which is of stone. This temple would stand first of all the temples of the Peloponnese, except that of Tegea, for the beauty of the stone and the neatness of the structure." This reference to the roof clearly refers to some peculiarity in its structure, and has led to a very interesting controversy. It had occurred to several architects that possibly the arched canopies to statues found on several Greek coins were real representations of the forms of the roofs under which they were placed. This theory has been worked out by Mr. E. Falkener, and his drawings, showing his proposed restoration, are very graceful. The Professor showed drawings of several of these coins. In conjunction with his son, he had made a careful search throughout the mass of fallen stones, in order, if possible, to find anything to solve this problem, and showed drawings of two stones found by him, splayed to a form of abutment; but he was unable to assign any definite position to either, and was doubtful as to whether the splay of one of them might not have been an accidental fracture. The Professor then described the excavations at Olympia, and showed a diagram plan,—a copy of the German plan,—which shows the state of the ruins as he saw them in 1884. The Temple of Juno is an object of great curiosity to an architect, on account of the difference in size and proportions of its columns, of which it has the unusual number of sixteen at the sides to only six in front. There are the Professor said, many other edifices of great interest in and about the Altis, but he must content himself with noticing one other only, viz., the Tholos, west of the *Hærem*, known as the Philippeum. It is thus described by Pausanias:—"A round building, on the top of which is a brazen poppy, as a clamp for the beams. It is built of baked brick, and there are some pillars round it." The general impression, supported by Freeman and Fergusson, appears to have been that such circular buildings were unknown to the Greeks. But we now have the Tholos at Elis, and another more curious at Epidaurus,—this round building having the hitherto unknown range of columns internally. Of the Tholos of Elis, nothing remains *in situ* but the foundations; but these are perfect, giving the general dimensions 49 ft. 6 in. in diameter, measured on the hottest step, the interior diameter of the *cella* being 24 ft. 8 in. in the clear. The Professor had carefully examined and measured the fragments scattered about, and with the help of the German restoration had succeeded in making out the greater part, and showed diagrams representing the building as restored by him. The fragments found enabled him to easily restore the peristyle and its ceiling, but the restoration of the *cella* presented a more difficult task. The most valuable fragment found was one which shows distinctly that the interior was decorated by a row of semi-engaged columns, said to have been Corinthian. The German drawings show nine of these, but the Professor thought that if there had been ten of them the present remains would fit in, and there would not be a column directly in front of the door. The Germans also have restored the roof with a kind of clearstory,—a restoration with which the Professor hardly agreed.

He had reason to think that the architect of this building, and of the Tholos at Epidaurus, lived in the fourth century. If so, these buildings, and that of Lyciscrates, would all be of the same date. The Professor's notes were, he said, but a summary of the result of the patient labour and research of others, and showed how many problems had still to be worked out in considering the architecture of the Greeks. This could best be done in the bright clear air of Greece, and the school at Athens, with Mr. Penrose at its head, was a boon to all, especially to those who might be fortunate enough to pursue their studies on the spot.

In the discussion which followed, Mr. W. Watkias Lloyd said he had felt much pleasure in going through the drawings with Professor Hayter Lewis, and there was a great deal undoubtedly that could be said and written about them. He would first of all notice that the circular building excavated by the Athenians, and which had been alluded to, was mentioned by Pausanias as having been built by Polyclethus, the great sculptor, to whom also the architecture of the theatre was due. He (the speaker) was particularly interested in the temple at Elis. That building was in direct contrast to any other Greek temple, having been evidently planned to accommodate a large concourse of people, which was not the case in Greek temples generally. The Greek temple was distinctly a *naos*, or dwelling-place for the statue of the god or goddess, and was not intended to accommodate large congregations, but for sacred ceremonies. The building at Elis, however, was distinctly the *Telesterion*—a great hall where the Eleusinian mysteries were celebrated. The seats all round the building evidently indicated that purpose, but it was a great relief to him when Professor Hayter Lewis demonstrated so clearly that the columns were not part of the original plan, for it was exceedingly difficult to explain how an assemblage of people could have taken part in any common ceremony if there was so much of what was now called "clerical eclipse" produced by a forest of columns. The general outline of the celebrations was known. The chief ceremony was performed on moonless nights, and a great and imposing effect was produced by the sudden transition from intense darkness to brilliant illumination. Besides that, a regular sacred drama was performed, with a good deal of singing and considerable movement of the congregation, each individual taking part in the ceremony, which, according to the ancient descriptions, was very much like what could now be seen in the Levant at Easter. The object of a large, square capacious building was to give a very considerable area for these celebrations, and to enable the Athenians to take individual and collective part in them. He had not quite lost hope that with the progress of investigation traces might still be found of the original bases of some of the supports. For, although the celebration took place on moonless nights, and, consequently, in the dark, he could not but suppose that a considerable part of the building must have been covered, especially from the use of the word *opæion*. He could not understand how any one could explain this, except as a distinct opening, but how it was managed he could not tell. For the information of those who cared to take further interest in the subject, he might say that in the recent edition of the "Encyclopædia Britannica" there was an article on the Mysteries, admirably written, and very satisfactory taken in conjunction with the architecture. That site might be said to be the most sacred of antiquity, the celebrations practised there being of a more imposing, and, he might almost say, of a more religious, character than any other celebrations which the Hellenic religion comprised. The entire genius of the Greeks was apparently bestowed in rendering them as impressive as possible. Æschylus himself was a native of the Eleusinian district, and is said to have designed the costumes for the celebrations. When it was considered how, in the passage from pagan to Christian ceremonies, there was so great a tendency to graft the old ceremonies on the new, he had a strong conviction that the cozes, chasubles, and other vestments used by the clergy at the present day were largely derived from the imagination of Æschylus, that great master of scenic effect. Professor Hayter Lewis had been good enough to refer to what he (the speaker) had done with respect to the little Temple of Diana, one of the

most remarkable examples of the application of proportion to architecture by the Greeks. Looking back to his old studies on the subject, made some thirty years ago, he had found a note which recalled the difficulty he had experienced in one part in finding what the principle was on which it had been planned and designed. It came right in every other respect, and at last he found the dimensions on the margin of Stuart's drawing did not correspond with the geometrical plan; when he corrected that he found everything to be right.

Professor Kerr proposed a vote of thanks to Professor Hayter Lewis, and expressed the pleasure it gave the members to see him that evening. It reminded him of old times. He was delighted to find that Professor Hayter Lewis had still leisure to pursue the most exalted studies of the profession. They would all agree that what had been so modestly laid before them that evening had been of the greatest aesthetic and archaeological value. Professor Hayter Lewis was a credit to the profession, and long might he continue to be so.

Mr. Charles Fowler seconded the resolution, and remarked that part of the pleasure of listening to their old friend was to observe the youthfulness, freshness, and vigour with which from time to time he put some interesting matter before the members.

The Chairman added that it was much to be regretted that the hour was so late. He was sure that other members would have wished to join in the discussion, and say something about the Professor's paper. Indeed, he himself would have liked to ask some questions, but he refrained from doing so on account of the lateness of the hour.

The vote of thanks was then put and carried by acclamation.

Professor Hayter Lewis replied, and expressed the pleasure it had afforded him to meet the members again.

The Chairman then announced the adjournment of the meeting to the 28th inst., when a paper will be read by Mr. Josiah Conder, on "The Architecture of Japan." Mr. Conder, he added, was now in England, and had an immense collection of drawings with him.

WILLESDEN NEW PUBLIC OFFICES COMPETITION.

The Willesden Local Board have received fifty-four sets of drawings in reply to their invitation to architects to send them designs for new offices to be erected in the Dyne-road, at the corner of Dunster Gardens, and just off the Kilburn high road. A large proportion of the competitors have succeeded in producing thoroughly practical working plans, and a good many of the designs have also a reasonable amount of architectural beauty, so that, although the two are not always in combination, the committee should have no difficulty in finding twelve sets of drawings to submit to a professional arbitrator (which is, we hear, what they propose to do), all of them representing buildings which would perfectly answer their purpose, except, perhaps, as regards the cost. The sum of 6,000*l.* allowed, and which is to cover boundary walls and all incidental expenses, including the architect's commission, is really too small if anything in the shape of architecture worthy of a public building is expected, and, although a few of the designs could no doubt be carried out for the money, that result has only been attained by a too evident economy and the smallest possible use of any architectural features.

No. 53, "Favete Linguis," is one of those that combine the charms of good architecture with a convenient and sensible plan. The drawings show a symmetrical Classical building of red brick and stone, with high-pitched green slate roofs; the centre portion, two stories high, with the large windows of the board-room in the upper part, surmounted by a stone dormer, and the roof crowned with a simple but well-designed lantern; the wings, projecting in front of the centre block, and being only one story high, complete a pleasing group. The entrance to the building is in the centre, and opens to a small hall, with the grand staircase beyond; the offices of the surveyor and his subordinates are to the left hand, where they get the north light, and those connected with the clerk's department are on the right, together with the larger committee-room and the collector's office. On the

upper floor the hoard-room occupies the whole of the front, and the back part is taken up with the smaller committee-room, the waiting-room, and a large cloak-room, &c., for the use of members of the Board. The drawings are spirited and neat, and do justice to one of the best designs in the collection.

Opposite to this set, as the designs were arranged in the Brondesbury Hall, was hung another very good one, No. 11, under the motto "Plan." This design is similar in conception and general disposition to No. 53, but great pains have been taken to keep it within the limit of cost. The elevations show a plain red brick and stone building, well grouped, but comparatively bare of architectural adornment, which is, indeed, almost wholly confined to a couple of plain stone cornices, some coupled brick pilasters between the windows of the first floor, and a simple lantern on the main roof. The general arrangement of the plan is similar to that of "Favete Linguis," but both committee-rooms are placed on the first floor and there is less lavatory accommodation. "Plus," No. 45, puts the clerk's offices on the upper floor and one committee-room, with the waiting-room, on the ground-floor to the right of the entrance, which is not so good an arrangement as that before described; otherwise the plan is a good one and the architecture above the average. "Bona Fide," No. 7, is another somewhat similar design, illustrated by a very taking perspective drawing. The mistake has been made of putting the surveyor's offices to the right of the entrance or on the south side of the building, and a large stone porch and other expensive features are shown; but in other respects the building would be a convenient as well as a dignified one. "Pro Bono Publico" is a good design of Jacobean character, with a good working plan, but expensive.

"Plan," No. 10, the second with this motto, has good Flemish Renaissance elevations, but the plan is straggling.

"Apex" is a good specimen of an asymmetrical design, which would produce a convenient building of a rather less ambitious type than most of the others.

"Nemesias" is a little too much like a private house. "Art" is a very good design indeed, but the entrance is rather awkwardly placed. "Dunster" is not done justice to by a poor set of drawings.

We noticed also "Forward," "Juhilee," "X. Y. Z.," "Brick," "St. Augustine," "Utile Dulci," "Per Ardua," Triangle in circle, and "Quod Petis hic est."

THE ARCHITECTURAL ASSOCIATION.

VISIT TO A NEW CHURCH AT WIMBLEDON.

The first Saturday afternoon visit of the Architectural Association for the present session was made on Saturday, the 12th inst., to the Roman Catholic Church of the Sacred Heart, Dalston-road, Wimbledon. The party of members was received by Mr. T. A. Walters, the architect.

The church is situated on a very sloping site, and at present only the nave is being built. The character of the work is Decorated, of a Lincolnshire type. The nave is 26 ft. 6 in. wide, and upwards of 50 ft. high. The aisles when built will be 16 ft. wide. Over alternate piers in the nave arcade are richly-carved niches, which will be filled with statues, and the aisle roof will be carried with pierced stone principals. It is proposed to brick up the chancel arch for the present, but a large decorated roof will be fixed in the opening at once. The internal stonework is executed in Beer stone, and the walls are to be plastered and decorated. The roof will be of stained deal, with decorated bosses. The external stonework is Ancaster, and the facing knapped flints. The internal effect of the church, even in its present incomplete condition, is very effective, and when completed it will be a very interesting specimen of modern church architecture.

**Friern Barnet Sewerage Works.**—The sewers in the above district, which have been constructed under the direction of Mr. Baldwin Latham, O.E., of Westminster, and comprise outlet sewers, "of which nearly four miles have been laid in tunnel at depths varying from 20 ft. to 70 ft.," have just been completed by Messrs. B. Cooke & Co., of Battersea, the contract sum being 23,000*l.*

THE LIVERPOOL CATHEDRAL COMPETITION.

SIR,—In the *Builder* of last week [p. 266] there appeared a letter, signed by Mr. J. Oldrid Scott and Mr. John P. Seddon, and headed "Liverpool Cathedral Memorial," stating that, at the suggestion of the Committee on Competitions of the Royal Institute of British Architects, the proposed memorial would be modified, and giving the terms of the new circular as modified.

This was laid before the Council of the Royal Institute, at their meeting on Monday, the 14th inst., when the subject of the proposed memorial and of the recent Liverpool Cathedral Competition was for the first time brought before them. We are consequently to ask you to allow us to state in your columns that the modified circular referred to has in no sense been approved by the Council or by our Competitions Committee; and that the Council feel very strongly that nothing should be done, by exhibition or otherwise, to present an award conscientiously arrived at by a professional assessor in any architectural competition.

J. MACVICAR ANDERSON, Hon. Secretary.  
WILLIAM H. WHITE, Secretary.  
Royal Institute of British Architects,  
Feb. 16.

SIR,—As the wording (no doubt unintentionally) of Messrs. Scott and Seddon's letter in your last week's issue has led many to think that the modified memorial had been approved by the Competitions Committee, allow me to state that this is in no way the case. Mr. Cole A. Adams being away unwell, I was deputed to see Mr. Scott by the Committee, and point out to him the portions to which exception was most strongly taken, which I did, and heard no more of it till the modified memorial appeared in your paper, without its ever having been before the Competitions Committee at all.

An exhibition of the drawings may or may not be desirable in London, but if entertained for the purpose of upsetting the assessor's award, would, I am certain, be strenuously opposed by the Competitions Committee.

ASTON WEBB.

19, Queen Anne's Gate, Feb. 17.

THE PROPOSED IMPERIAL INSTITUTE COMPETITION.

SIR,—I take the Imperial Institute to mean, 1st, a building (such as is suggested) to be erected by the contributions from all parts of the empire; to be 2ndly, consolidated into a useful repository for products and manufactures the results of the industries of the British Empire. Surely, if this is right, the competition ought to mark the Jubilee year with a lead in the higher direction in competitions, by making it wide in its scope, embracing every architectural student, offering substantial premiums (and many of them), that the result may be truly imperial, worthy of the committee in charge, the people from whom it has sprung, and the architect who shall create the successful design.

LIVERPUDDLIAN.  
February 16th, 1887.

SANITARY INSTITUTE OF GREAT BRITAIN EXAMINATIONS.

SIR,—With Mr. W. H. Colbran [see his letter, p. 201, ante], I was greatly astonished at the unprovoked attack made by your correspondent, Mr. Scott (p. 164), upon the Sanitary Institute, and I regret that he, himself a member of the Association of Municipal and Sanitary Engineers and Surveyors, could discover no better method of advocating the cause of that Association than by traducing the Sanitary Institute. His statements concerning the Institute are of so inaccurate a nature that I am again, and finally, induced to address you on the subject.

With regard to Mr. Scott's assertion that but few Local Authorities have even so much as heard of the existence of the Sanitary Institute, I may state that the Institute has, by special invitation of the respective Local Authorities, held successful Annual Congresses at various towns (including Leamington, Exeter, Croydon, Stafford, Newcastle, Leicester, Dublin, and Glasgow), attended by distinguished scientists, engineers, neighbouring and other local sanitary surveyors, medical men, and the public generally. By reason of the valuable papers there read and the discussions held thereupon, as also by the exhibition of sanitary apparatus and appliances and the awards of "diplomas" in connexion with meritorious sanitary inventions (adjudicated upon by some of the most able men of the day), these congresses have been the means of enormously advancing the popular interest in, and knowledge of, sanitary

science. (Over 40,000 persons visited the Sanitary Apparatus Exhibition of the last Congress.)

I am also told that I attach too much importance to the Sanitary Institute certificates in supposing they influence local authorities. Within late years it has, however, not been rare for a local authority in advertising for a surveyor or inspector of nuisances to specifically state that "other things being equal, preference will be given to a gentleman holding the Certificate of the Sanitary Institute." Did space permit I could produce abundant evidence to prove beyond doubt that not only do these certificates carry great weight, but that they afford a degree of security to a local authority in its choice of a surveyor far above such as is obtainable from ordinary testimonials.

Conducted by experts and men of great distinction, these examinations, owing to their difficult nature, are to all except real workers but as sour grapes. That they, nevertheless, have attained considerable popularity is indicated by the fact that nearly 200 Nuisance Inspectors' and over 40 Local Surveyors' Certificates have been awarded to gentlemen residing in every part of Great Britain, not to mention about 250 Inspectors, among which I trust the members of the Association of Municipal and Sanitary Engineers and Surveyors are numbered. In view of these Examinations being held only in the metropolis, their voluntary nature, and the fee attached thereto, also of the fact that surveyorships change hands but slowly, Mr. Scott's statement that a dozen Local Surveyors hold certificates is further evidence of popularity.

Feb. 16.

J. A. A.

\* The concluding portion of our correspondent's letter is not strictly relevant to the question, and is therefore omitted by us.

#### "HOUSE AGENTS."

SIR,—You would not willingly allow your columns to be the means of doing injustice to any class, and I therefore hope that you will admit a few words of comment on the article in your issue of the 12th instant on the subject of House Agents.

You think that the principal function of the agent is to bring the proposed purchaser and vendor together, and that for all further purposes the business would be better completed were he "eliminated from the proceedings." Now, of course, there are, as in most other callings, "agents and agents," but it is certain that this is utterly inapplicable to the case of offices of standing and reputation. In their case I venture to assert that their work subsequently to the introduction of the property to the notice of the tenant or purchaser is frequently of much more value and importance than the introduction itself. That clients are of this opinion is evinced by the frequency with which, after receiving a proposal themselves, they bring the business to the agent, that he may carry it out.

One of the most patent mistakes in your article is the assumption that the carrying out of the negotiation by the agent increases the expense to both parties. The agent is paid by a commission on the amount, payable if he does no more than find the tenant or purchaser, so that it is of no advantage to him that negotiations are prolonged; on the contrary, it involves expense to him and trouble without corresponding remuneration. You are very angry with agents for not promoting personal communication between principals. Now, an owner will often employ an agent precisely because he does not desire these "personal communications," which involve trouble and, of course, often lead to no result. Moreover, intending tenants and purchasers will not generally adopt your happy idea of "eliminating the agent," or, as they sometimes express it, "preferring a personal interview with the owner"; and this simply because they consider they may be able to drive a better bargain personally with an owner who may be less shrewd and "wide-awake" than themselves,—perhaps a lady inexperienced in business, an elderly gentleman, or an invalid. The agent is here only doing his duty in standing between his client and the sharp man of the world.

I have nothing to say of the supposed practice of agents misleading their clients as to prospects of disposal of their property and amount of inquiries, except that the practice does not exist in reputable offices. As to the agent maintaining high prices and preventing a settlement on lower terms, it is clear that if he looked only at his immediate profits it would be his interest to do just the reverse. He would let or sell twice as many properties if he were able and willing to offer them below their market value, and it is obvious that the commission on two sales at 1,500*l.* each would be better than one at 2,000*l.* Hence, when he advises a client, as he often has to do, to stand out for the higher price or rent, he is entitled to the credit of doing his duty to his employer, against his own immediate interest, and certainly does not deserve the somewhat hasty and ill-considered censures of the writer of the article.

EDWARD CHESTERON.

Kensington, Feb. 14, 1887.

