EXPERIMENT STATION RECORD

VOLUME XXXI

JULY-DECEMBER, 1914

WASHINGTON
GOVERNMENT PRINTING OFFICE
1915

U. S. DEPARTMENT OF AGRICULTURE.

Scientific Bureaus.

- WEATHER BUREAU—C. F. Marvin, *Chief*.
 BUREAU OF ANIMAL INDUSTRY—A. D. Melvin, *Chief*.
 BUREAU OF PLANT INDUSTRY—W. A. Taylor, *Chief*.
 FOREST SERVICE—H. S. Graves, *Forester*.
 BUREAU OF SOILS—Milton Whitney, *Chief*.
 BUREAU OF CHEMISTRY—C. L. Alsberg, *Chief*.
 BUREAU OF CROP ESTIMATES—L. M. Estabrook, *Statistician*.
 BUREAU OF ENTOMOLOGY—L. O. Howard, *Entomologist*.
 BUREAU OF BIOLOGICAL SURVEY—H. W. Henshaw, *Chief*.
 OFFICE OF PUBLIC ROADS—L. W. Page, *Director*.
 OFFICE OF MARKETS AND RURAL ORGANIZATION—C. J. Brand, *Chief*.

OFFICE OF EXPERIMENT STATIONS—A. C. True, *Director*.

THE AGRICULTURAL EXPERIMENT STATIONS.

ALABAMA—

- College Station: *Auburn*; J. F. Duggar.^a
 Canebrake Station: *Uniontown*; L. H. Moore.^a
 Tuskegee Station: *Tuskegee Institute*; G. W. Carver.^a

ALASKA—*Sitka*: C. C. Georgeson.^b

ARIZONA—*Tucson*: R. H. Forbes.^a

ARKANSAS—*Fayetteville*: M. Nelson.^a

CALIFORNIA—*Berkeley*: T. F. Hunt.^a

COLORADO—*Fort Collins*: C. P. Gillette.^a

CONNECTICUT—

- State Station: *New Haven*; } E. H. Jenkins.^a
 Storrs Station: *Storrs*;

DELAWARE—*Newark*: H. Hayward.^a

FLORIDA—*Gainesville*: P. H. Rolfs.^a

GEORGIA—*Experiment*: R. J. H. DeLoach.^a

GUAM—*Island of Guam*: A. C. Hartenbower.^c

HAWAII—

- Federal Station: *Honolulu*; J. M. Westgate.^c
 Sugar Planters' Station: *Honolulu*; H. P. Agee.^a

IDAHO—*Moscow*: J. S. Jones.^d

ILLINOIS—*Urbana*: E. Davenport.^a

INDIANA—*La Fayette*: A. Goss.^a

IOWA—*Ames*: C. F. Curtiss.^a

KANSAS—*Manhattan*: W. M. Jardine.^a

KENTUCKY—*Lexington*: J. H. Kastle.^a

LOUISIANA—

- State Station: *Baton Rouge*;
 Sugar Station: *Audubon Park*,
New Orleans;
 North La. Station: *Calhoun*;

MAINE—*Orono*: C. D. Woods.^a

MARYLAND—*College Park*: H. J. Patterson.^a

MASSACHUSETTS—*Amherst*: W. P. Brooks.^a

MICHIGAN—*East Lansing*: R. S. Shaw.^a

MINNESOTA—*University Farm, St. Paul*: A. F. Woods.^a

MISSISSIPPI—*Agricultural College*: E. R. Lloyd.^a

MISSOURI—

- College Station: *Columbia*; F. B. Mumford.^a
 Fruit Station: *Mountain Grove*; Paul Evans.^a

^a Director, ^b Special agent in charge,

MONTANA—*Bozeman*: F. B. Linfield.^a

NEBRASKA—*Lincoln*: E. A. Burnett.^a

NEVADA—*Reno*: S. B. Doten.^a

NEW HAMPSHIRE—*Durham*: J. C. Kendall.^a

NEW JERSEY—*New Brunswick*: J. G. Lipman.^a

NEW MEXICO—*State College*: Fabian Garcia.^a

NEW YORK—

- State Station: *Geneva*; W. H. Jordan.^a
 Cornell Station: *Ithaca*; B. T. Galloway.^a

NORTH CAROLINA—

- College Station: *West Raleigh*;
 State Station: *Raleigh*;

NORTH DAKOTA—*Agricultural College*: T. P. Cooper.^a

OHIO—*Wooster*: C. E. Thorne.^a

OKLAHOMA—*Stillwater*: W. L. Carlyle.^a

OREGON—*Corvallis*: A. B. Cordley.^a

PENNSYLVANIA—

- State College: R. L. Watts.^a
 State College: Institute of Animal Nutrition;
 H. P. Armsby.^a

PORTO RICO—

- Federal Station: *Mayaguez*; D. W. May.^b
 Insular Station: *Rio Piedras*; W. V. Tower.^a

RHODE ISLAND—*Kingston*: B. L. Hartwell.^a

SOUTH CAROLINA—*Clemson College*: J. N. Harper.^a

SOUTH DAKOTA—*Brookings*: J. W. Wilson.^a

TENNESSEE—*Knoxville*: H. A. Morgan.^a

TEXAS—*College Station*: B. Youngblood.^a

UTAH—*Logan*: E. D. Ball.^a

VERMONT—*Burlington*: J. L. Hills.^a

VIRGINIA—

- Blacksburg*: W. J. Schoene.^d
Norfolk: Truck Station; T. C. Johnson.^a

WASHINGTON—*Pullman*: I. D. Cardiff.^a

WEST VIRGINIA—*Morgantown*: E. D. Sander-son.^a

WISCONSIN—*Madison*: H. L. Russell.^a

WYOMING—*Laramie*: H. G. Knight.^a

^c Agronomist in charge. ^d Acting director.

OKLAHOMA STATION:	
Circular 24, December, 1913.....	156
Circular 25, January, 1914.....	138
Circular 26, January, 1914.....	131
Circular 27, March, 1914.....	357
Circular 28, March, 1914.....	354
Circular 29, April, 1914.....	336
Circular 30, April, 1914.....	474
Circular 31, May, 1914.....	553
Circular 32, June, 1914.....	532
Circular 33, June, 1914.....	592
Circular 34, July, 1914.....	829
Circular 35, July, 1914.....	832
OREGON STATION:	
Bulletin 117, April, 1914.....	414
Bulletin 118, June, 1914.....	818
Research Bulletin 3, March, 1914.....	407
PENNSYLVANIA STATION:	
Bulletin 128, February, 1914.....	45
Bulletin 129, March, 1914.....	236
Bulletin 130, April, 1914.....	437
PORTO RICO STATION:	
Bulletin 15, May 29, 1914.....	354
Bulletin 16, September 17, 1914.....	816
Annual Report, 1913.....	627, 634, 637, 644, 645, 664, 694
RHODE ISLAND STATION:	
Bulletin 156, March, 1914.....	473
Bulletin 157, April, 1914.....	485
Bulletin 158, May, 1914.....	572
Bulletin 159, June, 1914.....	781
Inspection Bulletin, May, 1914.....	467
Inspection Bulletin, June, 1914.....	624
SOUTH CAROLINA STATION:	
Bulletin 173, September, 1913.....	207
Bulletin 174, December, 1913.....	249
Bulletin 175, March, 1914.....	250
Circular 23, December, 1913.....	158
Circular 24, January, 1914.....	182
Circular 25, February, 1914.....	141
SOUTH DAKOTA STATION:	
Bulletin 148, January, 1914.....	470
Bulletin 149, March, 1914.....	435
Bulletin 150, April, 1914.....	438
TENNESSEE STATION:	
Bulletin 103, January, 1914.....	111
Bulletin 104, April, 1914.....	469
Bulletin 105, April, 1914.....	489
Bulletin 106, June, 1914.....	635
Bulletin 107, June, 1914.....	815
Bulletin 108, June, 1914.....	837
TEXAS STATION:	
Bulletin 162, December, 1913.....	71
Bulletin 163, December, 1913.....	65

UNITED STATES DEPARTMENT OF AGRICULTURE PUBLICATIONS
ABSTRACTED.

Annual Reports 1913.....	195
Journal Agricultural Research, vol. 2, No. 1, April, 1914.....	107, 130, 150, 153, 158
Journal Agricultural Research, vol. 2, No. 2, May, 1914.....	201, 237, 247, 252, 288
Journal Agricultural Research, vol. 2, No. 3, June, 1914... ..	445, 449, 450, 458, 476, 477
Journal Agricultural Research, vol. 2, No. 4, July, 1914.....	525, 540, 544, 574
Journal Agricultural Research, vol. 2, No. 5, August, 1914.....	747, 748
Bulletin 51, A Bacteriological and Chemical Study of Commercial Eggs in the Producing Districts of the Central West, Mary E. Pennington et al.	570
Bulletin 54, The Topographic Features of the Desert Basins of the United States with Reference to the Possible Occurrence of Potash, E. E. Free.....	218
Bulletin 61, Potash Salts and Other Salines in the Great Basin Region, G. J. Young.....	423
Bulletin 70, Immunization Tests with Glanders Vaccine, J. R. Mohler and A. Eichhorn.....	83
Bulletin 71, The Wet Lands of Southern Louisiana and Their Drainage, C. W. Okey.....	185
Bulletin 72, Suitability of Longleaf Pine for Paper Pulp, H. E. Surface and R. E. Cooper.....	144
Bulletin 73, Raising and Fattening Beef Calves in Alabama, D. T. Gray and W. F. Ward.....	169
Bulletin 75, Alfalfa Seed Production; Pollination Studies, C. V. Piper et al... ..	133
Bulletin 76, Laboratory and Field Assay of Arsenical Dipping Fluids, R. M. Chapin.....	115
Bulletin 77, Rocky Mountain Mine Timbers, N. deW. Betts.....	144
Bulletin 78, The So-called Tobacco Wireworm in Virginia, G. A. Runner.....	253
Bulletin 79, Research Studies on the Curing of Leaf Tobacco, W. W. Garner, C. W. Bacon, and C. L. Foubert.....	115
Bulletin 80, Effects of Varying Certain Cooking Conditions in Producing Soda Pulp from Aspen, H. E. Surface.....	715
Bulletin 81, The Potato Quarantine and the American Potato Industry, W. A. Orton.....	149
Bulletin 82, Powdery Scab (<i>Spongospora subterranea</i>) of Potatoes, I. E. Melhus.....	149
Bulletin 83, Farmers' Institute and Agricultural Extension Work in the United States in 1913, J. Hamilton.....	195
Bulletin 84, Experiments with Udo, the New Japanese Vegetable, D. Fairchild.....	140
Bulletin 85, The Cost of Pasteurizing Milk and Cream, J. T. Bowen.....	188
Bulletin 86, Tests of Wooden Barrels, J. A. Newlin.....	144
Bulletin 87, Flumes and Fluming, E. S. Bruce.....	485
Bulletin 88, The Control of the Codling Moth in the Pecos Valley in New Mexico, A. L. Quaintance.....	252
Bulletin 89, The Death of Chestnuts and Oaks due to <i>Armillaria mellea</i> , W. H. Long.....	246
Bulletin 90, The Rose Aphis, H. M. Russell.....	250
Bulletin 91, Cost and Methods of Clearing Land in the Lake States, H. Thompson and E. D. Strait.....	288

	Page.
Bulletin 92, Destruction of Germs of Infectious Bee Diseases by Heating, G. F. White.....	255
Bulletin 93, The Temperature of the Honeybee Cluster in Winter, E. F. Phillips and G. S. Demuth.....	254
Bulletin 94, Domestic Breeds of Sheep in America, E. L. Shaw and L. L. Heller.....	567
Bulletin 95, Insect Damage to the Cones and Seeds of Pacific Coast Conifers, J. M. Miller.....	548
Bulletin 96, The Temperature of the Bee Colony, B. N. Gates.....	553
Bulletin 97, Identification of Commercial Fertilizer Materials, W. H. Fry.....	517
Bulletin 98, The Application of Refrigeration to the Handling of Milk, J. T. Bowen.....	575
Bulletin 99, Tests of Selections from Hybrids and Commercial Varieties of Oats, C. W. Warburton et al.	527
Bulletin 100, Walnut Aphides in California, W. M. Davidson.....	753
Bulletin 101, Relative Resistance of Various Conifers to Injection with Creosote, C. H. Teesdale.....	743
Bulletin 102, Acidity as a Factor in Determining the Degree of Soundness of Corn, H. J. Besley and G. H. Baston.....	525
Bulletin 103, Alum in Foods.....	556
Bulletin 104, Thrips as Pollinators of Beet Flowers, H. B. Shaw.....	549
Bulletin 105, Progress Reports of Experiments in Dust Prevention and Road Preservation, 1913.....	686
Bulletin 106, The Granular Venereal Disease and Abortion in Cattle, W. L. Williams.....	779
Bulletin 107, Birds in Relation to the Alfalfa Weevil, E. R. Kalmbach.....	655
Bulletin 108, Harmful Effects of Aldehydes in Soils, O. Schreiner and J. J. Skinner.....	620
Bulletin 109, The Molds of Cigars and Their Prevention, R. H. True.....	613
Bulletin 110, Fattening Cattle in Alabama, D. T. Gray and W. F. Ward.....	664
Bulletin 111, The Sequoia Pitch Moth, a Menace to Pine in Western Montana, J. Brunner.....	652
Bulletin 112, The Oat Aphis, J. J. Davis.....	753
Bulletin 113, The Lesser Bud-Moth, E. W. Scott and J. H. Paine.....	755
Bulletin 114, Report Upon the Black and Boggy Swamps Drainage District, Hampton and Jasper Counties, S. C., F. G. Eason.....	684
Bulletin 115, Gate Structures for Irrigation Canals, F. C. Scobey.....	782
Bulletin 116, New Facts Concerning the White-Pine Blister Rust, P. Spaulding.....	647
Bulletin 117, Profits in Farming on Irrigated Areas in Utah Lake Valley, E. H. Thomson and H. M. Dixon.....	689
Bulletin 118, Experiments in the Destruction of Fly Larvæ in Horse Manure, F. C. Cook et al.	653
Bulletin 119, Five Oriental Species of Beans, C. V. Piper and W. J. Morse.....	739
Bulletin 120, Apple Powdery Mildew and its Control in the Pajaro Valley, W. S. Ballard and W. H. Volck.....	748
Bulletin 121, Spinning Tests of Upland Long-Staple Cottons, F. Taylor and W. A. Sherman.....	631
Bulletin 122, The Inorganic Composition of Some Important American Soils, W. O. Robinson.....	719
Farmers' Bulletin 573, The Angora Goat, L. L. Heller.....	75
Farmers' Bulletin 574, Poultry House Construction, A. R. Lee.....	93
Farmers' Bulletin 575, The Agricultural Outlook.....	73, 95
Farmers' Bulletin 576, Breeds of Sheep for the Farm, F. R. Marshall.....	75
Farmers' Bulletin 577, Growing Egyptian Cotton in the Salt River Valley, Arizona, E. W. Hudson.....	41

	Page.
Farmers' Bulletin 578, The Making and Feeding of Silage, T. E. Woodward...	72
Farmers' Bulletin 579, Crimson Clover: Utilization, J. M. Westgate.....	38
Farmers' Bulletin 580, Beef Production in the South, W. F. Ward and D. T. Gray.....	74
Farmers' Bulletin 581, The Agricultural Outlook.....	95
Farmers' Bulletin 582, Uses for Chestnut Timber Killed by the Bark Disease, J. C. Nellis.....	14.
Farmers' Bulletin 583, The Common Mole of the Eastern United States, T. H. Scheffer.....	154
Farmers' Bulletin 584, The Agricultural Outlook.....	190
Farmers' Bulletin 585, Natural and Artificial Incubation of Hens' Eggs, H. M. Lamon.....	173
Farmers' Bulletin 586, Collection and Preservation of Plant Material for Use in the Study of Agriculture, H. B. Derr and C. H. Lane.....	394
Farmers' Bulletin 587, Economic Value of North American Skunks, D. E. Lantz.....	370
Farmers' Bulletin 588, Economical Cattle Feeding in the Corn Belt, J. S. Cotton and W. F. Ward.....	468
Farmers' Bulletin 589, Homemade Silos, H. Rabild, A. K. Risser, and K. E. Parks.....	591
Farmers' Bulletin 590, The Agricultural Outlook.....	391
Farmers' Bulletin 591, The Classification and Grading of Cotton, D. E. Earle and W. S. Dean.....	433
Farmers' Bulletin 592, Stock-Watering Places on Western Grazing Lands, W. C. Barnes.....	366
Farmers' Bulletin 593, How to Use Farm Credit, T. N. Carver.....	389
Farmers' Bulletin 594, Shipping Eggs by Parcel Post, L. B. Flohr.....	370
Farmers' Bulletin 595, Arsenate of Lead as an Insecticide Against the Tobacco Hornworms in the Dark-Tobacco District, A. C. Morgan and D. C. Parman..	454
Farmers' Bulletin 596, The Culture of Winter Wheat in the Eastern United States, C. E. Leighty.....	438
Farmers' Bulletin 597, The Road Drag and How It is Used.....	486
Farmers' Bulletin 598, The Agricultural Outlook.....	391
Farmers' Bulletin 599, Pasture and Brain Crops for Hogs in the Pacific Northwest, B. Hunter.....	470
Farmers' Bulletin 600, An Outfit for Boring Taprooted Stumps for Blasting, H. Thompson.....	486
Farmers' Bulletin 601, A New System of Cotton Culture and Its Application, O. F. Cook.....	433
Farmers' Bulletin 602, Production of Clean Milk.....	771
Farmers' Bulletin 603, Arsenical Cattle Dips, R. M. Chapin.....	776
Farmers' Bulletin 604, The Agricultural Outlook.....	789
Farmers' Bulletin 605, Sudan Grass as a Forage Crop, H. N. Vinall.....	737
Farmers' Bulletin 606, Collection and Preservation of Insects for Use in the Study of Agriculture, C. H. Lane and N. Banks.....	792
Farmers' Bulletin 608, Removal of Garlic Flavor from Milk and Cream, S. H. Ayers and W. T. Johnson, jr.....	771
Farmers' Bulletin 609, Bird Houses and How to Build Them, N. Dearborn....	751
Farmers' Bulletin 610, Wild Onion: Methods of Eradication, H. R. Cox.....	739
Farmers' Bulletin 611, The Agricultural Outlook.....	789
Press Notice, January 14, 1914, Prickly Pear Cactus as a feed for Dairy Cows..	77
List of Workers in Agriculture and Home Economics in U. S. Department of Agriculture and Agricultural Colleges and Experiment Stations.....	599
Yearbook, 1913.....	316, 332, 333, 337, 340, 349, 356, 359, 367, 388, 396

	Page.
BUREAU OF ANIMAL INDUSTRY:	
Bulletin 110, pt. 3, A Biometrical Study of Egg Production in the Domestic Fowl, R. Pearl and F. M. Surface.....	669
Bighead in Sheep, H. J. Frederick.....	883
Effects of Tick Eradication on the Cattle Industry of the South, W. F. Ward.....	883
Progress and Results of Cattle-Tick Eradication.....	85
BUREAU OF BIOLOGICAL SURVEY:	
North American Fauna No. 36, Revision of the American Harvest Mice, A. H. Howell.....	647
BUREAU OF ENTOMOLOGY:	
Bulletin 26, technical series, American Black Flies or Buffalo Gnats, J. R. Malloch.....	254
Bulletin 27, pt. 2, technical series, Classification of the Aleyrodidæ, II, A. L. Quaintance and A. C. Baker.....	755
The Periodical Cicada in 1914, C. L. Marlatt.....	351
BUREAU OF PLANT INDUSTRY:	
Inventory of Seeds and Plants Imported, July 1 to September 30, 1912....	327
Menziesia, A New Stock-Poisoning Plant of the Northwestern States, C. D. Marsh.....	376
Work of the Huntley Experiment Farm, 1913, D. Hansen.....	828
Work of the Truckee-Carson Experiment Farm, 1913, F. B. Headley.....	828, 835, 889
BUREAU OF SOILS:	
Field Operation, 1911 (Thirteenth Report).....	512
Field Operations, 1913—	
Soil Survey of Ashley County, Arkansas, E. S. Vanatta et al.....	813
Soil Survey of Bradford County, Florida, W. C. Byers et al.....	813
Soil Survey of Gordon County, Georgia, J. O. Veatch.....	814
Soil Survey of Miller County, Georgia, R. T. Allen and E. J. Grimes..	814
WEATHER BUREAU:	
Bulletin Z, The Floods of 1913 in the Rivers of the Ohio and Lower Mississippi Valleys, A. J. Henry.....	214
Monthly Weather Review, Vol. 42, Nos. 1-2, January-February, 1914.....	212, 213, 229
Monthly Weather Review, Vol. 42, Nos. 3-4, March-April, 1914.....	614, 615
Climatological Data, Vol. 1, Nos. 1-2, January-February, 1914.....	213
Climatological Data, Vol. 1, Nos. 3-4, March-April, 1914.....	415
Climatological Data Vol. 1, Nos. 5-6, May-June, 1914.....	615
List of Meteorological Text-Books and Reference Books, 3rd edition (Document 512), C. F. Talman.....	509
Report, 1913.....	212
OFFICE OF EXPERIMENT STATIONS:	
Syllabus 15, Illustrated Lecture on the Homemade Fireless Cooker, Mrs. K. C. Davis and Angeline Wood.....	299
Syllabus 16, Illustrated Lecture on Swine in the United States, W. B. Jessee.....	694

	Page.
The determination of phosphoric acid in the soil, Hornberger	16
Citrate-soluble phosphoric acid in phosphates, Starodubowa and Jakuschkin...	16
The alundum crucible for the determination of phosphoric acid, Liberi.....	17
In regard to fertilizer analysis, Mitscherlich and Simmermacher.....	17
The determination of cellulose with nitric acid, Rao and Tollens.....	18
Estimation of sugar in honeys, comfits, jellies, sirups, etc., Muttelet.....	18
Detection of technical invert sugar with β -naphthol, Litterscheid	18
About honey examination, Buchner.....	18
Determination of sugar in bagasse, Pellet.....	18
Hot and cold digestion in beet analysis, Pellet.....	18
Relationship between weight of sugar beet and composition, Harris and Gortner.	19
Report of the department of chemistry, Jacobson and Adams.....	19

METEOROLOGY—WATER.

Weather science, Lempfert.....	19
Weather forecasting, Deeley.....	19
The agricultural meteorological service in Germany, Börnstein.....	19
Present organization of agricultural meteorology in Sweden, Hamberg.....	20
About climatological variations, Arctowski.....	20
The thermal state of the atmosphere, Boutaric.....	20
Measurements of the emanations content of soil air, Kähler.....	20
Variation with altitude of radium emanation of atmosphere, Wright and Smith..	20
The climate and weather of San Diego, California, Carpenter.....	21
Climate and meteorology of New Zealand, Bates.....	21
Monthly and annual rainfall from 1837 to 1912 at St. Paul, Minnesota.....	21
Composition of rain water collected in the Hebrides and in Iceland, Miller....	21
The economic value of tropical rainfall, Capus	21
The genesis of dew, Godden.....	22
A sliding rule for the determination of the dew point, Korff-Petersen.....	22
Combating hail.....	22
Electrical protection against hail in Gironde, Courty.....	22
Surface water supply of St. Lawrence River Basin, 1912, Covert et al.....	22

SOILS—FERTILIZERS.

The characterizing of soil according to the zeolitic silicates, Gans.....	22
Earth flows and structure soil in polar and subpolar regions, Sapper.....	23
Knox County soils, Hopkins, Mosier, Pettit, and Readhimer.....	23
Soil investigations, Sharp.....	24
Heat movement in pseudo-isotropic soil, Anderkó.....	24
An erosion study, Coffey.....	24
Lysimeter investigations, 1913, Richter.....	24
The effect of heat on solubility of mineral constituents of soil, McGeorge.....	25
The decomposition of cellulose in moor soil and peat, Daszewska.....	25
The decomposition of soil carbonates, McIntire.....	25
Management of soils to prevent blowing, Jardine.....	25
Contribution to the physiology of soil, Bernbeck.....	26
The distribution of bacteria in various soil types, Conn.....	26
Real and apparent nitrifying powers, Gainey.....	26
Studies on soil protozoa, Cunningham and Löhnis.....	26
Action of antiseptics in increasing growth of crops, Russell and Buddin.....	27
Fertilizers and soil organisms, Lumia.....	27
The purpose and interpretation of fertilizer experiments, Coffey.....	28
On the plans of fertilizer experiments, Gile.....	28
Row fertilizing experiments, Ahr.....	29
Pond fertilizing experiments, Kuhnert.....	29
An incompatibility in fertilizer mixing, Keitt.....	29
Injuries to the cornea by artificial fertilizers, Eickmeyer.....	29
The trade in fertilizing materials, Lambert.....	29
Consumption, production, and commerce in fertilizers in Russia, Piettre.....	29
Source, availability, and suitability of different plant foods, Williams.....	30
Composition and fertilizing value of farm crops and other materials, Williams..	30
[The guano situation in Peru].....	30
Peat-moss litter, Todd.....	30
Sulphate of ammonia industry of Germany, Skinner.....	30

	Page.
Potash shipments during 1914, Skinner.....	31
Occurrence and composition of some Alabama phosphates, Ross.....	31
On the action of lime and magnesia in the nutrition of plants, Haselhoff.....	31
Catalytic fertilizers, magnesium salts, etc., Munerati.....	31
Catalytic fertilizers, Boullanger.....	31
Radio-active fertilizers, Malpeaux.....	31
Recent experiments on the fertilizing action of sulphur, Boullanger.....	31
Fertilizer inspection.....	31
Inspection and analyses of commercial fertilizers, 1913, Trowbridge.....	31
Tabulated analyses of commercial fertilizers.....	31

AGRICULTURAL BOTANY.

Plant life, Farmer.....	32
A recording transpirometer, Blackman and Paine.....	32
Relation between structure and physiological characters, Takushkin and Vavilov.....	32
Anatomical coefficients and physiological characters of plants, Kolkunov.....	32
A contribution to the physiology of the purple sulphur bacteria, Skene.....	32
Some toxic and antitoxic effects in cultures of Spirogyra, Hoyt.....	32
Gaseous exchanges of plants with the atmosphere, Maquenne and Demoussy.....	33
Respiration of plants under various electrical conditions, Knight and Priestley.....	33
Studies on freezing and frost killing in plants, Maximow.....	34
A study of the effect of smoke and dust on plants, Sabachnikoff.....	34
The occurrence of rennet in <i>Rhizopus nigricans</i> , Durandard.....	34
Presence in leaves and flowers of yellow pigments, Combes.....	34
Differential mortality with respect to seed weight in <i>Pisum sativum</i> , Harris.....	35
Studies in seedless fruits, Negri.....	35
Origin of species in polymorphic genera, De Vries.....	35
The vegetation in the vicinity of Leyni in relation to agriculture, Ferrari.....	35
The flower-finder, Walton.....	35

FIELD CROPS.

Forage crops: Annual grasses and roots, Williams and Welton.....	35
Plants introduced into a desert valley as a result of irrigation, Parish.....	36
Irrigation experiments, True et al.....	36
Experiments with lime nitrogen, sulphate of ammonia, and nitrate of soda.....	36
Comparative fertilizer experiments with cereals in 1912, Wehnert.....	37
Soy beans and cowpeas, Wiancko, Fisher, and Cromer.....	37
Chemical analyses, Bigler.....	37
Grass mixtures for North Carolina pastures, Williams.....	37
The creeping rootstock of <i>Agropyron repens</i> , Knight.....	37
Alfalfa in Kansas, Jardine and Call.....	37
The management of blue-grass pastures, Carrier and Oakley.....	37
The premier clover for North Carolina farmers, Williams.....	38
Crimson clover: Utilization, Westgate.....	38
The growth of maize on cogan soil, Navarro.....	38
Applying fertilizers to corn and cotton by different methods, Williams.....	38
Effects of fertilizing materials upon the maturity of cotton, Williams.....	39
Fertilizer experiments with cotton in northern Alabama in 1913, Duggar et al.....	40
Method of improving cotton by seed selection, Winters.....	41
Buying cotton seed for planting, Winters.....	41
Long staple cotton in North Carolina, Williams.....	41
Growing Egyptian cotton in the Salt River Valley, Arizona, Hudson.....	41
Cotton in the Dominican Republic.....	41
Composition of hops grown in different parts of world, Tartar and Pilkington.....	41
Species and varieties of malangas cultivated in Cuba, Roig y Mesa et al.....	41
The influence of subsoiling on yield, Augstin.....	41
Notes on the culture of peanuts, Leplae.....	41
Fertilizer experiments with potatoes, Clausen.....	41
Experimental study on varieties of potatoes, 1910-11 and 1911-12, Tonnelier.....	42
Notes on potato growing.....	42
[Experiments with rape], Bieler.....	42
Production of rape seed near Shanghai, Wilder.....	42

EXPERIMENT STATION RECORD.

VOL. XXXI.

JULY, 1914.

No. 1.

With the continued enlargement and extension of the functions of the United States Department of Agriculture, the annual appropriation act providing for its support has become more and more a measure of much public interest. The latest of these acts, signed by President Wilson June 30, 1914, and carrying appropriations for the fiscal year commencing with the following day, is no exception in this respect, again establishing as it does the principle of federal aid to agriculture in the broadest use of the term, providing for the maintenance and development of its manifold activities to a larger extent than ever before, and opening the way to an increased efficiency through a reorganization of its work.

The total amount carried by the act is \$19,865,832. This is an increase of \$1,878,887, or over 11 per cent, over the previous year, and of \$804,500 over the estimates submitted by the Department. The increased allotments are distributed throughout the entire Department, and while many are designed to provide more adequately for its administrative and regulatory functions, which now absorb nearly two-thirds of the total appropriations, opportunity is also afforded for the extension of most of its lines of research, and especially for the development of its various forms of demonstration work.

In its general make-up, the law conforms closely to its immediate predecessor, and in fact is somewhat more rigidly confined to the routine work of the Department. There are, however, a number of items of new legislation. Thus, the Secretary of Agriculture is directed to prepare a plan for "reorganizing, redirecting, and systematizing the work of the Department of Agriculture as the interests of economical and efficient administration may require." This plan is to be submitted to Congress with the estimates of expenditures for the fiscal year 1915-16, these estimates being arranged on the basis of its provisions. A special object of the proposed reorganization is the elimination of the possibility of duplication, and the securing of close coordination of related lines of work.

Another provision increases the maximum salary which may be paid to investigators or others engaged in scientific work from

\$4,000 to \$4,500. Under the previous limit, a number of the more experienced investigators have been drawn away from the Department.

By a clause inserted in the section dealing with the Office of Experiment Stations, funds are given the Secretary of Agriculture to carry out the provisions of the Smith-Lever Extension Act. An extension of the franking privilege is also included under which all correspondence, bulletins, and reports for the furtherance of the purposes of that act may be transmitted in the mails free of postage by the college officer or other person connected with the extension department of the college designated by the Secretary of Agriculture, under regulations to be prescribed by the Postmaster General.

Great interest was again manifested in the demonstration and extension activities conducted by the Department itself, and some of the largest increases carried in the act are those for their further development. The sum of \$400,000 is definitely allotted to farmers' cooperative demonstration work outside the cotton belt, and \$673,240 for similar demonstrations in the areas threatened by the boll weevil. In the case of the latter work, a proviso is inserted restricting the expenditures to the funds provided and such cooperative funds as may be voluntarily contributed by state, county, and municipal agencies, associations of farmers and individual farmers, universities, colleges, boards of trade, chambers of commerce, other local associations of business men, business organizations, and individuals within the State. The allotment for the campaign against the cattle tick is increased from \$325,000 to \$400,000, of which \$50,000 may be used for live stock demonstration work in areas freed of ticks. There is also an appropriation of \$60,000 for experiments and demonstrations in cooperation with States or individuals in live stock production in the cane sugar and cotton districts, and one of \$40,000 to aid in the agricultural development of the government reclamation projects by assisting settlers through demonstrations, advice, and in other ways.

Most of the various regulatory or police functions assigned to the Department receive increased support. The permanent appropriation of \$3,000,000 for meat inspection is supplemented by a grant of \$375,000, an increase of \$175,000 over the previous year. This increase is mainly because of additional work through the inspection of imported meats, in accordance with the Tariff Act of 1913. The meat inspection is also extended to reindeer. The allotment for the enforcement of the Food and Drugs Act is increased by \$25,641, largely to meet the additional duties imposed by the recent extension of the act to include meat and meat food products and the amendment requiring the declaration of the net

weight in package and similar goods. An increase from \$10,000 to \$50,000 is provided for the protection of migratory game and insectivorous birds, and one from \$75,000 to \$100,000 for the cooperative fire protection of the forested watersheds of navigable streams. The appropriation for the enforcement of the plant quarantine act is increased from \$40,000 to \$50,000, with \$50,000 additional to enable cooperation with States quarantined against the interstate movement of Irish potatoes.

As usual there is considerable new legislation relating to forestry matters. The Appalachian Forest Reserve Act of 1911 is amended by increasing the proportion of the gross receipts from the National Forests acquired under its provisions which is returned to the respective States and counties, for the benefit of their public schools and roads, from five to twenty-five per cent. Provision is also made for the handling through the Treasury Department of funds contributed for cooperative work in the protection and improvement of the National Forests, as well as for forest investigations, and a requirement is inserted whereby all such contributions must annually be reported to Congress.

The appropriation for studies of the marketing and distribution of farm products is increased from \$50,000 to \$200,000. Authority is also given the Department for studies of cooperation among farmers in the United States in rural credits and other lines and to disseminate information on the subject, with an appropriation of \$40,000 for the purpose.

Other new projects for which definite appropriations are made include \$10,000 for the importation of Corriedale and other sheep for breeding purposes; \$5,000 for studying the grading, weighing, and handling of naval stores; \$7,000 for the publication of reports and maps dealing with the location, extent, etc., of the kelp beds on the Pacific Coast; \$10,000 for furnishing official cotton grades and samples to certain associations; \$5,000 for the improvement of an additional game preserve; and \$5,000 for agricultural extension work in Hawaii. Authority is also given for studies of seismology; a number of new insects and plant diseases, the handling of fish, oysters, and other foods and food products, and the utilization of agricultural products for clothing and other uses in the home. An exhibit by the Department, illustrative of farming in the subhumid regions, is provided for the International Dry Farming Congress to be held at Wichita, Kansas, October 7 to 17, 1914, with an appropriation of \$20,000 for the purpose.

Considering the appropriations definitely allotted to the several Bureaus, that of the Weather Bureau aggregates \$1,667,270. This is an apparent decrease of \$40,340, but this is mainly because no new

observatories are provided except a building at Neah Bay, Washington, to cost \$3,000. The allotments of the Bureau have been classified on a new basis, \$327,270 being available for statutory salaries; \$122,000 for carrying on investigations in meteorology, climatology, seismology, evaporation, and aerology, and the dissemination of meteorological, climatological, and marine information in the city of Washington; \$1,189,000 for similar expenses outside of Washington; and \$26,000 for the maintenance of a Bureau printing office in Washington. The Secretary is also directed to report to Congress relative to the future disposition of the plant at Mount Weather, Virginia, from which the extensive research work formerly carried on is being largely withdrawn.

An increase of \$288,830 is accorded the Bureau of Animal Industry, making its total \$2,320,026. This is in addition to the permanent annual appropriation of \$3,000,000 for meat inspection previously referred to and also to a special appropriation of \$600,000, approved February 23, 1914, of which \$50,000 was allotted to the inspection of virus, serums, etc., used in the treatment of animal diseases, \$100,000 for the investigation, treatment, and eradication of dourine, and the remainder for similar work with hog cholera. Among the largest items of increase in the Bureau's appropriation are those supplementing the meat inspection funds and for the tick eradication campaign already mentioned, and for work in dairying which receives \$256,490, an increase of \$78,590. The various items pertaining to animal husbandry are combined into a single group aggregating \$182,840, of which \$30,000 may be used for the horse breeding project, \$24,500 for the poultry studies, including the ostrich industry, and \$10,000 for sheep importation. The appropriation for inspection and quarantine work is \$625,520, and that for pathological investigations of animal diseases \$77,360.

The Bureau of Plant Industry receives \$3,616,045. This is an increase of \$948,050, about two-thirds of which is accounted for by the large additions to the funds for demonstration purposes previously mentioned, and the remainder chiefly by smaller increases apportioned among a large number of projects. The congressional seed distribution is continued on the usual basis and with an appropriation of \$257,000, as for the previous year. The Bureau also receives \$166,500 for the testing and distribution in quantities sufficient for practical field tests of new and rare seeds which from previous trials seem especially promising, and for the improvement of alfalfa, clover, and other forage crops, \$100,000 of this amount being available for the purchase and distribution of these new and rare seeds. The amount of \$74,600 is appropriated for the foreign seed and plant introduction.

Large appropriations are again made for the prosecution of studies with specific crops. Thus, for cotton \$91,000 is provided for an inquiry into ginning, grading, baling, and wrapping practices. This work is extended to include gin compressing and the distribution of the official grades of cotton samples, and the appropriation for testing the waste, tensile strength, and bleaching qualities of the various standard grades of cotton is increased from \$10,000 to \$60,000. For other fiber plant studies, especially with flax, \$20,850 is again allotted, as well as \$38,000 for acclimatization and adaptation work with cotton, corn, and other crops introduced from tropical regions. The tobacco studies receive \$25,000; the cereal investigations \$135,405, of which \$40,000 is for corn; the studies of grain handling and grading \$76,320; those of drug plants \$55,380; and those of sugar beets and the production of table sirup and the means of utilizing cane by-products \$41,495. For studies in fruit growing, handling, and marketing \$107,500 is available, together with \$56,320 for other horticultural work, and \$26,690 for the maintenance of the various departmental greenhouses and the Arlington Experimental Farm.

Another large division of the work has to do with plant diseases, \$37,000 being available for the maintenance of the general pathological laboratory and the herbarium of plant diseases, \$52,675 for fruit diseases, \$69,510 for those of forest trees and ornamentals, and \$46,000 for cotton and truck crops. For plant physiology and plant breeding there is allotted \$44,540, together with \$22,280 for the breeding and physiological study of alkali and drought resistant crops. There is also \$35,000 for soil bacteriology and plant nutrition studies, \$25,000 for biophysics, \$24,000 for economic and systematic botany, \$28,700 for studying and testing commercial seed, \$5,000 for studies of methods of utilizing logged-off lands, and \$230,380 for studies of crop production and land utilization under arid and semi-arid conditions.

The Forest Service receives as usual the largest allotment of any Bureau, its aggregate being \$5,548,256 as compared with \$5,399,679 for the previous year. There are also available the various appropriations under the Appalachian Forest Reserve Act already referred to, certain unexpended balances from the previous year, and an appropriation of \$100,000 for fighting and preventing forest fires in cases of extraordinary emergency, this being a reduction from \$200,000. The bulk of the appropriation is, of course, to be devoted to the protection and maintenance of the individual National Forests, with \$400,000 for the construction and maintenance of improvements, \$165,640 for reforestation, \$140,000 for studies of wood utilization and preservation, \$150,000 for forest fire protection, \$25,000 for range studies, \$83,728 for silvicultural and dendrological experi-

ments, and \$40,160 for miscellaneous forest studies and the dissemination of results. The selection and segregation of lands within National Forests that may be opened to entry under the homestead laws is to be continued under an appropriation of \$100,000, with an additional allotment of \$85,000 for the survey and listing of those lands chiefly valuable for agriculture.

The appropriations of the Bureau of Chemistry are increased from \$1,058,140 to \$1,077,581. The allotment for the enforcement of the Food and Drugs Act is \$634,301, with \$4,280 additional for the study and inspection of American food exports, \$50,000 for studies of the handling and marketing of poultry and eggs, \$20,000 for similar work with fish, oysters, etc., \$10,000 for biological investigations of food and drug products and their constituents, and \$52,400 for general investigations. Because of a transfer to the Bureau of Standards of the work of testing miscellaneous supplies purchased on contract for the various Departments of the Government, the appropriation for this purpose is reduced from \$40,000 to \$14,000.

The various lines of work of the Bureau of Soils and the Bureau of Entomology are continued much as at present, with small increases in a number of items. The Bureau of Soils receives \$360,635, an increase of \$26,615, of which \$11,500 is to extend the inquiry as to possible sources of natural fertilizers, particularly nitrogenous materials. The soil survey work of the Bureau is granted \$169,800, with \$20,000 additional for the examination and classification of agricultural lands in forest reserves in cooperation with the Forest Service, \$15,265 for studies in soil physics, \$22,350 for chemical investigations, and \$32,700 for soil fertility work. The increase of \$87,210 accorded the Bureau of Entomology is divided among its studies of several groups of insects, the largest single item of expenditure being as usual that for the gipsy and brown-tail moth campaign, for which \$310,000 is available. The total appropriation of the Bureau is \$829,420.

The Bureau of Biological Survey is granted \$281,290, an increase of \$110,300. This appropriation is to be used principally for administrative and police purposes, \$66,000 being allotted for the enforcement of the Lacey and McLean laws for the regulation of imports and interstate movement of game, birds, etc., \$21,000 for the maintenance of the various game preserves and transfer of game, and \$5,000 for the improvement of an additional preserve in Sullys Hill Park, North Dakota. The appropriations for studies of the food habits of birds and mammals and for other biological investigations, however, are nearly doubled, \$15,000 being granted for the destruction of ground squirrels on National Forests, \$5,000 for the study of a serious disease of wild ducks in Utah, \$95,000 for the destruction of wolves, prairie dogs, and other injurious animals,

the rearing of fur-bearing animals, and similar work, and \$26,500 for field studies of the distribution and migrations of water fowl and other birds and of the bird and mammal life of the public domain.

The Bureau of Statistics is rechristened the Bureau of Crop Estimates, the new designation representing more accurately, it is believed, the nature of its work and obviating confusion with results based on actual enumerations such as are made by the Bureau of the Census. Several changes are also made in the language prescribing the work of the Bureau, and the appropriation at its disposal is increased from \$243,680 to \$275,580. It is expected that these changes will permit of enlarging the scope and completeness of the data collected, notably as regards special crops and industries.

The various activities of the Office of Experiment Stations are continued and several of its functions are considerably extended. The total appropriation is \$1,930,780, of which \$1,440,000 is paid to the state experiment stations under the Hatch and Adams acts, and \$50,500 (a net increase of \$10,720) is for general expenses in connection with the enforcement of these acts and the Smith-Lever Act. The work of the Agricultural Education Service and of the Irrigation and Drainage Investigations is continued on the present basis with allotments of \$23,000, \$106,400, and \$96,280 respectively, and \$68,840 is granted for statutory salaries.

The total allotment for the insular experiment stations is \$120,000, of which the Alaska stations receive \$40,000 and those in Hawaii, Porto Rico, and Guam, \$35,000, \$30,000, and \$15,000, respectively. The act provides that of the allotment for the Hawaii Station \$5,000 may be used in agricultural extension work, the Territory receiving no funds under the Smith-Lever Act. The annual leave privileges of employees of the Department permanently assigned to Alaska, Hawaii, Porto Rico, and Guam are extended to correspond to those now applying to employees in Washington.

The appropriation for the Nutrition Investigations of the Office is increased from \$16,000 to \$25,760 and the authority hitherto granted to study means of utilizing agricultural products for food is broadened to include clothing and household equipment. With the enlarged appropriation it is proposed to continue and extend the studies of food with reference to nutritive value and economical use in the home, studying both popular and technical problems, the latter including, among other things, the calorimetric study of changes which take place in fruits and vegetables during ripening and storage. In the case of clothing and household equipment, such questions, considered from the standpoint of the expenditure of human energy, will be studied as the relative durability, economy,

and efficiency of comparable materials and articles for specific purposes, the protective power of clothing of different kinds, the relative value and efficiency of different materials and methods with reference to household labor, the relation of the diet to body efficiency, and similar questions. It is believed that the results of such investigations will be of much interest not only to the housekeeper but also to the general public since they will furnish definite information along lines hitherto very inadequately studied but of great importance in the consideration of questions of rational and economical living. They should also be of direct benefit to the farmer since agricultural production is influenced to a very great extent by the demands of the home.

The salary of the director of the Office of Public Roads is increased from \$4,000 to \$4,500, and the appropriations as a whole from \$279,400 to \$352,560. The principal increase is one of \$40,000 for studies of road building and maintenance, making \$145,000 available for the purpose, special emphasis to be directed to the ordinary sand-clay and dirt roads. Increases of \$4,800 are also granted for road management studies, \$6,260 for tests of road materials, and \$15,000 for field trials of various materials, types of construction, and road equipment.

The work of the remaining branches of the Department is continued substantially as at present. The increasing administrative work is evidenced in the enlarged allotments for the Office of the Secretary, rent, and miscellaneous expenses for which \$339,880, \$108,329, and \$110,000 respectively are available. As a result of recent legislation whereby the administrative auditing of accounts is now carried on in the several Bureaus, the appropriation for the Division of Accounts and Disbursements is reduced from \$104,370 to \$46,320. The Division of Publications receives \$189,500 and the Library \$45,360.

In connection with the appropriations included in the Act itself, reference should also be made to the funds derived in other ways. For the fiscal year under discussion, permanent appropriations under the Department aggregate, exclusive of those recently provided by the Smith-Lever Act, \$5,999,200, the largest items being those of \$3,000,000 for meat inspection and \$2,000,000 for the acquisition of lands for the protection of watersheds of navigable streams, and the remainder being almost wholly for forestry purposes. The appropriation act for sundry civil expenses carries an appropriation for the Department printing and binding of \$500,000, an increase of \$10,000, of which \$137,500 is for Farmers' Bulletins and \$47,000 for the Weather Bureau.

When it is recalled that large appropriations will also be available for agricultural education in the land-grant colleges under the Mor-

rill and Nelson acts, for the rural education work of the Bureau of Education, demonstration work in agriculture among the Indians, and the payment of the country's quota toward the support of the International Institute of Agriculture, the wide extent to which the principle of federal assistance to agriculture is being carried into practice becomes apparent, and the aggregate expenditure from the Federal funds appears increasingly impressive. As was pointed out by Chairman Lever of the House Committee on Agriculture, however, the entire agricultural appropriation is still inconsequential as compared with the total federal appropriations, the magnitude of the agricultural interests of the country, or even of the annual losses to farm products sustained through insect pests and plant diseases.

Moreover, the conviction is deepening that these appropriations are largely in the nature of a permanent investment for the benefit of the nation as a whole. In the words of Hon. C. G. Edwards of Georgia, "in extending these various benefits and advantages to the farmers we are but doing a simple justice to the sinew and backbone of our great citizenship. In helping the farmers we are helping the whole country, for every class is dependent upon the farmer. . . . We can do nothing that will make for the future welfare of our country more than to aid in this work, which means the establishing of farms and homes. . . . In making appropriations to improve agricultural conditions we are 'casting bread upon the waters,' that will return not only to feed the people of this country, but will mean a tremendous increase in our annual farm productions, and will add to the country's wealth, prosperity, happiness, and greatness."

RECENT WORK IN AGRICULTURAL SCIENCE.

AGRICULTURAL CHEMISTRY—AGROTECHNY.

Simple plant bases and their relation to the synthesis of proteins and lecithins, G. TRIER (*Über einfache Pflanzenbasen und ihre Beziehungen zum Aufbau der Eiweissstoffe und Lecithine. Berlin, 1912, pp. IV+117*).—This practically constitutes a review of the investigations of E. Schulze and his co-workers (abstracted from time to time) and the work of others in this field. Support is given to the Stoklasa theory that the formation of the simplest amino acids of proteins is inseparable from the formation of the components (bausteine) which go to make up the lecithins. The alcohols of the lecithins and the amino acids of the proteins are both deemed a result of Cannizzaro's aldehyde reaction.

The contents of the book include data on the development of alkaloid chemistry; alkaloids and their "bausteine;" the relation between cholin and betain; a new conception of the formation of cholin and betain as well as the simplest components (bausteine) of proteins and lecithins; formation of carbohydrates; Cannizzaro's reaction; the introduction of nitrogen in complexes predestined to become proteins and lecithins; nitrates and ammonium salts; function of phosphoric acid; the synthesis of lecithins; the methylating agent; the position of methyl alcohol and methyl compounds; transformations of glycerol aldehyde; the amino acids—serin derivatives; the formation of methylamin—the formamid hypothesis; the compounds of the C₄-series—asparagin; the compounds of the C₅- and C₆-series—glutamin, pentoses; urea and urea derivatives; cleavage of arginin; the rôle of hydrocyanic acid—Treib's hypothesis; unknown components (bausteine) of proteins; formation of trigonellin; significance of betain; intermediary formation of betain; components (bausteine) of plant and animal phosphatids; the author's studies in regard to the method of preparing lecithins from plant seeds; an explanation of the parallelism between protein and lecithin formation; biological functions of lecithins, etc.

In regard to our knowledge of phytin, M. A. JEGOROW (*Zhur. Opytn. Agron. (Russ. Jour. Expt. Landw.), 14 (1913), No. 4, pp. 229-237*).—The product yielded by Contardi's method for synthesizing phytin always contains inorganic phosphoric acid, and in the most favorable cases only one-half of the original phosphoric acid is present in the organic form when determined by the Schulze-Castoro method. In the experiments it was also shown that the inorganic phosphoric acid, which in the synthetic product exists as free acid, can be easily and completely extracted at room temperature with ether. The only organic phosphoric acid compound obtainable is one containing 22.6 per cent of organically bound phosphorus (P₂O₅ 51.76 per cent).

Investigation of the mannit occurring in asparagus juice, E. BUSOLT (*Jour. Landw., 60 (1912), No. 4, pp. 393-396*).—It has been previously pointed out by Tollens and Wichers (*E. S. R., 27, p. 502*) that asparagus juice does not seem

to contain mannit until after the juice is allowed to stand for a time, when mannit is produced through the agency of organisms or enzymes. In all probability mannit originates in the same manner in string beans.

The findings of Wichers and Tollens were verified by this work, and from the mannit the tri-acetal compound was prepared.

A contribution to our knowledge of the carbohydrates present in vegetables.—II, In regard to the carbohydrates present in the juice of green string beans.—III, The carbohydrates present in cauliflower, E. BUSOLT (*Jour. Landw.*, 61 (1913), No. 2, pp. 153-160).—From 10 kg. of green string beans 5,500 cc. of juice was obtained; 3,000 cc. of this juice was kept in a beaker without extra precautions for 8 days, then brought to the boiling point and concentrated to a sirupy consistency. Within 3 months' time a solid mass of crystals was obtained which was identified as mannit, and from the mannit a tri-acet-acetal compound was prepared. This finding is similar to that noted above, and elsewhere. Inositol (Vohl^a) was not noted. Juice boiled directly after collection and evaporated 8 days later to a sirup did not yield any crystals.

The work with cauliflower was practically a continuation of that reported by Dmochowski and Tollens (*E. S. R.*, 23, p. 415) but with special reference to the presence of glucose in the juice. Under no circumstances could glucose be noted but mannit crystals were obtained instead. The hexanitratates and tri-benz-acetal compounds were prepared from the mannit.

The organic nitrogen of Hawaiian soils, W. P. KELLEY and ALICE R. THOMPSON (*Hawaii Sta. Bul.* 33 (1914), pp. 22).—Studies are reported on the chemical nature of the organic nitrogen present in soils, using the acid method of hydrolysis and the following soils belonging to the laterite class common to the Hawaiian Islands: A silty loam taken from old pasture land containing considerable amounts of organic matter and where semiarid conditions prevail; a highly organic sandy soil from land recently cleared of a tropical jungle, and from a district where rainfall is heavy and drainage good; a silty loam used for pineapple culture, but formerly for pasture land, and in a semiarid district; a loam soil containing much gravel and from lands used previously for rice experiments, and which has served for aquatic agriculture for many years; two soils devoted to rice culture for 30 to 40 years, silty in character, and taken from the windward side of the Kanehoe district; a highly humus soil continuously used in rice culture for 30 or more years; and two silty soils devoted to aquatic agriculture, one to rice and the other to taro. So far as known, no nitrogenous fertilizers have been applied to these soils.

The amount of total nitrogen present in the soil, calculated to a dry basis, varied from 0.122 to 1.241 per cent (average 0.463 per cent). The nitrate nitrogen ranged from 0.05 to 1.751 per cent, and the ammoniacal nitrogen from 0.169 to 2.564 per cent of the total nitrogen, showing that these two forms constitute but a small proportion, the greater part being probably in organic form.

Soils representing unaerated conditions, with two exceptions, contained next to no nitrate. "The nitrate found in the remaining unaerated soils was formed almost entirely during the time of drying out in the laboratory."

"Upon boiling different soils with strong hydrochloric acid, the amounts of nitrogen dissolved ranged from 67.51 per cent to 91.88 per cent of the total nitrogen. With two exceptions, the relative percentages of amid nitrogen, split off in the hydrolysis, were approximately the same, amounting on the average to 23.91 per cent of the nitrogen dissolved. Basic nitrogen occurred

^aAnn. Chem. u. Pharm., 99 (1856), No. 1, pp. 125-128; 101 (1857), No. 1, pp. 50-58.

in the solutions in variable amounts, the average being 9.98 per cent of the soluble nitrogen. The percentages of nonbasic nitrogen, determined by difference, proved to be quite concordant in most of the soils, amounting on the average to 64.57 per cent of the soluble nitrogen."

The amids constitute a much higher percentage of the nitrogen of soils than are said to occur in vegetable proteins. On the other hand, the percentage of basic nitrogen was far less than exists in the majority of vegetable proteins.

The aquatic (anaerobic) soils showed a higher percentage of total nitrogen soluble in hydrochloric acid. On an average 70.69 per cent of total nitrogen was obtained from the aerated soils and 87.93 per cent from unaerated soils. This indicates that a putrefactive process predominates in submerged soils, as previously indicated (E. S. R., 30, p. 420), which leaves the nitrogenous substances more easily soluble in hydrochloric acid. "The amount of nitrogen soluble in 1 per cent hydrochloric acid was about twice as large as that of ammonia originally occurring in the soils. The solubility in 3 per cent sodium hydrate varied from 49.56 per cent to 76.62 per cent of the total nitrogen. Of the nitrogen thus dissolved, 57.85 per cent was precipitated by dilute hydrochloric acid, of which 11.93 per cent (expressed in percentage of the humus nitrogen) remained insoluble after boiling in strong hydrochloric acid for 10 hours. Amids comprised 28.77 per cent of the humus nitrogen, of which about one-half existed as amid in the original humus solutions, and which remained in solution upon acidifying with hydrochloric acid. The remaining half was split off when the humus, precipitated by hydrochloric acid, was subjected to acid hydrolysis. The basic nitrogen ranged from 4.39 per cent to 44.83 per cent of the humus nitrogen, increasing as the total nitrogen of the humus decreased. Nonbasic nitrogen was found to constitute 53.38 per cent of the humus nitrogen, of which 25.05 per cent existed as such in the original humus solutions.

"The amounts of amid and basic nitrogen in humus expressed as percentages of the humus nitrogen were found to be higher than the amounts obtained by subjecting the original soil to hydrolysis. In view of the large amounts of amid occurring in humus solutions, it was found better to use sodium hydrate as the solvent for extracting humus that is to be used for total humus nitrogen determinations. The humus of Hawaiian soils contains a small percentage of nitrogen (5.88 per cent as an average of 22 samples), in which respect the humus of these soils closely resembles that found in humid soils in the States."

See also previous notes by others (E. S. R., 25, pp. 622, 623; 26, pp. 320, 615, 616; 28, p. 813).

Some organic constituents of the culture solution and the mycelium of molds from soil, M. X. SULLIVAN (*Abs. in Science, n. ser., 38 (1913), No. 984, p. 678*).—An examination was made of the dried mycelium of mixed mold cultures from soil and of *Penicillium glaucum* grown on Raulin's solution and of the filtered solution after mold growth for organic constituents.

"In the mixed molds was found a large number of organic substances, many of which were subsequently found in *P. glaucum*. In the alcoholic soda extract of *P. glaucum* were found oleic and palmitic acids, a fatty acid melting at 54° C., a fatty acid which appears to be elaidic acid, hypoxanthin, guanin and adenin, histidin, thymin, and chlorin. In the direct alcohol extract was found mannit, cholesterol bodies, hypoxanthin, and cerebrosids. From mold grown on Raulin's solution plus peptone a small amount of guanidin was found. In the culture solution after a number of weeks' growth were found fatty acids, purin bases, a small quantity of a histidin-like body, pentose sugar, unidentified aldehydes, etc. Many of these compounds have been found in soil

and the conclusion is drawn that micro-organisms, such as yeasts, bacteria, and molds, play an important part in their formation.”

Polyatomic alcohols as sources of carbon for lower fungi, R. E. NEIDIG (*Jour. Biol. Chem.*, 16 (1913), No. 1, pp. 143-145; *abs. in Science*, n. ser., 38 (1913), No. 984, p. 675).—The alcohols used as regards their utilization by 4 genera and 8 species of molds were methyl alcohol, glycol, glycerol, erythrite, adonite, mannit, dulcete, and sorbite. The molds were cultivated in media containing these alcohols.

“It was found that methyl alcohol produced no growth, glycol induced germination only, glycerol produced strong cultures, erythrite could be used by the majority of molds and adonite by only a few, while all three of the hexatomic alcohols may be regarded as good sources of carbon. These results indicate that molds are able to use both optically active and inactive compounds as sources of carbon. If viewed from the standpoint of their oxidation products it is possible that active compounds are first formed and these are then utilized in the development of the molds.”

Influence of certain organic substances upon the secretion of diastase by various fungi, CHRISTINE CHAPMAN and W. C. ETHERIDGE (*Abs. in Science*, n. ser., 38 (1913), No. 984, p. 675).—The influence of varying concentrations of cane sugar, glucose, peptone, and tannic acid upon the secretion of diastase by *Aspergillus niger*, *A. oryzae*, *Penicillium expansum*, *P. camemberti*, *Mucor rouxii*, and *Cephalothecium roseum* was investigated. Czapek's solution was employed with the sugar replaced by 0.4 per cent soluble starch.

In general it was found that the presence of any of these organic substances retarded the action of diastase by the fungi, and the higher the concentration the greater the retardation.

Effect of acids upon the catalase of taka-diastrase, R. E. NEIDIG (*Abs. in Science*, n. ser., 38 (1913), No. 984, p. 675).—Data are given showing the inhibitory effects of several of the important inorganic and organic acids toward the catalase of taka-diastrase.

“Curves were platted for different acid concentrations which show the quantity of oxygen liberated at stated intervals. The acids, arranged in order of the magnitude of their inhibiting effect for equi-normal solutions, are as follows: Sulphuric, hydrochloric, oxalic, tartaric, citric, and acetic. The inhibiting effect of the first three was much more pronounced than that of the others. Neutralization of the acid solution usually restored some of the activity, the amount of increase depending upon the particular acid used. Van Slyke's amino-nitrogen apparatus was used in these experiments for measuring the amount of oxygen liberated.”

About the presence of stachyose in beans and other legumes, G. TANRET (*Bul. Soc. Chim. France*, 4. ser., 13 (1913), No. 4, pp. 176-182; *abs. in Chem. Ztg.*, 37 (1913), No. 33, p. 334).—Stachyose, when boiled with strontium oxid, forms an insoluble compound from which sugar can easily be obtained. This reaction was tried with various legumes and in all cases, with the exception of peas, crystallized stachyose could be obtained, although it was always mixed or combined with crystallized saccharose. According to this stachyose forms a portion of the coloring material in foodstuffs.

The juice of *Ficus coronata*, an incomplete vegetable pancreatic juice without amylase but with a predominating proteolytic enzym.—A comparison with *F. carica*, C. GERBER (*Compt. Rend. Acad. Sci. [Paris]*, 156 (1913), No. 25, pp. 1917-1919).—The latex of *F. coronata* is conspicuous for its absence of caoutchouc. When it leaves the tree it is without color and on standing it rapidly turns reddish brown but remains transparent. It contains an amylase and in this respect it resembles *Morus alba*. The lipolytic power of the latex

is twice as strong as that of *F. carica*. It is much more thermostable than the enzym of the latter. The proteolytic enzym (?), measured according to its coagulating power on milk, is four times as strong as that present in *F. carica* and also more thermostable. It coagulates at all temperatures and coagulates boiled milk much better than raw milk. The enzym causing the caseation is very sensitive toward boric acid and the chlorids of cadmium and copper

The decomposition of amygdalin and vicianin by enzym action, A. COMPTON (*Chem. News*, 106 (1912), No. 2758, pp. 163-165; *abs. in Chem. Ztg.*, 37 (1913), No. 28, p. 281).—If the biose in the amygdalin molecule is called amygdalose, the decomposition of amygdalin proceeds as follows:

Vicianin is also converted into hydrocyanic acid, benzaldehyde, and the biose vicianose if the glucosid is treated with an extract of *Vicia augustifolia*. If, however, almond emulsin is used, the simple sugars arabinose and glucose result:

As marked differences are shown in the above, the question is asked why the decomposition does not proceed according to the following scheme:

If it were possible to prepare an amygdalase free from amygdalinase, it is believed some new light would be thrown upon the above processes. In all probability the reactions occurring with the complex enzymes are dependent upon the amount of amygdalase and amygdalinase present in the mixture. If amygdalinase is present in the larger quantity, the reaction proceeds according to formula (C), but if amygdalase is in excess, the reaction according to formula (A) probably takes place.

The decomposition of cellulose by micro-organisms, A. KRAINSKY (*Zhur. Opytn. Agron. (Russ. Jour. Expt. Landw.)*, 14 (1913), No. 4, pp. 255-261, figs. 7).—For noting the cellulose-decomposing capacity of organisms a square or round piece of filter paper was used in Erlenmeyer flasks containing a mineral nutrient solution. The filter paper was so placed that a portion of it dipped into the nutrient medium and also touched the wall of the flask. The surface of the filter paper in these experiments was infected with an infusion of the soil obtained from a botanical garden, and the flasks with their contents were incubated at 30° C. At this temperature the filter paper became covered with fungi and the black and reddish cultures were particularly capable of producing pockets in the filter paper.

Two especially good cellulose-decomposing Actinomyces species were isolated in pure cultures. One of the cultures (*Actinomyces melanocyclus*) capable of producing black rings was found to be identical with *Micrococcus melanocyclus*, which has been described by Maerker, and produces red colonies on paper which soon become covered with black aerial spores. On glucose-agar

round colonies are formed which also will form black spores. The second culture, *A. albo-roseus*, on filter paper forms white, chalklike flakes, but later red pigment is produced which colors both the filter paper and the nutrient solution. On ammonium sulphate dextrose agar and on bouillon dextrose agar white aerial spores are produced, but on bouillon agar no aerial spores are obtained. The aerial spores of *A. melanocyclus* resemble cocci while those of *A. albo-roseus* are oval or bacilli-like. Although both of the organisms decompose cellulose, *A. melanocyclus* is stronger in this respect. Reducing sugars were not found in the culture medium.

A new and simple titrimetric method for determining thiosulphate in the presence of sulphites, J. BODNÁR (*Kísérlet. Közlem.*, 16 (1913), No. 4, pp. 554-561).—The method, which is used for lime-sulphur wash, depends upon the fact that silver thiosulphate will become decomposed by the interaction of water and sulphuric acid results. By simply titrating the sulphur content, the amount of thiosulphate taking part in the reaction can be estimated. The method can also be used for determining the titer of a sodium thiosulphate solution even though large amounts of sulphites are present.

By the iodometric method sulphites can be estimated when thiosulphates are present, providing the amount of thiosulphate is known. This can easily be determined by the author's method. The method has the advantage over Gutmann's method in so far that the presence of chlorids does not interfere with the results.

The detection and approximate determination of traces of thiosulphate in sulphites, J. BODNÁR (*Kísérlet. Közlem.*, 16 (1913), No. 4, pp. 562-566).—If silver nitrate is added to a sulphite solution (sodium sulphite), silver sulphite is deposited, which when exposed to the air will retain its color for a long time. Silver thiosulphate, on the other hand, loses its whiteness rapidly and turns lemon yellow, orange yellow, dark brown, and finally black. Consequently if silver nitrate is added to a sulphite solution which contains thiosulphate, a white precipitate is not obtained, but according to the amount of thiosulphate present a light yellow up to a black precipitate results.

The above reaction will detect as little as 0.3 cc. of fiftieth-normal sodium thiosulphate in 5 cc. of a 10 per cent sodium sulphite solution, corresponding to 0.09 per cent of sodium thiosulphate. As the intensity of the color is proportional to the amount of thiosulphate present, the method may serve as an approximate one for estimating the amount of thiosulphate in sodium sulphite.

The reactions of Reynold, Koninck, Musset, Arnold, and Gutmann were found less sensitive than the one proposed above.

Estimating the fineness and the chemical examination of flowers of sulphur and ground sulphur used for combating plant diseases, T. S. HOFMAN (*Verslag. Landbouwk. Onderzoek. Rijkslandbouwproefstat. [Netherlands], No. 14 (1913), pp. 1-8*).—In Holland sulphur is used chiefly for dusting vines and rose plants for combating mildew diseases. The fineness of sulphur determines to quite an extent its adhesive power, and for estimating the fineness a modification of Chancel's method is employed. According to the original method 5 gm. of sulphur is shaken with ether in a calibrated tube termed a "sulphurimeter," which is described in detail. The finer the sample of sulphur, the greater is the space which it occupies.

In order to reduce the error in these experimental tests 40 instead of 5 gm. of sulphur was taken, and instead of ether alcohol was used. The results obtained by Chancel's method and the modified method are reported.

For judging sulphur the following should be noted: (1) the color and the appearance; (2) the texture as noted by the tips of the fingers; (3) the appearance under the microscope; (4) the solubility in carbon bisulphid; (5) its

reaction; and (6) the content of arsenic, ash, moisture, and impurities or adulterations.

The estimation of small quantities of manganese and chromium in minerals and rocks, M. DITTRICH (*Ztschr. Anorgan. Chem.*, 80 (1913), No. 2, pp. 171-173; *abs. in Jour. Chem. Soc. [London]*, 104 (1913), No. 606, II, pp. 344, 345).—It is pointed out that the colorimetric method for manganese is often difficult to use because of the presence of chromium which changes the color of the solution. If, however, ammonia is added to the mixed solution of permanganate and chromate and the solution is warmed, all of the manganese and iron are precipitated in the hydroxid form. The washed precipitate can then be dissolved and oxidized and the manganese estimated with ammonium persulphate in the usual manner. The chromium can be determined colorimetrically by comparing it with a standard solution of potassium chromate after the removal of silver by sodium chlorid and concentrating. The method is not entirely accurate.

Drying in an electrically heated vacuum desiccator for determining the hygroscopicity of soils, R. HORNBERGER (*Landw. Vers. Stat.*, 82 (1913), No. 3-4, pp. 303-307).—Certain defects are present in the Mitscherlich desiccating apparatus. In this article the author relates his experiences with the apparatus and suggests various contrivances for overcoming the difficulties.

The determination of phosphoric acid in the soil, R. HORNBERGER (*Landw. Vers. Stat.*, 82 (1913), No. 3-4, pp. 299-302).—During the course of analyses of the hydrochloric extract of forest soils (red sandstone) a small part of the phosphomolybdate precipitate did not dissolve in ammonium hydroxid despite the fact that thorough washing was done. This material remained on the filter as a small white residue. The ammoniacal solution of the phosphomolybdate was not clear after filtration and after a few days clarification set in with a deposit of some whitish flakes. The deposit was found to consist of titanium. Tests were then made with artificial mixtures to determine how this disturbing factor could be removed. It is shown that when molybdic acid solution and ammonium nitrate are added to a nitric acid solution of the phosphate, some titanium is precipitated which remains insoluble when the phosphomolybdate is treated with ammonium hydroxid. A portion of this, which is present in a fine state, passes through the filter into the filtrate.

The titanium in the filtrate can be removed after allowing the solution to stand for a time but it is advisable to add to the wash water some ammonium chlorid in order to prevent the titanium from passing through the filter. The total elimination of titanium was not possible, but the least contamination of the ammonium phosphomolybdate precipitate takes place when the molybdate solution is in excess and no hydrochloric acid is present; under these conditions the percentage of phosphorus in the titanium precipitate is also the smallest. Both of these errors can be prevented if the titanium residue from the filtrate is fused with soda and the melt is extracted with water. The phosphorus goes into solution, the titanium remains behind, and after driving out the carbon dioxid the phosphoric acid can be determined in the usual manner.

Citrate-soluble phosphoric acid in some crude phosphates, M. A. STARODUBOWA and I. V. JAKUSCHKIN (*Izr. Moskov. Selsk. Khoz. Inst. (Ann. Inst. Agron. Moscou)*, 19 (1913), No. 2, pp. 377-395).—This investigation shows that crude phosphates of all kinds can be decomposed with acetic acid. It was furthermore noted that Wagner's reagent also attacks the most internal nucleus of all raw phosphates and consequently is of no value for judging adulterations in Thomas slag powders. Petermann's reagent can not be used, especially at low temperatures, for decomposing crude phosphates which are

unavailable for the Gramineæ, but when applied to phosphates which are capable of furnishing their phosphoric acid to the Gramineæ the reagent extracts a considerable amount of phosphoric acid.

Ordinary phosphorites show only traces of phosphoric acid with this method, and the phosphorites from Singilei yield about 4 per cent of citrate-soluble phosphoric acid, which is about one-fourth of all the phosphoric acid present in this fertilizer. Iron and aluminum phosphates are easily soluble in Petermann's reagent while calcium phosphate is almost insoluble.

The alundum crucible for the determination of phosphoric acid, G. LIBERI (*Ann. R. Staz. Chim. Agr. Sper. Roma*, 2. ser., 6 (1913), No. 2, pp. 247-255).—It is concluded that the alundum crucible will be of service for the determination of phosphoric anhydrid as magnesium pyrophosphate. It is necessary, however, to remove the impurities which are present in the crucible by washing with hydrochloric acid in order to obtain a comparatively constant weight.