\* As to the last matter, we will offer one experience as typical. A house was offered by an agent for a certain rent; the agent expressing himself willing, however, to submit an offer 10 per cent. lower. Customer declined this, but, finding out who the

owner was (not from the agent), offered him 20 per cent. less, which was accepted with an alacrity which showed even that less would have been taken. The premium, again in many cases, a mere farce, held up in the hope that some one will be good enough to take it *à discrétion*, and really serving only to frighten away offers.

#### "MASONS' WAGES."

SIR,—When perusing your valuable paper I was very much surprised at the suggestion made by your correspondent "G. C. W.," viz., that the masons' alleged grievances in London should be settled or alleviated by the master builders being persuaded to have their stone worked in London instead of at the quarries.

Why should an employer pay a quarter as much more by so doing than by having the stone worked at the quarries, to satisfy the whims or grievances (?) of men who (so far as my observation as a large employer of masons extends) would profess a grievance after every demand was supplied? To the best of my judgment all these "grievances" are known only to "Society" men, and were they not sought out and shown to them by others who are apparently paid for so doing, and have nothing else to do, my impression is they would never be known.

I do not hold with paying men less than their worth (nor more), and I feel sure every employer of labour will bear me out by stating that a different rate of wages should exist, so that indifferent, ill-tutored, careless, slow, or (more frequently) intemperate, and consequently unreliable and irregular men, should not be paid the same price as a constant, quick, good, reliable man. It is no encouragement for such to maintain his ability, or for the inferior to endeavour to better his powers, and so attain an increase of wages *pro rata*.

Now, reverting to "G. C. W.'s" remark about stone being worked at the quarries, the very statement he mentions as to the "builders taking contracts, then sub-letting the masonry to a sub-contracting mason, and the latter again letting it to be worked at the quarries," proves that stone can be, and is, worked cheaper there than anywhere, and consequently should be, and is, on the increase; and if the masons are grieved about it, let them come down to the quarries and work there, although, for my part, I would rather the "Society" men kept away.

In conclusion, if masters and men were only left alone more it would be better for them; and then, if the masters found good men, and the men good masters, they would work well together; and the bad, on the other side (masters and men), might also be left alone, and allowed to progress as best they could.

A QUARRY OWNER.

#### WASTE WATERS FOR FLUSHING PURPOSES.

SIR,—Will some of your readers kindly give their experience in using waste-water from kitchens, sculleries, &c., for flushing water-closets?

I believe some such an arrangement is in existence in some towns, and saves much expense in cost of fittings, water, &c.

HEALTH.

### The Student's Column.

#### FIELD WORK AND INSTRUMENTS.—VIII.

##### Surveying Instruments.

##### VIII.—THE CIRCUMFERENTOR.

THE circumferentor is an instrument principally intended for subterranean surveying, but is also useful for completing the survey of any thickly-wooded portion of a country, where it is found difficult to connect the direction of any particular base line with the adjacent portion of the work. In its simple form it constitutes a miner's dial, consisting of a circular box containing a very sensitive magnetic needle, mounted upon a stand with folding sight-vanes, which are raised perpendicular to the compass-box. In each vane there are slots and holes, one over the other, a fine line of silk, horsehair, or wire being strained down the centre of each slot, in a similar manner to the sight-vane of a prismatic compass, and the circular holes are each crossed by lines at right angles to one another, the intersection of which is used in ranging the opposite sight-vane in line with a distant station. These sight-vanes are alternate, the aperture serving as an eye-piece in the one, being exactly opposite the aperture by which the centre of an object is ranged in the other. With this instrument the direction of the roads and workings of a mine, or of a stream through a wood, may be roughly determined by a comparison with the magnetic meridian. In the prismatic compass the needle was seen to be attached to the card upon which

the degrees of a circle were graduated. In the circumferentor the needle revolves upon its bearing in the centre of the dial, and the divisions are marked upon the compass-box, as shown in fig. 2, which represents a plan of the instrument with the sight-vanes raised ready for use, as in fig. 1. In fig. 5 the instrument is shown closed with a cover over the compass-box and the sight-vanes folded down for the convenience of packing. The needle in fig. 2 is released to play freely by pulling out the stop-piece marked M. Fig. 3, which represents a plan of the underneath portion of the instrument, shows the position of this stop-piece with reference to the set-screw H, which clamps the instrument to its stand.

The fixed divisions upon the dial in the compass-box are marked very distinctly upon a raised circular rim, which forms the outer edge of the silvered plate, marked A, in the centre of which the needle is carried. These divisions are engraved consecutively to 360°, in a contrary direction to the figures upon the face of a watch, and are usually cut upon both the outer and the inner edges of the face of this rim, with the figures indicating the degrees placed in order in a circle between them, as shown in fig. 2. Upon the inner portion of this plate, the letter N. denotes the north, coincident with the line marked 360° upon the graduated rim, and the letter S., immediately opposite, denotes the south point upon the dial coincident with the line marked 180°. The plate over which the needle travels is further divided within the raised rim by cross lines at right angles to one another into four parts, each quadrant being semi-divided, and containing subdivisions reading from zero at the points marked N. and S., advancing in tens of degrees to 90° at the points marked E. and W. The inner circle of divisions upon the raised rim enables us to read to degrees the angle of intersection at the centre of the compass-box, between the direction of the needle pointing to the magnetic north over the line marked N. and S. upon the dial, and the line ranged by the sight-vanes, while the addition of the vernier,—an enlarged view of which is given in fig. 6,—enables us to record angles within three minutes, or one-twentieth of a degree.

The compass-box is connected with an exterior gimbal ring, the latter carrying the arms, upon the ends of which the sight-vanes D, D, are attached. The best instruments have spirit levels, B and C, fixed at right angles to one another upon these arms. The vernier is fixed to the inner edge of the box which holds the compass, its zero point being placed in the same vertical plane as the centre line of the sight-vanes, and in a line at right angles to the axis of the gimbal ring. A circular rack and pinion, worked by the milled screw, K, shown in fig. 3, communicates to the vernier plate an absolute horizontal motion round the outer circular rim of the dial-plate. By means of this rack-and-pinion movement, great steadiness of action is obtained. The gimbal ring carrying the sight-vanes can be fixed rigidly to the compass-box, by means of the turn stops, L, L, as shown in figs. 1 and 3, or inclined, as shown in fig. 4, when required to suit the declivity of a heading or tunnel. In fig. 4 it will be observed that the turn stops, L, L, are unclamped by reversing. With the use of an arc marked F, which can be attached by the screw E, or removed at pleasure, the gradient of a heading may be measured, while the compass-box remains level, and records the magnetic bearing. Two scales of graduations are engraved upon this arc, one indicating the degrees of a circle between zero and 45°, while the other scale gives the corresponding values of the versines of the angles registered, these amounting to 1.52 in 100 for an angle of 10°, 6.02 in 100 for 20°, 13.4 in 100 for 30°, 23.4 in 100 for 40°, and 29.29 in 100 for 45°.

The compass-box is commonly mounted upon a ball-and-socket tripod, fitted with a turned and bored ferrule-joint. In this respect it differs from the screwed head shown in the illustration of a ball-and-socket tripod stand, which accompanied our description of the prismatic compass. In mining work it is found convenient to have the legs of the tripod jointed in the centre, as low headings often occur. When the legs are required to be shortened to suit the headway, three pegs each, similar to the one marked P in the diagram, are supplied in the box, for screwing on to the middle portion of each leg.

In order to find the bearing of a line by the

FIG 5

FIG 6 THE VERNIER - ENLARGED -

$\frac{1}{19} - \frac{1}{20} = \frac{1}{380}$   $\times \frac{19}{1} = \frac{1}{20}$  OF 1° OR 3 MIN

circumferentor, place the instrument over the station point, with the gimbal ring clamped to the compass-box, as in fig. 1, and guided by the spirit bubbles, set it level by means of the ball-and-socket joint. The needle should be immediately released on setting the instrument. If the circumferentor has no spirit levels attached, it may be set up approximately level, by unclamping the needle, and noticing when it swings freely. Then turn the instrument round, so that the 360° or point marked N. upon the dial, is coincident with the marked or north end of the needle, and carefully make this coincidence when the needle comes to rest, as accurate as possible by turning the milled screw K, which is situated below the compass-box, and hence shown dotted in fig. 2. Having done this, tighten the set screw H. Then by means of the milled screw K, turn the sight-planes in the direction of the proposed line. Open if necessary the turn stops L L, and so place the sight-planes D D that the centre of the object viewed is bisected by the cross hairs. The dial-plate being as shown by the plan in Fig. 2, open upwards, the divisions can be read entirely round the circle, and the miner's lamp can be held over the compass-box without disturbing the instrument. It will be observed upon reference to the dial-plate in fig. 2 that in some instruments the right hand of the point marked N., when looking towards the north from the centre of the plate, is lettered west, and that the opposite point upon the left is lettered east. Thus the relative positions of east and west are reversed. The expression, the reverse bearing of a line, simply means that the bearing has been taken in a contrary direction; thus the reverse bearing of 34° east of north would be 34° west of south. It will, however, be found an advantage to maintain a uniformity of method in registering the angles, and always to book the relation that the magnetic north bears to the line of observation as recorded by the figured dial-plate. The process of "dialling a pit" is called by some "latching."

Miscellaneous.

**Sanitary Institute of Great Britain.**—The Right Hon. G. Slater Booth, M.P., has accepted the Presidency of the Congress of this Institute to be held at Bolton in September next.

**Obituary.**—The death took place on the 15th inst. of Mr. Henry James Phillips, one of the founders, and for thirty-three years secretary of the Temperance Building Society, in the sixtieth year of his age.

**Birmingham Students of the Institution of Civil Engineers.**—The members of the Association of Birmingham Students of this Institution held a meeting at the Colonnade Hotel, New-street, on the 10th inst., when a paper upon "The Sewerage of Towns," by Mr. J. S. Pickering, Stud. Inst. C.E., was read, in the absence of the writer, by Mr. W. Franks, Stud. Inst. C.E. Mr. E. Pritchard, M. Inst. C.E. (President), was in the chair.

**District Surveyors.**—Referring to the paragraph on p. 270 of our last issue, we see from the agenda of the meeting of the Metropolitan Board of Works for the 18th inst. that the Works and General Purposes Committee will present a report stating that they are not prepared to recommend the making, in the cases of future appointments to the office of District Surveyor, the additional regulations proposed by Mr. Samuel Price.

**The American Exhibition at Kensington.**—We hear that work on the buildings of the American Exhibition of the Arts, Industries, Manufactures, and Products of the United States, to be opened May 2nd at Earls-court, Kensington, is progressing very rapidly. Over 400 men are now at work on the grounds, and when the electric-light plant, for which a 600 horse-power engine and boiler are being put in place, is completed, night-work will be begun. The managers report that the applications for space in the building far exceed its capacity. Several large American railroad companies will make exhibits, illustrative of the agricultural and mineral products of the territory through which their lines ran.

**The Briton Insurance Office Buildings.** The block of buildings at the corner of Agar-street, in the Strand, which was originally occupied as the notorious British Bank, and until recently by the Briton Insurance Company, has been purchased by the British Medical Association, by whom it will shortly be occupied. The building has just been undergoing alterations and internal reconstruction to a very great extent. The ground-floor, which is intended to be set apart as the chief business offices of the Association, is being entirely rearranged. The walls and partitions dividing the offices on the first floor have all been removed, and a larger apartment formed, extending the entire depth of the building from the Strand frontage northwards, which is intended as the council-room of the Association, and immediately adjoining, on the east side, are several clerks' offices. The second and third floors have also been re-arranged as general offices. The whole of the roof has been removed, and a new roof constructed, lighting the top floor by a lantern, carried to the entire length. This last-named floor is intended to be occupied as the compositors' room in connexion with the *British Medical Journal*, which will be printed on the premises. The basement floor has been lowered to the extent of 18 in., and will contain the machinery for printing the *Journal*. The stone staircases from the ground to the upper floor of the building have been reconstructed and diverted, and lavatories formed at each floor landing. A lift has also been constructed from the basement communicating with the several floors to the top of the building. The works are being carried out from the designs of Messrs. Arding, Bond, & Buzzard, of Surrey-street, Strand. Messrs. G. H. & A. Bywaters, of King-street, Regent-street, are the contractors, and Mr. L. Williams is the foreman. Messrs. Wenham & Waters, of Croydon, have done the heating and ventilation work.

**The Sanitary Assurance Association.**—The sixth annual meeting of this Association was held at the Offices, 5, Argyll-place, W., on Monday, Sir Joseph Fayer in the chair. Mr. Joseph Hadley, secretary, read the annual report, from which it appeared that the business of the Association during 1886 had been much greater than in any previous year, the income having been 804l. as against 462l. in 1885. The report said that of all the properties inspected, in only two cases of first inspection had the arrangements been such that the Council could certify the sanitary condition of the property without alteration. The Executive Council reported having held several meetings for the purpose of revising the Sanitary Registration of Buildings Bill of 1886, and a new Bill had been prepared for presentation to the House of Commons. In the new Bill the principle of compulsory registration would be restricted to schools, colleges, hospitals, asylums, hotels, and lodging-houses. In the absence of Dr. Farquharson, M.P., from England, Mr. C. C. Lacaita, M.P., had taken charge of the Bill. General Sir Peter Lunsden, G.C.B., proposed the adoption of the report. This was seconded by Mr. Andrew Stirling, supported by Dr. Danford Thomas and Surgeon-General Cornish, C.I.E., and carried unanimously. The retiring members of the Executive Council, Lieut.-General Burne, C.B., and Mr. Andrew Stirling, were re-elected. Sir Joseph Fayer was re-elected President of the Association, and Professor T. Roger Smith, F.R.I.B.A. was re-elected Vice-President. With regard to the Sanitary Registration of Buildings Bill, to be introduced by Mr. C. C. Lacaita, we are informed that it will be backed by Dr. Farquharson, Sir W. Guyer Hunter, and Dr. Cameron.

**The New English Church at Cannes.**—St. George's Church, Cannes, was consecrated on Saturday last by the Bishop of Gibraltar. It has been erected as a memorial to the Duke of Albany, the design being submitted by Mr. A. W. Blomfield, M.A. The decorations of the church include two large stained-glass windows and a mosaic reredos, the gift of two English ladies and the work of Heaton, Butler, & Bayne, who have also other memorials in hand for the same church. We have already (p. 165, ante) published some particulars of the church, and we hope to give an illustration of it in an early number.

**Theatre Burned Down at Northampton.** The New Opera House at Northampton was burnt out early on Sunday morning.

PRICES CURRENT OF MATERIALS.

### The History of Art in Flanders.

THE three sumptuous volumes with which Canon Dehaisnes\* has enriched students of Medieval art deserve much more attention than the English press has thus far devoted to them.

The first volume consists of a *résumé* of the results arrived at by the author, and is adorned with some fifteen Dujardin plates. The other two volumes contain a series of documents or parts of documents mostly never before published. The learned editor has devoted his leisure time year after year to the search. He has hunted through one collection of archives after another, and found here the record of a payment made for a work of art, there an inventory of the possessions of an abbey or of a prince; now a huilder's account for work done at some château or other palatial residence; and again, the list of valuables robbed by highwaymen from a rich traveller. As we turn the pages we catch the strangest and most varied glimpses of the past, now and then lightened into actual visibility by some keen word or well-chosen expression unexpectedly flashing forth from the gloom of account-hooks or legal records. The Comte de Lahorde's somewhat similar work, entitled "Les Ducs de Bourgogne: Études sur les Lettres, les Arts, et l'Industrie pendant le XV<sup>e</sup> Siècle" (Paris, 1849-54), is well known to every student. It has been M. Dehaisnes' aim to do for the earlier centuries what M. de Lahorde did for the wonderfully busy and richly productive epoch which was contemporary with the reign of the Dukes of Burgundy over the provinces which now form the chief part of Belgium.

It will not be expected of us, in a notice like the present, that we should go further into the nature and extent of the documents published. Nine hundred and forty quarto pages are not to be quickly read, nor is it possible to test in a short time the accuracy of the transcriptions and printing contained in them. The ultimate test can only be applied by time and use. Our function is rather to point out to the possible reader what a work of this magnitude contains that is not to be found in existing books, so that he may be in a position to judge for himself whether it is worth his while to purchase it or not.

\* Histoire de l'Art dans la Flandre, &c., avant 1<sup>o</sup> XV<sup>e</sup> Siècle. Par Canon Dehaisnes. Three vols. Lille, 1886.

The first volume is divided into two parts, dealing respectively with the periods intervening between the barbarian invasions and the Crusades, and between the Crusades and the fifteenth century. An introductory chapter is followed by one dealing with social life and its relation to art in the earlier epoch. Four chapters are next devoted to the history of painting, sculpture, tapestry, goldsmith's work, and miniature between the same limits of time. The second portion of the history likewise commences with a general chapter, after which the reader is conducted to the towns, Tournai, Bruges, Ghent, Ypres, Lille, Douai, Valenciennes, Mons, Cambrai, Arras, and Saint-Omer, and to the abbeys near them, and shown how different arts were cultivated at these several centres. The influence exercised upon art by the reigning houses forms the subject of some half-dozen more chapters. A general *résumé* and discussion brings the historical portion to an end.

The author, in his preface, after sketching the scheme of his own work, proceeds to point out that no existing hook covers, or attempts to cover, the same ground, and undoubtedly he is right in his contention. He has undertaken to replace a chaos of disjointed studies made by men whose chief interests were with other places or times, by a cosmos of orderly statements based on thorough and exact investigation; and we may say at once that he has done his work, as it seems to us, very well indeed. He has not forgotten (as so many forget) that archives are interesting only in proportion as the things mentioned in them can be made visible, and the facts discoverable about those things interesting. He has carried on the study of works of ancient art along with the study of archives, and each study has served to quicken the other.

When the power of the Roman Empire faded away in the West, and the barbarian invasions began, the ancient culture was not at once submerged. Century after century saw important revivals attempted or achieved. In the district under consideration the seventh century was a very productive period. Christianity had taken root; churches and monasteries were raised and fitted in many places, and art in many forms flourished. The Merovingian kings were (for their day) enlightened patrons of the arts, especially of the art of the goldsmith. Still more successful was Charles the Great's attempt to revive the arts of the ancient world. Europe at the beginning of the ninth century seemed on the fair way to a productive civilisation. Before that century wore to a close the invasions of the Norsemen had devastated all the northern parts of the Continent, and most of the build-

ings which had survived from antiquity, or been made in the preceding centuries, were utterly destroyed. The craftsmen themselves were slain or sent wandering, and the nadir of civilisation was reached. The Abbey of St. Bavon, at Ghent, alone (in Belgium) possesses ruins of earlier date than the Crusades. It was built in the seventh century, and the very walls of that edifice seem, by some miracle, to be, in part at any rate, standing. In the tenth century new beginnings were made, but they were no longer attempts to revive past ideals. The barbarian deluge had finally done its work and spread over the district a new human soil with new ideals latent in it.

We have to wait for the great Renaissance till the twelfth century, and then it came, along with feudalism and an organised and powerful church, finally and for ever replacing the Imperial pagan Roman civilisation. Every art began to raise its head anew. Buildings of all sorts were wanted for the newly-constructed society which lived and laboured in towns, and fought behind and around castle walls, which worshipped in churches, required storehouses for its goods, heltries for its hells, town-halls for its magistrates. Tournai Cathedral is the Belgian edifice which contains within its fabric an epitome of the art of this epoch,—from the end of the eleventh to the beginning of the sixteenth century. Examples of both Romanesque and Gothic architecture are found in its different parts. Its walls were covered with paintings, its windows filled with storied glass, and its treasuries enriched with priceless works, amongst which the still existing shrine of St. Eleutherius, one of the finest works of thirteenth-century goldsmiths' work, always held the first place.

The provinces under consideration, like the rest of Europe, are to be regarded as an agglomeration of towns, each practically an independent republic. Art, therefore, developed along different lines in these various centres, and the student must pursue its course first in one place, then in another. Our author's chapters on the various towns are amongst the most valuable in his work. Ghent is memorable for her corporation of painters, who already possessed written statutes in the year 1338, whilst between that date and 1410 no fewer than 131 painters and 29 sculptors were entered upon the books. Bruges, of course, cultivated all the known arts, and led the way in civil architecture,—her town-hall, which fixed the type afterwards adopted in all the larger towns, being rebuilt between the years 1376 and 1402. Ypres is famous hoth for her splendid thirteenth-century Cloth Hall (about which the archives are unfortunately silent) and for being the home of the painter Melchior Broederlam. The archives of Douai

Details from the Organ-Screen, King's College Chapel.

yield excellent spoil. Our author has patiently read all the wills of her burghers, and thus is able to give us a glimpse into the houses of the rich men there, and to show us what splendour of tapestry, painted cloths, jewelry, cups, and the like they contained. Valenciennes produced the previously forgotten artist, Andieu Beauneven. His name was brought to light by M. Léopold Delisle, who proved him to have been the sculptor of the tomb of Charles V. at St. Denis. We now behold him as painter and miniaturist too, widely famed, and we are able even (by the aid of photography) to look upon two specimens of his excellent handicraft. He flourished about the end of the fourteenth century. Cambrai is full of varied interest. Its cathedral has a notable history. Not far off is Honcourt, where are the ruins of a famous Benedictine abbey, and whence came Villard de Honcourt, the architect, whose sketch-hook is known to all students of Medieval architecture. Arras, of course, brings with it the story of the tapestry industry, as to which M. Deshaimes has discovered two documents of the highest importance.

The inventories of the princes of the period are full of interesting records, by means of which we are enabled to reconstruct much that is lost. Future historians of art will have to devote careful attention to the chapters dealing with this part of the subject.

In conclusion, it may be said that the volumes are excellently printed, and are furnished with the most elaborate indices and with a glossary supplementary to the usual sources of information.

"Scientific News" is the name of a new sixpenny illustrated monthly, the first number of which will appear on the 1st of March.

#### ANCIENT WOOD AND IRON WORK IN CAMBRIDGE.

**U**NDER this title we have a valuable and interesting illustrative work\* on the very fine examples of wood and iron work to be found scattered about among the college buildings of Cambridge. The principal interest of the book is in the woodwork examples, which are more numerous and fine in their way than the ironwork, and which have been very well drawn, for the most part by Mr. Redfern, who has been, however, prevented, partly by illness and partly by official duties, from entirely completing the work (so we understand from the preface), and some of the concluding plates have been furnished by Mr. H. Chapman, of the Fitzwilliam Museum. The authorship of the letterpress portion, by Mr. J. Willis Clark, the author of the splendid "Architectural History of the University of Cambridge," which we reviewed last year, is a guarantee for the value and reliability of this portion of the work.

In a short preface Mr. Clark observes that the history of English woodwork has not received the attention it deserves, partly from the difficulty of dating the examples, "partly from unaccountable neglect on the part of archeologists." This last charge does not, we think, apply to architects and architectural students, who have drawn English woodwork as diligently as any other branch of our national architectural art, of which it may be considered to form a section; but they have naturally been more taken up with the artistic interest of the work than with questions of

history and archaeology. Cambridge offers the advantage of possessing a certain number of dated examples, a fact which gives them a historical interest in addition to their artistic value. We do not find, however, that so many of the works illustrated are actually dated as we should have been led to expect from the terms of the preface, nor does there appear to have been any attempt, in making-up the book, to arrange them in any definite or approximate chronological order. It would have been better if this had been done, as far as possible.

The greater part of the work illustrated is of the seventeenth century. There are two or three examples of Gothic work, of which the most important and the best is the desk-end and finial from King's College Chapel (plate 16). An ancient wooden door-frame from Jesus College, with a segmental head within a square-headed moulding (plate 14), is believed to have been part of the work carried out by Thomas Alcock, bishop of Ely, who transformed the nunnery of Rhadegund into Jesus College between 1497 and 1500. "It is framed," says Mr. Clark, "out of a few pieces of timber, moulded and chamfered; not, like modern doors, composed of several small members attached to each other by nails." This latter sarcasm refers, we presume, to the planted-on mouldings of the modern joiner; but all modern doors (*pace* Mr. Clark) are not made in that way. The other Gothic example is the door leading into the Hall Screens at Queen's College, assigned to about 1450, a date confirmed by the general style of the work, which, however, is not of the best type of that date, and is, in fact, a rather poor example, clumsy in execution and tame in character.

The richly-carved cabinet in the Master's Lodge at Trinity College (plate 13) may be regarded as a kind of link between the Gothic

\* Ancient Wood and Iron Work in Cambridge. By W. B. Redfern. Member of the Cambridge Antiquarian Society. The Letterpress by John Willis Clark, M.A. Cambridge: W. P. Spalding. London: W. Kent & Co.

and the Renaissance stamp of work of this kind. In this respect it is a highly curious and interesting example. Its general aspect is much more Medieval than Renaissance, in the manner in which every portion is crowded with ornament, and in the severe and straight lines within which this ornament is mostly confined. The front presents five main horizontal bands of ornament, divided by smaller subsidiary bands, formed by inlays in light yellow and brown woods on the front of the rails between the drawers. The upper drawer is faced with a pattern of common occurrence in early Renaissance or very late Gothic woodwork, consisting of radiating quasi-shell forms confined within semicircular bands. Then comes a rail, with inlaid leaf ornament of nearly Classic character; then the second drawer front, with a flowing naturalistic design of grapes and vine-leaves, distinctly Late Gothic in character, but growing from the mouth of a grotesque mask in a manner more common to Renaissance work. The rail under this is inlaid with a rather weak modification of the bead-and-reel ornament, the members separated by large spaces, and connected by a straight line running along the centre of the rail. The next drawer is a semi-Elizabethan strap pattern, but with leaves of a more Gothic form sprouting from it; and the front of the fourth and lowest drawer is of Late Gothic type, formed of a cresting of a common "Perpendicular" type, with an inverted cresting filling in the interspaces of the lower ornament. Below this, the band of ornament affixed as a finish is completely Renaissance in character, though rather rudely executed; the details are a central vase, with flowers springing from it, and sea-horses in relief on either side; the bottom line of the woodwork, which is clear of the floor, making a broken line, following the sinuosities of the design, in a manner quite out of keeping with the severe lines of the upper portion of the cabinet. The end uprights have an Ionic capital, with cherubs' heads and foliage of a Renaissance type. Altogether, it would be difficult to find in a single example a more curious and interesting illustration of Transition in ornamental style. The date is assigned, for reasons given, to 1612-13.

One of the best examples given is the Library Door of St. John's College, a portion of the woodwork finished in 1628, of a grand and massive Jacobean type. The door itself is framed with nine equally-spaced deeply-moulded panels, with ornamental devices in the centre; it is flanked by massive pilasters, with faces carved in strap ornament within panels. A carved oak settle, the property of Mr. Redfern (plate 7), very richly and beautifully decorated with detail of a more refined type than is always found in Jacobean work, is another example worthy of note. In regard to this and one or two other specimens of furniture which have the well-known form of very massive leg characteristic of the period (with a central bulb, as it may be called, a great deal thicker than the upper or lower portion of the leg) no information is given as to whether these legs are turned out of the solid, or whether the thicker portions are planted on. It is melancholy to think, but this bit of humbug is known to have been practised in some examples of the period, at all events.

One of the most interesting illustrations is the Bookcase-end from Pembroke College (plate 15), with a segmental pediment at the top, and a carved scroll projecting from each side at the foot. Mr. Clark's note on this latter feature is worth quoting:—

"To understand the meaning of the scrolls (or wings, as they are sometimes called) at the base of the bookcase-end, we must consider the ancient mode of arranging libraries. Throughout the Middle Ages, and in some of the seventeenth century, or even later, books were secured by chains. The reader sat on a fixed seat in front of the bookcase, and the chains were made long enough for him to hold his book on his knees, or to place it on a desk attached to the lower part of the bookcase. Subsequently, as the number of books increased, the seat for the reader was replaced by a case to contain books, and his seat was transferred to the bottom of the bookcase, where he sat with his back to the books, and with the volume which he wished to

consult on his knees. The end of the seat was concealed by ornamental scroll work, such as we see in the example before us. As time went on chaining was given up, and the reader's seat was no longer required. The scroll, however, had become a customary termination to a bookcase end, and survived throughout the seventeenth century. In many cases the ornamentation is exceedingly rich and beautiful."

But by far the finest piece of work illustrated is the example of carving from the details of the organ-screen in King's College Chapel (plate 18), of which we are enabled to give a reduced reproduction. The combination of breadth and holdness of style with delicacy and grace in detail in this work is truly remarkable, and we quite concur in Mr. Clark's opinion that it was probably executed by Italian artists. The style and *tournaire* of the head of the figure, especially, is essentially Italian. The letters H A on the shield stand for "Henry" and "Anne." Mr. Clark speaks of the whole work as "the most beautiful piece of wood-carving out of Italy," and he is probably not wrong in this estimate. "Some special good fortune," he adds, "seems to have protected it, for it has been spared alike by the fanatic and the restorer, and is standing at the present day in the same perfect condition as when it was executed three centuries ago."

Of the ironwork illustrated in the book, the best examples are from the gate at the west end of the avenue of Trinity College, and from the gates under the library of the same college. The details of the former, on Plate 23, are in a very fine and free wrought-iron style, but the main value of the book consists in the illustrations of woodwork, and in this respect it is a real acquisition, for which the best thanks are due to its producers.

#### NOTES.

WE are glad to see that Professor Huxley, whose opinion certainly ought to have great weight in such a matter, has been speaking out plainly, in more than one letter to the *Times*, against the ill-judged proposal to locate the Imperial and Colonial Institute at South Kensington, about which we have already expressed our opinion in equally decided terms. The only excuse really put forth for the proposed locality is the possibility or probability of obtaining a cheap site; and it is stated that the cost of any adequate site in the neighbourhood of Westminster would be practically prohibitory of the enterprise. We can only say that if the matter of the new building is not taken up as a national concern, on such a scale and in such a situation as will make it a worthy outward and visible sign and form of the intellectual, political, and commercial relations between England and her colonies, it had better be let alone altogether. It is a kind of thing that must be done well or not done at all. Professor Huxley seems disposed to advocate the view that the Institute should be situated in the City; we consider the neighbourhood of the seat of the Imperial Government the proper place for it: each view may have something to recommend it, according as we emphasise the commercial or the political significance of the proposed institution. Professor Huxley evidently regards it as, to use his own expression, "an intelligence department for the army of industry." Without undervaluing that side of the matter, we would regard it also as a centre for drawing closer the political relations between England and the Colonies, and in that light Westminster is certainly the proper neighbourhood for it, and the most dignified one in every sense. A South Kensington site is at variance with both conceptions of the functions of the Imperial Institute.

IN reply to Sir J. Goldsmid's question last week in the House of Commons as to whether the First Commissioner of Works intended to proceed with the new Admiralty and War Office buildings, Mr. Plunkett replied that a Special Committee had been appointed last April to reconsider the question, which Committee lapsed with the dissolution of

Parliament; but that a similar Committee would be appointed in a few days to consider the matter afresh. We are glad to hear it. We have always said that every justice should be done to the architects who had, by the mistakes of a former Committee (apparently mainly managed by an incompetent amateur "person of taste" who did not know the difference between drawing and architecture), been put into a position which their design certainly did not merit; but it is a very serious thing that a national building of such importance should be erected which will add nothing whatever to our metropolitan architecture but a bulk of architectural commonplace. It is to be hoped, however, that when the Committee is appointed, some care may be taken to select members who really know something of art and architecture, instead of such a party of mere nonentities (in this respect) as a late First Commissioner of Works got round him in order to carry out his silly scheme for making a sham-antique of Westminster Hall.

THE Government have had plenty of opportunity of judging how far their Railway Bill is likely to meet the grievances it is designed to remove, as deputations representing many different trades and industries have waited upon Baron de Worms and Lord Stanley of Preston to express their views and opinions. Like the representatives of the Railway Companies, however, they have failed to elicit any definite forecast of the proposed measure, but it will probably be brought forward early next week. Lord Stanley promised to hold the scale as fairly as possible between the conflicting interests, though the directors of the Companies,—judging from the remarks at the half-yearly meetings last week,—are very apprehensive of unfavourable results to themselves. They have apparently availed themselves of the opportunity which the delay in settling the controversy has afforded them of making various concessions in favour of the public, as Mr. Moon stated at the London and North-Western meeting that a large proportion of the falling-off in receipts (compared with the tonnage carried) was due to reductions in rates. He strongly advises all railway shareholders to study the book recently published by Mr. Grierson, to which we have had occasion to refer, and which, though open to criticism, is well worth perusal as a powerful contribution to the controversy from a managerial point of view, and as indicating some of the difficulties the railway companies have to contend with. It justifies the remark made by Mr. Thompson to a dissatisfied Midland shareholder at their meeting on Friday last: that it would be penny wise and pound foolish to run the risk of losing such men as the general managers and other leading officials by cutting down salaries. The fact is, the Midland chairman knew by experience that attractive and successful baits are held out from the Colonies and elsewhere to able and experienced railway officials, and that they can ill afford to play into the hands of such competitors at the present juncture.

THE debate on the Ambleside Railway Bill last week, which resulted in the second reading being passed by a majority of twelve (189 to 177), followed the usual lines to which we have been accustomed on such occasions; on the one side the opposition of those who would keep a quiet and picturesque district from intrusion, on the other side those who maintain that the people who want a railway know best why they want it, and that the working of the line as a paying concern depends upon the fact that a certain portion of the population, in the district and elsewhere, actually require it, since people are not in the habit of paying for railway tickets from purely philanthropic motives towards the promoters. We had the usual allegation made, that this is a line only promoted "in the interests of contractors," as if contractors could get a company formed to pay their charges without any prospect of the railway forming a substantial source of revenue. The chief opponent of the Bill, Mr. Bryce, is, of course, far too reasonable and enlightened a man to

give utterance to the foolish anathemas against all railways and railway works which we generally hear from the people who oppose a railway Bill on sentimental grounds; and he admitted that considerations of scenery must give way where great public benefit was concerned; he only denied that this was the case here, and Mr. Graham opposed the Bill "on the true democratic principle of preferring the happiness of the greater number of inhabitants," implying, of course, that the public beyond the immediate district had an interest in the preservation of the neighbourhood from railways. In that case let them show it by petitioning largely against the scheme, which it does not appear that they have done. On the other hand, both Mr. Lowther and Mr. Cavendish Bentinck, who knew the district well, gave strong evidence as to the wishes of the residents in favour of the railway. If this is the case, it is to no purpose to say that people in another part of the country do not wish for it. The inhabitants of the district are not to be deceived what they want, in order to please people who have no claims upon them. If the district is to be preserved intact for the benefit of the country, the Government should purchase it, as Mr. Labouchere proposed in the only practical sentence in a speech which was otherwise little more than amusing rant. We should regret seeing the railway made as much as any one would, as far as our own tastes and pleasures are concerned; but if it is understood that the residents wish for it, we do not see what argument is to stop the way fairly. We may observe, however, that in other similar cases, railways, when once made (in process of making they are always a nuisance), have not been found to deteriorate the landscape to anything like the extent predicted.

THE want of success of the Hull and Barnsley Railway, the fact that the Newbury and Didcot Railway Company are unable to pay the interest on their debenture stock in full, and the acknowledged failure, from the interest-bearing point of view, of the addition to the Underground line, are likely to make railway directors more careful than ever not to begin new extensions. In every country the time must come when branches and new lines cease to be profitable in themselves or to bring profit to trunk lines. Such a time has, it would seem, arrived in this country, and though here and there from time to time changing circumstances may allow a new line or a new branch to be made without loss, it seems pretty evident that the railways of England have nearly attained their permanent size.

WE understand that the following architects are to be invited to send in designs for the Imperial Institute building.—Dr. Rowand Anderson, Mr. Blomfield, Mr. Colcutt, Mr. Deane, Mr. T. G. Jackson, and Messrs. Aston Webb & Ingress Bell. No complaint can be made of the selection; from among these competitors we are pretty certain to have a fine building, and we only hope the authorities will secure the right site on which to place it.

WE referred recently (p. 209 and p. 214) to the decision of the Superintending Architect with reference to a proposed building on the west side of Brixton rise, at the corner of Trent-road, and to the reply of the Chairman of the Metropolitan Board of Works to a question put by Mr. Broadhurst in the House of Commons as to the position of the Superintending Architect. Several letters and a memorial were recently presented to the Board on this subject, asking, for reasons stated, whether means could be found for reviewing the decision, on the ground that the wrong portion of the road had been inadvertently brought specially under notice. These letters and memorial were referred by the Board to the Works and General Purposes Committee for consideration and report, and the Board, on the recommendation of the Committee, informed the parties that the Board had no power to take any action in the matter. It appears from the report of the Committee that the Vestry of Lambeth, having

received notice from a builder of his intention to erect three houses at the corner of Trent-road, requested the then Superintending Architect to decide the general line of buildings in that part of Brixton Hill with reference to the site upon which it was proposed to build. Mr. Hebb gave a decision to the effect that the general line of buildings on Brixton Hill, between Cornwall-road and Horsford-road, was a line 16 ft. back from the public footway. Mr. Hebb considered that the question was one of fact, and that he had no power to review his decision, and the Solicitor to the Board reports that there is high authority for the opinion that the certificate of the Superintending Architect, if valid, cannot be altered or withdrawn. The memorialists appear to have been under the impression that the Superintending Architect acts under the authority of the Board as regards the determination of general lines of buildings, but this impression is an erroneous one, and the Solicitor to the Board is clearly of opinion that the Superintending Architect, as a statutory officer, should not receive any directions from the Board as to the exercise of his discretion. The Metropolitan Board, on the 11th instant, on the motion of Mr. E. Rider Cook, passed a resolution referring it to the Works and General Purposes Committee to consider and report as to the advisability of applying to Parliament to give a right of appeal from the decision of the Superintending Architect with regard to questions of general lines of buildings.

IT is a coincidence worthy of passing note that the first two sessional papers which were read at the Institute this session, and which form the bulk of the reading in the first part of the new volume of "Transactions," just issued, are both by foreign members, and both upon the subject of colour. The importance of the subject has been too much overlooked both at Conduit-street and elsewhere in this country, but it is now steadily, if slowly, forcing itself to the front, and by the aid of such papers and the by no means unimportant assistance of the Owen Jones Studentship, and the removal of the prohibition of the use of colour in drawings submitted in competitions, it will, we may hope, very soon be better understood and more frequently called in to aid the architect. Signor Boni's paper is especially noticeable as giving an authentic and somewhat detailed account of a famous building of which little or nothing was really known to the present age before Signor Boni's researches.

WE have received a collection of twenty-nine plates, constituting the second volume of "The Glasgow Architectural Association Sketch-Book." The collection comprises a great number of pretty sketches and notes,—some of them executed with much taste and skill,—and a certain number of useful studies of detail. The sheets of scraps from France and Switzerland by Mr. A. N. Paterson and Mr. J. A. Campbell are particularly good; the same may, indeed, be said of Mr. J. Keppie's Italian doorways and of Mr. A. N. Prentice's sketches at Lincoln, Mr. J. Thomson's St. George's Windsor and Dryburgh Abbey, and Mr. William Ferguson's gables and dormers at Shrewsbury. Mr. A. R. Scott's west front of Dunblane Cathedral is quite the best of the measured work. The reproductions of water colours are rather black and heavy, but in other respects the "get up" of the plates is exceptionally successful.