In regard to fertilizer analysis, E. A. MITSCHERLICH and W. SIMMERMACHER (*Zentbl. Kunstdünger Indus.*, 18 (1913), No. 20, pp. 430, 431).—In a previous communication one of the authors has pointed out that the methods for judging a fertilizer and a soil should be founded on the same principles. This is especially true because a fertilizer is only assimilable when it becomes a part of the soil. As fertilizers when in the soil undergo a certain amount of change, analyses lose some of their significance. The results obtained with fertilizers in sand cultures, however, give figures which are of physiological and commercial value.

The purpose of this work is to bring together or connect the figures obtained for the solubility of fertilizers and those obtained in vegetative experiments as a result of using fertilizer. The logarithmic formula of the law of minimum is theoretically discussed and its validity is demonstrated from a practical standpoint. The principles for a new method of chemical fertilizer analysis, which depends upon the determination of the nutrient materials in the fertilizer and the estimation of the saturation concentration of the nutrients in water saturated with carbon dioxide at 15° C. are explained. The relation between the plant physiological and chemical fertilizer analysis is shown.

The determination of cellulose with nitric acid, V. RAO and B. TOLLENS (In *Festschrift zum siebenzigsten Geburtstage von Jacob Esser. Berlin, 1913*, pp. 49-56).—The methods compared in this study were the Cross and Bevan, Dmochowski and Tollens (*E. S. R.*, 23, p. 417), and J. König and the materials used were pure cellulose in the form of absorbent cotton, Swedish filter paper, common filter paper treated by Henneberg's method with 1.25 per cent sulphuric acid and 1.25 per cent potassium hydroxid, sulphate cellulose, sodium hydrate cellulose, crude wood fiber, jute, cacao shells, rice straw, wheat straw, rye flour, oat flour, ground American white corn, buckwheat, cotton-seed meal, marrow from *Aralia papyrifera* (which is used in China and Japan for making paper), and cacao beans. With the cacao beans it was first necessary to remove the fat when either the Cross and Bevan or the Dmochowski and Tollens method was used.

The Cross and Bevan method uniformly gave the highest results with all materials except the marrow of *A. papyrifera*, and these were not always similar to those obtained by multiplying the results obtained by the Dmochowski and Tollens method by 1.1. In some cases the factor was less than 1.1 and in others more. For jute and cereal straws it ranged from 1.16 to 1.38. Nitric acid in some cases attacks the cellulose more than chlorin, which is used in the Cross and Bevan method, but its employment is preferable since chlorin affects the health of the laboratory workers. It is first necessary, however, to establish the correct conversion factors.

Estimation of sugar in food products (honeys, comfits, jellies, marmalades, sirups, etc.), C. F. MUTTELET (*Ann. Falsif.*, 6 (1913), No. 53, pp. 138-143).—Constants for the following sugars were used in this work: Saccharose $[a]_D^{20} + 66.5$, glucose $+53$, levulose -93.5 , and invert sugar -20.25 .

The product under examination is made into a solution (A) which contains from 5 to 10 gm. of saccharin matter free from other reducing substances in 100 cc. Ten cc. of this is made up to 100 cc. (solution B) and used for the determination of the copper-reducing power, and the result for 100 cc. of solution A is expressed as p grams. The reduction after inversion is also determined and this for 100 cc. of solution A is expressed as q .

The rotation of the solution A is taken at 20° C. in a 200-mm. tube and the rotation designated as D . The amount of saccharose (S) present $= 0.95 (q-p)$ gm., which corresponds to a deviation of c , c being equal to $1.33 \times S$. The sum of the weight of the glucose (G) and levulose (L) $= G + L = p$, which corresponds to a rotation of $d = D - c$. The results obtained are multiplied by 10 if 10 gm. of substance is used to make the solution A. All of the above rotations are in circular degrees.

Detection of technical invert sugar with β -naphthol, F. M. LITERSCHIED (*Chem. Ztg.*, 37 (1913), No. 32, p. 321).—This reaction, like Fiehe's, depends upon the formation of a coloring matter. It is conducted as follows:

From 10 to 20 gm. of the honey, or other substance supposed to contain invert sugar, is rubbed up three or four times with 10 cc. of ether and the ethereal extracts filtered into a shallow porcelain dish. A small crystal of β -naphthol is dissolved in the ethereal filtrate and the dish set aside to allow a spontaneous evaporation of the ether. To the residue which remains is added from 4 to 5 cc. of an 88 to 90 per cent solution of pure sulphuric acid and observation made at intervals of the color changes which take place in the dish during a period of one-half hour. Honeys containing no technical invert sugar give a dirty yellow coloration which within one-half hour is yellowish green with a reddish hue. In a positive reaction the color is a Bordeaux to a violet red, its intensity depending upon the amount of invert sugar present.

In many cases the reaction can also be obtained by simply rubbing up the honey twice with ether containing one or two crystals of β -naphthol, decanting off the supernatant fluid into a porcelain dish, allowing it to evaporate, and adding sulphuric acid as described above.

This work will be reported upon later in more detail.

About honey examination, G. BUCHNER (*Ztschr. Öffentl. Chem.*, 19 (1913), No. 7, pp. 132, 133).—A so-called flower honey (Blütenhonig) apparently containing no glucose gave the Lund and Ley reaction, making it appear as though invert sugar was present, but was found on microscopical examination to contain crystals of calcium oxalate.

Determination of sugar in bagasse, H. PELLET (*Bul. Assoc. Chim. Sucr. et Distill.*, 30 (1913), No. 6, pp. 305-312; *abs. in Chem. Ztg.*, 37 (1913), No. 14, *Repert.*, p. 66).—The samples taken hourly are mixed together and minced in a mechanically driven chopping machine. The comminuted material is then extracted with hot water in a Zamaron-Norris apparatus which was modified by the author in order to allow it to be hermetically sealed. Sugar cane can also be extracted with the apparatus. The water in the bagasse may be determined by drying 50 gm. at 110° C. in an electric oven.

Hot and cold digestion in beet analysis, H. PELLET (*Bul. Assoc. Chim. Sucr. et Distill.*, 30 (1913), No. 6, pp. 328-334; *abs. in Chem. Ztg.*, 37 (1913), No. 14, *Repert.*, p. 66).—In view of Chappelle's statements (*E. S. R.*, 28, p. 413), some further tests were made with the hot and cold digestion methods. The results for sugar in both instances were alike.

Further notes on the relationship between the weight of the sugar beet and the composition of its juice, J. A. HARRIS and R. A. GORTNER (*Biochem. Bul.*, 2 (1913), No. 8, pp. 524-529, pl. 1).—A critical analysis of Novotný's results and those of Andrlík et al. (*E. S. R.*, 27, p. 642; 30, p. 536).

The authors conclude that the notes presented by Andrlík, Bartoš, and Urban "form a very slender basis for the conclusion (widely circulated by uncritical reviewers) that in beets of the same strain there is no negative correlation between weight and sugar content. Nevertheless one must recognize the possibility of the correctness of the conclusion. Should it prove to be valid, the suggestion follows that the negative correlation demonstrated in commercial cultures has a genetic origin, i. e., that strains characterized by large root size are also characterized by low sugar content, and that when these strains are intermingled and intercrossed in field cultures there results a negative correlation between the weight of the individual beet and the sugar content of its juice. Such a result would be of the greatest interest to breeders."

Report of the department of chemistry, C. A. JACOBSON and M. ADAMS (*Nevada Sta. Rpt. 1913*, pp. 47-50).—This details the work in progress and completed (*E. S. R.*, 25, p. 810; 26, p. 802; 27, p. 713; 28, pp. 608, 710; 29, p. 111).

In some experiments on wood distillation the products resulting from 4 woods were studied. "From a sample of 'fat' yellow pine a clear water-white sample of light oil, boiling at between 158 and 178°, and possessing many of the properties of the spirits of turpentine, has been obtained. This oil is now being examined to determine its chemical identity. Calculated from the results so far obtained, one cord of 'fat' yellow pine should yield 26 gal. of this turpentine-like oil. Besides this light oil, there have been obtained from the same wood, acetic acid, methyl alcohol, creosote, wood tar, and charcoal of commercial value. A sample of green yellow pine was also distilled and a sample of the above-mentioned light oil was obtained, but the yield was small, amounting to only about 5 gal. per cord. Samples of sagebrush and *Pinus monophylla* have also been distilled, but the assay of the distillate has not yet been completed."

METEOROLOGY—WATER.

Weather science, R. G. K. LEMPFERT (*London, Edinburgh, and New York*, [1912], pp. 94, figs. 16).—This brief treatise describes and discusses the observations of an individual station and the processes underlying weather changes, and shows how the observations at different places are combined in the study of the weather and in forecasting.

Weather forecasting, R. M. DEELEY (*Nature* [London], 93 (1914), No. 2316, pp. 58, 59).—A plea is made for better daily weather charts as a means of utilizing the great mass of data now "practically buried so far as the individual meteorologist is concerned."

The agricultural meteorological service in Germany, R. BÖRNSTEIN (*Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases*, 4 (1913), No. 11, pp. 1667-1672).—A brief description of this service is given. It is stated that the whole country is divided into meteorological service districts, each with its station and in some cases with substations. The most important duty of the service is the timely and prompt distribution of daily weather charts.

"In order to keep the whole meteorological service in close touch with practical agriculture, in most districts reliable collaborators (*Vertrauensmänner*) have been appointed. These are practical farmers, teachers of agriculture, and the like, at least one in each district, who constantly devote their atten-

tion to the meteorological service; they express their opinion on the weather forecast and follow all the details of the work. Their criticism of the forecast is expressed in figures and sent every week on post cards to the heads of the service. The value of these 'percentages of hits' is not very great, [and they] are not published; nevertheless, they often give the directors of the service useful hints and have thus, in spite of many objections, been kept up. Further, the Vertrauensmänner transmit to the directors many of the wishes and proposals arising from the daily practice of farming, and in this manner many valuable improvements have been made in the meteorological service."

The need of educating farmers to a better understanding and use of the weather charts is emphasized. "Lectures and discussions in meetings of associations, especially agricultural and educational, as well as special courses for teachers and the inclusion of meteorology in the curriculum of seminaries and universities, provide both for making grown-up people acquainted with the principles of meteorology and for introducing this branch of science into the schools."

Present organization of agricultural meteorology in Sweden, H. E. HAMBURG (*Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases, 5 (1914), No. 1, pp. 6-8*).—The meteorological service of Sweden is centralized in the State Meteorological Institute at Stockholm. There is no special service for agricultural meteorology, but an effort is made to collect data and to issue storm warnings and forecasts and publications of interest to agriculture. The *Swedish Monthly Meteorological Bulletin in the Interests of Agriculture* has been issued for over 30 years. "Each number contains a chart showing the quantity of rainfall, and a certain number of tables on the temperatures of the air and the soil, and the winds, besides communications from observers, etc." Special provision is made for observations in the interest of agriculture on storms, frosts, and ice, as well as for phenological observations.

A short list of references to articles bearing on the subject is given.

About climatical variations, H. ARCTOWSKI (*Amer. Jour. Sci., 4. ser., 37 (1914), No. 220, pp. 305-315, figs. 3*).—Various causes which produce climatic changes are discussed, the more important conclusions reached being "that more or less periodical changes of the solar constant must be the real primary cause of the various climatic variations. . . . Differences of 0.15 to 0.20 have been observed every year. Such differences, if permanent during some centuries or thousands of years, would produce the required differences of temperature."

The thermal state of the atmosphere, A. BOUTARIC (*Compt. Rend. Acad. Sci. [Paris], 158 (1914), No. 9, pp. 652-656*).—Methods of mathematical physics are applied in this article to the solution of the question of the causes of the fall in temperature of the atmosphere with elevation.

Measurements of the emanations content of soil air, K. KÄHLER (*Phys. Ztschr., 15 (1914), No. 1, pp. 27-31*).—Measurements by means of the Benndorf electrometer are recorded.

It was found that changes in atmospheric pressure exerted a great influence upon the amount of the radio-active emanations of the soil and also upon the escape of the emanations from the soil into the air. Sunshine favored the escape of the emanations but its action was masked by other factors.

A determination of the variation with altitude of the radium emanation content of the atmosphere, J. R. WRIGHT and O. F. SMITH (*Phys. Ztschr., 15 (1914), No. 1, pp. 31-39*).—The amount of radium emanations in the air at Manila at a height of 5 meters above the sea and on Mt. Pauai, 2,460 meters above sea level, was determined by the method of absorption in coconut charcoal.

The average of emanations per cubic meter of air was equivalent to 82.48×10^{-12} gm. for Manila, and 19.18×10^{-12} gm. for Mt. Pauai, the average ratio between the two being 4:1. The amount of emanations in the air varied at a given place within comparatively wide limits in dependence upon the meteorological conditions. With rainy weather and high winds the amount was very low, while with fine weather and low winds the amount was comparatively high. The content was much higher at night than during the day.

The climate and weather of San Diego, California, F. A. CARPENTER (*San Diego, 1913, pp. XII+118, pls. 13, figs. 15*).—This treatise, setting forth fully the characteristic as well as the unusual features of the weather and climate of San Diego, is based upon a continuous official meteorological record since 1849 and upon noninstrumental observations dating back to 1542.

Climate and meteorology of New Zealand, D. C. BATES (*New Zeal. Off. Yearbook 1913, pp. 34-50, pls. 5, fig. 1*).—Observations on temperature, pressure, rainfall, sunshine, wind, etc., during 1912 are summarized and discussed, and comparisons are made with the meteorological conditions of previous years. The generally favorable climatic conditions of the country are emphasized, and it is shown that these conditions are unusually conducive to health and agricultural productiveness.

The leading feature of the climate is the abundance and frequency of the rainfall and its comparatively uniform distribution. Sunshine and rain alternate fairly well throughout the year, with much greater predominance of the former. The rainfall is usually more intense and frequent during the night than during the day.

Monthly and annual rainfall from 1837 to 1912, inclusive, at St. Paul, Minnesota (*Ann. Rpt. Bd. Water Comrs. St. Paul, Minn., 13 (1912), pp. 116, 117, pl. 1; Engin. News, 70 (1913), No. 11, pp. 514, 515, figs. 2*).—The rainfall record for 1837-1911 is shown in tables and diagrams in the first report cited; the data for 1912 are added in the second article referred to. The highest annual rainfall recorded was 49.69 in. in 1849; the lowest, 10.21 in., in 1910. The mean annual rainfall for the whole period was 27.41 in.

Composition of rain water collected in the Hebrides and in Iceland, N. H. J. MILLER (*Jour. Scot. Met. Soc., 3. ser., 16, No. 30, pp. 141-158; abs. in Jour. Chem. Soc. [London], 106 (1914), No. 615, I, p. 128; Rothamsted Expt. Sta., Harpenden Ann. Rpt. 1913, pp. 20, 21*).—Determinations of ammonia and nitrate nitrogen and chlorin in samples of rain water collected at Vifilsstadir, Iceland, and at Butt of Lewis and other places in the Hebrides and on the west coast of Scotland are reported.

The results for ammonia and nitrate nitrogen were very low, the annual rainfall of 39.7 in. at Butt of Lewis containing only 0.034 parts of nitrogen as ammonia and 0.032 parts of nitrogen as nitrates per million; that of Vifilsstadir 0.091 and 0.03 parts, respectively. The total nitrogen per acre brought down by the rainfall was 0.6 lb. at Butt of Lewis and 1.065 lbs. at Vifilsstadir. The amounts at other places were somewhat higher (1.8 to 2.2 lbs.) but only about half the amount found in rain water at Rothamsted.

The chlorin content of the rain water varied from 7.8 parts per million per month, equivalent to 52.2 lbs. per acre annually at Vifilsstadir, to 749.9 parts per million, equivalent to 6,884 lbs. per acre at Butt of Lewis, and 759.6 parts per million, equivalent to 5,753 lbs. per acre, at Barrahead.

The economic value of tropical rainfall, G. CAPUS (*Ann. Géogr., 23 (1914), No. 128, pp. 109-126, figs. 4*).—Determinations of the nitrogen content of the rainfall at Hanoi, Tonkin, from April, 1902, to September, 1909, are reported and discussed.

The average annual rainfall during this period was 1.65 meters (5.4 ft.). The evaporation was approximately one-half of the rainfall. The average amount of nitric nitrogen brought down annually by the rain was 43.35 lbs. per acre, of ammoniacal nitrogen 11.58 lbs. These are much larger amounts than are found in the rainfall of temperate regions and sufficiently large to be of considerable economic importance from the fertilizing standpoint.

The genesis of dew, W. GODDEN (*Symons' Met. Mag.*, 48 (1913), No. 573, p. 163).—Observations on grass lands are briefly reported from which the general conclusion is drawn that about 69 per cent of a given dew deposit is exhaled by the grass, about 25 per cent is precipitated from the atmosphere, and the rest is derived from the soil.

A sliding rule for the determination of the dew point, absolute and relative humidity, as well as saturation deficiency, A. KORFF-PETERSEN (*Ztschr. Hyg. u. Infektionskrank.*, 77 (1914), No. 1, pp. 177-183, fig. 1).—The rule and its method of use are described.

Combating hail (*Bul. Soc. Nat. Agr. France*, 74 (1914), No. 2, pp. 130-144, 218-238).—An account is given of a discussion of this subject by a number of different persons, in which particular emphasis is laid upon the relation of forests to hailstorms and the possibility of reducing damage from this source by extension of the forest area.

Electrical protection against hail in Gironde, F. COURTY (*Vie Agr. et Rurale*, 3 (1914), No. 12, pp. 313-316, figs. 3).—Positive and negative results obtained with "electric niagaras" and similar devices are reviewed without definite conclusions as to their efficacy.

Surface water supply of St. Lawrence River Basin, 1912, C. C. COVERT, A. H. HORTON, and W. G. HOYT (*U. S. Geol. Survey, Water-Supply Paper 324* (1914), pp. 149, pls. 3).—This report presents results of measurements of flow made on streams tributary to Lakes Superior, Michigan, Huron, Erie, and Ontario, and to the St. Lawrence River.

A summary of mean discharge per square mile shows the almost entire lack of uniformity or agreement between any two streams, "which indicates that the discharge of each stream is a law unto itself, and that all projects dependent upon stream flow, if they are to be developed along the safest and most economical lines, must be based on records of stream flow collected with great care over a long series of years as near the location of the project under consideration as possible."

SOILS—FERTILIZERS.

The characterizing of soil according to the molecular composition of the silicates soluble in hydrochloric acid (zeolitic silicates), R. GANS (*Internat. Mitt. Bodenk.*, 3 (1913), No. 6, pp. 529-571).—The author summarizes the results of investigations by himself and others as follows:

The zeolitic silicates show the same general composition and behavior as the artificial aluminum silicates and may like them be considered as chemical compounds. As a result of weathering they do not always occur in the soil in pure form but are frequently mixed with decomposition products. They show the characteristic aluminum silicate molecular composition 3+Mols. SiO₂: 1 Mol. Al₂O₃: 1 Mol. base when protected from weathering by the carbonates of the alkaline earths, i. e., in neutral or alkaline soils. They show a less base content than 1 Mol. base: 1 Mol. Al₂O₃ when decomposed by acid (carbon dioxide) weathering solutions. The proportions of SiO₂ to Al₂O₃ remains 3+: 1 under such conditions, i. e., in acid soils. They show a less silica content than 3 Mol. SiO₂: 1 Mol. Al₂O₃ when decomposed by alkaline weathering solutions which

dissolve out a part of the silica. On this account, i. e., in neutral or alkaline soils, they are unable to combine 1 Mol. of base with 1 Mol. Al_2O_3 . This shows that the neutral, alkaline, or acid nature of the soil is indicated not by the percentage by weight of the bases extracted by boiling concentrated hydrochloric acid, but by the molecular relation of the bases to the silica and clay in the decomposing silicate. This relation best characterizes the condition of the soil.

The determination of the silica by the hydrochloric acid method according to Van Bemmelen is to be recommended. The molecular calculation of results of analysis should also include the uncombined bases.

The use of the Mitscherlich method of determining hygroscopicity is urgently recommended in the investigation of soils and the use of the method of calculation in equivalents advanced by De Sigmond (E. S. R., 28, p. 318) is discussed.

The molecular calculation is considered valuable whether dealing with a physical or a chemical combination in the weathered complex. It is of equal value for the calculation and judgment of soils whether the neutral reaction is due to the existence of neutral aluminum silicates or to an absorption maximum which shows the same molecular relation as the neutral aluminum silicate and whether the acid reaction is due to acid aluminum silicates or to absorptively unsatisfied gels of silica and alumina.

Earth flows and structure soil in polar and subpolar regions, K. SAPPER (*Internat. Mitt. Bodenk.*, 4 (1914), No. 1, pp. 52-67; *abs. in Rev. Sci. [Paris]*, 52 (1914), I, No. 12, p. 370).—The soil flows occurring in polar and subpolar regions are said to differ from those of tropical regions in that they are less fluid and the stone and earth constituents are not as a rule separated into homogeneous groups and layers by gravity. The soils are either homogeneous or heterogeneous according to the slope of the ground and the degree of the sorting and separating action produced by freezing and thawing, capillarity, and alternate wetting and drying.

The polygon and thufur soils of these regions (E. S. R., 30, p. 515) are said to occur in the more homogeneous forms of flowing soil, the so-called stone strips, nets, rings, and fields in the more heterogeneous forms. Several theories are advanced as to the exact manner of their formation.

Knox County soils, C. G. HOPKINS, J. G. MOSIER, J. H. PETTIT, and J. E. READHIMER (*Illinois Sta. Soil Rpt. 6* (1913), pp. 43, pls. 2, figs. 5).—This is the sixth of the series of the Illinois county soil reports, and deals briefly with the physiography, topography, and formation of the soils, and more fully with soil material and soil types, chemical composition of the soil, and field tests of the fertilizer requirements of certain of the prevailing types.

Knox County lies in the upper Illinois glaciation. The soils of the county are divided into three classes as follows: “(1) Upland prairie soils, rich in organic matter. These were originally covered with wild prairie grasses, the partially decayed roots of which have been the source of the organic matter. The flat prairie land contains the higher amount of this constituent because the grasses and roots grew more luxuriantly there and the higher moisture content largely preserved them from decay. (2) Upland timber soils, including those zones along stream courses over which forests once extended. These soils contain much less organic matter because the large roots of dead trees and the surface accumulations of leaves, twigs, and fallen trees were burned by forest fires or suffered almost complete decay. The timber lands are divided chiefly into two classes—the undulating and the hilly areas. (3) Swamp and bottom lands, which include the flood plains along streams and some small peaty swamp areas. . . .

"More than half the entire county is covered with the common prairie soil known as brown silt loam, and about one-third consists of two upland timber types, the yellow silt loam (hilly) and the yellow-gray silt loam (undulating), the former occupying almost one-fifth of the entire county. . . .

"The most significant fact revealed by the investigation of the Knox County soils is the low phosphorus content of the common brown silt loam prairie."

Soil investigations, [L. T. SHARP] (*Nevada Sta. Rpt. 1913, pp. 24-38*).—The first part of this paper discusses the soils of Nevada relative to fertility and crop production, and the second part reports the status of scientific investigations looking to soil improvement.

Chemical analyses of representative soil types show them to be "intrinsically rich in mineral plant food and naturally deficient in nitrogen." Alkali was present in various amounts in almost all the soils examined.

A series of experiments on the biological fixation of nitrogen did not warrant definite conclusions, but, "the evidence at hand . . . on the whole is rather favorable to the explanation of the accumulation of nitrates in Colorado soils . . . by Headden and Sackett" (*E. S. R., 29, p. 621; 30, p. 818*).

Studies of bacteria in soils as affected by irrigation showed that the water content most suitable for ammonification was not the optimum condition for nitrification. Ammonification was most rapid with 25 per cent water content, and was not markedly affected by differences of 3 per cent in water. On the other hand, 19 per cent of water was most advantageous for nitrification, and the rate of nitrification decreased over 50 per cent as the water content increased to 25 per cent. "It is probable that 18 to 20 per cent of water is the most suitable water content for this soil, . . . for the bacterial processes taking place in it."

Studies of colloids as protective substances for bacteria, particularly in the presence of alkalis, showed that aluminum hydroxid rendered sodium chlorid and sodium sulphate in solution at certain concentrations less toxic. Aluminum hydroxid and colloidal starch were more or less toxic to pure cultures of ammonifying organisms and slightly depressed ammonification with mixed cultures. Aluminum hydroxid stimulated nitrification to some extent.

Heat movement in pseudo-isotropic soil, A. v. ANDERKÓ (*Met. Ztschr., 30 (1913), No. 12, pp. 580-589*).—A mathematical exposition of heat movement in soils is given. This is based on the assumptions that a homogeneous pervious soil stratum, which would be isotropic but for the effect of meteorological factors and ground water variations, may be considered pseudo-isotropic, and that the sum of the factors, including amplitude, phase, and variations in heat capacity and conductivity, which influence heat movements in pseudo-isotropic soils, may be expressed by Fourier's law and modifications thereof.

An erosion study, G. N. COFFEY (*Jour. Amer. Soc. Agron., 5 (1914), No. 4, pp. 230-232*).—A method described for measuring the amount of material removed in suspension and solution from the surface of a given area consists of surrounding a small plat on all sides except the upper one with a split glazed tile surface drain so that surface wash from the plat is carried into this drain and thence through a pipe to a steel tank. For determining the plant food carried away in the drainage water two lines of tile are placed 30 in. deep surrounding the plat, the inner line being for the purpose of collecting subsoil drainage from the plat and the outer line for removing surrounding subsoil water.

Lysimeter investigations, 1913, G. RICHTER (*Mitt. Kaiser Wilhelms Inst. Landw. Bromberg, 6 (1914), No. 3, pp. 212-224*).—This is a brief account of a continuation of work by Krüger previously noted (*E. S. R., 29, p. 125*). It

reports investigations on the water economy of soil under summer barley and lupines as a stubble crop, on the influence of cultivation on evaporation, and on the approximate evaporation from plants and soil surfaces after sprinkling.

Fallow soil had a greater and soil planted to barley a less water content at the end of the vegetation period than at the beginning. Evaporation from fallow soil was 31 per cent and from the planted soils between 88 and 93 per cent of the rainfall and of the water artificially applied. The average transpiration by the barley plants was 68 per cent of the total evaporation. With lupines as a stubble crop the difference in evaporation from fallow and planted soil was less than with barley, the average transpiration from the crop being 58 per cent of the total evaporation. Owing to its wastefulness of water, however, the cultivation of lupine as a stubble or intermediate crop is thought to influence unfavorably the soil water balance particularly in light soils. Cultivation appreciably decreased evaporation and increased the quantity of water taken up by the soil. The evaporation after sprinkling varied, being on the average somewhat greater from fallow than from planted soil. The average approximate evaporation from the planted soil was 8 per cent of the water added. On the average the immediate loss by evaporation after sprinkling was at the rate of about 2,000 gal. per acre regardless of the amount of application.

It is concluded that the larger the application of water the better if due consideration be given the type of soil and plant and the limits of economy.

The effect of heat upon the solubility of the mineral constituents of the soil, W. McGEORGE (*Jour. Indus. and Engin. Chem.*, 6 (1914), No. 3, pp. 223-227).—The investigations on which this article is based have already been noted from another source (*E. S. R.*, 30, p. 419).

The decomposition of cellulose in moor soil and peat, WANDA DASZEWSKA (*Bul. Soc. Bot. Genève*, 2. ser., 4 (1912), No. 7, pp. 255-316).—Numerous species (some of them new) of micro-organisms isolated from moor soils or from peat are described and their behavior toward the decomposition of cellulose was studied.

The decomposition of cellulose by these organisms did not result in the formation of brown humus products. The hyphomycetes were more active in decomposing cellulose in the soil than bacteria. The dark color of humus is thought to be probably due to the color of mycelium and spores, to the brown and black pigments, and also to oxidizing substances (ferments) secreted by most of the hyphomycetes. The hyphomycetes bring about an aerobic decomposition of cellulose by means of cytase. The organisms grow in a water extract of peat if provided with a supply of carbon, cellulose being suitable in case of organisms which decompose this substance.

A bibliography of the subject is given.

The decomposition of soil carbonates, W. H. McINTIRE (*Science*, n. ser., 39 (1914), No. 1001, pp. 361, 362).—A brief note is given on investigations which have shown that calcium and magnesium carbonates quickly disappear as such when applied to the soil and which indicate that the magnesium carbonate and, to a less extent, the calcium carbonate react with and are fixed by silica. Titanium oxid was found to bring about the same decomposition as silica. The evidence secured indicates that magnesium carbonate does not exist in soils of humid climates.

Management of soils to prevent blowing, W. M. JARDINE (*Jour. Amer. Soc. Agron.*, 5 (1914), No. 4, pp. 213-217, pls. 3).—Attention is drawn to the injurious blowing of soils in the Great Plains area and methods of prevention are proposed. The importance of keeping the surface of blowing soils rough or corrugated is noted, and implements such as the alfalfa cultivator, spring-tooth harrow, corn cultivator, and the lister in extreme cases, are said to be

well adapted for their cultivation. Manure, straw, and trash also furnish effective protection when spread upon the land uniformly. "More extreme measures must be taken with [sandy soils], such as farming in strips, [and] allowing weeds or other vegetation to grow and form windbreaks on the alternate strips."

Contribution to the physiology of soil, BERNBECK (*Forstw. Centbl.*, n. ser., 36 (1914), No. 1, pp. 26-44).—This article discusses the importance of the "physiological depth" of soils, i. e., the depth of the soil layer in which roots grow, particularly in its relation to the free circulation of moist air in forest soils. Various means of increasing the physiological depth are described.

The distribution of bacteria in various soil types, H. J. CONN (*Jour. Amer. Soc. Agron.*, 5 (1914), No. 4, pp. 218-221).—The results of studies of the microflora of 14 different soils make "it evident that, both quantitatively and qualitatively, there is surprisingly little variation between the bacteria of different soils. Soil has its own distinctive types of bacteria, and they are not many in number." The predominating types observed in cultures in ordinary media, and not including nitrifying, nitrogen-fixing, and other forms, were as follows: (1) Peritrichic, spore-bearing, long rods (5 per cent)—*Bacillus mycoides*, *B. subtilis*, *B. megatherium*, and an unnamed type; (2) nonspore-bearing, short rods (50 per cent)—liquefying type (unnamed), and nonliquefying type (unnamed); (3) Pseudomonas (5 per cent)—*P. fluorescens* (liquefying), and nonliquefying type (unnamed); (4) Actinomycetes (40 per cent)—*A. chromogenus* (?) and *A. albus*.

"In every soil studied, whether a muck, a clay loam, a loam, or a sand, all of these types were found and no others occurred in appreciable numbers."

Real and apparent nitrifying powers, P. L. GAINNEY (*Science*, n. ser., 39 (1914), No. 992, pp. 35-37; *abs. in Chem. Abs.*, 8 (1914), No. 5, p. 978).—Data are presented to show that deducting the nitrate nitrogen originally present or that in an incubated check as is done in two of the methods commonly used to determine the nitrifying power or efficiency of soils does not give correct results when easily decomposable organic nitrogenous substances are added to soils containing nitrate nitrogen.

"Simply taking as the correct factor the amount found at the final analysis will probably approach nearer the truth than any other method now in practice." However, this method gives only the apparent nitrifying power of the soil since "there is absolutely no way of determining the actual amount formed that immediately disappears."

Studies on soil protozoa, A. CUNNINGHAM and F. LÖHNIS (*Centbl. Bakt. [etc.]*, 2. Abt., 39 (1914), No. 23-25, pp. 596-610).—The investigations reported dealt with the growth of protozoa on various media and the effect of heat on active and encysted forms.

The death point of active and encysted protozoa was found to be for flagellates 44° C. (active forms), 70-72° (cysts); for ciliates 54° (active forms), 72° (cysts); and for amœbæ 48° (active forms), 72° (cysts).

"In the case of the cysts the figures obtained are quite constant for the three forms of protozoa examined. The active forms, however, show marked differences in their power of resistance and it is noteworthy that the latter appears to be roughly in proportion to the average size of the individuals.

"The results show quite a marked difference between the powers of resistance to heat of the cysts and the active organisms—a difference at all events quite large enough to allow of the selection of an intermediate temperature which will kill all active forms but leave the cysts uninjured. In the fixing of this temperature, however, the retarding effect which heat has had upon excystation in these experiments must be kept in mind. It will, therefore, be

advisable to take a temperature as little above the death point of the active ciliates as is absolutely necessary to insure the killing of these organisms. Probably a temperature of 58 to 60° would be suitable for this purpose."

The action of antiseptics in increasing the growth of crops in soil, E. J. RUSSELL and W. BUDDIN (*Jour. Soc. Chem. Indus.*, 32 (1913), No. 24, pp. 1136-1142 figs. 5; *abs. in Chem. Zentbl.*, 1914, I, No. 8, pp. 806, 807; *Rothamsted Expt. Sta., Harpenden Ann. Rpt. 1913*, pp. 17, 18).—In continuation and extension of previous work (*E. S. R.*, 28, p. 538; 29, p. 122; 30, p. 219) the authors studied the relative effectiveness of individual volatile and nonvolatile antiseptics for partial sterilization of soils.

The action of toluene is said to be typical of that of the whole class of volatile antiseptics studied as it causes first a decrease and then an increase and also a change in type in the micro-organic population of the soil, the suspension of nitrification, a marked increase in ammonia production, and the liberation of very small amounts of ammonia. The volatile antiseptics studied are classed in order of their effectiveness as follows: Toluene, carbon bisulphid, benzene, cyclohexane, chloroform, ether, hexane, and methyl and ethyl alcohols.

"The nonvolatile antiseptics present a more complex case because they persist in the soil and modify the development of the bacterial flora." Cresol is said to be typical of this class and its later effects differ from those of the volatile antiseptics in that the bacterial numbers are unusually increased, the flora is less mixed and very simple, and the high numbers of organisms do not persist but decrease rapidly to the numbers in untreated soil. "Simultaneously there is an increase in the amount of ammonia formed in the soil, but nothing corresponding to the increase in bacterial numbers." Phenol resembles cresol in its action but the rise in bacterial numbers is more marked and there is an even smaller production of ammonia. Hydroquinone behaves somewhat like phenol, the quinone is similar but is less potent. Formaldehyde is normal in its initial behaviour but subsequently there is a marked rise in the amount of ammonia produced but no increase in the bacterial numbers above what occur in the untreated soil.

"Pyridin is the nearest approach to a nitrogenous antiseptic. All the non-volatile antiseptics in higher doses bring about a depression in the amount of nitrate revealed by analysis."

As regards their beneficial effect on plants grown in pot experiments with soils containing disease organisms the antiseptics tested are classed as follows: Most effective, formaldehyde and pyridin; medium, cresol, phenol, calcium sulphid, carbon bisulphid, toluene, benzene, and petrol; least effective, higher homologues of benzene and naphthalene and certain of its derivatives. "None of these antiseptics is as good as steam, either in increasing the amount of ammonia in the soil, in killing insect and fungoid pests, or in inducing a good fibrous root development."

It is concluded that antiseptics may be used with advantage in practice where the crop yield is limited by the supply of nitrogenous plant food, and where disease organisms and other detrimental forms are present and the micro-organic population of the soil has lost much of its effectiveness in producing ammonia from the nitrogen compounds therein.

A list of previous articles on the subject is given.

Fertilizers and soil organisms, C. LUMIA (*Mem. R. Accad. Lincei, Cl. Sci. Fis., Mat. e. Nat.*, 5. ser., 9 (1913), No. 12, pp. 457-471).—The results of the author's investigations and observations confirm results obtained in previous work (*E. S. R.*, 14, p. 647). He concludes that the mineral constituents of fertilizers and also carbohydrates exert a direct and favorable action on the micro-organisms of the soil, and may be in part utilized directly by some of

the higher plants, but have more frequently an indirect effect on plants by furnishing conditions favorable to organisms which supply them with nitrogen compounds and render phosphoric acid soluble.

The purpose and interpretation of fertilizer experiments, G. N. COFFEY (*Jour. Amer. Soc. Agron.*, 5 (1914), No. 4, pp. 222-230, fig. 1).—The principal points emphasized in this article are (1) the need of greater uniformity in the methods of fertilizer experimentation in order that the results secured may be more nearly comparable; (2) the advisability of determining the relative need of a soil, and of different soils, for the different fertilizing elements; (3) the reliability of the results secured from the use of the elements alone for this purpose; (4) the suggesting of a line along which it may be possible to work out a satisfactory plan for obtaining this information; and (5) the proposing of a method by means of which it may be possible to interpret the results of fertilizer experiments in a way most easily understood by the farmer.

The plan proposed would involve simple uniform tests of the three fertilizing constituents separately on all important soil types and from data so obtained calculating the most profitable fertilizer combinations to use. Such a method, based on tests of single fertilizer constituents at Wooster and Strongsville, Ohio, is applied in this article to experiments made at the two places named and at the Pennsylvania Station. The method of calculation is stated

as follows: $\frac{A \times IN \times CP}{IP \times CN} = X$, where A =amount of nitrogen (or potash) applied; IN =increase from nitrogen (or IK from potash); IP =increase from phosphorus; CP =cost of phosphorus; CN =cost of nitrogen (or CK cost of potash); and X =relative proportion for most profitable returns.

“The first part of the formula is predicated upon the theory that the relative need of a soil for the elements is proportional to the increases produced by these elements; the second upon the theory that the amount of these elements used should be varied in proportion to their cost. While these theories may not hold absolutely true, they probably represent as near an approach to a general statement as can be made at the present time.”

On the plans of fertilizer experiments, P. L. GILE (*Jour. Amer. Soc. Agron.*, 6 (1914), No. 1, pp. 36-41, fig. 1).—The application of the law of minimum as enunciated by Liebig and modified by Mitscherlich to field experiments is discussed, and it is pointed out that while the plain principles which common sense and the experience of investigators show should govern in the planning and execution of fertilizer tests are universally recognized they are not always followed. There are various considerations which make it probable that the increased growth of crops resulting from an increase of the element in minimum is represented by a curve as Mitscherlich holds and not a straight line as Liebig's definition of the law of minimum indicates. This is in accord with Hall's application of the law of diminishing returns to fertilizer experiments and with the excess (*Luxus*) consumption by plants of a fertilizer added in increasing amounts.

“With the variable conditions that field experiments are subject to, it is doubtful if the increased growth caused by fertilizers will often follow exactly the theoretical rate. For this reason it seems that a plan of a fertilizer test somewhat as follows would give results which are more accurate than many of the present plans for such experiments and yet afford conclusions that are not dependent on theoretical considerations.

“In a test of the availability of different forms of nitrogen, for instance, all the plats should receive phosphoric acid and potash in considerable excess. The standard, or most available form of nitrogen, as nitrate of soda, should be applied in several quantities, say at the rate of 20, 30, 40, 60, and 90

lbs. of nitrogen per acre, while all the other forms of nitrogen could be applied at the rate of, say 50 lbs. of nitrogen per acre. Then a comparison of the yields would show whether 20, 30, 40, or 60 lbs. of the standard form of nitrogen were required to give the same yield as the 50 lbs. of the unknown form of nitrogen. The ratio of the quantities giving the same yields would give the relative availabilities.

“Such a plan would show whether or not the quantities of fertilizers tested were in minimum and thus guard against errors which sometimes occur. The conclusions would also be valid whether Liebig’s or Mitscherlich’s law of minimum is the correct one. . . .

“The objection to this plan is that it multiplies the number of plats and so necessitates a larger area for the experiment. It seems better, however, to increase the number of different treatments by two or three, and so increase the accuracy of the whole work. If it is impracticable to test four or five quantities of the standard, or most available fertilizer, at least two quantities should be used, so that it will be evident that the smaller quantity (which can be used for the comparison) is not present in excess of the crop’s requirements.”

Row fertilizing experiments, AHR (*Mitt. Deut. Landw. Gesell.*, 29 (1914), Nos. 7, pp. 94–98; 8, pp. 123–125).—The general outcome of the experiments here reported was that with cereals row fertilizing showed no advantage over the usual method of application. With beets, however, the results were decidedly better with row fertilizing.

Pond fertilizing experiments, KUHNERT (*Monatsh. Landw.*, 6 (1913), No. 12, pp. 353–371).—Experiments with various fertilizing materials and mixtures to promote the growth of food plants and thus increase the fish product of ponds are reported.

An incompatibility in fertilizer mixing, T. E. KEITT (*Abs. in Science*, n. ser., 39 (1914), No. 1001, pp. 363, 364).—It is stated that “when basic slag is mixed with muriate of potash or kainit a large proportion of the potash becomes insoluble in water. The insoluble compound thus formed is very slightly soluble in neutral ammonium citrate of sp. gr. 1.09, and only slightly soluble in citric acid, but is readily soluble in hydrochloric acid of sp. gr. 1.1115.”

Injuries to the cornea by artificial fertilizers, J. EICKMEYER (*Über Hornhautverletzungen durch künstliche Düngemittel. Inaug. Diss., Univ. Rostock, 1911; abs. in Zentbl. Biochem. u. Biophys.*, 14 (1912), Nos. 3–4, p. 154).—Tests were made with rabbits to verify some clinical findings noted in man as to the effect of artificial fertilizers on the eye.

Superphosphates were found to produce a slight conjunctivitis and a transient cloudiness of the cornea; Thomas slag produced a marked conjunctivitis with a transient turbidity of the cornea and residual scars; calcium cyanamid incited a marked neurotic conjunctivitis and also keratitis. When brought on the cornea as a paste these substances showed a marked toxicity.

The trade in fertilizing materials, M. LAMBERT (*Jour. Agr. Prat.*, n. ser., 27 (1914), No. 7, pp. 214–216).—This article briefly discusses recent developments in the trade in sodium nitrate, ammonium sulphate, calcium cyanamid and nitrate, phosphates, and potash salts.

Consumption, production, and commerce in artificial fertilizers in Russia, PIETTRE (*Bul. Mens. Off. Renseig. Agr. [Paris]*, 12 (1913), No. 5, pp. 585–587).—Statistics of consumption, importation, and production during the last ten years are briefly summarized showing that, while the total amount of fertilizer used in Russia is still comparatively small, there has been a remarkable increase both in importation and home production during recent years.

Source, availability, and suitability of different forms of plant food constituents to different crops, C. B. WILLIAMS (*North Carolina Sta. Circ. 11 (1914)*, pp. 5).—This is a brief popular discussion of the subject.

Composition and fertilizing value of farm crops and other farm materials, C. B. WILLIAMS (*North Carolina Sta. Circ. 6 (1913)*, folio).—Tables show the fertilizing constituents, the value of various farm products, and other data.

[The guano situation in Peru] (*Peru To-day*, 5 (1913), Nos. 4, pp. 858, 859; 6, pp. 957-959; *West Coast Leader*, 2 (1913), No. 80, p. 11; abs. in *Internat. Inst. Agr. [Rome]*, *Mo. Bul. Agr. Intel. and Plant Diseases*, 5 (1914), No. 2, pp. 204-207).—From reviews of the annual report of the Peruvian Guano Company for the year ended March 31, 1913, and the financial message of the President of the Republic dated September 5, 1913, it is noted that the guano extracted during the year for domestic use in accordance with the agreement between the Peruvian Government and the guano company entered into in 1909 was 24,350 (Spanish) tons of high grade guano containing 9.18 per cent of nitrogen (which was only 20 per cent of the amount demanded by the users) and 12,242 tons of low grade guano containing less than 3 per cent of nitrogen. The total amount of guano extracted under this agreement since 1909 has been high grade 93,297 tons, low grade 44,044 tons, or a total of 137,341 tons. The Peruvian corporation which assumed certain obligations of the Peruvian Government in 1890 in exchange for the right to extract and export guano not to exceed 2,000,000 tons has exported to date 1,134,918 tons. It is stated that from 1841 to 1879, when the industry was at its height, over 12,000,000 tons of guano was exported.

Realizing that the frequent disturbance of the guano-producing birds consequent upon unrestricted extraction of the guano is seriously interfering with the renewal of the deposits, the Peruvian Government has employed experts to report upon means of preventing the disappearance of the birds and has taken steps to provide for rotation in working the deposits and a closed season of five months each year to protect the birds.

Peat-moss litter, W. F. TODD (*Jour. Amer. Peat Soc.*, 6 (1913), No. 4, pp. 161-166; abs. in *Engin. Mag.*, 46 (1914), No. 6, pp. 985-987).—Attention is called to the deodorizing, disinfecting, and absorbent properties of peat moss which specially fit it for use as a litter. It is said to furnish good bedding, to keep the hoofs of animals in good condition, and to yield a very valuable manure in which flies do not breed.

Sulphate of ammonia industry of Germany, R. P. SKINNER (*Daily Cons. and Trade Rpts. [U. S.]*, 17 (1914), No. 54, p. 878).—Brief reference is made to the activities of two large rival firms manufacturing ammonium sulphate in Germany, and statistics of imports and exports of this material are given.

It is stated that the imports were 34,626 metric tons in 1913 as compared with 23,097 tons in 1912. The exports amounted to 75,868 tons in 1913 as compared with 56,948 tons in 1912. The exports to the United States amounted to 5,629 tons in 1913.

Potash shipments during 1914, R. P. SKINNER (*Daily Cons. and Trade Rpts. [U. S.]*, 17 (1914), No. 56, p. 909; *Commercial Fert.*, 8 (1914), No. 3, p. 16; *Jour. Indus. and Engin. Chem.*, 6 (1914), No. 5, p. 429).—Statistics of the deliveries for domestic and foreign consumption during the year 1914 in accordance with the provisions of the Potash Syndicate law and of actual exports of potash salts from Germany during 1912 and 1913 are given.

The deliveries agreed upon are for domestic consumption 635,300 metric tons of pure potash, and for foreign consumption 531,300 tons. The total exports in 1913 amounted to 1,829,617 metric tons valued at \$22,164,000.

Occurrence and composition of some Alabama phosphates, B. B. ROSS (*Abs. in Science, n. ser.*, 39 (1914), No. 1001, p. 363).—It is stated that "large quantities of phosphate-bearing strata are found in Alabama, apparently closely associated with a thick bed of rotten limestone and with green sands; their formation is ascribed to a leaching of this phosphatic limestone. This view is confirmed by analyses of boulders, which showed that the weathered layers contain considerably less phosphate than the unweathered portion. Much of this phosphate deposit could not be worked economically at the present time, but it may be capable of later development when other fields become partly exhausted. The green sands contain both potash and phosphate, and many possess local value as a fertilizer."

On the action of lime and magnesia in the nutrition of plants, E. HASELHOFF (*Landw. Jahrb.* 45 (1913), No. 4, pp. 609-633; *abs. in Ztschr. Angew. Chem.*, 27 (1914), No. 37, *Referatenteil*, p. 298).—A series of pot experiments with different crops are reported, the results of which do not substantiate Loew's theory regarding the necessity for a definite ratio of lime to magnesia for each kind of crop.

Catalytic fertilizers, magnesium salts, etc., O. MUNERATI (*Bol. Quind. Soc. Agr. Ital.*, 19 (1914), No. 4, pp. 116-119).—A number of experiments with manganese sulphate and magnesium sulphate, which gave results not entirely conclusive but generally showing some increase from the use of these substances, are reported.

Catalytic fertilizers, E. BOULLANGER (*Vie Agr. et Rurale*, 2 (1913), No. 9, pp. 244-247).—This is a summary of results of experiments by the author and others with manganese salts on oats, wheat, barley, beets, potatoes, grasses, and garden vegetables, and with aluminum and sodium silicates and iron sulphate on garden crops. The results were not conclusive but are thought to warrant further investigation.

Radio-active fertilizers, L. MALPEAUX (*Vie Agr. et Rurale*, 2 (1913), No. 9, pp. 241, 242; *abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases*, 4 (1913), No. 4, p. 563; *Chem. Abs.*, 8 (1914), No. 5, p. 979).—A mineral substance showing a small degree of radio-activity was used at rates of from 22 to 40 lbs. per acre in combination with the ordinary fertilizing materials in pot and field experiments. The radio-active material apparently increased the yield of oats and crimson clover in pot experiments and of oats, mangels, and sugar beets in field experiments. It exerted no effect on the composition of the sugar beets.

Recent experiments on the fertilizing action of sulphur, E. BOULLANGER (*Vie Agr. et Rurale*, 2 (1913), No. 9, pp. 247, 248).—A very brief note is given on recent experiments tending to show the importance of sulphur as a fertilizer.

Fertilizer inspection (*Maine Sta. Off. Insp.* 53 (1913), pp. 105-140).—Reports of analyses of samples of fertilizers found on sale in Maine in 1913 are published in this circular, together with other pertinent information relating to the inspection, composition, valuation, and use of fertilizers, along the lines previously noted (*E. S. R.*, 28, p. 126).

Inspection and analyses of commercial fertilizers, 1913, P. F. TROWBRIDGE (*Missouri Sta. Bul.* 116 (1914), pp. 347-399).—Analyses and valuations of about 500 samples of fertilizers examined during the year are reported. It is stated that the amount of fertilizer sold in the State during the year was far in excess of that of any previous year.

Tabulated analyses of commercial fertilizers (*Penn. Dept. Agr. Buls.* 242 (1913), pp. 87; 244 (1914), pp. 65).—These two bulletins give in detail the results of inspection, including analyses and valuations of fertilizers in Pennsylvania in 1913.

AGRICULTURAL BOTANY.

Plant life, J. B. FARMER (*New York and London, 1913, pp. 255, figs. 28*).—In this book the author has sought to describe the salient features of plant life from the viewpoint of function. Technicalities have been avoided as much as possible and he has purposely omitted many things usually given in such a work in order to treat of matters not generally discussed in popular treatises.

A recording transpirometer, V. H. BLACKMAN and S. G. PAINE (*Ann. Bot. [London], 28 (1914), No. 109, pp. 109–113, pl. 1, fig. 1*).—The authors describe an instrument that is said to be comparatively accurate and of low cost which is believed to be well adapted for physiological experiments.

Anatomical investigations on the relation between structure and physiological characters of plants, O. V. IAKUSHKIN and N. VAVILOV (*Zhur. Opytn. Agron. (Russ. Jour. Expt. Landw.), 13 (1912), No. 6, pp. 830–861*).—Describing and summarizing studies carried out by them in relation to the views of Kolku-nov (*E. S. R., 20, p. 129; 21, p. 543*) to the effect that there exists a correlation between the size of leaf cells and stomata on the one hand and the physiological characters (as related to drought resistance, productivity, etc.) on the other, the authors state that their findings rather oppose than support such correlation.

The reciprocal relations between anatomical coefficients and physiological characters of plants, V. V. KOLKUNOV (*Zhur. Opytn. Agron. (Russ. Jour. Expt. Landw.), 14 (1913), No. 6, pp. 321–340*).—A reply to the above, presenting further arguments in support of the author's views.

A contribution to the physiology of the purple sulphur bacteria, M. SKENE (*New Phytol., 13 (1914), No. 1–2, pp. 1–17*).—The author gives the results of investigations on some of the purple sulphur bacteria, in which he states that attempts to obtain pure cultures have been without success. In mixed cultures *Amœbobacter*, and probably also *Lamprocystis*, thrive best in mineral solutions containing ammonium sulphate as a source of nitrogen and lime as a neutralizing agent. Organic sources of nitrogen and carbon, as far as tested, were unfavorable and in general inhibited the growth of the bacteria. Development of these organisms can take place only in the presence of hydrogen sulphid and growth only in the presence of light. The purple sulphur bacteria require free oxygen, which is probably supplied them by associated green organisms.

Some toxic and antitoxic effects in cultures of *Spirogyra*, W. D. HOYT (*Bul. Torrey Bot. Club, 40 (1913), No. 7, pp. 333–352*).—A report is given of experiments conducted to determine a nutrient solution suitable for algal growth under laboratory conditions.

Crone's solution was found to be the best solution tested, while that of Molisch was almost as satisfactory. Sachs's solution and that of Knop were decidedly unfavorable. Tap water and ordinary distilled water of the laboratory were found markedly toxic to this species of *Spirogyra*. The toxicity of tap water was partially removed by concentrating it and was entirely removed by heating to 144° C., or by distillation in glass. The toxicity of ordinary distilled water was partially corrected by adding to the culture lime, chalk, solid agar, dry sphagnum moss, colloidal platinum, or other absorbents.

The results obtained seem to indicate that the toxic materials present in the tap water were almost wholly volatile, while those in distilled water were mostly nonvolatile, probably derived from the supply pipes and from the still. Where potassium nitrate, potassium phosphate, potassium chlorid, magnesium sulphate, and calcium chlorid were used singly or in combination, a mixture of the three potassium salts was found as toxic as potassium chlorid used

alone. Potassium chlorid, magnesium sulphate, and calcium chlorid were found to be extremely toxic when used singly, but mixtures of any two were less toxic than a solution of a single compound. Good growth was obtained only when the salts of all three metals were present in favorable proportions. The toxicity of magnesium sulphate was completely counteracted by potassium chlorid or by calcium chlorid. Weak solutions of some of the toxic salts were improved by the addition of animal charcoal or colloidal platinum, and it seems the effect of powdered calcium carbonate in counteracting the toxicity of the nutrient salts was due in part to the adsorptive action of the solid.

Recent studies on gaseous exchanges of green plants with the atmosphere, L. MAQUENNE and E. DEMOUSSY (*Nouvelles Recherches sur les Échanges Gazeux des Plantes Vertes avec l'Atmosphère. Paris, 1913, pp. 166, pls. 4, figs. 3*).—This is a somewhat detailed account of the authors' more recent work (*E. S. R.*, 29, p. 27). It includes findings and deductions from studies, chiefly on *Euonymus japonica*, regarding respiration of leaves under different conditions, such as darkness and variable pressure, also an exposition of methods employed in measuring respiratory coefficients of the influence of carbon dioxid contained in the air, of chlorophyll activity, etc. Of the more general conclusions stated at some length a few may be summarized as follows:

The respiratory coefficient of leaves is variably influenced by age and activity of the tissues; also by illumination and temperature, given degrees of which correspond to the chemical composition noted in the plant and are apparently related to the activity of diastases therein. When a plant is in equilibrium with external conditions there exists a simple relation between the real respiratory quotient thereof, its coefficient of absorption for carbon dioxid at the existing temperature, the density of the charge within the apparatus, and the apparent respiratory quotient in the same conditions, this relation permitting the approximate calculation of one of these magnitudes when the others are known.

The coefficient of absorption of carbon dioxid by green plants varies with temperature according to the law of solubility therefor. It appears to be for thin leaves about double the coefficient of solubility of pure carbon dioxid, which thus appears to supersaturate the cellular structure. The phenomenon of assimilation does not sensibly modify the relations between hydrogen and oxygen in the composition of vegetable tissues. The variations of ratio noted in gaseous exchanges, diurnal or nocturnal, between a plant and the atmosphere and consequently the changes of composition in the plant organs, are thought to be attributable mainly to the influence exerted by heat.

The respiration of plants under various electrical conditions, R. C. KNIGHT and J. H. PRIESTLEY (*Ann. Bot. [London], 28 (1914), No. 109, pp. 135-161, figs. 6*).—The authors state that field trials on the effect of electrical conditions upon plant growth (*E. S. R.*, 23, p. 326) have suggested that an increased crop or an earlier ripening may be the result of such treatment. In the present paper an attempt has been made to analyze this apparent effect by determining the effect of such electrical conditions upon respiration.

The experiments have shown that direct currents of a density 10^{-8} to 10^{-4} amperes have no effect on the respiration of peas other than that due to accompanying changes of temperature. Overhead discharges producing a current of density less than 3×10^{-8} amperes have no effect on respiration. When higher currents were employed a definite increase of carbon dioxid was observed, which is attributed wholly to the rise of temperature caused by the discharge. In the field, where the currents are too small to produce any appreciable rise of temperature, the authors are of the opinion that electrifica-

tion would have no effect upon respiration, and that explanation for any acceleration of growth must be sought in other functions of the plant.

The gaseous products of electrical discharge in air are said to have no effect upon germinating peas but are deleterious to young seedlings.

Experimental and critical studies on freezing and frost killing in plants, N. A. MAXIMOW (*Jahrb. Wiss. Bot. [Pringsheim]*, 53 (1914), No. 3, pp. 327-420, figs. 6).—Reviewing briefly previous communications by himself (E. S. R., 2S, p. 630) and others on the death point of plant cells as related to composition, concentration, and freezing points of the contained or containing solutions, the author gives details and results of his more recent studies, concluding that killing by cold is probably due not simply to low temperatures as such (implying a specific temperature minimum), but to physico-chemical changes set up in the plasma colloids during the formation of ice therein. A bibliography is appended.

A study of the effect of smoke and dust on plants, V. SABACHNIKOFF (*Contribution à l'Étude des Fumées et des Poussières Industrielles dans leurs Rapports avec la Végétation. Thesis, Univ. Nancy, 1913, pp. 252, pls. 10, figs. 8*).—The author gives a critical review of available literature on the subject, describing in detail some of the recent investigations conducted in Germany, Austria, and France.

An account is also given of his investigations on the effect of sulphuric acid in the air on the vitality and reproductive power of pollen and on the development of grain in wheat. Open flowers and growing heads of wheat plants were placed within aspirators and atmospheres containing known quantities of sulphuric acid were drawn over them. It was found that exposure for more than 24 hours to a concentration of more than 1:13,000 parts of sulphuric acid was fatal to the action of pollen and a proportion in excess of 1:30,000 was detrimental to the reproduction of plants. In the experiments with wheat at the time of flowering, sulphuric acid 1:10,000 completely prevented seed formation. A concentration of 1:30,000 notably reduced the average number and weight of the seed formed. Diminution in average weight was in proportion to concentration of sulphuric acid. The injury is considered to be largely confined to the reproductive organs of the plant.

A bibliography of more than 200 titles is given.

The occurrence of rennet in *Rhizopus nigricans*, M. DURANDARD (*Compt. Rend. Acad. Sci. [Paris]*, 158 (1914), No. 4, pp. 270-272).—The author reports experiments which demonstrated the presence of an active rennet in the mycelium of *R. nigricans* that rapidly coagulated milk at proper temperatures. The optimum temperature for the activity of the enzym was about 50° C., with a cessation of activity at 10°, and at 60° it was entirely destroyed. At a temperature of 55° the enzym required 50 times as long a period to bring about the coagulation of milk as was needed at the optimum temperature.

On the presence in leaves and flowers not containing anthocyanin of yellow pigments which may be transformed into anthocyanin, R. COMBES (*Compt. Rend. Acad. Sci. [Paris]*, 158 (1914), No. 4, pp. 272-274).—In continuation of his studies on the autumn coloration of *Ampelopsis hederacea* (E. S. R., 30, p. 729) the author has investigated a number of other plants to determine whether anthocyanin is formed by the transformation of other pigments. Studies were made of privet, several varieties of grapes, the foliage of some of which redden in autumn while others turn yellow, and of narcissus, the flowers of which contain a yellow pigment.

In the case of privet and the varieties of grapes that redden on the approach of winter, the red color is brought about by the oxidation of the yellow pigment

normally present in the leaves. In the varieties which have yellow leaves or which do not normally redden and in the yellow flowers of narcissus the pigment may be changed into a red coloring material by reduction.

On differential mortality with respect to seed weight occurring in field cultures of *Pisum sativum*, J. A. HARRIS (*Amer. Nat.*, 48 (1914), No. 566, pp. 83-86).—Claiming to have shown previously (*E. S. R.*, 28, p. 636; 29, p. 829) that for the dwarf varieties of *Phaseolus vulgaris* the mortality of apparently perfect seeds (failure to germinate or to complete the life cycle) is not random, the author reports on an extension of these studies to *P. sativum*. He states that in these Leguminosæ the mortality which occurs before germination is differential, but that in both cases wider series of experiments and refinement of methods of analysis are necessary to establish fully the nature and immediate (physical or chemical) cause of this selective death rate.

Studies in seedless fruits, G. NEGRI (*Ann. R. Accad. Agr. Torino*, 55 (1912), pp. 517-581).—The author gives the results of extended investigations on the subject of fruit development without seed formation, and describes apogamous, parthenocarpic, and other forms of fruit in which the ovary is stimulated to development without the ovules being fertilized. A bibliography is appended.

Origin of species in polymorphic genera, H. DE VRIES (*Rev. Gén. Sci.*, 25 (1914), No. 5, pp. 187-191).—From his observations and experiments the author concludes that in as polymorphous a group of plants as *Oenothera* mutation is not a special quality of *O. lamarckiana* alone, but is also a characteristic of other species. It is held that mutation is a cause of the wide range of forms observed in many wild species as well as in cultivated forms of many plants. *O. lamarckiana* is considered as possessing a considerable number of characters that are in a state of very unstable equilibrium, and to this fact is due the succession of forms that have been experimentally derived therefrom.

The vegetation in the vicinity of Leyni in relation to agriculture, E. FERRARI (*Ann. R. Accad. Agr. Torino*, 55 (1912), pp. 459-515).—A report is given of a study of the various types of plant associations with reference to the possible agricultural adaptations of the soil.

The flower-finder, G. L. WALTON (*Philadelphia and London*, 1914, pp. XXVI+394, pls. 17, figs. 573).—This is a popular work for the identification of common wild flowers, and is designed for the novice who wishes to determine some of the more common fruits and flowers. The plan is to identify the flowers and fruits by their color and other marked characteristics. Charts are furnished for the different colors which are commonly represented in wild flowers, from which references to definite groups are given, and, except where only slight differences occur, all of the species are illustrated by line drawings.

FIELD CROPS.

Forage crops: Annual grasses and roots, C. G. WILLIAMS and F. A. WELTON (*Ohio Sta. Bul.* 269 (1914), pp. 165-197, figs. 18).—This bulletin gives cultural notes for corn for silage, sorghums, millets, rye, wheat, oats, mangels, sugar beets, turnips, and rape.

Tables show analyses and yields per acre of 8 varieties of corn for silage for 5 years. The total yields ranged from 4.86 to 20.71 tons per acre, protein from 463.6 to 567.6 lbs., crude fiber from 1,204.5 to 1,795.5 lbs., nitrogen-free extract 3,880.8 to 4,700.2 lbs., and fat from 94.5 to 144.8 lbs. per acre.

Results of tests for thickness of planting corn for the silo showed "that the differences in yield of corn per acre vary widely with the season. In 1909 and 1912 the 4-in. drilling led by a wide margin, while in 1911 and 1913 it was a little behind the 6-in., and but slightly ahead of the 10-in. In 4 of the 5 years

the 12-in. planting has given the lowest yield, of all." During the seasons of excessive rainfall the 4-in. plantings make the large yields. In seasons when the rainfall is short or moderate the lead over the 12-in. planting is less than 1 ton per acre on the average.

Cane was found to be inferior to corn for silage under Ohio conditions.

In a variety test of both saccharin and nonsaccharin varieties of sorghums covering 7 years the average yields of green forage per acre ranged from 4.8 to 13.9 tons for the different varieties. Yields in millet variety tests for 7 years, including 9 varieties, ranged from 0.6 (Early Fortune broom corn) to 9.2 (Japan barnyard) tons per acre of dry forage.

Of oats and field peas it is noted, from tests in seeding them, 1:2, 1½:1½, and 2:1 bu. per acre, "that when total tonnage is the chief object, oats should predominate, and when the chief object is feed of high quality the peas should be in excess."

Plants introduced into a desert valley as a result of irrigation, S. B. PARISH (*Plant World*, 16 (1913), No. 10, pp. 275-280).—In this article the author notes the extent of occurrence of the following weeds that have been introduced into the Imperial Valley, Cal., incidental to crop cultivation: *Amaranthus palmeri*, *Ambrosia psilostachya*, *Aster exilis*, *A. spinosus*, *Atriplex semibaccata*, *Baccharis glutinosus*, *Brassica nigra*, *Chloris elegans*, *Chenopodium murale*, *Cynodon dactylon*, *Datura discolor*, *Echinochloa zelayensis*, *E. colona*, *Eclipta alba*, *Erigeron canadense*, *Helianthus annuus*, *Holcus halepensis*, *Leptochloa imbricata*, *Lippia nodiflora*, *Malva parviflora*, *Melilotus indica*, *Paspalum distichum*, *Pluchea sericea*, *Physalis wrightii*, *Portulaca oleracea*, *Salix exigua*, *Scirpus paludosus*, *Selaria glauca*, *Sesbania macrocarpa*, *Sesuvium sessile*, *Sida hederacea*, *Solanum elaeagnifolium*, *Sonchus asper*, *S. oleraceus*, *Tribulus terrestris*, *Xanthium commune*, and *X. canadense*.

Irrigation experiments, G. H. TRUE ET AL. (*Nevada Sta. Rpt. 1913, p. 17*).—One season's results of irrigation experiments with White Australian wheat and Siberian oats are here reported. The schedule of irrigation was based upon the time of heading of the grain and varied from 3 irrigations before and 2 after heading to 1 before and 1 after heading.

The largest yield of wheat, 549 lbs. per acre, was obtained with 2 irrigations before and 2 after heading, which applied water to the depth of 0.92 ft.; the smallest yield, 332 lbs. per acre, with 1 irrigation before and 1 after heading, which applied water to the depth of 1.08 ft.

With oats the largest yield, 340 lbs. per acre, was obtained with 1 irrigation before and 2 after heading, which applied water to the depth of 1.08 ft.; smallest yield, 232 lbs. per acre, was obtained with 1 irrigation before and 1 after heading, which applied water to the depth of 0.89 ft.

Comparative fertilizer experiments with lime nitrogen, sulphate of ammonia, and nitrate of soda on some hoed crops in 1912 (*Landw. Wchnbl. Schles. Holst.*, 63 (1913), No. 52, pp. 1040-1044).—Compared on a basis of net returns, the nitrate of soda plat was the only one that gave a uniformly profitable yield with beets. The lime nitrogen and ammonia plats did not always show a net profit, although the average of seven tests gave a positive return.

With potatoes the only plats to give a uniformly profitable return were those that received lime nitrogen; the other plats showed fluctuations. The average of 5 tests shows a plus return with the sulphate of ammonia and a minus return with the nitrate of soda.

With cabbage the yields from the sulphate of ammonia plats were the only ones that gave a uniformly profitable net return, while both of the other plats gave some losses.

With cauliflower the plats all gave profitable returns, the largest being from the sulphate of ammonia plat.

All of the plats in the experiment received P_2O_5 and K_2O to make up a complete fertilizer for the crops.

Comparative fertilizer experiments with cereals in 1912, WEHNERT (*Landw. Wchnbl. Schles. Holst.*, 63 (1913), No. 51, pp. 1010-1016).—In testing the value of lime nitrogen, nitrate of soda, and sulphate of ammonia on oats and barley the best yields of grain and straw were obtained with sulphate of ammonia in general on all classes of soil tested.

Soy beans and cowpeas, A. T. WIANCKO, M. L. FISHER, and C. O. CROMER (*Indiana Sta. Bul.* 172 (1914), pp. 421-438, figs. 8).—This bulletin, continuing previous work (E. S. R., 18, p. 1038), reports tests of cultural methods suited to Indiana conditions, includes some historical notes, and describes 18 varieties of soy beans and 11 varieties of cowpeas with yield data.

It is noted that both soy beans and cowpeas are well adapted to the climatic conditions of Indiana and that they have a wider soil adaptation than most of the common crops. One of the most important uses is regarded as sowing after harvest, on wheat or oat stubble, early potatoes, cannery peas, and as an orchard cover crop. Used in this way data show that after wheat, for the years 1909-1912, the average yield per acre of soy beans in green weight of tops was 10,660 lbs. and of roots to a depth of 18 in., 2,355 lbs., containing 81.8 and 10.9 lbs. of nitrogen, respectively. The average yield per acre of cowpeas in green weight of tops was 12,872 lbs. and of roots to the depth of 18 in. 2,691 lbs., containing 96.2 and 16.7 lbs. nitrogen, respectively.

Several years' experiments on methods and rates of planting soy beans for seed and hay production show that solid drilled, using about 60 lbs. seed per acre, gave larger yields per acre of both grain (21.7 bu.) and of hay (6,368 lbs.) than drilling in rows 24, 28, 32, 40, and 42 in. apart or broadcast. The seed yields with cowpeas were too small to warrant conclusions.

Chemical analyses, P. BIGLER (*Relat. Min. Agr. Indus. e Com.*, Brazil, No. 2 (1911), pp. 180-183).—This gives in tabular form very complete analyses of 28 samples of sugar cane and of 81 samples of cassava.

Grass mixtures for North Carolina pastures, C. B. WILLIAMS (*North Carolina Sta. Circ.* 9 (1913), pp. 6).—Grass mixtures for permanent pastures in the coastal plains, Piedmont, and mountainous sections for uplands and lowlands are given, together with cultural notes.

The creeping rootstock of *Agropyron repens*, MARGERY KNIGHT (*Jour. Bot.* [London], 51 (1913), No. 612, pp. 341-343, pl. 1).—This article describes the plant as a whole and the structure of the stem, the structure and development of the leaf, and the origin of the leaf and roots.

Alfalfa in Kansas, W. M. JARDINE and L. E. CALL (*Kansas Sta. Bul.* 197 (1914), pp. 577-610 figs. 15).—This bulletin gives data on cultural methods, including inoculation, row seeding, handling of hay and seed crop, influence of alfalfa on soil fertility and on succeeding crops, rotation, and animal and insect pests.

The effect of 10 tons per acre of barnyard manure applied to wheat before seeding to alfalfa in 1907 on an old cultivated field was as follows: Yield of alfalfa in 1908, manured 8,560 lbs., unmanured 4,104 lbs.; in 1909, manured 11,856 lbs., unmanured 8,541 lbs. The effect of acid phosphate for 4 seasons, 1910-1913, was shown in an increased net income of \$8.74 per acre. See also a previous note (E. S. R., 20, p. 473).

The management of blue-grass pastures, L. CARRIER and R. A. OAKLEY (*Virginia Sta. Bul.* 204 (1914), pp. 3-18, figs. 8).—The results in these experiments, conducted in cooperation with the Bureau of Plant Industry of this

Department, were measured in hay production and in gain in steers per acre that were pastured on the fields.