THE extensive demolitions for the widening of Upper-street, Islington, are nearly completed. They include, along the eastern side, all the buildings,—excepting Dowbiggin's parish church of St. Mary, opened in 1754, and the quite modern dispensary,—from the Unity Church southwards to the Green, *olim* old Paradise-row, being Nos. 276 to 331, and comprising the Fox tavern and the Congregational chapel; and, along the western side, Nos. 156 to 168, between the approach to Waterloo-terrace and Barnsbury-street. On this latter ground a site of about 10,000 ft. superficial is reserved for the construction thereon of artisans' dwellings. Very nearly

all of these houses are planned in the large-scale map of 1805-6 belonging to the parochial authorities. The index to that admirable piece of work has, we are informed, been mislaid; but we gather from other sources that the rows of houses along the church side of the street were, at one time, severally known as Upper-terrace, Rufford's-buildings, and Church-row. On the opposite side of the way yet remain one or two tenements of much earlier date than the current century. Albeit in a local survey of the year 1735 the now Upper-street is set out, for the most part, in the guise of a village highway.

AFTER having been for some time in the market for sale at auction, the Jervaux Abbey demesne has just been purchased for, we understand, 310,000*l.* (exclusively of the value of the timber) by Mr. S. Cunliffe Lister, of Bradford, manufacturer. This important and beautiful old property, situated in the vale of Wensleydale, formed portion of the Yorkshire estates held by the Marquess of Ailesbury's trustees in the North Riding. Watered by the river Ure, it comprises some 10,002 acres, yielding a gross rental estimated at say 11,600*l.* a year. About five years ago Mr. Lister also bought of Admiral O. Harcourt's widow, for 400,000*l.*, the adjoining Swinton Park property of nearly 23,000 acres in extent. Whilst all trustworthy authorities do not agree in reckoning the abbots of this famous Cistercian monastery amongst the few "mitred" abbots north of the Trent, there seems to be small question that they did on occasion assume that proud distinction. This is apparent from the mitres which are carved on the incised slab in the chapter-house of Peter de Snape, seventeenth abbot, who died in 1436, and on the slab, in Middleham Church hard by, of Robert Thornton, died 1533, twenty-second abbot. Moreover, we learn from Stowe's chronicle that the lord abbot of Jervaux, taking precedence of his Cistercian fellows from Bellalund and Fountains, ranked as thirty-sixth on the roll of the sixty-one abbots who, with many other dignitaries, attended to King Edward I.'s summons for a great Parliament at Carlisle in 1307. Of ruins are extant the church, cloister, choir, transept, chapter-house, and refectory. This property, lying in a district that has for several generations been famed for its horse-breeding, passed to the Bruce family by the marriage in 1676 of Elizabeth, daughter of Lord Beauchamp, with Thomas, Earl of Elgin and Ailesbury. We follow the now customary spelling of the name, but may observe that in the earlier charters and down to Abbot Thornton's time it appears as Jorevall, Jorevalle, and Jorevalis. We subsequently meet with more than twenty-five other forms, including Gerovall, Gervise, and Yorevank, until we come to the quite modern and prosaic Jarvis. The worldly "Prior Aymer of Jorvaulx Abbey" will be remembered by all readers of "Ivanhoe." The East Tanfield, the Tanfield Lodge, the Wath, and the Swainby and Whorlton Castle properties form the complement of the whole estates. The sale was made by private arrangement with Messrs. Chinnock, Galsworthy, & Chinnock.

THE numerous suggestions put forward for "holstering up the Crystal Palace, both at the special meeting of Saturday last and in the letters of individual correspondents, each offering his panacea, form, it must be admitted, sufficiently amusing reading, and suggest the idea that most of the persons interested in the concern are more or less out of their minds. Mr. Morgin Howard, M.P., the mover of the first resolution at the meeting referred to, concluded his speech by asking "Why should not the Crystal Palace be the home of the proposed Imperial Institute?"—a query followed by "loud and renewed cheers." If the management of the Palace has been influenced by any persons who are idiots enough to make and to applaud such a proposition, it is not difficult to understand how it has come to grief. The whole meeting seems to have been a demonstration in favour of the eleemosynary support

of the Palace for the benefit of shareholders and season-ticket-holders against all ordinary considerations of logic, fairness, and common-sense. The letter of Mr. G. P. Witt, which followed the report of the meeting in Monday's *Times*, made some practical criticisms as to the management (or want of management) of the Palace; the *laissez-faire* way in which it has for some time been allowed to go on; the neglect to seize such an opportunity, for instance, as the sale of "Old London," which was allowed to go for an old song as builder's materials,—and so on. It seems to have been supposed for some time past that the Palace could go on merely from its acquired reputation, with little attempt at putting new life into it. "A Bystander" suggests that the directors should try private enterprise, and invite tenders for leasing the building for a term of years. But those who make these suggestions forget the nature of the structure they are dealing with. What contractor in his senses would take, at any remunerative rent, a great greenhouse like that, with all the inevitable and increasing expenditure for repairs, with the expectation of obtaining an adequate percentage on the enterprise? That is what is at the bottom of the difficulty. The building is a glass and iron structure of an essentially temporary character, and it has now arrived at a period in its history when extensive repairs and even a great deal of reconstruction must be necessary,—a side of the matter which none of the writers to the *Times* seem to be in the least aware of. The moral of the whole business is,—if you want a permanent institution, erect a permanent building for it.

#### EDINBURGH MUNICIPAL BUILDINGS COMPETITION.

In response to the advertisement issued by the Magistrates and Council of the City of Edinburgh in August last for competitive designs for the proposed New Municipal Buildings, fifty-six sets of designs have been sent in, each illustrated by an average of fourteen sheets of drawings. These comprise plans, elevations, and sections to a scale of 10 ft. to an inch; block plan to a smaller scale, and one or more sheets of half-inch-scale details of parts. The greater number of the designs submitted come from across the Border, most of the more eminent Scotch architects having refrained from competing, believing that some of the conditions of competition were unsatisfactory, and, further, that there was some uncertainty as to whether the buildings would be carried out or not. Several of the younger Scotch architects show designs of conspicuous merit, and one of them has secured the second premium, the other two premiums falling to London practitioners.

The site, which is an enlargement of that at present occupied by the Municipal Buildings, may be described as a square with a notch out of one angle, or as a short L, having its base to High-street, opposite the eastern end of St. Giles's Cathedral, Parliament-square, and the Crown Offices, with its head stretching northwards to Cockburn-street. The northern end, though nominally the back of the building, is really its most important frontage, as it stands at an elevation of 65 ft. above Princes-street, from which an uninterrupted view of it will be obtained across the intervening valley and gardens. The site may be said to occupy the eastern end of the crest of the Castle Hill, the western extremity of which is occupied by the Castle itself, while the *coup d'œil* between the two embraces, such important public buildings as the Bank of Scotland, the Free Church Assembly Hall, the Established Church Assembly Hall spire, and the crown-topped tower of St. Giles's, to say nothing of the historical and picturesque old buildings which crowd the Castle Hill. Another feature which adds to the architectural possibilities of the northern frontage is the fact that the level of Cockburn-street is considerably below that of High-street. Most competitors have recognised the paramount importance of the mass and grouping of their designs towards Princes-street, and, while giving due consideration to the treatment of the High-street façade, have directed their chief efforts to the realisation of an effective composition as viewed along the

line of Princes-street. The eastern and western limits of the site are bounded by open closes or lanes of a minimum width of 20 ft., but the adjacent buildings on the northern half of the site are so low as to leave the greater part of the new building visible above their roofs. Regarding the height and openness of the site, which is eminently one to be seen from numerous stand-points, and in the view of which the surrounding buildings cannot be excluded, it is a matter of special regret that perspective drawings were prohibited in the competition.

Mr. Alfred Waterhouse, R.A., was appointed architectural assessor to advise the Corporation in the award of the premiums, and after a careful examination of the whole of the designs submitted, which are advantageously hung in the Waverley Market, he has made the award which we announced last week, and the full text of which we now give on another page.

The premiated designs become the absolute property of the Magistrates and Town Council, who are at liberty to employ any one they think fit to carry out the work.

"Edina Classica."—This is the design to which the first premium has been awarded. The plan shows a long quadrangle or courtyard, 108 ft. by 70 ft., with the buildings ranged round the east, west, and north sides, the south side being open except for a colonnaded screen, arranged for foot and carriage traffic towards High-street. In the centre of the north end of the courtyard is the principal entrance and staircase, while immediately within the colonnade in the south-east and south-west angles of the courtyard are placed two minor entrances, with staircases for the ordinary business public. Continuous corridors connect these three staircases on the several floors. They are lighted from the side closes or lanes, the apartments entering from them being lighted from the courtyard. Availing themselves of the inequalities of ground-level, the authors (Messrs. Leeming & Leeming) have provided what they call two ground-floors, one a flight above and the other a flight below the level of the courtyard. On the latter level are placed the Burgh Assessor and Burgh Engineer, the Collector of Police, several of the Registrars, and the City Roads department, and on the latter level the Town Clerk and City Chamberlain. To right and left of the principal entrance are located the Burgh Court-house and the rest of the Registrars. On the first floor, occupying the north block, immediately over the Town Clerk and City Chamberlain's department, and overlooking Princes-street and the Firth of Forth, are the Council Chamber and committee-rooms, Lord Provost's room, &c., while on the same level, in the east and west wings, are placed the Water Trust Offices, the Dean of Guild Court-room, and the Superintendent of Works office. The Clydesdale Bank premises are entirely detached from the Municipal Buildings, which is a very good feature. Over the bank premises are the Heriot Trust offices, connected by a bridge on the first-floor level with the main building. The architecture is a severe type of Palladian Classic, the various parts towards High-street being well composed. The extremities of this façade are accentuated by small domes, and a large dome is placed over the grand staircase, centering with the courtyard and the north elevation. This elevation is much lacking in interest. The architectural base of the building is four stories high, and all of equal height, while the rustication and fenestration are the same in each. Over this is a columnar treatment extending through two stories, with an entablature and balustrade over, which gives a perfectly straight sky-line,—there being no roof or chimneys shown,—broken only by the great dome. The great severity of style and simplicity of treatment towards Cockburn-street is insisted upon by the authors as most suitable for the situation by contrast with its surroundings. This is not the view we should take of the situation, the whole grouping of the Castle Hill appealing for something in harmony, not in contrast, with its picturesque formation. While it is true that the breaks in the line of frontage would give a less rigid sky-line in perspective than is seen in the geometric drawing, yet an elevation of 170 ft. in length and 120 ft. in height seems to call for more than one feature in its composition. The drawings are a marvellous example of painstaking and careful draughtsmanship, and are beyond all praise in their style; it is not a type of draughtsmanship that every one would care to emulate; and the constantly-increasing

importance given to draughtsmanship in competitions is a matter to be regretted. Draughtsmanship is not architecture, and the most beautiful execution of drawings will not atone for want of force and originality in the actual building. The estimated cost of the building is 98,000*l.*, but it may be said of this as of the majority of the other estimates, that it is rather under than over the mark.

"Nineteenth Century."—This design is by Mr. Malcolm Stark, of Glasgow, and was awarded the second premium. It has a central quadrangle with buildings on all four sides, those on the east, west, and south sides being restricted in height to 45 ft., measuring to the top of the balustrade. The plan, which is perhaps the most easily read in the room, is strikingly symmetrical and well balanced. The principal staircases and the two minor staircases, with their connecting corridors, are placed similarly to those of "Edina Classica." The Council-rooms, which are arranged with much staleness and convenience, are, as in "Edina Classica," placed on the first floor in the north block, but in this case the Town Clerk and City Chamberlain are on the same level, occupying the east and west blocks, the officials' rooms being placed so as to give them command of their departments, and easy access to the Council and Committee rooms. The Collectors' offices, in connexion with the Police and Water Trust, are most conveniently placed for the ratepayers, while the Burgh Court and Dean of Guild Court, in the eastern extremity of the High-street front, are well isolated from departments with which they have no connexion, and are themselves convenient of access. The architectural treatment shows a free rendering of Classic, recalling some portions of the Louvre. A high campanile is placed at the east end of the High-street façade, while towards Princes-street the composition is well grouped by a central colonnade with pediment over, supported by two towers finished after the manner of the two western towers of St. Paul's, and supported by side roofs running at right angles to that over the central pediment. The sheet of details is beautifully drawn, and exhibits a familiarity with the ornamental detail of the free type of Classic chosen. The estimated cost is 120,000*l.*, with the great tower, and 112,740*l.* without. An alternative elevation is shown omitting the tower, by which the design loses nothing and would be less likely to detract from the tower of St. Giles's.

"In my Defence."—This design, which was submitted by Mr. J. W. Simpson and Mr. E. J. Milner Allen, has taken the third premium. The plan is arranged with buildings round the four sides of a central quadrangle, but the quad is divided across its centre by a lavatory block, which reduces it to two courts, each about 45 ft. by 35 ft., which become simply wells for light. The northern one measures 105 ft. from the ground to the top of the balustrade. While the two other premiated designs light their corridors from the surrounding closes, and their apartments from the central quadrangle, this design reverses that arrangement, and lights the corridors from the courts and the apartments from the closes. To secure good light at the side, the east and west wings have been set back from the boundary-line, so as to secure a sufficient open space between them and the adjacent buildings. By placing the corridors to the inside of the block their length is greatly reduced, but the dignity and beauty of the open quadrangle is lost, and in this case has not been compensated for by any special dignity in the entrance-halls and staircase. This design also differs from the others premiated in that it places the Town Clerk and City Chamberlain on the ground floor and the Council Chambers on the first floor, towards High-street, and the minor officials and offices in the north block. By this means a south light is obtained to the important apartments, but a due regard to the site and outlook would dictate the north wing as the proper place for the Council Chambers. In the matter of architectural style "French Renaissance" has been adopted by the authors because, while susceptible of great dignity and breadth of treatment, it is also more readily adapted to modern requirements in regard to the proportion of window to wall space than the Italian, while it possesses a common resemblance in many of its forms to the Scottish Baronial Architecture." The authors have not made the most of the style chosen, the treat-

ment of the various façades being thin and over-restrained, while the detail shows more of modern French feeling than a close acquaintance with the Renaissance of François I. They have also placed themselves under voluntary restriction by omitting any tower or dome which might compete with St. Giles's. This is a point which it would be well to observe in the execution of the building, and the authors would probably not have suffered by the omission of perspectives showing the grouping of the building with its surroundings had been permitted.

"Fortuna."—The plans sent in under this motto are hung next to those of "Edina Classica," to which they bear a striking resemblance in general disposition. Starting upon the same basis, that is, with the axis of the building struck from the centre of the Market Cross, the buildings surround three sides and part of the fourth side of a quadrangle, the centre portion of the south side being open, with a colonnaded screen. The principal and minor entrances and staircases, the Town Clerk's and City Chamberlain's offices, and the suite of rooms for the use of the Town Council, are placed identically as in "Edina Classica." The corridor in the east wing has a break in the centre of its length, which gives the plan a somewhat involved appearance. The type of architecture chosen is the Scottish phase of the Classic Renaissance, of which the author quotes the quadrangle of the present Municipal buildings as a good example. He has certainly treated it in an able and skilful way, and shows a set of elevations in every way superior to those of "Edina Classica," and much better suited to the situation. The fenestration and mural treatment of the walls all round are well proportioned and full of interest, while the details show this type of Classic to be at once dignified, refined, and plastic. There is a dome over the centre of the Cockburn-street front, and a tower at the east end of the High-street front. The estimated cost is 125,000.

"Ora et Labora."—This plan also has the buildings grouped round three sides of a quadrangle, 95 ft. by 80 ft., open on the south side. The position of the Council Chambers on the first floor of the north wing, and the arrangement and lighting of the grand staircase, are very similar to those of "Nineteenth Century," but the rooms of the various officials are not so well disposed. The authors have selected Italian Renaissance as being "a style combining the simplicity of outline required by the site, the dignity of appearance befitting the abode of a great civic body, and the freedom of treatment rendered necessary by the more complex requirements of the age," and it is not too much to say that they have attained all the objects which prompted them in their selection. For scholarly handling, dignified treatment, and refinement of detail, especially as exhibited in the Cockburn-street elevation, this design is probably without a rival in the room. A broad massive base, pierced with windows just sufficiently enriched and varied to avoid monotony, supports a rusticated story with square-headed windows. The upper floor which rests upon this has a range of Corinthian columns standing clear from the wall behind and carrying a full entablature. These columns are spaced into three groups in the length of the façade, and between each group is a deeply recessed balcony from the Lord Provost's and the Town Councillors' rooms respectively. To the left the receding masses terminate in a great campanile modelled closely upon that of St. Mark's, Venice, the whole combining in producing an effect which it would be an acquisition to Edinburgh to obtain. The cost is put down at 250,000, but is probably much overestimated.

"Light and Air."—This plan, which is so highly spoken of in Mr. Waterhouse's report, stands quite alone in its arrangement. It is cruciform in shape, with the head of the cross next High-street, and the four extending northwards towards Cockburn-street, while from the extremity of the cross arms corridors lead to east and west wings at the respective extremities of the site. Like "Edina Classica," the authors have availed themselves of the inequalities of ground level to form two so-called ground floors. On the lower of the two are placed the Collector of Police and some minor officials, and on the upper the City Chamberlain in the left arm or transept, the Town Clerk in the right, and the Water Trust office in the centre or main body of the cross. The first

floor is principally occupied with the suite of apartments for the Town Council, the Council Chamber being placed at the northern extremity of the cross. Whatever its merits may be as an ideal plan,—and Mr. Waterhouse has given his opinion in no uncertain language,—it is not at all adapted to the site in question; while the elevations can only be described as bad specimens of modern German-Greek, which would produce a jarring discord if set upon the Castle Hill.

"Fiat."—This design, while adopting the three-sided courtyard centring with the Makret Cross, differs from those previously described, in that it aims at the isolation rather than the connexion of the various departments into which the municipal business is divided. To secure this there are, in addition to the principal entrance in the centre of the north side of the quadrangle, four minor entrances giving direct access to the offices of the various officials, internal communication between the departments being also provided. This arrangement is possibly one which would work well enough in practice, but is not one which produces an effective or telling plan upon paper. The Council Rooms are placed where they ought to be,—in the north block on the first-floor level. The architectural treatment is Classic, of a healthy masculine type, with a dome over the centre of the north wing, and a tower in the centre of the eastern wing of the High-street façade. The elevations are holdly and well drawn, and show a familiarity with Italian Renaissance. The estimated cost is 125,000.

"N. D. L. V."—The authors of this design seem to have had the same object in view as that of the authors of the design last described, viz., the isolation of the various working departments, which they have sought to accomplish in a similar manner, though in the first floor in this design there is a wide and well-lighted corridor running round the four sides of the quadrangle. The state entrance to the Council Room is directly from the High-street, and the principal staircase is placed in the centre of the east side of the quadrangle. The elevations are Classic, of the same healthy character as that of "Fiat," with bold late sixteenth-century detail. They are most effectively drawn, and show an individuality rising far above the conventional setting-out of Classic façades, though exception might be taken to the main tower rising from the top of a pedimented portico.

We will return to the subject next week, when we hope to illustrate the three premiated designs. In the meantime we give on p. 330 the official report of Mr. Waterhouse as the professional referee in the competition.

#### CLISSOLD PARK, STOKE NEWINGTON.

STATUTORY notice is given of a project to purchase the freehold of certain lands and buildings at present held by the Ecclesiastical Commissioners in St. Mary, Stoke Newington, parish, for purposes of public recreation and benefit. The land consists of some fifty-three acres, now known as Clissold, or Stoke Newington, Park, which it is proposed to vest, as regards their maintenance and regulation, in the Metropolitan Board of Works. The residence and its site therein are to be committed to the Vestry for use or adaptation to "the purposes of a vestry-hall, public museum, free library, public baths, or washhouses, or any other parochial purposes." The intended Act provides for contribution towards the necessary funds by the Metropolitan Board of Works, the Corporation of London, the South Hornsey Local Board, together with various other local or district boards; as well as by the Charity Commissioners and the trustees of the City of London Parochial Charities when established as provided by the City of London Parochial Charities Act, 1883.

Lying within the Fishery Division of Ossington Hundred, the area in question is bounded by thoroughfares whose names bear witness to the once universally rural character of their surroundings. Thus, to the east and west respectively are Queen Elizabeth's-walk and the Green-lanes; Lordship-park and Manor-road pass northwards; its southern confines extend to Church-street and Paradise-row. Through its broad rich meadows meanders the New River, whose gently-flowing stream, fresh from the reservoirs and filter-beds near to Fishery Park, sweeps with bold curve, and amidst some of the most varied and luxuriant foliage that

northern London can show. Hard by, beyond Queen Elizabeth's-walk, behind the church, lies the *ci-devant* seat\* of Thomas Gunston, whose sister, Mary, became second wife to Alderman Sir Thomas Abney, the zealous Hanoverian member for the City. Watts had been received into his house at Theobalds by Sir Thomas in 1712. On his host's death (1722) he continued with Lady Abney and her daughters, and with them removed, in 1733, to the house her brother had built in Newington. Watts had, ere this, spent five years at Newington as tutor in Sir John Hartopp's family. With a constancy of friendship and uniformity of conduct not often to be found, writes Dr. Johnson, Sir Thomas Abney and his family treated Watts for thirty-six years with all the kindness that friendship could prompt and all the attention that respect could dictate. In the 115 acres of Finsbury Park we see what still remains of the Bishop of London's hunting-ground, Hornsey Wood, being another relic of the forest which, here traversed by the Emainic Way, extended over Middlesex. Before the Dissolution, Hornsey formed one of the great shire manors that appertained to the see of London. Brownswood, in Hornsey, and Newington manors are commemorated to this day by prebendal stalls at St. Paul's Cathedral. Stoke Newington figures in Domesday Survey as Newtome; as Stoc or Stoke Neweton in the fourteenth century; and here, in 1649, were yet left 77 acres of woodland in demesne.

We gather that this estate, lately the residence of the Rev. Augustus Clissold, belonged for many years past to the Crawshaw family. From a published letter of Mr. George Crawshaw it appears that twelve months ago the property consisted of two portions, one of 25½ acres, freehold, and the other a perpetual leasehold of 27½ acres, over which the Ecclesiastical Commissioners had such rights as to hunting, fishing, and hawkling, as were set up by the lease which was first granted by the sport-loving Dean and Chapter of St. Paul's. This lease was held at 100l. per annum and a fat turkey. That the park preserved much of its pristine character is doubtless due to conditions which prevented the granting of building leases or the felling of trees. Mr. Crawshaw used to admit visitors on Saturday and Sunday afternoons, in summertime, into the leasehold portion of his grounds. So sensible was he of their value to the public that, whilst ready to sell 20 acres of the freehold, he reserved the remaining 5½ acres on which the old house stands, because, he says, of the extreme beauty of the grounds, which, together with the well-timbered leasehold, and the shaded and encircling waters of the New River, make up a whole which he trusted would never be destroyed. "But," adds he, "my power to prevent this is limited by my life." Mr. Crawshaw, however, has since parted with all his interest in the whole of the property. The parishioners are most anxious to secure this, the one only space that is left to them, and it is to be hoped that, as at Kilburn and Highgate, the Commissioners will prove willing to meet them with a liberal spirit. It is understood, as matters now stand, that they are ready to accept a sum of 95,000l. for the property.

#### Manchester Architectural Association.

The ordinary fortnightly meeting of this Association was held on the 22nd inst., at the Diocesan Buildings, Mr. L. Booth, President, in the chair. Mr. W. H. Rawle read a paper on "The Architectural Assistant," which dwelt more upon the social prospects than upon the technical details pertaining to the duties of that member of the profession. His argument was that the complaint of want of employment was due more to the overcrowding continually going on of pupils, &c., rather than to the low state of the building trade. This ultimately affected every architect, of whatever standing. The author proposed as the most immediate attempt to lessen this evil that statistics should be collected as to the real number of pupils, and disseminated in pamphlet form throughout the architects' offices of the country. A discussion followed, in which Messrs. Hodgson, Mould, Ward, Stelfox, and the Chairman took part.

\* Now the Abney Park Cemetery, south of Stamford Hill. The house was pulled down in 1814.

† Vide the *Times*, January 14th, 1886. With this letter should be read a communication, in that paper of 7th inst., by Mr. H. R. Williams, Chairman of the Hornsey Local Board.

## MR. WALTER CRANE ON "THE ARCHITECTURE OF ART."\*

ART AND COMMERCIALISM.

THE architecture of art is a somewhat comprehensive title, and you might not unreasonably expect of me, before proceeding with the structure and treatment of the subject in perspective, to give some sort of scale sketch, ground plan, and elevation, so that the general drift of my argument may be understood.

I do not propose to deal exactly with the various forms and styles of architecture as they are and have been manifested in plastic or graphic art; or with the predilections of different designers and painters for certain forms over others as accessory to their compositions, interesting as such a comparative study might be. I am taking the term "architecture" in its widest sense, considering it not only as an art in its connexion with and effect upon other arts, but as the fundamental, comprehensive, and sustaining framework both of life and thought,—the historic and living background which influences and moulds all our ideas,—the set-scene upon which is enacted the ever shifting drama of art.

In comparing the art of the present day with the art of the past, especially of any well-defined epoch, whether Mediæval or Classical, we cannot fail to be struck with one great distinction underlying all superficial differences. Whereas art in past ages seems to have germinated and to have been continually evolved in new forms,—to be alive, and spontaneous, as it were, growing like a thing of nature, and expanding with man's ideas of nature, beauty, and life,—in our day this sense of spontaneity, this natural growth, is scarcely felt. Conscious and laborious effort takes the place of spontaneous invention, and originality is crushed by the weight of authority and precedent. The student is confounded and abashed by the mass of examples,—the dry bones in the strata of museums and hooks of what were once living and breathing organisms in the world of beauty. No form of architecture or art seems to spring naturally and unaffectedly out of the actual necessities and demands of daily life.

I have heard it said that the Great Exhibition of 1851 is to be held accountable to a great extent for the vulgarising and commercialising of art, and especially for the great break-up of old traditions of craftsmanship and design. But in so far as this took place it was only the effect of causes lying far deeper in the great economic changes affecting the conditions of the production of all works whatsoever, which had been going on during the three previous centuries. That exhibition, as succeeding ones have done, merely summed up the results of these changes, and showed their effects for good or evil, declaring, to all whom it might concern, that the apotheosis of commercialism meant the degradation of art.

"This will seem a hard saying to such as are accustomed to believe that the accumulation of riches and the welfare of art go hand in hand. It is the boast of modern commerce that, to use its own phrase, it has placed art "within the reach of all." But will this fair picture bear examination from more than one point of view? Does it not, like some others, look best at a distance? Is there not reason to believe that the promises of Commerce, even when kept to the ear, are broken to the hope?"

Take, for instance, one of the most obvious effects of its action in house-building. Trading on the national shibboleth, "An Englishman's house is his castle," and taking advantage of those centralising tendencies which have led to the enormous increase of cities, commercialism has produced those miles and miles of brick-edges which have ruined the architectural character and proportion of every large town in the kingdom. What then are these? These are your Englishmen's castles, on a small scale, it is true, and run together,—semi-detached or by the dozen. There are not hills enough for the castles required, and what hills there are belong to somebody else. What is easier than to build them side by side? They will help to support each other, and economise bricks, mortar, and ground; and why trouble to make a fresh design for each castle? The little lord's wants are much the same as the big one's, only on a smaller scale,

like his purse. He must, of course, have his outer line of defences,—his portcullis and draw-bridge,—well, at least, his iron railing and portico, that he may speak with his enemy, the tax-gatherer, in the gate. Then, as matter of course, dining-room, drawing-room, bed and bath rooms, gas and water laid on. Why should not he be happy and comfortable? It is all "so cheap, too!" Yet the speculative man, the man of profits,—the kindly builders who multiply these miniature strongholds for the average Briton, wherein he may defy all the world but his landlord,—we do not account exactly as public benefactors! Here are the bee-cells ready made for the occupants of the national hive,—dwellings for the average man. Never mind if they do not always fit him. We cannot be expected to take account of round or square bodies. If the majority are hexagonal the rest must put up with the inconvenience and a little squeezing. Great is Average! We will not speak of other cells and cellars, dear at any price, where our working-bees and bees-out-of-work have to pack with even less range of choice, and without even the pretence of art or comfort.

Jack is rarely able to build his own house nowadays, so Jerry builds it for him; but the well-known drama of rat and cat, the dog and the cow "with the crumpled horn" is still enacted, with, perhaps, some changes in the cast, and new scenery and dresses.

Meanwhile, how fares it with art in the house that Jerry built? Do the streets produced on these principles, and at such a terrible rate, lend themselves either to pictorial or decorative treatment? Do they suggest any ideas even, except, perhaps, of the dustman? How is it possible that they should?

Well, but the man of profits is ready again. The Briton can get his art cheap, too. "Wholesale or retail." He can have cheap dados and bits of coloured glass thrown in here and there. If these are not enough, he can fill his house with "Early" or late "English" furniture, "surmounted by something Japanese." Should his aspirations remain still unsatisfied, he can take the illustrated magazines to tell him about every art under the sun, and how it is done. In fact, if the literature of the subject could make artists and craftsmen, every street should be bristling with them.

Every Christmas scatters oil-paintings after our first masters, fresh from the printing-press, over the British empire. A shilling or so will secure a whole gallery. Was ever anything like it in any age of art? Truly no. Still, we are not happy. We are not happy about our art. We English, especially, we allow Frenchmen or Belgians to teach us painting, and our American cousin how to do nearly everything else.

Now, I am not going to say it is all the fault of the Royal Academy. That institution, as regards its chief feature, the annual exhibition, is only another engine of the man of profits, which, frankly recognising the commercialism of the age, endeavours, "by special appointment" and self-election, to adapt the business of picture-painting to it, without troubling much about architecture and sculpture, and leaving the applied arts to apply elsewhere, or shift for themselves. It is but due to say, however, that the Academy endeavours to counteract the influence of the new masters in the summer by the examples of the old masters in the winter; on the principle, perhaps, of the Mediæval system of doing penance.

In the course of evolution we are passing through a period of disintegration and differentiation. Art cannot escape the tendencies and influences of its time, which, indeed, it is of its very nature to illustrate. The artist, like all other workmen, has become more and more specialised, and the unity of the arts has been broken up. The painter is no longer the master-craftsman among his workmen and apprentices, prepared to do all things in the province of design from the pattern on the hem of a garment to the painting of an altar-piece. He is now rather the juggler in the market-place, who with a particular sleight of hand can command a particular phase of sea or sky; or he has the trick of the flattering glass in portraiture. Perchance he seeks to draw iron tears down the cheeks,—not Plato's, but of the philanthropic Plutus, and golden ones from his pocket by peculiar domestic pathos; or, in stage lights, by the contrasts of wealth and misery, chilling his blood by melodramatic horrors; or by seeking to glorify his patron in

his happy hunting-ground, surrounded by the images of his sacred animals.

Painting, perhaps, has always been more or less at the bidding of the dominant orders of its day, but more notably so since she left her roof tree and parted company with architecture and sculpture and all the fair and fascinating troop, controlled by a common impulse and a common devotion that throng in the splendid retinue of Design.

We look back down the long vista of ages and epochs and read their spirit in the unmistakable language of art, coloured as it is by the human systems and beliefs of which it is the monument. Whether, as in the wall paintings and reliefs of Ancient Egypt and Assyria, it is devoted to the glorification of military or sacerdotal despotism, or the systematised symbolism of an ancient nature-worship, humanised and made beautiful by the Greek informed by freedom and life; captive and decaying amid the corruption of ancient Rome; or, fused with a new splendour from the East, rising in the solemn magnificence of Byzantine architecture; and so, through the Gothic, flowering in the vivid imagination of the Middle Ages absorbed in the new mysticism, yet, through the Church, linked to the hopes as well as the fears of humanity. Then, with the new thoughts and ambitions of the Renaissance, art rekindles her lamp at the shattered shrine of classical sculpture and learning, until, overwhelmed with artifice and pedantry in succeeding centuries, she is forced back to nature and life again on the threshold of our own time.

But, again, she is in danger from a new tyranny in that unscrupulous commercialism, which is not less dangerous because less tangible, and not less despotic because it is masked under the forms of political liberty.

Steam machinery, like a many-headed, many-handed dragon, rules industry literally with a rod of iron, and fain would it make Art prisoner too. Intended for the service of man, and for the saving of human labour, it has, under our economical system, enslaved humanity instead, and becomes an engine for the production of profits,—an express train in the race for wealth, only checked by the brake of what is called over-production. Who can tell what will be the end of the journey? We are driven to the conclusion that the whole force of our economic system is against spontaneous art; that it is, in spite of it, if there is any life left in art yet.

As William Morris has so strikingly pointed out, the system of producing all things for profit, which has succeeded the old one of producing for use,—the necessity of selling in the big world market; division of labour; and lastly, machine labour, have rapidly destroyed the art of the people, as they are fast vulgarising and destroying all local characteristics in art in the surroundings of common life, in all countries open to the trader.

The system of absolute individual ownership of land, which, with the advance of commercialism, has displaced the ancient system of tenure, and defrauded the people of their common rights wholesale, naturally leads to much destruction of natural beauty, or where not destroyed, it is made inaccessible. The same system, too, is answerable for what may be called the destruction of architecture in the abnormal growth of the big towns, already alluded to, which year by year throw out their long and aimless feelers, that literally feed upon the green country. When we speak of our advance in the spread of education, we too often forget that no education of the schools can really compensate for the loss of those influences of an early life passed amid hills and woods, or by the sea, which are an education in a lore never to be forgotten. The village child who knows the birds, and can tell you where they build their nests, has learned straight from nature's book, which is the best of primers, and no system of elementary education can take its place.

Overshadowed by such conditions of life as falls to the general lot, what wonder is it that we should get our art by accident,—that it should be, in a great measure, the art of accident, in spite of elaborate systems of art-training, and the elaborate unlearning of them which sometimes follows. Happily the sense of beauty and nature cannot be altogether suppressed under the most perverse social condition. It is sometimes urged in defence of modern life that it has artistic aspects, that strange and wonderful momentary effects are

\* A paper by Mr. Walter Crane, read at the meeting of the Architectural Association on the 18th inst., as elsewhere mentioned.

seen in London smoke fogs, for instance, amid the fiery eyes of railway signals, and on our blackened Stygian rivers where the Charon of the coal-wharf plies his trade. I have even heard a mosaic of beauty defend those tattered monuments of commercial effrontery and theatrical competition on their advertisement boardings covered with vari-coloured posters, as, in certain lights, becoming transfigured so as to rival the tints of a Japanese fan. The glow, the light fades, and with it such momentary exaltations of spirit; the north-east wind succeeds the south-west, and there being no dignity of form or beauty of proportion in our streets and public places they are apt to look more sordid and miserable than before. It is one thing to point out accidental beauties in the midst of monstrosities,—jewels on dung-hills, as it were,—and quite another to defend the monstrosities for the sake of accidental beauties. Ours would, indeed, be a hard lot if the sun never shone or the seasons did not return. Grace and spirit of movement may, indeed, be shown by a child dancing to the strains of a barrel-organ in a squalid anucky street, but one would rather see her on a village green dancing to a shepherd's pipe. We should aim at a condition of things which would not keep beauty at a distance from common life, or on the footing of an occasional visitor. No artist should be satisfied with such a cold relationship.

If we believe that art is not the mere toy of wealth, or the superficial boudoirism of fashion, not a revolving kalidoscope of dead styles, but, in its true sense, the spontaneous expression of the delight in life, and the aspiration of a free people, before all things, then, in order that art may express itself in this way, it is necessary that there should be something like a common life. We have no common life, because we have no life in common. Art is split up into cliques as society into classes. Art should know neither. We want a vernacular in art, a consentaneousness of thought and feeling throughout society,—not mere formal or verbal agreement, or dead level of uniformity, but,—comprehending and harmonising individual variety with collective unity, which can only be developed among a people intellectually, politically, and socially free.

The signs of our times point unmistakably to great changes working in the direction I have indicated, which cannot fail to produce corresponding results in art.

Consider, for instance, the probable effect on domestic architecture of a collective, communistic mode of living. Instead of our rows and rows of brick boxes, only varied by piles of them in barracks, there would probably be a demand for quite another type of dwelling. We might see something like a revival or a development of the plan of house which for so many ages proved so serviceable to humanity, from Homer to the end of the Middle Ages. The great hall as the common living-room, with smaller ones for sleep or study connected with it. At all events, buildings of such a type, and groups, would certainly lead to more dignity of result in architecture than the houses built under the influence of our complex and artificial life, and under our present systems of tenure, are ever likely to do. We all know that a church gives higher opportunities to an architect than a private house, yet the Gothic church is but the survival of the Gothic hall. It was a secular form before it was sacred.

Then, too, the only chance for the mural painter and monumental sculptor is in public buildings. If buildings of the type I have mentioned became common, there would be plenty of scope and work for them, and the decorative artists generally; and so we might reasonably expect that painting and the sister arts would be restored to, perhaps, greater than their former dignity, beauty, and invention.

The decline of art corresponds with its conversion into portable forms of private property, used as material for commercial speculation. Its spirit and aims under such influences naturally become entirely different. All really great works of art are public works, monumental, collective, generic: expressing the ideas of a race, a community, a united people, not the ideas of a class. It is evident enough in our own time that art needs some higher inspiration than that of the cash-box. She suffers from an intellectual lethargy that cannot be cured by a prescription from the cheque-book. These are, at best, but stimulants that force an unhealthy excitement,—a feverish and fitful activity at the expense of the whole system.

Private patronage may be able to command a measure both of skill and beauty, no doubt; but it is, as a rule, beauty of a lesser kind, and conceived in a narrower spirit, because, being addressed rather to the personal tastes and preferences of an individual, it is less likely to call forth the full expression of an artist's mind. While the fancies of rich and great persons, when their day is past, often come to be looked upon as curiosities, the art of a people as expressed in their public buildings and monuments, possesses a kind of immortality. We know the splendid results in art which grow on the rock of Athens and the cities of Mediaeval Italy. Our own cathedrals, too, bear witness to the greater solemnity and impressiveness, as well as vitality, of public and co-operative art. Is it too much to suppose, seeing the intimate connexion between political and social condition and artistic expression, and how both are affected by economical laws, that in the free federated communes which, not improbably, will, in the future, succeed jealous nationalities dominated by centralised governments, with a large increase of leisure and opportunity for cultivation and enjoyment, the arts will reach a higher and fuller development than any the world has known?

Hence comes it that most of the present efforts made to revive the arts and crafts among the people, without reference to their economic condition, are like so many attempts to grow the tree leaves downwards; or as if an architect should put up an elaborate scaffolding and begin with his roof before he had decided on the ground plan, dug the foundations, or thought of the drainage.

Real progress we must not expect to make until we have re-established the unity of the arts,—a very different thing from uniformity. My friend Mr. Sedding, in a discourse read awhile ago, in his generous enthusiasm was for assigning, in his mind's eye, the mural decoration of an ideal modern cathedral to various well-known popular painters. I believe even I myself was allowed a corner to amuse the children in. I have as great an admiration for the talents of my contemporaries as any one, but I cannot conceal from myself that to let us all loose on the wall in this kind of way with no greater preparation for dwelling together in unity, in the artistic sense, than is afforded under the conditions of the modern picture-show would be a very doubtful experiment. It would be, metaphorically speaking, something like an attempt to anticipate the millennium by trying to persuade the lion to lie down with the lamb, or the cow and the bear to feed, in the same cage. But in the fifteenth century Mr. Sedding would have been safe enough. Architecture comprehended, as it should do, all the arts. The painter worked in harmony with the carver and metal-worker, because each probably had a considerable knowledge of the other's craft, as well as of the limitations of his own. Artists, therefore, knew what they wanted to do, and did it. There was nothing mysterious in this, taking into account the way in which men worked in these days, and learned their crafts; but it is a little depressing to think, with all our superiority in exact science and mechanism, how far we are from anything like certainty in art.