The results of 3 years' investigations have shown that "in the grazing experiments at Blacksburg, very little benefit was derived from the cultural treatment by disking and harrowing of blue-grass sod, indicating that this practice can not be recommended, at least without qualification.

"Heavy grazing gave 1,485 lbs. of gain on $2\frac{1}{2}$ acres of land in 3 years. Light grazing gave 838 lbs. of gain in the same time on an equal area. The heavily grazed field had a more even turf and was much freer from weeds than the lightly grazed field at the close of the 5 years' experiment. More blue-grass pastures are injured by undergrazing than by overgrazing. Heavy grazing is not practicable on pastures used for finishing fat cattle, since it is necessary to have a surplus of grass in order to do this. In this case it is recommended that those areas of pasture that are worst infested with broom sedge and other weeds be fenced and grazed down closely with young stock or sheep for 2 years, until the sod has improved; then the pasture can be used again to finish fat cattle.

"Very little, if any, advantage was secured by grazing cattle in different fields, alternately, as compared with continuous grazing on the same field. The practice of alternate grazing is of doubtful value.

"The results reported here were obtained on a limestone soil, and on a blue-grass red-top pasture. Whether the same results would be obtained on other types of soil or on other grasses, we can not say."

A series of plat experiments with fertilizers for weed eradication is in progress, and while not continued long enough to justify conclusions indicates that it will pay to use from 200 to 300 lbs. acid phosphate per acre every five or six years on ordinary blue-grass pastures.

The premier clover for North Carolina farmers, C. B. WILLIAMS (*North Carolina Sta. Circ. 7 (1913), pp. 5*).—Methods of culture, harvest, and grazing are given for crimson clover with notes on food value.

Crimson clover: Utilization, J. M. WESTGATE (*U. S. Dept. Agr., Farmers' Bul. 579 (1914), pp. 10, figs. 7*).—Continuing a previous publication (*E. S. R., 29, p. 633*), the author discusses the time of cutting, harvesting, spontaneous combustion, feeding value, and hair balls in considering crimson clover as a hay crop. Instances are noted in which this crop has been also successfully used as a soiling crop, as pasture, as a soil improver, and as a cover crop.

The growth of maize on cogon soil, A. F. NAVARRO (*Philippine Agr. and Forester, 2 (1912), No. 1-3, pp. 11-18*).—This paper reports the results of pot experiments in which cogon soils were leached with NH_3 , with water, burned, and treated with chemical sterilizers, chemical fertilizers, stable manure, and silkworm excrement. In order to discover a method of making this kind of soil productive, leaf measurements of the corn plants were taken daily and the following conclusions drawn:

"The application of lime to cogon soil is decidedly beneficial. The cogon soil used was deficient in nitrogen in whatever form. The application of manure, obtained from the stable or silkworm house, results in much more active growth. The sterilization of the soil is beneficial. Various methods of improving the growth of maize on cogon land have been found, but no practical solution of the problem undertaken."

Effects of applying commercial fertilizers to corn and cotton by different methods, C. B. WILLIAMS (*North Carolina Sta. Circ. 8 (1913), pp. 4*).—The data show an increased yield with both corn and cotton when fertilizer was applied in the furrow instead of broadcast. Fertilizer applied 3 times as deep as usual had no influence over ordinary depth with corn. With cotton the

greatest depth seemed to give larger yields when broadcasted, but had no influence when applied in the row.

Dividing the entire fertilizer application seemed to have no effect on the corn crop. On clay soils cotton yielded less when the application was divided, one-half applied at planting time and one-half July 1, but on fine sandy soil the reverse was noted.

"At the experiment station [clay soil] and Iredell farms [sandy clay soil] with cotton the best results were secured by using dried blood or cotton-seed meal and applying it all at planting in the row with the carriers of phosphoric acid and potash. At the Edgecombe farm [fine sandy loam] the highest yield of seed cotton on an average was secured where half of the nitrogen as dried blood was supplied in the row at planting with the phosphoric acid and potash and the remaining half of the nitrogen application reserved and made as a side dressing in the form of nitrate of soda about July 1. With corn at the Edgecombe farm, dividing the blood application and applying half with the other materials in the row at the planting of the corn and adding the other half as a side dressing about July 1 produced better results than applying all the blood at planting, or half of the nitrogen as blood at planting and the other half as nitrate of soda as a side application, or all nitrogen in the form of nitrate, half at planting with phosphoric acid and potash and the other half as a side application about the first of July. At the experiment station farm with corn, the best results were secured where half of the nitrogen as blood was applied with the potassic and phosphatic materials at planting and the other half of the nitrogen as nitrate of soda was used about July 1, and where all the nitrogen was supplied by nitrate of soda, half being applied at planting with other materials and half later as a side dressing alongside of the rows. At the Iredell farm dividing the blood application, or substituting nitrate in part or in whole for the blood and dividing the application of the nitrate of soda, did not produce as large yield as was secured where all the nitrogen as blood was applied with the phosphoric acid and potash at planting, or where the whole application—blood being the carrier of nitrogen—was divided, half being applied at planting in the row and the other half being put on as a side-dressing about the first of July."

The advisability of applying the entire fertilizer application at planting time on close texture soils is noted, while it may be divided, especially the nitrogen, on open soils and the first application made in an organic form and the second in a mineral form.

Effects of different fertilizing materials upon the maturity of cotton, C. B. WILLIAMS (*North Carolina Sta. Circ. 12 (1914), pp. 4*).—The effect of different carriers of phosphoric acid on the maturity of the cotton crop is noted as follows: With acid phosphate added to an application consisting of manure salt and dried blood, there was almost 13 per cent increase in seed cotton open of total crop at the first picking and more than 7 per cent increase at the end of the second picking. This application also gave 22 per cent more open at the first picking and 12 per cent at the end of the second picking than was secured from the no-fertilizer plat. Basic slag was found to hasten maturity even more than acid phosphate, as practically one-half of the cotton was open at the first picking on the plat which received this material in connection with manure salt and dried blood. This was about 12.5 per cent more than with acid phosphate. When this latter material was applied in the drill in connection with a ton of stable manure per acre, the effects upon hastening maturity were markedly reduced. Where high-grade finely ground phosphate rock was used at the rate of 274 lbs. per acre in connection with a ton of stable manure,

and both were applied in the drill, the percentage of total seed cotton opened at the first picking was about 35 per cent and at the end of the second more than 20 per cent greater than on an unfertilized plat adjacent.

As to the effect of different carriers of nitrogen when 78 lbs. of high-grade dried blood was added to acid phosphate and manure salt, the percentage of total crop open at the first picking was increased 3.3 per cent. Where one-half the blood was replaced an equivalent of nitrate of soda, used as a side dressing and applied early in July, the percentage of total crop open at the first picking was generally greater. When one-fifth of the nitrogen was derived from nitrate of soda and the remaining four-fifths from dried blood there was a rather marked increase in the percentage of total crop open at the first picking. When the nitrogen was derived from blood, one-half of which was applied at planting and the remainder as a side dressing, early in July, a larger percentage of total crop opened at the first picking than where nitrate of soda was divided and applied in the same way. With cotton seed applied in the drill at planting, the effect upon maturity was about the same with dried blood; while with stable manure there was a material increase in the percentage of total crop open at the first picking, but no difference at the second picking.

In regard to potash it is noted that as its proportion increased the percentage of total crop opened at the first picking gradually diminished, except for the year 1907, August of which had about 3 in. less rainfall than was normal.

For the types of soil studied, increasing from 200 to 800 or 1,200 lbs., the amount of the application per acre of a fertilizer analyzing 7 per cent available phosphoric acid, $2\frac{1}{2}$ per cent nitrogen, and $2\frac{1}{2}$ per cent potash, was accompanied generally by an increased percentage of the seed cotton open at the first picking.

The following tentative deductions are made relative to the influence of fertilizer upon the growth of cotton: "(1) Fertilization with ordinary applications of commercial fertilizers hastens maturity. (2) Sandy and sandy loam soils, whether fertilized or unfertilized, yield larger percentages of total cotton open at the first 2 pickings combined than do red clay soils. (3) Heavy phosphoric acid (N-P₂-K) fertilization on sandy and sandy loam soils, and medium heavy (N-P₂-K) applications of phosphoric acid from basic slag, have produced the largest percentages of total seed cotton open at the first picking. (4) Normal (N-P-K) fertilization yields on both sandy and red clay soils a larger percentage open at the first picking than high nitrogen (N₃-P-K) applications. (5) High nitrogen (N₃-P-K) applications generally yield on all types of soil studied larger percentages of total yield open at the first picking than high potash (N-P-K₃) applications. (6) Air-slaked lime alone does not hasten maturity, but when used in connection with commercial fertilizer it augments their influence in hastening maturity."

Local fertilizer experiments with cotton in northern Alabama in 1913, J. F. DUGGAR, J. T. WILLIAMSON, and L. J. HAWLEY (*Alabama Col. Sta. Bul. 175 (1914), pp. 3-47*).—"This bulletin records the results of 32 fertilizer experiments with cotton, conducted by the Alabama Experiment Station in the counties of the northern half of Alabama in 1913. Of these, 21 are regarded as conclusive.

In 17 of the conclusive experiments cotton-seed meal was apparently needed and profitable. In 12 experiments, phosphate was more effective than kainit; in 3 it was about equally as important as kainit; and in 2 tests, it was less effective than kainit, though apparently needed. Kainit was apparently needed to a greater or less extent in 16 tests.

"As a rule, the complete fertilizers were more profitable than cotton-seed meal, acid phosphate, or kainit applied singly or in pairs. The complete fertilizers were also the most profitable applications in 1911 and 1912 in north Alabama. In the general average it was more effective and more profitable in all

3 years to apply 100 lbs. of kainit in a complete fertilizer than to use 200 lbs. of kainit. The average of the conclusive experiments shows that in 1913 in north Alabama 100 lbs. of nitrate of soda applied after the plants were 6 in. high was more effective and profitable than was 200 lbs. of cotton-seed meal applied before planting."

Method of improving cotton by seed selection, R. Y. WINTERS (*North Carolina Sta. Circ. 3 (1913), pp. 4, fig. 1*).—Methods of selection through the third year in the plant-to-row system of crop improvement with cotton are given.

Buying cotton seed for planting, R. Y. WINTERS (*North Carolina Sta. Circ. 14 (1914), pp. 2*).—Cautions to buyers and suggestions for the home growing of cotton seed are given.

Long staple cotton in North Carolina, C. B. WILLIAMS (*North Carolina Sta. Circ. 13 (1914), pp. 3*).—Statistical notes are given with suggestions for growing and ginning upland long-staple varieties.

Growing Egyptian cotton in the Salt River Valley, Arizona, E. W. HUDSON (*U. S. Dept. Agr., Farmers' Bul. 577 (1914), pp. 8*).—In order to foster the cultivation of Egyptian cotton for the production of large yields of uniformly long and strong fiber this publication describes methods of preparing the land and irrigating and cultivating the crop which have proved successful in the Salt River Valley. The subjects taken up include selection, slope, and early preparation of land, preparation of the seed bed, planting, early cultivation, early irrigation, thinning, late cultivation, late irrigation, picking, ginning, and baling.

Cotton in the Dominican Republic (*Bul. Pan Amer. Union, 37 (1913), No. 5, pp. 677-680, figs. 2*).—This describes the methods of cultivation employed in a successful attempt to cultivate cotton under irrigation in the Yaque Valley, near Monte Cristi. The product of 350 acres is noted as being "extremely long, fine, and strong, averaging very even, and is graded as 1½-in. staple."

A comparative study of the composition of hops grown in different parts of the world, H. V. TARTAR and B. PILKINGTON (*Jour. Indus. and Engin. Chem., 5 (1913), No. 6, pp. 478-480*).—Previously noted from another source (E. S. R., 29, p. 534).

Species and varieties of malangas cultivated in Cuba, J. T. ROIG Y MESA ET AL. (*Estac. Expt. Agron. Cuba Bol. 21 (1913), pp. 26, pls. 11*).—This describes 11 varieties of *Xanthosoma* and *Colocasia*, with their chemical analyses and methods of cultivation.

The influences of subsoiling on yield, AUGSTIN (*Illus. Landw. Ztg., 33 (1913), No. 32, pp. 303, 304, figs. 2*).—Oats showed an increased yield of both straw and grain when the land was subsoiled to a depth of from 24 to 27.5 cm. (9.4 to 11.7 in.).

Notes on the culture of peanuts, E. LEPLAE (*Bul. Agr. Congo Belge, 4 (1913), No. 3, pp. 610-627, figs. 4*).—This gives notes on the peanut industry in the Belgian Kongo district and describes methods of cultivation in practice there.

Fertilizer experiments with potatoes, CLAUSEN (*Illus. Landw. Ztg., 33 (1913), No. 18, pp. 164-166, fig. 1*).—Results here noted give relative yields as follows: With complete fertilizer 100, without nitrogen 44, without phosphorus 76, without potash 67, with complete fertilizer plus lime 80, and without fertilizer 39.

In another experiment the peculiar influence of a deficiency of potash in the presence of lime-nitrogen and Thomas slag is noted. The relative yields were complete fertilizer 100, without nitrogen 76.4, without phosphorus 69.4, without potash 36, and unfertilized 41.5. The small yield without the potash is explained as a result of a physical action of the lime nitrogen and Thomas slag on the soil, which was of a light sandy nature.

Experimental study on varieties of potatoes for the periods 1910-11 and 1911-12, A. C. TONNELIER (*Buenos Aires: Min. Agr., 1913, pp. 147, figs. 147*).—Notes on about 500 varieties of potatoes include methods of cultivation, rainfall, and yield per hectare which ranged from 120 to 43,480 kg. This work was done at the experiment station.

Notes on potato growing (*Queensland Agr. Jour., 31 (1913), No. 6, pp. 343-348*).—There was an average gain of 2 tons, 5 cwt. of tubers per acre when the seed potatoes were allowed to sprout before planting. Certainty of a perfect stand by this method is noted as the chief gain factor. The heaviest yields were secured when the sets were planted 1½ ft. apart, in rows 3 ft. apart. Earthing up in rows running north and south gave an increase in yield of about 2 tons over earthing up in rows running east and west when potatoes were planted 3 ft. apart each way.

[Experiments with rape], BIELER (*Illus. Landw. Ztg., 33 (1913), No. 90, p. 815*).—This paper reports results of variety tests of rape for the years 1906, 1908, 1910, and 1911 and notes a correlation between rainfall and vegetation period of rape as follows: 238 mm. and 48 days, 196 mm. and 39 days, 208 mm. and 57 days, and 123 mm. and 39 days.

In a culture experiment soil preparation by plowing 8 in. and subsoiling 12 in. deep gave a greater yield of rape seed, while plowing to the depth of 14 in. without subsoiling gave larger yields of straw than other methods, including plowing to the depth of 8 in. without subsoiling.

Production of rape seed near Shanghai, A. P. WILDER (*Daily Cons. and Trade Rpts. [U. S.], 16 (1913), No. 300, p. 1435*).—This notes the production of rape seed in the Loongwah district, China, where yields reach 1,600 lbs. per acre. The manufacture of oil is also noted.

The cultivation of rice in Uruguay, T. KESSISSOGLU (*Rev. Min. Indus. Uruguay, 1 (1913), No. 5, pp. 45-112, figs. 42*).—Aside from methods of cultivation employed in Uruguay this gives botanical characteristics, history and classification of rice, and some notes on results of variety and cultural tests at the National Institute of Agronomy at Montevideo, between October, 1912, and April, 1913.

The composition of sugar beets grown in the northern counties, S. H. COLLINS and A. A. HALL (*Jour. Soc. Chem. Indus., 32 (1913), No. 19, pp. 929-931*).—The tabulated results of analyses of the sugar-beet crops of 1911-12 under various manurial treatments are given. The sugar content ranged from 12.45 to 16.85 per cent.

Sugar-beet seeds, SCHRIBAUX (*Bul. Soc. Agr. France, 1913, May 1, pp. 322-326*).—This paper discusses methods of placing valuations on beet seeds of different sizes based on germination tests. A scale of seed weights and germinative ability, based upon the author's experiments, is presented.

Sugar beet seeds, M. A. DEMOLON (*Bul. Soc. Agr. France, 1913, May 1, pp. 326-328*).—In studying the influence of the size of beet seeds on the product very small (100 balls=0.4 gm.), small (100 balls=0.8 gm.), medium (100 balls=1.6 gm.), and large seeds (100 balls=2.22 gm.) yielded 354, 330, 390, and 371 gm., respectively.

Experiments in selection of sugar cane, A. H. ROSENFELD and T. C. BARBER (*Rev. Indus. y Agr. Tucumán, 4 (1913), No. 5, pp. 200-204*).—The average results of 3 years' work of selection gave a yield of 48,378 kg. per hectare as compared with 39,732 kg. for unselected canes.

Experiments on thinning sugar cane in the row, A. H. ROSENFELD and J. A. HALL (*Rev. Indus. y Agr. Tucumán, 4 (1913), No. 4, pp. 150-152*).—The results showed a yield of 41,653 kg. per hectare without thinning as compared with 38,326 kg. for the thinned area.

Mutation in tobacco, H. K. HAYES and E. G. BEINHART (*Science, n. ser.*, 39 (1914), No. 992, pp. 34, 35).—This paper notes the appearance of a new type of tobacco plant, discovered in a crop of "Cuban" tobacco in Connecticut that had been selfed for five generations. The new type occurred in about one in a million from the 1910 seed crop and bore from 62 to 80 leaves per plant, about 50 per cent more than the normal type, and thus far has bred true, thus indicating that mutation must have taken place after fertilization.

The inheritance of certain characters of beets and turnips.—II, Turnips, B. KAJANUS (*Ztschr. Pflanzenzücht.*, 1 (1913), No. 4, pp. 419-463, pls. 3, figs. 2).—This continues work previously noted (E. S. R., 29, p. 832).

From the results of crossing turnips of different colored flesh, of different shape of roots, and of different leaf characters of several species, the author concludes that form is a constant factor; that violet red color (anthocyanin) is either stabile or labile; that dark red is dominant over light red or colorless; that there are two types of green color, one of chlorophyll origin at the root crown, and the other a greenish tint accompanying the yellow topped roots; that the color of the yellow topped turnips is recessive with green and red; that the yellow flesh color is recessive with the white flesh; that the orange-yellow flower color and yellow flesh, and lemon-yellow flower color and white flesh, are correlated; that smooth and hairy characters of the leaves form a Mendelian pair; and that the side tubercles on the roots of the hybrids are probably due to bacteria infection.

Hairy vetch, C. B. WILLIAMS (*North Carolina Sta. Circ.* 10 (1913), pp. 5, fig. 1).—Cultural notes, together with comments on its use for soil improvement, pasturage, and food value, are given.

Notes on wheat, J. CASCÓN (*Bol. Agr. Téc. y Econ.* 5 (1913), No. 59, pp. 1013-1024).—A study of the effect of climatic factors on the yield and baking qualities of wheat showed that the rainfall was very important in connection with clean cultivation and the use of nitrate of soda as a fertilizer.

The methods employed in testing grass seeds, G. H. PETHYBRIDGE (*Jour. Econ. Biol.*, 7 (1912), No. 2, pp. 41-49, fig. 1).—The author believes that the method used by the Irish Seed-Testing Station, in which the seed containing no caryopsis is not counted as an impurity, gives nearer the correct value of the seed sample than the method used on the Continent that attempts to discard the empty seeds and bases the germination test on the full seeds only.

Shall seed be tested in artificial media or in soil? L. HILTNER (*Prakt. Bl. Pflanzenbau u. Schutz, n. ser.*, 11 (1913), Nos. 7, pp. 85-91; 8, pp. 104-106).—From a review of investigations on the subject the author concludes that brick dust is the most practical medium for seed-testing stations, but that the ideal way would be to use soil from each field where the seed is destined to be planted in order to determine the true agricultural value.

Germination tests, G. H. TRUE ET AL. (*Nevada Sta. Rpt.* 1913, pp. 23, 24).—Results of testing seed for growers, dealers, and farmers in the State led to the conclusion "that the presence of either brown or green seeds lessens the value of [alfalfa] seed from a commercial standpoint. Our many tests of western-grown alfalfa seed have shown that in practically all samples there is quite a large percentage of hard seeds that will not germinate in even 28 days. Dry-farm alfalfa seed contains a larger percentage of hard seeds."

Seed inspection (*Maine Sta. Off. Insp.* 52 (1913), pp. 93-104).—This publication gives the chief requirements of the Maine seed law, discusses the seed industry in the State, and gives results of inspecting 1,211 samples of seeds during 1913.

Culture and weed extermination experiments at Warsaw in 1912, K. STÖRMER (*Deut. Landw. Presse*, 40 (1913), No. 37, pp. 445, 446).—The best

results are reported to have been obtained by the use of a ridging implement with oats and barley as compared with harrowing or hand cultivating.

Spraying with a 25 per cent solution of iron sulphate when wild mustard had put out its third leaf proved destructive to it in a field of oats.

On the castration of plants, E. HECKEL (*Rev. Sci. [Paris]*, 51 (1913), I, No. 8, pp. 225-228).—The author reports increases in the sugar content of sorghum and maize plants, in some cases as much as 133 per cent, after complete or partial castration by removing both male and female organs or only the female organs.

Under what conditions is the theory of probabilities applicable in agricultural experiments? B. BAULE (*Fühling's Landw. Ztg.*, 62 (1913), No. 5, pp. 160-180, figs. 8).—This is a mathematical discussion based upon Gauss' law of division, applied to field work.

HORTICULTURE.

A market garden and truck survey of the Ohio and Kanawha River Valleys in West Virginia, A. L. DACY (*West Virginia Sta. Bul.* 143 (1914), pp. 34, figs. 13).—The author here presents the results of a survey by himself and R. R. Jeffries of the vegetable growing industry in the Ohio and Kanawha river valleys, including also several miles of bottom lands on a number of creeks. The survey was conducted as a basis for the further study of the problems affecting the market gardening and trucking industry in the State. The data discussed deal with the extent of the industry, cultural practices, and methods of marketing.

The survey showed that vegetable growing is already of considerable magnitude in the Ohio and Kanawha River Valleys and that the average returns are much greater than those from the ordinary farm crops. While it is believed that better cultural methods would yield an increased amount of vegetables, the chief hindrance to the development of the industry appears to be a scarcity of labor to farm the land.

The home vegetable garden, T. C. JOHNSON and F. E. MILLER (*Virginia Truck Sta. Bul.* 10 (1914), pp. 207-266, figs. 9).—A practical treatise on vegetable growing with special reference to the home garden. Introductory considerations deal with the general principles of vegetable growing. Cultural details are then given for growing various kinds of vegetables, including muskmelons and watermelons, adapted for growing in Virginia.

Tomato investigations, J. G. BOYLE (*Indiana Sta. Bul.* 165 (1913), popular ed., pp. 3-8, figs. 3).—A popular summary of the bulletin previously noted (*E. S. R.*, 29, p. 434).

Report on foreign markets for Oregon fruit and laws governing importations, S. F. LAMB (*Ann. Rpt. Oreg. State Hort. Soc.*, 4 (1912), Sup. [pub. 1914], pp. 89).—A compilation of data and information secured from consular reports, showing the status of various foreign markets with reference to the utilization of fresh, dried, and canned fruits. Statistics of fruit imports of foreign countries, together with laws and regulations of foreign countries concerning American fruits, are also given.

Fruit culture and cold storage, P. BERGÉS (*An. Soc. Rural Argentina*, 48 (1914), No. 1, pp. 36-53, figs. 11).—This comprises a statistical study of the production, consumption, and commerce of fruits in Argentina, together with suggestions relative to means of extending the fruit industry in which special attention is given to the employment of precooling and refrigeration in the storage and transit of fruits.

The establishment of an apple orchard, A. J. FARLEY (*New Jersey Stas. Circ. 31, pp. 3-8*).—Practical instructions are given for the establishment and care of a young apple orchard during the first season.

Cost of an apple orchard to bearing age, M. C. BURRITT (*Rural New Yorker, 73 (1914), Nos. 4245, p. 344; 4246, p. 406; 4247, p. 468*).—The author outlines his methods of keeping records and presents data showing the cost of growing to bearing age of two particular apple orchards, one 11 years old filled one way with plums and the other 6 years old filled both ways with peaches.

He concludes from his own experience that by the use of tree fillers and intercrops an orchard at 10 years of age can be made practically selfsupporting. At the same time the opinion is advanced that on the average the net profits from orchards during their entire life time do not greatly exceed the net returns from ordinary field crops. The author calls attention to the importance of keeping accurate records of orchards for their entire life time in order to avoid false ideas of profits and to steady land values.

Apples on Long Island, P. E. NOSTRAND (*Rural New Yorker, 73 (1914), Nos. 4245, p. 341; 4246, p. 403; 4247, p. 443; 4248, p. 485*).—In this article the author briefly describes his experience in growing apples and gives notes on the character and condition of a large number of varieties tested in his orchard. In most cases twenty or more trees of each variety were planted.

The apple in Pennsylvania: Varieties, planting, and general care, J. P. STEWART (*Pennsylvania Sta. Bul. 128 (1914), pp. 109-136, figs. 11*).—This bulletin contains practical directions for the planting, care, and management of an apple orchard, including also a descriptive list of varieties adapted for planting in various sections of Pennsylvania. The subject matter is based largely on the station's experiments and observations in orcharding which have been in progress for a number of years.

Tillage and sod mulch in the Hitchings orchard, U. P. HEDRICK (*New York State Sta. Bul. 375 (1914), pp. 55-80, pls. 7*).—This is the second report on the station's comparative tests of tillage and sod mulch in apple orchard culture. The first report gave the results secured for the first five years in an orchard in the apple belt of western New York, and tillage was found to be the better treatment (*E. S. R., 21, p. 238*). The experiment described in the present report has been carried on for a period of ten years in the Hitchings orchard near Syracuse, which orchard has become famous because, contrary to the usual practice of tillage followed by a cover crop, the sod mulch system, commonly known as the Hitchings method, has been used with great success.

The tests were made in a level valley plat of 2-year-old trees, in a plat of 9-year-old trees on the lower part of a rolling hill, and in a plat of 10-year-old trees higher up on the hillside. In each plat half of the land was in tillage and half in sod. The tilled plats were plowed early in the spring and cultivated from seven to eleven times, a cover crop, usually of clover, following. In the sod plats was a mixed growth of orchard grass and blue grass, the grasses being mowed usually about the middle of June and left as they fell to form the "sod mulch." All plats were given identical care except as to the above soil treatment.

The young orchard matured so slowly that no yield data were secured. In the bearing sections the trees in sod bore an average of a little less than 4 bu. per tree per year, or about $\frac{4}{5}$ bu. per tree more than the trees under tillage. Year in and year out there was little difference in size between the apples in the two sections. In the young orchard the trees grew somewhat better and more uniformly on the tilled plat, while in the bearing sections the trees appeared to thrive as well under either method of culture. The cost of tillage ranged from \$11.22 per acre on the level plat to \$24.33 per acre on the rough

hill plat, or an average of \$16.28 per acre for tilling the 3 plats, whereas mowing on the 3 sod plats averaged only 72 cts. per acre.

No analyses were made of the soil in these plats at the beginning of the experiment, but analyses made at the end of the 10-year period indicate that tillage has tended to deplete the soil of humus and nitrogen more than is good for apple land. These results, combined with the author's observations in recent years, led to the conclusion that cover crops alone in many cases are not sufficient to supply tilled orchards with humus and nitrogen, and that the deficiency must be made up by an occasional application of stable manure, or by occasionally keeping the orchard in clover sod for a season.

The author attributes the superiority of the sod-mulch method in the hill sections of the Hitchings orchard to the existence of a deep soil and hillside seepage which furnishes an abundance of moisture for both trees and grass. Summing up these investigations as a whole tillage is believed to be unquestionably the best method of caring for the majority of the apple orchards in New York. On the other hand, the Hitchings method of sod-mulching apple trees may be used advantageously in steep hillside orchards inclined to wash badly under tillage, on land which is too rocky to be readily tilled, on soils having considerable depth and retentive of moisture, and under certain economic conditions under which it seems desirable to make a larger acreage in sod counterbalance a greater productiveness under tillage, thereby bringing the net income to the same level.

Sod mulch sometimes a success, F. H. HALL (*New York State Sta. Bul. 375 (1914)*, popular ed., pp. 3-8).—A popular edition of the above.

Ten years' profits from an apple orchard, U. P. HEDRICK (*New York State Sta. Bul. 376 (1914)*, pp. 81-90, pl. 1).—The author here presents data on the cost of various operations, yields, and selling prices for a period of 10 years for an orchard in which the station has carried on a comparative test of sod mulch and tillage (*E. S. R.*, 21, p. 238). The data, as far as possible, are given for three units, the barrel of apples, the tree, and the acre.

Summarizing the results for the whole period, the average annual yield of the orchard has been 79.2 bbl. of firsts and seconds per acre and 37.6 bbl. of culls or cider stock per acre. The firsts and seconds cost \$1.29 to produce and sold for \$2.60, leaving a profit of \$1.31 per barrel or \$103.49 per acre. There was a loss of \$7.89 per acre on the culls, making the average net profit per acre \$95.60. The author points out that the cost of production is somewhat high, since the State can not do work as cheaply as an individual. On the other hand, the extra cost has been offset by the good condition of the orchard at the end of the experiment. It is believed that the profits are much greater than those from the average plantation in New York.

Wholesale prices of apples and receipts of apples in New York City for twenty years, H. B. KNAPP (*New York Cornell Sta. Circ. 22 (1914)*, pp. 13-19).—This comprises a statistical study of receipts and wholesale prices of apples during the 20-year period 1893-1913. The receipts are shown for each year and month. The average prices are given by years and months and also the average prices of different varieties of apples. A comparison is made of the rise in price with the changes in price of other products.

In the last 10 years apples show an increase in price of 9½ per cent as compared with the previous 10 years. In the same period the price of cotton has increased 64 per cent, corn 42 per cent, hay 33 per cent, oats 38 per cent, potatoes 28 per cent, and wheat 37 per cent.

Our best German varieties of fruits.—I, Apples (*Unsere besten deutschen Obstsorten. Band I: Aepfel. Wiesbaden [1914]*, pp. 47, pls. 41).—This is the first of a 3-volume series describing the more important orchard fruits of Ger-

many. The present volume contains color plates of 41 varieties of apples, each plate being accompanied by a detailed description of the tree and fruit and information relative to its adaptability to soil and climate, productivity, ripening period, etc.

On the breeding of wine grapes, DERN (*Beitr. Pflanzenzucht, No. 4 (1914), pp. 37-57*).—In this paper the author shows in a general way what has been accomplished in the improvement of wine grapes by means of selection alone, points out many difficulties which will be met in the attempt to improve grapes by breeding, and outlines some of the principal points which the breeder should have in mind in improving wine grapes.

The effects of frost on grafted vines in the Vaudois vineyards, H. FAES and F. PORCHET (*Prog. Agr. et. Vit. (Ed. l'Est-Centre), 35 (1914), No. 13, pp. 391-397*).—In order to obtain some light on the opinion expressed in many sections that European grapes grafted on American vines are more resistant to frost conditions, the authors made observations on a number of varieties, both grafted and ungrafted, in Vaudois vineyards after the spring frosts in 1913. From the data secured they conclude that the seeming superiority of the grafted vines is due to their young age as compared with the ungrafted vines rather than to any greater natural resistance to frost.

On the grafting of wine grapes, J. BERNATSKY (*Jahresber. Ver. Angew. Bot., 11 (1913), pt. 1, pp. 60-79*).—The author here calls attention to the failures which have frequently resulted in the attempt to reconstitute European vineyards by grafting on American stocks and discusses in detail the selection of stocks and scions, the principles of grafting, nursery practices, and planting operations with special reference to the successful reconstitution of vineyards.

Report on the wine and fruit industries of Argentina, MACKIE (*Diplo. and Cons. Rpts. [London], Misc. Ser., No. 687 (1914), pp. 22*).—A general survey of the wine and fruit industries of Argentina, prepared under the direction of the British consular service.

A résumé of investigations on the genus *Rubus*, B. LIDFORSS (*Ztschr. Induktive Abstam. u. Vererbungslehre, 12 (1914), No. 1, pp. 1-13*).—This comprises a posthumous manuscript by the author and here presented by W. Johansen dealing with his hybridization experiments with the genus *Rubus*.

[Strawberries and tomatoes at Wisley, 1913] (*Jour. Roy. Hort. Soc. [London], 39 (1913), No. 2, pp. 401-414*).—Descriptive notes are given on 76 varieties of strawberries and some 90 varieties of tomatoes tested at the Wisley Gardens in 1913.

Tropical and subtropical fruits in California, F. W. POPENOE (*Jour. Roy. Hort. Soc. [London], 39 (1913), No. 2, pp. 330-337, pls. 5*).—This comprises horticultural notes on those tropical and subtropical fruits in California which have become so well established as to be offered by the trade. An additional list is given of fruits and plants many of which have not as yet passed beyond the experimental stage.

The atemoya, a new fruit for the Tropics, P. J. WESTER (*Philippine Agr. Rev. [English Ed.], 7 (1914), No. 2, pp. 70-72, pl. 1*).—As a result of his pollination experiments with Annonas (*E. S. R., 24, p. 341*) the author secured a number of hybrid forms one of which, a cross between the sugar apple (*Annona squamosa*) and the cherimoya (*A. cherimola*), has fruited for the first time. This fruit, which has been given the name atemoya, is practically identical with the prominent carpelled cherimoyas and appears to combine to a certain degree the adaptability of the sugar apple to grow well in low altitudes near the equator with the excellent flavor of the subtropical cherimoya which does not succeed well in such situations.

Banana culture, O. W. BARRETT (*Philippine Agr. Rev.* [English Ed.], 7 (1914), No. 2, pp. 58-64, pl. 1).—This circular comprises a brief practical treatise on banana culture with special reference to Philippine conditions.

Practical cacao planting in Grenada, W. M. MALINS-SMITH (*West India Com. Circ.*, 28 (1913), Nos. 379, pp. 153-155; 380, pp. 175-177, figs. 2; 381, pp. 198-200, fig. 1; 382, pp. 225, 226, fig. 1; 383, p. 246; 384, pp. 270, 271; 385, pp. 293-296; 386, pp. 317, 318; 387, pp. 343-345; 388, pp. 365-367; 389, pp. 393, 394, fig. 1; 390, pp. 416-419; 391, pp. 438-440; 392, pp. 461-463; 393, pp. 484-487; 394, pp. 508-510; 395, pp. 533-536; 396, pp. 557-560, pl. 1, figs. 3).—A series of articles comprising as a whole a treatise on cacao planting and cultivation with special reference to conditions in Grenada.

Cultivation of the coconut palm in Burma, A. M. SAWYER (*Dept. Agr. Burma Bul.* 11 (1914), pp. 9, pls. 7).—A brief practical treatise on the establishment, care, and maintenance of a coconut plantation.

Hybridity and hybridization among edible citrus, L. TRABUT (*Jour. Agr. Trop.*, 14 (1914), No. 153, pp. 65-69).—The author calls attention to various natural variations and artificial crosses which occur among citrus fruits, points out the stability and superiority of certain hybrid forms, and suggests the utilization of hybridization for the improvement of orange groves.

The world's production and commerce in citrus fruits and their by-products, F. O. WALLSCHLAEGER (*Citrus Protect. League Cal. Bul.* 11 (1914), pp. 3+95+7).—This comprises a statistical account of the production and commerce in citrus fruits and their by-products for the various citrus producing regions of the world. The subject matter is based upon data collected by various branches of the United States Government, together with data and information which has accumulated in the office of the California Citrus Protective League.

The citrus fruit crop of the world is equal to about 100,000,000 boxes or 250,000 carloads of California size. The five most important countries in the order of their production are the United States, Spain, Italy, Japan, and Palestine. The United States and Spain each produce approximately 30 per cent and Italy 25 per cent of the total crop.

The kumquat (*Citrus japonica*), TRABUT (*Bul. Sci. Pharmacol.*, 21 (1914), No. 3, pp. 129-137, figs. 4).—A monograph on the kumquat with reference to its botany, distribution, varieties, and culture.

Notes on Siamese pomelos, H. H. BOYLE (*Philippine Agr. Rev.* [English Ed.], 7 (1914), No. 2, pp. 65-69, pls. 5).—This comprises horticultural notes on pomelos and some other fruits observed during a visit to the seedless pomelo plantations of Siam.

Tulips, J. JACOB (*London and Edinburgh*, [1912], pp. XI+116, pls. 8).—A popular manual of tulip culture both under glass and in the open, including information with reference to propagating and breeding tulips, diseases, and selection of varieties. Some of the principal incidents in the history of tulips commencing with the year 1554, including bibliographic references, are also given.

Violas at Wisley, 1913 (*Jour. Roy. Hort. Soc.* [London], 39 (1913), No. 2, pp. 381-400).—Brief descriptive notes are given of some 276 varieties of violas and pansies tested at the Wisley Gardens in 1913.

The "Illinois way" of beautifying the farm, W. MILLER (*Illinois Sta. Circ.* 170 (1914), pp. 36, figs. 113).—This circular treats of beautifying the farm by the judicious selection and arrangement of shrubs, flowers, vines, and trees. Special attention is directed to the utilization of trees and shrubs that grow wild in Illinois. Consideration is given to plantings for windbreaks, screening unsightly objects, creating desirable views from the house, foundation

plantings, lawn borders and shrubbery, flower gardens, and borders of native plants. A plea is made for the establishment of permanent country homes with surroundings in which the local color shall be restored and preserved.

The text is fully illustrated and lists are given of plants for special needs.

Insecticide and fungicide inspection (*Maine Sta. Off. Insp. 54* (1913), pp. 141-148).—Analyses are reported of insecticides and fungicides examined by the station during the year. They include samples of arsenate of lead, Paris green, arsenite of zinc paste, Bordeaux mixture, lime-sulphur solutions, water soluble arsenical compounds, and miscellaneous insecticides.

FORESTRY.

A handbook of forestry, W. F. A. HUDSON (*Watford, England, [1913], pp. 82, figs. 25*).—A short treatise on the general principles of practical forestry with special reference to English estates. The work is intended primarily for the general estate manager, whose duties usually include the care and management of woodland.

The cultivation of osiers and willows (*Bd. Agr. and Fisheries [London], Misc. Pubs. 18* (1913), pp. 33, pls. 6).—A popular cultural treatise including also information relative to varieties and the preparation of willows for market.

The intensive management of high mountain forests, A. KUBELKA (*Die intensive Bewirtschaftung der Hochgebirgsforste. Vienna and Leipsic, 1912, pp. VIII+86*).—A treatise on forest management in high mountain regions in which special consideration is given to the application of Wagner's principles of spacial arrangement in forests (E. S. R., 20, p. 645) to this type of forestry.

Other important phases discussed include the development of a permanent system of log roads, the preparation and execution of working plans, various systems of working, and silvicultural practices.

The forests of the western Caucasus, E. A. RÜBEL (*Jour. Ecology, 2* (1914), No. 1, pp. 39-42, pls. 3).—This comprises a brief phytogeographical sketch of the forests of the western portion of the Caucasus range.

DISEASES OF PLANTS.

International collaboration looking to control of pests and diseases of plants, J. RITZEMA BOS (*Tijdschr. Plantenziekten, 19* (1913), No. 6, pp. 153-235).—This is a general review of plant pests and diseases, losses therefrom, and means in use or available for control thereof, in various countries or regions, and urging international cooperation to that end.

Report on plant diseases in Ohio for 1912, A. D. SELBY (*Ohio State Hort. Soc. Ann. Rpt., 46* (1913), pp. 100-110).—According to the author, the year 1912 was characterized by low temperatures during the winter months, followed by a cold belated spring. The effect of low temperatures and winter injury to trees and shrubs is described at length, after which brief notes are given on the fungus diseases reported upon the principal horticultural, vegetable, and field crops of the State.

Mycological notes, A. C. TUNSTALL (*Indian Tea Assoc., Sci. Dept. Quart. Jour., 1913, No. 4, pp. 108, 109*).—The author describes the sleeping disease of tomato due to *Fusarium lycopersici*, which has made its appearance in India, and also gives an account of some investigations on red rust. It was found that fruiting bodies of *Stilbum nanum* resemble those of the alga *Cephaleuros mycoidea*, but they have no connection with the true red rust of tea.

Plant sanitation in Malaya (*India-Rubber Jour.*, 47 (1914), No. 7, pp. 19, 20).—The text of the enactment of 1913 for the protection of trees, plants, and cultivated products in the Federated Malay States is given.

Soil alkalinity and plant chlorosis, J. CROCHETELLE (*Jour. Agr. Prat.*, n. ser., 26 (1913), Nos. 47, pp. 657, 658; 49, pp. 725-727).—Results of experiments in heavy liming of sandy soil bearing colza are held to show that the assimilation of phosphoric acid is hindered by the presence of much lime, and that this latter condition is in causal relation with chlorosis on alkaline soils.

Biological treatment of diseases in plants, C. VON TUBEUF (*Naturw. Ztschr. Forst u. Landw.*, 12 (1914), No. 1, pp. 11-19).—*Pinus lambertiana*, already infected with blister rust (*Cronartium ribicolum*), was dusted with conidia of *Tuberculina maxima* late in May, 1913. Early in November the latter fungus was found to have developed considerably and to have dusted with conidia the neighboring pustules of the former. Observations are to be continued with the hope that *T. maxima* may prove able to weaken and check *C. ribicolum* at least on the larger pines.

A bibliography is appended.

Chemical means for combating pests of agricultural plants, E. MOLZ (*Fühling's Landw. Ztg.*, 62 (1913), No. 23, pp. 822-838).—This is a general review of numerous chemical preparations and their employment and value as protection against vegetable or animal parasites during recent years, as reported by various investigators.

Some factors influencing the efficiency of Bordeaux mixture, L. A. HAWKINS (*Prog. Agr. et Vit. (Ed. l'Est-Centre)*, 35 (1914), Nos. 3, pp. 72-78; 5, pp. 142-146; 7, pp. 210-215).—The substance of this article has already been noted from another source (*E. S. R.*, 28, p. 537).

Resistance of grains to parasitic fungi, N. VAVILOV (*Trudy Selektiv. Stantsii Moskov. Selsk. Khoz. Inst. (Arb. Vers. Stat. Pflanzenzüch. Mosk. Landw. Inst.)*, 1 (1913), No. 1, pp. 1-108, pls. 3).—This is an account of studies regarding susceptibility of wheat and oat varieties to fungus attack; also regarding the relation of their disease resistance to structure and environment and the value of these characters as criteria for classification. The results are given in considerable detail.

Parasitic injury to winter grains, K. STÖRMER and R. KLEINE (*Illus. Landw. Ztg.*, 33 (1913), No. 31, pp. 296-298, fig. 1).—This is substantially the same as an article previously noted (*E. S. R.*, 29, p. 446). In that notice, the strength of the corrosive sublimate solution recommended, which was by mistake given as 0.001 per cent, should have been given as 0.1 per cent, or 1:1000.

Smut protection and the influence of cropping time on output and health of crop, H. C. MÜLLER, E. MOLZ, and O. MORGENTHALER (*Landw. Vers. Stat.*, 33 (1913), No. 3-4, pp. 211-220).—Giving tabulated results of studies on summer wheat and barley, the authors show that late planting decreased the attack of *Helminthosporium* on barley, but increased that of loose smut on wheat; and that attack on the latter grain by the wheat fly (*Chlorops taniopus*) was enormously increased by planting a few weeks later. It is stated also that later planting of summer wheat decreased sensibly the germinability of the resulting seed grain and that the grain from stalks infested by *Chlorops* showed lower germinability than did wheat from normal grains.

Studies on the biology of loose smut of barley, J. BROILLI and W. SCHIKOREA (*Ber. Deut. Bot. Gesell.*, 31 (1913), No. 7, pp. 336-339, fig. 1).—Pursuant to previous work of Broilli (*E. S. R.*, 24, p. 647), the authors made a study of *Ustilago hordei nuda* in embryos of grains selected from barley artificially inoculated.

Of 21 plants grown from seeds suspected to be infected 13 developed loose smut and from these the fungus was cultivated, proving to be *U. hordei nuda*. The work is being carried forward with a view to the possibility of developing a variety resistant to loose smut.

Three cases of monstrosity in maize, L. DE LA BARREDA (*Bol. Dir. Gen. Agr. [Mexico], Rev. Agr., 2 (1912), No. 9, pp. 803-808, pl. 1*).—The author gives a description and discussion of three ears of maize presenting curious anomalies of growth, two specimens showing attack by *Ustilago maydis*.

The downy mildew of maize, E. J. BUTLER (*Mem. Dept. Agr. India, Bot. Ser., 5 (1913), No. 5, pp. 275-280, pls. 2*).—The author describes a disease of maize due to *Sclerospora maydis*, which is said not to have been previously known in India. The fungus was first discovered in Java and made its appearance on the Pusa Farm in 1912. The presence of the fungus becomes apparent before the plants have attained full growth. The lower leaves are usually normal, but the upper part is chlorotic.

For the control of this disease prevention of the formation of oospores is recommended, and for this purpose the removal and destruction of all diseased plants before their wilting is advised.

Observations on the downy mildew (*Sclerospora graminicola*) of pearl millet and sorghum, G. S. KULKARNI (*Mem. Dept. Agr. India, Bot. Ser., 5 (1913), No. 5, pp. 268-274, pls. 2*).—According to the author this fungus is found on pearl millet, sorghum, Italian millet, and teosinte. The effect of the fungus on pearl millet and on sorghum is described at some length.

Cross-inoculations with cultures of the fungus taken from both the hosts failed to produce infection. This is believed to have been due possibly to the fact that infection occurs only at the seedling stage or that there may be biological forms of the same species. The author is led to believe, from his investigations, that the two fungi are distinct and he draws up contrasting characters for the different varieties. He states that the conidia lose their vitality after a few hours and that it is as yet unknown how the fungus passes from year to year. A test made of the seed to determine whether they might carry the fungus resulted in the production of sound plants.

Foot disease of wheat, E. ROBERT (*Jour. Agr. Prat., n. ser., 26 (1913), No. 49, pp. 715, 716*).—It is stated that foot disease of wheat is serious following a mild, moist winter, resulting in a somewhat rank vegetative growth, and that this disease is also favored by short term rotation, heavy seeding in the drill, and varietal precocity of growth.

Stalk disease of wheat, A. BOIJEAU (*Prog. Agr. et Vit. (Ed. l'Est-Centre), 35 (1914), No. 8, pp. 242-247*).—Noting the considerably increased intensity of foot disease of wheat in 1913, the author states that certain factors appear to be influential in this connection, as mild and moist winters, incomplete soil fertility or wrong time of manuring, running the ground to wheat too constantly year after year, and bad physical condition of the soil in the spring.

Employment of later maturing varieties, as far as permitted by climatic conditions, is suggested.

Pythium debaryanum, E. J. BUTLER (*Mem. Dept. Agr. India, Bot. Ser., 5 (1913), No. 5, pp. 262-267, pl. 1*).—A description is given of this fungus, which is said to be of recent recognition in India. In the article the author describes the attack on seeds of castor beans which had been sown in unsterilized soil.

Potato diseases, E. FOEX and C. PERRET (*Vie Agr. et Rurale, 3 (1914), No. 5, pp. 129-134, figs. 2*).—This is a condensed review of recent studies reported by various authors on leaf curl, leaf roll, blackleg, etc., of potato, and their alleged causes, in connection with preventive or remedial measures tested or proposed. A bibliography is given.

Potato diseases in New Jersey, M. T. COOK and G. W. MARTIN (*New Jersey Stas. Circ.* 33, pp. 24, figs. 13).—A description is given of some of the more common diseases of potatoes, with suggestions for their control.

Leaf roll of potato, O. APPEL and O. SCHLUMBERGER (*Mitt. K. Biol. Anst. Land u. Forstw.*, No. 12 (1912), pp. 14, 15).—No conclusions are drawn from the variable relations observed between weight of crop obtained and weight of tubers planted in case of seed potatoes showing leaf roll. The experiments have been continued.

Colocasia blight caused by *Phytophthora colocasiæ*, E. J. BUTLER and G. S. KULKARNI (*Mem. Dept. Agr. India, Bot. Ser.*, 5 (1913), No. 5, pp. 233-261, pls. 4).—The authors describe a widely distributed disease of Colocasia, or taro.

The disease is said to be found practically wherever the plant is cultivated and also occurs on wild specimens in moist localities. In severe attacks all the leaves may be destroyed and the plant killed, or in milder attacks the older leaves are more or less destroyed by the fungus, in which case the corms may be entirely lacking or if any are formed they will be small and shrunken. Infection of the corm was noticed comparatively recently, while the attack on the leaves had been known for a number of years. On the corm a dry rot of rather soft texture is formed. Microscopic characters of the fungus, results of inoculation experiments, etc., are given. From the inoculation experiments it is found that Colocasia is the only representative of the family Araceæ that serves as a host for this fungus. The systematic relationship of the fungus is discussed at some length, after which suggestions are given for prevention of its attack. The means suggested include spraying, removal and destruction of spotted leaves, and selection of sound corms for planting.

The mosaic disease of the tomato and related plants, L. E. MELCHERS (*Ohio Nat.*, 13 (1913), No. 8, pp. 149-175, figs. 3).—The author presents a review and bibliography of the essential literature of mosaic disease of plants and gives brief description of his investigations on the mosaic disease of tomato and potato.

The disease is said to be quite prevalent on tomatoes, especially when grown under glass, and frequently appears in Ohio on the main crops. It was noticed in February, 1913, on potatoes grown in the greenhouse, the first symptoms appearing when the plants had attained a height of approximately 18 in. The disease appeared spontaneously without pruning, mutilation, or artificial stimulation, but thus far has not been observed on potatoes growing in the field. Histological studies were made of the tissues and no characteristic abnormalities were observed on the tomato. In potato leaves sections of the mottled areas were readily distinguished by the shape and size of the palisade cells. Their length was from one-half to one-third that of normal cells and their thickness was usually somewhat increased. The spongy parenchyma was somewhat abnormal in appearance in the yellow regions which contained fewer chloroplasts.

An extended discussion is given of the characteristics of the mosaic disease on different plants, theories regarding its cause, and preventive measures.

Root knot in the tomato, H. A. WAGER (*So. African Jour. Sci.*, 10 (1913), No. 3, pp. 51-53, pl. 1, fig. 1).—A description is given of a nematode disease of tomatoes, which the author believes is due to a species differing from *Heterodera radiculicola* as described in the United States and elsewhere.

Preliminary report on a disease of melons and cucumbers, Z. KAMERLING (*Bul. Min. Agr., Indus. e Com. [Brazil]*, 2 (1913), No. 4, pp. 157-161, pls. 2).—The author reports briefly the partial study of a cucumber and melon disorder, in connection with which *Heterodera radiculicola* was noted.

Disease susceptibility of apple varieties in Ohio, A. D. SELBY (*Ohio State Hort. Soc. Ann. Rpt.*, 46 (1913), pp. 75-78).—A tabular list is given of disease susceptibility in Ohio of 38 varieties of apples to crown gall, collar rot, blister canker, twig blight, scab, bitter rot, blotch, black rot of fruit and canker, fruit spot or Baldwin spot, and fungus fruit spot due to *Cylindrosporium pomi*.

Black spot canker or apple tree anthracnose, W. H. LAWRENCE (*Bien. Rpt. Bd. Hort. Oregon*, 12 (1911-12), pp. 93-97).—The author gives a description of the black spot canker due to *Glæosporium malicorticis*, the perfect form of which is *Neofabrea malicorticis*. A previous account of his investigations on this subject has been noted (*E. S. R.*, 16, p. 790). Among the more important facts recently observed regarding it, is the occurrence of the disease on stored fruit from orchards in which anthracnose canker was not known to occur.

The author advises thorough, repeated spraying for the control of this fungus, autumn spraying following the maturing of the fruit being considered of decided advantage over later applications. The use of a Bordeaux petroleum emulsion was briefly tested and seems to be of considerable promise.

The control of apple blotch, D. E. LEWIS (*Kansas Sta. Bul.* 196 (1913), pp. 517-574, figs. 21).—An account is given of experiments for the control of the apple blotch due to *Phyllosticta solitaria*. This disease is of rather common occurrence in the orchards of Kansas, frequently causing over 90 per cent of injury to susceptible varieties.

The author states that it may be successfully controlled by the application of Bordeaux mixture the first season sprayed, and by the continued use of this fungicide during successive seasons it can be almost completely eradicated from an orchard in from four to six years. The 3:4:50 formula of Bordeaux mixture is recommended for use. Lime-sulphur solution was found less effective than Bordeaux mixture for the control of apple blotch, but during wet weather its use is recommended in place of Bordeaux mixture on account of the tendency of the latter fungicide to russet the fruit. The work of eradicating the disease can be hastened by cutting back trees and the commercial value of the fruit correspondingly increased.

The control of fire or pome blight, W. H. LAWRENCE (*Bien. Rpt. Bd. Hort. Oregon*, 12 (1911-12), pp. 107-109).—A description is given of the bacterial blight of apples and pears, and attention is called to the necessity for organized effort for its control.

Treatments for fruit tree diseases, P. PERRONNE (*Prog. Agr. et Vit. (Ed. l'Est-Centre)*, 35 (1914), No. 2, pp. 57-60).—The author details chemical and surgical treatments claimed to prove beneficial under given conditions in case of peach rust, and black spot of pear trees.

A new disease of pear, P. PASSY (*Jour. Soc. Nat. Hort. France*, 4. ser., 14 (1913), May, pp. 288, 289; *Rev. Hort. [Paris]*, 85 (1913), No. 11, pp. 252, 253).—A description is given of a disease of pear trees which has been recognized for about a dozen years.

The cause is not definitely known, although it is believed possibly to be bacterial in its origin. The progress of the disease is shown in the checking of development of the shoots in midseason, at which time the epidermis loses its smooth appearance and takes on a purplish color, later becoming roughened. The following year the branches showing signs of the disease are purplish in color and rough, and in case of severe attack the leaves fail to develop. In some instances the cracking of the epidermis is quite marked, the slits extending to a considerable depth. As is indicated above, little is known regarding this disease, which is still under observation.

Treatment of court-noué with tar, J. BERTRAND (*Prog. Agr. et Vit. (Ed. l'Est-Centre)*, 35 (1914), No. 3, pp. 80-84).—This is mainly a favorable discus-

sion of the work and conclusions reported by Lamouroux (E. S. R., 30, p. 246) regarding treatment of grape stocks with coal tar for court-noué.

Spots characteristic of downy mildew, L. RAVAZ (*Prog. Agr. et Vit. (Ed. l'Est-Centre)*, 35 (1914), No. 5, p. 141, pl. 1).—Both the yellow or so-called oil spots (often the first indication of the mildew) and the whitish patches (usually seen only on the lower surfaces of the leaves) are shown in natural color. A later discussion of the significance of each is promised.

Does *Cronartium ribicola* overwinter on the currant? F. C. STEWART and W. H. RANKIN (*New York State Sta. Bul.* 374 (1914), pp. 41-53, pls. 3, fig. 1; *abs. in Phytopathology*, 4 (1914), No. 1, p. 43).—The occurrence of this fungus on currants at the New York State Station for several years led to the suspicion that possibly the fungus might winter-over on the black currant. A large number of black currant plants thoroughly infested with *Cronartium* were divided into six lots and sent to widely separated experiment stations for observation. No *Cronartium* was to be found on the new leaves and attempts at inoculation by means of infected leaves wintered in wire cages out of doors also failed. It is concluded that *C. ribicola* rarely if ever overwinters on currants.

In the same connection the authors report the finding of two 15-year-old white pines affected with *Peridermium strobi* in May, 1913. These trees have been destroyed so as to prevent the further spread of the disease.

Do dormant currant plants carry pine rust? F. H. HALL (*New York State Sta. Bul.* 374 (1914), popular ed., pp. 4, fig. 1).—A popular edition of the above.

A disease of agaves, I. H. BURKILL (*Gard. Bul. Straits Settlements*, 1 (1913), No. 6, pp. 193, 194).—The author reports a disease of agaves in Singapore due to a fungus attacking the mature leaves on the upper surface, rendering them useless for the extraction of fiber. The attack, which is briefly described, is said to resemble in some respects that of a *Colletotrichum*, while the spores resemble those of a *Coryneum*.

Cutting and burning the leaves as soon as the disease is noted is recommended.

Cacao canker, J. KUYPER (*Dept. Landb. Suriname Bul.* 31 (1913), pp. 29-33).—The author reports studies on cacao canker pursuant to the work of Rorer (E. S. R., 23, p. 748), Petch (E. S. R., 25, p. 46), and Rutgers (E. S. R., 29, p. 248), in which all the stem and fruit infections made by him with a fungus claimed to be *Phytophthora faberi* produced effects characteristic of cacao canker, the control showing no such results. He has not yet succeeded in isolating this fungus from these lesions.

Citrus canker, H. E. STEVENS (*Florida Sta. Bul.* 122 (1914), pp. 111-113, figs. 4).—A preliminary account is given of a new citrus disease which was first observed in the fall of 1912 and again in the spring of 1913, when leaves and twigs of grapefruit were found badly infected.

The disease in general has the same appearance on leaves, fruit, and twigs. It appears in small circular spots from one-sixteenth to one-fourth of an inch across, occurring either singly or several together. The spots are raised above the surrounding tissue, are light brown in color, and are composed of a spongy mass of dead cells covered by a thin white or gray membrane, which finally ruptures and turns outward forming a ragged margin around the spot. On the older twigs pronounced cankers are formed.

The disease at first was thought to be an unusual manifestation of scab, scaly bark, or possibly anthracnose, but it was found to differ materially from any of these. The organism causing it has not yet been determined, but it is probably due to some fungus. A number of species of fungi have been found associated with the spots and some of these are under investigation. The disease appears to be confined mainly to the grapefruit, the sweet orange

apparently not being affected. It is infectious and the climatic condition of Florida appears to favor its rapid spread. In addition to Florida it is known to occur also in Alabama and may exist in Texas.

The author recommends the careful inspection of nursery stock, the destruction by burning of small affected trees, and the pruning off and burning of all diseased parts of larger trees.

[Root diseases of lime trees in Dominica], H. A. TEMPANY (*Imp. Dept. Agr. West Indies, Rpt. Agr. Dept. Dominica, 1912-13, pp. 9-14*).—The author gives an account of investigations by F. A. South on stem canker diseases of lime trees, the black root disease due to *Rosellinia* sp., and the red root disease caused by *Sphaerostilbe* sp., together with suggestions for their control so far as definite means are known.

A leaf disease of papaya, A. MAUBLANC (*Bol. Min. Agr., Indus. e Com. [Brazil], 2 (1913), No. 1, pp. 126-130, pl. 1*).—This is substantially the same as an article previously noted from another source (*E. S. R.*, 29, p. 848).

[Recent mycological tours], A. C. TUNSTALL (*Indian Tea Assoc., Sci. Dept. Quart. Jour., 1912, No. 4, pp. 105-108*).—This is a brief account of tours through several districts, noting the presence and relative importance to tea growers of *Ustulina zonata*, *Hymenochæte noxia*, *Cephaluros virescens*, *Læstadia theæ*, and *Botryodiplodia theobromæ* in the different sections. *H. noxia* was found apparently spreading through the medium of a wooden fence along which the adjacent tea bushes were dying from this fungus.

Mycologist's notes, A. C. TUNSTALL (*Indian Tea Assoc., Sci. Dept. Quart. Jour., 1913, No. 1, pp. 30-32*).—The author reports some observations made on plant disorders while visiting several stations.

Hymenochæte noxia was the most prevalent of the root diseases of tea met with. *Ustulina zonata* was found on tea in a few gardens. *Rosellinia*, observed in some shady patches of tea, had apparently done harm in only one case. Blister blight of the leaves, due to *Exobasidium vexans*, was seen as early as January, the starting places showing signs of having borne a continued crop of fungus throughout the cold weather. Removal of infection centers has considerably reduced this blight. Copper blight (*Læstadia theæ*), though common, appears to do but little damage.

[Some diseases of tea], A. C. TUNSTALL (*Indian Tea Assoc., Sci. Dept. Quart. Jour., 1913, No. 4, pp. 104-106*).—A description is given of die-back due to *Glæosporium* sp., blister blight, and canker.

The die-back, it is said, may be controlled by spraying with Bordeaux mixture. The blister blight, caused by *Exobasidium vexans*, has been studied at considerable length and no evidence has been found that it occurs on any other plant than tea. It is considered probable that the disease must pass the winter in an active state on the tea plant itself, and that thorough spraying with Bordeaux mixture or similar fungicide would probably control it. Studies on the cause of canker have failed to show how the fungus enters the plant, and thus far no definite means for killing it have been discovered.

Fungi parasitic on the tea plant in northeast India, I, A. C. TUNSTALL (*Indian Tea Assoc., Sci. Dept. Quart. Jour., 1913, No. 4, pp. 100-103*).—The author describes attacks of *Pythium debaryanum* and *Mucor mucedo* on tea plants.

[Mosquito blight of tea], P. H. CARPENTER (*Indian Tea Assoc., Sci. Dept. Quart. Jour., 1912, No. 4, pp. 104, 105*).—Reporting an inspection tour in several districts, the author notes that in Cachar the most important pest found is mosquito blight. This appeared to be worse in 1912 than for many years past. It is said to affect tea grown on a peat soil earlier and more se-

verely than on other soils. The light leaved varieties are said to appear much less susceptible to this disease than the others grown in these districts.

A note on the treatment of blister blight, A. C. TUNSTALL (*Indian Tea Assoc., Sci. Dept. Quart. Jour.*, 1913, No. 2, pp. 50-53).—The author reports recent observations in Assam and Darjeeling leading to the conclusions that *Exobasidium vexans* is able to attack tea only and that the disease passes the winter in an active stage, no dormant stage or special winter form being known. Wind may carry spores for long distances, this fact requiring cooperation over wide areas. Treatments described include the application to dormant bushes of a solution composed of 2 lbs. sodium hydrate to 10 gal. water; to green bushes, one consisting of 6 lbs. each of copper sulphate and quicklime to 100 gal. water; and in rainy seasons of 2 oz. each of common salt and lime to 1 gal. water. The spraying fluid, it is said, is most economically applied from below.

Root disease of tea, A. C. TUNSTALL (*Indian Tea Assoc., Sci. Dept. Quart. Jour.*, 1912, No. 1, pp. 17-22).—This is a digest of a circular by Petch, which has already been noted (E. S. R., 25, p. 47).

A root disease of tea, A. C. TUNSTALL (*Indian Tea Assoc., Sci. Dept. Quart. Jour.*, 1913, No. 2, pp. 54, 55).—*Fomes lucidus* is reported to have been observed to attack tea. Recent researches are said to have shown also that this is a dangerous parasite of betel nut palm and other trees as reported by Butler (E. S. R., 29, p. 445).

Preliminary note on a disease of *Basella rubra*, E. RANGEL (*Bol. Min. Agr., Indus. e Com. [Brazil]*, 2 (1913), No. 4, pp. 177-180, pls. 2; *Lavoura*; *Bol. Soc. Nac. Agr. [Brazil]*, 17 (1913), Nos. 7-8, pp. 136-140, pl. 1).—A leaf disease of *B. rubra* was ascribed to a fungus studied and named *Stagonospora basellæ* n. sp., in association with another fungus which was named *Phyllosticta basellæ* n. sp.

Nematode studies, SCHWARTZ (*Mitt. K. Biol. Anst. Land u. Forstw.*, No. 12 (1912), pp. 26, 27, fig. 1).—The author notes the discovery in lily-of-the-valley of a nematode which is described under the name *Aphelenchus aderholdi* n. sp. A second species appearing in tap water, named *A. mycogenes* n. sp., is said to be closely related to *A. olesistus*. *Tylenchus dipsaci* is reported as causing galls on phlox.

Parasitism of mistletoe, N. VAN POEIEBEN (*Tijdschr. Plantenziekten*, 18 (1912), Nos. 5-6, pp. 101-113, pl. 1; *Bul. Soc. Cent. Forest. Belg.*, 20 (1913), No. 12, pp. 834-844).—A case, discussed in considerable detail, of *Viscum album* growing in a large cluster on an otherwise leafless graft terminating an apical branch of *Sorbus aucuparia*, is cited as possibly throwing some light on the actual or potential nutritive relations between parasite and host.

Witches' broom on Juniper, E. HEINRICHER (*Naturw. Ztschr. Forst u. Landw.*, 12 (1914), No. 1, pp. 36-39, fig. 1).—The author states that *Arceuthobium oxycedri* easily parasitized *Juniperus communis*, producing characteristic witches' broom thereon.

A fruit rot of *Hevea brasiliensis* in Kamerun, L. PETERS (*Mitt. K. Biol. Anst. Land u. Forstw.*, No. 12 (1912), pp. 18-22).—Reporting a fruit and seed rot of *H. brasiliensis*, the author states that along with a *Phytophthora*, other fungi and several bacteria are found, regarding which further studies are considered desirable.

ECONOMIC ZOOLOGY—ENTOMOLOGY.

Zoological record, D. SHARP (*Zool. Rec.*, 48 (1911), pp. XII+[1298]; 49 (1912), pp. XII+[1374]).—These volumes record the zoological literature relating chiefly to the years 1911 and 1912, respectively.

The ornithofaunistic, ornithophenologic, and ornithobibliographic literature of Hungary prior to 1910 (*Aquila*, 20 (1913), No. 1-4, pp. 252-330).—The literature here listed alphabetically by authors consists of 3,090 titles.

The wanderings of animals, H. GADOW (*Cambridge [England] and New York, 1913*, pp. VI+150, pls. 17; rev. in *Sci. Prog. Twentieth Cent.*, 8 (1914), No. 31, p. 578).—The chapters of this work deal with the history of geographical distribution, features of environment, numbers and density of species, former configurations of land and water, and distribution of selected groups. A bibliography is appended.

Introduction to the study of mimicry, A. JACOBI (*Mimikry und Verwandte Erscheinungen. Brunswick, 1913*, pp. IX+216, figs. 13; rev. in *Nature [London]*, 92 (1914), No. 2311, pp. 653-655).—The chapters of this work relate to protective coloring, protective resemblance, warning colors, mimicry or protective imitation, the imitation of aculeate Hymenoptera or "Sphecoïdie," the imitation of ants or "Myrmecoidie," the imitation of beetles, imitation among Lepidoptera, and the general characteristics of mimetic Lepidoptera.

A bibliography of 59 titles is appended. The review is by E. B. Poulton.

Observations on the relation between flower color and insects, E. M. EAST and R. W. GLASER (*Psyche*, 21 (1914), No. 1, pp. 27-30).—In experiments with 10 average plants of each of the 4 colors, white, yellow, red, and purple, it was found that 39.1 per cent of the white, 18.12 per cent of the yellow, 15.21 per cent of the red, and 16.74 per cent of the purple flowers were fertilized. The authors estimate that about 6 per cent of the pollination of colored types was made by night flyers (Sphingidæ, etc.) while during the same period these insects pollinated from 20 to 25 per cent of the white type.

Birds of Ontario in relation to agriculture, C. W. NASH (*Ontario Dept. Agr. Bul.* 218 (1913), pp. 124, figs. 48).—A revised edition of a bulletin previously noted (*E. S. R.*, 22, p. 153).

Notes on some birds of Trinidad and Tobago, G. ST. C. FEILDEN (*Bul. Dept. Agr. Trinidad and Tobago*, 13 (1914), No. 77, pp. 25-33).—This annotated list of some of the more common birds includes economic notes.

Preliminary note on birds as carriers of the chestnut blight fungus, F. D. HEALD and R. A. STUDHALTER (*Science, n. ser.*, 38 (1913), No. 973, pp. 278-280).—The results of the authors' experiments in the spring of 1913 to determine whether birds carry the spores of the blight fungus are summarized as follows: The spores of the blight fungus carried by birds are pycnosporoes and not ascosporoes; the maximum numbers are carried during the few days following rain periods; and the pycnosporoes carried are brushed off from either the normal or diseased bark, or both, in the movements of the birds over these surfaces.

Birds as destroyers of grasshoppers in California, H. C. BRYANT (*Auk*, 31 (1914), No. 2, pp. 168-177).—Much of the data here presented has been previously noted from another source (*E. S. R.*, 28, p. 351).

[Insect pests in Tunis] (*Bul. Dir. Gén. Agr. Com. et Colon. Tunis*, 17 (1913), No. 71, Sup., pp. 31-51, pls. 2).—This report of studies conducted at the Tunis Agricultural Parasitology Station treats of the Hessian fly, the granary weevil, the rice weevil, the wheat bulb-fly (*Hylemyia coarctata*), and the Angoumois grain moth.

[Insect enemies of plants and animals] (*Vie Agr. et Rurale*, 3 (1914), No. 14, pp. 365-391, figs. 21).—This includes a general review of the subject by G. Guénaux (pp. 365-372), methods of combating flies by Vaillard (pp. 373-378), the employment of bacteria in destroying field mice by L. Perrier (pp. 378-382), the fumigation of plants with hydrocyanic acid by P. Marchal (pp. 383-386), the manner of combating insect enemies of plants by parasites and pred-

ators by A. Vuillet (pp. 386-389), and the insect enemies of the beet in southern France by F. Picard (pp. 390, 391).

The destruction of mosquitoes, fleas, flies, pediculi, and other insect carriers of disease, J. S. PURDY (*Rpt. Austral. Assoc. Adv. Sci.*, 13 (1911), pp. 662-673).—A general discussion.

Reducing insect injury to stored corn, W. E. HINDS (*Alabama Col. Sta. Bul.* 176 (1914), pp. 51-68, pls. 4).—This bulletin describes the more important insect enemies of stored corn and means by which their injury can be prevented.

In storage tests about fifty times as many weevils were found on early corn up to midwinter as late matured corn. It was found that the value of the grain saved by husking will more than pay for the labor required. The practice of storing corn wet and salted is decidedly favorable to insect injuries. In a study of varieties weevil resistance was found to depend first upon the length and tightness of the husk covering upon the maturing ear.