Whether the interest of scientific discovery and research has had anything to do with diverting man's faculty of invention into another channel, and life does not allow time for the exercise of both, I do not pretend to say; but when Science and Art touch each other with the tips of their fingers,—when Science, for instance, asks for the aid of Art in mounting electric lights, or in order to fit any mechanical invention in daily use, it is very noticeable how artistic adroitness of adaptation, applied so as to secure a logical and beautiful result, lags behind the scientific invention. It is as if Science, continually creating new systems of nerves and ganglia in working order, was hard put to it to find bodies or frames to fit them, to make them presentable to humanity.

No doubt the demands upon a designer in the present day, owing to the march of mechanical invention, are very heavy; but the commercial pressure and hurry which is greatly answerable for that are heavier still upon him. Thought is all-powerful, but there is no time to think. Fancy and imagination might play about the humblest accessory, but there is no time to play; and "all work" as well as the uncertainty of work,—and no play," as the

saw saith, "makes Jack," if not "a dull," certainly an anxious boy.

But depend upon it, in conditions fair to humanity, art wants but little encouragement,—only freedom and sympathy. The seed will grow fast enough in a favourable soil and climate, and bring forth flower and fruit after its kind in due season.

For art is in its highest sense the faculty of expression, the language of life. The richer, the fuller the life, the happier and more baronious its conditions, the more varied and beautiful will be the forms of its outcome in art.

But it is deep down in the life of the people that we must dig the foundations, and out of common speech and common labour and handicraft must be shaped the stones of this architecture of art. Without such foundations, and without the cement of fellowship; without due recognition of the equality and unity of all workers, and their mutual interdependence in building the great structure, we shall have no enduring monument to be a delight to ourselves, and a memorial of us to those that come after. Brilliant toys, it may be, we shall have; surprises and stimulants; joyless elaboration, and pedantic weight of learning; gorgeous exotics; and flowers and fruits forced for the jaded appetite of a society in its decline; but we must give up all hope of vital and harmonious art, enshrined in a casket of beautiful architecture.

#### PROFESSOR MIDDLETON ON THE EARLY DEVELOPMENT OF MEDIAEVAL SCULPTURE.

ROYAL ACADEMY OF ARTS.

PROFESSOR MIDDLETON delivered the first of two lectures on Mediaeval sculpture on Monday evening at the Royal Academy. He commenced by remarking that by the beginning of the fourth century, in the reign of Constantine, the art of sculpture had reached the lowest possible stage of degradation. That was due to the fact that men had gone on, with failing technical skill and rapid loss of any true feeling for beauty, copying and copying again,—each generation of sculptors growing feebler than the one before it,—till at last they could only produce work that was hopelessly dull in design and brutally coarse in execution. Nothing was more depressing than the sculpture of that period. The early sculpture of the Greeks in the seventh century B.C. was, perhaps, ruder and even uglier in form, but in their works there was a distinct promise of something better, a sort of dim foreshadowing of the glorious era that was to come. Even the rudest work of the savage had usually some spark of original design, and, consequently, some degree of life and vigour; but in the Roman sculpture of the fourth century there was nothing to redeem its hopeless, heavy stupidity. It was this exceedingly debased form of Classical art that the early Christians adopted, and though they possessed no superior or technical skill or knowledge of the human form, yet the mere fact that their subjects were inspired by a real living faith gave a value and vigour to their reliefs which was far beyond anything Pagan of the same time. In sculpture, as in painting, whatever art the early Christians had was purely Classical in style; and though completely new sets of motives were introduced, yet the older influence clung closely to all their conceptions and their methods of treating them. In that respect the contrast was very strong between the earliest Christian art,—that of Rome, as seen in the Catacombs,—and that of the next stage of the art of sculpture, that which was developed at Byzantium after Constantine's removal of the seat of empire. No gloomy subjects were introduced by the early Christian artist; Christ was never represented in suffering nor as threatening a coming judgment. The catacomb subjects were always scenes exemplifying His friendly power, His miracles, and His beneficence. His passion and sufferings were only hinted at by Old Testament scenes, which were taken as anti-types. This cheerful spirit was inherited from the older faith, in which terrors of Hell had practically little part. It was very different from the mental state shown in the later art of Byzantium, which seemed to be overshadowed by a gloomy sense of the fabled horrors of the Christian Hell. Instead of the beautiful Classical symbolical rendering of the mystery of death and the soul by a butterfly escaped

from its dead chrysalis body,—a notion invented by the Greeks, and adopted by the Pagan Romans,—instead of this, we found death associated with such things as grinning skeletons and hideous fiends hovering round the dying man, ready to dispute with the angels the possession of his escaping soul. The earliest Christian art was imbued with the Classical love of the beautiful, and with an evident wish to avoid the horrible. In another respect, too, it offered the widest possible contrast to the art of Byzantine times, in which Christ and sacred scenes were represented so as to be as unlike as possible to anything in the earlier art of Greece or Rome. The Early Christians, on the contrary, adopted as much as possible the artistic conceptions of their contemporary pagans. Christ was represented by them like the Greek Orpheus, wearing the Phrygian cap and holding the *pedum*, surrounded by a crowd of listening animals, or riding in triumph into Jerusalem with a face of the most exquisite youthful beauty. The art of this earliest Christian period spread over a space of about two hundred years or more, and owing to its close connexion with the contemporary Pagan art (in which a rapid decadence was going on) we found that the earlier the example the better it was, both in design and execution. The finest early Christian work was in ivory and wood; skill in these smaller branches of plastic art lingered long after large sculpture was very coarse and poor, as was often the way with the minor arts, as might be seen in Roman coins and gems, and in gold and silver work. The removal of the capital of the Roman Empire to Byzantium changed the whole character of art. Byzantine art was essentially ascetic, and strongly opposed to that of Classic times. What spirituality there was in Greek art was in the main such as could be expressed in the outward form, and there was no suggestion of those purely spiritual gifts and excellences which could exist more fully in a less perfectly constructed body. In the earliest Christian art this intimate connexion of outward and inward graces was still insisted on; but with the development of the Oriental ascetic form of Christianity a wholly different class of ideas came in. The moral and spiritual qualities became the essential ones: the body and its earthly perfection became not only subordinate, but was regarded as an obstacle to the higher gifts. Art was called upon to illustrate the inner life of the soul, unconnected with its earthly tabernacle. The chief Christian virtues had no necessary connexion with nobility of face or strength of limb,—any bodily beauty was an unimportant accident. The Greek god was necessarily strong and beautiful, but the Christian saints warned against the powers of Evil with the help of bodily emaciation and privations which were destructive to physical beauty, and thus the notions of ugliness and sanctity became most intimately connected in the monkish mind. The great struggles and victories of the Christian saints involved mental anguish and bodily pain, which were utterly foreign to the serene well-balanced state of mind and body in the Hellenic god or hero. The old tranquil spirit was gone, and life was made gloomy by coming shadows of judgment and hell, with its legions of hideous fiends,—malignant in expression and loathsome in form. These spiritual fears and trials and struggles of man could in no way be adequately expressed in sculpture, and hence for a long time painting and mosaic took the prominent place which in earlier times had been occupied by the plastic art. The sufferings of Christ, the Crucifixion, and subjects of that kind were insisted to an art like sculpture, which called for harmonious beauty, quiet dignity, and restraint of expression. For a long time the Church struggled hard to limit the use of art to decorative ornament, and strove to prohibit the representation, by painting or sculpture, of sacred persons or scenes. This struggle, fostered by the ascetic Oriental spirit which had then come over the church, lasted for a very long time. Ultimately, a compromise was made, and representations of sacred scenes and personages were permitted, but only with the stipulation that Christ and the saints should be depicted without any of the sensual beauty which had glorified the gods of Greece and Rome. A rigid set of dogmatic rules was framed by the ecclesiastical powers as to the way in which each saint or scene should be represented, and these rules prescribed the arrangement of the drapery, the

colours to be used, &c. Thus it happened that what should have been the highest branches of Byzantine art were petrified into a monotonous formalism, which, as years went on, became deficient in vigour of drawing and devoid of individual spirit. The result was the inevitable degradation which always followed on repeated copyism. Owing to this practice of repetition it was often very difficult to guess the date of a work of art from internal evidence. The practice of this petrified art was still going on in the monasteries and churches of Greece and Russia.

#### THE ARCHITECTURAL ASSOCIATION.

THE ninth meeting of this Association for the present session was held on Friday, the 18th inst., at 9, Conduit-street, Mr. J. A. Gotch (President) in the chair.

The following new members were elected, viz., Messrs. E. J. Baker, G. Westrup, A. E. Toms, L. W. Todd, H. J. Curley, W. Hynam, H. F. Clark, and H. C. Fitt.

The Chairman intimated that a special business meeting of the Association would be held on the 4th of March, for the purpose of making an alteration in Rule 3, by inserting the words "and periodical publication," after the words "special classes."

A letter was read from Sir Frederick Abel, on behalf of the Prince of Wales, inviting the co-operation of the members in favour of the Imperial Institute. The Chairman stated that the Committee would be happy to receive any subscriptions, and to duly forward them.

A vote of thanks was passed to Mr. T. A. Walters, architect of the Roman Catholic Church of the Sacred Heart, Wimbleton, for accompanying the members over the building the other afternoon, as mentioned in our last.

It was announced that a visit would take place this Saturday, the 26th inst., to St. George's College and to St. George's Cathedral new schools, where the architect of the latter building, Mr. Leonard Stokes, will accompany the members. Several other forthcoming visits were also notified, for particulars of which see our advertisement columns.

A letter was read from Mr. Thos. Blashill, thanking the members for their kindly expressions at the last meeting in connexion with his appointment as Superintendent Architect to the Metropolitan Board of Works.

The Hon. Librarian announced several donations to the library, cordial votes of thanks being passed to the givers.

Mr. Walter Crane then read a paper entitled "The Architecture of Art," which we print *in extenso* in other columns of this week's *Builder*.

Of the discussion which followed we postpone our report.

### Illustrations.

#### MARBLE CHIMNEY-PIECE, CHÂTEAU DE FONTAINEBLEAU.

THE marble chimney-piece here represented adorns the guard-room of the chateau. It measures 5m. 3c. in height, and 4m. in width. It is made up partly of fragments of a celebrated chimney-piece called *la belle cheminée*, which stood in a room fitted up by Louis XV. as a theatre, in 1725. It was rebuilt in 1835 by King Louis Philippe, who largely contributed to the restoration of the chateau. It is in consequence of this that the monogram LP may be observed engraved in the frieze, in a cartouche between two Cupids and surmounted by the Royal crown. The *belle cheminée* was the work of Matthieu Jaquet,\* who undertook it by order of Henry IV., in 1594, and took five years to complete it. The two standing figures, symbolical of Strength and Peace, are attributed to Pierre de Franceville, or Franqueville, a Flemish sculptor, who was born at Cambrai in 1510, died at Paris about 1615, and is frequently designated "de Franceville." He appears to have been assisted in the work by his pupil and son-in-law, Francesco Bordoni. These two statues are part of the *belle cheminée*, and so is the greater part of the ornament which sur-

rounds the bust of Henry IV. On the older chimney-piece was an equestrian statue, in blue marble, of this king, also executed by Jaquet, and which is at present to be seen on the chimney-piece of the Salle St. Louis. The bas-relief representing the battle of Ivry, which accompanied it, was removed to the museum of the Louvre.

#### UPPER PART OF CHIMNEY-PIECE, ETC., IN THE PALAIS DE JUSTICE, BRUGES.

This chimney-piece was erected after the designs and under the directions of Lancelot Blondell. The chimney-piece proper is of black Dinant marble, and was carved in 1529 by Guyot de Beaugrant. It consists of an entablature resting on two jambs in the form of pillars, the bases of which are Flamboyant in style. The alabaster frieze is decorated with four bas-reliefs illustrating the story of Susanna, designed and carved by the same artist, who also executed the four Cupids at the corners and the alabaster moulding under the statues. The wooden upper part (1529-31) was doubtless erected as a trophy to commemorate the victory of Pavia, February 24th, 1525, and the Treaty of Madrid, January 16th, 1526, confirmed by that of Cambray, called the "Paix des Dames," August 9th, 1529, one of the articles of which released Flanders from all subjection to Franco and recognised its independence. This portion is divided into three compartments; the centre is occupied by the statue of Charles V. as Count of Flanders, holding the insignia of the Order of the Golden Fleece. The coat of arms of the county adorns the front of his cuirass. He holds up a naked sword in his right hand, and in the left carries an orb surmounted by a cross, while behind him is a throne decorated with half-length portraits of his father and mother, Philippe le Beau and Jeanne la Folle. On the back of the seat are carved two portraits in medallions, one of Charles de Launay, the conqueror of Pavia, to whom Francis I. returned his sword; and the other of Margaret of Austria, the aunt of the Emperor, who, by negotiating the Treaty of Cambray, consolidated the power acquired by that victory. Two pillars support the pediment. The tympanum of the archivolts is occupied by two winged Cupids, holding laurel crowns. Over the pediment is an escutcheon containing the imperial arms surrounded by the collar of the Golden Fleece, and surmounted by a helmet with festoons, on which is the imperial crown with the Gallic cock for a crest in sign of victory. On each side of the throne are the pillars of Hercules, with the arms of the various States under the dominion of Charles, those of Naples and Navarre, the two latest acquisitions, being the most distant from the statue. Farther off are sixteen escutcheons with the arms of the Emperor's grandparents. On the pilasters at the salient angles two groups of boys support medallions with profile portraits of Francis I. and Eleanor of Austria, the Emperor's sister, whose marriage ratified the treaty. In front of the compartment to the right of the Emperor are placed the statues of Maximilian and Marie of Burgundy, his paternal grandparents, and in front of that, to the left, those of Ferdinand of Arragon and Isabella of Castille, his maternal grandparents, surrounded by escutcheons and streamers. Among the accessory ornaments may be observed, to the right, the Cross of Burgundy, with the flint and steel surrounded by flakes of fire and the motto of Maximilian, "Halt Mas." To the left is the bow and sheath of arrows, the emblem adopted by Ferdinand and Isabella to symbolise the union of the kingdoms of the Peninsula. The five statues were carved by Guyot de Beaugrant, the details by seventeen other sculptors, the chief of whom were Rogor de Smet, Herman Glosencamp, Jacques Crépen, and Adrien Rasch. The whole was without doubt meant to be coloured, and the empty cartouches to receive inscriptions. The admirably-conceived design of the monument reveals exquisite feeling and a profound study of the subject. The more one examines the arrangement of the details the more one is struck with the poetic feeling of the author. Everything is in its right place and in perfect harmony. The forms are those of the Renaissance period. It is a trophy erected in honour of Charles V. and entirely Pagan in its conception. The execution of all the details is perfect, and testifies to the great skill of the Flemish sculptors of that period.

\* Matthieu Jaquet, born at Fontainebleau about 1550, died in 1619. He was a pupil and coadjutor of his father, Jaquet of Limoges.

ST. SAVIOUR'S UNION INFIRMARY,  
CHAMPION HILL.

This infirmary has just been completed, and will shortly be opened. It is situated in East Dulwich-grove, near the Champion-hill station on the London and Brighton Railway, and is for the sick poor of the parishes of St. Saviour and St. George-the-Martyr, Southwark, and St. Mary, Newington, which three parishes constitute the St. Saviour's Union. The buildings stand on a piece of ground about seven acres in extent, having a frontage of 700 ft. towards East Dulwich-grove.

The sick wards are arranged as shown on the block plan, with their axes placed north and south, the main front of the building, shown in the illustration, facing East Dulwich-grove. Accommodation is afforded for about 732 inmates. There are twenty-four large wards, to hold from twenty-six to thirty beds each, and twenty-four separation wards for two beds each, for cases which require isolation. The open balconies at the ends of the wards are large enough to allow of three or four patients being wheeled in their beds on to them. The warming of the wards is partly provided for by two double open fireplaces in the centre, with descending flues carried through the floors, and by fresh air brought from the outside through zinc tubes to the backs of the fires, where it is warmed before passing into the wards. In addition to these fireplaces there are two rows of hot-water pipes down each side of the ward. Gratings under each bed, with sliding traps, admit fresh air, which in winter is warmed as it passes over the hot pipes.

There are six three-light gas pendants in each ward, having enamelled iron hoods which direct the products of combustion, and also the vitiated air from the wards, into tubes placed transversely above the ceilings. Each end of these is open to the air, and has a balanced flap, which closes at whichever end there is an inward pressure of air, leaving the other end open to allow of the egress of the heated air. The wards have glazed brick skirtings, 3 in. high, all round, and the floors will be waxed. The water-closets at the ends of the wards have Omer D. Ward's "Household" closets, with water-waste preventing cisterns. The baths are of porcelain, and are detached from the walls, with a space of a few inches between them and the floor. The floors of the bath-rooms, water-closets, and lobbies, are paved with red tiles. There is a dado of glazed bricks, in cream and brown bands, round the walls. The lavatories in the bath-rooms were supplied by Messrs. Finch & Co., of Holborn. Cannon's hot-water radiators are placed in the bath-rooms, lobbies, and water-closets. Each of the ward blocks has a hydraulic bed lift, and two hand-power lifts for food, &c., manufactured by Messrs. Clark, Bunnell, & Co., of Deptford.

Advantage has been taken of a fall in the ground from west to east to construct the end block (marked D), with a basement story, of open piers and arches, allowing a free circulation of the air beneath the ground floor.

The connecting corridors between the administrative block and the several ward blocks are 9 ft. wide. They are at the ground, first, and second floor levels. The ground-floor corridors are enclosed, but have large windows, the sashes of which will open. The first-floor corridors are open, with an arched ceiling at the sides to support the floor of the corridor over. The piers and arches of this arcade are of ornamental cement concrete, specially manufactured by the Imperial Stone Company, East Greenwich. The floors of the corridors are paved with asphalt. On the ground floors they have a border, on each side, of red tiles, about 2 ft. wide. The corridor on the ground floor of the administrative block is paved with ornamental tiles.

Beneath the ground-floor corridors are lower ones, partly underground, extending from the coal-cellars to the ward blocks. In these are placed the gas, water, and steam mains, where they are more easily accessible than if they had been buried in the ground. There is also a tramway, of 20-in. gango, for trolleys to convey coals, &c. By this means not only will a great saving of labour be effected, but the dirt and inconvenience arising from the passage of dirty clothes, coals, &c., through the building will be avoided.

The administrative block is central. A view of the front of it forms one of our illustrations. The west wing is the medical superintendent's

house. It is connected with the main corridor on the ground-floor only. The east wing contains the committee-room, with bedrooms over for the matron, assistant matron, head nurses, &c. In the central portion of this block are situated various offices for the superintendent, clerks, and stewards, and matrons' sitting-rooms. Over these is the chapel. It is 70 ft. long, 28 ft. wide, and 28 ft. high to the apex of the ceiling, which is of plaster, wagon-shaped, and with ornamental wooden principals. There is a panelled dado of painted wood, 4 ft. high, round the walls. The west wing at the rear of the administrative block contains the stores on the ground-floor, and in the east wing are the nurses' mess and day rooms. The basement, which extends under the centre and the two wings, contains extensive cellars for beer, coals, &c., and larders. The kitchen is in the centre at the rear of the administrative block, on the ground-floor level. The cooking apparatus consists of four large steamers, a Wareneizer, two gas roasting-ovens, and gas hot-plates, soap and tea coppers, vegetable steamers, open range, &c. Bedrooms for about seventy nurses and servants are placed on the first and second floors of the east and west wings at the rear of the administrative block; these bedrooms are entirely detached from the main block. Communication with it is provided in case of fire by light iron bridges on the second floor.