The insect enemies of cotton in Africa, F. ZACHER (*Arb. K. Biol. Anst. Land u. Forstw.*, 9 (1913), No. 1, pp. 121-232, figs. 83).—A discussion of the more important cotton insects, their injury, means of control, etc. A bibliography is appended. See also a previous note (E. S. R., 30, p. 752).

[Insect enemies of the peanut], A. CHEVALIER (*Jour. Agr. Trop.*, 13 (1913), No. 141, pp. 73-76).—A brief discussion of the more important pests.

Animal enemies of the sugar beet in 1913, O. FALLADA (*Österr. Ungar. Ztschr. Zuckerindus. u. Landw.*, 43 (1914), No. 1, pp. 19-23, fig. 1).—This is the author's annual review (E. S. R., 28, p. 352).

The insect enemies of the coco palm in the South Sea Islands, F. ZACHER (*Arb. K. Biol. Anst. Land u. Forstw.*, 9 (1913), No. 1, pp. 73-120, figs. 38).—Fifty insect enemies of the coconut palm are dealt with, particular attention being given to the rhinoceros beetle (*Oryctes rhinoceros*). A bibliography of the more important literature relating to the subject is included.

[Insect enemies of the lime in the West Indies], H. A. BALLOU and F. W. SOUTH (*Imp. Dept. Agr. West Indies Pamphlet* 72 (1913), pp. 39-61, figs. 13).—The scale insects mentioned are the purple scale, the white scale or orange snow scale (*Chionaspis citri*), the green scale (*Coccus ciridis*), the California red scale (*Chrysomphalus aurantii*), the West Indian red scale (*Selenaspidus articulatus*), the Florida red scale (*C. aonidum*), and the hemispherical scale. The other pests mentioned are the citrus rust mite, the bark borer *Leptostylus praemorsus*, the twig borer of limes (*Elaphidion mite*), and root borers. Remedial measures, natural enemies, internal parasites, and insecticides and their use are then briefly discussed.

White ants and fungi, T. PETCH (*Ann. Roy. Bot. Gard. Peradeniya*, 5 (1913), No. 6, pp. 389-393).—This is a discussion of the probable association of termites with *Entoloma microcarpum*.

The black termite of Ceylon (*Eutermes monoceros*), T. PETCH (*Ann. Roy. Bot. Gard. Peradeniya*, 5 (1913), No. 6, pp. 395-420, pls. 9, figs. 2).—A detailed account of this species including its nest, the external structure, the processional habit, food, etc.

Achaeta moria, a sisal hemp pest, KRÄNZLIN (*Pflanzer*, 9 (1913), No. 11, pp. 568-570; *abs. in Internat. Inst. Agr. [Rome]*, *Mo. Bul. Agr. Intel. and Plant Diseases*, 5 (1914), No. 2, p. 286).—This orthopteran is reported to have injured year-old plants in plantations of *Agave rigida sisalana* by consuming the lower leaves just above the junction with the stem.

Studies of inheritance and evolution in Orthoptera, I. R. K. NABOURS (*Jour. Genetics*, 3 (1914), No. 3, pp. 141-170, pl. 1, figs. 3).—"The inheritance behavior of the color patterns in these orthopterous insects shows clearly the Mendelian

type of inheritance, and the essential result of these experiments has been the extension of this principle to a considerable number of types of a phylogenetically low group of ametabolous insects."

On two new species of Thysanoptera from the West Indies, C. B. WILLIAMS (*Jour. Econ. Biol.*, 8 (1913), No. 4, pp. 209-215, figs. 2).—*Corynothrips stenopterus* and *Frankliniella melanommatus*, taken in large numbers from cassava plants at the agricultural experiment station, at Kingstown, St. Vincent, West Indies, are described as new to science.

Records and descriptions of British Thysanoptera, C. B. WILLIAMS (*Jour. Econ. Biol.*, 8 (1913), No. 4, pp. 216-230, figs. 3).—The author has found the method of collecting flowers in paper bags recommended by Uzel to be of considerable value since it is possible to obtain material in this way from untrained correspondents in various parts of the country. It is stated that in this way pea thrips (*Frankliniella robusta*) were received from 24 counties in England, Wales, and Ireland.

Eurygaster integriceps and new methods of combating it by means of parasites, I. V. VASIL'EV (*Trudy Būaro Ent. [St. Petersburg.], 4 (1913), No. 11, pp. 81, figs. 31; abs. in Rev. Appl. Ent., 1 (1913), Ser. A, No. 11, pp. 446-450*).—Next to the Morocco locust this plant bug is the most serious pest of crops. During the last two or three decades it has caused immense devastation in Transcaucasia and Transcaspia and is also known in Caucasia. In Transcaspia its principal injury is to winter wheat, the cultivation of which predominates in that country, barley being damaged to only a small degree. A number of important parasitic enemies of this pest are discussed, including 2 tachinids and 5 proctotrupids of the genus *Telenomus*.

The last part of the work relates to methods of combating the pest by means of its parasites, it being pointed out that only the egg parasites have a practical importance in this respect. The experimental transportation of the egg parasite *Telenomus vassilievi* from central Asia to the government of Kharkof is described.

The periodical cicada or seventeen-year locust, H. A. GOSSARD (*Ohio Sta. Circ. 142 (1914), pp. 41-47, figs. 7*).—This circular has been prepared with a view to furnishing information on the periodical cicada, which is due to appear over most of eastern Ohio during the summer of 1914.

A catalogue of the Psyllidæ, G. AULMANN (*Psyllidarum Catalogus. Berlin, 1913, pp. 92*).—A synonymic catalogue of the Psyllidæ of the world, in which 478 species are listed.

A note on *Oxyrhachys tarundus*, N. C. CHATTERJEE (*Indian Forester, 40 (1914), No. 2, pp. 75-79, pls. 2*).—This membracid is reported as injuring *Albizzia lebbek*, *A. procera*, *Acacia catechu*, and *Phyllanthus émblica* trees. Attention is called to the fact that the habits of this *Oxyrhachys* are very similar to those of *Ceresa bubalus*, described by Marlatt (*E. S. R.*, 9, p. 675).

Morphology and biology of the Membracidæ of Kansas, HAZEL E. BRANCH (*Kans. Univ. Sci. Bul.*, 8 (1913), No. 3, pp. 75-115, pls. 17).—This report of life history and morphological studies of the Membracidæ of Kansas includes tables for the separations of the subfamilies, tribes, genera, and species occurring in Kansas. A list of food plants and a bibliography are appended.

The obliteration of sexual reproduction in *Chermes*, P. MARCHAL (*IV. Conf. Internat. Génétique Paris, Compt. Rend. et Raps., 1911, pp. 488-490*).—In an article previously noted (*E. S. R.*, 19, p. 860) the author has reported the results of his research on the life history of *Chermes pini*. In the indigenous race of this species sexual reproduction does not take place. Although large numbers of functionless females are produced, not a single male has been observed. On the other hand, the oriental race of *C. pini* possesses a normal

sexual stage. The author designates this phenomenon, in which the males are absent, as spanandry.

Since the previous account was published a very similar case of the obliteration of sexual reproduction has been observed in *C. strobi* which lives on *Pinus strobus*. A rudimentary sexual stage takes place on *Picea nigra*. Winged forms migrate in large numbers to *P. nigra* where they give rise solely to females. It is probable that in America there exists another race of *C. strobi*, in which the normal sexual stage occurs on *Picea*. A third type on which the sexual stage has hitherto been thought to be completely obliterated, is found in *C. picæ*. This species lives on *Abies pectinata*; it is very near *C. nusslini*, from which it is distinguished morphologically and also by the fact that sexual reproduction does not occur. The author has found that in *C. picæ* winged forms occasionally may appear. These forms do not migrate to *Picea*, but remain on *A. pectinata* where they produce parthenogenetic forms.

Mealy bug parasites in the Far East, H. S. SMITH (*Mo. Bul. Com. Hort. Cal.*, 3 (1914), No. 1, pp. 26-29).—Previously noted from another source (E. S. R., 30, p. 753).

Appearance of *Icerya purchasi* and *Novius cardinalis* in the District of Beira Baixa (Portugal), C. MENDES (*Broteria, Ser. Zool.*, 11 (1913), No. 2, p. 146; *abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases*, 4 (1913), No. 8, p. 1310).—The occurrence in 1910 of a large number of fluted scales on acacias (*Acacia melanoxylon*) in Beira Baixa was followed by the appearance of the lady beetle *N. cardinalis*, and within a year all the fluted scales were destroyed by this predator.

The San José scale, the oyster shell bark louse, and the scurfy bark louse, J. S. HOUSER (*Ohio Sta. Circ.* 143 (1914), pp. 49-62, figs. 11).—Brief popular accounts of these three scale pests and directions for combating them.

On the zygotic constitution of dominant and recessive whites in the silkworm, *Bombyx mori*, K. TOYAMA and S. MORI (*Ztschr. Induktive Abstam. u. Vererbungslehre*, 10 (1913), No. 3, pp. 233-241).—This report of studies conducted at Tokio includes a bibliography of 15 titles.

Turnip moth larvæ injuring tobacco in Hungary, B. GROF (*Magyar Dohánynyjsag*, 30 (1913), No. 11, pp. 3, 4; *abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases*, 4 (1913), No. 8, p. 1307).—The larva of *Agrotis segetum* is reported to tunnel in the ground about 2 in. below the surface and destroy the roots of tobacco.

The spraying of oak trees in Richmond Park (*Entomologist*, 46 (1913), No. 601, p. 195).—This note relates to the spraying of some 400 oak trees with lead chromate for the control of defoliating caterpillars.

Beetles becoming parasites, V. L. KELLOGG (*Science, n. ser.*, 39 (1914), No. 1001, pp. 360, 361).—The beetles mentioned include the beaver parasite *Platypsylla castoris*, which lives all its life both as a larva and adult on its host; *Leptinus testaceus*, which frequents the nests of field mice, shrews, and other small mammals of similar habit, and has also been taken from bumblebees' nests; *Leptinillus validus*, which occurs on beavers in the Hudson Bay region; and *Lyrosoma opaca*, a silphid found in the North Pacific about the tenanted nests of the murrets.

Oak pests.—The oak twig girdler (*Agrilus politus*), L. CHILDS (*Mo. Bul. Com. Hort. Cal.*, 3 (1914), No. 3, pp. 150-155, figs. 3).—The injury to live oak (*Quercus agrifolia*) by the oak twig girdler is said to be very conspicuous, the attacks upon the smaller twigs resulting more particularly in damage to the appearance of the tree. The author's pruning experiments in 1911-12 are said to have proved conclusively that the injury can be almost entirely eliminated by occasional cutting out of the attacked twigs in individual trees even

though there is not an entire clean up of all surrounding infestations. The cutting out and burning of infested branches should be undertaken between October 1 and April 1.

Two enemies of the American red oak, J. HOUBA (*Bul. Soc. Cent. Forest. Belg.*, 20 (1913), No. 4, pp. 249-255, figs. 4).—Two enemies of *Quercus rubra*, namely, *Xyleborus dispar* and *Trypodendron quercus* or *X. quercus*, are said to have made their appearance in the vicinity of Marche, Belgium.

Damage to Austrian pine in the Marne by *Pityogenes bidentatus*, A. VUILLET (*Rev. Phytopath. Appl.*, 1 (1913), No. 8, pp. 111, 112; *abs. in Rev. Appl. Ent.*, 1 (1913), Ser. A, No. 11, p. 423).—Plantations of *Pinus austriaca* in the Department of Marne are reported to have been seriously injured during the year through attacks of this beetle (*P. bidentatus*). The author states that it is also the most serious enemy of all other species of pine in France. It appears to confine its attack to trees of from 5 to 10 years old, boring galleries in the smaller branches immediately beneath the bark.

The pest is more or less successfully dealt with by leaving cut branches in the forest after the spring cutting, and, following the deposition of the eggs thereon by the beetles, collecting and burning the branches.

The yellow-headed coffee borer (*Dirphya* [*Nitocris*] *princeps*), C. C. GOWDEY (*Bul. Ent. Research*, 4 (1914), No. 4, pp. 279-281, fig. 1).—This beetle is a source of injury to coffee in the Chagwe District, Uganda, having first come to attention in 1910, when some of the estates, especially the older ones, suffered serious damage. The trees attacked by this pest, if allowed to remain untreated (by the injection of a few drops of carbon bisulphid or carbon tetrachlorid into the tunnels or the borer) are either killed outright or broken off by the wind.

Notes on the life history of *Cyrtotrachelus longipes*, D. O. WITT (*Indian Forester*, 39 (1913), No. 6, pp. 265-272, pl. 1).—This paper reports biological studies of *C. longipes*, based upon observations of its attack of bamboo (*Dendrocalamus strictus*). Life history studies based upon observations of its attack on *Melocanna bambusoides* have previously been reported by Stebbing.^a

On the biology of *Phytonomus murinus* and its parasites, N. A. GROSSHEIM (*Reprint from Ent. Věstnik [Kiev]*, 2 (1913), No. 1, pp. 21, figs. 15; *abs. in Rev. Appl. Ent.*, 2 (1914), Ser. A, No. 2, pp. 108-110).—This is a report of investigations conducted in the government of Kuban in response to a request from this Department for information on the parasites of the alfalfa weevil.

Parasites of all stages of the weevil were discovered. The larva of an undetermined pteromalid feeds externally upon the eggs, the percentage of infestation being 13.33. *Canidiella curculionis*, an external parasite, attacks the larvæ of the host in the later stages, the parasitism reaching 3.16 per cent. The larvæ of *P. murinus* are also infested by two chalcidids, *Tetrastichus* sp., which is a primary internal parasite, and *Dibrachoides* (*Pteromalus*) *dynaster*, an external parasite, the percentage of parasitism by these two species being low. The pupæ of *P. murinus* were parasitized externally by *Eulophus* sp., and internally by *Pimpla maculator*, the latter being the most important enemy and attacking 25 per cent of the pupæ.

During the year the natural enemies destroyed 71 per cent of the weevils.

Consumption of a hive of bees during the year, R. HOMMEL (*Vie Agr. et Rurale*, 2 (1913), No. 22, pp. 653-655, figs. 2; *abs. in Internat. Inst. Agr. [Rome]*, *Mo. Bul. Agr. Intel. and Plant Diseases*, 4 (1913), No. 8, pp. 1266, 1267).—It is stated that "the daily consumption of a bee varies from 0.003 to 0.12 gm. ac-

^a Departmental Notes on Insects that Affect Forestry, II (Calcutta, 1903, pp. 193-197).

ording to the conditions of life, with a fairly general mean of 0.03 gm. The total food consumed by a worker larva in its feeding period is 0.4 gm.; the daily consumption of a drone is 0.04 to 0.05 gm."

It is estimated that the total annual consumption of a hive of bees is 480 lbs., of which maintenance of the bees requires 400 lbs., feeding of brood 70 lbs., and wax production 10 lbs.

Report on a collection of Hymenoptera made in Guam, Marianne Islands, D. T. FULLAWAY (*Proc. Hawaii. Ent. Soc.*, 2 (1913), No. 5, pp. 282-290).—In this paper, which is based upon a collection of insects made by the author during the course of an official trip to the island of Guam in 1911, 53 species are listed and 11 are described as new to science. These include several species of some economic importance, namely, *Scleroderma duarteantum*, reared from a colopterous larva in cacao; *Allotropa thompsoni*, reared from a mealy bug (*Pseudococcus* sp.) on *Abrus abrus*; and *Cirrospiloideus guamensis*, reared from lepidoterous miners in *Terminalia catappa* and *Heritiera littoralis*.

A list by W. M. Wheeler of the Formicidæ collected has previously been noted (*E. S. R.*, 27, p. 264).

A note on two species of bassid Ichneumonidæ parasitic on a species of syrphid larva, A. E. CAMERON (*Entomologist*, 46 (1913), No. 599, pp. 130, 131).—During the course of investigations at the University of Manchester the author found that pupæ of *Platycheirus albimanus* were parasitized by the two ichneumonids *Homocidus dimidiatus* and *H. tarsatorius*. This syrphid is said to prey upon *Pterocallis tilia*, an aphid infesting lime trees (*Tilia grandiflora*).

On some new and other species of Hymenoptera in the collections of the zoological branch of the Forest Research Institute, Dehra Dun, P. CAMERON (*Indian Forest Rec.*, 4 (1913), No. 2, pp. III+53).—The first part of this paper (pp. 1-20) deals with the parasitic Hymenoptera reared at Dehra Dun from the lac (*Tachardia*) and sal insects. Several of the genera and species which are here described and enumerated appear to be of economic importance.

The second part (pp. 21-33) on some new and other species of nonparasitic Hymenoptera includes a description of a new species of sawfly (*Lophyrus indicus*).

Oophthora semblidis (*Pentarthron carpocapsæ*), description, biology, and utilization of it in the struggle with *Carpocapsa pomonella*, A. F. RADETZKY (*Turkest. Ent. Stansiâ*, 1913, pp. 28, pl. 1; *abs. in Rev. Appl. Ent.*, 1 (1913), Ser. A, No. 11, pp. 431, 432).—This chalcidid egg parasite is said to be the most important enemy of the codling moth in many districts of Russia.

The eradication of mosquitoes by the cultivation of bats, C. A. R. CAMPBELL (*Abs. in Internat. Inst. Agr. [Rome] Mo. Bul. Agr. Intel. and Plant Diseases*, 4 (1913), No. 8, pp. 1175-1181, pls. 2).—The author points out that mosquitoes may form as high as 90 per cent of the food of bats. A wooden tower or "hygiostatic guano-producing bat roost," which he has devised for the colonization and protection of bats and erected near a large body of standing water located 10 miles south of the city of San Antonio, Tex., is described and illustrated, and the results obtained with it during the years 1911 and 1912 are reported.

"The commercial feature in the propagation of bats will insure its adoption, the hygienic benefits that follow will protect the community in which they are erected, especially the poorer classes who know nothing of the dangers of the mosquitoes or the use of screens, and amongst whom we find the most sickness. When we propagate this most useful creature, he not only destroys the disease-producing mosquito that serves it as food, but it actually converts that most malevolent of insects into a high grade fertilizer."

House flies and disease, E. H. ROSS (*Jour. Roy. Soc. Arts*, 62 (1914), No. 3200, pp. 388-397).—A popular discussion.

Fruit flies and other insects attacking cultivated and wild fruits in New South Wales, W. B. GURNEY (*Dept. Agr. N. S. Wales Farmers' Bul.* 55 (1912), pp. 31, figs. 41).—Most of the data here presented have been previously noted from another source (E. S. R., 27, p. 54).

A dipterous parasite of *Glossina morsitans*, E. E. AUSTEN (*Bul. Ent. Research*, 5 (1914), No. 1, pp. 91-93, fig. 1).—A bombyliid of the subfamily Exoprosopinae, reared from a pupa of *G. morsitans* collected in northern Rhodesia and here described as *Villa lloydi* n. sp., is said to be the first dipteran to be recorded as parasitic on any tsetse fly.

[The rearing of pomace flies on sterile media], A. DELCOURT and E. GUYÉNOT (*IV. Conf. Internat. Génétique Paris, Compt. Rend. et Raps.*, 1911, pp. 478-487).—The authors have succeeded in rearing five generations of *Drosophila ampelophila* and one of *D. confusa* in absolutely sterile conditions and here describe the means by which this was successfully accomplished.

Oil sprays.—Five years' successful use, P. R. JONES (*Better Fruit*, 8 (1914), No. 7, pp. 33-38).—The author gives a general résumé of the different types of oil and oil preparations that have been used in the past throughout the United States, with special reference to the Pacific coast, with data on the types of oil used and the ones that should be used, manner of making emulsions and miscible oils, the insects against which they should be used, safety to the tree from these preparations, and the cost of the treatment.

FOODS—HUMAN NUTRITION.

Clams, oysters, scallops (*Maine Sta. Off. Insp.* 55 (1913), pp. 149-156).—The handling and marketing of shellfish are discussed on the basis of experimental studies, with special reference to the state pure food law.

Fresh clams opened in the laboratory "gave in dry matter from the drained meat 24.9 per cent of total dry solids." The sample analyzed from a lot of clams which had been soaked gave 15.9 per cent total dry matter, a difference of 9 per cent.

"Dealers and shippers of clams in this State are practically unanimous in the thought that opened clams will not keep longer than 24 hours in their own liquor." The almost universal practice to open the clams as promptly as possible after digging and throw the clam liquids away and then wash the clams in fresh water renders dealers liable to prosecution, provided there is evidence that the clams have been soaked or adulterated in any way.

With a view to testing the effects of different methods of handling, clams were examined which were opened raw and which were opened after dipping in hot sea water and after dipping in hot fresh water. "The highest percentages of dry solids in the clams were obtained from those that were opened raw. In general the dry solids of clams were slightly lower in hot salt water than when opened raw, and considerably lower when dipped in hot fresh water than in the case of either of the others. The Keag River clams which were opened in hot salt water carried 20.7 per cent of dry solids of clams. When allowed to soak overnight in salt water the solids fell in the clams to 15.3 per cent."

To comply with the Maine food standards, "opened clams must be sold drained and without any surplus liquid. . . . They may be rinsed in water but must not remain in water more than 1 minute. When it is desired to heat clams before they are opened they may be immersed in hot water not more than 2 minutes. They may then be immediately put into cold water for not more than 2

minutes. The clams then should be opened, drained and handled exactly the same as raw opened clams. Natural clam liquid or juice may be sold as such but can not be mixed with opened clams and the mixture sold as clams. The solids and liquids of clams are quite constant. By laboratory methods it is readily ascertained whether the above conditions have been complied with."

The results of the examination of a number of samples of clams are reported.

Data are also given regarding the examination of a number of samples of oysters and of scallops. It is pointed out that the situation as regards oysters "has steadily and markedly improved during the past five years," with reference to the proportion of total solids and total dry matter present.

"Scallops as sold in the market consist of the large muscle that holds the two shells together. The remainder of the scallop is thrown away as unfit for food. There are two species of scallop, the giant scallop which is the one that is fished in Maine waters, and the ordinary scallop of more southern waters. . . .

"The scallops grow in deep water and are obtained by dredging. The Maine fishing grounds extend from Penobscot Bay east. As a rule the fishermen open and 'cut' their scallops the night of the day of fishing. As soon as the scallops are 'cut' the edible portion or muscle is put in a tub with salt water. They are usually delivered to the shippers in this condition."

The method of handling and marketing scallops is described. After weighing, dealers usually wash them with fresh water, drain them, keep them in sea water overnight (1 gal. to a 10-gal. bucket of scallops), then wash them again in fresh water, drain them, and after draining ship them in bags placed in tubs containing chopped ice. The shippers claim that the scallops are covered with a slime and that it is necessary to wash them thoroughly in fresh water or else the scallops will not keep. They also claim that this method of shipping is better than shipping in vessels surrounded by ice. The results obtained in the examination of scallops make it probable that "Maine scallops treated as outlined above would carry not less than 20 per cent dry matter in the scallops, with an average higher than that figure."

The food value of fish after cold storage (*Jour. Amer. Med. Assoc.*, 62 (1914), No. 3, pp. 208, 209).—A digest of data in which it is pointed out that although the possibilities of preserving fresh fish by the freezing process are excellent, such processes "do not give a clean bill of health to animal tissues removed from cold storage and exposed until sold or even kept iced in a common refrigerator. Neither can spoiled food be adequately preserved by any method. It is unfortunate that the efficiency of useful processes is sometimes impugned by unjustifiable applications of it. This has been true of cold storage."

Studies on the ripening and decomposition of meat, D. OTTOLENGHI (*Ztschr. Untersuch. Nahr. u. Genussmitl.*, 26 (1913), No. 12, pp. 728-758, figs. 8).—On the basis of physico-chemical and bacteriological studies of the changes which take place in meat during ripening and the early stages of decomposition, the author proposes a method for judging the relative freshness of meat. He regards the method as simple, rapid, and adequate for the purpose, providing the results of bacteriological studies are also taken into account.

The slaughtering and meat packing industry (*Thirteenth Census U. S.*, 10 (1913), pp. 331-353, figs. 2).—According to the classification adopted for presenting the statistics of the Census for 1909, the slaughtering and meat packing industry includes wholesale slaughtering and meat packing establishments, public abattoirs, and establishments making a specialty of manufacturing sausage, but does not include the retail butcher business. The report distinguishes three classes of establishments: (1) Those whose chief products are cured and

packed meats; (2) those whose chief products are fresh meats; and (3) those whose chief product is sausage.

Of the 1,641 establishments canvassed, 40 per cent were engaged primarily in slaughtering and meat packing; "these establishments employed 90.7 per cent of the total number of wage-earners and contributed products to the value of \$1,204,248,578, or 87.9 per cent of the total for the industry as a whole. Although establishments engaged chiefly in slaughtering formed approximately 1/3 (34.4 per cent) of the total number, they employed only 7.2 per cent of the total number of wage-earners, and the value of their products represented but 11 per cent of the total for the entire industry. The 420 establishments engaged chiefly in the manufacture of sausage reported 2.1 per cent of the wage-earners and contributed 1.1 per cent of the total value of products. In the case of establishments engaged primarily in meat packing, the cost of materials equaled 88 per cent of the value of products; in the case of those engaged primarily in slaughtering, 87.4 per cent; and of those making sausage, 75.8 per cent."

Eggs from the standpoint of nutrition, DELAYE (*Bul. Soc. Chim. Belg.*, 27 (1913), No. 12, pp. 310, 311).—In connection with this discussion of the nutritive value of eggs, statistics regarding egg production, particularly in Belgium, are given.

A study of flours and meals of different sorts, E. GURY (*Mitt. Lebensm. Untersuch. u. Hyg., Schweiz. Gsndhsamt.*, 4 (1913), No. 3, pp. 112-121, fig. 1).—Determinations of water, water absorbing power, protein, gluten, cellulose, and gliadin were made with ground wheat, rice, beans, potatoes, and other materials. The results obtained are reported, but the article as a whole is chiefly concerned with a comparison of methods.

Flour-mill and gristmill industry (*Thirteenth Census U. S.*, 10 (1913), pp. 403-426, figs. 2).—Of the 23,652 mills canvassed for this report, which covers the year 1909, more than half were custom mills, but of the total value of the products (\$938,699,958), only \$55,115,553, or 5.9 per cent, was contributed by this class. "More than three-fourths of the merchant mills were engaged chiefly in the manufacture of wheat flour and other products intended for human consumption, and the value of the products of these mills was \$832,790,364, or 88.7 per cent of the total for all mills combined.

"For both custom and merchant mills the value of products includes the estimated value of the flour and other products obtained from grain ground on a custom basis, and, similarly, the figures for cost of materials include the estimated cost of such grain. . . . "The flour-mill and gristmill industry is one in which the cost of materials constitutes a very large proportion of the total value of products, the process of manufacture itself being relatively simple and inexpensive. The total cost of the materials used by all mills in 1909 was \$813,891,347, which was equal to about seven-eighth (86.7 per cent) of the total value of products, while the value added by manufacture (that is, the value of products less the cost of materials) was only \$124,808,611."

Digestion experiments on men with cotton-seed meal, J. B. RATHER (*Texas Sta. Bul.* 163 (1913), pp. 26).—In continuation of earlier work (E. S. R., 23, p. 566), using men as subjects, the author studied the digestibility of cotton-seed meal in comparison with meat and canned chicken loaf, these foods being used as a part of a simple mixed diet. The cotton-seed meal (or flour) was made into bread with corn meal, in the proportion of 1:2 in the first case and of about 1:4 in the second case. The urine was analyzed as well as the food and feces.

According to the author's summary, "7 digestion experiments were made with men; 3 being with cotton-seed meal, 2 with cotton-seed flour, and 2 with meat.

"The digestibility of the protein of cotton-seed meal averaged 77.6 per cent and that of cotton-seed meal-flour 78.4 per cent. . . . It is eight-tenths as digestible as that of meat and nine-tenths as digestible as that of cereals, and equally as digestible as that of peas and beans.

"The digestibility of the fat of cotton-seed meal and flour appears to be very high. The fats are probably digested about 95 per cent and the carbohydrates about 68 per cent. The fat of meat was digested 99 per cent. . . .

"Cotton-seed food products made from 1 part cotton-seed meal and 4 parts wheat flour contain from one-third to less than one-half more digestible protein than eggs. The digestible fat and carbohydrates of cotton-seed meal, calculated as fat, are nearly equal in amount to that of beef flank, and more than equal to that of beef loin and mutton leg."

A number of recipes are given for making cotton-seed meal food products. In the author's opinion, these foods are as palatable as similar ones made from corn meal or wheat flour.

"In preparing cotton-seed cakes or bread, use 1 part cotton-seed meal or flour to 4 parts corn meal or wheat flour, and use the same recipes commonly used for wheat and corn bread and cakes. . . .

"One part of fresh, sweet meal, sifted free from hulls and lint should be used mixed with at least 4 parts of corn meal or wheat flour. Diluted in this way, few people will be able to eat more than 2 oz. of cotton-seed meal daily. Cotton-seed meal should not be eaten in addition to meat, unless it is known that too little meat is being eaten."

In a preface to the bulletin, G. S. Fraps summarizes similar data regarding the general question of the use of cotton-seed meal as food for man.

Rice cleaning and polishing (*Thirteenth Census U. S., 10 (1913), pp. 451-459*).—Of the 71 establishments included in making the report for 1909, 41 were engaged exclusively in merchant milling, 8 exclusively in custom milling, and 22 in both merchant and custom milling, but largely merchant milling. In 1904 there were 12 mills engaged exclusively in merchant milling, 31 exclusively in custom milling, and 31 in both merchant and custom milling, the larger part of the operations of mills of the last class being custom milling.

A total of 1,777 persons were engaged in the 71 establishments included. Of these, 1,239 were wage-earners. "The value of products was \$22,371,457, but the value added by manufacture was only \$2,870,377."

In a comparison of the present with earlier statistics, it is pointed out that "rice has been cultivated in the United States for more than 200 years, and prior to the Civil War had reached considerable proportions. The largest gain, however, has occurred during the last decade, during which period the production quadrupled."

With the exception of Oregon and Washington, where only foreign-grown rice was treated, the rice cleaning and polishing industry in the United States was confined in 1909 to six Southern States (Arkansas, Louisiana, South Carolina, Texas, Georgia, and North Carolina). The establishments there treated domestic rice exclusively. Louisiana reported 56 per cent of the total value of products, and Texas 36.4 per cent.

The soy bean and its use for food and condimental purposes, C. GRIMME (*Konserv. Ztg., 15 (1914), Nos. 1, pp. 1-3; 2, pp. 10, 11*).—Data are presented regarding the manufacture, characteristics, composition, and uses of soy bean milk, soy bean cheese (curd), soy bean bread, soy sauce, and other products.

Servian plum butter (*Konserv. Ztg., 15 (1914), No. 2, pp. 11, 12*).—A summary of studies by W. Brunetti on the composition and characteristics of a large number of samples.

Canning and preserving (*Thirteenth Census U. S., 10 (1913), pp. 379-401, fig. 1*).—Statistics are presented for the year 1909 in comparison with other years for the canning and preserving industry as a whole. Four classes of establishments are taken into account, namely: (1) Those whose chief products are canned and preserved fruits and vegetables, including dried and packed fruits put up by the packing house; (2) those whose chief products are canned and cured fish, including pickled, smoked, and dried fish; (3) those whose chief products are canned oysters and clams; and (4) those whose chief products are pickles, preserves, jellies, sauces, etc.

In 1909 the industry as a whole gave employment on the average to 71,972 persons, of whom 59,968 were wage-earners, and paid out \$26,945,466 in salaries and wages.

"In the canning and preserving industry the cost of materials constitutes a large proportion of the total value of products, the processes of manufacture being relatively simple and inexpensive. The combined cost of the materials used by all four branches of the industry in 1909 was \$101,823,059, which is equal to 64.8 per cent of the total value of products (\$157,101,201). . . .

"In the case of establishments engaged primarily in canning fruits and vegetables the cost of materials represented 68.4 per cent of the value of products; in the case of those handling fish principally, 62.4 per cent; of those chiefly canning oysters and clams, 55.8 per cent; and of those making chiefly pickles, preserves, and sauces, 58.4 per cent. It should be noted that the cost of cans and other containers is an important factor in the cost of materials."

Tin poisoning from canned asparagus, A. FRIEDMANN (*Ztschr. Hyg. u. Infektionskrank.*, 75 (1913), No. 1, pp. 55-61).—Experimental data led the author to conclude that canned asparagus may be the cause of tin poisoning.

Carbonated and other beverages (*Maine Sta. Off. Insp. 56 (1914), pp. 12*).—Data are given regarding the character of malt extract and beerlike beverages containing a low percentage of alcohol and also regarding the examination of a number of bottling establishments.

Laws, rules, and regulations pertaining to [foods, drugs, etc.] (In *Nebr. Food, Drug, Dairy and Oil Com. Laws, Lincoln, 1913, pp. 77*).—The text of the laws pertaining to foods, drugs, paints and oils, cold storage, petroleum products, weights and measures, commission merchants, and other related subjects is included.

Report upon an act relative to the cold storage of certain food products (*Ann. Rpt. Bd. Health Mass., 44 (1912), pp. 453-462*).—Data are given regarding the licensed cold-storage or refrigerating warehouses and cold-storage rooms in the State. Rules and regulations governing the business of cold storage, made under the provisions of the state law, are given in full.

Results of analyses of food samples (*Mo. Bul. Ind. Bd. Health, 16 (1913), No. 11, p. 277*).—According to the data summarized, out of a total of 1,257 samples of miscellaneous foodstuffs examined during the year ended September 30, 1913, 31.9 per cent were adulterated.

Food and drug inspection (*Ann. Rpt. Bd. Health Mass., 44 (1912), pp. 381-391*).—Out of a total of 7,617 samples examined, 1,780 did not conform to the provisions of the state law.

Report of the analyst, H. C. LYTHGOE (*Ann. Rpt. Bd. Health Mass., 44 (1912), pp. 393-452, figs. 3*).—Details are given of the year's work in the examination of foods and drugs. See above.

[Examination of food materials], H. E. WIEDEMANN ET AL. (*Bul. Food and Drug Dept. Missouri [1913], pp. 46*).—Data are given regarding a large number of samples.

Of 370 samples of food materials, soft drinks, and miscellaneous materials examined, 147 were not passed. Reports of inspection work and of the legal department of the pure food and drug work are included.

Drugs (*Maine Sta. Off. Insp.* 48 (1913), pp. 21-28).—Data are given regarding the inspection of drug stores and the examination of a number of drugs.

Protection of food offered for sale (*Maine Sta. Off. Insp.* 49 (1913), pp. 29-36).—Questions which have to do with the contamination and protection of food are discussed, with special reference to the provisions of the Maine state law.

[The possibility of conveying typhoid fever by clothing, contaminated food, and soiled fingers], S. L. CUMMINS (*Jour. Roy. Army Med. Corps*, 20 (1913), No. 6, pp. 635-665, fig. 1).—In an article on the causation and prevention of enteric fever in military service, with special reference to the importance of typhoid carriers, experimental data are reported which demonstrate the possibility of conveying this disease by means of the clothing and the soiled fingers of typhoid carriers, as well as the results of experiments which have to do with the possibility of the survival of the living *Bacillus typhosus* in foods and of the infection of foods by typhoid carriers.

"It is obvious that the contamination of food before cooking will usually be rendered harmless when the temperature of the food is raised. Contamination after cooking will be very dangerous even if the food is consumed immediately after the contamination takes place. The fingers of a typhoid carrier may be the vehicles of millions of germs. A single drop of urine . . . may contain anything from 1,000,000 to 300,000,000 typhoid bacilli, and these will multiply in soup at the temperature of serving. Again, soup contaminated, allowed to cool, and 'warmed up' again to a temperature just pleasant for drinking, may be very dangerous, especially if the soup has been covered to keep out dust in the interim."

Fecal contamination of roller towels (*Ann. Rpt. Bd. Health Mass.*, 44 (1912), pp. 549-552).—The experimental data reported showed that a considerable portion of public roller towels became thus contaminated. The possibility of spreading typhoid infection by such means is pointed out. Such work has a direct bearing on the possibility of conveying disease by means of contaminated food.

The grocer's encyclopedia, compiled by A. WARD (*New York*, 1911, pp. 748, pls. 80, figs. 373).—This volume, designed especially for grocers and general storekeepers, gives data regarding foods and their origin and care in the home and market, and other general information. The material is arranged alphabetically and the text is supplemented by numerous illustrations.

Yearly and monthly prices of the most important foodstuffs and other household materials in 155 districts in Prussia in the year 1911 (*Preuss. Statis.*, No. 232 (1911), pp. XIII+196).—A large amount of statistical data is presented. The introduction is contributed by F. Kühnert.

Dining at the Alexandra Trust (*Epicure*, 21 (1914), No. 242, p. 28).—In an article by P. Gibbs from the *Daily Chronicle*, London, some information is given regarding the sale of wholesome and nutritious, yet inexpensive, meals at this hotel designed for working people.

Portable rations, G. FAHEY (*Jour. Roy. Army Med. Corps*, 21 (1913), No. 1, pp. 87-89).—Suggestions are made regarding the make-up of a portable ration for army use which would supply the food necessary for a number of days.

[Menu making and the nutritive value of meals], EMMA S. JACOBS (*Jour. Home Econ.*, 6 (1914), No. 1, pp. 15-20, 57-62).—The author discusses ways in which the results of studies of housekeeping problems may be made of practi-

cal use to the housekeeper in arranging a diet which is in reasonable accord with dietary standards, due regard being paid to cost and to character of materials.

Feeding experiments with isolated food substances, T. B. OSBORNE, L. B. MENDEL, and EDNA L. FERRY (*Carnegie Inst. Washington Pub. 156, pt. 2 (1911), pp. III+55-138, pls. 2, figs. 108*).—Continuing work previously noted (E. S. R., 25, p. 864), the authors report investigations of the nutrition factors which influence growth. In the experimental data cited laboratory animals (rats) were used.

Especial attention is paid to such problems as the suspension of growth on a maintenance diet, the effect of stunting on the growth impulse, the effect of partial starvation on body weight and on the nervous system, a comparison of milk and mixed diet, and a study of isolated proteins and "protein-free" milk. Conclusions from the authors' discussion of the results presented and their bearings follow:

"A comparison of the two groups of proteins—those adequate and those inadequate for growth purposes—at once reveals the fact that the latter category comprises proteins (gliadin, hordein, zein) commonly spoken of as chemically 'incomplete.' They lack one or more of the amino acid complexes which are obtainable from the so-called 'complete' proteins. None of them furnish glycocoll or lysin, and zein in addition is devoid of tryptophane. By feeding relatively small quantities of proteins like casein with gliadin growth begins at once. Here we can determine the minimum of suitable protein to satisfy this growth requirement. . . . The addition of amino acids to 'complete,' as it were, the inadequate proteins can now be studied amid controllable factors; the biological rôle of hydrolyzed proteins and the significance of complete hydrolysis or digestion in nutrition can be examined anew.

"The experiences which have demonstrated the striking differences in value of the individual proteins and the small proportion of casein which suffices to induce growth instead of standstill . . . emphasize the importance of the purity of the protein fed. . . .

"The animals must here have synthesized their phosphorous compounds from inorganic phosphorus. Whether milk production and other functions calling for such synthetic reactions will continue adequately is open to investigation. It is also noteworthy that all of our animals grow on a dietary that is purin-free, or essentially so. Here the question of purin synthesis suggests itself. It is apparent, e. g., in the case of gliadin, that the grown as well as ungrown rats may be maintained for long periods on single proteins.

"With such an ideal nonprotein dietary component at hand amino acid substitutions can be attempted in the adult as well as in the growing animal. The protein minimum (or minima) is also open to accurate investigation. With a method of feeding devised which will permit a differentiation between growth and maintenance, which furnishes an energy-yielding protein-free component that is appropriate, and leaves the protein as the sole variable in the dietary, we believe that further contributions can be made to the problems of nutrition."

Influencing the bone growth by food poor in phosphorus, G. SCHMORL (*Arch. Expt. Path. u. Pharmakol.*, 73 (1913), No. 4, pp. 313-346, fig. 1; *abs. in Chem. Zentbl.*, 1913, II, No. 21, pp. 1813, 1814).—In experiments with laboratory animals (dogs) it was found that food poor in phosphorus resulted in a diminished production of bone substance.

Experiments bearing on the functions of the liver in the metabolism of fats, I. H. S. RAPER (*Jour. Biol. Chem.*, 14 (1913), No. 2, pp. 117-134).—In this, the first of his studies of the digestion and absorption of fat, the author reports

experiments on the hepatic functions in fat metabolism, using laboratory animals as subjects.

According to the author's summary, "coconut oil administered to cats or dogs by the mouth can be detected in the liver in 5 or 6 hours. The amount present after times varying from 5 to 12 hours does not exceed 6 per cent of that absorbed."

When a solution of coconut oil soaps containing glycerin and bile salts was run into the small intestine, and when a very fine emulsion of coconut oil was given intravenously, much larger percentages, respectively, of the absorbed fatty acid and of the oil were found in the liver.

"It is probable that the greater retention of the oil by the liver when it is administered in the form of soap or a fine emulsion is partly due to the anesthetic and partly to the rapidity of administration.

"When coconut oil is being absorbed, the fat in the chyle contains fatty acids with an average higher molecular weight than those in the oil administered. It is probable, therefore, that the lower fatty acids in the oil are partly absorbed as sodium salts.

"The volatile acids obtained from the liver in the above sets of experiments absorbed more iodine than the volatile acids from normal livers. The increase was not great but it probably indicates that saturated fatty acids containing 10, 12, or 14 carbon atoms may become unsaturated in the liver."

On the re-inspiration of expired air, T. R. CROWDER (*Arch. Int. Med.*, 12 (1913), No. 4, pp. 420-450; *abs. in Zentbl. Biochem. u. Biophys.*, 16 (1913), No. 1-2, p. 48).—According to the author's conclusion, with complete body rest, from 1 to 2 per cent of the expired air is again inspired.

A study of the hygienic condition of the air in textile mills with reference to the influence of artificial humidification, H. W. CLARK and S. DEM. GAGE (*Ann. Rpt. Bd. Health Mass.*, 44 (1912), pp. 659-692).—Methods for examining air are described and the effect of humidifying air discussed on the basis of the experimental data recorded.

ANIMAL PRODUCTION.

Genetics, H. E. WALTER (*New York*, 1913, pp. XIV+272, pl. 1, figs. 71).—Chapters are included in this book on the carriers of the heritage, variation, mutation, the inheritance of acquired characters, the pure line, segregation and dominance, reversion to old types and the making of new ones, blending inheritance, the determination of sex, the application to man, and human conservation. A bibliography of 26 references is appended.

The present state of the question of inbreeding in Germany, H. KRAEMER (*Internat. Inst. Agr. [Rome]*, *Mo. Bul. Agr. Intel. and Plant Diseases*, 4 (1913), No. 8, pp. 1150-1157).—It is stated that "in Germany in all the important branches of stock breeding the question of inbreeding is being most actively studied. Instead of entertaining opinions, views, and prejudices, the tendency is to form a solid foundation of facts. These efforts have a far-reaching importance and in all cases when the herd books have allowed it they have obtained valuable results. It has been found everywhere that really important breeding animals always belong to families in which the excellence of their blood is especially due to a few preeminent ancestors, and when this is recognized the real value of inbreeding and of lines of blood is put in its true light. . . . On the whole the present tendency is toward emphasizing selection, a more rigorous picking out of favorable hereditary variations."

Respiration and assimilation in ruminants, N. ZUNTZ, R. VON DER HEIDE, KLEIN, ET AL. (*Landw. Vers. Stat.*, 79-80 (1913), pp. 781-814, fig. 1).—This outlines methods for the study of the respiration and assimilation processes in the ruminant, giving a description of the respiration apparatus used.

Importance of calcium and phosphoric acid in the animal organism.—II, Value of the principal phosphorus compounds to the ruminant, G. FINGERLING (*Landw. Vers. Stat.*, 79-80 (1913), pp. 847-870).—Results of experiments in the feeding of casein, phytin, lecithin, nuclein, sodium nucleinate, and disodium phosphate in rations to goats indicated that a comparatively large percentage of the P_2O_5 in these phosphorus-containing materials was retained by the animal body.

Calculation of market value of feeding stuffs, T. PFEIFFER (*Landw. Vers. Stat.*, 79-80 (1913), pp. 279-321).—Basing his calculations on the manurial value of the nitrogen, potash, and phosphoric acid contained in feeding stuffs, the digestible protein, and Kellner's starch values, the author estimates the actual value of various feeding stuffs as determined by local prices.

Method of estimating the market value of feeding stuffs on the Kellnebasis, H. NEUBAUER (*Landw. Vers. Stat.*, 79-80 (1913), pp. 465-490, fig. 1).—Taking the local prices for a number of feeding stuffs, the author calculates the actual market value per kilogram of starch and of digestible protein. A graduated scale is then proposed for estimating the value of feeds, based on fluctuating market prices.

Composition and digestibility of the chloroform extract of hays and fodders, G. S. FRAPS and J. B. RATHER (*Texas Sta. Bul.* 162 (1913), pp. 5-20).—These studies have been previously reported from another source (*E. S. R.*, 28, p. 69), and continue earlier work (*E. S. R.*, 28, p. 108). The composition and average digestibility of the constituents of chloroform extract of the following hays and fodders are given: Alfalfa hay, Bermuda hay, buffalo grass hay, bur clover, corn shucks, Guam grass, Johnson grass, Johnson grass hay, Kafir corn fodder, millet, oat hay, Para grass hay, peanut hay, rice straw (Japan), rice straw (Honduras), sorghum hay, and vetch hay.

Preliminary investigation into the variation in the physical composition of wheat milling offals, H. T. CRANFIELD (*Jour. Agr. Sci. [England]*, 6 (1914), No. 1, pp. 102-110).—With a view to obtaining a definite classification of wheat milling offals, a study was made of the appearance, physical composition, sieving, apparent density, proportion of flour, and purity of a large number of samples ranging in grade from fine middlings to coarse bran.

The samples were graded into 10 classes by their appearance. The percentage of moisture varied in different samples, ranging from 16.21 to 11.37, but is not regarded as a factor to be considered in this classification. The germ content of the offals was small and was also of little importance. The husk and flour constituents were found to be the most important items in solving the problems of grading. The separation of the flour from the husk by sieving was found to be impracticable.

The following method was evolved for determining the densities of husk and flour, and gave figures showing quite a large variation between the finest and coarsest offals: "About 20 gm. of the offal was dried in a steam oven at 100° C. for 5 hours (this was found to be ample time for completely drying the substance). After cooling in a desiccator 15 gm. was quickly weighed out and transferred to a 100 cc. graduated cylinder, the cylinder being gently tapped while the offal was sifted in. The cylinder was then jolted on a wooden slab until the contents had reached approximately a constant volume. Finally a 100-gm. lead weight (made to fit the cylinder exactly, and having a stout rubber

washer glued to the bottom) was gently lowered on to the surface of the offal in the cylinder, and the tapping continued until the volume was constant. The whole test occupied not more than 4 minutes."

With normal samples the method gave results agreeing fairly well with the classification according to appearance. It is assumed that the apparent density figure varies directly as the percentages of flour and husk and the fineness of these two fractions. The proportion of flour in the sample was determined by estimating the percentage of starch in the substance and multiplying this by a factor. The washings from a sample of the offal were centrifuged, the deposit of starch washed with alcohol, dried, and weighed, and the percentage of crude starch calculated. Fine offals contained protein matter ranging from 2.3 to 3.8 per cent, and coarse offals approximately 13.5 per cent. The crude starch percentage ranged from approximately 45 in the first group to 15 per cent in the tenth group.

A purity test showed the principal impurities to be weed seeds and oat husk. It is believed that these and other impurities should be excluded from commercial products so far as possible. It is recommended that a series of determinations, consisting of percentage of moisture, apparent density, percentage of starch, and purity be agreed upon; that a series of grades of offals be arranged with stated limits for percentage of starch and apparent density; that limits be set for all offals as regards percentage of moisture and purity; that local names be dropped as far as possible and such names as "fourths," "thirds," "seconds," "bran," and "broad bran" be utilized for the standard grades; and that millers be asked to cooperate in some definite scheme for bringing all wheat offals within the range of a system of standardization such as suggested here.

The making and feeding of silage, T. E. WOODWARD ET AL. (*U. S. Dept. Agr., Farmers' Bul. 578 (1914), pp. 24, figs. 6*).—This is a revision of and supersedes Farmers' Bulletin 556 (E. S. R., 29, p. 869).

Silos and ensilage, W. R. DODSON and C. H. STAPLES (*Louisiana Stas. Bul. 143 (1914), pp. 20, figs. 15*).—This bulletin contains general information on silo construction, silage crops, and rations containing silage.

Composition and value of grapevines as feed material, M. KLING (*Landw. Vers. Stat., 79-80 (1913), pp. 737-771*).—In this article numerous experiments are cited showing the value of grapevines as feed material for milch cattle and sheep.

The average composition of various portions of the vine is reported as follows:

Composition of grapevines.

Portion of vine.	Water.	Protein.	Fat.	Nitrogen-free extract.	Fiber.	Ash.
	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>
Entire vine.....	72.59	3.85	0.90	15.06	5.52	2.08
Wood, material.....	71.43	1.33	.25	16.60	9.04	1.35
Foliage.....	73.06	4.86	1.16	14.47	4.08	2.37

The digestibility of the foliage was found to be protein 59 per cent, fat 79, nitrogen-free extract 65, fiber 38; and for the woody material, 15; 88, 42, and 19 per cent, respectively. The ash of the foliage was found to contain phosphoric acid 11.66 per cent, calcium 32.04, and potassium 18.61; the woody material, 11.99, 19.77, and 34.04 per cent, respectively; and the entire vine, 11.56, 29.91 and 21.45 per cent, respectively.

A bibliography of 27 references is appended.

Commercial feeding stuffs, R. E. STALLINGS (*Bul. Ga. Dept. Agr., No. 60 (1913), pp. 119, fig. 1*).—This reports analyses of the following feeding stuffs: Molasses feed, meat scrap, alfalfa meal, dried-beet pulp, rice bran, rice polish, tankage, crushed oats, proprietary mixed feeds, poultry and stock feeds, cotton-seed meal, wheat shorts, wheat bran, wheat middlings, ship stuff, white shorts, corn meal, corn bran, hominy meal, and cracked corn.

The text of the law regulating the sale of feeding stuffs is included, together with rules and regulations relating to the law, standards of purity of grain as adopted by the commissioner of agriculture and state chemist, grades for commercial corn, definitions of feeds, etc.

Feeding stuff inspection (*Maine Sta. Off. Insp. 50 (1913), pp. 37-76*).—Analyses are reported of the following feeding stuffs: Cotton-seed meal, gluten meal, linseed meal, distillers' grains, red dog flour, wheat middlings, bran, hominy feed, and various mixed and proprietary feeds.

The chief requirements of the Maine feeding stuffs law are enumerated.

The analysis and registration of commercial feedstuffs, L. A. FITZ (*Kansas Sta. Bul. 195 (1913), pp. 493-520*).—This bulletin gives a list of firms registering feeds for the fiscal year ended June 30, 1914, with guaranties, a table giving average analyses of mill products for the previous year, a discussion of the state feeding stuffs law, and other data.

Feeding stuffs, A. P. SANDLES (*Off. Rpt. Sec. Ohio Bd. Agr. on Feed Stuffs, 1912, pp. 128*).—This reports analyses of the following feeding stuffs: Germ oil meal, malt sprouts, cotton-seed meal, alfalfa meal, meat meal, hominy feed, dried distillers' grains, tankage, molasses feeds, gluten feed, gluten meal, rice meal, bran, chop, dried beet pulp, linseed meal, screenings, beef scrap, barley sprouts, proprietary mixed feeds, etc. There are included definitions of the various feeding stuffs, articles on screenings and their use, cotton-seed meal, cereal milling offals, tankage, and other subjects relating to the feeding of animals. There is also given an index to manufacturers and dealers in feeding stuffs, and the text of the Ohio feed stuffs law.

Live stock of the United States (*U. S. Dept. Agr., Farmers' Bul. 575 (1914), pp. 1-29, 34-39*).—"The estimates for January 1, 1914, indicate that there are 20,962,000 horses and 4,449,000 mules in the United States, an average annual increase of about 1.4 per cent over the number shown by the Census of 1910. It is estimated that the average farm price of horses has increased from \$108.03 in the census year to \$109.32 in January, 1914, and in the case of mules from \$120.20 to \$123.85 in the same period. On this basis the total farm value of horses is \$2,291,638,000 and of mules \$551,017,000, . . . an increase of \$194,082,000 over the census year and represents an annual increase of wealth from these sources of \$48,520,000.

"The estimates indicate a slight increase in the number of milch cows since the census year, equivalent to an increase of about 0.5 per cent, the estimated number now being 20,737,000. On the other hand, the average farm price of milch cows has increased from \$35.29 in the census year to \$53.94 in January, 1914, or an increase of 50.7 per cent. On this basis the farm value of milch cows now in the United States is estimated at \$1,118,487,000 as compared with their estimated value in the census year of \$727,802,000 . . .

"With regard to meat animals, that is, 'other cattle,' sheep, and swine, the estimates indicate a steady and fairly uniform decrease in the number of cattle and sheep, a slight increase in the number of swine, and a considerable increase in the average farm price of cattle and swine since the census year of 1910. In the case of cattle the number has decreased from 41,178,000 in the census year to 35,855,000 in January, 1914 . . . In the case of sheep the number is estimated to have decreased from 52,448,000 in the census year to 49,719,000

. . . In the case of swine, the Bureau of the Census reported 58,186,000 on April 15, 1910; on January 1, 1914, it is estimated that there were 58,933,000 in the United States . . .

"As compared with the census year 1910 it is estimated that the farm price of cattle other than milch cows has increased from \$19.07 to \$31.13, or 63.2 per cent . . . The price of sheep has decreased from an estimated average farm value of \$4.12 in 1910 to \$4.04 in 1914; swine increased from \$9.17 to \$10.40 per head in the same period, or 13.4 per cent.

"The estimated total number of these 3 classes of meat animals on January 1, 1914, is 144,507,000 as compared with 151,812,000 in the census year of 1910, or a decrease of 7,305,000 animals; but because of the higher prices the present farm value of these animals is estimated at \$1,930,087,000 as compared with \$1,534,600,000 in the census year, or an increase in valuation of \$395,487,000."

Relatively to the population, which has increased from 91,972,000 to 98,646,000, there is an accumulated shortage in the past 4 years of 3.5 per cent in the number of horses and 9.8 per cent in number of mules, 4.4 in milch cows, 19.2 in other cattle, 11.6 in sheep, and 5.2 per cent in swine. The contributing causes to the shortage in number of animals and the geographic redistribution of all classes of farm animals are discussed.

The per capita consumption of meat was 213.4 lbs. in 1900, 198.4 lbs. in 1909, 160.3 lbs. for 1914; and the total consumption was 16,220,000,000 lbs. in 1900, 17,966,000,000 lbs. in 1909, and as roughly estimated 15,810,000,000 lbs. of meat in 1914. The total production of meat was 18,653,000,000 lbs. in 1900, 19,229,000,000 lbs. in 1909, and the estimate for 1914 is 16,675,000,000 lbs. Exports of meat decreased from 1900 to the fiscal year 1913 by 64.5 per cent. The total number of cattle, including a few introduced for breeding purposes, imported in 1912 was 318,372, in 1913, 421,649, and in the first 5 months of 1914, 404,313, almost entirely from Mexico and Canada. The imported sheep of 1912 number 23,588, for 1913, 15,428, and for the first 5 months of 1914, 75,620, mostly from Canada. During the first 6 months of the fiscal year 1914, the imports of beef and veal had a total of 33,645,364 lbs., of mutton and lamb 439,065 lbs., of pork 286,871 lbs., and of bacon and hams 116,130 lbs. Previous imports have been very small. The principal countries contributing to the total imported meat and meat products were in order of magnitude of contribution Argentina, Canada, and Australia.

A comparative table of old and new tariff rates on meat animals and the principal meat and meat animal products is given.

Live stock report, Chicago, 1913 (*Union Stock Yard and Transit Co. Chicago, Ann. Live Stock Rpt.*, 48 (1913), pp. 56).—This report gives the receipts and shipments of live stock at the Union Stock Yards, Chicago, for 1913, together with a summary of receipts, shipments, and valuation of all live stock during the past 48 years, the range in prices during the year for cattle, horses, sheep, and hogs, and an account of the grand champion steers and carloads of fat cattle shown at the International Stock Show during the past 13 years.

Beef production in the South, W. F. WARD and D. T. GRAY (*U. S. Dept. Agr., Farmers' Bul.* 580 (1914), pp. 20, figs. 9).—Popular instructions are given on handling and feeding beef cattle, the best breeds for the South, and the best pasture plants. Numerous cattle-feeding experiments, previously reported from other sources, are cited.

Experiments on the moorland pastures, B. TACKE (*Landw. Jahrb.*, 44 (1913), No. 1-2, pp. 193-267, figs. 4).—This article reports results of extended experiments covering a period of 7 years with steers and oxen pastured on drained

and limed moorland meadows. The average daily gains ranged between 1.93 and 2.47 kg. per hectare (1.7 to 2.2 lbs. per acre).

Utilization of skim milk as feed for calves.—Summary of experiments carried out on 60 calves, A. PIROCCHI (*Ann. Ist. Agr. [Milan]*, 11 (1912-13), pp. 9-19, figs. 3; *Internat. Inst. Agr. [Rome]*, *Mo. Bul. Agr. Intel. and Plant Diseases*, 4 (1913), No. 8, pp. 1157-1164, pl. 1, fig. 1).—As the result of feeding trials with 60 calves it is concluded that skim milk mixed with oleomargarine and starch treated with diastasin (a saccharifying substance extracted from malt) or with levulin (a distillery product having the power of transforming starch into dextrin) may be advantageously employed as feed for calves destined for the butcher.

The jerked beef industry in Argentina, J. E. RICHELET (*Bol. Min. Agr. [Buenos Aires]*, 14 (1912), No. 9, pp. 986-1029; *abs. in Internat. Inst. Agr. [Rome]*, *Mo. Bul. Agr. Intel. and Plant Diseases*, 4 (1913), No. 4, pp. 643-645).—It is stated that in 1911 12,975 tons of jerked or salted meat were exported from Argentina. While the industry has been injured by the rise of the cold stored meat trade it is thought that there is yet a considerable field for it, especially in Brazil, where a large portion of the beef consumed consists of the jerked product. The method of preparing jerked beef consists in passing the flesh from the quarters, neck, and ribs through one or more vats of brine. It is then stacked with salt in heaps about 10 ft. high. The stacks are undone every day, the meat is hung in the sun for 7 or 8 hours, and the stacks are re-made in reverse order. The process lasts from 12 days to a month according to the weather.

Primitive breeds of sheep and their crosses (*Pastoral Rev.*, 24 (1914), No. 1, pp. 49, 50, figs. 3).—An account of the crossing of black ewes of Welsh origin, Exmoor-bred Cheviots, and Scotch black-faced ewes with a ram from the island of Soay. It is the purpose of these experiments to furnish information on the problems of the inheritance of color and born reversion, and on the influence of environment on the wool, constitution, and fertility of sheep generally. Illustrations are given of a Manx ram, a representative of a breed that exists in small numbers in the Isle of Man and described as the smallest of breeds; of the Hebridean sheep, originally introduced from Norway; and the Piebald sheep, a breed which has been lost in antiquity.

Breeds of sheep for the farm, F. R. MARSHALL (*U. S. Dept. Agr., Farmers' Bul.* 576 (1914), pp. 16, figs. 10).—This discusses the breed characteristics and utility value of the various breeds of middle-wooled and long-wooled sheep.

Mutton, T. G. PATERSON (*Univ. Minn., Dept. Agr. Ext. Bul.* 45, pp. 16, figs. 27).—This is a popular bulletin treating of the dressing and preparation of mutton for market and table purposes.

The Angora goat, L. L. HELLER (*U. S. Dept. Agr., Farmers' Bul.* 573 (1914), pp. 16, figs. 6).—This treats of the advantages, origin, distribution, breed characteristics, utility value, feed, care, and management of Angora goats, and the value and use of mohair. A score card for Angora goats is included.

The utilization of skim milk and potatoes by feeding to pigs, HANSEN (*Mitt. Ver. Deut. Schweinezüchter*, 20 (1913), No. 13, pp. 264-268; *abs. in Internat. Inst. Agr. [Rome]*, *Mo. Bul. Agr. Intel. and Plant Diseases*, 4 (1913), No. 8, pp. 1264, 1265).—German pig-feeding methods are discussed, in which 10-week-old pigs are given a feed composed of barley, meat, and fish meal, equal parts. At the age of from 20 to 24 weeks they reach a weight of 237 to 242 lbs., having made a daily gain of about 1.32 lbs. The feeding of skim milk and potatoes to hogs is shown to be a profitable method for pork production.

Advertising stallions and jacks under the Indiana stallion enrollment law, D. O. THOMPSON (*Indiana Sta. Circ.* 43 (1914), pp. 8).—This circular

explains the provisions as to advertising stallions and jacks under the Indiana stallion enrollment law.

Diversified poultry farming, A. L. CLARK (*New Jersey Stas. Circ. 32*, pp. 3-16).—This circular discusses the production of winter eggs, broilers, roasting chickens, capons, day-old chicks, eggs for hatching, fall pullets, and breeding stock, including methods of management.

A new method for the industrial preservation of eggs, M. DE KEGHEL (*Rev. Chim. Indus.*, 24 (1913), No. 277, pp. 12-18; *abs. in Internat. Inst. Agr. [Rome]*, *Mo. Bul. Agr. Intel. and Plant Diseases*, 4 (1913), No. 4, p. 618).—A coating material for the preservation of eggs is compounded according to the following formula: Peanut oil 14 gm., palm oil 20, coconut oil 16, prepared lard 47, spermaceti 2, trioxymethylene 1, and powdered thymol 0.05 gm. Before the eggs are coated they should be sterilized with a 0.2 per cent solution of fluorid of silver.

It is stated that eggs preserved in this way had the same appearance and taste after 18 months as fresh eggs. The cost price of the coating material is estimated at 6d. (12 cts.) per 100 eggs, and the total preserving cost at 1s. 8d. per 100 eggs.

Importation of eggs from China, J. E. OLMSTEAD (*Cong. Rec.*, 51 (1914), No. 49, p. 3538).—It is stated that there have recently arrived in the markets of the coast cities large shipments of eggs imported from China. These eggs are being sold a few cents under the price of American eggs and are used largely by restaurants and bakeries. It is claimed that such importations may work hardship on the American producer, and that the Chinese eggs are produced under conditions that render them unfit for human consumption.

Pigeon raising, ALICE MACLEOD (*New York, 1913*, pp. 113, figs. 2).—This treats of the feed, care, and management of pigeons for commercial purposes.

DAIRY FARMING—⁵DAIRYING.

Making the dairy pay, N. F. HULL (*New York, Chicago, and Springfield, Mass., 1913*, pp. 84, pls. 15, figs. 30).—A popular treatise on dairy management.

Conformation of cows and milk yield, J. REIMERS (*Abs. in Mitt. Deut. Landw. Gesell.*, 28 (1913), No. 17, pp. 255-257; *Jour. Bd. Agr. [London]*, 20 (1914), No. 10, pp. 906, 907).—In a study made of 300 Friesian cattle from 2½ to 3 years old to determine the relation between conformation and milk yield, it was found that "the milk yield increases slightly with increasing length of body until the latter reaches a certain point, after which there appears to be a slight decrease in the yield. Abnormal length of body apparently has the effect of lowering the milk secretion. The milk yield increases with increasing height of crupper, but the increase can by no means be called regular, and a strong connection between the two factors could not be established. Animals with small or with very deep breasts appear to give a smaller yield than animals which are normal in this respect, but the difference was too slight to make the deduction of practical value.

"There is no regular relationship between milk yield and length of hind quarters, or width between haunches, or breadth of pelvis. Animals with normal breadth of pelvis give more milk than those with larger or small breadth of pelvis, but the difference is not important." No relation could be found between the shape of hind quarters and milk yield. The best milkers had the worst thigh, although there was no regular connection between this and yield. See also a previous note (E. S. R., 27, p. 675).

Report of the Dickinson County Cow-Testing Association, O. E. REED (*Kansas Sta. Circ. 35* (1914), pp. 8, figs. 3).—This circular reports the results

from the first year of a cow-testing association including 134 cows, with an average production of 6,019 lbs. milk and 246 lbs. milk fat, at a net profit of \$54.89. Great variations were found in the various animals. The general advantages of cow-testing associations are discussed.

Dairy feeding and the home mixing of feeds, A. S. Cook (*New Jersey Stas. Circ. 7 (rev.)*, pp. 14).—This circular explains the principles involved in the balancing of feed rations for dairy cows and illustrates the use of these principles in compounding rations and grain mixtures. A number of desirable grain mixtures that may be fed with the different roughages are suggested.

[Feeding experiments] (*Min. Agr. et Trav. Pub. [Belgium], Off. Rural Raps. et Communs.*, No. 2 (1912), pp. 160).—This reports numerous private feeding experiments with dairy cattle conducted on farms throughout France and Belgium.

Comparison of alfalfa hay and alfalfa silage as a feed for dairy cows, G. H. TRUE ET AL. (*Nevada Sta. Rpt. 1913*, p. 39).—In a preliminary trial with 4 dairy cows, 2 fed on alfalfa hay and a grain ration, and 2 on alfalfa silage and a grain ration, it became evident that alfalfa silage alone could not be used as the only roughage, and a portion of the silage was replaced by hay. It was noticed in this connection that while alfalfa silage and alfalfa hay caused constipation, the silage alone resulted in the opposite effect. It is believed from the results obtained from this preliminary experiment that alfalfa silage has no beneficial effect on milk production.

Prickly pear cactus as a feed for dairy cows (*U. S. Dept. Agr. Press Notice, 1914, January 14*, pp. 2).—In experiments conducted by this Department at Brownsville, Tex., in feeding prickly pear cactus to dairy cows, this feed was found to be very palatable and when judiciously fed was in no way detrimental to the cow or her product. From 60 to 100 lbs. of the pear per cow per day appeared to be a satisfactory amount. Larger quantities caused a laxative condition. The pear was found to be low in protein and high in mineral matter, with from 87 to 93 per cent of water.

Compared with other roughages the pear was found to have a relative value for production of milk fat wherein 1 lb. of sorghum hay, sorghum silage, or cotton-seed hulls is equal to 10.1, 3.3, and 8.8 lbs., respectively, of pear. The feeding of pear apparently decreased the total amount of milk fat and the percentage of solids-not-fat, but increased the total yield of milk. The pear produced a higher colored butter than did the dry feed, but the flavor of the milk was not impaired in any way. Cows fed pear appeared to be more sensitive to cold weather than when fed dry feed. Pear-fed cows required but little drinking water. Both spiny and spineless varieties were fed in these trials, but no difference could be detected in chemical composition or feeding values for milk production.

Effect of concentrated feeds on butter (*Mark Lane Express, 111 (1914), No. 4300*, p. 295).—The results of general experience on the effect of concentrated feeds on butter are summarized, particularly crushed barley and barley meals, malt sprouts and brewers' grains, crushed oats, wheat bran, crushed rye and rye offals, crushed maize and maize offals, crushed buckwheat and buckwheat offals, peas and beans, vetches, cotton-seed meal and cake, peanut cake, coconut cake, linseed cake, palm-nut cake and meal, rape-seed oil residues, sesame cake, sunflower cake, meat meal, fish meal, and fresh and dried sugar-beet slices.

Weight of butter (*Maine Sta. Off. Insp. 51 (1913), pp. 77-92*).—Continuing previous work as to short weight butter (*E. S. R.*, 28, p. 879), it is shown that, while there is still much short weight, on the whole an improvement is noted

in the dairy situation. Recommendations to manufacturer, jobber, retailer, and consumer relative to ascertaining the correct weight of butter are given.

A comparison of the microscopical method and the plate method of counting bacteria in milk, J. D. BREW (*New York State Sta. Bul. 373 (1914), pp. 38, pls. 2, figs. 2*).—This bulletin gives the results of comparative studies between the direct microscopic method and the plate method of counting bacteria as applied to market milk. The milk from 37 dairy farms was examined, although the conclusions were based largely on the results obtained from 4 of these in which cases more extensive and detailed examinations were made.

“The microscopical method used in this work consisted in measuring out 0.01 cc. of milk taken directly from a well-shaken sample by means of a specially graduated and accurately calibrated pipette. The drop of milk was deposited on a clean glass slide and spread over an area of 1 sq. cm. with a stiff, straight needle. Duplicate smears of each sample were made on the same slide. The milk was then dried by gentle heat which was obtained by means of a level wooden surface over a steam radiator. Care was exercised not to allow the smears to become too hot as this made them check and thereby made satisfactory staining impossible. As soon as dry, the slides were placed for a short time in a Coplin staining jar containing xylol to remove the fat. They were then taken out and the surplus xylol about the edges of the slide wiped off with filter paper. The smears were dried and then fixed to the slide by means of a 95 per cent solution of alcohol. Immediately thereafter they were stained from 2 to 3 minutes in Loeffler's methylene blue, after which they were decolorized to a light blue in a 95 per cent solution of alcohol. The counting was done under a 1.9 mm. oil-immersion lens.”

The results of these studies indicate that there is a well-defined relationship existing between the direct microscopic count and the plate count. This is more apparent in long series of examinations than in short series which renders it impossible in individual samples to establish a definite ratio whereby the results obtained by the one method can be interpreted on the basis of the other method. “The relative differences between the two counts are greater where the bacteria are few in number. In samples of milk showing plate counts of less than 10,000 per cubic centimeter, the count by the microscope shows approximately 44 times as many individual bacteria, or 17 times as many when the clumps and isolated bacteria are counted as units, individual bacteria in the clumps not being counted. In those samples which give a plate count of about 1,000,000 per cubic centimeter, the count made with the microscope shows approximately 5 times as many individual bacteria; or when the isolated bacteria and clumps of bacteria are counted as units the number of these units is slightly less than the number of colonies given by the plate method.