The laundry buildings consist of an officers' wash-house, 25 ft. long, 16 ft. wide, with laundry, 25 ft. by 21 ft. The patients' wash-house is 40 ft. long, 25 ft. wide. Adjoining it is a double drying-closet, containing thirty-two horses; and beyond is the laundry, 53 ft. long, 25 ft. wide; there is also a small wash-house for foul linen. Attached to each of the patients' wash-houses is a room for receiving the dirty clothes, and a delivery-room. Attached to each of the laundries are drying-rooms for the clothes. The steam washing-machines, wringers, and calendaring machine, steam mangles, &c., were manufactured by Messrs. Clements, Jeakes, & Co., of Great Russell-street, Bloomsbury, who also supplied the cooking apparatus.

The Boiler House adjoins the laundries. There are three "Lancashire" steam boilers, each 26 ft. long and 6 ft. 6 in. diameter. The chimney-shaft is about 70 ft. high; it is octagonal, 5 ft. diameter at the top, and stands on a base 7 ft. square. There are two of Marshall's horizontal engines, 12-h.p. each. Hot water is laid on to all wash-up and slopsinks, and to lavatory basins, the supply being obtained for them from Dudley steam water-heaters, which are placed in specially-constructed chambers under each ward-block, the steam being conveyed to the heaters from the boilers in pipes placed in the subways; the steam-pipes are coated with asbestos.

The water-supply will be obtained from an artesian well, sunk by Messrs. Baker & Sons 200 ft. into the chalk which underlies the site at a depth of 90 ft. from the surface. The water will be pumped from the well into cisterns at various parts of the building, and also into two large cast-iron tanks, holding 8,000 gallons each, which are placed in the towers of the administrative block, to form a reserved supply of water for use in case of fire. Hydrants are placed in all the wards and on the landings of the stairs adjoining them, also in the corridors of the administrative block.

The drains have been laid in straight lines, with manholes at intervals for access and for admitting fresh air where practicable. The foul air from the main sewers in the streets is cut off by Kenon's intercepting traps and ventilated manholes. There is a flushing-tank at the head of the main drain at the back of the building. All the soil-pipes are fixed outside of the buildings, and to insure a constant circulation of air in them they are open at the top and at the feet, just above the traps into which they discharge. The waste-pipes from baths, sinks, &c., discharge over open trapped receivers, and are carried above the eaves of the roofs, with open ends.

The receiving wards are situated close to the entrance-gates in front of the building. They contain two wards,—one for males and one for females,—with attendants' rooms, clothes-stores, bath-rooms. There are also two padded rooms lined with indiarubber also supplied by Messrs. Pocock & Co.

The porter's lodge adjoins the entrance-gates, and contains an office, parlour, and bedrooms for the porter.

Blenheim telephones are fitted in the medical

superintendent's house, the centre of each floor of ward blocks, and at various other points in the building.

Externally the walls are faced with Leicester red bricks with dressings of Ancaster stone; there is a wrought-iron railing along the front towards East Dulwich-grove.

The contracts for the building, the engineers' work, and the laying out of the grounds, have been carried out by Messrs. Kirk & Randall, of Woolwich, at a total of about 86,000/.

The gasfitter's work was executed by Mr. Clarke, of Moorgate-street, City, at a cost of 1,003/.

Mr. Davis has acted as clerk of works, and Messrs. H. Jarvis & Son are the architects.

ST. JOHN'S CHURCH, WELLINGTON-  
ROAD, RHYL.

This new church is erected on a corner site at the junction of River-street and Wellington-road, Rhyll.

The design has been ruled by the conditions under which the church had to be built, the site being broad in proportion to its length. The design was selected in a limited competition, the instructions to the competing architects being that the church was to be designed for a large congregation with the least possible obstruction by columns, &c. On plan the church is a parallelogram, 77 ft. by 57 ft., with a west-end bay and side aisles, the centre portion of the church being carried up in an octagonal form by arches springing from the main walls, the western bay being supported by two massive granite columns. The chancel, 30 ft. by 26 ft. in prolongation eastwardly of the western bay, opens into the nave by a massive stone arch. The organ-chamber, 19 ft. by 12 ft., is arranged on the south front, with choir and clergy vestries on the north elevation. Spacious porches are arranged at the west end.

Accommodation is provided for about 750 sittings.

The material used for walls is local limestone with Groespyr stone dressings.

The roofs are covered with green slates, and internally are of open-timber work in pitch-pine. The floors are of wood-block paving.

The cost of the edifice, complete, will be about 5,000/., and it is intended to consecrate it early in the summer.

Mr. A. Torlington, of Rhyll, was the contractor. Mr. W. Webb acted as clerk of works, the architect being Mr. David Walker, of Dale-street, Liverpool.

COMPETITIVE DESIGN FOR ST. PAUL'S  
CHURCH, KENSINGTON.

This is a design lately submitted in a limited competition for the above church. It was proposed to erect the church in red brick and terra cotta. The drawing is by the architect, Mr. R. A. Briggs, A.R.I.B.A., of Devonshire-square, Bishopsgate-street.

**Free Lectures on Matters Connected with Building.**—Under the auspices of the Worshipful Company of Carpenters, the following course of lectures has been arranged for delivery at Carpenters' Hall, London-wall:—Wednesday, March 2, Mr. Banister Fletcher, F.R.I.B.A. Warden of the Company, on "English Carpenters and Foreign Competition"; March 9, Professor A. B. W. Kennedy, M.I.C.E., on "Girders and Beams"; March 16, Mr. F. Chambers, F.R.I.B.A., on "Joinery"; March 23, Mr. Lacy W. Ridge, F.R.I.B.A., on "Half-Timbered Houses"; March 30, Professor T. Roger Smith, F.R.I.B.A., on "Bricks and Brickwork"; and April 6, Professor A. H. Church, M.A., on "Wood,—its Chemistry, its Decay, and its Preservation." Admission will be by ticket, to be obtained at the Hall, and at all the large builders'; also of the Secretaries of the Royal Institute of British Architects, and the Architectural Association, 9, Conduit-street, W., and at the Architectural Museum, Tufton-street, Westminster. The lectures will commence at 8 p.m.

**Fareham Cemetery Competition.**—Mr. Albert L. Guy, High-street, Lewisham, has been appointed Architect to the Fareham Burial Board, Hants, from among thirty competitors for the erection of cemetery chapels, lodge, mortuary, &c.

DESIGN FOR ST. PAUL'S CHURCH, KENSINGTON; BY MR. R. A. BRIGGS, ARCHITECT.

St. Etienne le Vieux, Caen.—Sketched by Mr. F. Williamson.

#### ST. ETIENNE LE VIEUX, CAEN.

The above sketch shows a view from the north aisle, looking across the nave. The church, which is a fine specimen of fifteenth-century Gothic, is now used as a storehouse for various municipal lumber.

#### WOOD CARVING.

A LECTURE was delivered on Thursday, the 17th inst., before the members of the Society for the Encouragement of the Fine Arts, No. 9, Conduit-street, by Mr. G. A. Rogers, on "Wood Carving." There was a good attendance of ladies and gentlemen.

Mr. George Godwin, F.R.S., presided, and in introducing the lecturer said that Mr. Rogers came of an artistic family. Probably some in that room remembered, as he did, his father, who came to be called "Grinling Gibbons Rogers," and who produced some very fine work. The lecturer's brother, Harry Rogers, was a very clever designer, and died too young. His sister, Miss Rogers, had shown her information and taste and talent in some works out art in Palestine.

Mr. Rogers, in the course of his lecture, the full title of which was "A Slight Outline of the History of Wood Carving," said that the art had, unfortunately, very little recorded history. It was not easy to account for this, for in all ages when wood-carving was mentioned at all it was mentioned with admiration. But however much the works themselves had been admired and appreciated, the names of the executors had not been handed down to posterity except in very rare instances. Carvers seemed never to have thought of signing works by carving their names or cyphers on them until

within the last two or three centuries. The earliest-known specimens of wood-carving were Egyptian, and were discovered in a sealed tomb beneath the Pyramids of Abousyr,—the ancient Basirus,—and were probably between five and six thousand years old. One of them was a grotesque little god, and the other was a very delicately-executed dog-headed ape, the anatomy of which was clear and distinct. These were in the lecturer's possession. The lecturer next referred to the wood-carvings of Solomon's Temple at Jerusalem, the commission for which was, according to the Biblical record, given to a man of Tyre, who was skilful to work in stone and wood, but whose name was not mentioned, although, curiously enough, we were carefully informed of the name, and even as to the parentage, of the brassworker employed. In the time of Pericles all the most celebrated sculptors in marble and bronze worked also in wood, choosing cedar, cypress, and ebony as their chief materials. All the Oriental countries, no doubt, had much work for the wood sculptors to do, but perhaps the Persians, who had always been renowned for the decorative arts, were amongst the most advanced. With the spread of Christianity, and the consequent building of churches and cathedrals all over Europe, wood-carving received much encouragement, and itinerant bands of wood-carvers found much employment. They were very probably the designers of much of the work they executed. Having entered a protest against the denudation of our cathedrals and churches of their wood-carving,—evidence of which was afforded by the fine collection of wood-carvings of the late Mr. Cottingham, and by other collections,—Mr. Rogers remarked that much had been done by such men as Shaw, Carter, Wyatt, Twopenny, the Chairman (Mr. Godwin), and others, to

register, by drawings and descriptions, the old wood-carving extant in this country, but no society had organised a thorough investigation. The period of the Renaissance found many carvers of talent ready to carry out the designs and instructions of the new leaders of art. Amongst the most conspicuous for ability amongst the Italian wood-carvers was Barili. Donatello also worked in wood, though very rarely, but what he did was superb. In Germany the great name of Albert Dürer was supreme, not so much because of his own actual handiwork, as by reason of the influence he exerted over the carvers of his time. France, especially in the southern districts, produced a grand display of Renaissance work. Spain was a little later. The Elizabethan and Jacobean era constituted a strongly-marked period in English wood-carving, which culminated in the advent of Grinling Gibbons, who was born in Spru-alley, a little turning leading out of the Strand (and now improved into Craven-street) in the year 1648. He was "discovered" by Evelyn in 1671. There were many critics who, while admiring the wonderful handicraftsmanship of Gibbons, considered his taste in design almost vulgar, and his large groups, and pendants and garlands of fruit and flowers, in questionable taste. But it should be remembered that the taste of the period was for rather pronounced decoration, probably brought about by Rubens and his contemporary artists, in whose paintings we saw heavy bunches and garlands of flowers and not too ethereal angelettes. Gibbons was not free to work out his own fancies, but had to follow the fashion of the times. Every now and then, however, he reverted to what was perhaps his own particular taste in carving,—portraits in medallion in half-relief, carved in boxwood or pear-tree-wood, or copies from paintings or engravings. These were the works he executed when he wished to make a present to some valued friend or patron. In conventional scroll-work he effected a material change and a vast improvement, infusing into it a little of the Italian spirit, but still keeping the stalks thick enough to support the conventional leafage, which the Italians did not. He introduced some of this scroll-work into nearly everything he did. Gibbons died at his house in Bow-street in 1721. Having mentioned and briefly described some of the principal works of this master, and condemned the way in which some of the finest of them had had their finer lines choked up by the house-painter (under the mistaken notion that paint prevented the ravages of insects, instead of merely hiding them), the lecturer went on to refer to the works of Chippendale and his coadjutors, who were, however, more of cabinet-makers than wood-carvers. He then glanced at the works of wood-carvers on the Continent co-reval with the work of Gibbons and his successors, and passed on to mention the work of his father, Mr. William Gibbs Rogers, who was born in Dover in 1792, and for whom it was claimed that he had probably done more than any one else to foster the art of wood-carving in this country during the present century. In conclusion, the lecturer offered some suggestions for the encouragement of wood-carving in England. He denied that the art had died out in this country, contending that much good work, never seen by the critics, was produced every year. What he considered was wanted was a Hall of Wood-carving, in a central position in London, where carvers could send for exhibition the works they had executed, if only for a few days. If such a hall or place of exhibition were established it would be many months before erroneous impressions as to the capabilities of modern carvers would be removed. Such a hall he should like to see managed by the wood-carvers of the metropolis. There was already in existence a small society, with a library and a small collection of specimens. That might form the nucleus of the proposed new institution, which, as it would show what could be done by English carvers, would prevent work from going out of the country. Mr. Rogers said he intended to move further in this matter later on, when he had seen how his proposals were received.

We may add that the lecture was an exceedingly interesting one, and we regret that the great pressure on our space just now has obliged us to give only a brief summary of it.

In opening the discussion,

The Chairman said he was sure they must all feel very much obliged to Mr. Rogers for the inte-

resting sketch that he had given them of the history of wood-carving. He believed, however, that Mr. Rogers must be wrong in thinking that Grinling Gibbons carried on wood-carving for his own amusement, having some other means of living. Considering the enormous amount of his work in England, he must have given, not a portion, but the whole of his time, if only to the direction of it. He did not know whether any of them had seen an interesting collection of his work in St. James's Church, Piccadilly, restored some years ago. There was also a figure of King James at the back of Parliament-street, said to be by Gibbons. He did not know whether this was quite certain, but it had been stated positively to be his. As to the exhibition of modern work,—the "Hall of Carving" would be a very interesting thing if it could be carried out, but he was afraid no great difficulty would be found in the way, viz. that the carvers themselves would not send their works. In truth, a great deal of work was done under one name which was executed by other persons. He had found, on many occasions, that the masters would not give the names of those who executed the work. They gave a very good reason for that, which was, that these men would be marked, and that they would lose them. And that, he thought, would be one of the great difficulties in the way of the proposed exhibition. However, he, for one, would be very glad to do anything in the direction Mr. Rogers had pointed out. He was afraid there was, at present, very little encouragement for wood-carvers, and he did not find, from the many inquiries he had made that week, in view of the fact that he should have to appear before the meeting that evening, that there were many good wood-carvers to be had. He found that if any work was wanted in a hurry, and good men to do it, there was great difficulty in obtaining them. Moreover, there were few designers. Now, in another direction,—by a public institution in which he was interested, some very handsome premiums were offered for designs to commemorate this Jubilee Year. Nothing had yet been decided upon, but he was sorry to say the result was very unsatisfactory. The specimens were anything but good, and the number small,—only a dozen. The fact was, it took a long time to make a carver, and the public were not willing to pay the price for work of that description; they were not willing to pay a price that would encourage men to devote themselves to it. He was one of the earliest and one of the staunchest friends of the system introduced at South Kensington, but seeing what he did every week, knowing that more than 600 schools and classes of art were at work all over the country, that the Government paid 26,000*l.* a year towards Schools of Art alone, that there were from thirty to forty thousand students in those schools, one was forced to ask whether the result of that teaching had been what they had a right to expect (applause). What was the cause of it? He had no doubt the teaching apparatus there was perfect, and that good men were employed, but surely by this time there should have been a genius or two manufactured (applause). Most certainly it was not so, and he found in every direction the impression that there was a want of designers. He would not occupy their time or take off from their memory what Mr. Rogers had said to them, but he hoped some good would follow from the lecture. There was a great deal of wasted writing power and talking power in this country. These lectures went on and people said: "Yes, very interesting; we hope to see such and such a state of things," but so effort was made. The daily press were too much occupied with other matters; the lectures were reported in the technical journals, which the outside public took care not to read (laughter); and so things went on year after year and nothing was done. He hoped some little interest would spring out of that meeting, and that those who had the time might do something to aid the progress of wood-carving in England (applause).

Mr. W. Cave Thomas remarked that he did not know that there was much encouragement given to wood-carvers in this country. If they went into foreign churches, they would see there figures in an artistic sense which could only have been produced by wood-carvers who had been educated as artists. The wood-carving they saw was developed in ancient times, when the art was encouraged by the noble and the rich. Now they began at the bottom end, by

schools for wood-carving. They must begin at the top, by the demand, and by demand they would get the supply.

Mr. G. C. Haité said that students at schools of art, or "students of art" as they delighted to call themselves, having learned drawing, all wanted to become artists; that was to say, they all wanted to paint pictures, as if that were the only form of art. He objected to wood-carving being termed a minor art; it was applied art.

Mr. Loftus Brock said that the British Archaeological Association would gladly receive and carefully examine at their meetings any articles of antique art, and if Mr. Rogers or any of his friends would be kind enough to send a series of wood-carvings, they would be inspected with pleasure, and he and many of his friends would be happy to do all they could to further the progress of this noble art. Referring to the wood-carving in some London churches, he observed that those who examined it must have been struck with the way in which the stiff, formal lines of the architecture were relieved by the graceful execution of the wood-carving.

The lecturer, replying to a remark made by the chairman, said he had not intended to convey the impression that Grinling Gibbons was an amateur, and not a professional carver. It was only up to the time when he was discovered by Evelyn at Deptford that he spoke of him as an amateur.

Votes of thanks were then passed to the lecturer and the chairman, and the proceedings terminated.

#### MR. WATERHOUSE'S REPORT ON THE EDINBURGH COMPETITION.

This following is the text of the report of Mr. Waterhouse, R.A., on the designs submitted in the competition for the proposed Municipal Buildings:—

"No. 20, New Cavendish-street, Portland-place, W. 14th February, 1887.  
To the Hon. the Lord Provost of Edinburgh.

My Lord,—The task with which you have honoured me of acting as the professional adviser of the Corporation in the matter of your Municipal Buildings competition, I have found to be one of no ordinary difficulty.

In the first place, the majority of the designs sent in are of greater merit than I could in such cases, so as to somewhat perplex me by the choice at my disposal. There are some ten or twelve sets of drawings out of the fifty-six, any of which would, I believe, if realised in stone, be a credit to their authors, and a conspicuous ornament even among the many which already contribute to the beauty of your city.

Secondly, the fact of the competitors themselves being left to form their own idea of the amount of money which might be expended on the building has led many of them to indulge in dreams of magnificence which, had you fixed a limit, would doubtless not have been hazarded. As no limit was assigned, I have not thought myself at liberty to exclude any design on the question of cost, though, in making this report, I have, of course, taken it, *certis paribus*, into due consideration.

I may here say that, speaking generally, it will be necessary not to place too much reliance on the authors' estimates of their designs; for whereas one may think his work can be executed for an average of 5*l.* per cubic foot, the surveyors of another competitor for very much the same class of work, value his design at 1*s.* 9*d.* per cubic foot.

The total estimates vary from 66,000*l.* to 250,000*l.*, and the number of cubic feet where given (which is not always the case) from 1,747,588 to 3,776,486, proving, I think, that a different system of measurement has been adopted in different cases.

Thirdly, the absence of perspective views has made it difficult, even to a professional eye, to judge accurately of the effect of a building on the distribution of whose masses so much depends. I am aware that the admission of perspective views in competition has been much abused; but drawings in outline only, from a given point, would have materially assisted in the solution of this problem. Generally, the absence of perspective views has made it difficult, even to a professional eye, to judge accurately of the effect of a building on the distribution of whose masses so much depends. I am aware that the admission of perspective views in competition has been much abused; but drawings in outline only, from a given point, would have materially assisted in the solution of this problem.

Fourthly, the absence of perspective views has made it difficult, even to a professional eye, to judge accurately of the effect of a building on the distribution of whose masses so much depends. I am aware that the admission of perspective views in competition has been much abused; but drawings in outline only, from a given point, would have materially assisted in the solution of this problem.