It is concluded that the bacterial count obtained in milk by the direct microscopic method is equally as good if not a better criterion of its bacterial content than the count obtained by the plate method, and has these decided practical advantages: “The number of bacteria can be shown in a given sample of milk within a very few minutes. The apparatus required is less expensive than that required for the plate method and the examinations necessary for commercial grading can be made by men who are not trained bacteriologists. The morphology of the bacteria present may be determined as well as the approximate number present. The microscope frequently shows many bacteria present in samples of milk while agar plate counts from the same samples are low.”

It is hoped that this method can be made of practical use to the milk dealer, butter maker, and cheese maker as a means of grading milk according to its

bacterial condition. It is recognized, however, that the adoption of this method would involve a readjustment of present bacteriological standards and for this reason it is not recommended that such changes in standards be made until more comprehensive data have been secured. The practical application of the microscopical method in the examination of dried milk smears has not yet been fully determined, and there are also questions as to how rapidly dead bacteria undergo dissolution in milk and whether they can be distinguished from living ones by means of stains or other technique which must be answered before the technique can be used in a practical way for the examination of pasteurized milk or for milks where many bacteria have died from one cause or another.

Pure milk production and the abortion bacillus, E. C. SCHROEDER (*Amer. Vet. Rev.*, 44 (1914), No. 4, pp. 467-475).—In this paper the author points out the prevalence of the abortion bacillus in the milk of dairy herds and the menace to public health of such contaminated milk. It is concluded that it is imperatively necessary to resort to heat as a simple and inexpensive expedient to make all milk safe before it is fed as food.

Fruity or sweet flavor in Cheddar cheese, S. F. EDWARDS (*Centbl. Bakt. [etc.]*, 2. *Abt.*, 39 (1913), No. 18-19, pp. 449-455, pls. 3).—This reports a study made of the fruity or sweet flavors which have been found to develop in Cheddar cheese.

Twelve varieties of flavors were determined and their cause ascribed to various torulæ. Studies made of these torulæ under various conditions tend to show that the off-flavor develops early and does not pass off as the cheese gets older; that the torulæ die out eventually, although some were alive at the end of a year; and that the thermal death point of all 12 varieties studied lies between 65 and 70° C. with an exposure of 10 minutes.

Although the chemistry of the flavor production has not been worked upon, it is thought that the flavor is due to the formation of esters during the process of fermentation.

[Dairy laws] (*Boston*, 1912, pp. 53).—This is a manual of the dairy laws of Massachusetts relating to dairy products and their imitations, with a digest of Supreme Court decisions thereon.

Cost of milk inspection (*Cream. and Milk Plant Mo.*, 2 (1913), No. 4, p. 32).—Replies from 184 cities in answer to inquiries sent out by the U. S. Department of Agriculture are summarized, and indicated that 22 cities were not spending any money for milk inspection and only 43 spent 5 cts. or more per capita. The average of all cities reporting milk inspection spent 4.4 cts. per capita.

VETERINARY MEDICINE.

Report of the veterinary director general and live stock commissioner for the year ending March 31, 1912, J. G. RUTHERFORD (*Rpt. Vet. Dir. Gen. and Live Stock Comr. Canada*, 1912, pp. 480, pls. 29).—Among the more important papers presented in the appendixes, which take up the greater part of this report, are the report of the pathologist (pp. 71-91) by C. H. Higgins, which includes papers on Tuberculosis in Poultry and Blackhead in Turkeys; report of the first assistant pathologist (pp. 92-99) by S. Hadwen which includes papers on The Life History of *Ixodes angustus*, previously noted (*E. S. R.*, 30, p. 60), Notes on Ticks, and a List of Ticks Captured; report of the second assistant pathologist (pp. 100-102) by E. A. Watson, which deals largely with dourine; Special Report on Hog Cholera (pp. 103-105) by A. E. Moore; The Control and Eradication of Glanders (pp. 115-122) by C. D. McGilvray; the text of the animal contagious diseases act and the regulations made thereunder

relating to quarantine and the control of disease (pp. 149-158); quarantine regulations (pp. 159-183); an address on Bovine Tuberculosis (pp. 335-337) by J. G. Rutherford; Further Report on the Dourine of Western Canada, part I (pp. 465-472) by E. A. Watson; and a paper on Trypanosomes Found in Canadian Mammals (pp. 473-476) by E. A. Watson and S. Hadwen, previously noted from another source (E. S. R., 27, p. 81).

The determination of the minimal lethal dose of various toxic substances and its relationship to the body weight in warm-blooded animals, together with considerations bearing on the dosage of drugs, G. DREYER and E. W. A. WALKER (*Proc. Roy. Soc. [London], Ser. B, 87 (1914), No. B 595, pp. 319-330*).—"In warm-blooded animals of the same species but of different weights dosage must be calculated in relation to the body surface. This result agrees with the conclusion already reached by Moore [E. S. R., 21, p. 581] though on different grounds. This statement is to be explained on the ground that the concentration in the plasma of any given substance administered is dependent on the volume of the circulating blood, which is itself proportional to the body surface in any given species of animal. It follows that in the accurate measurement and standardization of toxic substances and antitoxins it will now be possible to make use of animals of different weights within a given species instead of using only animals of an arbitrarily selected weight, as has hitherto been necessary. Results in dosage calculated from one species of animal can not directly be applied to another species merely by taking surface into due consideration, since tolerance and intolerance are specific characters which are shown to be in many cases independent of the size of the species concerned."

A bibliography of 25 references is appended.

A note on nitrous oxid as an anesthetic in animal experimentation, D. H. DOLLEY (*Jour. Expt. Med., 19 (1914), No. 4, pp. 372-375, fig. 1*).—"Nitrous oxid, administered by means of the Gatch apparatus, as a preliminary anesthetic to ether has been found to be superior for the dog in rapidity of action, in promotion of ease of handling, and in absence of disorder; the anesthesia may be maintained solely by nitrous oxid in combination with oxygen; it is economical; and its use is instructive to students from closer imitation of current surgical methods."

Poisoning by castor seeds (*Ricinus*), G. D. LANDER (*Vet. Rec., 26 (1914), No. 1341, pp. 614-618*).—Attention is called to the fact that in spite of the well-known dangerous character of the castor oil seed (*Ricinus communis*) it is not uncommonly encountered in horse mixtures and in cakes.

Critical and experimental data in regard to the formation of leukins, R. SCHNEIDER (*Arch. Hyg., 75 (1912), No. 4-5, pp. 167-188; abs. in Ztschr. Immunitätsf. u. Expt. Ther., II, Ref., 5 (1912), No. 9, p. 157*).—This is a discussion of the work of Pettersson and his coworkers. The endolysins obtained by Pettersson are considered secretory products which correspond to the leukins, and the results obtained by Pettersson do not discredit those reported by the author because other technique was used.

Digesting leucocytes in a 5 per cent serum-sodium chlorid (0.85 per cent NaCl solution) at body temperature is deemed the best method for obtaining bactericidal substances from the guinea pig. Serum is added for the purpose of stimulating the leucocytes to yield the bactericidal substances. The bactericidal substances can only be obtained from dead leucocytes when the cell structure has been thoroughly disintegrated.

Bacteria, M. SCHOTTELIUS, trans. by H. GEOGHEGAN (*London, 1912, 2. ed., pp. XII+324, pls. 10, figs. 33*).—This small book contains chapters as follows: Position of bacteria in the scheme of nature and in regard to other forms of

life; bacteriological research methods; disease and the means of combating infectious diseases; immunity and protective inoculation; infectious diseases; and protozoa as pathogenic organisms. The subjects are discussed chiefly from the human medical standpoint.

The present status of our knowledge of the pathogenic rôle of helminths, B. GALLI-VALERIO (*Centbl. Bakt. [etc.]*, 1. Abt., Ref., 61 (1914), No. 4, pp. 97-115).—A review with references to the literature on the subject.

The sporotrichoses, DE BEURMANN and GOUGEROT (*Les Sporotrichoses*. Paris, 1912, pp. 852, pls. 8, figs. 181).—The first part of the work (pp. 41-192) consists of a comparative study of the sporotrichoses and the Sporotrichum pathogens, their botanical classification, etc. The second part (pp. 195-309) relates to the sporotrichosis of de Beurmann, its frequency and geographical distribution, the etiology and pathogeny of sporotrichoses, clinical forms, a study of the localizations of sporotrichosis, polymorphism and multiplicity of forms, evolution, diagnosis, prognosis, treatment, pathological anatomy, experimental sporotrichoses, spontaneous sporotrichoses of animals, etc. A bibliography of 24 pages is appended.

Argas and spirochetes, E. MARCHOUX and L. COUVY (*Ann. Inst. Pasteur*, 27 (1913), No. 8, pp. 620-643).—This second part of the paper previously noted (E. S. R., 29, p. 563) deals with the virus in the tick.

Concerning the filterability of *Spirochæta duttoni*, J. L. TODD and S. B. WOLBACH (*Jour. Med. Research*, 30 (1914), No. 1, pp. 27-36).—“*S. duttoni* in an infective form can be forced through a Berkefeld filter by pressures of over 50 lbs. to the square inch. *S. duttoni* can not be filtered through a Berkefeld filter in an infective form by atmospheric pressure.”

The cultivation of a free living filterable spirochete (*Spirochæta elusa*; new species).—A preliminary report, S. B. WOLBACH and C. A. L. BINGER (*Jour. Med. Research*, 30 (1914), No. 1, pp. 9-22, pls. 3).—This relates to studies of a spirochete developed from the filtrate of pond water to which the name *S. elusa* is given.

“The chief importance to be attached to the cultivation of the spirochete here reported lies in its morphological similarities to the pathogenic spirochetes and in its filterability. The ease with which it is cultivated offers opportunities for the determination of the nature of the coiled and sporelike forms and the granules. The fact that this spirochete forms definite colonies on solid media, similar in appearance to the colonies formed by bacteria, will undoubtedly be taken as evidence for the close relationship between spirochetes and bacteria.

“The filterability of this spirochete, together with positive filtration experiments recorded for relapsing fever spirochetes by Novy and Breinl, and by Todd [see above], indicate that by this method a means may be found for separating spirochetes from bacteria which should open the way to the systematic study of free living spirochetes and those saprophytic in man and animals.”

The distribution and morphology of *Spirochæta duttoni* and *S. kochi* in experimentally infected ticks (*Ornithodoros moubata*), S. B. WOLBACH (*Jour. Med. Research*, 30 (1914), No. 1, pp. 37-48, pls. 3).—“The modified Giemsa stain employed is a reliable method of demonstrating spirochetes in the tissues of ticks. The two strains of spirochetes studied, *S. duttoni* and *S. kochi*, migrate through all the organs and tissues of the ticks. Multiplication of spirochetes does not take place in epithelial cells of the tick, but does occur in tissues of the connective tissue group. The minute granules and comma bodies found in epithelial cells, and probably those in other tissues, are not stages in the development of spirochetes. Large granules, coiled and encysted forms derived from spirochetes, occur in various connective tissue structures, and may pos-

sibly represent resting or multiplication stages. By virtue of the power to invade tissues, the spirochetes studied may be transmitted in any secretory or excretory product of infected ticks."

Multiplication in *Triatoma infestans* of the mal de caderas trypanosome, A. NEIVA (*Abs. in Bul. Inst. Pasteur*, 12 (1914), No. 1, p. 46).—The author records the occurrence of mal de caderas in the States of Bahia, Pernambuco, Piauhy, and Goyaz. Tabanids of the genus *Chrysops* are thought by the author to be largely concerned in the transmission of *Trypanosoma equinum* in central Brazil. The feces of the reduviid *T. infestans* have been found to be infective.

A note on the pathogenicity of *Trypanosoma lewisi*, W. H. BROWN (*Jour. Expt. Med.*, 19 (1914), No. 4, pp. 406-410).—"Some strains of *T. lewisi* may at times produce rapidly fatal infections in a large percentage of the rats infected. In such strains of *T. lewisi*, a sufficient degree of pathogenicity may persist to warrant the designation of these strains as pathogenic. The pathogenicity of a given strain of *T. lewisi* is not constant, but is subject to marked and even sudden variations."

Anthrax vaccination in Japan, N. NITTA (*Bul. Inst. Infect. Diseases Anim., Japan*, No. 1 (1913), pp. 49).—Anthrax is widespread in Japan and occurs each year in various parts of the country, including Korea. According to the official statistics that have been collected during 25 years (1887-1911), about 12,259 cases have occurred. In many other instances the presence of the disease has not been reported.

In the tests some of the vaccines were made by the Pasteur method, and an anthrax spore vaccine according to the method of Chienkowsky, Lange, and Deutsch. The spore vaccine remained active from 2 to 4 years. Preliminary experiments were made with rabbits, pigs, sheep, calves, and horses.

The practical results obtained with Deutsch's spore vaccine prepared by the author and also with Sobernheim's serum-simultaneous method are reported. In 1905, 144 animals, i. e., 139 bovines and 5 horses, were vaccinated with Deutsch's vaccine; only 1 horse was lost. In 1908, 27,310 bovines and 3,886 horses received spore vaccine, and only 1 horse died from spontaneous anthrax. Of the bovines 96.69 per cent showed no systemic reaction or only a local reaction; 3.26 per cent, a local reaction with a rise in temperature; and 0.01 per cent only a rise in temperature. Observations on the remaining 11 animals could not be taken. Of the horses 98.74 per cent showed either no reaction or only a local reaction; 1.21 per cent, a rise in temperature and a local reaction; in 0.05 per cent the reaction was not determined.

Anthrax serum was found to have both protective and curative powers for both man and animal. The protective powers, however, last only a few weeks, and in order to increase the efficiency of the serum a dose of vaccine should follow its administration.

The number of animals vaccinated in 1904 according to the serum-simultaneous method of Sobernheim was 3,615, consisting of 2,350 bovines and 1,265 horses. Of the bovines 94.3 per cent gave no general or only a local reaction; 2.98 per cent gave a local reaction and a rise in temperature; 2.68 per cent, a rise in temperature only; and with one animal no observation could be taken. Of the horses 99.05 per cent gave no reaction or only a local one; 0.79, a local reaction and a rise in temperature; and 0.16 per cent, only a rise in temperature.

The animals vaccinated since 1909 consisted of 347 goats and 269 hogs. No losses resulted from the vaccinations but one goat died of spontaneous anthrax. Of 77 animals treated with serum alone, 57, or 74 per cent, survived.

Ascoli's method is considered the best for the valuation of anthrax sera.

The diagnosis of glanders, J. R. MOHLER and A. EICHHORN (*Amer. Vet. Rev.*, 44 (1914), No. 4, pp. 437-447, figs. 2).—This work emphasizes the value of the mallein eye test as a first-hand means of the veterinarian for diagnosing glanders in horses. The test is deemed simple, practical, and comparatively accurate. The complement fixation test, when used in conjunction with the agglutination test, is regarded as the best laboratory method today, especially since the conglutination test (*E. S. R.*, 28, p. 478) and the precipitation test have been found to be unreliable.

The laboratory methods are deemed a valuable means for substantiating the findings obtained by the practicing veterinarian with the ophthalmic test, especially where a certain amount of doubt exists. "The Bureau of Animal Industry, in consideration of the favorable results obtained from this test, has decided to recognize the [eye test] for interstate shipments of equines, . . . Horses offered for shipment to Canada must continue to be tested by the simultaneous method, as the ophthalmic test has not yet been officially recognized by the Canadian authorities. . . . It has been employed by inspectors of the Bureau of Animal Industry in their field work, and reports are accessible regarding its action for diagnostic purposes on more than 8,000 cases. The results from all sources were uniformly satisfactory."

One of the most essential features for the success of the test is to employ a mallein of the proper concentration. The presence of 0.5 per cent of carbolic acid in the concentrated mallein as a preservative does not interfere with the test. The crude mallein is preferred to the dried mallein.

The method of making the test and the precautions to be taken are described in detail. In the appendix the results obtained with the test in Austria are discussed.

Immunization tests with glanders vaccine, J. R. MOHLER and A. EICHHORN (*U. S. Dept. Agr. Bul.* 70 (1914), pp. 13).—"The results obtained by these investigations appear to be sufficient to demonstrate the unsatisfactory results of this method of immunization. Of the 13 immunized animals, 9 contracted the disease from natural exposure, which is a large proportion when it is considered that all animals were aged and kept most of the time during the exposure out of doors. Of the 4 remaining immunized horses, 1 died of impaction after the second vaccination, while the other 3 animals were killed . . . in order to ascertain by post-mortem examination the possibility of glanders existing in these animals which had given positive serum reaction, but which had returned to normal."

The occurrence of tubercle bacilli in the circulating blood, A. ROTHACKER and CHARON (*Centbl. Bakt. [etc.]*, 1. Abt., *Orig.*, 69 (1913), No. 7, pp. 478-496).—The results of the test show that the Stäubli-Schnitter method gives microscopical preparations which contain acid-fast bacilli other than tubercle bacilli. Many artifacts are also produced which are often mistaken for the tubercle bacillus. According to this, the only criterion for judging the presence of tubercle bacilli is the animal test.

Of the 46 specimens of blood examined, taken during all stages of the disease, only one, a case of miliary tuberculosis, gave a positive animal test. On the other hand, 12 cases showed with the Ziehl-Neelson method acid-fast bacilli which gave suspicions of being of tuberculous origin. The amount of these organisms was always in proportion to the gravity of the disease.

A bibliography comprising 68 titles is appended.

Tubercle bacilli in the blood, JANE L. BERRY (*Jour. Infect. Diseases*, 14 (1914), No. 1, pp. 162-175).—"Notwithstanding the large number of investigators who have made a study of the presence of tubercle bacilli in the circulating blood, it is nevertheless a fact that the most striking point about the

results so far obtained is the total lack of agreement between the reports of the different workers." "As a preliminary to this work, examinations of blood taken from normal animals and human beings were made. In this way specimens from 13 horses, 9 goats, and 3 laboratory workers were examined with negative findings in all cases."

In the main experiments blood was obtained from patients (human beings) giving a history of tubercle bacilli in the sputum. The Kinyoun ligroin method was used for the determination of the tubercle bacilli. "In all, blood specimens were taken from 50 tuberculous patients, 2 specimens obtained from 1 individual, 1 month apart, making a total of 51 specimens examined. Of these, 13 were from patients in the second stage, and 38 from patients in the third stage of the disease, 4 of the latter being bed patients. Six patients have since died, the first 3 at intervals of from 17 days to 1 month, the last 3 in from 1 month to 5 weeks after the taking of the blood specimens."

Careful search was made for tubercle bacilli but in all cases the results were absolutely negative and no acid-fast organisms of any kind were found in the smears. A few rods were occasionally seen but never any which showed acid-fast staining properties. "Owing to the invariably negative microscopic results, no animals were inoculated, as it had been thought best to wait for some positive indications from the microscopic work before beginning animal tests."

A review of the literature is embodied in the article.

The elimination of tubercle bacilli in the feces of tuberculous bovines, C. TITZE, H. THIERINGER, and E. JAHN (*Arb. K. Gsndhtsamt.*, 45 (1913), No. 1, pp. 1-34).—Following a review of the literature on this subject, especially of the work reported by Schroeder and Cotton (*E. S. R.*, 19, p. 181), the insufficiency of information relative to how often the feces of bovines, showing no signs of clinical tuberculosis but giving a tuberculin reaction, eliminate tubercle bacilli is emphasized.

In the experiments reported by the authors it was necessary to use the anti-formin method because the feces were found to contain other micro-organisms which often caused the untimely death of a number of guinea pigs. Some of these were Gram-positive and resembled the micro-organisms producing braxy in sheep; others were Gram-negative, among which were some identified as belonging to the coli group, staphylococci, and streptococci. The strength of the antiformin used was a 15 per cent solution, with an exposure of from 2 to 4 hours. The exposure of tubercle bacilli to antiformin for 36 hours did not affect the virulence nor the acid fastness of these organisms.

The feces from 96 bovines were tested for the presence of tubercle bacilli, and the results show that under certain conditions tubercle bacilli may be eliminated with the feces of tubercular animals having open pulmonary tuberculosis. This is probably due to these animals swallowing some of the sputum and passing the bacilli per rectum. In animals giving only a tuberculin reaction and showing no clinical evidence of tuberculosis, tubercle bacilli were never found in the feces, therefore the conclusions of Schroeder and Cotton and of the British commission (*E. S. R.*, 21, p. 481) could not be confirmed. Pigs are deemed more easily infected by the droppings of tubercular bovines than bovines themselves.

The detailed protocols of all the experiments are given in the article.

Protecting influence of protein diet against tuberculosis, O. HORNEMANN and E. THOMAS (*Deut. Med. Wchnschr.*, 39 (1913), No. 48, pp. 2345, 2346; *abs. in Jour. Amer. Med. Assoc.*, 62 (1914), No. 2, p. 169).—Young pigs fed systematically with casein were much more resistant toward the disease conveyed by

inoculation with tubercle bacilli than other pigs of the same litter fed with carbohydrates and fat.

Experiments regarding the vaccination of cattle against tuberculosis by the intravenous injection of tubercle bacilli of the human and avian types, J. M'FADYEAN, A. L. SHEATHER, J. T. EDWARDS, and F. C. MINETT (*Jour. Compar. Path. and Ther.*, 26 (1913), No. 4, pp. 327-390, figs. 3).—The chief purpose of the experiments was to test the efficiency of intravenous injections of the avian type of tubercle bacilli in immunizing cattle against bovine tubercle bacilli. For comparison, some animals were vaccinated with tubercle bacilli of the human type. The conclusions drawn from the work are as follows:

"By the intravenous inoculation of avian tubercle bacilli it is possible to confer on healthy calves a markedly increased power of resistance to infection with bacilli of the bovine type. Such a method of vaccinating young cattle against tuberculosis involves little or no risk to the animals. When the vaccination of young cattle against tuberculosis is considered advisable, avian bacilli should be preferred to human, in order to avoid the danger of infecting human beings with bacilli persisting in the bodies of the vaccinated animals and passed out with their milk.

Piroplasmosis and anaplasmosis, DESCAZEUX (*Bul. Soc. Cent. Méd. Vét.*, 91 (1914), No. 4, pp. 103-106).—In the State of Sao Paulo, Brazil, these diseases constitute a veritable plague for imported cattle, the mortality from the two diseases at times being as high as from 80 to 95 per cent. Piroplasmosis is caused entirely by *Piroplasma bigeminum* and anaplasmosis by *Anaplasma marginale* and *A. centrale*, both of the latter causing forms which are nearly always fatal. Piroplasmosis is widespread throughout the State, while anaplasmosis exists only in certain limited regions. The information at hand shows that anaplasmosis has been introduced into the State of Sao Paulo with imported animals. Immunity measures are discussed.

The etiology, pathology, and therapeutics of bovine piroplasmosis in the State of Sao Paulo, J. DESCAZEUX (*Bul. Soc. Cent. Méd. Vét.*, 90 (1913), No. 22, pp. 392-410, figs. 4).—It is stated that trypanblue when injected subcutaneously always has a curative effect in artificial cases of piroplasmosis but that in cases naturally contracted it is not always efficacious. The autoagglutination of erythrocytes always precedes the appearance of piroplasms in the blood. The gravity of the affection is not dependent upon the number of piroplasms but upon their virulence.

Report on the use of salvarsan in septic pneumonia of bovines, STEINHAUSZ (*Ab. in Rev. Gén. Méd. Vét.*, 22 (1913), No. 263, pp. 617, 618).—During the course of an epidemic of septic pneumonia in valuable animals the author administered salvarsan. From 0.5 to 0.9 grains were used without danger on calves under 3 weeks of age. It is said to have given excellent results and to merit recommendation.

Verminous bronchitis in bovines, G. MOUSSU (*Rec. Méd. Vét.*, 90 (1913), No. 21, pp. 677-684).—This disease, due to *Strongylus micrurus*, is said to have caused an enormous loss of cattle in the valleys of the Seine and Loire, France.

Studies of the development of *Hypoderma bovis* and means for its destruction, A. LUCET (*Compt. Rend. Acad. Sci. [Paris]*, 158 (1914), No. 11, pp. 812-814).—A report of studies of the ox warble, which is a source of great loss to agriculturists in France.

Progress and results of cattle tick eradication (*U. S. Dept. Agr., Bur. Anim. Indus., Progress and Results of Cattle-Tick Eradication, 1914, pp. 12*).—This summary of the results obtained in the eradication of *Margaropus annulatus* is based upon about 1,000 replies to a questionnaire carried on among stockmen

and farmers in eleven States in the territory bordering on the quarantine line, being on a larger scale than that previously reported (E. S. R., 27, p. 184).

The parasitic diseases of sheep in the Province of Algiers (*Rev. Sci. [Paris]*, 52 (1914), I, No. 6, pp. 179, 180).—A discussion of the various ascarids, flukes, tapeworms, and strongyles affecting sheep in Algeria.

Contribution to the study of necrobacillosis: A specific epizootic form of necrobacillosis in the goat, G. E. PESADORI (*Clin. Vet. [Milan]*, *Rass. Pol. Sanit. e Ig.*, 36 (1913), No. 18, pp. 816-819; *abs. in Vet. Rec.*, 26 (1914), No. 1339, p. 574).—This article relates to a contagious affection of the claws of goats which appeared in Calabrian districts at the beginning of the winter of 1912-13, some 10,000 animals being affected in the course of 2 months. Sheep and cattle kept under the same conditions as the goats and constantly exposed to the infection remained free from the disease. The necrosis bacillus, which gains entry into the organism through lesions in the horn and in the cleft of the claws, is thought to have been the cause.

Hog cholera, R. A. CRAIG and R. A. WHITING (*Indiana Sta. Bul.* 173 (1914), pp. 441-474, figs. 18).—A general account of hog cholera with hygienic preventive measures and treatment, including the preparation and administration of antihog cholera serum. The text of the state law relative to swine diseases is appended.

Combating hog cholera by vaccination, PFEILER (*Mitt. Ver. Deut. Schweinezüchter*, 18 (1911), No. 7, pp. 103-110).—In this lecture it is pointed out that the disease caused by the filterable virus is more serious than the one produced by the *Bacillus suispestifer voldagsen*. It probably is a different disease and Dammann (E. S. R., 24, p. 390) according to the author, has satisfied himself to this effect.

The various facts surrounding the vaccination of hogs with antihog cholera serum and the cause of the disease are discussed with much detail and in a popular manner.

[Hog cholera], UHLENHUTH (*Mitt. Ver. Deut. Schweinezüchter*, 18 (1911), No. 7, pp. 110-113).—While corrosive sublimate and carbolic acid do not kill hog cholera virus in a comparatively short time, a 6 per cent cresol soap solution, or a 1:6 or 1:20 per cent calcium hypochlorite solution will destroy it within 1 hour. The virus is very resistant to cold but drying at a temperature of 78° C. will destroy it. Heating for one-half hour at 58° does not render it avirulent. When inclosed in fermenting manure the virus dies.

Hogs which have recovered from an attack of the disease but which are otherwise in an unsatisfactory condition are often found to be virus carriers. The urine of young pigs is especially dangerous and is often the chief cause of the spread of the disease. The secretion from the eyes and nose is very dangerous, for this may be inhaled or may come in contact with the mucous membrane of healthy animals, thus causing the disease.

The material with reference to the *Bacillus suispestifer*, which is considered a secondary invader, has been adequately noted from other sources (E. S. R., 20, p. 1082; 25, p. 589). See also other notes (E. S. R., 26, p. 785).

Investigating the infectious diseases of the hog, PFEILER (*Mitt. Ver. Deut. Schweinezüchter*, 19 (1912), No. 7, pp. 138-145).—This discusses the possibility of using chemotherapeutic agents, especially in the chronic form of hog cholera.

While the filterable virus as a cause of hog cholera is not doubted, many cases of what seem to be hog cholera do not show the presence of a filterable virus. These cases often have present the *Bacillus suispestifer* and closely related organisms.

Much can be said with reference to the need of accurate diagnosis of hog cholera because there are often cases in which it is difficult to decide whether it is hog cholera or swine plague.

The above is discussed by Wassermann, Händel, and Lehmann.

The relation of shoat typhoid to virus hog cholera, W. PFEILER and R. STANDFUSS (*Ztschr. Infektionskrankh. u. Hyg. Haustiere*, 14 (1913), No. 7, pp. 409-421).—Uhlenhuth and his school hold that the *Bacillus völdagsen* is simply a secondary invader and only a variety of the *B. suispestifer* (Salmon and Smith). Shoat typhoid and hog cholera are diseases caused by entirely different factors. Shoat typhoid is of greater significance than is usually supposed. The disease is present in numerous instances in many places in Germany and other portions of the European Continent.

In some previous tests (E. S. R., 28, p. 183) it was shown that shoats immunized passively against hog cholera and unimmunized shoats became infected with shoat typhoid when fed with the *B. völdagsen*. As passive immunity lasts only a relatively short time, the authors in the present investigation thought it best first to immunize passively and then to infect the animals with virus in order to produce an active immunity toward hog cholera. Accordingly four pigs about 8 weeks old, having weights up to 25 kg., received a primary injection of 10 cc. of serum and 2 cc. of vaccine I (Gans), and 14 days later an injection of 3 cc. of vaccine II. Whether hogs can be immunized actively against hog cholera by this method is to be discussed in another paper. However, three of the pigs did not take the disease, although two received one-eighth of a loopful of the culture of the *B. völdagsen* and the remainder were kept in the same corral with infected animals; one of the latter group died after 6 weeks and came to autopsy. The results seemed to indicate that pigs immunized against hog cholera are immune to pig typhoid.

On this account the experiments were repeated with eight pigs, four being immunized against hog cholera and the remainder kept as controls. All of the animals were exposed to the natural source of infection. One of the four unimmunized animals died within 12 days from unknown causes, no changes being noted in the organs. Another did not become sick but was used later for some other tests and eventually died of hog cholera. No changes characteristic of hog typhoid were present, but from its organs the *B. völdagsen* was obtained. The remaining two animals of the group remained sound. Of the pigs immunized passively-actively against hog cholera three became sick with pig typhoid. One died of typhoid, another was slaughtered, a third was backward in growth, and died 4 months later as the result of virus infection but with lesions characteristic of pig typhoid. The fourth was also stunted in growth and was probably affected with typhoid.

The above tests, according to the authors, emphasize the fact that shoat typhoid can occur without a previous primary infection with hog-cholera virus and that it is due to an independent pathogenic organism. This disease must be considered an entity different from hog cholera.

Forage poisoning or equine encephalomyelitis, A. T. KINSLEY (*Proc. Amer. Vet. Med. Assoc.*, 50 (1913), pp. 413-438, pls. 2).—A general discussion of the subject with references to the literature.

The etiology of equine influenza, L. PANISSET (*Rev. Gén. Méd. Vét.*, 22 (1913), No. 263, pp. 606-612).—A review of recent literature on the subject.

The treatment of equine pneumonia with iodocol, E. HOUEMER (*Rev. Gén. Méd. Vét.*, 22 (1913), No. 257-258, pp. 217-221, figs. 4; *abs. in Ann. Méd. Vét.*, 62 (1913), No. 12, pp. 689, 690).—It is stated that the daily injection of 5 cc. of iodocol for 6 days results in rapid improvement, the temperature ordinarily dropping after the second injection. The iodocol appears to have special elec-

tive action on the lungs and a remarkable action on the fever. It is said to be a sterile isotonic solution of free and pure iodine in the colloidal state, which may be purchased in ampoules of 1, 2, 5, or 10 cc. The injections may be made hypodermically, intramuscularly, or intravenously, the last-named method being preferable.

Poultry diseases and their treatment, B. F. KAUFF (Chicago, 1914, pp. 185, figs. 56).—This is intended to fill a demand for a book on poultry diseases for veterinary and poultry husbandry students and for veterinary practitioners. The chapter headings are as follows: Anatomy, sanitation, external parasites, internal parasites, diseases of the digestive tract, diseases of the blood, constitutional diseases, diseases of the liver, diseases of the ovary and oviduct, tumors, diseases of the respiratory passages, disease of the legs and feet, diseases of the brain, bacteria of the intestinal tract of chickens, the egg, isolation of non-layers, malformations and fractures, wounds, and anesthesia.

Investigations of the filterable virus of avian diphtheria and contagious epithelioma of birds, S. VON RÄTZ (*Monatsh. Prakt. Tierheilk.*, 25 (1913), No. 1-2, pp. 41-46).—The introduction of the virus from diphtheritic pseudomembranes of the throat into the scarified skin produced pathological changes characteristic of epithelioma and, inversely, the introduction of particles of epitheliomatous tumors into the mucosa of the mouth and pharynx produced diphtheritic lesions. In later experiments here reported, in which filtrates of emulsified substances from a Nordmeyer-Berkefeld filter were used, similar results were obtained.

The author concludes that these affections of fowls are only two forms of a disease of which the causative agent is a filterable virus.

RURAL ENGINEERING.

Report of proceedings of the seventh annual convention of the Western Canada Irrigation Association (*Rpt. Proc. Ann. Conv. West. Canada Irrig. Assoc.*, 7 (1913), pp. 204, pls. 3, figs. 32).—Some of the special articles in this report are as follows: The Work of the International Irrigation Congress, by A. Hooker; Irrigation Practice in Utah, by R. H. Lyman; Irrigation Practice in Oregon, by J. H. Lewis; The Irrigation Farmer, by W. Huckvale; Colonization and the Irrigator, by J. T. Hinkle; Irrigation and Immigration, by J. S. Dennis; Conservation and Irrigation, by J. White; Government Education Along Irrigation Lines, by W. J. Elliott; Forestry and Irrigation, by R. H. Campbell; Irrigation and Land Settlement in Australia, by J. W. A. Kelly; and Live Stock and Irrigation, by H. C. McMullen.

Preliminary report on ground water for irrigation in the vicinity of Wichita, Kansas, O. E. MEINZER (*U. S. Geol. Survey, Water-Supply Paper 345-A* (1914), pp. 9).—This paper, the first of an annual volume to be entitled Contributions to the Hydrology of the United States, gives an outline of the geology of the Wichita region with especial reference to its water resources. Types of wells and well casing methods are briefly discussed, and a table of partial analyses of the ground waters in the vicinity of Wichita is given which shows "that although the ground waters are generally somewhat hard and otherwise mineralized they differ widely in the quantities of mineral matter that they contain. . . . A large proportion of the samples analyzed represent waters that are satisfactory for irrigation use, but a few of the most highly mineralized samples approach the danger line, especially in their content of common salt. However, with the relatively humid conditions that prevail in this region and the consequent dilution and leaching that will result from the rain water, injury from the salt in even the more highly mineralized waters

need not be feared except where the soil is clayey or already impregnated with alkali."

As regards the adequacy in quantity for irrigation of the water supplies "the danger of exhausting the supply is believed to be so remote that it need not prevent anyone from making developments that will otherwise be profitable."

The items to be included in estimating the annual cost of irrigation are enumerated and it is thought "that with good management, both in regard to pumping and in regard to agricultural or horticultural practice, irrigation can be made profitable for raising vegetables and certain fruits and probably also alfalfa and some other field crops. . . . [However] because of the lack of quantitative knowledge as to the increase in crop values that will in the long run result from irrigation, this movement should be prosecuted with conservatism and developments should be made only after deliberate consideration of all the factors involved."

A bibliography is appended.

The diversion of irrigating water from Arizona streams, A. L. HARRIS (*Proc. Amer. Soc. Civ. Engin.*, 40 (1914), No. 1, pp. 39-58, figs. 5).—This paper deals with the principal features in the author's experience in the design of diversion works for both government and private irrigation projects in Arizona. The chief points discussed are the design of diverting dams and gates.

Hydraulic power in the Alps region, R. DE LA BROUSSE ET AL. (*Min. Agr. [France], Serv. Grandes Forces Hydraul. Région Alpes, Result. Etudes et Trav.* 4 (1910), pp. 556, pls. 6, figs. 14; *Sup.*, I, pls. 8; II, pls. 33; 5 (1911), pp. 530, pl. 1, figs. 4; *Sup.*, pls. 8; 6 (1911), pp. 494, pl. 1, figs. 14, *Sup.*, pls. 44).—This report deals with the hydraulic resources of the Alps for both power and irrigation, and contains a large amount of hydraulic and hydrographic data.

Comparative studies of problems of agricultural hydraulics in Java, British India, and Indo China, A. NORMANDIN (*Bul. Econ. Indochine, n. ser.*, 16 (1913), No. 104, pp. 784-810).—This is a comparative study of economic problems, more particularly of the irrigation and drainage of lands in Java, British India, and Indo China, taking up particularly the necessity of irrigation, finished and projected work, duty of water, irrigation by pumping, general irrigation investigations, and the several phases of drainage. It is concluded that the works of agricultural hydraulics projected in Indo China will probably be neither excessive in cost nor a source of direct benefit, and that the benefit derived will in no way compare with the benefits derived from similar works executed in British India.

Drainage and irrigation.—Management of irrigation systems, R. S. STOCKTON (*Engin. and Contract.*, 41 (1914), No. 4, pp. 141-150, figs. 11).—This article expresses opinions and ideas "resulting from some years of observation and experience in connection with the construction, operation, and maintenance of irrigation systems with especial reference to the viewpoint of the management."

The selection and cost of a small pumping plant, B. A. ETCHEVERRY (*California Sta. Circ.* 117 (1914), pp. 30, figs. 8).—This bulletin contains in addition to matter previously noted from other sources (E. S. R., 28, pp. 83, 484; 30, p. 485), brief discussions of types of pumping machinery, including the air-lift pump and hydraulic ram. A bibliography of related works is appended.

The discharge capacity of semicircular steel flumes, E. A. MORITZ (*Engin. News*, 71 (1914), No. 4, pp. 192-195, fig. 1).—The author computes mathematically the discharge capacity of semicircular steel flumes, and gives tables of the discharges and corresponding velocities for standard sizes calculated by the Kutter formula for values of n of 0.012 and 0.015, which he states correspond to the smoothest and roughest flumes, respectively. The tables are based on a

freeboard of 1 in. for each foot in diameter. By a mathematical analysis he shows that "any semicircular flume will carry 36 per cent more when running full than when running with a freeboard of 1 in. per foot of diameter."

Examples are given to illustrate the use and flexibility of the tables.

Corrugated iron construction on the Sacramento Valley irrigation project, E. C. MILLS (*Engin. News*, 71 (1914), No. 4, pp. 174-176, figs. 4).—This article describes the water-distribution structures on this project, which for permanent construction consist only of concrete and corrugated iron or a combination of the two. The features especially emphasized are corrugated pipe headgate construction, corrugated pipe delivery boxes, lateral road crossings, inverted siphons for natural drainage, road drainage structures, and sheet-iron flumes.

A study of economic conduit location, C. E. HICKOK (*Proc. Amer. Soc. Civ. Engin.*, 39 (1913), No. 19, pp. 2185-2190, figs. 2; *Engin. and Contract.*, 41 (1914), No. 2, pp. 80, 81, fig. 1; *Engin. Rec.*, 69 (1914), No. 3, pp. 83, 84, figs. 2).—This article includes a diagram which gives the equivalent lengths from an economic standpoint of various types of conduits and a discussion of its application in the economic location of conduits.

A treatise on roads and pavements, I. O. BAKER (*New York and London, 1913, 2. ed., enl., pp. 698, figs. 171*).—The object of this book is to give a discussion from the point of view of the engineer of the principles involved in the construction of country roads and city pavements. It is attempted to show that the science of road making and maintenance is based upon well established elementary principles, and that the art depends upon correct reasoning from the principles rather than in attempting to follow rules or methods of construction. "In some cases practical experience has not yet determined the best method of procedure, and in these cases the conflicting views with the reasons for each are fully stated."

Considerable space is given to the economics and location of country roads and to the construction and maintenance of earth roads. The topics discussed are road economics, road location, earth roads, gravel roads, broken-stone roads, miscellaneous roads, equestrian roads and horse-race tracks, pavement economics, street design, street drainage, curbs and gutters, pavement foundations, asphalt pavements, brick pavements, cobblestone pavement, stone-block pavement, wood-block pavements, comparison of pavements, sidewalks, bicycle paths and race tracks, and automobile roads and concrete pavements.

A glossary of road terms, H. P. BOULNOIS (*Surveyor*, 44 (1913), Nos. 1136, pp. 621-626; 1137, pp. 663-667; 1138, pp. 700, 701; 1139, pp. 723-730).—This is a compilation of terms which are used in connection with English road construction.

The principles of the application of power to road transport, H. E. WIMPERIS (*London, 1913, pp. XV+130, pls. 5, figs. 20*).—This work deals with the principles of the application of power to road transportation.

A general survey of the subject, taking up the use of steam, internal combustion, and electrical power for transportation, and discussing necessary power per ton mile and resistance to motion relative to loads, speeds, wheel diameters, tires, etc., is followed by a discussion of power, speed and resistance measurement, road tests, and power loss in engine friction and in transmission. Types of steam and internal combustion engines and vehicles on which they are used are described, and the relationship of engine dimensions and gear ratios to work and the proper design of vehicles are discussed in some detail.

Experimental road construction in Scotland, J. W. SMITH and D. RONALD (*Surveyor*, 45 (1914), No. 1147, pp. 44-49, figs. 4).—A draft of specifications and conditions for this work is given.

Test of a 40-ft. reinforced concrete highway bridge, D. A. ABRAMS (*Amer. Soc. Testing Materials Proc.*, 13 (1913), pp. 884-922, figs. 24).—A 3½ years' test of a 40-ft. reinforced concrete through-girder highway bridge with an 18-ft. roadway, in which the bridge sustained unusual and excessive loading, is reported in detail.

Some properties of building materials, B. F. E. KEELING (*Cairo Sci. Jour.*, 7 (1913), No. 80, pp. 97-103, fig. 1).—In this article the results of experiments on the physical properties of sand-lime bricks and of walls made with them, and also on some other properties of buildings, are reported.

Results obtained with the autoclave tests for cement, H. J. FORCE (*Amer. Soc. Testing Materials Proc.*, 13 (1913), pp. 740-796, figs. 8).—This paper gives the results of comparative tests of various brands of cement, some of which failed to pass and others of which passed the autoclave test previously noted (E. S. R., 28, p. 290).

On the ground that the grinding of the raw material and the proper burning plays a most important part in the quality of Portland cement, the author believes "that the failure of cement to pass the autoclave test is due very largely to the coarser granules which do not become hydrated when the cement is set up, and that the failure of these granules to become fully hydrated is due to their chemical composition, that is, the granules are composed largely of dicalcium silicate with a smaller proportion of tricalcium silicate. Granules of this composition fail to hydrate properly in the period of 24 hours, and consequently when brought in contact with heat and pressure, together with moisture, slaking of the dicalcium silicate is quickly brought about, with the result that a large percentage of expansion occurs together with a proportionate decrease in tensile strength. On the other hand, if the proportion of tricalcium silicate is largely in excess of the dicalcium silicate, then we may expect a more stable product and one which will show considerably less expansion under the autoclave test and which should remain constant in volume in after years."

Tests of natural concrete aggregates, R. S. GREENMAN (*Cement Era*, 11 (1913), No. 8, pp. 41, 42; *Amer. Soc. Testing Materials Proc.*, 13 (1913), pp. 828-833).—Results of tests are reported which indicate that both the laboratory tests and carefully made field tests and inspections of aggregate present ways and means of indicating what the natural aggregate, either fine or coarse, will actually do in the concrete in place.

Fine particles [in cement] estimated by rate of hydration, H. S. SPACKMAN (*Cement Era*, 11 (1913), No. 7, pp. 83, 85; *Amer. Soc. Testing Materials Proc.*, 13 (1913), pp. 714-719).—Tests of a normal cement passing the standard specifications of the American Society for Testing Materials showed a definite relation existing between fineness of grinding on one hand and rate and extent of hydration on the other.

Apparatus for determining consistency [of cement paste], C. M. CHAPMAN (*Concrete-Cement Age*, 3 (1913), No. 1, pp. 8, 9, figs. 3; *Amer. Soc. Testing Materials Proc.*, 13 (1913), pp. 1045-1052, figs. 3).—A method for determining the consistency of neat cement paste consists in depositing the mortar or concrete in a form of suitable size and shape on a glass or metal surface, then removing the form and noting the settling either with or without the assistance of a jar or shock of the unsupported mass. A low form of large area is used for soft wet mixtures, and smaller, taller forms for drier mixtures.

The limits beyond which the method is useless lie between that consistency which is fluid enough to flow freely, and that which is too stiff to alter its form under the influence of a comparatively light shock.

Thermal activities of Portland cement during the period of setting, L. N. BEALS, JR. (*Amer. Soc. Testing Materials Proc.*, 13 (1913), pp. 720-739, figs. 9).—

The peculiarities of curves obtained by plating calories of heat evolved by cement during the period of setting against the time of setting "seemed to indicate that the time of set and tensile strength are due to the colloidal nature of cement. This is seemingly supported by references to the well known characteristics of colloids."

Solubility of cement tile, W. H. DAY (*Ann. Rpt. Ontario Agr. Col. and Expt. Farm*, 38 (1912), pp. 43-45).—Tests of the solubility of cement tile led to the conclusion that in ordinary soil water there is no danger of dissolving and crumbling in good cement tile which are not weaker in mixture than 1:4, are thoroughly mixed, are of wet mixture firmly packed, are dried slowly during initial set and kept wet for a week, and then well seasoned.

Gas engines and producers, L. S. MARKS and S. S. WYER (*Chicago*, 1913, pp. [8]+62+5, pls. 3, figs. 36).—This is a treatise on the modern development of the internal-combustion motor, and of efficient methods of fuel economy and power production. The work "is designed to present theoretical and practical information in such form as to appeal both to the engineer and to the untrained person who is merely interested in the subject."

The subject matter under the division of gas and oil engines is as follows: The external-combustion motor, the internal-combustion motor, the modern gas engine, thermodynamics of the Otto cycle, ignition, governing, starting, water jackets, the explosive mixture, the exhaust, modification of the Otto cycle, gas-engine fuels, large gas engines, liquid fuels, and kerosene and crude-oil engines. Under the division of gas producers are the topics of gaseous fuels, history and manufacture of producer gas, gasification losses, rules, representative types, gas cleaning, uses of producer gas, producer-gas power plants, and gas poisoning.

A new kerosene carbureter, G. M. HOLLEY (*Gas Engine*, 16 (1914), No. 1, pp. 32-34, figs. 3).—A carbureter is described and diagrammatically illustrated which is so arranged that in starting the engine the mixture consists of both gasoline and kerosene. The gasoline supply is constant and the kerosene supply can be slowly increased until the engine is heated and running smoothly on a high kerosene mixture, at which point the gasoline may be cut off. This device is said to accomplish prompt and smokeless starting.

A unique kerosene carbureter, J. A. LUCAS (*Power*, 39 (1914), No. 1, pp. 14, 15, fig. 1).—This article describes and illustrates a kerosene carbureter, so designed that the kerosene mixture when very rich is partially ignited and thereby heated before entering the combustion chamber. From the heating chamber the mixture passes to the mixing chamber, where it is properly proportioned, and then into the combustion chamber. This device is said to allow a motor to start when cold, on kerosene, "apparently as easily as on gasoline," and also to prevent excessive carbonization.

Specifications for motor power spraying machines (*Fruit-Grower and Farmer*, 25 (1914), No. 2, pp. 18, 19).—Specifications for motor spraying machines of several different makes are given in a table.

How to harvest ice rapidly, H. B. WOOD (*Sci. Amer. Sup.*, 77 (1914), No. 1984, pp. 18, 19).—The author calls attention to the prime importance of speed in the harvesting of ice and describes methods of saving time and preventing delays.

Destroying stumps with acids, H. C. COGGINS (*Agr. Gaz. N. S. Wales*, 24 (1913), No. 11, pp. 967, 968).—Tests with sulphuric and nitric acids in varying proportions for stump destroying proved unsatisfactory with both dry and green stumps. It is concluded that sound stumps can not be destroyed with either sulphuric or nitric acid, or both. The method is also wasteful of time and the handling of acids dangerous.

Poultry house construction, A. R. LEE (*U. S. Dept. Agr., Farmers' Bul. 574 (1914), pp. 20, figs. 13*).—This points out and explains the essential principles of poultry house construction, contains pictures of houses and fixtures which have given satisfaction in various sections of the country, accompanied by plans, specifications, and bills of material, and gives hints on construction.

A practical farm ice storage house, M. COOPER (*Ohio Farmer, 133 (1914), No. 3, pp. 1, 2, figs. 4*).—This article describes the location, design, and construction of a practical farm ice house.

House heating fuel tests, W. H. MEEKER and H. W. WAGNER (*Iowa Engin. Expt. Sta. Bul. 33 (1913), pp. 85, figs. 16*).—Tests of coals and cokes commonly used in Iowa for house heating, to determine the fuel cost for developing a definite amount of available heat and the attention required and inconvenience experienced in keeping up heat with different fuels, are reported with test data, tables, diagrams, etc.

The following table is a summary of the average heating costs for the different classes of fuels tried:

Summary of evaporative costs with various fuels.

Class of fuel.	No. of tests.	No. of fuels.	Average cost per ton.	Average cost per 1,000 lbs. equivalent evaporative (212° F.).	Season cost for 8-room house.
				<i>Cents.</i>	
Iowa soft coals.....	15	6	\$3.86	37.4	\$64.70
Illinois soft coals.....	11	5	4.70	40.6	70.10
Other soft coals.....	3	2	6.87	47.1	81.40
Cokes.....	6	4	8.50	52.3	90.50
Anthracite.....	2	2	9.50	61.8	106.90
Iowa peat.....	1	1	4.50	144.1	249.00
Average.....			5.90	45.6	78.80

Rural hygiene, I. W. BREWER (*Philadelphia and London. 1913, pp. 233, pls. 13, figs. 9*).—This is the second edition of this work (E. S. R., 23, p. 191).

RURAL ECONOMICS.

The new agrarianism, C. W. DAHLINGER (*New York and London, 1913, pp. V+249*).—The author traces the evolution of industry in the United States, explains the fundamental causes of complaints against corporate wealth, describes the condition of agriculture in Ireland, England, Germany, and Denmark, and concludes that the principal factor in promoting agricultural progress is education and satisfactory financial support.

Slav farmers on the "abandoned farm" area of Connecticut, A. E. CANCE (*Survey, 27 (1911), No. 1, pp. 951-956, figs. 6*).—The author describes the settlement of Slavic and Jewish immigrants on the Connecticut highlands, and concludes that their general lack of success is due to the exhausted condition of the soil, exorbitant prices paid for the land, isolated location, and the out-of-date system of agriculture.

What farmers use (*Minneapolis, Minn., 1913, pp. 303, figs. 12*).—This book contains data showing the number of farms in Minnesota, the Dakotas, and Wisconsin reporting the use of the various kinds of food, agricultural implements, seed, and live stock.

Information concerning agriculture in Argentina, A. HERMES and H. HOLTMEIER (*Ber. Landw. Reichsamte Innern, No. 29 (1913), pp. VIII+311, pls. 64*).

figs. 1).—This volume contains a detailed description of the geology, soil, moisture, and climatic conditions, peoples and colonization, systems of cultivation, live stock, agricultural organizations and their improvement, and trade in animal produce, in Argentina, and details concerning a number of typical agricultural establishments. Statistical data, illustrations, and diagrams supplement the text.

An agricultural faggot, R. H. REW (*Westminster, 1913, pp. XII+187*).—This is a collection of papers on the following subjects relating to English agriculture: Farming in olden times, agriculture under free trade, English markets and fairs, the migration of agricultural laborers, the middleman in agriculture, combination among farmers, cooperation for the sale of farm produce, the nation's food supply, selling stock by live weight, and British and French agriculture.

The determination of the fertilizer requirements of soils, M. HOFFMANN (*Arb. Deut. Landw. Gesell., No. 251 (1913), pp. 182, pl. 1, figs. 5*).—This report summarizes the results of experiments with fertilizers on the Calvörde estate from 1869 to 1912 and on a number of other estates from 1907 to 1912. The results are discussed especially from the economic standpoint.

Investigation of the management, organization, and profitableness of a large farm in the black earth region of Volhynia, J. KLEIN (*Mitt. Landw. Inst. Breslau, 7 (1914), No. 1, pp. 49-200, figs. 11*).—The author discusses the following factors that enter into the management of a farm in the black earth region of Russia: The soil, climate, influence of climate upon yields, proportion of land under different types of cultivation, monthly distribution, kinds, and management of labor, capital invested in land, buildings, animals, and fertilizers, and cost and revenue from various farm crops. Most of the records shown cover a period of more than 15 years.

The agricultural law; its improvement and enforcement, C. J. HUDSON (*N. Y. Dept. Agr. Bul. 47 (1913), pp. 1217-1224, pl. 1*).—The author states that the purpose of the laws applying to agriculture in New York is to provide means for making the farms more productive, to search out by rigid inspection diseases of plant and animal life and to prescribe and apply the remedy, to stay the ravages of insect pests, and to perform those numerous things which the farmer, either singly or collectively, is unable to perform for himself. He suggests some improvements that might be made in the laws already existing, and discusses what the rigid enforcement of those already on the statute book would mean.

Can European cooperative credit methods be applied to American farming? E. W. KEMMERER (*N. Y. Dept. Agr. Bul. 47 (1913), pp. 1291-1300, pl. 1*).—The author gives as the reasons for the lack of development of short-term agricultural credit in the United States the system of extensive cultivation, the unsettled character of a considerable part of our agricultural population, the heterogeneous character of many rural communities, and the isolation of our farmers. He concludes that conditions are becoming more favorable for the adopting of this type of credit, but that the initiative in the establishment of rural credit banks should be taken by the farmers themselves and that only a reasonable amount of government supervision seems desirable.

Agricultural accident insurance in Belgium, M. E. VLEBERGH (*Internat. Inst. Agr. [Rome], Mo. Bul. Econ. and Soc. Intel., 5 (1914), No. 2, pp. 37-49*).—According to the law passed in December, 1903, the farmer became liable for accidents to his laborers similarly to other classes of employers. In applying the law it became evident that the farmer himself or members of his family needed compensation for accidents as well as his laborers, so there was or-

ganized a mutual insurance society to meet this demand. The author explains the working of these associations, the results obtained, and the changes that are deemed necessary to establish the system on a more equitable basis.

The cooperative insurance of live stock in England and Wales, J. WILSON (*Jour. Roy. Statis. Soc.*, 77 (1914), No. 2, pp. 145-158).—The author, in investigating live stock insurance, found that there were in 1911 832 unregistered pig clubs composed of 30,529 members and insuring 53,981 pigs, and in 1912 31 registered pig insurance societies with 1,461 members and 3,066 pigs. From a study of these organizations he concludes that the average death rate was less than 5 per cent and would require an average net income from insurance contributions of less than 2s. per pig per annum.

The experience of 86 cow insurance societies, consisting of 3,579 members and insuring 9,974 cows and calves, showed an average death rate of 2½ per cent and an average loss of less than 5s. per cow per annum.

To guaranty success he advises that the societies maintain a substantial reserve and, if possible, reinsure in some large insurance organization.

The agricultural outlook, C. M. DAUGHERTY, F. ANDREWS, W. J. T. DUVEL, and G. K. HOLMES (*U. S. Dept. Agr., Farmers' Bul. 581* (1914), pp. 50).—The world's acreage and production of corn, oats, barley, rye, potatoes, and flax are shown by statistical tables for 1911-1913 inclusive, and for every country for which data are available. Accompanying each table is a general discussion of the data shown and the purpose to which the different products are put in the various countries. The imports of corn from Argentina and oats from Canada are thoroughly analyzed.

It is also pointed out that within the last few months the imports of chilled and frozen beef from Argentina have amounted to 9,000,000 lbs. monthly, but this amount adds only a little over 1 per cent to the national supply of the United States. Since a great deal of this meat is imported by Chicago packing house companies having slaughterhouses in Argentina it can not be assumed that they are using Argentina beef to beat down the prices of Chicago beef. The number of cattle in Argentina during the last 5 years has remained about the same. That country can not increase its beef supply permanently until the slaughter actually lessens sufficiently to give its herds opportunity and time to increase.

The efforts of the various European countries to supplement the American cotton crop resulted in the production of slightly over 100,000 bales in 1912. There are many counties in Texas and other States that each produce from ¼ to ½ of this amount.

Following these discussions is a paper setting forth the crop reporting system and the sources of crop information in foreign countries.

[Stocks of potatoes on hand, January 1, 1914, and world's wheat crop and crop values for 1913], G. K. HOLMES (*U. S. Dept. Agr., Farmers' Bul. 575* (1914), pp. 29-33, 40-43).—The estimated proportion of potatoes remaining in growers' hands was larger on January 1, 1914, than has been the case in the four years past, and the proportion in dealers' hands smaller than for any year of the last four, except on January 1, 1912.

For the first time on record the world's wheat crop is estimated as over 4,000,000,000 bu.

The value of certain enumerated crops is shown for 1909-1913. These crops comprised 79.4 per cent of the value of all crops taken in the census and increased from \$4,357,595,000 in 1909 to \$4,905,881,000 in 1913. Statistical tables are given showing by States the value of crops enumerated, rank of each State, and their relative increase or decrease; stocks of potatoes in growers' and in

dealers' hands on January 1, 1914; and the price per bushel on December 1 and March 1. The area and production of wheat for 1911-1913 are shown for all countries for which data are available.

[Agricultural statistics of the British Empire and foreign countries], R. H. REW (*Bd. Agr. and Fisheries [London], Agr. Statis., 47 (1912), No. 5, pp. 369-515*).—This report contains data showing the area under crops and amounts produced for 1910, 1911, and 1912, the number of live stock for the latest year available with comparative data for earlier years, and prices of agricultural produce for a series of years. The countries included consist of the United Kingdom, the principal British colonies, and practically all the foreign countries that have data regarding crops and live stock.

Return of prices of crops, live stock, and other Irish agricultural products, T. BUTLER (*Dept. Agr. and Tech. Instr. Ireland, Agr. Statis. 1912, pp. 81, fig. 1*).—This annual statement contains prices of the principal farm crops, live stock, beef, mutton, pork, butter, eggs, and wool. The weekly prices are shown for 1912 and the annual prices for 1893-1912. Diagrams are appended showing fluctuations in the more important items.

Agricultural statistics of Saxony, WUBZBURGER (*Statis. Jahrb. Königr. Sachsen, 41 (1913), pp. 112-126, 161-170*).—This is the annual statement showing areas devoted to the principal field crops, the total yield and yield per hectare, the uses of cultivated land, the total number of live stock and the number slaughtered, and the prices of the principal agricultural products.

The commerce of France with Russia (*Bul. Mens. Off. Renseig. Agr. [Paris], 12 (1913), Nos. 7, pp. 841-862; 9, pp. 1095-1110; 10, pp. 1215-1227; 11, pp. 1344-1358*).—In these articles is outlined the trade of France with Russia in the principal agricultural products, live animals, and animal products by showing for 1911 the total amount exported and the destination. The text is supplemented with statistical tables showing for practically all the items mentioned details for 1911, and for the more important items details for earlier years.

AGRICULTURAL EDUCATION.

Organization of agricultural education and extension, A. F. WOODS (*Coop. Manager and Farmer, 3 (1914), No. 6, pp. 53-56*).—The author reviews present facilities for agricultural education in this country and calls attention briefly to some of the dangers threatening educational work. In summarizing he says "we are entering a new economic stage of development in which waste must give way to conservation, ignorance to knowledge, rule of thumb to scientific method, selfishness to cooperation in its best sense of division of labor."

Agricultural education in secondary schools, A. W. NOLAN (*School News and Pract. Ed., 26 (1913), No. 11, pp. 484-486*).—A plan is given for the organization of country life clubs, subordinated to the Collegiate Country Life Club of America (E. S. R., 29, p. 199), for the development of the industrial, commercial, and social side of farming and to be carried out as a part of secondary agricultural courses.

The high school agriculture clubs, P. I. DOUGHERTY (*Univ. Cal. Jour. Agr., 1 (1914), No. 6, pp. 8-11*).—Twenty high school clubs of agriculture have been organized in California by the students of the college of agriculture for the purpose of improving social and economic conditions in the country. A copy of the constitution adopted is given, together with an outline for a potato growing contest for club members only and reference to work done by these clubs.

Club work in Ohio, L. S. IVINS (*Rural Educator, 3 (1914), No. 3, pp. 57, 49*).—An account is given of the cause of the rapid development, organization, and

value of club work in Ohio which now includes activities in corn and wheat growing, domestic science, and potato, apple, tobacco, vegetable, back yard garden, melon, and better lawn contests.

Industrial education in Oregon, ALICE L. WEBB (*Rural Educator*, 3 (1914), No. 3, pp. 44, 45).—This is an account of industrial education in the public schools of Oregon, in which 2 field men gave their entire time to visiting the schools of every county, thus giving instruction to 41,105 children on the preparation of exhibits for school and state fairs. Three faculty members of the college of agriculture reached 7,035 additional children. The college distributed 4 extension bulletins to aid in this work and also offered lectures and demonstrations on different phases of agriculture and home economics in 21 high schools on 25 different occasions. Last year 88 children's fairs were held throughout the State with a total prize list of \$20,000 and 75,000 exhibitors. The recent legislature appropriated \$6,000 for this field work.

Mutual forest societies of elementary school children, G. ADAM (*Vie Agr. et Rurale*, 3 (1914), No. 11, pp. 283-285, figs. 3).—The author describes the objects, work, and results of mutual forest societies of elementary school children in the Department of the Vosges, France. The aim is to give children practical and theoretical instruction in silviculture and grafting, to teach them to love the trees and respect birds' nests, to know the beneficial and injurious insects of the forests, etc. The movement was begun 10 years ago and in 1912-13 there were 39 societies with 1,652 members. The number of societies has subsequently increased to 49.

Will school-gardening survive? H. M. BENEDICT (*Nature-Study Rev.*, 9 (1913), No. 8, pp. 257-262).—In this discussion the author maintains that the success of the garden depends on the ensurance of the crop, and that, therefore, "three fundamental necessities must be met by a successful system for the development of the home garden movement in cities, viz, obtaining garden experts; bringing these experts into contact with the children in their homes; welding them into a permanent coherent effective organization for the continuous increase of home gardens, a definite factor added to the life of the city for the years to come." Such a system has been originated in Cincinnati where both community and home gardens are being developed with much the larger emphasis upon the home garden. This system which is described is essentially a cooperative arrangement between the department of botany of the University of Cincinnati and the public school authorities, the latter paying additional salary to those teachers desiring to become official garden inspectors after school hours and during the summer, while the university offers special garden courses to train such teachers for their work.

Credit for home work in agriculture (*Rural Educator*, 3 (1914), No. 3, p. 41).—A list of projects that may be performed at home by rural school pupils in Sauk County, Wisconsin, is given, together with rating awarded when satisfactorily completed.

Developing home economics work in Missouri, BAB BELL (*Missouri Bd. Agr. Mo. Bul.*, 11 (1913), No. 11, pp. 23, figs. 5).—This bulletin discusses home economics with a view to awakening interest, and sets forth a more definite plan of work which is to be conducted under the auspices of the state board of agriculture. A copy of a circular, prepared in part by the author, is included for a boys' and girls' corn and home economics contest, containing score cards for the different classes of work as well as other data.

Agricultural home economics instruction in foreign countries, P. SCHINDLER (*Ann. Sci. Agron.*, 4. ser., 2 (1913), II, No. 6, pp. 727-742).—The author dis-

cusses the economic, practical, and moral rôle of the agricultural home economics school and calls attention to three principal types of agricultural home economics instruction, viz, the analytical course or school in individual subjects, such as cooking, sewing, etc., instruction preparing for the home, and professional instruction as found in the national systems of education of England, Belgium, Sweden, Norway, Switzerland, and Hungary, which are described.

Woman's place in agriculture (*3. Cong. Internat. Cercles Fermières Gand, 1913, Compt. Rend., pp. [133]*).—This is a report of the proceedings of the Third International Congress of Farm Women's Clubs held at Ghent June 12 to 15, 1913.

The professional place of the farm woman (*3. Cong. Internat. Cercles Fermières Gand, 1913, Raps. Sect. 2, pp. [112]*).—This section's report consists of discussions on farm women's work in dairying, poultry raising, kitchen gardening, keeping accounts, and flower and shrubbery ornamentation.

Associations of farm women (*3. Cong. Internat. Cercles Fermières Gand., 1913, Raps. Sect. 1, pp. [183]*).—This report contains accounts of the organization, work, and results of farm women's associations in Belgium, Poland, Ireland, the United States, France, Province of Hainaut (Belgium), Kizkimfelegyhaza (Hungary), and the Province of Ontario, Canada, also some ideas relative to rural desertion, some social laws interesting to agriculture, the itinerant home economics course, and the report of the Women's Agricultural and Horticultural International Union.

The farm woman, the mother of the family, and the housekeeper (*3. Cong. Internat. Cercles Fermières Gand., 1913, Raps. Sect. 3, pp. [195]*).—The papers presented relate to the farm woman's role in home education, child hygiene, clothing, village esthetics, furnishing and decorating the home, food of the lower class, utilization and conservation of vegetables and fruits, looking after the professional education of children and keeping them on the farm, and organizing rural recreation.

Farmers' clubs, their organization and work (*North Carolina Sta. Circ. 15 (1914), pp. 11*).—Information is given on how to start a farmers' club, where to obtain material for discussion, and the importance of organization, followed by a topical and seasonal arrangement of subjects, with references.

MISCELLANEOUS.

Annual Report of Nevada Station, 1913 (*Nevada Sta. Rpt. 1913, pp. 61*).—This contains the organization list, a financial statement for the fiscal year ended June 30, 1913, a report of the director, departmental reports, the experimental work of which is for the most part abstracted elsewhere in this issue, and a list of available publications.

Thirty-second Annual Report of Ohio Station, 1913 (*Ohio Sta. Bul. 263 (1913), pp. XXX, fig. 1*).—This contains the organization list, a report of the board of control, a financial statement for the fiscal year ended June 30, 1913, and a report of the director summarizing the work and publications of the station during the year.

Press Bulletins (*Ohio Sta. Bul. 263 (1913), pp. 543-546*).—Reprints of press bulletins on the following subjects: Grasshoppers; the county experiment farm—how it will be managed and what it is expected to accomplish; seed treatment to prevent oat smut; and warbles or bots in cattle.

NOTES.

Arizona University.—An agricultural extension service has been established with S. F. Morse, who has been acting professor of agriculture and agriculturist during the past year, as superintendent. It is planned to carry on this work largely through traveling field agents and lecturers. Some special lines to be developed are the collection of data as to the business side of Arizona farming, demonstrations, personal advice, the formation of local and state organizations of farmers, and the maintenance at headquarters of an exchange bureau or clearing house of agricultural information, especially as regards sources of live stock, seeds and other farm products, farm help, etc.

California University and Station.—At the recent commencement, the degree of LL. D. was conferred upon Dr. E. W. Hilgard, from 1874 to 1906 professor of agriculture and dean of the College of Agriculture. E. H. Hagemann, instructor in dairying and assistant in dairy industries, has resigned.

Iowa College.—At the recent commencement, the degree of D. Sc. was conferred upon Hon. James Wilson, ex-Secretary of Agriculture. The graduating class in agriculture numbered 114, of whom it is stated about four-fifths are planning to take up farming immediately.

A mock auction sale of college live stock was recently held, about 500 students participating. The students had charge of the assembly and advertising of the stock and prizes were awarded for the best work in exhibiting, bidding, etc. The mock auction aroused great interest and it is announced that it will be made an annual event.

A. E. Potts, assistant in cheese making in Cornell University, has been appointed instructor in dairying.

Maryland College.—The dedication of Calvert Hall, the new dormitory, took place May 30, the principal address being given by Hon. W. P. Borland of Missouri. The day was observed as Farmers' Day, opportunity being afforded for an inspection of the lines of work at the college and station, including demonstrations of hog cholera serum and the summer meeting of the State Horticultural Society.

The college has arranged to inaugurate a department for the training of teachers in agricultural and vocational subjects for the rural schools. A 4-year course of regular college grade will be offered, and a summer school for rural teachers including instruction in agriculture, home economics, and the sciences generally was held during July. It is expected to organize a model high school in connection with the department in which will be incorporated the work now assigned to the preparatory and subfreshman classes. It will also be used for practice teaching.

Michigan College.—An important decision by the State Supreme Court was announced May 29, declaring unconstitutional the recent appropriation act in which the legislature had included a provision that "no part of this or any other appropriation shall be available in case a sum in excess of \$35,000 from any or all sources shall be expended in any one fiscal year for the maintenance

of the mechanical and engineering department." This provision was held unconstitutional on the ground that the state constitution "has given to the relator the general supervision of the college and the direction and control of all agricultural college funds. So long as the relator employs them for the purposes intended by the grant, it is beyond the power of the legislature to control the relator's use of the funds received from the Federal Government and long ago appropriated to the agricultural college. Undoubtedly the grant of funds was to the State and the disposition of them wholly within the power of the State, acting through its legislature, in accordance with the conditions of the trust imposed. . . . I am called upon to neither affirm nor deny the proposition that the legislature may now appropriate the federal fund, in whole or in part, to some other institution, withdrawing it, or some of it, from the agricultural college, so long as it keeps faith with the Congress. The legislature has not withdrawn it from the college nor appropriated it, or any part of it, to another institution. It remains an agricultural college fund, within the meaning of the constitution, devoted, under the supervision and direction of the relator, to the college and to the purposes expressed in the grant, in state legislation, and, finally, in the constitution of the State. It is required to be annually applied to the specific objects of the original gift, grant or appropriation. Necessarily, it must be so applied, under existing conditions, by the constitutional supervisors of the fund, and of the college, and not by the legislature. It follows that the legislature exceeded its powers in attempting to deprive the relator of its constitutional control of agricultural college funds derived from the Federal Government."

The effect of this decision is to restrict the appropriations for the current year to the same basis as for the previous appropriation act, thus making a reduction in the college tax levy from $\frac{1}{6}$ mill to $\frac{1}{10}$ mill, and considerably handicapping development for the present.

Nebraska University and Station.—Dr. R. A. Emerson has resigned as professor of horticulture and horticulturist, beginning September 1, to accept a position as professor and head of the department of plant breeding in Cornell University.

Nevada University.—President J. E. Stubbs died very suddenly May 7. Dr. Stubbs was born in Ashland, Ohio, March 19, 1850, and educated in the Ohio Wesleyan University, Drew Theological Seminary, and the University of Berlin. He had been successively superintendent of schools in Ashland, president of Baldwin University at Berea, Ohio, and since 1894 president of the university, and until 1912 director of the station. During this long period of development he had contributed greatly to the upbuilding of the institution. He was also a well-known figure in the Association of American Agricultural Colleges and Experiment Stations, serving as its president in 1899–1900, and on various committees.

Rhode Island Station.—L. P. Howard, a 1914 graduate of the Massachusetts College, has been appointed assistant in chemistry and has entered upon his duties.

The rôle of yellow pigment in chloroplasts, Iwanowski.....	128
Studies on the chemical process of anthocyanin pigment formation, Combes.....	128
Some conditions of formation and decomposition of starch, Lundegårdh.....	128
Physiology of latex in some rubber plants, Tobler.....	128
Microchemical recognition and distribution of aluminum in plants, Kratzmann.....	129
Some effects of colloidal metals on Spirogyra, Hoyt.....	129
Influence of radio-activity on plants, Malpeaux.....	129
Penetrative power of violet and ultraviolet rays in leaves, Dangeard.....	129
Axial abscission as the result of traumatic stimuli, Gortner and Harris.....	129
The survival of plant tissues after freezing, Russell.....	130
The frost problem up to date, Frazer.....	130
Can selection improve the quality of a pure strain of plants? Hagedoorn.....	130
Coloration of the seed coat of cowpeas, Mann.....	130
On the appearance of sterile "dwarfs" in <i>Humulus lupulus</i> , Salmon.....	130

FIELD CROPS.

A table for estimating statistical constants, Pearl and Miner.....	130
Note on the accuracy of bushel-weight determinations, Barber.....	131
Influence of shape and size of plats in tests of varieties of grain, Barber.....	131
Deep plowing and subsoiling, Wright.....	131
The improvement of plants, Blaringhem.....	131
The breeding of forage grasses, Lang.....	131
The history of the cultivated cereals, I, Schulz.....	131
Culture of legumes with special reference to nitrogen assimilation, Heinze.....	131
The inoculation of legumes, Brown.....	131
Influence of soil volume and available plant food on cereals, Burmester.....	132
Leguminous crops in North Carolina, Parker.....	132
Some examples of the potash requirements of legumes, Clausen.....	132
Plants for the desert, Semler.....	132
Desert plants of Mexico, Ochoterena.....	132
Field experiments, Woods.....	132
Report of the agricultural experimental station in St. Croix, 1912.....	133
Field experiments and demonstrations.....	133
[Field crop experiments], Smith.....	133
Alfalfa seed production; pollination studies, Piper et al.....	133
Barley culture in Wisconsin, Moore and Stone.....	134
Cactus opuntia as a forage crop for arid regions.....	134
Chilian clover, Hadfield.....	134
Studies in variation of red clover, Pammel and Clark.....	134
Pollination of clover, Pammel and King.....	134
Inheritance of recurring somatic variation in maize, Emerson.....	135
Maize variety trial, 1912, McMillan.....	135
Cotton experiments, 1913, Ricks, Ferris, Ames, and Walker.....	136
Recent trials with cotton in Grenada, Auchinleck.....	136
Cotton production in the German colonies, Supf.....	136
Cultivation of kapok to replace that of caoutchouc, Cantzler.....	136
Germination of oats, Brioux.....	136
Effect of certain artificial manures on the bushel weight of oats.....	136
The potato question, Planchon.....	137
Potato-spraying experiments at Rush in 1913, Stewart.....	137
Thoroughness pays in potato spraying, Hall.....	137
Prickly pear as a forage plant, Martinez.....	137
The classification of rice in the Central Provinces, Graham.....	137
Experiments with sulphate of ammonia and nitrate of soda on rye, Wehnert.....	137
Silver beet: Its use as a forage crop, Macpherson.....	137
Possible economies in sugar production, Dodson.....	137
Sweet potatoes, Mooring.....	138
Tobacco breeding, Lang.....	138
Variation in tobacco, Hayes.....	138
Changes produced by selection in experiments with tobacco, East and Hayes.....	138
Field experiments with wheat, 1912, Chapman et al.....	139

	Page.
Seed tests made at the station during 1913, Munn.....	139
Purity of farm seeds in 1913, Hall.....	139
Results of seed tests for 1913, Taylor and App.....	139
Report of seed tests for 1913, Burgess.....	139
Better seed, Harris.....	139
Homemade seed-corn testers, Hughes.....	139
Unlawful Iowa weeds and their extermination, Pammel and King.....	139

HORTICULTURE.

Commercial gardening, edited by Weathers.....	140
Effect of an increased carbonic acid in the air on green plants, Fischer.....	140
Experiments with udo, the new Japanese vegetable, Fairchild.....	140
An apple chimera, Castle.....	140
Pollination in orchards.—II, The flowering of pears, Chittenden.....	140
The effect of fertilizers in a cultivated orchard, Gourley.....	141
Spraying for orchard and vineyard in South Carolina, Conradi and Barre.....	141
Analyses for poison of apples sprayed with lead arsenate in midsummer, Woods..	141
Analyses of materials sold as insecticides and fungicides, Cathcart et al.....	142
Making a garden of small fruits, Rockwell.....	142
Currants and gooseberries, Palmer.....	142
Propagation of the seedless breadfruit, Wester.....	142
Cacao culture in Samoa, Demandt.....	142
New researches into some statistics of Coffea, Van der Wolk.....	142
Fruits of a date palm in the Tertiary deposits of eastern Texas, Berry.....	142
The present state of olive growing in Italy, Bracci.....	142
Chestnut breeding experience, Van Fleet.....	142
California gardens, Murmann.....	143
Garden flowers as they grow, Essenhigh-Corke and Thomas.....	143
The rose book, Thomas et al.....	143

FORESTRY.

Silviculture, Jacquot.....	143
Forest protection, von Fürst.....	143
Forest trees, shrubs, and bushes, Gatin.....	143
Contribution to the knowledge of the oil palm (<i>Elæis guineensis</i>), Beccari.....	143
Rubber, its sources, cultivation, and preparation, Brown.....	143
Rubber culture.—I, <i>Hevea brasiliensis</i> , Zaepernick.....	144
Suitability of long-leaf pine for paper pulp, Surface and Cooper.....	144
Uses for chestnut timber killed by the bark disease, Nellis.....	144
Rocky Mountain mine timbers, Betts.....	144
Tests of wooden barrels, Newlin.....	144

DISEASES OF PLANTS.

Organization in various countries for the protection of plants, Saulnier.....	145
Problems and progress in plant pathology, Jones.....	145
Agricultural bacteriology, special inquiries, Hutchinson.....	145
Notes on some rusts in India, Butler.....	145
The ascosporic condition of the genus <i>Aschersonia</i> , Thaxter.....	145
Plasmodiophoraceæ and their relation to Mycetozoa and Chytrideæ, Schwartz..	145
North American Uredineæ, Holway.....	145
Some observations on a peculiar soil disease, Collinge.....	146
Injury by smelter smoke in southeastern Tennessee, Hedgcock.....	146
A study in cereal rusts, physiological races, Stakman.....	146
[Grain diseases].....	147
[The stem rot of cereals], Mangin.....	147
Experiments on control of loose smut of barley and wheat, Schander.....	147
Bad germination of wheat seed.....	148
Causes of soil sickness in wheat lands, etc., Bolley.....	148
Danger in threshing machines.....	148
Finger-and-toe disease of crucifers, Berthault.....	148
Finger-and-toe, Fron.....	148
Finger-and-toe of crucifers, Gay.....	148
Finger-and-toe of crucifers and a disease of carrots, Passy.....	149
Finger-and-toe disease in Brussels sprouts.....	149

	Page.
Control of black canker of potato, Spieckermann.....	149
Phloëm necrosis as cause or symptom of leaf roll, Schander and Tiesenhäusen.....	149
Wart disease of potatoes.....	149
Powdery scab (<i>Spongospora subterranea</i>) of potatoes, Melhus.....	149
The potato quarantine and the American potato industry, Orton.....	149
The black rust of Deli tobacco, Honing.....	149
The effect of dust from cement mills on the setting of fruit, Anderson.....	150
Fruit culture in Normandy, Porter.....	150
A rust new on apples, pears, and other pome fruits, O'Gara.....	150
Experiments with apple leaf spot fungi, Roberts.....	151
Spraying experiments and apple diseases in 1913, Morse.....	151
Observations on the anatomy and other features of the black knot, Stewart.....	151
Court-noué, Barry.....	151
The downy mildew of the grape, Héron.....	151
Comparative tests of fungicides for control of downy mildew, Mahoux.....	152
Notes on diseases of citraceous plants, Jarvis.....	152
Some notes on the scab of grapefruit, Fawcett.....	152
[A fungus disease of coffee].....	152
<i>Orobanche cumana</i> on sunflower, Mal'tsev.....	153
Californian thistle rust, Cockayne.....	153
The symptoms of chestnut tree blight and the blight fungus, Heald.....	153
Longevity of pycnospores of blight fungus in soil, Heald and Gardner.....	153
Pine rust and its transmission, Haack.....	153
An unusual case of electrical injury to street trees, Cromie.....	153
Notes on preparation of insecticides and fungicides, Vermorel and Dantony.....	153

ECONOMIC ZOOLOGY—ENTOMOLOGY.

Comparative physiology of invertebrates, Jordan.....	154
The common mole of the eastern United States, Scheffer.....	154
Work of California gray squirrel on conifer seed in southern Sierras, Berry.....	154
Squirrels and sugar pine reproduction, Jotter.....	154
[Habits of pheasants], Field, Graham, and Adams.....	154
The nutrition and habits of the angleworm in relation to agriculture, Keup.....	154
Helminthological investigations, Gravier.....	154
Economic zoology.....	155
The life story of insects, Carpenter.....	155
Report of the entomologist of Arizona for 1913.....	155
Forty-fourth annual report of the Entomological Society of Ontario, 1913.....	155
Tuberculosis in insects, Metalnikoff.....	155
Insect damage to Russian crops.....	155
The fight against <i>Lachnus persicæ</i> , termites, and ants by carbolineum, Smirnov.....	155
Tables for the identification of insect enemies of spruce and fir, Koch.....	155
The insects attacking cork stoppers, Feytaud.....	155
The Hevea termite of Java, Dammerman.....	156
The cranberry toad bug, Sitrine and Fulton.....	156
The biology of the bedbug.—III, Habits of the adult, Girault.....	156
The chinch bug in Ontario, Hudson.....	156
Burn the bugs.....	156
Currant and gooseberry aphids in Maine, Patch.....	157
Suppression of the cottony cushion scale in Louisiana, Tucker.....	157
Coccidæ of Japan, V, Kuwana.....	157
<i>Euxoa segetum</i> and how to combat it, Sopotzko.....	157
On the appearance in Bessarabia of <i>Clysia ambiguella</i> , Vitkovsky.....	157
Appearance of <i>Phlyctænodes sticticalis</i> and <i>Cassida nebulosa</i> , Vassiliev.....	157
<i>Tortrix forskaleana</i> , Trägårdh.....	157
On German gall flies and galls, Rübssaamen.....	157
On a method of fighting <i>Psila rosæ</i> , Vassiliev.....	158
Controlling flies, Conradi et al.....	158
Corn-leaf blotch miner, Phillips.....	158
A new species of grass grub.—A serious pest of forest trees, Cockayne.....	159
The life history and bionomics of <i>Cryptorhynchus lapathi</i> , Scheidter.....	159
On the biology of <i>Tropinota turanica</i> , Troitzky.....	159
On an egg-eating parasite of <i>Rhynchites auratus</i> , Troitzky.....	159
Contributions to the British Braconidæ.—I, Meteoridæ, Lyle.....	159
Life histories of Indian insects.—IV, Hymenoptera, Dutt.....	159

	Page.
Spider enemies of bees, Levandovsky.....	159
<i>Bryobia pratiosa</i> , Trägårdh.....	159
Transmission of <i>Trypanosoma cruzi</i> by <i>Rhipicephalus sanguineus</i> , Neiva.....	159
Rocky Mountain spotted fever, Fricks.....	160

FOODS—HUMAN NUTRITION.

Changes in composition of nitrogenous constituents of meat extracts, Wright....	160
The chemical composition of meat extract.....	161
The food value of skim milk and the nutritive value of condensed skim milk.....	161
Eggs considered from the point of view of food value, Delaye.....	161
Lard, McGill.....	161
Vegetable foods; their distinctive characteristics and classification, Rusby.....	161
The digestion of vegetable foods, Gies.....	161
Gastric digestion of the proteins of bread and raw meat in man, Zunz and Cerf.....	161
Composition of corn-meal products and digestibility of protein, Rammstedt....	161
Influence of artificial drying on quality of grains for bread making, Neumann....	162
Effects of nitrogen peroxid on the constituents of flour, Moore and Wilson....	162
The chemical composition of paddy mill products, Warth and Darabsett.....	163
On the powdered sugar of commerce, Bailey and Jackson.....	164
The chemistry of a cup of coffee.....	164
Composition of essence of coffee—presence of pyridin, Bertrand and Weisweiler.....	165
Commodities and provisions.....	165
Municipal laboratory of chemistry.....	166
Construction of public slaughterhouses and markets, Schwarz and Heiss.....	166
The school lunch system [in the Philippines].....	166
The ship's commissary officer, Dyer.....	166
The work involved in the combustion processes of the body, Höber.....	166
Protozoan protoplasm in fatigue, Underhill and Woodruff.....	167

ANIMAL PRODUCTION.

Live stock on farms and elsewhere.....	167
Live stock products and domestic animals sold or slaughtered on farms.....	167
Feeding corn silage to farm animals, Pew, Evvard, and Kildee.....	168
[Analyses of feeding stuffs].....	168
[Animal husbandry], Haecker.....	168
The brains of the domestic animals, Kraemer.....	168
The importance of measurements in the improvement of the breeds, Voitellier.....	168
The red cattle of Flanders, Raquet.....	169
[Cattle of northern Spain], Codina.....	169
Winter steer feeding, 1912-13, Skinner and King.....	169
Raising and fattening beef calves in Alabama, Gray and Ward.....	169
Pig feeding, Grace.....	169
A rotation of grazing crops for hogs.....	169
Management and breeding of horses, Harper.....	169
Whole world buying our fast horses.....	169
The Welsh pony, Dargan.....	170
Poitou mule breeding.....	170
Studies on the physiology of reproduction in the domestic fowl, VI, Curtis.....	170
The bacteriology of the hen's egg, Rettger.....	171
Carbon dioxid in incubation, Lamson, jr., and Edmond.....	172
Natural and artificial incubation of hens' eggs, Lamon.....	173
Electro-cardiogram for embryo chicks, Wertheim-Salomonsen.....	173

DAIRY FARMING—DAIRYING.

Dairying, Sheldon.....	173
Dairying in Nova Scotia.....	173
[Dairy husbandry].....	173
[Dairy husbandry], Haecker.....	173
Manuring of grass land for milk and meat, Davis.....	173
Feeding of cattle on phosphatic pasture, Seltensperger.....	174
Dairy herd records for fourteen years, Frandsen and Haecker.....	174
A new Holstein record.....	174
Nourishment of young animals with self and foreign milk, Schrape.....	174

	Page.
The etiology of epidemic septic sore throat.....	174
Provision of the agricultural law relating to dairy products, 1913.....	175
Sanitary inspection of market milk, Gooren.....	175
Isoelectric point of man, cow, goat, dog, and guinea pig milk casein, Ylppö.....	175
Electric sterilization of milk.....	175
Ozonization of milk, Wiener.....	175
Free and volatile fatty acids of fresh butter fat, Buzr and Weise.....	175
The variability of <i>Bacillus bulgaricus</i> , Christeller.....	175
The keeping quality of sweet cream butter.....	175
Preservation of butter by sodium bicarbonate and sodium nitrate, Bordas.....	176
Nut butter.....	176
The ripening of mold cheeses and the ferments involved therein, Mazé.....	176
Oleomargarin, Van Voornveld.....	176
Bibliography of references on milk and milk products during 1912, Huyge.....	176

VETERINARY MEDICINE.

Report of the veterinary director general for 1913, Torrance.....	176
Report of the territorial veterinarian, 1911-12, Nørgaard and Case.....	177
Annual report of the chief veterinary officer for 1912, Stockman.....	177
Report of Bengal Veterinary College and Department, Raymond and Smith.....	177
Report on civil veterinary department, Burma, for 1913, Evans.....	177
Veterinary diseases, Balfour, Archibald, et al.....	177
Bacteriology, microbiology, and serum therapy, Besson, translated by Hutchens.....	177
A compend of parasitology, Brumpt.....	177
Investigations of scabies and scab mites, Fiebiger.....	177
Chemotherapy, Ehrlich.....	177
The relation of the leucocytic bacteriolysin to body fluids, Manwaring.....	178
Toxic action and disinfecting agents, Kühl.....	178
Technical errors in protective vaccination, Laufer.....	178
Synthetic antigens for meiostagmin reaction used for malignant growths, Izar.....	178
An improvement in the meiostagmin reaction, Köhler and Luger.....	178
Autoserotherapy in pleuritis, Haan.....	179
A dry placenta powder and its use in Abderhalden's method, King.....	179
The biological diagnosis of pregnancy, Engelhorn.....	179
The serum diagnosis of pregnancy, Judd.....	179
The serodiagnosis of pregnancy, Jaworski and Szymanowski.....	179
Diagnosis of pregnancy with optical method and dialysis, Freund and Brahm.....	179
Experiences with the Abderhalden pregnancy reaction, Schlimpert and Hendry.....	180
Abderhalden's reaction with placenta and serum, Schlimpert and Issel.....	180
Serology of eclampsia, Stange.....	180
Abderhalden's dialysis method, Falk.....	180
Valuation of precipitating anthrax serum, Rickmann and Joseph.....	181
Symptomatic anthrax, Wulff.....	181
Blackleg and diseases resembling symptomatic anthrax, Wulff.....	181
Diagnosis of blackleg by examining the bile, III, Wulff.....	181
The precipitation diagnosis in tuberculosis, Morelli.....	181
The intradermal reaction in bovines, Dalkiewicz.....	181
Is tuberculin nontoxic for the healthy organism? Geibel.....	182
The relation of bovine tuberculosis to human tuberculosis, Möllers.....	182
Tuberculosis of food animals and its relation to the public health, Jowett.....	182
Tuberculosis of the tonsils in a heifer, Chaussé.....	182
Tuberculous orchitis in a horse, Darmagnac.....	182
Concerning the pure cultivation of Bang's bacillus, Ascoli.....	182
Addresses to the general assembly on tick eradication.....	182
<i>Onchocerca gibsoni</i> in Australian cattle, Gilruth and Sweet.....	182
Anthrax in hogs and the Ascoli anthrax precipitation reaction, Seibold.....	182
Thermoprecipitation for detecting hog erysipelas, Gauss.....	183
Spread of hog epizootics through vaccinating against erysipelas, Jakob et al.....	183
Testing the vaccinating substances against swine plague, Dürkop.....	183
Mammary botryomycosis in the mare, Plötner.....	184
Vaccinating against the pectoral form of equine influenza (Brustseuche), Konew.....	184
Protective and curative vaccination for pectoral equine influenza, Bromberger.....	184
Nematodes parasitic in domestic fowls, Henry and Sizov.....	184
Parasitism in relation to birds, Jones.....	184

RURAL ENGINEERING.

	Page.
[Agricultural engineering].....	185
Rural engineering.....	185
Water conservation and irrigation.....	185
The wet lands of southern Louisiana and their drainage, Okey.....	185
Better roads, Tannatt.....	185
Forest road construction, Stoetzer.....	185
The cause and the prevention of cracking in concrete roads, Spackman.....	185
Approximate stresses produced by a concentrated load, Pearl.....	186
Strength of large pipes, Cooper and Weinmann.....	186
Reinforced concrete construction, Hool.....	186
[Farm power and machinery].....	186
Farm motors, Potter.....	186
The adaptation of kerosene to gasoline engines, Richter and Pierce.....	187
The use of internal combustion motors in Danish agriculture, Feilberg.....	187
The science of laying out and the art of plowing with power.....	187
Recent tests of mechanical cultivation in France, Coupan.....	187
Motor cultivation by tractors or rotating cultivators, De Meyenburg.....	188
Basis for the testing of mechanical cultivating implements, Giordano.....	188
Motor-drawn and motor-operated grain binders, Ringelmann.....	188
Experiments with an electrically driven threshing machine, Coupan.....	188
Operating characteristics of centrifugal pumps, Morrison, jr.....	188
The cost of pasteurizing milk and cream, Bowen.....	188
Electric stimulation of plant growth, Peaslee.....	189
The dissolving of zinc from pipes by water supplies, Lehmann.....	189
The hot-water supply plant for private houses, Gullino.....	189
Elements of heating, Irwin.....	189
Some suggested designs for sewage-treatment plants, Hansen.....	190
A combination cesspool and septic tank, Duling.....	190
A new suggested method of water testing for plumbing fixtures, Shade.....	190
Plumbing practice, as seen by the inspector.....	190

RURAL ECONOMICS.

The agricultural outlook.....	190
Agricultural production in West Virginia, Johnson.....	190
Some indications of the economic and agricultural progress of Argentina.....	191
[Agricultural statistics of British India].....	191
[Land tenure, agriculture, and live stock in New Zealand], Fraser.....	191
[International statistics of agriculture].....	191
Is scarcity to be preferred to plenty? Johnson.....	191
History and description of a farm in the valley of the Unstrut, Schöne.....	191
The division of capital in agriculture as between landlord and tenant, Paget..	192
Landed proprietors and agriculture in Norway.....	192
Farm credit conditions in a cotton State, Haney.....	192
Helping the farmer to keep his farm, Breitung.....	192
Report of New York delegates on the American Commission, Allen and Mitchell.	192
Instruction in marketing.....	192
The story of the C. W. S., Redfern.....	193
Organization and present status of the Prussian Chamber of Agriculture, Oberg..	193

AGRICULTURAL EDUCATION.

Rural life and education, Cubberley.....	193
Educational resources of village and rural communities, Hart.....	193
[Instruction in agriculture and domestic science], Harris.....	193
The agricultural instruction act.....	194
[Progress in agricultural education in Canada in 1913].....	194
Agricultural organization in Belgium.....	194
Nature study and the teaching of elementary agriculture, Comstock.....	194
Some students' work.....	194
The present status of nature study in the elementary schools, Patterson.....	194
The school gardens of Saginaw, Passolt.....	195
Should school gardens survive? Cromwell.....	195
Supervising a community garden in summer, Waters.....	195
The lay of the land, Needham.....	195
Farmers' institute and extension work in the United States in 1913, Hamilton..	195

MISCELLANEOUS.

	Page.
Annual Reports of the Department of Agriculture, 1913.....	195
Twentieth Annual Report of Minnesota Station, 1912.....	195
Twenty-first Annual Report of Minnesota Station, 1913.....	195
Report of the director, 1913, Lipinan.....	196
Finances, meteorology, index.....	196
Relation of the station to the college and to extension, Doten.....	196
[Annual Report of the Rothamsted Experimental Station, 1913], Russell.....	196
Organization of experimental work in agriculture in German colonies, Busse..	196
Laws relating to work of department of agriculture of Washington.....	196
New Jersey handbook of agriculture, compiled by Clark.....	196
The farmers' ready reference book.....	196
Scientific writings by the late William McMurtrie, compiled by McMurtrie....	196

LIST OF EXPERIMENT STATION AND DEPARTMENT PUBLICATIONS REVIEWED.

<i>Stations in the United States.</i>	<i>Page.</i>	<i>Stations in the United States—Contd.</i>	<i>Page.</i>
Connecticut Storrs Station:	Page.	Utah Station:	Page.
Bul. 75, Nov., 1913.....	171	Circ. 16, Mar., 1914.....	139
Bul. 76, Mar., 1914.....	172	West Virginia Station:	
Indiana Station:		Bul. 144, Mar., 1914.....	190
Bul. 167 (popular ed.), Oct., 1913.....	169	Wisconsin Station:	
Iowa Station:		Bul. 212 (rev. ed.), Mar., 1914.....	134
Circ. 1, Mar., 1912.....	139	<i>U. S. Department of Agriculture.</i>	
Circ. 2, 2 ed., Apr., 1913.....	125	An. Rpts. 1913.....	195
Circ. 5, Dec., 1912.....	139	Jour. Agr. Research, vol. 2, No. 1, Apr., 1914.....	107, 130, 150, 153, 158
Circ. 6, Jan., 1913.....	168	Bul. 71, The Wet Lands of Southern Louisiana and Their Drainage, C. W. Okey.....	185
Circ. 7, Apr., 1913.....	127	Bul. 72, Suitability of Longleaf Pine for Paper Pulp, H. E. Surface and R. E. Cooper.....	144
Circ. 8, Apr., 1913.....	131	Bul. 73, Raising and Fattening Beef Calves in Alabama, D. T. Gray and W. F. Ward.....	167
Circ. 9, Apr., 1913.....	122	Bul. 75, Alfalfa Seed Production; Pollination Studies, C. V. Piper et al.....	133
Circ. 10, Apr., 1913.....	122	Bul. 76, Laboratory and Field Assay of Arsenical Dipping Fluids, R. M. Chapin.....	115
Louisiana Stations:		Bul. 77, Rocky Mountain Mine Timbers, N. de W. Betts.....	144
Bul. 144, Apr., 1914.....	117	Bul. 79, Research Studies on the Curing of Leaf Tobacco, W. W. Garner, C. W. Bacon, and C. L. Foubert.....	115
Bul. 145, Apr., 1914.....	157	Bul. 81, The Potato Quarantine and the American Potato Industry, W. A. Orton.....	149
Maine Station:		Bul. 82, Powdery Scab (<i>Spongospora subterranea</i>) of Potatoes, I. E. Melhus.....	149
Bul. 222, Dec., 1913.....	117, 196	Bul. 83, Farmers' Institute and Agricultural Extension Work in the United States in 1913, J. Hamilton.....	195
Bul. 223, Jan., 1914.....	151	Bul. 84, Experiments With Udo, the New Japanese Vegetable, D. Fairchild.....	140
Bul. 224, Feb., 1914.....	132, 141	Bul. 85, The Cost of Pasteurizing Milk and Cream, J. T. Bowen....	188
Bul. 225, Feb., 1914.....	157	Bul. 86, Tests of Wooden Barrels, J. A. Newlin.....	144
Bul. 226, Mar., 1914.....	130, 131	Farmers' Bul. 582, Uses for Chestnut Timber Killed by the Bark Disease, J. C. Nellis.....	144
Minnesota Station:		Farmers' Bul. 583, The Common Mole of the Eastern United States, T. H. Scheffer.....	154
Bul. 138, Feb., 1914.....	146	Farmers' Bul. 584, The Agricultural Outlook.....	190
Twentieth An. Rpt. 1912.....	195	Farmers' Bul. 585, Natural and Artificial Incubation of Hens' Eggs, H. M. Lamon.....	173
Twenty-first An. Rpt. 1913.....	168, 173, 195		
Mississippi Station:			
Bul. 164, Feb., 1914.....	136		
Nebraska Station:			
Bul. 139, Apr. 6, 1914.....	174		
Research Bul. 4, Feb. 1, 1914.....	135		
New Hampshire Station:			
Bul. 166, Sept., 1913.....	139		
Bul. 167, Dec., 1913.....	126		
Bul. 168, Jan., 1914.....	141		
New Jersey Stations:			
Bul. 260, June 29, 1913.....	124		
Bul. 261, Dec. 6, 1913.....	126

EXPERIMENT STATION RECORD.

VOL. XXXI.

AUGUST, 1914.

No. 2.

The place of the publication in the activities of the agricultural colleges and experiment stations is increasing in importance and prominence year by year. It is an expression of the broadening field of publicity work at these institutions, and likewise of the growth of their reading constituencies. It is a recognition of the fact that the colleges and stations are working for all the people, and not merely for the few who come in direct contact with them.

Very naturally this development has led to greater attention to the making of these publications, in order that they may effectively carry the message, and to systematic provision for this service. What was at one time an incidental feature has become a prominent and important one, and this has developed a special class of workers. It is at once a division of labor and an interesting recognition of the need for the handling of publications by experts with training and insight such as to make them capable of this special form of work.

So recently as 1911 at only three experiment stations—Iowa, New York State, and Wisconsin—had officers designated as editors been appointed, and one of these was also serving as librarian. By July, 1913, however, the number had so increased that a meeting of the agricultural editors and publicity men of the mid-western colleges was held at the University of Illinois, and this gathering developed a belief in the desirability of an organization of national scope. As a result of this, a conference was held at the Kentucky Experiment Station June 25 and 26, 1914, which brought together representatives of thirteen States, as well as this Department, and found institutions in numerous other States eligible for membership. An interesting program, dealing with various phases of the details of bulletin editing and distribution, as well as of agricultural college and experiment station publicity work, was presented as discussed in detail on page 199 of this issue, and a formal organization was effected, to be known as the American Association of Agricultural College Editors, with provision for committee activities and annual meetings. Much interest and enthusiasm were displayed by those in attendance, and it seems probable that the next meeting, which is

expected to convene at the University of Wisconsin in June, 1915, will find the new association established on a permanent basis.

The mere addition of another to the steadily lengthening list of associations, societies, and similar groups of workers in the various fields of agriculture is nowadays much too common to excite more than momentary general interest, and perhaps a doubt as to whether the process of organization is not being carried close to the limits of expediency. Such a query is particularly likely to suggest itself in the case of a body of workers some of whose duties are of a semi-administrative and delegated nature, and many of whose problems are in the first instance the problems of administrative officers, and as such have received through existing organizations considerable attention from time to time.

The desirability of an additional association was therefore a matter which early received the attention of the Lexington conference, and the decision that the step was warranted was reached after its consideration from several points of view. Thus, it was felt that while the formulating of general policies pertaining to publications was unquestionably a problem for administrative heads, there still remained many details as to the ways and means of working out these policies, in which the exchange of ideas and the combined judgment of those directly in charge could be of much usefulness. For instance, one of the papers on the program was a discussion of the processes used in bulletin illustration. This is a topic obviously of too specialized a nature to justify its inclusion in the congested program of such organizations as the Association of American Agricultural Colleges and Experiment Stations or the Society for the Promotion of Agricultural Science, although it is a subject concerning which much less is understood by many of those immediately concerned than its importance warrants.

In the case of topics of more general interest it was thought that joint programs might occasionally be arranged with other organizations. As a means to this end the new association included among its standing committees one on cooperation with other agencies. Such a committee would be available to participate, if desired, in functions similar to those contemplated by a committee appointed by the Agricultural Libraries Section of the American Library Association at its last meeting, which is to submit suggestions relative to the improvement of station publications from the bibliographical standpoint to the Association of American Agricultural Colleges and Experiment Stations. It is quite evident that from a joint consideration of such a topic from the administrative, editorial, and bibliographical points of view, most helpful suggestions could be expected.

The maintenance of an organization of agricultural college editors, and this term it should be stated was so defined as to include those engaged in similar work in the experiment stations and this Department, should also be of value in establishing ideals and standards in this comparatively new occupation. The special requirements which have led individual institutions to provide for an editorial corps have been quite varied, and in consequence prominence has sometimes been given to duties somewhat analogous to those of a press agent, in others approximating those of a proofreader or printing clerk, and in others embracing work of a grade demanding not only technical knowledge and editorial ability but a substantial scientific education.

It is quite probable, and perhaps not wholly undesirable, that this diversity will continue for a considerable period. The work undoubtedly represents different grades of requirement, but it affords opportunity for the exercise of a high grade of technical and scientific understanding. Indeed, some of the difficulties encountered have been due to a lack of this, which has prevented the development of sympathetic, cooperative relations between the author or scientific worker and the editor. Such relations are much to be desired, and are worthy of attention to bring about mutual understanding. Experience has shown the difficulty of attracting to such editorial service men whose equipment and training have qualified them to make it a life work. This is partly due to an underrating of the status of such men and a failure to make the positions sufficiently attractive. Men will have to be developed who combine taste for such work with the necessary knowledge, and we shall have such men in greater abundance when high standards tend to elevate their positions and give them due recognition. An association devoted to the interests of the otherwise isolated individuals in this field will not only serve to call attention to this growing branch of activity, but also give standing and recognition to it. Likewise, if these agricultural editors through their conferences and their concerted influence bring about a higher standard of excellence in the publications they will not only dignify their own work but that of the class of publications they represent.

The fundamental object of the new association should be the improvement of the publications of the institutions represented. In the words of Dr. Kastle, of the Kentucky Experiment Station, in an address of welcome to the delegates, it should be the mission "more than anything else to give some tone and dignity and solid and enduring worth to all of our communications." This of course, as already suggested, is a problem which will demand the best thought of the director, the investigator, the extension worker, and the libra-

rian, as well as the editor, but in many of its details it constitutes the latter's special problem and one still far from solution.

Great improvement, to be sure, has already been effected over the earlier days. In attractiveness of appearance and attention to mechanical details the change is both notable and commendable, and there has also been great gain in the direction of adapting the publications more closely to the needs of those whom they are intended to reach. The average station bulletin now has a popular summary or it may be a popular edition, and the publications of most institutions are classified according to their technical or popular character. The old charge of "shooting over the farmer's head" is much less justified than ever before, and in fact the danger in some cases is that of underestimating the farmer's real stature and understanding.

One result of the earnest desire upon all sides to make the publications genuinely useful has been not only to popularize the style of the regular station bulletin, but also to multiply widely the channels of communication, especially by means of the extension service. A vast increase has thus been seen in the number of circulars of information, leaflets, etc. The agricultural press has been utilized as never before, and within recent years the newspapers, both those circulating in country districts and those for city readers, have been furnished in increasing abundance with press bulletins, notices, and in many States with plate matter itself, dealing with farm life in nearly every phase.

Much of this effort has been very useful, particularly in bringing before the public in an intimate way the work of the colleges and stations at a time when their purposes and value were too little understood and appreciated. Ten years ago these institutions as a class needed legitimate advertising, and there is still every reason why they should keep in close touch with their constituents. There are, however, tendencies in some of the modern methods of disseminating information, broadcast as it were, which may well be looked upon with some apprehension. Our publication work has often been too much of the "touch and go" character, with no "follow up." New ideas have to be pressed home persistently, and should not be left to propagate themselves.

On the other hand, it was ably pointed out by Dr. Kastle that "as agricultural institutions we are literally deluging the world in printer's ink, and in the matter of our publications there is a vast amount of unnecessary duplication of work and frequently an unnecessary exploitation of the individual rather than the cause." Hence this activity calls for intelligent control and direction; and unless it is in the hands of men of good judgment and the proper point of view successful control is very difficult. Some of these tendencies of course, as Dr. Kastle explained, are by no means confined

to workers in agricultural science, yet it is most desirable that the present general good will toward agriculture should be retained, and it is well to reflect upon the possibility of a reaction in case public sentiment should for any reason ever become surfeited.

The fact is that the whole subject of extension publications is comparatively new. It seems probable that we are still in a transition stage, with much yet to be learned as to the best forms and methods in this sort of instruction. Just at present, therefore, an interchange of views and experiences, such as constituted a prominent portion of the Lexington program, would seem to be a most useful preliminary in the sifting of the wheat from the chaff.

One of the most important considerations, although not always appreciated in the preparation even of station bulletins and similar publications, is their permanent value as works of reference. Seldom can information by the printed page be so timed as to reach the farmer precisely when desired, but this is less essential if the information is in such form as will lead him to preserve it for the day of need. He should therefore be encouraged to build up his own library, and an important step in this direction is sending him publications which it is worth his while to preserve. Such publications, even when of an extension nature, will be readily differentiated from much of the material prepared for newspapers and magazines and intended chiefly to arouse interest or stimulate further inquiry, as their primary purpose will be not to entertain but to inform. A spectacular method of presentation will thus be of much less importance than substantial subject matter, plainly stated and so arranged as to be found readily by a busy man when desired.

It is well to make even this class of publications attractive, but better than a multitude of illustrations or the embellishments of the most approved newspaper or magazine style may be the use of a durable grade of paper or the supplying of an adequate index or table of contents. The abolition of unnumbered publications—the bane of every librarian, professional or otherwise—and the reduction of publications to as few series as possible will also favor the preservation of this material. These benefits, moreover, will not be confined to individual farmers, but will also be most helpful to libraries, schools, etc. Of late a great demand for agricultural information is being made on public libraries in both country and city as a result of the prevailing interest of all classes of people in rural life; but too often the libraries are so handicapped by the apparently limited regard of the authors for bibliographical considerations as to make them hesitate to undertake the complicated task of obtaining order from the chaotic mass which is descending upon them.

If the conception of the college or station publication as a contribution to a permanent record could become more general, the volume of such literature might be appreciably reduced but the standards of quality would be speedily elevated. The scientist would be less likely to publish prematurely and more likely to look upon the publication as the culminating stage of his research. Likewise, the editor, the director, and the librarian, as well as the general public, would see in the material not only its immediate news value but its larger significance to the future as well as to the present as a work of reference.

No one will question the chance for improvement in our publication work or the desirability of having it receive thoughtful attention and suggestion from men whose work tends to make them experts. The American Association of Agricultural College Editors, consisting of those primarily engaged in the preparation of these publications, would seem to possess a special opportunity for service along such lines, particularly if it can secure the cooperation of other organizations. Its formation at this time may, therefore, be regarded as of considerable importance, and its efforts to accomplish the purposes for which it has been established will be awaited with much interest and expectancy.

RECENT WORK IN AGRICULTURAL SCIENCE.

AGRICULTURAL CHEMISTRY—AGROTECHNY.

Flavor of Roquefort cheese, J. N. CURRIE (*U. S. Dept. Agr., Jour. Agr. Research*, 2 (1914), No. 1, pp. 1-14).—The purpose of this investigation was to identify and explain the occurrence of any substances which are responsible for the peculiar peppery or hot taste present in well-ripened Roquefort cheese.

The neutral flavor solution of Suzuki et al. (*E. S. R.*, 24, p. 382) from 750 gm. of Roquefort cheese showed a total amount of acidity in ester combination corresponding to 0.44 decinormal cc. The proportional numbers obtained by the Duclaux distillation approximated the constants for acetic acid. The odor of Roquefort cheese suggests that part of its flavor may be due to the presence of ethyl acetate, but the quantity present makes it doubtful whether it would materially affect the test. It was noted that the amount of volatile insoluble fatty acids of milk fat increased with the ripening of the cheese, and these when found floating on the surface of the distillate had a peppery taste.

From five fractions, the barium salts of caproic, caprylic, capric, butyric, and acetic acids were obtained. The chief constituent of the insoluble acids was capric acid. The quantitative estimations made it evident that a small amount of formic acid is present also. The peppery taste of Roquefort cheese is ascribed to the presence of caproic, caprylic, and capric acids and their easily hydrolyzable salts which originate from a hydrolysis of the fat of milk. Evidently in the normal ripening of Roquefort cheese very few of the acids originate from the putrefaction of proteins. The small quantity of acetic and formic acids present can result from a fermentation of carbohydrates in the early stages of ripening or they may be the products of a partial oxidation of higher acids or glycerol by mold.

Studies are also reported on the action of *Penicillium roqueforti* on butter fat. Czapek's solution, in which cane sugar was replaced by 3 gm. of fresh, filtered milk fat, was employed as the nutrient medium. The results when compared with the controls showed a hydrolysis of about two-thirds of the fat. When the mold was grown on fresh curd "the fat showed decided decomposition, but there was only a meager accumulation of soluble and volatile acids. A culture at the age of 45 days contained only 0.75 decinormal cc. of soluble acids in 500 cc. of distillate. A culture similarly grown but in the presence of *Bacillus lactis acidi* contained only 0.8 decinormal cc. of soluble acids in a like volume of distillate. The acid number of the fat in both cultures showed that more than one-half of it had been hydrolyzed. . . . The enzymotic studies show that *P. roqueforti* is well supplied with an enzyme capable of hydrolyzing both simple esters and triglycerids."

A bibliography of literature cited is appended.

On the influence of preliminary heating upon peptic and tryptic proteolysis, A. H. BIZARRO (*Jour. Physiol.*, 46 (1913), No. 3, pp. 267-284, figs. 6).— "Sørensen's formaldehyde method was applied to the study of the influence of

heating upon the peptic and tryptic digestion in vitro of white of egg, gelatin, fibrin, beef, and casein. The number of cubic centimeters of sodium hydrate required to neutralize the digestion mixture increases clearly after the thirteenth day of peptic digestion of ovalbumin and gelatin; also in the eighth day of beef; and after the second day digestion of casein and fibrin.

"The above results, as could be foreseen, gave no clear conclusions about the digestive activity of pepsin, but they decisively bear out the view of the slow liberation of amino-acids groupings by this enzym. Preliminary heating of egg white at 120 to 140° C. makes trypsin proteolysis more active. Preliminary heating increases the tryptic digestion of fibrin, casein, and beef, and decreases that of gelatin. The amino-acids groupings in tryptic solutions increase after 15 hours' digestion."

The kinetics of invertase action, L. MICHAELS and MISS M. L. MENTEN (*Biochem. Ztschr.*, 49 (1913), No. 5, pp. 333-369, figs. 19).—Saccharose apparently combines with invertase to form a compound with a dissociation constant of 0.0167. The combination is labile according to the equation 1 molecule saccharose-invertase compound \rightarrow 1 molecule fructose + 1 molecule glucose + 1 molecule invertase. Invertase also has an affinity for fructose, glucose, the higher alcohols (mannit, glycerol), and other carbohydrates, but not for lactose. The affinity, however, is smaller than for saccharose and the compound is not labile.

The concentration of all the compounds can be calculated from the law of mass action, and fairly accurate dissociation constants can therefore be easily supplied for each. The most exact dissociation constant is for the saccharose-invertase compound. As the decomposition of the saccharose-invertase compound must be a monomolecular reaction, the rate of decomposition of the saccharose is proportional to the concentration of the saccharose-invertase compound.

The localization of betain in plants, V. STANĚK (*Ztschr. Zuckerindus. Böhmen*, 37 (1913), No. 8, pp. 385-390; *abs. in Chem. Ztg.*, 37 (1913), No. 65, *Repert.*, p. 296).—The data show that betain is very unevenly distributed in plants, but is chiefly present in young leaves and shoots which are still green. Probably this substance plays a part in the nitrogen economy of the plant. Seeds do not contain betain as a reserve material.

Studies in the chemistry and physiology of the leaves of the betel vine (*Piper betle*), and of the commercial bleaching of betel-vine leaves, H. H. MANN, D. L. SAHASRABUDDHE, and V. G. PATWARDHAN (*Mem. Dept. Agr. India, Chem. Ser.*, 3 (1913), No. 2, pp. 17-63).—An investigation of certain aspects of the chemistry and physiology of this plant, which is reported under the following heads: "(1) The occurrence of nitrates in betel-vine leaves and plants, and their relationship to the growth of their vine; (2) the sugars, starch, tannin, essential oil, and other normal constituents of the betel vine and their relationship to the growth of the vine; (3) the commercial bleaching of the betel-vine leaf, and the chemical changes by which it is accompanied."

Chemical studies on the lime-sulphur-lead arsenate spray mixture, W. E. RUTH (*Jour. Indus. and Engin. Chem.*, 5 (1913), No. 10, pp. 847-850).—Previously noted from another source (*E. S. R.*, 29, p. 802).

The titrimetric determination of ammonia, L. W. WINKLER (*Ztschr. Angew. Chem.*, 26 (1913), No. 31; *Aufsatzteil*, pp. 231, 232; *abs. in Chem. Ztg.*, 37 (1913), No. 65, *Repert.*, p. 293).—Instead of either hydrochloric acid or sulphuric acid solutions, boric acid (3 gm. of crystallized boric acid in 100 cc. of water) in excess can be employed to collect the ammonia on distillation. As boric acid reacts neutrally toward Congo red and methyl orange, the excess of boric acid present can be titrated with standard hydrochloric acid solution.

A rapid method for the determination of ammoniacal nitrogen with formaldehyde, GAILLOT (*Ann. Chim. Analyt.*, 18 (1913), No. 1, pp. 15-17).—For sulphate of ammonia the procedure is as follows:

Five gm. of the ammonium salt under examination is dissolved in water and then made up to a bulk of 100 cc.; 20 cc. of the filtered solution, to which a few drops of formaldehyde has been added, is neutralized with potassium hydroxid as ammonium sulphate is always a little acid; about 5 cc. of neutral 40 per cent formaldehyde solution is added, the acid liberated titrated with normal potassium hydroxid, and the number of cubic centimeters of alkali used multiplied by 1,500. The resulting figure shows the amount of ammoniacal nitrogen in 100 gm. of sulphate of ammonia. The free ammonia in such substances is determined by direct titration and can be found in the same solution.

For simplifying the calculations the author proposes employing a solution of potassium hydroxid of which each cubic centimeter corresponds to 0.035 gm. of sulphuric acid. Each cubic centimeter of the potassium hydroxid solution made in this manner will correspond to 0.01 gm. of ammoniacal nitrogen.

The method gives the same figures which are yielded by the classical method for determining ammoniacal nitrogen.

A rapid method for determining formaldehyde, GAILLOT (*Ann. Chim. Analyt.*, 18 (1913), No. 1, pp. 17, 18).—The principle of this method is the same as that underlying the method described above, namely, if ammonia in combination with an acid is brought into contact with formaldehyde, an insoluble compound, hexamethylene tetramin, is formed ($6\text{H.COH} + 4\text{NH}_3 = (\text{CH}_2)_6\text{N}_4 + 6\text{H}_2\text{O}$), and the acid radical of the ammonium salt is liberated. This acid can be titrated with an alkali, using phenolphthalein as the indicator, and referred to the factor for calculating formaldehyde.

Comparison of methods for the determination of dissolved oxygen, J. W. SALE and W. W. SKINNER (*Abs. in Science, n. ser.*, 38 (1913), No. 985, p. 716).—This is a comparative study of the Winkler and modified Levy methods with the gasometric method for oxygen. With pure and moderately diluted saline waters the Winkler method gave accurate results, and the Levy method results which were low. "The Winkler method also gives closely agreeing results in duplicate and triplicate determinations on such waters, for the most part within 0.02 cc. oxygen per liter. Only that modification of the Levy method in which sodium carbonate is used to precipitate the iron salts was compared."

New precipitants for copper, P. A. KOBER (*Abs. in Science, n. ser.*, 38 (1913), No. 985, p. 712).—"Two new precipitants for copper are proposed which form very insoluble compounds of copper (less than 0.6 part in 1,000,000 remains unprecipitated). These are amino acids, phenylglycin and normal amino caproic acid, which may be useful in estimating Fehling's and other solutions for unreduced copper and in removing copper quantitatively from substances which interfere with its iodometric titration."

The determination of sulphur in certain culture media, H. W. REDFIELD and C. HUCKLE (*Abs. in Science, n. ser.*, 38 (1913), No. 985, pp. 715, 716).—A study was made of the amount of total sulphur broken down in simple peptone media by the so-called "putrefactive bacteria," "of the forms of sulphur most readily used by them, and of the forms in which the sulphur exists after the action of the bacteria, whether as fixed sulphur or as loosely bound sulphur, or as easily oxidized sulphur, or as a volatile sulphur compound such as hydrogen sulphid, when culture flasks of different size and shape were used and when air or carbon dioxid was passed over the cultures."

A comparative study of methods for determining sulphur in peptone, H. W. REDFIELD and C. HUCKLE (*Abs. in Science, n. ser.*, 38 (1913), No. 985,

p. 715).—The best results were obtained with the Liebig-Koch method for peptone. For the determination of the easily oxidizable part of the sulphur, digestion with a saturated solution of chlorate of potash in nitric acid proved the most valuable.

The determination of sulphur and chlorin in the rice plant, ALICE R. THOMPSON (*Jour. Amer. Chem. Soc.*, 35 (1913), No. 10, pp. 1628–1634).—Previously noted from another source (*E. S. R.*, 29, p. 231).

The determination of humus in heavy clay soils, W. BEAM (*Cairo Sci. Jour.*, 7 (1913), No. 85, pp. 219–224).—In continuation of work previously reported (*E. S. R.*, 28, p. 19), certain soils were encountered which were difficult to treat even by the method of washing with carbon dioxid. In looking for the cause of this, it was found that the acid employed for the extraction of the magnesium and calcium had a marked effect upon the rapidity of the subsequent filtration when the washing was done by water or carbonated water.

With an increase in the strength of the acid, the difficulties in washing increased. “The use on the other hand of a weaker acid than that of 1 per cent, commonly employed, results in a marked advantage in this respect; but it was not found practicable, as a rule, to carry the dilution below 0.5 per cent . . . since the extraction of the calcium and magnesium may be incomplete, the proportion of humus found being, in such cases, below the truth. A still further improvement was effected by substituting for the solution of carbonic acid a very dilute solution of hydrochloric acid—about 0.02 per cent.” The use of such dilute hydrochloric acid for the washing makes the method applicable to all classes of soils with ease and certainty.

Working with soils from the Nile no marked differences were noted in the results when ammonia up to a strength of 16 per cent was used (*E. S. R.*, 24, p. 9), providing the soils were in a properly flocculated condition. When this is not the case, a stronger ammonia may lead to higher results; the proper humus figures can only be obtained after repeated extraction with ammonia. The author prefers 4 per cent ammonia. Although the filtrate obtained is quite clear in the method recommended by the author, it is deemed advisable to add 0.5 gm. of ammonium carbonate as suggested by Rather (*E. S. R.*, 25, p. 614) to each 100 cc. of the ammoniacal solution. If ammonium carbonate is employed in too large amounts, the figures will be far below the truth. “It is interesting to note that if in the modified official method the washing out of the acid is effected by the use of 0.02 per cent hydrochloric acid, practically the whole of the chlorid in the ammoniacal extract is carried down with the clay when the solution is treated with ammonium carbonate.”

The humus in the soils of the Sudan can be very accurately estimated by the colorimetric method. “In the case of soils of approximately the same composition as regards proportion of clay and humus the latter may be determined by direct boiling with 0.5 per cent sodium carbonate solution, preferably after previous boiling with distilled water in order to disintegrate the soil. Five gm. of the latter is treated with 400 cc. of distilled water in an enameled iron vessel and boiled for five minutes; 20 cc. of a hot solution containing 2.5 gm. of sodium carbonate is then added and the boiling continued for exactly one minute. The liquid is cooled as rapidly as possible, made up to 500 cc., and allowed to stand over night in a covered beaker. If not perfectly clear the supernatant liquid is filtered through an asbestos filter. A small Buchner funnel is suitable. The comparison is made with a similar soil of known humus content treated in the same way.

“The most accurate results are obtained by treating the soil with acid, as in the gravimetric determination, followed by extraction with ammonia. The

removal of the excess of hydrochloric acid is of course not necessary. Using this method the comparison may be made between soils of greatly varying composition both as regards clay and humus."

The influence of ammonium carbonate upon the determination of humus.—A rapid and efficient filtration procedure, W. H. MACINTIRE and J. I. HARDY (*Tennessee Sta. Bul. 103 (1914), pp. 47-76, figs. 2*).—In this work the authors have modified the Rather method (*E. S. R., 25, p. 614*) by reducing the ammonium carbonate required to 1 gm. and filtering the entire mixture immediately after adding the carbonate and after the 36-hour period in which the soil was in contact with ammonia. The Buchner funnel and suction were used in the operation. By the use of this apparatus, etc., the time of filtration of the humus extract is shortened. While the introduction of the ammonium carbonate accelerates filtration, extra care must be exercised to shake the mixture gently after the addition of the carbonate, otherwise filtration is retarded.

As a filtering medium the soil itself is preferred. Although sand when added to the soil at the time of filtration increases the speed of filtration, the results obtained with it are not uniform. The modification recommended reduces the amount of ash obtained. The results obtained with the modification are more in accord with those yielded by the Smith and Mooers-Hampton methods than by the Rather method. No sediments were found in the humus solution after standing for six months. If the soil is allowed to stand in contact with the ammoniacal solution containing carbonate a change in the humus content of the solution takes place.

"Because of the two distinctly opposite influences of ammonium carbonate, and occlusion effected, the period of contact of soil with carbonate is an important factor, and in the modification is reduced to the minimum. The decrease in humus resulting from the addition of carbonate can not be attributed to lessening of alkalinity. There is no chemical precipitation from the humus solution effected by the addition of ammonium carbonate. There is no fixation of carbonate, chemical or mechanical, in the solution free from contact with the soil. The physical effects (occlusion) of 25-gm. charges of normal carbonate and acid carbonate of ammonia and mixtures of the two salts are greater than their solvent action in both water and ammonia solutions, the reverse being the case with the smaller treatments. Twelve-hour contact with 4 per cent ammonia converted all acid carbonate in the three amounts used to normal carbonate, but 2-hour contact does not convert all of the bicarbonate in 2½- and 25-gm. charges of the salt.

"Pure clay may be easily filtered immediately by the modified procedure. . . .

"A solution of the black meadow soil was not freed from excess of iron by the later modification suggested by Rather. Ammonium sulphid removed both iron and organic matter from ammonia solution. Carbon bisulphid eliminated iron without any apparent effect on the organic matter of the ammonia solution. In such unusual cases where the ash is shown to be due to $\text{Fe}_2(\text{OH})_6$ instead of to clay the application of a correction of 33 per cent is suggested. . . .

"Repeated digestions and filtrations by the 1-gm. modification upon the same soils have given solutions practically identical in analysis. It is emphasized that the original official method directs the use of 4 per cent NH_3 instead of 4 per cent NH_4OH , as is erroneously given in Bulletin 107 (rev.) of the Bureau of Chemistry."

Estimation of the lime requirement of soils, J. A. BIZZELL and T. L. LYON (*Jour. Indus. and Engin. Chem.*, 5 (1913), No. 12, pp. 1011, 1012; *abs. in Science, n. ser.*, 38 (1913), No. 983, p. 640).—This is a modification of the Albert method (*E. S. R.*, 23, p. 11), as follows:

“Place 25 gm. of the air-dried soil in a Jena Kjeldahl flask. Cover with 50 cc. boiled distilled water and add 50 cc. tenth-normal barium hydroxid solution. Digest in a briskly boiling water bath for one hour with occasional shaking. Remove from the water bath, add 150 cc. distilled water and 5 gm. solid ammonium chlorid. Connect the flask with a nitrogen distillation apparatus and distill. Collect the distillate (150 cc.) in tenth-normal acid and titrate, using methyl orange as indicator. The strength of the barium hydroxid is determined by titrating directly 50 cc. of the solution, using methyl orange as indicator. The difference between the two titrations, therefore, represents the amount of barium hydroxid absorbed by the soil. A correction is made for the slight decomposition of ammonium chlorid when heated with soil.”

The estimation of citric acid-soluble phosphoric acid in Thomas slag powders according to the citrate and Lorenz methods, H. NEUBAUER (*Landw. Vers. Stat.*, 82 (1913), No. 5-6, pp. 465-475).—The results obtained with the Lorenz method were found to agree with the true phosphoric acid content present in the fertilizer. It was furthermore noted that the presence of citric acid had no effect upon the results obtained by the Lorenz method.

The results given by the citrate method were always high even though the specifications proposed by Popp (*E. S. R.*, 29, p. 410) were closely followed. The chief reason for the high results is said to be the precipitation of several milligrams of calcium oxid as tricalcium phosphate. As weighable amounts of phosphoric acid do not remain in the filtrate, due to the incomplete precipitation of this acid, compensation for the calcium weighed as phosphoric acid is not possible. The error is deemed greater in Thomas slag powder than that found in the estimation of the water-soluble phosphoric acid in superphosphates, inasmuch as slag powder contains much more calcium.

The loss in lecithin phosphoric acid, R. COHN (*Chem. Ztg.*, 37 (1913), No. 57, pp. 581-583).—Lecithin is usually not entirely extracted by ether, consequently certain investigators, notably among them Hoppe-Seyler, recommend the use of alcohol in the method for the purpose of breaking up the lecithin protein complexes. According to theory adsorption of the lecithin by the coagulated proteins would not take place, but, on the other hand, such goods as egg yolk, baked goods containing eggs, lecithin preparations, etc., show a loss of their lecithin content extractable by ether as time goes on. If only cleavage took place, the amount of lecithin extractable by ether should be higher.

In order to determine whether this loss is really due to adsorption, fresh egg yolks were treated with dilute copper sulphate solution and 0.71 per cent (90 per cent) of the total lecithin was extracted by ether. Without the use of copper sulphate only 0.45 per cent of lecithin was obtained. Adsorption was found to take place when lecithin was added to white of egg, but when treated with alcohol and ether almost all of the entire amount added was recovered. Heating 20 hours at 100° C. was found to bring about a retrogression not only of the ether-soluble lecithin but also of the total lecithin phosphoric acid. The difficulty of extracting the total sulphuric acid in vulcanized rubber is stated as an analogous case. The author believes that the diminution of ether-soluble phosphoric acid can be explained by the adsorption theory.

Recommendations for the revision of the section on honey and honey surrogates (*Mitt. Lebensm. Untersuch. u. Hyg., Schweiz. Gsndtsamt.*, 4 (1913),

No. 2, pp. 67-76).—This deals with the methods for ripe, unripe, artificial, and sugar honey.

Contribution to our knowledge of foreign honeys, J. FIEHE and P. STEGMÜLLER (*Arb. K. Gsndhtsamt.*, 44 (1913), No. 1, pp. 78-149).—This work is prefaced by abstracts of reports of consuls in regard to the sale of honey in Austria-Hungary, Russia, Spain, Portugal, Greece, the United States, Mexico, Brazil, Argentina, Chile, Cuba, Jamaica, and Australia. Cuba, the United States, Mexico, and Chile supply the greatest amount of honey to Germany.

The purpose of the investigation was to compare the variations which occur among the various constituents of foreign honeys with German honeys. The number of honeys examined was 112, and the tests made were organoleptic, as well as chemical and physical. All of the methods are described in detail and some are criticized.

The moisture determinations of 111 samples of foreign honeys with few exceptions compared well with the German product, varying between 14.94 and 24.28 per cent, with an average of 18.3 per cent. The invert sugar content varied between 61.96 and 78.84 per cent, with an average of 73.48 per cent. The honeys, with 3 exceptions, gave a levorotation. The saccharose content fluctuated between 0.12 and 15.4 per cent, with an average of 2.42 per cent. In 4 cases it exceeded 10 per cent, and these, according to the figures prescribed, were considered immature honeys. The sugar-free dry substance (all nonsugars inclusive of dextrin), for which the German standard is 1.5 per cent, varied between 1.75 and 13.42 per cent, with an average of 5.84 per cent. The acidity, expressed as formic acid, varied between 0.027 and 0.204 per cent, the requirement being 0.2 per cent. The protein precipitation, obtained by Lund's method, varied between 0.37 and 4.35 cc., with an average of 1.13 cc., although according to Lund this should be between 0.6 and 2.7 cc., with an average of 1.1 cc. Ley's reaction for detecting the presence of artificial invert sugar gave faulty results in 18 out of 88 cases, while Fiehe's method gave good results. The ash content varied between 0.027 and 0.673 per cent, with an average of 0.15 per cent. The highest ash content was noted with coniferous honeys, and the lowest with rosemary and thyme honeys. The standards call for from 0.18 to 0.8 per cent. Phosphates (determined after ashing) were present to the extent of from 0.0075 to 0.0932 per cent (calculated as P_2O_5), with an average of 0.0198 per cent. Calculated to 100 parts of ash the figures varied between 5.7 and 35.5 per cent.

Alkalinity of the ash, when titrated against azolitmin paper, was lower than when methyl orange is used as the indicator. This criterion is deemed valuable, since many sugars used for adulterating honey give a very low alkalinity figure.

Proposed method for detecting adulteration of cider vinegar with distilled vinegar, S. L. CRAWFORD (*Jour. Indus. and Engin. Chem.*, 5 (1913), No. 10, pp. 845-847).—The principle of the method rests on the fact that cider vinegar contains an appreciable amount of a volatile substance which reduces Fehling's solution. Distilled vinegar, when diluted to 4 per cent acid, contains only traces of this substance.

"The proposed method is to take 50 cc. of sample, dilute to 250 cc., and distill over 200 cc. into a 250 cc. flask. Neutralize and make up to the mark. Take 50 cc. of this distillate and determine sugars by the method given in Bureau of Chemistry Bulletin 107. The result is given as invert sugar according to Munson and Walker's tables."

Analyses of authentic distilled and cider vinegars are included.

Detection of alkaloids in beverages, J. BODNÁR (*Kísérlet. Közlem.*, 16 (1913), No. 5, pp. 683-693).—The Dragendorf method for the detection of alkaloids, as given in König's treatise (E. S. R., 15, p. 991), is criticized.

Tests in regard to the tannin substances in Malabar tea and the use of tannin in the preparation of tea, K. A. R. BOSSCHA and A. D. MAURENBEECHER (*Dept. Landb., Nijv. en Handel [Dutch East Indies], Meded. Proefstat. Thee*, No. 24 (1913), pp. 9-17).—This deals with the tannin substances present in Malabar green tea leaves and with the effect which the addition of extraneous tannin before rolling has upon the ultimate quality of the tea.

The tannin substances were obtained in a pure state and tested with various reagents. From the mother liquor obtained after removing the lead acetate precipitate of tannin a substance was extracted which resembled gallic acid. The specific rotation of the tannin was not of the same magnitude as noted by Nanninga (E. S. R., 13, p. 823).

The tea, after being treated with tannin, rolled, and fermented, was submitted to a tea expert for judgment as to quality. The results varied considerably, and as the price of tannin is high its use in the preparation of tea is discouraged.

Proposals for the section on wine (*Mitt. Lebensm. Untersuch. u. Hyg., Schweiz. Gsndhtsamt.*, 4 (1913), No. 2, pp. 77-87).—The definitions for various kinds of wines and the methods for their analysis are considered.

Recommendations for the revision of the section on spiritous liquors (*Mitt. Lebensm. Untersuch. u. Hyg., Schweiz. Gsndhtsamt.*, 4 (1913), No. 2, pp. 88-111).—In this, recommendations are included for definitions and methods for judging distilled liquors.

Proposals for the section on milk products, exclusive of butter, of the Swiss food book (*Mitt. Lebensm. Untersuch. u. Hyg., Schweiz. Gsndhtsamt.*, 4 (1913), No. 2, pp. 49-66).—These are the recommendations for the revision of the chapters relating to these products, including data as to cream, skim milk, buttermilk, whey, cow's milk, kefir, yoghurt and similar products, sweetened and unsweetened condensed milk, cheese, and infant foods. The methods and the standards are dealt with.

Nephelometric determination of proteins; casein, globulin, and albumin in milk, P. A. KOBER (*Jour. Amer. Chem. Soc.*, 35 (1913), No. 10, pp. 1585-1593, figs. 3).—In this paper an accurate description and illustration of the nephelometer devised by the author is given. In addition some results of tests with the method and milks from different sources are presented which show close agreement with the figures obtained by the official method. The time for determining casein and the albumin-globulin fraction is reduced to 30 minutes.

The precipitants tried were acetic acid, half and entirely saturated magnesium sulphate and ammonium sulphate solutions, and a 3 per cent solution of sulphosalicylic acid. The most suitable precipitants are those which precipitate quantitatively and which do not agglutinate appreciably in less than 10 to 20 minutes. The method favored consists of precipitating the total proteins with sulphosalicylic acid solutions and determining the nephelometric index. Casein is determined by difference; it is first removed by the official method and the nephelometric index of the filtrate is noted. The fat is removed with ether and the membranes of the fat globules are dissolved with sodium hydroxid.

A new rapid method for the estimation of casein in milk, W. O. WALKER (*Ann. Rpts. Dairymen's Assocs. Ontario*, 1912, pp. 36-38).—Briefly the method consists of estimating with ninth-normal potassium hydroxid the acids liberated from casein through the agency of formaldehyde.

For conducting the test 16.3 cc. of the milk is placed in a beaker with 1 cc. of 1:500 phenolphthalein and the acidity is neutralized with standard alkali, care being taken that the color is brought to a good deep pink. Two cc. of neutral formaldehyde solution, 40 per cent, is then added and the mixture titrated with standard alkali solution until the pink coloration reappears. The number of cubic centimeters of alkali used represents the percentage of casein in the milk.

The time required for the test is about 2 minutes. The test is recommended as a basis for paying for milk in cheese factories.

The analysis of unsweetened evaporated milk, C. A. A. UTT (*Jour. Indus. and Engin. Chem.*, 5 (1913), No. 2, pp. 168, 169).—The sample is mixed and if fat is seen on the surface, it is necessary to warm it after adding a little sodium hydroxid. For the estimation of the fat, weigh 4.5 gm. of the milk into a 10 per cent Babcock bottle with from 6 to 8 cc. of sulphuric acid (specific gravity 1.8); shake until a chocolate brown color is obtained, and place for from 15 to 20 minutes in boiling water. After cooling add hot dilute sulphuric acid 1:1 until the bottle is two-thirds full, and centrifuge for 5 minutes. "Fill to the neck with hot, half-strength sulphuric acid and whirl 3 minutes. Add hot water to bring the fat column into the neck of the bottle and whirl 2 minutes. Read at 120 to 125° F. from the bottom of the column to the extreme top of the meniscus. The reading multiplied by 4 gives the percentage of fat."

Laboratory and field assay of arsenical dipping fluids, R. M. CHAPIN (*U. S. Dept. Agr. Bul.* 76 (1914), pp. 17, fig. 1).—There are various factors which tend to render arsenical dipping fluids of uncertain composition. Chiefly amongst these are the use of low grade chemicals in their preparation, evaporation, or leakage from the bath, oxidation of arsenious oxid to arsenic acid, especially through the agency of micro-organisms, and the converse phenomenon of reduction to arsenate. There is therefore needed an analytical control of the dipping solutions, and laboratory tests are described for actual arsenious oxid and total arsenic, which can be executed by persons who have but a limited training in chemistry. In addition a portable testing outfit is described which has been devised for bureau inspectors in the field and with which it is possible, without any chemical knowledge whatever, to determine, at the side of the vat and in a few minutes, the strength of the arsenical solution prepared according to the standard formula. The apparatus required is illustrated and the criterions for judging the results obtained by the methods are stated.

Determination and detection of methyl alcohol, T. VON FELLEBERG (*Mitt. Lebensm. Untersuch. u. Hyg., Schweiz. Gsndhtsamt.*, 4 (1913), No. 3, pp. 122-146, figs. 2).—This deals with a quantitative physical method for determining methyl alcohol, which in principle is similar to that used by Röse in determining higher alcohols. It is shown that if a solution containing a definite percentage of alcohol is shaken with ether, the point at which the ether-water, etc., solution separates differs with the kind of alcohol present. With methyl alcohol the water-alcohol layer becomes greater while with ethyl alcohol it becomes less.

For the method a special form of apparatus has been devised. Its use for detecting methyl alcohol in brandies is shown, and the work includes a method for concentrating solutions containing methyl alcohol, which is done by salting out the ethyl alcohol and higher alcohols with potassium hydroxid. This allows the detection of 1:100,000 parts of methyl alcohol by the Denigés method. Methyl alcohol is also shown to be a product resulting from the fermentation of fruit residues.

Research studies on the curing of leaf tobacco, W. W. GARNER, C. W. BACON, and C. L. FOUBERT (*U. S. Dept. Agr. Bul.* 79 (1914), pp. 40).—This is a

study of the chemical and physiological changes which occur in tobacco during the process of drying the ripe leaf is a specially constructed barn and under such conditions as will develop the desired properties or qualities. Very little attention has been paid to this phase of tobacco curing and most of the investigations deal with fermentation or after-fermentation or to certain special phases of the subject.

Curing is considered essentially a vital process, and this seems to be proved by the fact that killing the protoplasm at very low or high temperatures or with poisons, such as chloroform, prevents normal curing. Imperfect curing can not, therefore, be fully corrected by subsequent fermentation.

The results of experiments covering several years show the loss in weight of dry matter in air curing when the leaf is primed (leaves picked from the stalk as they mature or "ripen" and arranged on strings or sticks suitable for hanging in the curing shed) or cured on the stalks, and were confined to the cigar-wrapper leaf section of Connecticut. The types of tobacco included in the experiments were Havana Seed, Halladay, and a so-called John Williams broadleaf. It was found that "the average loss in weight of dry matter in curing the picked leaves is 12 to 15 per cent, while in curing the leaves on the stalk the loss in dry weight is approximately twice as great. In other words, a cigar-wrapper leaf picked from the stalk will weigh after curing approximately 14 to 18 per cent more than would the same leaf when cured on the stalk. In the curing of the export and manufacturing types and of cigar-filler types, which are harvested in a riper or more mature condition, the loss in weight of dry matter is greater than in the case of cigar-wrapper leaf, frequently amounting to 35 to 40 per cent, even when the leaves are picked from the stalk in harvesting."

In a 4-year experiment the content of pure ash of cured leaves was higher than the uncured leaves and in proportion to the loss in dry weight. While the green leaves contained considerable and variable amounts of starch, the cured leaves were practically free, as shown by the iodine test. The cigar-wrapper leaf types contain less starch at the time of harvesting than other commercial types of leaf, because they are at a less mature stage when harvested and are produced under conditions less favorable to the accumulation of starch during the ripening period. "One of the most marked physiological differences between the green and cured leaves is the content of protein insoluble in dilute acid. In all cases the protein content of the cured leaves is much less than that of the uncured leaves. The content of nitric acid in the green and in the cured leaves is about the same. The green leaves at most contain only traces of ammonia, while the cured leaves contain considerable quantities. The cured leaves contain relatively much larger quantities of amid and amido compounds than the green leaves. The relative content of total nitrogen is somewhat less in the green than in the cured leaves."