The greater number of designs show one or more towers or domes, some of the former rising to a very considerable elevation. Though, no doubt, in the majority of cases, these features add materially to the beauty of the building in itself, it becomes a question whether, on this particular site, it is desirable to introduce what would render the very beautiful view of your cathedral, as seen from Princess-street, an insignificant object.

The intrinsic beauty of those features in them-

selves may, in one or two cases, overbalance this fear; but it appears to me worthy of grave consideration. The site is no ordinary one, and the building has to be considered with reference to its historical and picturesque surroundings.

By far the greater number of designs have followed broadly the main features of the present buildings as to plan,—that is to say, placing in the centre a large quadrangle. Some of the surrounding sites in this quadrangle with buildings on all sides, whilst others open it out to the south, with merely a screen, as at present, between the courtyard and the street. The plans which have followed this general scheme may also be subdivided into those which have their east and west rooms well lighted by looking into the wide quadrangle, and those which make them face the surrounding close on the opposite sides, of which there is no security against the buildings being raised even higher than they are at present.

Some competitors, though putting their rooms looking outwards,—an arrangement which has, of course, the advantage of materially shortening the length of their corridors of communication,—have taken the precaution to set back their east and west frontages to a greater or less extent, so as to permanently secure a hotter supply of light and air to their rooms looking outwards in those directions.

The one most marked exception to the foregoing general arrangement is supplied by the design numbered 11, under motto "Light and Air." This is enclosed in a close, slightly recessed from High-street, and has two wings connected with the main building by covered bridges, under which Warriston-close and Allan's-close are carried towards High-street, somewhat diverted from their present courses. The authors certainly justify, in a very remarkable degree, the motto they have adopted. Every room has the maximum amount of light and air, while the corridors and staircases are exceptionally well lighted, and there would also be, I think, quite an exceptional elegance about their colonnaded central area and staircases. Though bare of ornament and monotonous in its fenestration, the exterior maintains the same horizontal lines in every part, and is not without dignity, while the colonnades, which are carried to the ends, which would otherwise would be too severe. The disposition of the plan would produce fine masses of light and shade among the blocks of building when seen in perspective. No towers rise above the roofs to compete with that of St. Giles's, and the treatment of the steps of Warriston-close, sweeping round with their high retaining walls, give a very striking and noble effect, and considerably to the general effect. In point of cost, the design is without a rival considering its excellences, and I have reason to believe its author's estimate of 75,866*l.* is not likely to be much exceeded; while their scheme admits of the retention of the block of buildings at the north-west corner of the site. These and other considerations would influence me to give the merit and Air the highest place.

I regret, however, to have to point out that the south-west wing is so placed as not merely to divert the close from its present line (that might possibly have been allowed), but also to close up some of the windows and doors at present existing on the west side of Warriston-close. I feel, therefore, in justice to the merit and Air, cannot, on this account, recommend their design for one of the prizes.

After mature deliberation, therefore, I have come to the conclusion to recommend:—

No. 5, "Edina Classica," for the first prize.

No. 7, "Nineteenth Century," for the second prize; and

No. 40, "In my Defence" (with heraldic device), for the third prize.

No. 5, principally from its very admirable plan and elevation towards Cockburn-street (the execution of the design is beyond all praise, but that does not influence my choice); No. 7, principally from the beauty of its details, and its elevations generally, especially that towards Cockburn-street; and No. 40, principally from its general excellence of plan, refinement of details, and moderate cost.

In recommending these designs for the awards, I am painfully aware how nearly several others, some of whose merits I have had the pleasure of pointing out, have been passed over (though it was probably unnecessary to have done so), equal these in general excellence, and, if they were, are their superiors in some isolated respects; but, so far as I can judge, after a lengthy consideration, the balance is in favour of the three designs I have mentioned.

I cannot quite pass over in silence another design, No. 29 (mentioned in a sheet), which I have attempted to make your present building give you the greater part of the scheduled accommodation by adding a new north-west wing and additions to the east and west of the quadrangle; while some amelioration is given to the bareness of the north front by high-pitched roofs and well-designed chimneys. This scheme leaves some of the existing buildings on the site untouched. I do not think that the fact of its retaining so much of the present municipal offices puts No. 29 entirely out of the competition; but the omission of the Clydesdale Bank from his scheme, I think, does do so, though it is true that the author leaves unoccupied space on which it could be erected. Having alluded to this design, I ought to point out that, having kept the old building, it obliges the author to assign

to some of the principal officers apartments which would only be from 9 ft. to 10 ft. high.—I am, my Lord, your faithful servant,

ALFRED WATERHOUSE."

PROVIDENT INSTITUTION OF BUILDERS' FOREMEN AND CLERKS OF WORKS.

ANNUAL DINNER.

THE annual dinner of this excellent and old-established, but not sufficiently well-known, Institution, was held in the Venetian Saloon of the Holborn Restaurant on Saturday evening last, under the presidency of Mr. Ex-Sheriff George Burt, J.P. (late of the firm of Mowlem, Burt, & Freeman), who was supported by a large number of the members and others interested in the well-being of the Institution. The usual loyal and patriotic toasts having been disposed of (Mr. George Burt, jun., responding on behalf of the "Army, Navy, and Volunteers,"

The Chairman (Mr. Ex-Sheriff Burt) proposed the toast of the evening, "Success to the Provident Institution of Builders' Foremen and Clerks of Works." He expressed his satisfaction at presiding over such a large gathering, from which he hoped that much good would accrue to what was a very noble Institution; for it was one which not only promoted self-help amongst its members, but it afforded help to those who could not help themselves. But he thought it was very desirable to impress upon the members the need of getting others to join them, because in these days of competition every man, in the building trades especially, had to stand upright in his own shoes, and, while doing the honest best for himself, he ought to endeavour to make some provision for his own old age or for those whom he might leave behind him. Such provision he would be enabled to make by joining the Provident Institution of Builders' Foremen and Clerks of Works. He should like to see a great increase in the number of members, for of late there had been some falling off in that respect. Founded in 1842, the Institution had now been in existence for forty-five years, and it still possessed considerable funded property, so that its benefits might, with mutual advantage, be extended over a much larger number of members than it at present had on its roll. Since its establishment it had, he found, paid upwards of 6,000*l.* in pensions and funeral grants; and during the last year the amount disbursed was 258*l.* 10*s.* In short, the Institution was one well worthy of the support of the building trade, and of builders' foremen and clerks of works in particular. He regretted the absence, through indisposition, of the respected Governor of the Institution (Mr. George Plucknett), and Mr. Howard Collis had written expressing regret at inability to be present, but enclosing a subscription. In conclusion, the Chairman, after remarking that the Institution seemed to include in its ranks the *élite* of the classes for whom it was intended, the Chairman gave the toast, coupled with the name of Mr. J. W. H. Bedford, the Corresponding Secretary.

The toast was very heartily received, and Mr. Bedford, in responding, referred to the account of the work done by the Institution, as set forth in the last annual report.

Mr. J. Merrifield, the Financial Secretary, proposed "The Health of the Governor of the Institution, George Plucknett, Esq.," and expressed his great regret, which he knew was shared by all present, at Mr. Plucknett's absence. He had rendered very valuable services to the Institution, and they all wished him long life and happiness.

Mr. G. Groome, in an entertaining speech, proposed "The Donors and Honorary Subscribers," coupled with the name of Mr. Thomas Stirling, who briefly replied.

Mr. W. Horwood proposed "The Trustees" (Mr. G. Plucknett, F.S.A., Mr. P. C. Hardwick, F.S.A., Mr. W. Scrivener, and Mr. F. J. Dove), coupled with the name of Mr. Scrivener, who replied, urging the members to make renewed efforts to extend the good work of the Institution.

The Chairman, in felicitous terms, proposed "The Architects,"—for whom, unfortunately, there was no one present to reply.

The other toasts were "The Builders," proposed by Mr. Ben. Turner, and replied to by Mr. George Burt, jun.; "The Visitors," proposed by Mr. Stapleton and replied to by Mr. Scott Moncrieff, C.E.; "The Press," proposed by Mr. Thomas Stirling and coupled with the name of our representative; "The Directors and Officers of the Institution," proposed by the Chairman and coupled with the name of Mr. Groome; and "The Chairman."

During the evening subscriptions and donations to the funds of the Institution amounting to upwards of sixty guineas (including twenty-one guineas from the Chairman and fifteen guineas from Messrs. John Mowlem & Co.) were announced, although no appeal was made for funds.

It may be added that the offices of the Institution are at No. 9, Conduit-street, Regent-street, where meetings are held on the first and third Wednesdays in every month at 8:30 p.m. Inquiries on those evenings, or letters addressed to the Corresponding Secretary, Mr. Bedford, will elicit further particulars as to the working of the Institution.

THE LIVERPOOL CATHEDRAL COMPETITION.

SIR,—In order to correct the misapprehension which appears to exist as to the motives for exhibiting the Liverpool Cathedral designs in London, it can hardly be wrong to inform you that Mr. Christian, in a letter to Mr. J. O. Scott, has written that he has "no objection whatever to the exhibition of the drawings in London provided only my report is with them." He does not, of course, agree to the memorial asking for it after the resolution of the Council of the R.I.B.A. last week, yet it is obvious he does not flinch from the ordeal; and why, then, should the Institute, if it be considered that he has made any judgment at all? And if none other than that of his summary, viz.,—"There is a further and larger question that must be faced, and that is whether in any of the designs can be found the church of the future most suitable for the Cathedral of Liverpool," *à fortiori* there can be no objection to the exhibition proposed, whatever may be the private opinions of the promoters, or by whomsoever the original suggestion of it may have been made.

JOHN P. SEDDON.

1, Queen Anne's Gate, Feb. 24.

\* \* \* We insert the foregoing as a matter of personal explanation, but we regret to find that there continues to be any inclination to doubt the finality of Mr. Christian's report.

A JUDGE'S RULING AS TO PAYMENT FOR QUANTITIES.

SIR,—Will you kindly allow us to ask, through the medium of your valuable journal, the advice and, as far as possible, the co-operation of our brother architects and quantity surveyors, in defending a principle in which we believe all who supply quantities are interested?

Our case is this. We have been summoned in the Swansea County-court by a builder who has carried out some work under us, for the return of 50*l.*, being monies paid us by him some time since for quantities, together with other items for lithography, &c., charged for at the rate of 2*s.* per cent., he contending that he was not liable to pay, and ought not to have paid for such quantities. His reasons for this are immaterial, as the judge ruled that he was liable to pay for the quantities, which had been prepared with the knowledge and approval of the Building Committee of the work in question, and who were aware of the charges, which were specified in the quantities in the usual way.

The Judge, however, added that he considered the charges made for quantities were too high, and that he thought 20*l.* sufficient payment for the whole. His verdict was, therefore, that we should repay the plaintiff the sum of 30*l.*, together with all costs.

We believe your readers will at once see the effect this decision will have upon the profession; as, if such is the law,—and such it is until the verdict is upset by a Superior Court,—architects and surveyors cannot demand a greater payment for quantities than about three-quarters per cent., while they are at the mercy of any dissatisfied holder who may during the last six years have paid them for quantities at a higher rate than this, and who may choose, from spite or any other cause, to demand the return of the money.

The amount awarded, together with costs, has been paid into Court, and notice of appeal given.

This course will probably involve us in a very considerable outlay, trouble, and anxiety, and we should not have taken it, but have put up with the loss, however hard we may have considered it, had we not felt the principle involved was of so much importance. We trust such of your readers as are of the same opinion will help us to carry on the fight, and that they will, as, once, as the matter is pressing, communicate with us.

The architects of Swansea sympathise with us, and promise us their active co-operation.

BUCKNALL & JENNINGS.

Worcester-place, Swansea, February 22nd, 1887.

"MASONS' WAGES."

SIR,—I trust you will kindly allow me a small space in your next issue to reply to some of the remarks of your correspondent, "A Quarry Owner" [p. 302, ante].

It is not my intention on this occasion to say a word relative to what he said about Society men, except that I do not think anyone could form an idea from my previous letter [p. 266 ante] whether I believe in London Society Masons or not.

I do not deny that stone can be worked cheaper at the quarries; but the cause of the cheapness is not far to seek, to a practical man. A quarry owner uses fresh quarry stuff, which is of course soft and unseasoned. It is obvious that he if lime stone, grit stone, or free stone, it should be well seasoned

before being wrought; if it is not so it cannot be expected to resist the London atmosphere.

Then, again, there is the fixing of this quarry-worked stuff. Who can know better than the fixer whether it is properly worked or not? My experience is that the cost of fixing is twice what it should be, and the cleaning down much more.

Now, there is another important question connected with this subject. I have seen large quantities of worked stone delivered to the railway station, carted from there to a sub-contracting mason's yard, unloaded, kept there for some time, then reloaded and sent to the job.

Surely, if this system of sub-contracting and re-sub-letting is a genuine business, it would be better to pay the journeyman mason at the quarries a higher rate of wages and waste less in needless cartage, &c.

February 22nd, 1887. G. C. W.

SIR,—Permit me to say a few words in reply to "Quarry Owner" [p. 302, ante], or, rather, to ask if architects are not justified in having what many experienced architects specify; that is, to have the stone prepared on the job or in London. For various reasons, too numerous to mention, the proper place to work the stone is under the immediate supervision of a practical clerk of works, certainly not at the quarries. Again, stone is generally specified to be "selected." Not much chance of this when it is worked at the quarries, and the job standing for stone. It does not require a very lynx-eyed clerk of works to see at a glance if the stone is sub-let. How is it that many clerks of works appear to wince at this system of sub-letting? This is the great evil of slovenly work in any one trade, and a mere get-over work at the price paid. I think architects and clerks of works would be doing a great justice to all trades and clients to help stop this system of sub-letting work.

G. R. J.

\* \* \* On this subject we have also received a long letter, signed "Working Mason," but our space being filled before it came to hand, we cannot find room for it. The writer condemns the practice of working stone at the quarries, characterises piece-work and overtime as the "two great degenerators of the working-class," and denounces the practicability of a sliding-scale of wages for masons.

PERSHORE ABBEY LANTERN TOWER.

SIR,—May I point out the similarity between the details of Pershore tower (so cleverly shown in the elevation and section you give in the *Builder* for this date) and those of Salisbury Cathedral tower? Those curious oblong quatrefoils are exactly the same in both. The pillar buttresses between the upper windows finish with weatherings on the north side, and are much more effective than as shown in the elevation you reproduce (I quote from measured details taken some eighteen years ago) with Mr. Hawley Lloyd of Birmingham). Mr. Lloyd was of opinion that the restoration of the pinnacles was injudicious, and I agree with him that they were undoubtedly intended to finish somewhat like the turrets at Leverington, or Stamford, or Chichester, without any spires. Their outline as restored is of too early a feeling, and their height appears to dwarf the tower. Pershore men call them "table legs." When I first knew the church a part of one of the Norman arches peeped out over the lean-to roof of the fragment of the north transept; the effect was very happy, and lent additional height to the tower; it was unfortunately covered up by a higher roof, for no sufficient reason.

A few miles from Pershore is a noble tower that I had a hand in spoiling—Worcester. Behind the upper canopies were gable-looking openings, locally called "the oven mouths." They threw up the canopies boldly; we left them out, and weakened the effect.

At Malvern, those "oven mouths" may be seen in the same position; though they are smaller, the effect is good. The great turrets at Worcester were damaged by widening the bases of the spires, thus swallowing up the charming little cluster of pinnacles and flying buttresses round them.

In restoration, it is unsafe to indulge in improvements. The old Goths knew what they were about. We copyists do not, always.

W. LUNS.

Southsea, Feb. 19.

"WASH-OUT" VERSUS VALVE CLOSETS.

SIR,—In reading your report of the eighth meeting of the Architectural Association [p. 198, ante], and the discussion which followed thereon [p. 264, ante], I was much struck at the prejudice shown against wash-out water-closets. In fact, to my mind, it appeared that those who spoke in favour of the valve-closet could not have had experience of the "wash-out." I fitted up in a proper manner with a syphon cistern giving a full flush, such as are in common use here in Southsea.

The advantages of the wash-out over the valve closet are that it can be procured in glazed earthenware, trap and all; there is no action beneath the seat to corrode or get out of order, and the bottom of the pan will not corrode (as stated by Mr. Smoother), if only ordinary cleanliness is used, the same as is necessary with any other apparatus.

For my part, as owner of large property fitted up

with "wash-outs," I emphatically pronounce them to have proved perfect sanitary closets, and as a practical builder and plumber am certain that I am competent to judge. A. G. GERMAN.  
Southsea, Feb. 12th, 1887.

WASTE WATER FOR FLUSHING WATER CLOSETS.

SIR,—In reply to your correspondent [p. 302, *ante*], in reference to the above, permit me to say that there are apparatus in this town for flushing water closets by using waste-water from slop-stones, sinks, lavatories, down-spouts, surface-water, &c., and which are actuated in a similar manner to the ordinary water-closets generally in use. It may, however, be worked by the foot, the seat, or the door. A much better flush is obtained, which is caused by the large volume of water which may be used each time, and the impetus given to it; the result having a most salutary effect. A saving of forty per cent. on the present mode of construction is obtained.

By the use of this system 2,737l. 10s. per annum is saved in the cost of 73,000,000 gallons of town's water, which would be used by every 10,000 closets on the ordinary principle.

Three hundred pounds a year is also saved in reducing the volume of sewage to be treated at the sewage works by 73,000,000 gallons, making a total saving yearly, per 10,000 closets, of 3,037l. 10s., exclusive of the saving of forty per cent. on the original cost of closets.

I may also add, for the information of "Health" that any ordinary water-closet can be altered to the system under notice, where the water-rate and other charges would be saved.

The inconvenience caused by the freezing of the water-closet cast-iron, and the consequent inoperative condition of the water-closet, rendering it unfit for use,—otherwise than to cause a nuisance,—is obviated.

The nuisance referred to as being caused by using the closet when frozen has resulted, in a prolonged frost, in very serious consequences to health. In conclusion, I may say that the system is causing much interest in this neighbourhood, on account of its simplicity and effectiveness, and in my opinion, it will soon be generally adopted.

I shall be pleased to furnish any further information on the subject, either to your correspondent "Health," or any of your readers.

JAMES T. PEARSON.  
Borough Engineer's Office, Bursley, Feb. 23.

WILLESDEN PUBLIC OFFICES COMPETITION.

SIR,—In your criticism of the plans submitted for the Willesden Local Board Offices [p. 301, *ante*], you state that the design "Bona Fide" has the Surveyor's office to the south. Permit me to explain that I proposed, as an alteration, to face the building to Dunster-gardens, which would then give the Surveyor his north light, and admit of the front building being seen from the main road. But a similar position would be maintained if it faced the Dyne-road by simply reversing the plan. This is clearly shown on the block plan, which escaped your notice.

THE AUTHOR OF THE DESIGN "BONA FIDE."

AUSTRALIAN INTERCOLONIAL RAILWAY COMMUNICATION.

SIR,—Your sanguine anticipation [see "Notes," p. 276, *ante*] of the time when it will be possible to run a through train from Perth to Brisbane through the capitals of the Australian Colonies will unfortunately not be realised yet awhile, if ever, as the several Governments have taken careful precautions to thwart such an arrangement by providing each colony with a different gauge (with one important exception from its neighbours). They are as follows, in geographical order:—Western Australia, 3 ft. 6 in.; South Australia, 3 ft. 6 in. and 5 ft. 3 in.; Victoria, 5 ft. 3 in.; New South Wales, 4 ft. 8 in.; Queensland, 3 ft. 6 in. The exception is of importance, since through South Australia luxuriating in two gauges, and the chief lines round Adelaide being on the 5 ft. 3 in. gauge, the main line connecting Adelaide with the Victorian railways agrees with them as to gauge, and through trains in this one case will be able to run through between Adelaide and Melbourne. This line is just finished, if it be not already opened, and will be used for conveying the English mails to Victoria and New South Wales, and will lessen the present time considerably.