The changes produced in the leaf harvested on the stalk were the same as in the leaf harvested by priming. In a 3-year experiment the composition of cigar-wrapper leaf cured on the stalk and the uncured leaf were compared. "As in the primed leaves, the ash content of the whole leaf is higher in the cured than in the uncured leaves. The cured leaves are again practically free from starch and reducing sugars, except where the curing was incomplete. The difference as regards protein is similar to those noted in the cured and uncured leaves in the preceding experiments. The differences with reference to amid and amido compounds are somewhat variable, but it is evident that the cured leaf does not contain appreciably larger quantities of these constituents, relatively, than the green leaf, and the same is true as to ammonia. It is clear that the cured leaves contain considerably less total nitrogen than the green leaves."

The changes taking place in the leaf top in air curing consist of an entire loss in starch and reducing sugars, a decrease of pentosans and malic acid, and an increase in citric acid, while the cellulose content remains unchanged. "There is a large decrease in protein, in some cases amounting to 60 per cent of the total, and a considerable decrease in nicotin and total nitrogen. Appreciable quantities of ammonia are formed in the process. In the curing of picked leaves the chemical changes appear to be due almost wholly to respiration, while in curing the leaves on the stalk the phenomenon of translocation from the leaf into the stalk plays an important rôle. This translocation, which constitutes the essential physiological difference in the two methods of curing involves the transfer into the stalk of the amid and amido compounds derived from the protein, ammonia, and a portion of the mineral constituents, nitrate, and, doubtless, a portion of the carbohydrates. The picked leaves after curing contain, therefore, much larger quantities of amid and amido compounds, and ammonia, and somewhat larger quantities of mineral matter and nitrate than the leaves cured on the stalk.

"The physiological processes characteristic of tobacco curing indicate the presence of diastatic, proteolytic, and deamidizing enzymes, and probably also of oxidases. The process of starvation to which the leaves are subjected leads to an increased secretion of diastase during the progress of the curing. Temperature has a very marked effect on the rate of curing. The rate of curing increases very rapidly with rise in temperature up to the killing point of the protoplasm (about 130° F.). The moderate use of artificial heat in air curing does not materially affect the final result in curing so far as measured by the ordinary methods of chemical analysis, provided other conditions remain favorable in both cases. Thorough wilting in the initial stages of the curing promotes the progress of the process, provided the further drying of the leaf is not allowed to proceed too rapidly."

The experimental error in sampling sugar cane, J. W. LEATHER (*Mem. Dept. Agr. India, Chem. Ser., 3 (1913), No. 4, pp. 107-133, fig. 1*).—The results tabulated are those obtained in the experimental grounds at Pusa and a sugar factory at Parsa, India.

The clarification of Louisiana cane juices, W. E. CROSS (*Louisiana Stas. Bul. 144 (1914), pp. 39*).—The studies recorded in this bulletin deal with the sulphitation and the carbonation processes for the clarification of cane and beet juices. They were carried on in the laboratory and sugarhouse of the Sugar Experiment Station, and preliminary reports on certain parts of the work have already appeared in the scientific literature. A chapter on treating sirup is also included.

METEOROLOGY—WATER.

Meteorological observations, J. S. STEVENS (*Maine Sta. Bul. 222 (1913), pp. 319, 320*).—Observations at Orono, Me., on temperature, precipitation, cloudiness, and wind during 1913 are compared with the means of similar observations for 45 years. The mean temperature for 1913 was 45.45° F., the mean for 45 years 42.57°; the precipitation for 1913 was 44 in., for 45 years 43.33 in.; the snowfall for 1913 was 34.3 in., for 45 years 90.4 in.; the number of days on which there was a precipitation of 0.01 in. or more was 112, the number of clear days 126, and the number of cloudy days 140; and the total movement of wind in miles, 52,484.

Surface water supply of the Missouri River Basin, 1911, W. A. LAMB, W. B. FREEMAN, and R. RICHARDS (*U. S. Geol. Survey, Water-Supply Paper 306 (1914), pp. 374, pls. 4*).—This paper presents results of measurements of

flow made on the Missouri River proper and tributary basins during 1911. Tables are included giving gage heights and daily and monthly discharges at each station. Information is also given regarding the legal aspects of the appropriation of water, particularly for irrigation purposes.

Surface water supply of the Colorado River Basin, 1911, R. FOLLANSBEE, W. B. FREEMAN, and G. C. BALDWIN (*U. S. Geol. Survey, Water-Supply Paper 309 (1914), pp. 266, pls. 4*).—This paper presents results of measurements of flow made on Green River and the main Colorado River and tributary basins. Tables are included giving gage heights and daily and monthly discharges at each station. A report is also given of the flood of October, 1911, in the region of the San Juan, San Miguel, and La Plata Mountains, which resulted in severe agricultural losses.

Surface water supply of the South Atlantic coast and eastern Gulf of Mexico Basins, 1912, W. E. HALL and C. H. PIERCE (*U. S. Geol. Survey, Water-Supply Paper 322 (1914), pp. 98, pls. 4*).—This paper reports the results of measurements of flow made during 1912 in the James, Roanoke, Yadkin, Savannah, Santee, and Altamaha River Basins on the South Atlantic coast, and in the Apalachicola, Choctawhatchee, Escambia, Mobile, and Pearl River Basins of the east coast of the Gulf of Mexico. Tables are also included giving gage heights and daily and monthly discharges at each station.

SOILS—FERTILIZERS.

Treatise on soils for farmers and foresters, E. A. MITSCHERLICH (*Bodenkunde für Land- und Forstwirte. Berlin, 1913, 2 rev. ed., pp. XI+317, figs. 35*).—In this complete revision of his previous work (*E. S. R., 17, p. 838*), the author incorporates the more important results of progress in soil investigation during the past seven years. In recognition of the pronounced tendency during this period to develop physiological soil study in place of geological and physical soil investigations, the author treats the subject largely from the former viewpoint and emphasizes only those chemical and physical properties of soil which condition plant growth.

Various conceptions of the law of minimum figure prominently in the treatment of the subject. Liebig's law of minimum is used qualitatively, but in view of the importance of a quantitative plant-physiological study of soils which is especially emphasized, the work is based chiefly on the author's quantitative conception of the law of minimum which is explained in its various applications to soil study.

The work is divided into two parts, the first treating the theoretical side of the subject in which soil energy, in the form of heat, and soil water are considered as the physical factors of plant growth, and the different plant foods as chemical factors. It is attempted to determine definitely on what specific properties of the soil these factors depend and, as far as possible, the particular influence which each factor exerts on plant growth.

The second part summarizes the practical application of the physical and chemical factors and conditions dealt with in the first part, in the cultivation, improvement, and judging of soils, and in measures used by practical farmers and foresters in their work. For convenience in this respect, soils are divided into three types among which there is considered to be a distinct transition, namely, light soils of which dry sandy and damp moor soils are subdivisions, medium soils, and heavy soils, particularly tenacious clays.

Mathematical tables and formulas useful in the study of soils, are appended.

Moor cultivation in Austria, W. BERSCH (*Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases, 4 (1913), No. 11, pp. 1672-1677*).—The

proper measures in the cultivation of these moors are pointed out briefly as potash and phosphoric acid fertilization, applied in the spring, liming, fall plowing, sufficient but not excessive tile drainage, and green manuring.

The fertility map of the Delta, B. F. E. KEELING (*Cairo Sci. Jour.*, 8 (1914), No. 88, pp. 1-3).—A brief description is given of the survey of the Delta of the Nile, with reference to the agricultural value of the lands, which is now in progress. The lands are being classified as good, medium, bad, uncultivated, and under reclamation. The agricultural value of the lands is determined to a large extent by the amount of alkali they contain.

Soils, H. J. VIPOND (*Union So. Africa Dept. Agr. Rept. 1912-13*, pp. 297-304).—The results of chemical analyses of a number of samples of soils from different parts of South Africa are similar to those previously noted (E. S. R., 29, p. 514), the average percentage of nitrogen being fair, and of lime and available phosphoric acid very low, and the only noteworthy difference being an increase in total and available potash.

Analyses of ten samples of alkaline soils showed the presence of considerable amounts of sodium carbonate and bicarbonate, and a smaller amount of sodium chlorid.

Laterite, its consideration in the light of colloid chemistry, A. LUZ (*Kolloid Ztschr.*, 14, (1914), No. 2, pp. 81-90).—The author briefly reviews a number of opinions regarding the origin, formation, and composition of laterite, showing the variation and development in these views during the past century. The more recent general opinion is that laterite is a product of advanced weathering of materials containing crystalline aluminum silicates which, in the process of laterization, have been transformed by degrees into complexes containing, first, colloidal aluminum silicates and colloidal iron hydroxid; second, colloidal aluminum hydroxid, colloidal silica, and colloidal iron hydroxid; and, third, crystalline aluminum hydroxid, colloidal silica, and crystalline limonite.

Critical remarks on the determination of the adsorptive power of the soil, T. OBYNG (*Kolloid Ztschr.*, 14 (1914), No. 2, pp. 105-108).—In connection with other criticisms of views regarding colloid chemistry the author points out the narrow limits within which the colorimetric method is of value for determining the adsorptive surfaces and power of soils.

The influence of irrigation and crop production on soil nitrification, I. G. McBETH and N. R. SMITH (*Centbl. Bakt. [etc.]*, 2. Abt., 40 (1914), No. 1-8, pp. 24-51, figs. 6).—This is an account of investigations, carried on in cooperation between the Bureau of Plant Industry of this Department and the Utah Experiment Station, which were made with soils of the irrigated experiment farm of the station. The results are summarized as follows:

“The application of irrigation water reduced the nitrifying power of the soils as determined by laboratory methods.

“The plats continuously cropped to alfalfa, potatoes, oats, and corn all showed a higher nitrifying power than the corresponding fallow plats. The stimulating effect of crop production on the nitrifying power of the soils was most marked in the alfalfa land.

“The nitrifying power of the soils was very weak below the second-foot zone, and almost no increase in nitrates was secured below the fifth-foot zone. About 90 per cent of the nitrate formed in the first 5 ft. was produced in the upper 18 in. The application of irrigation water did not change the relative nitrifying power of the different foot sections.

“The moisture content of the nonirrigated plats during the summer months fell far below the quantity required for active nitrification. No increase in nitric nitrogen took place when the soil samples contained as little as 5 per cent of moisture.

"The addition of a quantity of nitrogen as ammonium sulphate greater than 170 parts per million to each 100 gm. of soil sample showed an inhibiting action on the nitrifying organisms."

The formation and decomposition of humus as well as its action on nitrogen assimilation, F. LÖHNIS and H. H. GREEN (*Zentbl. Bakt. [etc.]*, 2. *Abt.*, 40 (1914), No. 1-8, pp. 52-60; *abs. in Chem. Zentbl.*, 1914, I, No. 12, pp. 1212, 1213).—Experiments are reported in which stable manure, green manure, straw, peat, and sugar were mixed with sand in the proportion of 1:10 and allowed to undergo humification for 4½ months both with and without access of air.

The process was most rapid with stable manure, somewhat slower with green manure, and slowest with straw. The sugar yielded almost no humus and the peat underwent a slight oxidation. Partial aeration was most favorable to humification. With full aeration a considerable part of the nitrogen of stable manure and green manure was nitrified. At the same time, in the case of green manure there was a large loss of free ammonia.

Substances obtained from the humified materials by treatment with soda solution and hydrochloric acid were mixed with soil and allowed to undergo nitrification for five weeks. In this way characteristic differences were observed. The largest amount of nitrate was obtained from the green manure humus, but practically identical results were obtained with humus derived from stable manure subjected to aeration. On the other hand, humus derived from stable manure without aeration yielded much less nitrate. The nitrogen compounds of peat humus were nitrified to a very slight extent. The straw humus interfered with the nitrification process in the same manner as undecomposed straw.

The fixation of nitrogen by *Azotobacter* in mannite solution was appreciably promoted by the addition of small amounts of humus (0.2 per cent). The stable manure humus was especially favorable to such fixation. The other forms of humus gave very nearly the same results, not only among themselves but as compared with soil extract rich in iron. The favorable effect on nitrogen fixation appeared to be due more to an improvement of the nutrient medium in chemical properties than to increased adsorption of oxygen and nitrogen. In the latter direction the experiments showed no pronounced differences.

The effect of copper, zinc, iron, and lead salts on ammonification and nitrification in soils, C. B. LIPMAN and P. S. BURGESS (*Univ. Cal. Pubs., Agr. Sci.*, 1 (1914), No. 6, pp. 127-139).—Experiments carried out by the direct soil culture method, described in a previous article (*E. S. R.*, 26, p. 322), led to the conclusion that "copper, zinc, iron, and lead exercise toxic effects on the ammonifying flora of a sandy soil from southern California in all concentrations, ranging from 50 to 2,500 parts per million of their sulphates; such toxicity is relatively small, however, and is more marked at concentrations below 0.1 per cent than above it, in most cases; the metals named exercise no stimulating effect on the ammonifying flora at any concentration. Copper, zinc, iron, and lead exercise marked stimulating effects on the nitrifying flora of the same soil and frequently more than double the normal nitrate yield; the same metals may in very small concentrations exercise toxic effects on the nitrifying flora or no effect at all, but they are markedly stimulating at much higher concentrations; with the one exception of lead sulphate, the metals named showed very marked stimulation for nitrification even at 0.15 per cent, the highest concentration employed . . . A brief discussion is given of possible causes for the effects of the metallic salts under consideration on the soil flora."

The decomposition of silicates by soil bacteria and yeasts, II, K. BASSALIK (*Ztschr. Gärungsphysiol.*, 3 (1913), No. 1, pp. 15-42; *abs. in Centbl. Bakt. [etc.]*, 2. Abt., 40 (1914), No. 9-10, pp. 193, 194).—Orthoclase, microcline, oligoclase, labradorite, nephelin, leucite, potash mica, magnesia mica, olivine, augite, hornblend, tourmaline, and apatite were subjected in fine powdered condition to the action of *Bacillus extorquens*, a crude culture of nitrite bacteria, a crude culture of butyric-acid bacteria (*Clostridium pasteurianum*), and beer yeast.

The solvent action of *B. extorquens* was greatest in the case of nephelin, magnesia mica, and augite, of which from 4 to 6 per cent was dissolved while only about 2 per cent was dissolved in the case of the other minerals. The butyric-acid bacteria gave like results, except that they showed a special capacity for decomposing apatite. *B. extorquens* produced in from 100 to 200 days carbon dioxid equivalent to from three-fourths to four-fifths of the total weight of the mineral. The beer yeast produced about twice as much carbon dioxid as *B. extorquens*, but its solvent action was relatively small. On the other hand the nitrite bacteria, although producing a relatively small amount of acid, showed a comparatively high solvent power.

The results indicate that in the solution of phosphorite the organic acids are of special importance.

A list of references to literature of the subject is given.

Nitrogen assimilation in the presence of nitrates, H. PRINGSHEIM (*Centbl. Bakt. [etc.]*, 2. Abt., 40 (1914), No. 1-8, pp. 21-23).—Experiments are reported which showed that with a sufficient supply of energy-producing materials nitrogen was fixed by *Clostridium americanum* in the presence of nitrates, although to a less extent. Nitrogen fixation was increased by the presence of *Penicillium glaucum* in the colostrum culture.

The chemical composition of the cells of *Azotobacter chroococcum*, W. L. OMELIANSKY and N. O. SIEBER (*Hoppe-Seyler's Ztschr. Physiol. Chem.*, 88 (1913), No. 6, pp. 445-459; *abs. in Jour. Chem. Soc. [London]*, 106 (1914), No. 616, I, p. 235).—The characteristic dark brown growth of this organism obtained in agar cultures containing the usual mineral salts with 2 per cent dextrin after about six days' incubation at 30° C. was dried rapidly at 30° C. and analyzed. The material was found to contain 6.63 per cent of water, 4.16 per cent of ash, and 12.92 per cent of protein.

The nature of the nitrogen-free substance was not determined, but it appeared to belong to the polysaccharids. Among the products of hydrolysis, lysin was found in larger proportion than arginin, with only minute traces of histidin.

The behavior of soils sterilized by heat, VOGEL (*Centbl. Bakt. [etc.]*, 2. Abt., 40 (1914), No. 11-13, pp. 280-284).—Sodium nitrate in a sterile 5 per cent solution remained unchanged when added to unsterilized soils and to soils sterilized for 30 minutes at two atmospheres in the autoclave but was rapidly reduced to nitrite in the sterilized soils when they were inoculated with cultures of denitrifying organisms. Steaming of soils at 100° C. for different periods did not prevent subsequent nitrate reduction. It is concluded that simple steaming of soils effects incomplete sterilization and that nitrate reduction following supposed sterilization is due to certain denitrifying organisms which survive the steaming and become active, rather than to chemical agencies.

Bacteriological studies of field soils.—III, The effects of barnyard manure, P. E. BROWN (*Centbl. Bakt. [etc.]*, 2. Abt., 39 (1913), No. 20-22, pp. 523-542).—The author briefly reviews investigations by others, and in continuation of previous experiments (E. S. R., 28, p. 120) reports studies of the effect of treatment with barnyard manure on the bacterial activities in loam soil under field conditions, and also on the relation between bacterial activities and actual crop yields. The soil was treated with 8, 12, 16, and 20 tons of manure per acre.

Applications of manure up to 16 tons per acre increased the number of organisms in, and also the ammonifying and nitrifying powers of the soil. The greatest increases occurred between the untreated soil and that receiving 8 tons per acre, and between the latter and that to which 12 tons per acre were applied. "In most cases only a very slight increase occurred in the soil on which 16 tons were used over that where 12 tons were added. Twenty tons of manure per acre caused a depression in numbers of bacteria, in ammonifying power, and in nitrifying power, . . . the results being lower than those secured when 12 tons per acre were added." There was a close relationship between the ammonifying power of the soils and the number of organisms present.

Albumin agar permitted of the development of larger numbers of soil organisms, and also a greater differentiation between the soils of the various plats, than the modified synthetic agar. "The casein fresh soil method of testing the ammonifying power of the soil was the simplest, permitted of the greatest differentiation between different soils, and in general was the most satisfactory. The ammonium sulphate fresh soil method for testing the nitrifying power of the soil showed the greatest differences between the various soils and is recommended as the more rational method.

"The nitrifying power and the ammonifying power of the soil . . . proceeded in the same direction.

"Applications of manure up to 16 tons per acre increased the yield of corn from the plats in this series, the greatest increases occurring between the [untreated] plat and that receiving 8 tons per acre, and between the latter and the plat to which 12 tons per acre were added. A very slight further increase occurred when 16 tons per acre were applied. Twenty tons of manure per acre depressed the crop yield below that obtained when 12 tons per acre were added.

"The results of the bacteriological tests and the crop yields coincided almost exactly, [indicating] . . . that there is a close relationship between bacterial activities and the fertility or crop-producing power of soils. The depression in crop yields and bacterial activities caused by 20 tons of manure per acre can not be attributed to denitrification, as tests by the Giltay solution method and the soil method give no evidence of losses of nitrogen. The depression must therefore be due to physiological or other causes."

Farm manures, P. E. BROWN (*Iowa Sta. Circ. 9 (1913), pp. 3-16, figs. 2*).—This is a popular presentation of the character, value, and importance and methods of using manure of farm animals.

Green manuring and soil fertility, P. E. BROWN (*Iowa Sta. Circ. 10 (1913), pp. 3-15, figs. 6*).—The value and importance of green manuring, especially for Iowa soils, are popularly presented.

[Cave deposits, manures, limes, and limestones], H. J. VIPOND (*Union So. Africa Dept. Agr. Rpt. 1912-13, pp. 304, 305*).—Analyses of these materials for fertilizing constituents are reported.

Report of the superintendent of the guano islands, W. R. ZEEDERBERG (*Union So. Africa Dept. Agr. Rpt. 1912-13, pp. 351-355*).—The guano islands, lying mainly along the west and southwest coasts of South Africa, yielded during 1912 6,372½ tons of guano having the following average composition: Nitrogen 11.51 per cent, potash 2.20, phosphoric acid soluble in water 3.04, phosphoric acid soluble in citrate solution 9.25, total phosphoric acid 9.62, and lime 9.66 per cent. The supply was much less than the demand for home consumption.

Peat, C. A. DAVIS (*U. S. Geol. Survey, Mineral Resources of the United States, 1912, pt. 2, pp. 497-501*).—This article deals briefly with the production

and consumption of peat in the United States and the preparation and use of peat fuel in Europe.

It is stated that the output of peat fuel in the United States in 1912 was 1,300 tons. The production for use as fertilizer was 41,080 tons. Approximately 3,000 tons was used for mixing with prepared stock foods, and 2,000 tons for the production of paper stock. The total production for all purposes was 47,380 tons. The imports, mainly peat stable litter from Holland, amounted to 9,053 tons.

Results of drilling manures in Hungary, C. KERPELY (*Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases, 4 (1913), No. 11, pp. 1696-1703*).—The results of experiments on farms in different parts of Hungary in comparing the effect of drilling and broadcasting superphosphate and other fertilizing materials on winter wheat and rye, spring barley, oats, wheat, and sugar beets are summarized in this article.

It was found, as a rule, that drilling was more effective than broadcasting in increasing the yield and was more economical of fertilizer. No injurious effect on germination was observed even when quantities as large as 232 lbs. per acre of superphosphate were drilled in with the seed in both wet and dry seasons, although the superiority of drilling was more pronounced in the dry season. The yield of both straw and grain and the quality of the grain was improved by drilling.

The beneficial effect of drilling was especially marked in the case of sugar beets. In cases in which sugar beets did not respond at all to broadcast fertilizing a small quantity of the fertilizers drilled with the seed was very effective. With this crop sodium nitrate and potash salts were used in addition to superphosphate. An injurious effect of the nitrate was observed only when it was used in amounts exceeding 93 lbs. per acre. Moderate applications of potash salts applied in the drill had no injurious effect on germination and were more effective than broadcast applications. Drill applications did not decrease the sugar content of the beets, but on the contrary in some cases increased it.

It is stated that the results were so convincing that it is probable that the system of fertilizing in the drill will be generally adopted in agricultural practice in Hungary.

Experimental results obtained of recent years by the section of agricultural chemistry of the Central Agricultural Experiment Station of Stockholm, H. G. SÖDERBAUM (*Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases, 4 (1913), No. 11, pp. 1677-1681*).—A brief review is given of experiments with nitrogenous, phosphatic, and miscellaneous fertilizing materials which have been noted from time to time in the *Record*.

Do fertilizer salts have an influence in forming soil crusts? H. HESSLER (*Besteht ein Einfluss der Düngesalze auf die Verkrustung? Diss. Univ. Gissen, 1912, pp. 41*).—The coherence was determined of cylinders of soil of different chemical and physical properties which had been mixed with solutions of varying strengths of sodium nitrate, salt, kainit, 40 per cent potash salt, and sylvin, as well as with potash and soda solution and tap and distilled water, and then dried at 70° C.

As a rule the salts tested increased the coherence of the soil, the most active in this respect being salt, followed in descending order by sodium nitrate, sylvin, kainit, and potash. The effect of the salts varied widely with the character of the soil, being especially dependent upon the size of the soil particles and the proportion of colloid substances present.

Field experiments on the availability of nitrogenous fertilizers, J. G. LIPMAN, A. W. BLAIR, ET AL. (*New Jersey Stas. Bul.* 260 (1913), pp. 3-33, pls. 5).—Supplementing cylinder experiments previously reported upon (E. S. R., 28, p. 725), an attempt was made “to show the relative availability of nitrogenous fertilizer materials, and the influence of lime on the availability of soil organic matter, by means of field experiments conducted on 1/20-acre plats, with a rotation of corn, oats, wheat, and grass.”

The experiments here reported were made on a fairly heavy loam soil and covered one 5-year rotation (1909-1913). The nitrogenous fertilizers used (equivalent to 16 lbs. of sodium nitrate per plat) included sodium nitrate, calcium nitrate, calcium cyanamid, ammonium sulphate, dried blood, tankage, and dried fish besides horse and cow manure and leguminous and nonleguminous green manures, with a basal fertilizer of acid phosphate and potassium chlorid. One series of plats received 1 ton per acre of ground limestone at the beginning of the rotation; the other was unlimed.

Analyses of the soil at the beginning and end of the rotation “indicate that the plats have lost in total nitrogen, even those which have each year received heavy applications of manure and commercial nitrogenous fertilizers. The limed plats have lost nitrogen to a greater extent than the unlimed plats. . . . All plats are now distinctly acid, requiring from 1,000 to 2,200 lbs of lime (CaO) per 2,000,000 lbs. of soil to correct the acidity. The present lime requirement of the plats which were limed in the beginning is, on an average, about 700 lbs. per acre less than that of the unlimed plats.”

Volunteer clover was more abundant and richer in nitrogen on the limed plats, as was the yield of dry matter and the percentage of nitrogen recovered, in nearly all cases in the first crop after liming but not thereafter.

“The percentage of nitrogen in the dry matter was generally highest on those plats that received the heaviest application of nitrogen, as, for example, those that received both manure and nitrate of soda. The average percentage of nitrogen in the dry matter was practically the same on the limed and unlimed plats.

“The average percentage of nitrogen recovered for the first crop was more than twice as high on the limed as on the unlimed plats. For the succeeding crops the average recovery did not differ much on the two sections. The highest average recovery for the five years, unlimed, was 49.99 per cent, with ammonium sulphate, and the next highest, 43.98 per cent, with nitrate of soda. The highest average recovery for the limed plats was 55.76 per cent, with calcium nitrate, and the next highest, 47.93 per cent, with ammonium sulphate.

“The average recoveries with the nitrates, ammonium sulphate, and calcium cyanamid were distinctly higher than with an equivalent amount of nitrogen in the form of dried blood, fish, and tankage.

“Although the largest yields of dry matter were obtained from plats receiving manure and manure with nitrate of soda, the recoveries from these plats were lower than the recoveries from plats that received dried blood, fish, and concentrated tankage. They are likewise lower than the recoveries from plats that received their nitrogen in the form of green alfalfa. The plats receiving green alfalfa and nitrate of soda have given higher yields of dry matter and higher recoveries of nitrogen than plats receiving blood, fish, and tankage.”

In general “results point to a higher availability, and a higher percentage recovery, for nitrogen in the form of calcium and sodium nitrate, ammonium sulphate, and calcium cyanamid than for nitrogen in the form of dried blood, fish, and concentrated tankage.”

Phosphatic fertilizers, A. GRÉGOIRE (*Rev. Écon. Internat.*, 11 (1914), I, No. 2, pp. 359-376).—The history and present status of the use of phosphatic fertilizers are briefly reviewed.

Action of ammonium citrate on mono, di, and tricalcium phosphates, T. WARYNSKI and J. LANGEL (*Ann. Chim. Analyt.*, 19 (1914), No. 1, pp. 1-6; *abs. in Jour. Soc. Chem. Indus.*, 33 (1914), No. 3, p. 153).—It was found that all three phosphates are soluble to an appreciable extent in ammonium citrate solution, and so can not be accurately separated by the use of this solvent. Solution was found to be complete in about an hour. The greatest differences in solubility of the phosphates were observed when extraction was made in the cold and the citrate solution was saturated.

Superphosphate vinasse, a new fertilizer, H. STOLTZENBERG (*Chem. Ztg.*, 38 (1914), No. 8, pp. 81, 82; *abs. in Jour. Soc. Chem. Indus.*, 33 (1914), No. 3, p. 153; *Chem. Zentbl.*, 1914, I, No. 12, p. 1213).—Vinasse is considered a valuable fertilizer on account of its high nitrogen and potash content, but it was found that the residue from the evaporation of beet pulp is too hygroscopic on account of the presence of bases, such as betain, for use as a solid manure. When 2.5 parts of the pulp was used with 3 parts of the superphosphate a friable mass was obtained which could be kept for months without change. This material contained 2.25 per cent of nitrogen, 6.33 of potash, 11.53 of citrate-soluble phosphoric acid, and 8.48 per cent of water-soluble phosphoric acid. One-half of the material was soluble in water and 30 per cent of it consisted of unaltered organic matter.

Potash salts: Summary for 1912, W. C. PHALEN (*U. S. Geol. Survey, Mineral Resources of the United States, 1912, pt. 2, pp. 877-908*).—A brief account is given of progress in investigations during 1912 by the U. S. Geological Survey and the Bureau of Soils of the U. S. Department of Agriculture with regard to the discovery of new sources of potash in the United States.

A bibliography of recent papers on the subject is appended.

Lime, R. W. STONE (*U. S. Geol. Survey, Mineral Resources of the United States, 1912, pt. 2, pp. 651-668*).—Statistics of production and consumption of lime and data regarding the occurrence of limestone in the United States are summarized in this article. The total production in 1912 was 3,529,462 tons, an increase of 136,547 tons over that produced in 1911. There was a marked decline in price of lime and a decrease in the number of producers during the year.

A bibliography of recent papers on the subject is appended.

Gypsum, R. W. STONE (*U. S. Geol. Survey, Mineral Resources of the United States, 1912, pt. 2, pp. 637-649*).—Statistics of production and consumption in the United States and other countries are summarized. The total production in the United States in 1912 was 2,500,757 tons, an increase of 176,787 tons over the amount mined in 1911. Of this 53,065 tons was sold for use as land plaster.

A bibliography of recent papers on the subject is appended.

The composition and agricultural value of carbonate of lime from causticizing plant, J. HENDRICK (*Jour. Soc. Chem. Indus.*, 33 (1914), No. 3, pp. 122-126).—This is a full account of analyses and field experiments which have already been noted (*E. S. R.*, 30, p. 127).

Liming Iowa soils, P. E. BROWN (*Iowa Sta. Circ.* 2, 2. ed. (1913), pp. 3-8, pl. 1).—This is a popular discussion of the subject.

The action of sulphur on the bacterial activities of the soil, J. VOGEL (*Centbl. Bakt. [etc.]*, 2. Abt., 40 (1914), No. 1-8, pp. 60-83; *abs. in Chem. Zentbl.*, 1914, I, No. 12, p. 1212).—Experiments are reported which indicate quite positively a decided effect of sulphur in promoting various bacterial activities in the soil, such as ammonification, nitrification, and nitrogen fixation.

The so-called "catalytic action" of manganese and boron compounds on the cultivation of the sugar beet, H. PELLET (*Bul. Assoc. Chim. Sucr. et Distill.*, 31 (1913), No. 6, pp. 419-424; *abs. in Jour. Soc. Chem. Indus.*, 33 (1914), No. 3, p. 153; *Chem. Zentbl.*, 1914, I, No. 8, p. 807; *Chem. Ztg.*, 38 (1914), No. 11, *Reper.*, p. 47).—Experiments at the Rovigo Experiment Station in Italy are referred to as showing that manganese and boron compounds, both singly and in combination with aluminum compounds, had no effect on the growth or yield of the sugar beet or on the purity of its juice. The reliability of results of other experiments indicating favorable effects from the use of these compounds is questioned.

The fertilizer inspection for 1913, B. E. CURRY, T. O. SMITH, ET AL. (*New Hampshire Sta. Bul.* 167 (1913), pp. 11).—Analyses of 187 samples of fertilizers sold in the State during the year are reported.

Analyses and valuations of commercial fertilizers and ground bone, C. S. CATHCART ET AL. (*New Jersey Stas. Bul.* 261 (1913), pp. 3-64).—This bulletin completes the report of inspection of fertilizers in New Jersey during 1913, giving analyses and valuations of fertilizers in addition to those reported in Bulletin 259 (E. S. R., 30, p. 327) and discussing the results of the inspection as a whole.

During the year 122 manufacturers and jobbers registered 2,078 brands of fertilizers for sale in the State, 1,617 being mixed goods and 461 fertilizer materials. Of the samples collected 944 were analyzed. Of the 623 brands of mixed fertilizers examined 457 were found to be as guaranteed. Considering the shipments of fertilizers as a whole, the full amount of plant food guaranteed was delivered, but a study of the individual analyses shows that this average was due to a balancing of excesses and deficiencies.

The average composition, valuation, and selling price of the fertilizers examined during the year were as follows: Total nitrogen, 2.63 per cent; total phosphoric acid, 9.28; available phosphoric acid, 7.74; insoluble phosphoric acid, 1.54; potash, 7.13; station's valuation, \$23.22; and selling price, \$29.37.

According to the certified statements which the law requires manufacturers to make on April 1 and November 1 of each year, the amount of fertilizers sold in the State during 1913 was 156,661 tons, valued at about \$4,500,000.

Fertilizer registrations, C. S. CATHCART (*New Jersey Stas. Bul.* 264 (1914), pp. 3-45).—This is a list, accompanied by guaranteed minimum analyses, of mixed fertilizers and fertilizing materials which are to be offered for sale in New Jersey during the year ending October 31, 1914.

[Fertilizer inspection in North Carolina 1912 to 1913], B. W. KILGORE ET AL. (*N. C. Dept. Agr. Bul.*, 34 (1913), No. 10, pp. 198).—Analyses and valuations of samples of fertilizers (and cotton-seed meal) collected during the fall of 1912 and the spring of 1913 are reported. A list of brands registered, with their guaranteed analyses, is also given. It is stated that the fertilizers and meals were found to be generally what was claimed for them.

AGRICULTURAL BOTANY.

Agricultural bacteriology, C. M. HUTCHINSON (*Ann. Rpt. Bd. Sci. Advice India*, 1911-12, pp. 128-131).—A report is made on the work of the bacteriological section, in which the author states that the method of determining the bacteriological activity of the soil by plate counts has been abandoned in favor of methods depending upon the measurement of the physiological activity of the soil organisms.

As a result of his studies it has been ascertained that the rate of formation of carbon dioxide in the soil is directly proportional to the biological activity of that soil. It is also learned that temperature plays an important part in deciding whether ammonification will proceed at such a rate as to allow concurrent nitrification. Some experiments were conducted which demonstrated that where intense bacterial action is taking place in soil any nitrates present may be reduced without the occurrence of anaerobic conditions, and it is probable that the nitrate is utilized as a source of nitrogen by bacteria. In another series of experiments it was determined that in puddled soil the anaerobic conditions prevailing prevented the formation of nitrate, confirming the conclusions of others that the rice plant obtains its nitrogen in the form of ammonia and that the use of nitrate of soda as a rice fertilizer results in a loss of nitrogen through denitrification.

Some brief notes are given on a bacterial disease of tobacco due to *Bacillus solanacearum*, and a bacterial disease of wheat which was found to be attacked by a bacillus closely resembling *Pseudomonas hyacinthi*.

On the fungi of the soil, II, ELIZABETH DALE (*Ann. Mycol.*, 12 (1914), No. 1, pp. 33-62, pls. 5).—In continuance of previous work (E. S. R., 28, p. 524), the author reports her studies on the fungus flora of three other samples of soil, namely, chalk, uncultivated mountain peat, and black earth of reclaimed fenland. These gave respectively 29, 20, and 18 species, representing respectively 16, 13, and 13 genera, a few species and several genera being found in two or more of the soils examined. None is known to be new.

Bacteria and soil fertility, P. E. BROWN (*Iowa Sta. Circ.* 7 (1913), pp. 16, figs. 9).—This is a popular discussion of bacteria, and some of their functions in soils are described.

The mycorrhizas of forest trees, W. B. McDougall (*Amer. Jour. Bot.*, 1 (1914), No. 2, pp. 51-74, pls. 4, fig. 1).—This is a detailed account of a previous paper (E. S. R., 30, p. 132).

In the present report the author describes six forms of ectotrophic mycorrhizas and adds four species to the known list of fungi which form ectotrophic mycorrhizas. These are *Russula* sp., *Boletus scaber fuscus*, *Cortinarius* sp., and *Scleroderma vulgare*. It is said that at least four and probably more species of mushrooms may form mycorrhizas on the same tree.

Infection for the formation of ectotrophic mycorrhizas is said to take place by a fungus penetrating the outer portion of the epidermal wall of the root and then branching and spreading in all directions. As soon as a complete mantle of mycelium is formed over the root, any further length of growth is inhibited. On this account the root is stimulated to form branches which in turn are soon infected. The fruiting bodies of an ectotrophic fungus are usually produced soon after the mycorrhiza is formed. Both ectotrophic and endotrophic mycorrhizas are normally annual. They are formed during the summer, reach their fullest development late in the autumn, persist throughout the winter, and die in the spring.

The roots of maple are infected through root hairs in the production of endotrophic mycorrhizas. The mycorrhizas of maples are said to be sometimes in symbiotic association and at other times the fungus can only be considered as an internal parasite of the roots. The ectotrophic mycorrhizas, on the other hand, are not in any sense symbiotic associations, but are considered as parasites on the roots of the trees.

The relation of living chlorophyll to light, D. IWANOWSKI (*Ber. Deut. Bot. Gesell.*, 31 (1914), No. 10, pp. 600-612, fig. 1).—Detailing studies carried out by himself with foliage differing as to thickness, as to area (as related to vol-

ume), and as to coloration in exposure to light, the author concludes that the surprising stability of living chlorophyll is comprehensible only on the hypothesis of a colloidal condition of that pigment.

Investigations on the pigments in chromoleucites, V. LUBIMENKO (*Compt. Rend. Acad. Sci. [Paris]*, 158 (1914), No. 7, pp. 510-513).—After calling attention to the change in chlorophyll in the pericarp of fruits, etc., which results in the accumulation of yellow and red pigments in the chloroleucites, the author gives an account of investigations as to the nature of the pigments which thus replace chlorophyll. Oxygen is found necessary for the formation of these pigments and while it is thought that there are probably a considerable number of pigments which replace chlorophyll, they are all connected with lycopin and rhodoxanthin, which are isomeric with carotin and xanthophyll.

The rôle of yellow pigment in chloroplasts, D. IWANOWSKI (*Ber. Deut. Bot. Gesell.*, 31 (1914), No. 10, pp. 613-617).—Discussing the decomposing effects of light on chlorophyll in solution, the author states that an increase in the proportion of yellow pigment in alcoholic solutions is accompanied by an augmentation of stability in the chlorophyll content. From this he infers a protective influence of the yellow pigment on the chlorophyll.

Studies on the chemical process of anthocyanin pigment formation, R. COMBES (*Ber. Deut. Bot. Gesell.*, 31 (1914), No. 10, pp. 570-578).—The author, continuing to report on recent studies (*E. S. R.*, 31, p. 35), summarizes substantially as follows:

In certain cells of *Ampelopsis hederacea* green growing cells showed a yellowish brown substance very closely related to the anthocyanin pigment of red leaves of the same plant and apparently transformable into that pigment by reduction, a change which normally occurs on the checking of leaf growth in autumn.

The experimental production of anthocyanin outside the leaf may, it is claimed, be regarded as an accomplished fact, and leaf reddening may now be considered as a process not of oxidation, but of reduction. The author expects to present in a later communication some new evidence in this connection and a new theory of leaf coloration based upon results of recent studies.

Some conditions of formation and decomposition of starch, H. LUNDEGÄRDH (*Jahrb. Wiss. Bot. [Pringsheim]*, 53 (1914), No. 3, pp. 421-463).—The author gives somewhat detailed results of studies made on transformation relations observable under various conditions in seeds or shoots of plants representing a number of divergent groups, stating in conclusion that while few entirely new facts have been brought out, it is safe to conclude that the simple transformations starch \rightleftharpoons sugar and starch \rightleftharpoons oil can not be completely explained by the ordinary conception of reversibility.

Physiology of latex in some rubber plants, F. TOBLER (*Ber. Deut. Bot. Gesell.*, 31 (1914), No. 10, pp. 617-620).—A study of *Mascarenhasia elastica* showed that the sap from tapped trees was richer in caoutchouc in damp weather, in leaves exposed to light, in young leaves, and in plants having insufficient nitrogenous materials in their food supply. Sprouts arising at points of injury to the trunk developed a greater degree of milkiness in the sap than did the main stem.

In case of *Manihot glaziovii* a definite cycle of change in composition of the sap exuded after tapping was noted. The caoutchouc content of growing parts increased to a maximum near the point of most active growth. Partial girdling was followed by thickening of sap in neighboring vessels in association with an increase of bacteria therein.

All plants having milky latex except *M. elastica* were shown to be subject to attack by snails, this result tending to invalidate the claim that the presence of milky sap or caoutchouc in the leaves is protective against these animals.

The microchemical recognition and the distribution of aluminum in plants, E. KRATZMANN (*Sitzber. K. Akad. Wiss. [Vienna], Math. Naturw. Kl., 122 (1913), II, No. 2, pp. 311-336, figs. 6; abs. in Rev. Sci. [Paris], 52 (1914), I, No. 12, pp. 369, 370*).—The author has made a study of the occurrence of aluminum in plant tissues by microchemical methods based upon the formation of the double sulphate of cæsium and aluminum. He examined several hundred plants representing many families and found that aluminum is present quite extensively in the plant kingdom, certain species being extremely rich in that substance. There did not appear to be any connection between the aluminum content of the plant and the botanical relationship of the species, for notable variations were noticed in different specimens of the same genus and species. In certain cryptogams aluminum was found concentrated in the foliar lobes carrying the spore bearing organs, and the content in flowers was found in some instances greater than that in other parts of the plant.

Some effects of colloidal metals on *Spirogyra*, W. D. HOYT (*Bot. Gaz., 57 (1914), No. 3, pp. 193-212, figs. 4*).—From the author's account of studies as detailed, it may be stated that colloidal silver, though injurious to *Spirogyra* when used alone even in weak concentrations, was rendered less so by addition of colloidal platinum, animal charcoal, or inorganic salts. Colloidal gold with sodium hydrate was only slightly injurious. Colloidal platinum, almost harmless itself, partially corrected the toxicity of tap water, distilled water, and solutions of potassium chlorid, magnesium sulphate, and colloidal silver. Toxic solutions of sodium hydrate were rendered less so by colloidal gold, platinum, and silver, but not by gold chlorid.

Filaments of *Spirogyra*, originally from the same culture but grown for a time in different media, exhibited different reactions in the solutions of colloidal gold and sodium hydrate as well as in the other toxic solutions employed.

A bibliography is appended.

Influence of radio-activity on plants, L. MALPEAUX (*Vie Agr. et Rurale, 3 (1914), No. 11, pp. 289-293, figs. 3*).—A report is given of the effect of a fertilizer material that is claimed to have radio-active properties on the growth of rye grass, oats, turnips, sugar beets, fodder beets, and potatoes, comparisons being made with the same plants grown with and without complete fertilizers. The plants subjected to the radio-active substance appeared to be stimulated to some extent and were darker green in color, but the yields were but little if any greater than where a complete fertilizer was used. In case of the root crops, there was apparently some increase in the sugar content, which it was thought could be attributed to the radio-active substance.

Penetrative power of violet and ultraviolet rays in regard to leaves, P. A. DANGEARD (*Compt. Rend. Acad. Sci. [Paris], 158 (1914), No. 5, pp. 369, 370*).—Reporting a study on the penetrability of foliage of several species of plants, the author shows that the various species can be arranged in classes differing in this respect, some being much more readily penetrable by the shorter wave lengths than is glass of corresponding thickness. It is thought that the facts observed may furnish a new point of departure for a study of the nature and cause of differences occurring in leaves.

Axial abscission in *Impatiens sultani* as the result of traumatic stimuli, R. A. GORTNER and J. A. HARRIS (*Amer. Jour. Bot., 1 (1914), No. 1, pp. 48-50*).—The authors describe an abscission in *I. sultani* as the result of injury due to greenhouse pests, the removal from a shaded room and transplanting out of

doors, cutting across the stems in the internodes, etc. In nearly every instance the stem was cut off at the next or some lower node by the formation of an absciss-layer.

The survival of plant tissues after freezing, W. RUSSELL (*Compt. Rend. Acad. Sci. [Paris]*, 158 (1914), No. 7, pp. 508-510).—In a study of the effect of freezing on a number of plants, the author found that while after thawing the plants might show a wilted condition the ultimate death of the plant might be delayed for several days and even weeks. He claims that where thickened secondary tissues were present among thin-walled parenchyma cells the former were very slow in showing the effect of freezing. He concludes that the death of a plant from freezing is rarely immediate, but that it is delayed in proportion to the uninjured elements, the destruction proceeding with more or less rapidity from cell to cell.

The frost problem up to date, C. FRAZER (*Country Gent.*, 79 (1914), No. 8, pp. 360, 392, fig. 1).—This is a brief statement of two recent theories of frost injury to fruit, and of selected results of experiments and observations supporting the conclusion that both the duration of the frozen state and the rate of defrosting are important in determining the effect of cold on the fruit. It is held that even if orchard heating has been delayed until after a freezing temperature has been reached, there may be time to save the fruit. Tabular results of studies on resistance of various fruits at different stages are quoted.

Can selection improve the quality of a pure strain of plants? C. and A. HAGEDOORN (*Jour. Bd. Agr. [London]*, 20 (1914), No. 10, pp. 857-860, pl. 1).—As bearing upon the common belief that unselected seed automatically deteriorates, the author cites the results of selective breeding of wheat carried on by L. de Vilmorin and descendants since about 1850, showing reproductions of photographs of a dozen specimen ears of the present generation side by side with those of the original parents. The long-continued selection has produced no apparent change, thus supporting experimentally the statement that in a strain once pure of a self-fertilized plant, no amount of selection can produce amelioration or deterioration, as is possible with habitually cross-fertilized plants.

Coloration of the seed coat of cowpeas, A. MANN (*U. S. Dept. Agr., Jour. Agr. Research*, 2 (1914), No. 1, pp. 33-56, pl. 1, figs. 2).—This is a detailed account of an investigation previously noted (*E. S. R.*, 27, p. 632), in which a study was made of the seed coats of various cultivated cowpeas to determine whether the diversity in the color scheme and kinds of pigments in the seeds have a direct bearing on the problem of heredity.

On the appearance of sterile "dwarfs" in *Humulus lupulus*, E. S. SALMON (*Jour. Genetics*, 3 (1914), No. 3, pp. 195-200, pls. 2).—The author reports the occurrence, in a large number of crosses made between similar varieties of hops and various individual male hops, of certain individuals which are characterized by their total or almost total inability to climb and their complete sterility, no flowers being produced.

FIELD CROPS.

A table for estimating the probable significance of statistical constants, R. PEARL and J. R. MINER (*Maine Sta. Bul.* 226 (1914), pp. 85-88).—This paper discusses the significance usually put upon the probable error in any given case by biometric workers and points to errors in such considerations. A table is presented, designed to be useful to statistical workers, which sets forth, for a series of ratios between a statistical deviation and the "probable error" of the error distribution, first, the probability that a deviation as great

as or greater than the given one will occur and, second, the odds against the occurrence of such deviations.

Note on the accuracy of bushel weight determinations, C. W. BARBER (*Maine Sta. Bul. 226 (1914)*, pp. 69-75, figs. 2).—After testing the accuracy of different methods of filling the bucket of the ordinary grain tester the author gives data to show that with oats the one wherein the grain was poured into the bucket and settled by shaking five times gave more accurate results than filling by dipping and with and without settling. It is noted that "this method, in comparison with that involving no settling of the grain, lowers the standard deviation 38.5 per cent and the coefficient of variation 44.9 per cent."

It was found that the standard grain tester gave results of a high degree of accuracy.

Note on the influence of shape and size of plats in tests of varieties of grain, C. W. BARBER (*Maine Sta. Bul. 226 (1914)*, pp. 76-84).—In this paper the author discusses the significance of heavy and light seeding, of the length of the periphery of different sized and shaped plats, of the relation of an area 6 in. wide within the border of a plat to the total area of the plat, and of the relation of marginal drill length to total drill length in different shaped plats in the calculations of comparative yields in variety tests.

Data and computations are presented in support of the conclusions that "of rectangular plats of a unit area a square has the shortest periphery and accordingly presents the smallest number of plants along the borders. Therefore a square plat is a more accurate basis for the determination of the value of varieties than any other rectangular shaped plat of equal area. It is clear that in a long narrow plat more plants will be subjected to the conditions afforded by the pathways than in a square of the same area. Also, in small plats proportionately more plants will stand along the border than in large plats."

Deep plowing and subsoiling, A. H. WRIGHT (*Oklahoma Sta. Circ. 26 (1914)*, pp. 8).—This circular reports results in subsoil plowing for 10 years with corn, cotton, and oats on a medium upland soil, described as physically a silt loam. It is concluded that subsoiling was not advisable as a farm practice, as neither soil moisture nor crop yield were increased thereby.

The improvement of plants, L. BLARINGHEM (*Le Perfectionnement des Plantes. Paris, 1913*, pp. XII+13-192, figs. 30).—This work contains 7 chapters, discussing plant collections and botanical gardens, polymorphism of cultivated plants, pure lines and pedigrees, crossing of species, crossing of varieties, hybrid mutations and selection, with a bibliography on each topic.

The breeding of forage grasses, H. LANG (*Jahresber. Ver. Angew. Bot., 10 (1912)*, pp. 1-17, figs. 2).—This article reviews recent work in the breeding of grasses, describes modern methods, and gives plans for breeding plats.

The history of the cultivated cereals, I. A. SCHULZ (*Die Geschichte der kultivierten Getreide, I. Halle, 1913*, pp. 134).—This book gives the histories of wheat, rye, barley, and oats as derived from the most authoritative literature on the subject. Bibliographies are found at the end of each chapter.

Some further observations on the culture of legumes with special reference to nitrogen assimilation, B. HEINZE (*Jahresber. Ver. Angew. Bot., 10 (1912)*, pp. 75-114).—Continuing previous work (E. S. R., 20, p. 740; 24, p. 430), the author reviews certain literature on this subject and discusses some phases of inoculation with pure cultures and with soil in different soil types with lupines and serradella, and in rotation with other legumes.

The inoculation of legumes, P. E. BROWN (*Iowa Sta. Circ. 8 (1913)*, pp. 3-14, figs. 5).—This circular describes the soil transfer and pure culture methods of inoculations and discusses their efficiency in field practice.

Influence of soil volume and available plant food on the ratio between root development and yield of cereals, H. BURMESTER (*Jour. Landw.*, 61 (1913), No. 2, pp. 135-152).—The results of 2 years' experiments with wheat, rye, oats, and barley grown in pots of different sizes showed that the soil volume at the disposal of the plants had very little influence either on the absolute weight of the roots or upon the ratio between the root and the above-ground part in mature plants.

It was found by reducing the amount of available plant food in the pots that the growth of the above-ground part was curtailed much more severely than was the root system, thus producing a narrower ratio between the parts than when an optimum amount of food was available. It is noted, therefore, that on poor grades of soil the above-ground part does not develop in proportion to the richness of the soil, for the root development robs it in direct ratio to the poverty of the soil.

Leguminous crops in North Carolina, T. B. PARKER (*Bul. N. C. Dept. Agr.*, 34 (1913), No. 7, pp. 54, figs. 36).—This bulletin gives notes on the soil treatment for legumes and methods of cultivation of red, mammoth, crimson, bur, sweet, and Lespedeza clovers, alfalfa, vetches, cowpeas, soy beans, and velvet beans.

Some examples of the potash requirements of legumes, CLAUSEN (*Illus. Landw. Zig.*, 33 (1913), No. 100, pp. 910, 911, figs. 4).—Results of several experiments are given in which small yields were obtained with limited or no applications of potash in the presence of otherwise complete fertilizers. With deficient applications of certain fertilizers, the yields of red clover were as follows: With complete fertilizer 3,839 kg. per hectare (about 3,419 lbs. per acre) of dried hay, without nitrogen 3,970, without phosphoric acid 3,017, without potash 2,360, and unfertilized 1,397 kg.

Plants for the desert, H. SEMLER (*Bol. Min. Agr., Indus. e Com. [Brasil]*, 2 (1913), No. 4, pp. 71-96).—This article includes notes on about 30 kinds of cultivated plants found in arid and semiarid districts, with a list of seedsmen in several countries that handle such plants and their seeds or cuttings.

Desert plants of Mexico, I. OCHOTERENA (*Mem. y Rev. Soc. Cient. "Antonio Alzate,"* 33 (1913), No. 1-8, pp. 93-113, pls. 15).—This article discusses the composition, structure, and classification of the agaves and yuccas found in Durango.

Field experiments, C. D. WOODS (*Maine Sta. Bul.* 224 (1914), pp. 25-46).—The results of 3 years' experiments at Highmoor farm indicated that little was gained by the addition of Thomas slag as a top dressing for grass lands other than maintaining the fertility of the soil.

In regard to methods of planting potatoes it is noted that "in the 3 years' experiments comparing the usual method practiced in Aroostook County with deeper planted seed and a lower, broader ridge than is commonly used there showed that so far as yield was concerned there is nothing to choose in that locality between the two methods. The deep planted and medium planted gave practically the same yields at Highmoor farm with the advantage (though within experimental error) in favor of the medium planted. The medium planted and medium ridge gave considerably better yields at Highmoor farm than the shallow planted and high ridge. The medium ridge is cultivated as cheaply as the shallow ridge and is harvested nearly as easily. The deep planted are cultivated at less cost than either of the two other methods but are far more difficult to harvest. The results indicate that for Aroostook County the shallow planted high ridge is well suited to the climatic conditions. And they also clearly indicate that for the lower counties in the State with

their lesser rainfall during the growing season the medium planted with the broad low ridge cultivation is preferably to either of the others."

From some results of soy-bean experiments the author concludes that "soy beans can be grown in parts of Maine where corn thrives. Where early corn matures, the early white soy bean will usually mature. Where Sanford corn ears, the early medium soy bean will form pods. . . .

"It is doubtful if it would be profitable to grow soy beans for seed in Maine. The varieties that will ripen seed in this climate make small vine growth. The crop is best adapted for feeding green or for silage. . . . A yield of 8 tons of green crop is an average in average seasons on average soil."

Directions are given for the use of iron sulphate as a spray to destroy wild mustard and related plants in fields of sown cereals. Further, "the experience indicates that with a field of potatoes badly infested with mustard spraying with sulphate of iron solution may be resorted to with a reasonable expectation that the yield of tubers will not be diminished. At present such a treatment can only be recommended as a rather extreme measure."

Report of the work done by the agricultural experimental station in St. Croix during the year [ended June 30, 1912] (*Rpt. Agr. Expt. Sta. St. Croix, 1911-12, pp. 61, pls. 8, figs. 10*).—This is a report of progress on the work of this station which was recently established. Results of variety tests with sugar cane, cotton, maize, and sorghum, and soil analyses are reported, with meteorological observations.

Field experiments and demonstrations (*North of Scot. Col. Agr. Leaflets, 1912, pp. VI+166, figs. 2*).—This gives results of variety and manurial tests with cereals, turnips, carrots, sugar beets, mangels, potatoes, alfalfa, grass, and weeds during 1912 in 10 county districts of Scotland.

[Field crop experiments], F. SMITH (*Ann. Rpt. Chinsurah Agr. Sta. [India], 1912, pp. 4-10*).—This reports manurial and variety tests with rice, hemp, soy beans, sugar cane, flax, wheat, mustard, lentils, etc.

Alfalfa seed production; pollination studies, C. V. PIPER, M. W. EVANS, R. MCKEE, and W. J. MORSE (*U. S. Dept. Agr. Bul. 75 (1914), pp. 32, fig. 1*).—Earlier investigations along this line are reviewed. The structure of the alfalfa flower is described and the relation of tripping to the development of the seed.

The results of these studies of pollination of alfalfa flowers brought out the following conclusions: "Alfalfa flowers remain fully susceptible to pollination from the time of opening until the petals wither. Pollination is ordinarily effected when the elastic staminal column has become 'tripped.' No evidence was found to favor Burkill's theory that tripping effects the rupture of the stigmatic cells and that this is an important factor in fertilization. Flowers tripped in various ways to prevent any stimulation or rupturing of the stigma by contact set pods equally as well as those tripped naturally.

"Flowers tripped artificially, and therefore self-pollinated, set pods freely. In one series of experiments on 77 plants at 7 different places, 9,074 flowers set 2,784 pods when artificially tripped (a percentage of 30.68), while 8,939 flowers on the same plants exposed to natural conditions set 1,499 pods (16.76 per cent). The pods from artificially tripped flowers contained an average of 1.72 seeds each, while those from naturally tripped flowers averaged 2.22 seeds each.

"Pollination from a different flower on the same plant is no more effective than self-pollination, but pollen from another plant increases both the proportion of pods set and the number of seeds per pod. It makes but little difference whether the pollen parent be the same or a different variety. . . .

"There is a wide range of variability in alfalfa plants as regards the readiness with which the flowers become tripped, either automatically or by the

aid of external objects, and also in their ability to set fruit when tripped. The number of pods set is not proportional to the number of flowers, as a smaller proportion of pods is produced on many-flowered racemes than on few-flowered racemes.

"Automatic tripping takes place most frequently in hot sunshine. Humidity is doubtless also a factor. Automatic tripping can readily be observed by focusing a burning glass on open flowers or by simply bringing shaded flowers into the sunshine on a hot day.

"Insects are the natural agents of cross-pollination in alfalfa, but even where they are scarce, good crops of seed may be produced. Bumblebees and leaf-cutting bees (*Megachile*) are the most efficient insects to trip alfalfa flowers. Honeybees secure much honey from alfalfa flowers, but trip only a very small percentage of the blossoms. Night-flying insects are of negligible value. Butterflies have never been observed to trip a flower during the course of these studies. Rain or wind causes but few alfalfa flowers to become tripped.

"Automatic tripping with consequent self-pollination probably results in the setting of as many pods as does tripping by insect visitors, at least in the West. This conclusion is also in accord with the observation that excellent seed crops are produced in sections where bumblebees and other insects capable of tripping alfalfa flowers are decidedly scarce."

Barley culture in Wisconsin, R. A. MOORE and A. L. STONE (*Wisconsin Sta. Bul. 212 (1914), rev. ed., pp. 20, figs. 9*).—This revision (E. S. R., 25, p. 531) contains additional data, together with a score card and directions for scoring barley.

The average yield of pedigree barley for 6 years as produced by members of the Wisconsin Experiment Association is given as 34 bu. per acre as against 29.3 bu. with other varieties. Pedigree barley at the station yielded an average of 44.8 bu. per acre for the 5 years, 1908–1912, while common barley grown by Wisconsin farmers averaged for the same period 27.7 bu.

Cactus *Opuntia* as a forage crop for arid regions (*Bol. Min. Agr., Indus. e Com. [Brazil], 2 (1913), No. 4, pp. 141–150*).—This gives notes on the cultivation and uses of this crop.

Chilian clover, J. W. HADFIELD (*Agr. Gaz. N. S. Wales, 24 (1913), No. 10, pp. 857–859, pl. 1, figs. 3*).—This notes the trial of Chilian clover, *Trifolium pratense perenne*, which thrived at the Hawkesbury Agricultural College, whereas all the other varieties of clover practically failed.

Studies in variation of red clover, EDNA C. PAMMEL and CLARISSA CLARK (*Proc. Iowa Acad. Sci., 18 (1911), pp. 47–53, pls. 4*).—This paper presents data obtained in a study of variation in the number of flowers in heads, variation in length of flowers (stamen tubes), and size of pollen grains for first, second, and third crops grown on black loam, black loam underlaid with gravel, and alluvial soils.

It is noted that "the second crop clover has more flowers in the head than the first crop clover, and that black loam underlaid with gravel is the best soil for the production of red clover." The range extended from 53 to 142 flowers per head, with a mean of 90.44. The length was found to vary from 0.6 to 1 cm. The width of pollen grains varied from 20 to 40 μ , and the length from 28 to 68 μ .

Pollination of clover, L. H. PAMMEL and CHARLOTTE M. KING (*Proc. Iowa Acad. Sci., 18 (1911), pp. 35–45, figs. 3*).—This paper describes the structure of the flower of red clover and data upon the visit of insects to flowers as observed for various periods on different areas. In 814 seconds 381 visits were recorded. That clover is not self-fertilized was indicated in the thrashing of

over 600 heads that had been covered and in which no seeds were found. It is noted that the second crop exceeded the first in the number of seeds per head.

The inheritance of recurring somatic variation in variegated ears of maize, R. A. EMERSON (*Nebraska Sta. Research Bul. 4 (1914), pp. 5-35, figs. 3; Amer. Nat., 48 (1914), No. 566, pp. 87-115, figs. 3*).—In studying the inheritance of variegation in a variety of maize, known as "calico" corn, the author has reached the following conclusions:

"A somatic variation in maize is shown to be inherited in simple Mendelian fashion. The variation has to do with the development of a dark red pigment (or in one stock a brown pigment) in the pericarp of the grains, often associated with the development of an apparently similar pigment in the cob and husks.

"Plants in which this pigment has a variegated pattern may show any amount of red pericarp, including wholly self-red ears, large or small patches of self-red grains, scattered self-red grains, grains with a simple stripe of red covering from perhaps nine-tenths to one-tenth of the surface, grains with several prominent stripes and those with a single minute streak, ears with most of the grains prominently striped and ears that are noncolored except for a single partly colored grain, and probably also plants with wholly self-red and others with wholly colorless ears.

"It is shown that the amount of pigment developed in the pericarp of variegated seeds bears a definite relation to the development of color in the progeny of such seeds. This relation is not such that seeds showing say nine-tenths, one-half, or one-tenth red will produce or even tend to produce plants whose ears as a whole or whose individual grains are, respectively, nine-tenths, one-half, or one-tenth red. Experimental results indicate rather that the more color in the pericarp of the seeds planted the more likely are they to produce plants with wholly self-red ears, and correspondingly, the less likely to yield plants with variegated ears.

"Self-red ears thus produced are shown to behave in inheritance just as if they were hybrids between self-red and variegated races or between self-red and non-red races, the behavior in any given case depending upon whether the parent variegated ears were homozygous or heterozygous for variegated pericarp and whether they were self-pollinated or crossed with white.

"It is suggested that these results may be interpreted by the assumption that a genetic factor for variegation, V , is changed to a self-color factor, S , in a somatic cell. All pericarp cells directly descended from this modified cell will, it is assumed, develop color, and of the gametes arising from such modified cells one-half will carry the S factor and one-half the V factor if only one of the two V factors of the somatic cells is changed, or all such gametes will carry S if both V factors are changed. The V factor is thought of as a sort of temporary, recessive inhibitor that sooner or later permanently loses its power to inhibit color development, becoming thereby an S factor. Or it may be that the dominant factor, S , is temporarily inactive, but sooner or later becomes permanently active. Again, the S factor may repeatedly arise de novo. The cause of any such change in factors is beyond intelligent discussion at present.

"The results of Correns with *Mirabilis* and of de Vries with *Antirrhinum* are shown to be subject to the same analysis as that used to interpret the results secured with maize."

Maize variety trial, 1912, J. G. McMILLAN (*Agr. Gaz. N. S. Wales, 24 (1913), No. 12, pp. 1061, 1062*).—In a test of 12 varieties of maize from the United States the yields ranged from 30.75 to 58.64 bu. per acre.

Cotton experiments, 1913, R. J. RICKS, E. B. FERRIS, C. T. AMES, and G. B. WALKER (*Mississippi Sta. Bul. 164 (1914), pp. 3-21*).—In this bulletin are found tables giving temperature and rainfall data for 1913, the results of fertilizer tests and planting distance experiments at the central station, variety and fertilizer tests at the McNeill and Holly Springs substations, and variety tests at the Delta substation.

It is noted that no profitable results have been secured at the central station from the use of potash, which has for the most part been applied in the form of kainit, other than on soils where cotton rusts badly. During 1913 there was rust in practically all of the experimental plats excepts those to which had been applied barnyard manure and kainit. The increased yields from the use of nitrogenous and phosphatic materials have also been small. However, the reverse of this is true on the brown loam and piney woods soils of the State, since these fertilizers give profitable returns when used there. In all of the plats where acid phosphate was used it has been noted that the cotton opened up much earlier in the fall.

The results at the Holly Springs substation showed that "the use of both nitrogen and phosphorus, either alone or in combination, has given very satisfactory results. Phosphorus hastens maturity, and valley land that is slow in maturing a crop can be very greatly benefited by its use. The use of potash, either alone or in combination with other elements, appears to be unnecessary in these soils.

"On thin uplands, the use of an equal mixture of acid phosphate and cottonseed meal, at the rate of 200 to 300 lbs. per acre, gives very satisfactory results, and has done so for the past 8 years. Two hundred lbs. of this mixture has increased the yield of seed cotton in many instances over 500 lbs. per year. On the more fertile soils the quantity of phosphorus may be increased to advantage. After leguminous crops, acid phosphate alone, 200 to 300 lbs. per acre, can be used to profit.

"Where leguminous crops are to be grown (no legume will make satisfactory growth on the thin uplands of this section without the use of about 2 tons of crushed or ground limestone per acre), the use of 300 to 400 lbs. of rock floats under the legume will give good results. Where the rock floats is mixed with manure, or with compost, the phosphorus is made available for plant use."

Recent trials with cotton in Grenada, G. AUCHINLECK (*West Indian Bul., 13 (1913), No. 4, pp. 358-366*).—A brief note is given on some cultural trials and on a bacterial disease that results fatally to cotton.

Cotton production in the German colonies, K. SUPF (*Verhandl. Baumwollbau Kom., Kolon. Wirtschaft. Kom., No. 1 (1913), pp. 3-32, pls. 5*).—This discusses the possibility of growing cotton in German East Africa and notes an attempt by the natives to cultivate it.

Cultivation of kapok to replace that of caoutchouc, O. CANTZLER (*Verhandl. Baumwollbau Kom., Kolon. Wirtschaft. Kom., No. 1 (1913), pp. 52-68*).—This article discusses the possibilities of kapok as a crop in the German Colonies to take the place of caoutchouc, the price of which is reported to be continually decreasing.

Germination of oats, C. BRIOUX (*Vie Agr. et Rurale, 2 (1913), No. 47, pp. 531-533*).—This discusses the results of experiments on the germinative ability of oat seeds when aerated and when partially dried.

Effect of certain artificial manures on the bushel weight of oats (*Dept. Agr. and Tech. Instr. Ireland Jour., 13 (1913), No. 4, pp. 705-707*).—The results give averages of experiments conducted at several centers in Ireland, presented in tabular form, with the following conclusions:

In no instance was the difference between the bushel weights of the grain from any two of the plats very great. In all three series of experiments grain of the highest bushel weight, $37\frac{3}{4}$ lbs., was obtained from the plats fertilized with 1 cwt. sulphate of ammonia, 3 cwt. superphosphate, and 3 cwt. kainit per acre. There was very little difference between the bushel weights of the samples of grain from the plats manured with complete mixtures containing varying quantities of superphosphate and kainit. The poorest quality grain was obtained from the unmanured plats and that dressed with sulphate of ammonia alone. Of the four nitrogenous manures nitrate of soda has produced the lightest grain each season. The results from calcium cyanamid and nitrate of lime were identical.

The potato question, L. PLANCHON (*Bul. Sci. Pharmacol.*, 20 (1913), No. 12, pp. 728-737).—In this paper the author reviews the most important literature on the history, species, and the theory of mutation in *Solanum tuberosum*, *S. maglia*, and *S. commersonii*.

Potato spraying experiments at Rush in 1913, F. C. STEWART (*New York State Sta. Bul.* 379 (1914), pp. 3-9).—During the summer of 1913 an extensive series of potato-spraying experiments was conducted in the vicinity of Rush, N. Y. In each of 66 fields a portion of one row (one-fiftieth acre) was very thoroughly sprayed by hand every two weeks. At digging time the yield of this row was compared with that of an adjacent row which had not received the special spraying. In 47 of the fields no spraying was done by the owner, while in the other 19 fields more or less of such spraying was done.

"In the 47 unsprayed fields the spraying done by the station increased the average yield by 17.76 bu. per acre, or 16.4 per cent; and in the 19 sprayed fields, by 15.04 bu. per acre, or 11.2 per cent. It is believed that the increase obtained was due to the partial control of tipburn which was quite plentiful in some fields, the better control of Colorado potato beetles (not well controlled by the owner in a few cases), and stimulation of the plants. Late blight was entirely absent and early blight and flea beetles scarce. Probably the gain from spraying would have been considerably larger had not the plants been killed prematurely by an early frost."

Thoroughness pays in potato spraying, F. H. HALL (*New York State Sta. Bul.* 379, popular ed. (1914), pp. 3, 4).—A popular edition of the above.

Prickly pear as a forage plant, J. E. MARTINEZ (*Bol. Dir. Gen. Agr. [Mexico]*, *Rev. Agr.*, 2 (1912), No. 10, pp. 908-912).—Notes are given on the culture of this plant as a forage crop in the State of Oaxaca.

Preliminary note on the classification of rice in the Central Provinces, R. J. D. GRAHAM (*Mem. Dept. Agr. India, Bot. Ser.*, 6 (1913), No. 7, pp. 209-229, pls. 5).—This includes a description of methods of cultivation employed in the Central Provinces, as well as preliminary notes on two schemes of classification of rices based on the agricultural and grain characteristics. ✓

Comparative fertilizer experiments with sulphate of ammonia and nitrate of soda on winter rye in 1912, WEHNERT (*Landw. Wechnbl. Schles. Holst.*, 64 (1914), No. 2, pp. 26-30).—With applications of sulphate of ammonia and nitrate of soda to furnish equal amounts of nitrogen, rye yielded at the rate of 461 kg. per hectare with the latter and 633 kg. with the former as the increase over no application of nitrogenous fertilizers and the average of results at 10 centers.

Silver beet: Its use as a forage crop, A. MACPHERSON (*New Zeal. Dept. Agr., Indus., and Com. Bul.* 36, n. ser. (1913), pp. 12, figs. 6).—A note on its cultivation and management as a forage crop of much promise.

Possible economies in sugar production, W. R. DODSON (*La. Planter*, 52 (1914), No. 2, pp. 25-27).—This paper, read before the Louisiana Sugar

Planters' Association at its January, 1914, meeting, discusses the unfavorable conditions confronting the sugar planters.

As remedies that will aid the planters to continue to produce sugar at a profit are discussed the following: Increasing tonnage may lessen the cost of production, and this may be secured by enriching the soil and improving the stand and the methods of tillage. As methods of enriching the soil are suggested the use of crop rotation with legumes, and the plowing under and making silage of the tops. It is noted that over a million tons of cane tops are burned annually in Louisiana.

The production of cattle, hogs, dairy products, truck crops, fruits, grain, and forage crops is discussed as diversifications that may gradually take the place of cane growing to some extent with profit, especially on the small farms.

Sweet potatoes, D. C. MOORING (*Oklahoma Sta. Circ. 25 (1914), pp. 12, figs. 3*).—This circular gives directions for the production of sweet potatoes, covering the subjects of soil, soil preparation, propagation, pulling "slips," setting plants, cultivation, harvesting, and storing, with a description of 10 varieties of sweet potatoes, and directions for the construction of a wooden sweet potato house.

Tobacco breeding, H. LANG (*Jahresber. Ver. Angew. Bot., 10 (1912), pp. 18-30, fig. 1*).—This article reviews recent work in tobacco breeding, describes modern methods used in producing commercial tobacco and tobacco seed, and gives a plan for breeding plants.

Variation in tobacco, H. K. HAYES (*Jour. Heredity, 5 (1914), No. 1, pp. 40-46, figs. 5*).—From experiments conducted at New Haven and Bloomfield, Conn., and Forest Hills, Mass., with a Cuban variety of tobacco the author concludes that "environment is of great importance in any system of tobacco breeding, and quantitative characters and especially quality of cured leaf are in a large measure dependent on this feature. Change of environment, however, does not cause a breaking up of type, and whatever variations occur due to environment appear alike in all plants of a particular type.

"Heredity is the second important factor, and poor types will give unfavorable results even under the best environmental conditions. Any system of tobacco breeding must take both heredity and environment into account. The only known means of producing variability as a source of new types is by crossing. The number of new forms which will appear due to a particular cross will depend on the number of germinal characters by which the parent plants differ."

A genetic analysis of the changes produced by selection in experiments with tobacco, E. M. EAST and H. K. HAYES (*Amer. Nat., 48 (1914), No. 565, pp. 5-48, figs. 9*).—This paper records data collected to throw light on the theory that continued selection of the extreme values of certain quantitative characters in successive self-fertilized generations of a number of strains produces no changes in the mean values of the characters.

From observations of the behavior of the character complex number of leaves of numerous families of hybrid tobacco carried to F_7 , the authors believe they have demonstrated by even these few data that either plant or animal populations can reach such a state of constancy by inbreeding that no profitable results can afterwards be obtained by the practical breeder, and that a homozygous condition does occur in a definite proportion of F_2 offspring and can be propagated commercially at once if a sufficient number of families are grown to be relatively certain of including the desired combination.

"As to the problem of theoretical importance, the question of the true constancy of homozygotes generation after generation, we believe it to be fair to conclude that a state so constant is reached that even for the theoretical purposes of experimental genetics it may be assumed as actually constant.

Further experiment and larger numbers may show that selection can always cause a shift in the mean, but will necessarily be a shift so slight that it can be detected only by a long continued experiment and enormous numbers."

It is noted that "mutations may occur. We have shown the origin of one family by a very wide mutation. In this particular case it was not difficult to show that a constitutional change took place in a single germ cell of the mother plant."

Field experiments with wheat, 1912, H. K. CHAPMAN, R. W. McDIARMID, J. W. SHAW, H. BARTLETT, and H. J. KELLY (*Agr. Gaz. N. S. Wales, 24 (1913), No. 12, pp. 1039-1050*).—This paper reports work in progress on the comparative value of bone dust, superphosphate, rock phosphate, bone charcoal, and Thomas phosphate as wheat fertilizers at the Cowra, Wagga, Bathurst, Glen Innes, and Nyngan experimental farms.

Seed tests made at the station during 1913, M. T. MUNN (*New York State Sta. Bul. 378 (1914), pp. 113-137*).—This bulletin describes the methods employed in making a purity test by "count," and states that "during the year 292 official samples of seed were drawn from dealers' stocks by authorized representatives of the commissioner of agriculture. Analyses of these samples showed 17.5 per cent to be violations of the seed law, i. e., they contained in excess of 3 per cent by count of foul or foreign seed and were not so-labeled. Lawn grass and grass seed mixtures were the most frequent violations, with alsike clover, red clover, and redtop grass, respectively, coming next in order. . . ."

"From correspondents, 975 seed samples were received during the year, and a practical report covering the quality, noxious weed-seed content, adulterants, and general appearance of each sample was given. These voluntary examinations revealed apparently the same seed-trade conditions as did the seed examinations of the previous year."

Purity of farm seeds in 1913, F. H. HALL (*New York State Sta. Bul. 378, popular ed. (1914), pp. 2-4*).—A popular edition of the above.

Results of seed tests for 1913, F. W. TAYLOR and F. APP (*New Hampshire Sta. Bul. 166 (1913), pp. 18*).—This bulletin gives tabulated results of testing 107 samples of seeds from December 1, 1912, to September 1, 1913, the text of the seed law of New Hampshire, and suggestions regarding sampling and the handling of samples.

Report of seed tests for 1913, J. L. BURGESS (*Bul. N. C. Dept. Agr., 34 (1913), No. 9, pp. 48, figs. 2*).—This bulletin gives the results of testing 732 samples of seeds, lists the weed seeds that commonly occur in certain commercial seeds, and notes the effective working of the North Carolina seed law.

Better seed, F. S. HARRIS (*Utah Sta. Circ. 16 (1914), pp. 47-52*).—The need of seed improvement is pointed out, and some directions are given for growing and storing better seeds on the farm.

Homemade seed corn testers, H. D. HUGHES (*Iowa Sta. Circ. 1 (1912), pp. 4, figs. 2*).—This gives directions for making and using the sawdust box tester and the rag doll tester.

Unlawful Iowa weeds and their extermination, L. H. PAMMEL and CHARLOTTE M. KING (*Iowa Sta. Circ. 5 (1912), pp. 3-18, figs. 15*).—This circular gives part of the text of the Iowa weed law, including penalties, and describes and gives methods of eradication of quack grass, Canada thistle, cocklebur, mustard, milkweed, dock, buckhorn or rib grass, wild parsnip, horse nettle, morning-glory, Indian mallow or butter print, burdock, wild timothy or drop-seed grass, squirrel tail or wild barley, foxtail, shoofly, chicory, dodder, and wild carrot.

HORTICULTURE.

Commercial gardening, edited by J. WEATHERS (*London, 1913, vols. 1, pp. XII+239, pls. 17, figs. 179; 2, pp. XII+235, pls. 16, figs. 138; 3, pp. XII+240, pls. 16, figs. 90; 4, pp. XII+244, pls. 17, figs. 124*).—A practical and scientific treatise for market gardeners; fruit, flower, and vegetable growers; nurserymen; etc., prepared by many practical specialists and dealing primarily with conditions in Great Britain.

In volume 1 consideration is given to the general aspects of commercial gardening; the science of plant growing; methods of propagation; the science of the soil; manures and manuring; insect pests; garden friends; fungus diseases; fungicides and insecticides; glasshouse building; and heating apparatus. Volume 2 contains horticultural descriptions and cultural details with reference to hardy and half hardy herbaceous plants, bulbs, and flowers; stove and greenhouse plants and flowers; and ferns. Volume 3 discusses commercial fruit growing in general; fruit growing in Worcestershire, Scotland, and Ireland; diseases of fruit caused by fungi, etc.; and grading and packing fruit. Consideration is then given to the various pip fruits, stone fruits, small fruits, figs, grapes, nuts, and melons with reference to varieties, culture, and care. The concluding sections of this volume discuss garden surveying, leveling, and mensuration; and market garden accounts. Volume 4 deals with trees, shrubs, and woody climbers; conifers and taxads; vegetable growing for market; sweet herbs and small salads; and French gardening or intensive cultivation.

The effect of an increased amount of carbonic acid in the air on green plants, H. FISCHER (*Jahresber. Ver. Angew. Bot., 11 (1913), No. 1, pp. 1-8*).—This paper summarizes the author's investigations, previously noted (E. S. R., 28, p. 837).

Experiments with udo, the new Japanese vegetable, D. FAIRCHILD (*U. S. Dept. Agr. Bul. 84 (1914), pp. 15, figs. 12*).—The author here reports experiments conducted since 1906 with udo (*Aralia cordata*), a Japanese vegetable valued for its blanched shoots. Information is given relative to methods of cultivation, preparing, and cooking. Other phases discussed include early experiments with udo, relatives, varieties, climatic requirements, and diseases of udo.

Udo is said to be adapted to New England, the Atlantic States as far south as the Carolinas, the rainy region of Puget Sound, and the trucking sections of California about Sacramento. Although the plant has not thus far assumed commercial importance it is believed that it is now sufficiently well-known to test out its economic value, as compared with such plants as celery, asparagus, and eggplant.

An apple chimera, W. E. CASTLE (*Jour. Heredity, 5 (1914), No. 5, pp. 200-202, figs. 3*).—The author here illustrates and describes an apple in which Golden Russet and Boston Stripe are combined in the same fruit. In the specimens here illustrated the stem end of the fruit is Golden Russet and the calyx end is Boston Stripe, although it is stated that the reverse of this sometimes occurs. The parent stock of the tree was Boston Stripe on which Golden Russet was grafted. The trees producing these apples bear only a few fruits of this composition. The rest of the crop belongs entirely to one or the other of the two varieties concerned.

Pollination in orchards.—II, The flowering of pears, F. J. CHITTENDEN (*Jour. Roy. Hort. Soc. [London], 39 (1913), No. 2, pp. 366-372*).—In continuation of a previous study relative to the blooming time of apples (E. S. R., 26, p. 440), data are here given showing the varieties of pears growing in the

Wisley Gardens, arranged in order according to the average date of flowering for the period 1908 to 1913.

The author concludes that there is a general regularity in the order of the flowering of pears as with apples. Although deviations from this order may occur each season they are not sufficiently marked to destroy the value of the list as a guide to varieties that should be planted near one another in order to facilitate pollination.

The effects of fertilizers in a cultivated orchard, J. H. GOURLEY (*New Hampshire Sta. Bul. 168 (1914), pp. 3-31, figs. 15*).—In this bulletin the author reviews the more important investigations dealing with the fertilization of apple orchards and gives the results of various culture and fertilizer treatments on a bearing Baldwin apple orchard for a 5-year period. The orchard in question was about 26 years old when the experiment started and had previously been growing in sod and yielding unsatisfactory crops. The hay crop was removed annually. The orchard was divided into some 12 plats, which included the sod-mulch treatment, cultivation the odd year followed by a cover crop and seeded the even year, cultivation the even year followed by a cover crop and seeded the odd year, clean cultivation throughout the season, and cultivation and cover crop with complete fertilizers and with fertilizers containing excesses of phosphorus, nitrogen, and potassium. A portion of the fertilizer plats was also limed. The factors considered in this experiment are yield, growth, and size of fruit.

The results secured for the 5-year period show all methods of treatment to be superior to growing trees in sod. The plat which has been cultivated annually every two weeks until September 1 without using a cover crop has given better yield and growth than cultivation every other year with a cover crop in the alternate year. A good system of culture such as cultivating the orchard every two weeks until midsummer then seeding down with crimson clover, has given practically as good results in yield of fruit and growth of tree as that obtained by the addition of a complete fertilizer or one in which either phosphoric acid, potash, or nitrogen are used in excess in the complete fertilizer. Thus far no cash return has been secured for the fertilizer that has been used in the orchard. Size of fruit has been increased by the use of fertilizers, especially those high in nitrogen and potash, and reports for the year 1913 show that the area and weight of the leaves were increased by the use of fertilizers. Lime had no appreciable effect on any of the factors considered. Color of fruit has not been increased by any combination of fertilizers employed.

Spraying program for orchard and vineyard in South Carolina, A. F. CONRADI and H. W. BARRE (*South Carolina Sta. Circ. 25 (1914), pp. 8*).—This circular contains concise directions for the summer spraying of orchard fruits and grapes, including instructions for preparing spray mixtures.

Analyses for poison of apples sprayed with arsenate of lead in midsummer, C. D. WOODS (*Maine Sta. Bul. 224 (1914), pp. 46-48*).—In connection with some spraying experiments for the control of brown-tail moths in the orchard at Highmoor farm the trees were sprayed with arsenate of lead the first week in August. Analyses were made of the apples at the harvest time to determine whether appreciable quantities of arsenic could be found in the fruit.

The results of the spraying and the analyses indicated that midsummer spraying with lead arsenate is an effective way of combating the brown-tail moth, and that the amount of arsenic or of lead that will remain at harvest upon the apples sprayed in midsummer with arsenate of lead is so slight as to have no practical bearing.

Analyses of materials sold as insecticides and fungicides, C. S. CATHCART, R. L. WILLIS, and W. H. PEARSON (*New Jersey Stas. Bul.* 262 (1913), pp. 3-11).—This bulletin contains analyses of some 50 samples of various materials examined by the station in 1913. They include products sold as Paris green, lead arsenate, Bordeaux and lead arsenate mixtures, Bordeaux mixtures, zinc arsenite, Electro Bordo Pulp, lime-sulphur solutions, and atomic sulphur.

Making a garden of small fruits, F. F. ROCKWELL (*New York, 1914*, pp. 56, pls. 8).—A small practical treatise for the amateur gardener.

Currants and gooseberries, E. F. PALMER (*Ontario Dept. Agr. Bul.* 222 (1914), pp. 36, figs. 22).—This bulletin discusses the extent and importance of the currant and gooseberry industries of Ontario and describes the most approved methods of culture for the home garden and commercial plantation.

Propagation of the seedless breadfruit, P. J. WESTER (*Philippine Agr. Rev.* [English Ed.], 7 (1914), No. 3, pp. 97-99, pl. 1, fig. 1).—A method of propagating the seedless breadfruit by root cuttings is here described. This method, which consists of propagating the cuttings in a bed of sand or sandy loam, has yielded over 75 per cent of healthy plants.

Cacao culture in Samoa, E. DEMANDT (*Tropenpflanzer, Beihefte*, 15 (1914), No. 2-3, pp. IX+135-307, figs. 54).—A practical treatise on the establishment, care, and management of cacao plantations in Samoa, including information relative to insect pests and diseases of cacao, working plans, and cost and yield data.

New researches into some statistics of *Coffea*, P. C. VAN DER WOLK (*Ztschr. Induktive Abstam. u. Vererbungslehre*, 11 (1914), No. 4, pp. 355-359, fig. 1).—A further report on the author's biometric study of fluctuating variability in leaf length and internodal length in coffee plants (*E. S. R.*, 30, p. 534).

Fruits of a date palm in the tertiary deposits of eastern Texas, E. W. BERRY (*Amer. Jour. Sci.*, 4. ser., 37 (1914), No. 221, pp. 403-406, figs. 2).—This comprises a note on the recent discovery of the fossil fruits of a species of date palm in the tertiary deposits of eastern Texas.

The present state of olive growing in Italy, F. BRACCI (*Internat. Inst. Agr.* [Rome], *Mo. Bul. Agr. Intel. and Plant Diseases*, 4 (1913), No. 10, pp. 1496-1502).—A brief survey of the olive industry in Italy, including statistics of production and notes of various conditions which have tended to decrease the production during the past 30 years.

Chestnut breeding experience, W. VAN FLEET (*Jour. Heredity*, 5 (1914), No. 1, pp. 19-25, figs. 9).—This comprises a popular account of the author's work in breeding chestnuts during the past 20 years. The native species were used to a considerable extent in the earlier work, but these were later abandoned owing to the advent of the chestnut bark disease in 1907. Selection work was then continued with self- and chance-pollinated individuals of the chinquapin and certain Asiatic types.

Of the hybrids which have been secured, trees having *Castanea americana* in any combination have nearly all disappeared. The crosses of Asiatic and native chestnuts showed a greater blight resistance than crosses of European and native nuts. The chinquapin-European hybrids are readily affected by blight but have great recuperative powers, bearing nuts the second year on suckers springing from the bases of diseased stems. Chinquapin-native crosses are very susceptible as a rule and do not recover readily. The wild chinquapin itself appears measurably resistant. The Asiatic chestnuts and the chinquapin-Asiatic hybrids are plainly highly resistant. Few have shown any appearance of infection and when noticeable the injury is quite local in character. Second generation seedlings of chinquapin-*crenata* crosses show no disease at all though always exposed to infection.

Some of the more promising chinquapin hybrids are illustrated and described.

California gardens, E. O. MURMANN (*Los Angeles, Cal., 1914, pp. 116, figs. 153*).—This work contains some fifty plans for gardens, including all the different types which are popular in this country and abroad. Although designed primarily for California bungalows they are adaptable to any type of house and for various climates with the substitution of suitable plants.

Garden flowers as they grow, H. ESSENHIGH-CORKE and H. H. THOMAS (*London, New York, Toronto, and Melbourne, 1913, pp. 197, pls. 20*).—A popular work containing photographs in color of a number of our more important garden flowers, including descriptive notes dealing with their horticultural characteristics, special requirements, and desirability for planting.

The rose book, H. H. THOMAS ET AL. (*London, New York, Toronto, and Melbourne, 1914, pp. XI+283, pls. 72, figs. 9*).—This work is offered as a complete guide for amateur rose growers. The subject matter is discussed under the following general headings: Roses to begin with, roses to proceed with, some very practical matters, rose growing under glass, round the year in the rose garden, and lists of varieties for various purposes.

FORESTRY.

Silviculture, A. JACQUOT (*Sylviculture. Paris and Nancy, 1913, pp. XIV+243, figs. 8*).—A practical manual on silviculture, prepared with special reference to conditions in France. It is intended as a guide to estate owners, managers of forest domains, reforesters, and students.

Forest protection, H. VON FÜRST (*Die Lehre vom Waldschutz. Berlin, 1912, 7. rev. ed., pp. VIII+190, pls. 5*).—A revised edition of Kauschinger's *Lehre vom Waldschutz*, the first edition of which appeared in 1846. Forest protection is here considered under three general headings—protection of the forest against inorganic nature, protection against organic nature, and protection against depredations by man.

Forest trees, shrubs, and bushes, C. L. GATIN (*Les Arbres, Arbustes, et Arbrisseaux Forestiers. Paris, 1913, pp. LX+116, pls. 102, figs. 32*).—This is the first volume of a practical encyclopedia for naturalists in preparation by various authors.

Descriptions with illustrations in color are given of about 100 species of the more common forest trees, shrubs, and bushes of Europe. In addition to the botanical characteristics of the species, information is given relative to their distribution with special reference to France, special characteristics, requirements, economic importance, diseases, and insect pests, the birds which nest in them, etc.

Contribution to the knowledge of the oil palm (*Elæis guineensis*), O. BECCARI (*Agr. Colon. [Italy], 8 (1914), Nos. 1, pp. 5-37, pls. 4; 2, pp. 108-118, pls. 8; 3, pp. 201-212, pls. 3; 4, pp. 255-270, pls. 2, fig. 1*).—This comprises a study of the oil palm varieties of tropical Africa. Introductory considerations deal with the habitat, geographical distribution, economic importance, agricultural requirements, extraction of oil, and reproductive characteristics of the oil palm.

Rubber, its sources, cultivation, and preparation, H. BROWN (*London, 1914, pp. XIII+245, pls. 12, figs. 4*).—This work is offered as an account of the present position of rubber production with special reference to West Africa. Consideration is given to the characteristics and natural distribution of the rubber tree, plantation practices, and the more technical questions connected with the tapping, collection, and preparation of rubber.

Rubber culture.—I, *Hevea brasiliensis*, H. ZAEPERNICK (*Kautschukulturen*. Berlin, 1914, vol. 1, pp. XV+178, figs. 34).—This is the first of a series of works dealing with rubber culture, and treats of the plantation culture and exploitation of *Hevea brasiliensis* in various tropical countries. In addition to cultural practice information is given relative to tapping operations, methods of coagulating rubber, and estimates on the cost of producing plantation rubber.

Suitability of longleaf pine for paper pulp, H. E. SURFACE and R. E. COOPER (*U. S. Dept. Agr. Bul. 72 (1914), pp. 26*).—This bulletin reports a series of tests conducted at the U. S. Forest Products Laboratory, Madison, Wis. In order to determine the suitability of southern pines for paper pulps, to ascertain the effects of varying cooking conditions in the sulphate process of pulp making, and to compare the sulphate process with the soda process.

Results thus far secured show conclusively that longleaf pine is well adapted for the manufacture of natural-color kraft pulps and papers, and that the sulphate process of pulp making applied to this wood affords products of better quality and of higher yields than the soda process. Kraft papers can be made from longleaf pine that are equal or superior in quality to the imported and domestic kraft papers now on the market. The high gravity of the wood and the resultant high yield of pulp per cord give longleaf pine an advantage possessed by few, if any other, commercially important woods suited for pulp making.

Uses for chestnut timber killed by the bark disease, J. C. NELLIS (*U. S. Dept. Agr., Farmers' Bul. 582 (1914), pp. 24, figs. 8*).—This bulletin contains information of value to wood-lot owners relative to the utilization of chestnut timber that has been killed by the bark disease. Preliminary strength tests conducted by the Forest Service upon chestnut killed by the bark disease indicate that sound wood from dead trees is fully as strong as wood from healthy trees, providing that the trees have not been injured by insects, decay, or checking. Checking starts in small trees in the second year, and in all trees is rapid from the fifth year on. In order that the timber may be placed on the market before it begins to deteriorate it is advised that diseased chestnut be cut during the first winter after infection.

Rocky Mountain mine timbers, N. DE W. BETTS (*U. S. Dept. Agr. Bul. 77 (1914), pp. 34, figs. 7*).—Bending and crushing tests of a number of kinds of timber used in Colorado for mine beams, props, and caps are reported in tabular form and discussed. Data are also presented as to the consumption and production of mine timbers in Colorado, including production by species, the cost for different sizes, and the life of mine timbers. The methods used in the tests, together with data on individual crushing and bending tests are appended.

The tests included green, air-dried, and fire-killed timber. They indicated that air-dried mine props and caps are much superior to green ones as to strength at the elastic limit, strength at maximum load, and stiffness. With the exception of Douglas fir there seems to be as much variation in the strength of one species procured in different places as among the different species themselves. This is attributed to defects which are usually found in material used for caps and props. The unit strength and stiffness of 16 ft. round beams decreased with an increase in diameter. Beams cut from timber standing dead for about 30 years showed a strength intermediate between green and air-dried material cut from live timber. The tests indicated that timber cut from dead trees can be graded as to decay and defects on the same basis as other material.

Tests of wooden barrels, J. A. NEWLIN (*U. S. Dept. Agr. Bul. 86 (1914), pp. 12, pls. 6*).—The author here reports tests of barrels made from quarter-sawed white oak which were conducted in cooperation with the Bureau for

the Safe Transportation of Dangerous Explosives in order to obtain data upon which specifications and changes in the design of wooden barrels used in the transportation of dangerous liquids might be based.

DISEASES OF PLANTS.

The organization in various countries of the service for the protection of plants, J. M. SAULNIER (*Le Service de Protection des Plantes dans les Divers Pays. Rome: Internat. Inst. Agr., 1914, 2. ed., pp. XIII+305, pl. 1, fig. 1*).—This monograph gives the organization of different countries relating to the study of fungus and insect parasites of plants, rules for inspection, etc., following the general plan previously noted (E. S. R., 26, p. 445).

In addition to the countries reported in the previous edition, there are included in the present monograph Argentina, Austria, Hungary, Brazil, Costa Rica, Egypt, United States, Algeria, New Zealand, Union of South Africa, Greece, Guatemala, Japan, Norway, and Servia.

Problems and progress in plant pathology, L. R. JONES (*Amer. Jour. Bot., 1 (1914), No. 3, pp. 97-111*).—This is an address delivered by the author as the retiring president of the Botanical Society of America, read at the Atlanta meeting December 31, 1913, in which a review is given of recent progress in the investigation of plant diseases, particular attention being paid to American investigations. Some of the problems of disease control are pointed out.

Agricultural bacteriology, special inquiries, C. M. HUTCHINSON (*Ann. Rpt. Bd. Sci. Advice India, 1912-13, pp. 126-128*).—Notes are given on the rice disease due to nematodes, a brief account of which has been noted by Butler (E. S. R., 30, p. 49), an indigo disease which is apparently of bacterial origin, and a potato rot. From rotting tubers two bacteria were found invariably present and the rotting of the tubers took place in the presence of these bacteria wherever the dry tubers had suffered mechanical injury, or where uninjured tubers were kept in a moist condition for a few hours.

Notes on some rusts in India, E. J. BUTLER (*Ann. Mycol., 12 (1914), No. 1, pp. 76-82, figs. 4*).—Descriptions are given of leaf rusts named as follows: *Kuehneola fici* on *Ficus glomerata*, *Coleosporium oldenlandiæ* on *Oldenlandia aspera*, and *Puccinia kühni* on *Saccharum spontaneum*.

The ascosporic condition of the genus *Aschersonia*, R. THAXTER (*Bot. Gaz., 57 (1914), No. 4, pp. 308-313, fig. 1*).—The author has made a study of some of the species of entomogenous fungi in Trinidad and describes the ascosporic stage of *A. turbinata*.

The Plasmodiophoraceæ and their relationship to the Mycetozoa and the Chytrideæ, E. J. SCHWARTZ (*Ann. Bot. [London], 28 (1914), No. 110, pp. 227-240, pl. 1*).—As a result of a cytological and life history study of the species of Plasmodiophoraceæ, the author agrees with Maire and Tison (E. S. R., 21, p. 423; 25, p. 43) that the Plasmodiophoraceæ should form a separate order intermediate between the Sporozoa and Myxomycetes. He also describes three new species of *Ligniera* as follows: *L. bellidis* on roots of *Bellis perennis*, *L. menthæ* on *Mentha pulegium*, and *L. alismatis* on *Alisma plantago*. All the species of this genus are said to be root parasites and infection takes place near the root tips. They are said not to cause hypertrophy in the host plants and on this account are somewhat difficult of recognition.

A bibliography is appended.

North American Uredineæ, E. W. D. HOLWAY (*Minneapolis, Minn., 1913, vol. 1, pt. 4, pp. 81-95, pls. 8*).—The author describes the species of *Puccinia* occurring on the Araliaceæ, Umbelliferae, and Cornaceæ of North America.

Some observations on a peculiar soil disease, W. E. COLLINGE (*Jour. Bd. Agr. [London]*, 20 (1914), No. 10, pp. 875-879).—The author reports experiments in treating plats that had shown abnormal conditions and lowered returns during some years of cultivation in wheat, oats, rye, mangolds, and potatoes. Unslaked lime, 12 to 15 cwt. per acre, showed little or no improvement, but with sulphur at from 4 to 6 cwt. per acre there were produced normal or improved crops. The use of 8 cwt. killed many of the plants. Untreated plats showed steady deterioration from year to year.

The author thinks this disease may be due to bacteria which interfere with the nutrition of the plant; but he refers, in this connection, to the contributions of Russell and Hutchison, dealing with the alleged influence of protozoa in the soil (*E. S. R.*, 22, p. 121; 24, p. 621).

Injury by smelter smoke in southeastern Tennessee, G. G. HEDGCOCK (*Jour. Wash. Acad. Sci.*, 4 (1914), No. 4, pp. 70, 71).—The author states that the injury to vegetation in this region still extends in the same general direction from the sources of injurious gases as reported by Haywood (*E. S. R.*, 19, p. 222; 23, p. 430), the slightly lower degree of injury corresponding to the observed greater extension in area. Prevailing winds are important or decisive factors as to distance and direction. The injury is most severe with conifers and in upland regions. Garden beans, which are especially susceptible, afford a delicate index as to the direction and distance of extension. The injury, which is attributed mainly to sulphur dioxid, shows characteristic features and the various trees affected show resistance thereto in a definite order, which is set forth.

A study in cereal rusts, physiological races, E. C. STAKMAN (*Minnesota Sta. Bul.* 138 (1914), pp. 56, pls. 9).—The author presents the results of an investigation undertaken with the object of determining the possibility of developing and breaking down physiological races of rusts as well as obtaining information concerning some of the factors influencing varying resistance in immune or semi-immune varieties of wheat.

Inoculation experiments were carried on with *Puccinia graminis hordei*, *P. graminis avenæ*, *P. graminis secalis*, and *P. graminis tritici* obtained from their respective hosts in the fields at the station and cultivated through at least a dozen successive transfer generations. In nearly all of the experiments with biologic forms the rust had been confined to its own host for at least 20 generations. Spores of the rusts were placed on leaves of various varieties of wheat, barley, oats, rye, einkorn, and emmer, after which the conditions were made as favorable as possible for the development of the fungus, either by producing a high moisture condition or the use of anesthetics, excessive fertilization, leaf injury, etc.

It was found that direct transfers of *P. graminis* may be made from oats to wheat and rye. The rusts from oats and barley used in the experiments could be readily transferred to rye. The use of anesthetics had some effect in rendering an immune plant slightly more susceptible to rust, while leaf injury apparently had no effect. High fertilization, by increasing the virulence of the attack on semi-immune forms, is thought to have some influence in breaking down biologic forms. The author found that there was apparently a physiological and probably a slight morphological change in the rust fungus when grown continuously on a semi-immune host, the change manifesting itself, however, very gradually as an adaptation to the new host. It is believed that biologic forms of cereal rusts, at least *P. graminis tritici*, do not lose their specialization tendencies when grown on barberry. The degree of incompatibility of host and parasite was found to vary greatly. In semicompatible forms comparatively

large leaf areas are sometimes killed, indicating a killing of host cells by the fungus and a consequent death of the mycelium itself. In this respect they resemble very closely some of the rust resistant forms of wheat, and this is thought to throw light on the question of resistance to *P. graminis*.

In the second part of the bulletin the author discusses rust resistant varieties of wheat.

It was found that in making inoculations in the greenhouse on wheats resistant to *P. graminis tritici*, only two, Khapli, an Indian emmer, and Kubanka 2094, possessed a very marked degree of real resistance, although a number of other forms were fairly resistant in the field. It was observed that the more resistant a form proved, the more pronounced was the tendency of the rust to kill small areas of the leaf. The length of incubation period was found to be correlated to some extent with the degree of immunity, those forms being most nearly immune having the longest incubation period. Infection secured on partially resistant varieties as a result of inoculations with æcidiospores and primary uredospores proved only slightly more virulent than did that secured by means of inoculation with long-time uredospores.

Experiments with drought-resistant durum wheats grown in a very dry soil and with Minnesota No. 163 in wet soil indicated that normal conditions for the host plant are probably the most favorable ones for rust development. The presence or absence of excessive amounts of fertilizer elements was not found to directly affect immunity or susceptibility of wheats. The addition of copper sulphate, copper carbonate, and iron sulphate to nutrient media in which plants were grown did not markedly diminish the amount of rust when they were used in such concentration as to permit the normal development of the host plants. A comparison of the sequence of infection in susceptible and immune forms showed that the fungus gained entrance into the host plant in the same manner in both cases, growing readily in the tissues of the susceptible variety, while it does not thrive in the immune forms. The reason for this is believed to be a physiological incompatibility.

A bibliography is appended.

[Grain diseases] (*Edinb. and East of Scot. Col. Agr. Rpt. 30 (1913), pp. 15-19*).—Barley leaf stripe (*Helminthosporium gramineum* and *H. teres*) is said to cause injury only where it is excessively abundant. Early sowing favored attack, whereas late planting hindered it. The removal and destruction of plants attacked by leaf stripe has proved a good method of eradicating the disease. Formalin and copper sulphate treatment of seeds greatly reduced leaf stripe.

[The stem rot of cereals], L. MANGIN (*Jour. Agr. Prat., n. ser., 27 (1914), No. 8, pp. 236-239*).—The author recognizes two forms of stem diseases of cereals, one due to *Leptosphaeria* and *Ophiobolus*, and the other to *Fusarium* spp., among the best known being *F. nivale*. All the species of the fungi attack cereals near the ground, causing a weakening of the stems and often resulting in very considerable losses.

Experiments on control of loose smut of barley and wheat, R. SCHANDER (*Mitt. Kaiser Wilhelms Inst. Landw. Bromberg, 6 (1914), No. 2, pp. 132-139, pl. 1*).—Regarding the plan and principle of control of loose smut as determined by previous investigations (E. S. R., 28, p. 646), the author gives attention to the possibility of simplifying the process, and of reducing injury caused to germination and yield by such treatment.

The work and results are exhibited in tabular form, permitting the inference that the second treatment employing hot water (52 or 53° C.) can not well be dispensed with or shortened from 10 to 5 minutes. Other features are discussed and the work is to be continued.

Bad germination of wheat seed (*Jour. Bd. Agr. [London]*, 20 (1914), No. 10, pp. 894-896, pl. 1).—This is a report, with discussion, of the findings in case of wheat submitted for investigation at Kew.

Germination tests gave a percentage of 81, which was increased to 93 by slightly cutting the seeds. This result suggested, and examination demonstrated, the presence of disease. This was ascribed to the fungus *Cladosporium graminum*, which blackened the chaff and shriveled the embryos of the seeds attacked. It is stated that the mycelium dormant in the seeds becomes active under the conditions favorable to germination. In bad cases every portion of the ear is attached. It is often present in the hairs on the chaff and in the bristle-like hairs forming the beard, apparently dissolving the cell wall to some extent, as the threads exceed the original cavities in size. In addition to the persistent mycelium, numerous microsclerotia are formed which act as resting spores, germinating in spring, producing very minute secondary conidia which infect the living plant, and rapidly spreading the disease.

Causes of soil sickness in wheat lands, etc., H. L. BOLLEY (*North Dakota Sta. Bul.* 107 (1913), pp. 96, figs. 45).—This is a detailed account of the author's investigations, which have led to his theory that diminished yields of wheat in the Northwest are due to fungus attack and not to soil depletion (E. S. R., 25, p. 650). Various phases of the investigations have been previously noted (E. S. R., 28, p. 442; 29, pp. 515, 516). A number of species of *Helminthosporium*, *Fusarium*, *Colletotrichum*, *Alternaria*, *Cephalothecium*, and *Macrosporium* are found associated with wheat sick soils either singly or in various combinations. These fungi have also been found infesting seed, thus providing for the spread of disease to new areas.

The author considers a lack of rotation responsible, in part at least, for the presence of the fungi in the soil, and for controlling the troubles due to soil or seed infestation he recommends the avoidance of mixed varieties of cereals, planting of pure varieties of seed, selection of well cured, plump, heavy seeds, disinfection of seed, and rotation of crops.

Danger in threshing machines (*Country Gent.*, 79 (1914), No. 6, p. 250).—Attention has been called by H. T. Güssow to the losses due to dissemination of smut diseases by public service threshing machines. A method of disinfecting the machines with formalin is described, which is claimed to be simple, effective, comparatively inexpensive, and capable of application with little loss of time while traveling from farm to farm.

Finger-and-toe disease of crucifers, P. BERTHAULT (*Jour. Agr. Prat.*, n. ser., 26 (1913), No. 48, pp. 692-694, figs. 2).—A distinction is drawn between the forms of injury inflicted upon crucifers by *Plasmodiophora brassicæ* and that due apparently to certain gall producing insects.

Finger-and-toe, G. FRON (*Jour. Agr. Prat.*, n. ser., 26 (1913), No. 49, pp. 730, 731).—Referring to the article above noted, the author reports that soil on which cruciferous crops had been severely injured in spots by *Plasmodiophora brassicæ* during the previous year showed serious shortage on the same areas when planted in carrots, though no organism was found in the plants affected.

Finger-and-toe of crucifers, A. GAY (*Jour. Agr. Prat.*, n. ser., 26 (1913), No. 52, pp. 816, 817).—The author reports that an examination following the above suggestion by Fron showed that in case of carrots following crucifers nearly every case of poor success of the former crop occurred on spots where the latter crop had previously been affected with *Plasmodiophora brassicæ*. The question is raised whether the presence of certain insects might not prove to be significant in this connection.

Finger-and-toe of crucifers and a disease of carrots, P. PASSY (*Jour. Agr. Prat.*, n. ser., 27 (1914), No. 3, pp. 87, 88).—Referring to the reports above noted, the author cites a case of spinach decreasing in returns since 1911. *Plasmodiophora brassicæ* had not been known in these plats previously, and no injury to the roots was apparent. The loss is considered due to some cause not yet determined.

Finger-and-toe disease in Brussels sprouts (Worcester Co. Expt. Gard., Droitwich, Ann. Rpt. 1912; abs. in Jour. Bd. Agr. [London], 20 (1914), No. 11, p. 1010).—Land that finger-and-toe disease had rendered useless for growing Brussels sprouts before 1903 was subjected for five years to treatment with gas lime, quicklime dug in, or quicklime left on the surface. In 1911 plats receiving the last two treatments yielded 97.82 per cent of clean rooted plants. Apterite and vaporite were tried in place of the gas lime, but without results. A further trial showed that a surface dressing of quicklime gave better results than one of iron sulphate.

Control of black canker of potato, SPIECKERMANN (*Illus. Landw. Ztg.*, 34 (1914), Nos. 2, pp. 7-9, figs. 3; 3, p. 16, fig. 1).—In experiments with fungicides against *Chrysophlyctis endobiotica* the best results are claimed from sulphur in soil applications. There was no seriously injurious effect on the growth of the plant.

Phloëm necrosis as cause or symptom of leaf roll, R. SCHANDER and M. TIESENHAUSEN (*Mitt. Kaiser Wilhelms Inst. Landw. Bromberg*, 6 (1914), No. 2, pp. 115-124, figs. 4).—Referring to views expressed by Quanjer (*E. S. R.*, 29, p. 347), the authors state that their recent investigations, here discussed, only in part confirm the conclusions of that author. They do not regard phloëm necrosis as the cause of leaf roll of potato, but as a secondary phenomenon probably due to some functional disturbance not yet fully understood.

Wart disease of potatoes (Gard. Chron., 3. ser., 55 (1914), No. 1416, pp. 106, 107).—The text is given of the order of the British Board of Agriculture and Fisheries known as the wart disease of potatoes (infected areas) order of 1914. It relates to protection against potato canker, due to *Synchytrium endobioticum*, giving definitions, regulations, penalties, etc., with a list of resistant varieties recommended for planting on premises already infected with the disease.

Powdery scab (Spongospora subterranea) of potatoes, I. E. MELHUS (*U. S. Dept. Agr. Bul.* 82 (1914), pp. 16, pls. 3).—This is a description of the powdery scab of potatoes, which is well known in Europe, particularly in the British Isles, and which has lately been found present in parts of the United States (*E. S. R.*, 29, pp. 448, 550). A bibliography is appended.

The potato quarantine and the American potato industry, W. A. ORTON (*U. S. Dept. Agr. Bul.* 81 (1914), pp. 20, fig. 1).—After describing a number of the more destructive diseases of the potato the author gives the text of orders relating to the regulation of the importation of potatoes and the potato quarantine order. By the latter order the stoppage of potato importations from Canada and all countries of Europe for an indefinite period has been brought about largely on account of the occurrence of the powdery scab (*Spongospora subterranea*). Under certain regulations potatoes will be allowed to enter this country from nonquarantined countries when properly inspected and certified to by officials in the country of origin.

A discussion is given of the potato crop of the United States and of the desirability for utilization of surplus potatoes.

The black rust of Deli tobacco, J. A. HONING (*Bul. Deli Proefstat. Medan*, No. 1 (1914), pp. 16, pls. 2).—This disease, which is called by planters black

rust to distinguish it from another rust that is said to be of nonparasitic nature, is characterized by the occurrence of spots on the leaves, surrounded by a dark green border, indicating the extension of the diseased tissue. Usually the disease appears only in tobacco fields at higher elevations, although in wet seasons it occurs also on the lower estates. The cause of the disease is said to be *Bacterium pseudozooglææ* n. sp. A technical description of the bacterium is given and its cultural relations are described. The bacterium is said to be not strictly parasitic, but becomes so under special conditions, among which humidity is the most important.

A brief bibliography is appended.

The effect of dust from cement mills on the setting of fruit, P. J. ANDERSON (*Plant World*, 17 (1914), No. 3, pp. 57-68).—This is an account of investigations carried on by the author, a preliminary note of which has appeared elsewhere (*E. S. R.*, 27, p. 152).

Summarizing the results of the investigations, the author states that dust from cement kiln stacks containing a large amount of alkaline, soluble calcium salts was found to settle on vegetation within a radius of 2 miles from the mills. When the dust falls on fruit blossoms some of it goes into solution in the stigmatic secretions and pollen falling on the stigma will not germinate and the flowers are not fertilized. Artificial tests show that pollen will not germinate in even very weak solutions of the dust. When blossoms of apple and other fruits were dusted as fast as they opened, only a very small proportion set fruit.

Fruit culture in Normandy, J. PORTER (*Jour. Bd. Agr. [London]*, 20 (1914), No. 10, pp. 860-865, figs. 2).—Along with other information the author notes that black scab, the chief fungus pest of pears at the present time, may be prevented by frequent spraying with soda Bordeaux or Burgundy mixture during the year. In winter, however, he finds it cheaper and apparently as effective to use a 7 per cent solution of iron sulphate in place of the soda Bordeaux.

A rust new on apples, pears, and other pome fruits, P. J. O'GARA (*Science*, n. ser., 39 (1914), No. 1008, pp. 620, 621).—A description is given of a rust due to *Æcidium blasdaleanum*, the telial stage of which is said to be *Gymnosporangium blasdaleanum*, parasitic on the incense cedar of the Pacific coast. The disease was first noticed in 1908 and has since been under observation. It is said to occur rather sparingly on apples, but attacks certain varieties of pears very seriously. The rust is not roestelia-like, as in the case of the common apple rust. Its host plants, so far as known, include apple, crab apple, various pears, mountain ash, quince, serviceberry, and thorn apple.

Experiments with apple leaf spot fungi, J. W. ROBERTS (*U. S. Dept. Agr., Jour. Agr. Research*, 2 (1914), No. 1, pp. 57-66, pl. 1).—A study was made of certain leaf spot fungi to determine whether they were capable of enlarging spots already formed.

In these experiments inoculations were made both in the greenhouse and orchard on unsterilized leaves, by spraying spores on leaves which contained dead spots made by touching them with the heated end of a steel rod. It was found that under certain conditions *Alternaria mali* was able to enlarge the dead spots on the apple leaves, from which it is concluded that this species is a rather strong facultative parasite. *Coniothyrium pirinum* was found to possess but little power of enlarging dead areas and, according to the author, may therefore be classified as a saprophyte or at least as a weak facultative parasite. *Coryneum foliicolum*, *Phyllosticta limitata*, *Monochaetia mali*, and *Phomopsis mali* are, so far as the apple leaf is concerned, believed to be purely saprophytic.

A technical description of *A. mali* n. sp. is given.

Spraying experiments and apple diseases in 1913, W. J. MORSE (*Maine Sta. Bul.* 223 (1914), pp. 24, pls. 4).—This bulletin constitutes a fourth report of a series on orchard spraying experiments (E. S. R., 29, p. 145) and gives the results of the experiments and observations of 1913.

Plats of apple trees were sprayed with Bordeaux mixture, various treatments of lime-sulphur solution, soluble sulphur, atomic sulphur, arsenate of lead, and arsenite of zinc used in connection with the lime-sulphur solution. The effect of the different fungicides on the foliage and fruit was carefully noted, and the results obtained supplement those previously given for 1912.

In 1913 the efficiency of the first spray application was not as marked as in 1912. It was suggested in the previous account that a dilution of lime sulphur 20 per cent stronger than the standard could be used on Ben Davis trees with little danger of injury and greater efficiency, and the results in 1913 confirmed the conclusion based on the previous year's work. The use of Bordeaux mixture resulted in a smaller percentage of scabby apples, but a larger proportion of those which were russeted. The use of lime sulphur gave a very efficient control of scab and the fruit was less injured than where Bordeaux mixture was employed. Soluble sulphur used at the rate of 2 lbs. to 50 gal. of water produced severe leaf injury, although it appeared to be fairly efficient so far as the control of apple scab was concerned. The use of atomic sulphur was followed by satisfactory results, no spray injury being observed, but the author does not consider its recommendation warranted without further test.

A description is given of the use of arsenate of lead as a fungicide, and where 2 lbs. of dry arsenate of lead was used in 50 gal. of water the control of the scab was better than on the other trees except those sprayed with Bordeaux mixture and the stronger lime-sulphur solution. This would indicate a strong fungicidal action for arsenate of lead, and it is thought probable that efficient scab control with a minimum of fruit russeting might be obtained by its use, supplemented by Bordeaux mixture or a strong lime-sulphur solution used as a dormant spray.

An account is given of investigations on the source of spring infection by apple scab, previously noted (E. S. R., 30, p. 542).

Notes are also given on the observance of *Nectria ditissima* in Maine.

Some observations on the anatomy and other features of the black knot, A. STEWART (*Amer. Jour. Bot.*, 1 (1914), No. 3, pp. 112-126, pls. 2).—This is a more detailed account of work reported previously (E. S. R., 30, p. 150).

Court-noué, S. BARRY (*Prog. Agr. et Vit. (Ed. l'Est-Centre)*, 35 (1914), No. 5, pp. 146, 147).—The author, giving briefly his experience in grape culture, covering some 50 years, states that while some vines under his care have been somewhat subject to court-noué for many years without very serious damage, others, including some vines of later planting, have suffered severely. A portion of the latter are now being given a trial with the coal tar treatment.

The downy mildew of the grape, G. HÉRON (*Jour. Agr. Prat. Vit. et Écon. Rurale Midi France*, 109 (1913), No. 5, pp. 192-204).—An account is given of the author's experiments for the control of the downy mildew by the use of Burgundy mixture.

On the basis of the results which he secured, he recommends the use of a freshly prepared mixture containing 2 per cent copper sulphate, or in very humid years a 3 per cent mixture. For successful control frequent applications of the fungicide should be made at the beginning of the appearance of the disease, and it is stated that the different sprayings may be profitably alternated with treatments with copper acetate or a simple solution of copper sulphate.

For proper spraying the fungicide should be applied under sufficient pressure to thoroughly vaporize the solution. In order better to cover the grapes, the removal of some of the leaves on the vine is recommended.

Comparative tests of different fungicides for the control of the downy mildew of grapes, J. MAHOUX (*Rev. Vit.*, 41 (1914), No. 1049, pp. 91-94).—The author reports upon the comparative value of a dozen fungicides for the control of the downy mildew of grapes, comparisons being made with ordinary Burgundy mixture.

The season of 1913 is said to have been a very favorable one for the development of the fungus. The best results were obtained with Burgundy mixture, to which were added casein, saponin, and gelatin to increase the spreading power of the mixture, copper acetate solution, and an iron-copper sulphate solution. Ordinary Burgundy mixture gave nearly as good results, but the others tested were not favorable in their action, especially if used in more dilute strengths than advocated by their manufacturers. When sprayed upon the upper side of the foliage, as is most commonly done, none of the mixtures showed any superiority over ordinary Burgundy mixture if the amount of copper in them was less than that in the Burgundy mixture. Where the more adhesive fungicides are used, the author recommends that they should be applied from below and in such quantities as are necessary to cover the leaves and grapes. He claims there is no economy in attempting to lower the cost by reducing the amount of fungicide used in seasons that are favorable for the growth of the fungus.

Notes on diseases of citraceous plants, E. JARVIS (*Queensland Agr. Jour.*, n. ser., 1 (1914), No. 4, pp. 268-271).—As the result of recent investigations the author has found a number of diseases of citrus trees, and he describes a collar rot due to *Fusarium limonis*, a root rot caused by *Armillaria* sp., and a gumming disease, the cause of which is not definitely stated. In connection with these disease preventive measures are suggested for their control.

Some notes on the scab of grapefruit, G. L. FAWCETT (*Porto Rico Prog.*, 6 (1914), No. 22, pp. 6, 7).—A brief description is given of the scab of grapefruit. This the author says may be controlled by spraying with Bordeaux mixture, but as the use of the fungicide would tend to destroy beneficial fungi which hold in check scale insects, it is not thought advisable to spray except as a last resort, in which case an insecticide should follow the use of a fungicide. Control measures involve the removal of any growth that is infected, and he states that fungi occurring on cover crops, such as pigeon peas and the sword bean, will produce scabs resembling the true citrus scab. As yet no definite connection between these diseases has been determined.

The author states that his attention has recently been called to the claims that *Diplodia natalensis* causes considerable decay on fruit shipped from Porto Rico, but that he has been unable to discover it in typically affected specimens. The fruits were, however, infected with the well-known withertip fungus (*Colletotrichum glaucosporioides*).

[A fungus disease of coffee] (*Planters' Chron.*, 9 (1914), No. 3, pp. 32, 33).—An injurious disease of coffee trees is described as noted in the Province of Coorg, British India. It is said to occur in patches on the collar of the trees with little or no tendency to spread, but all the trees affected are usually killed, as are young healthy trees planted in their places, the fungus remaining active in the soil. It is thought the organism may be *Irpex flavus*. Remedial measures recommended include burning all affected wood, heavy liming of the soil, use of Bordeaux mixture painted on the stems, and the free admission of light and air to the affected parts.

Orobanche cumana on sunflower, A. MAL'TSEV (*Trudy Bûro Prikl. Bot. (Bul. Angew. Bot.)*, 6 (1913), No. 2, pp. 111-120).—The author reports the parasitism of the above species of Orobanche on the sunflower (*Helianthus annuus*). The spread of the parasite is said to be restricted somewhat by *Phytomyza orobanchia*.

California thistle rust, A. H. COCKAYNE (*Jour. Agr. [New Zeal.]*, 8 (1914), No. 1, pp. 50-53, fig. 1).—A description is given of *Puccinia suaveolens*, which is said to have become established in New Zealand where it is restricted to the California or Canada thistle (*Cnicus arvensis*) and the cornflower (*Centaurea cyanus*). The fungus is thought to be probably of some value in combating the thistle, but success in its spread will depend upon the ability to obtain artificial infections, and for this purpose studies are needed to determine the proper stage in the growth of the plant. The author believes that the best time for successful inoculation would be while the growth of healthy plants is quite young.

The symptoms of chestnut tree blight and a brief description of the blight fungus, F. D. HEALD (*Penn. Chestnut Tree Blight Com. Bul.* 5 (1913), pp. 15, pls. 16).—The author has given a description of the chestnut blight, the fungus causing it, symptoms of the disease, effects, methods of spread, etc.

Longevity of pycnospores of the chestnut blight fungus in soil, F. D. HEALD and M. W. GARDNER (*U. S. Dept. Agr., Jour. Agr. Research*, 2 (1914), No. 1, pp. 67-75; *abs. in Phytopathology*, 4 (1914), No. 1, pp. 51, 52).—A report is given of investigations made to determine the power of resistance of the pycnospores of the chestnut blight fungus to desiccation in the soil under field conditions during the intervals between rains and during a prolonged period of drying in the laboratory.

In the field test samples of soils taken from bases of diseased trees after a rain and after 13 days' drying gave from 84,000 to 2,412,000 viable spores per gram of soil. When dried in the laboratory there was a gradual decrease in the viable spores, the longevity limit varying from 54 to 119 days.

Pine rust and its transmission, HAACK (*Ztschr. Forst u. Jagdw.*, 46 (1914), No. 1, pp. 3-46, pls. 2, fig. 1).—This is an account of studies continued from 1906 to 1913 at Eberswalde on questions connected with *Peridermium pini*.

This disease is said to appear most commonly in young foliage-bearing branches, each center being due apparently to a separate infection. The fungus is said to proceed directly from pine to pine by means of æcidiospores, requiring no intermediate host and infection occurring mostly between May 15 and July 1. Injuries to the young vegetation are thought to aid greatly the attack. Some trees appeared to be especially susceptible, some to be nearly immune to the fungus. Shoots may live some time after being seriously attacked.

Thoroughgoing removal of affected parts in case of young trees and cutting out badly diseased older trees are insisted upon as means of greatly minimizing the damage, which otherwise is considerable.

An unusual case of electrical injury to street trees, G. A. CROMIE (*Sci. Amer. Sup.*, 77 (1914), No. 1985, pp. 36, 37, figs. 5).—Several examples are discussed of injury to trees by electrical currents, especially in one case following a change of the negative or return current to the overhead wire. Insulation decreased the injury done. Chemical analysis showed traces of copper and zinc in sections of wood taken some distance from the point of contact with the wire containing both these metals, which was always found to be partly eaten away at that point.

Notes on the preparation of insecticides and fungicides, V. VERMOREL and E. DANTONY (*Notes sur les Préparations Insecticides, Fongicides et Bouillies Mouillantes. Montpellier and Villefranche* [1914], pp. 58).—In this publication

a résumé is given of investigations carried on at the viticultural station at Villefranche during the past three years on insecticides, fungicides, adhesives, etc. Most of the articles referred to have been noted previously.

ECONOMIC ZOOLOGY—ENTOMOLOGY.

Comparative physiology of invertebrates, H. JORDAN (*Vergleichende Physiologie Wirbelloser Tiere*. Jena, 1913, vol. 1, pp. XXII+738, figs. 277; rev. in *Science*, n. ser., 38 (1913), No. 971, pp. 197-199).—This first volume deals with nutrition.

The common mole of the eastern United States, T. H. SCHEFFER (*U. S. Dept. Agr., Farmers' Bul. 583* (1914), pp. 10, figs. 4).—This is a popular account of the common mole, its habits, nature of its injury, control measures, etc. A report of the author's studies of the common mole has been noted (*E. S. R.*, 23, p. 752).

This mole (*Scalopus aquaticus*) is found almost everywhere south of the New England States, New York, Michigan, and central Wisconsin, except in the mountain regions. In the latter districts and in the greater part of Pennsylvania, New York, and New England the common mole is replaced by the star-nosed mole (*Condylura cristata*) and Brewer's mole (*Parascalops breweri*).

Work of California gray squirrel on conifer seed in the southern Sierras, S. BERRY (*Proc. Soc. Amer. Foresters*, 9 (1914), No. 1, pp. 95-97).—The California gray squirrel (*Sciurus griseus*) is said to be very numerous throughout the yellow and sugar pine regions of the southern Sierras during the summer months, and apparently devotes a large portion of its time to cutting pine cones. During the summer of 1910 it was observed in the act of cutting sugar pine cones over widely distributed areas within the Sierra and Sequoia National Forests during the first days of June. The squirrels are continuously at work destroying seed for a period of 3 months prior to September 1, and any seed dropped or scattered during this period is yet immature and will not germinate. Thus it appears that in the destruction of so large an amount of seed the California gray squirrel is not only a serious menace to reproduction and hinders the forestation of idle land, but its work causes the reproduction to consist mostly of the less valuable species, due to the fact that the seed of sugar pine and yellow pine is the most frequently eaten, while seed of inferior species like fir and cedar is not touched when the others can be found. It is, therefore, thought desirable that the present game laws be so amended as to remove the protection from the California gray squirrel, at least in counties where there is coniferous timber.

Squirrels and sugar pine reproduction, E. V. JOTTER (*Proc. Soc. Amer. Foresters*, 9 (1914), No. 1, pp. 98-101).—This paper relates to the destruction of sugar pine seed by squirrels, as noted above.

[Habits of pheasants], G. W. FIELD, G. H. GRAHAM, and W. C. ADAMS (*Mass. House Representatives Doc. 2049* (1914), pp. 14; abs. in *Auk*, 31 (1914), No. 2, pp. 271, 272).—This special report of the Massachusetts Board of Commissioners on Fisheries and Game relative to the habits of pheasants includes a summary of the history of introduced pheasants within the State, value, methods adopted in rearing, etc.

The nutrition and habits of the angleworm in its relation to agriculture, E. KEUP (*Mitt. Deut. Landw. Gesell.*, 28 (1913), Nos. 39, pp. 538-542; 40, pp. 552-555; 41, pp. 466-570).—A report of studies.

Helminthological investigations, C. GRAVIER (*Rev. Gén. Sci.*, 25 (1914), No. 4, pp. 149-160).—This is a review of studies of plathelminths, nematodes, Acanthocephala, etc., published during the years 1909-1911, inclusive.

Economic zoology (*Ann. Rpt. Bd. Sci. Advice India, 1911-12, pp. 160-171*).—The first part of this paper by H. Maxwell-Lefroy deals with agricultural entomology; the second part by A. D. Imms with forest entomology.

The life story of insects, G. H. CARPENTER (*Cambridge, England, and New York, 1913, pp. 134, pl. 1, figs. 23*).—This is a popular account.

Report of the entomologist of the Arizona Commission of Agriculture and Horticulture for the year ending June 30, 1913 (*Ariz. Com. Agr. and Hort. Ann. Rpt., 5 (1913), pp. 11-48, pls. 3, figs. 11*).—The first part of this report (pp. 11-32), by A. W. Morrill and O. C. Bartlett, relates to the inspection of plant, fruit, and seed importations; the second part (pp. 33-48), by A. W. Morrill, consists of notes on the important insects of the year.

Forty-fourth annual report of the Entomological Society of Ontario, 1913 (*Ann. Rpt. Ent. Soc. Ontario, 44 (1913), pp. 131, figs. 58*).—Among the more important papers here presented are Insects of the Season in Ontario, by L. Cæsar (pp. 49-53); The Immature Stages of the Tenthredinoidea, by A. D. MacGillivray (pp. 54-75); Adaptation in the Gall Midges, by E. P. Felt (pp. 76-82); Chrysomelians of Ontario, by F. J. A. Morris (pp. 83-94); and Insect Galls, by A. Cosens (pp. 97-104).

Tuberculosis in insects, S. METALNIKOFF (*Compt. Rend. Soc. Biol. [Paris], 76 (1914), No. 2, pp. 95, 96; abs. in Rev. Appl. Ent., 2 (1914), Ser. B, No. 3, pp. 53, 54*).—In earlier papers (*E. S. R., 20, p. 186; 26, p. 250*) the author has shown that the tubercle bacillus when injected into the larva of the bee moth (*Galleria mellonella*) is quickly destroyed and the larva not affected. Further experiments have shown that this destruction of the bacillus is due probably to a lipolytic ferment in the body of the larva.

Experiments have also been carried on with other insects, particularly with caterpillars of *Achræa grisella*, which also feed upon the wax in beehives. Bacilli of the human type when injected in large numbers were all destroyed within a few hours. Tests of other types showed that the bovine type is quickly destroyed but the fish type cause the infection and death of the larvæ at ordinary room temperature. When the temperature was raised to 35° C. the injected fish bacilli were destroyed.

Insect damage to Russian crops (*Izv. Glav. Uprav. Zemleusgrois. i Zeml. [St. Petersburg], No. 30 (1913); abs. in Rev. Appl. Ent., 1 (1913), Ser. A, No. 11, pp. 458, 459*).—The insects mentioned as the source of injury include the Hessian fly, the wheat chafer (*Anisoplia austriaca*), the larvæ of *Phlyctænodes sticticalis* which damages the seeds of vetches, maize, beets, etc., aphids, thrips, wireworms, and cutworms.

The fight against *Lachnus persicæ*, termites, and ants by means of carbolineum, D. SMIRNOV (*Turkest. Selsk. Khoz [Tashkend], No. 8 (1913), pp. 783-786; abs. in Rev. Appl. Ent., 2 (1914), Ser. A, No. 2, pp. 73, 74*).—The author reports excellent results from the use of carbolineum in combating plant lice (*L. persicæ*), termites (*Hodotermes turkestanicus*), and ants (*Camponotus maculatus turkestanicus*), the carbolineum acting as a repellent.

Tables for the identification of insect enemies of spruce and fir, R. KOCH (*Tabellen zur Bestimmung schädlicher Insekten an Fichte und Tanne nach den Frassbeschädigungen. Berlin, 1910, pp. VIII+112, figs. 150*).—These tables are based upon the feeding habits of the insects.

The insects attacking cork stoppers, J. FEYTAUD (*Rev. Vit., 40 (1913), Nos. 1039, pp. 565-568, pl. 1, figs. 2; 1040, pp. 598-603, figs. 4; 1045, pp. 738-740*).—A summarized account of the more important enemies of cork stoppers, which represent the Coleoptera, Isoptera, and Lepidoptera and means for their control. The tineids are said to be the most important pests.

The Hevea termite of Java, K. W. DAMMERMAN (*Dept. Landb., Nijv. en Handel [Dutch East Indies], Meded. Afdel. Plantenziekten, No. 3 (1913), pp. 12, pls. 2, figs. 2*).—This paper includes an account of the occurrence, injury, life history, and methods of combating *Coptotermes gestroi*, together with a list of its host plants.

The cranberry toad-bug, F. A. SIRRINE and B. B. FULTON (*New York State Sta. Bul. 377 (1914), pp. 91-112, pls. 8, figs. 4*).—The cranberry toad-bug, a fulgorid (*Phylloscelis atri*), is reported to have caused a peculiar dying of the new growth of cranberry vines on Long Island prior to and during 1911 and 1912. It does not appear to be widely disseminated, and many bogs are practically free from it; but on two Long Island bogs, one at Riverhead and one at Calverton, the crop of fruit had been greatly reduced, the loss varying from one-half to three-fourths of a normal crop during the past three years. Wherever the insects feed on the new growth both new shoots and fruit are killed outright; while if they happen to feed only on the old wood the berries on all branches beyond the feeding point are shriveled and dwarfed.

A brief discussion of the synonymy of the species is followed by a technical description of the life stages, notes on its life history and habits, effect of its feeding on vine and fruit, enemies, and experiments with methods of control. It is stated that the cranberry appears to be the only host plant of this insect.

“There is but one brood of the insects during the year. The egg is elongate-oval in shape, with a short stalk at one end. The egg-laying period extends from September 1 to the middle of October. The female runs over the ground, dragging the egg by the stalked end, so that its viscid surface becomes covered with sand and dirt before it is dropped. Hatching begins on June 25 to 30 of the following summer, and a few may not hatch until early in August. Nymphs usually group together to feed, and may live a long time on the same branch if not disturbed. The insect has five nymphal instars. The first adults appear about the first of August, the males maturing first.

“The nymphs secrete a white, cottony substance which adheres to the branch, and this, with the excrement and molted skins, is more easily detected than the insect. The first symptom of injury is the closing in toward the branch of the leaves on the new growth.

“Tests were made of two methods of control, flooding and spraying. Of these, the former is recommended where it is possible, and should be practiced between August 1 and 15. All weeds on and near the bog should be cut. A cloudy period should be selected, and a good wind favors efficient control. Bugs on the surface of the water should be sprayed with kerosene. All grass, weeds, and drift on the shore should be burned with a burning torch-spray.

“Spraying is the only possible remedy on ‘dry bogs.’ When the vines contain much old wood they should be mowed at the usual season for cutting and, between August 1 and 15, sprayed with soap solution, 1 lb. to 7 gal., making two applications, using 200 gal. per acre.”

Preliminary studies on the biology of the bedbug (*Cimex lectularius*).—III, Facts obtained concerning the habits of the adult, A. A. GIRAULT (*Jour. Econ. Biol., 9 (1914), No. 1, pp. 25-45*).—This third part of the paper previously noted (*E. S. R., 28, p. 654*) deals with biological observations of the adult.

The chinch bug in Ontario, H. F. HUDSON (*Canada Expt. Farms Ent. Circ. 3 (1914), pp. 13, figs. 3*).—A general account of this pest, a serious outbreak of which occurred in Ontario in 1911.

Burn the bugs (*Oklahoma Sta. Circ. 24 (1913), p. 1, fig. 1*).—This circular first presents the governor’s proclamation designating December 18, 1913, as a day to be observed in destroying all hiding places in which chinch bugs had

sought winter quarters. This is followed by suggestive rules prepared by the entomologist, C. E. SANBORN, relative to burning hibernating places.

Currant and gooseberry aphids in Maine, EDITH M. PATCH (*Maine Sta. Bul.* 225 (1914), pp. 49-68, pls. 4, figs. 11).—Eight species of plant lice which have been found feeding upon currants and gooseberries in Maine are here described, three, namely, *Aphis varians*, *A. sanborni*, and *Myzus dispar*, being new to science. It is stated that none of the eight appears to pass the whole of its life cycle on currants or gooseberries.

Part 4 of a food plant catalogue of the Aphidæ of the world (E. S. R., 30, p. 854) is appended (pp. 61-68).

Suppression of the cottony cushion scale in Louisiana, E. S. TUCKER (*Louisiana Stas. Bul.* 145 (1914), pp. 2-8, figs. 3).—The cottony cushion scale (*Icerya purchasi*) was first observed in Louisiana in October, 1912, on a row of small orange trees adjacent to a nursery near New Orleans. The trees were destroyed and the pest was thought to have been eradicated but in June of the following year it was found in groves of orange, mandarin, and tangerine trees on three private estates of about 5 acres in extent. Spraying tests were made with different sprays and sprayers but inspections made in each case about two weeks after application showed a few scales to have escaped. Thus it was necessary to cut and burn all trees and other infested vegetation. It is thought that kerosene emulsion to which potassium cyanid has been added at the rate of 1 oz. to each gallon of the stock emulsion may eradicate the scale if applied in the early stages of infestation. A brief description is given of the pest, its food plants, natural enemies, etc. There is said to be no authentic record of the occurrence of this pest in Louisiana prior to 1912.

Coccidæ of Japan, V. S. I. KUWANA (*Jour. Ent. and Zool.*, 6 (1914), No. 1, pp. 1-11, figs. 39).—This fifth part (E. S. R., 23, p. 54) presents descriptions of 8 species of Coccidæ new to science.

Euxoa segetum and how to combat it, A. SOPOTZKO (*Chto Takoe Ozimyi Cherv i Kak s Nim Borot'siû. Moscow: Ent. Sta. Zemstvo Govt. Tula, 1913, pp. 11, pl. 1, figs. 2; abs. in Rev. Appl. Ent.*, 1 (1913), Ser. A, No. 11, pp. 462, 463).—This is a popular description of *E. segetum*, which is said to have destroyed 270,000 acres of crops in the Government of Tula, Moscow, in 1909, with an equal damage in some neighboring governments. Accounts of its life history, diseases, parasites, and methods of combating it are included.

On the appearance in Bessarabia of Clysia ambiguella, N. VITKOVSKY (*Reprint from Vîestnik Vinodîel.*, No. 7 (1913), pp. 3; *abs. in Rev. Appl. Ent.*, 1 (1913), Ser. A, No. 11, p. 461).—This enemy of the vine is said to occur in great numbers in Bessarabia, Crimea, Caucasus, and the Government of Astrakhan.

The appearance of Phlyctænodes sticticalis in increasing numbers, and also of the larvæ of Cassida nebulosa, E. M. VASSILLIEV (*Trudy Opytn. Ent. Stantsii Vseross. Obshch. Sakh. Zavod. [Kief], 1912, pp. 31-45, figs. 5; abs. in Rev. Appl. Ent.*, 2 (1914), Ser. A, No. 2, p. 63).—This presents biologic and economic data.

Tortrix forskaleana, I. TRÄGÅRDH (*Meddel. Centralanst. Försöksv. Jordbruksområdet*, No. 15 (1914), pp. 20, figs. 17).—An account of the life history of this tortricid enemy of the maple based upon studies made in the vicinity of Stockholm.

On German gall flies and galls, E. H. RÜBSAAMEN (*Ztschr. Wiss. Insektenbiol.*, 6 (1910), Nos. 4, pp. 125-133; 6-7, pp. 199-204; 8-9, pp. 283-289; 10, pp. 336-342; 12, pp. 415-425; 7 (1911), Nos. 1, pp. 13-16; 2, pp. 51-56; 3, pp. 82-85; 4, pp. 120-125; 5-6, pp. 168-172; 9, pp. 278-282; 11, pp. 350-353; 12, pp. 390-394;

8 (1912), Nos. 2, pp. 48-51; 3, pp. 97-102; 5, pp. 157-162; 6-7, pp. 214-218; 8-9, pp. 284-289; 11, pp. 354-357; 12, pp. 376-379, figs. 73).—This account includes descriptions of many new genera and species of Itonididæ (Cecidomyiidæ).

On a method of fighting *Psila rosæ*, E. M. VASSILIEV (Reprint from *Sadovod i Ogorodnik* [Kief], 1913, pp. 6; abs. in *Rev. Appl. Ent.*, 1 (1913), Ser. A, No. 11, p. 463).—This circular relates to the carrot fly which occurs in the neighborhood of St. Petersburg and Moscow, and in the Government of Moghilef and Poland.

Controlling flies, A. F. CONRADI ET AL. (*South Carolina Sta. Circ.* 23 (1913), pp. 14, figs. 6).—This general account, with control measures for the house and stable fly, includes a report of work carried on with traps and sprays during the season of 1913. Laboratory tests in spraying manure showed that 98 per cent of the maggots were killed in 24 hours with a solution of arsenite of soda 4 lbs., molasses 2 qt., and water 50 gal.

Corn-leaf blotch miner, W. J. PHILLIPS (*U. S. Dept. Agr., Jour. Agr. Research*, 2 (1914), No. 1, pp. 15-31, pls. 5, figs. 6).—While the corn-leaf blotch miner (*Agromyza parvicornis*) up to the present time has not proved to be a serious pest, mainly because of the large number of parasites that attack it, it is pointed out that considerable injury may be done in their partial absence.

In young corn plants and in the small grasses and grains the larvæ work from the tip of the leaf toward the base, devouring all of the tissue between the upper and lower epidermis. In small plants the larvæ work the entire width of the leaf, leaving only the epidermis of the upper and lower surfaces. Soon after the work is done the leaves have a colorless appearance and in a few days they turn brown and curl up. One larva is said to be sufficient to destroy a young corn leaf although as many as four have been found in a single leaf in the field and as many as eight or ten in a leaf in the rearing cages. When the plants become older and tougher the miners do not devour all the tissue between the two leaf surfaces, thus the greatest injury is wrought when the plants are young. If very abundant, however, the larvæ could cause serious injury to corn in advanced stages of growth.

The species seems to show a preference for corn, next to which it prefers the broad hairy-leaved varieties of millet. Occasionally it is found in crab-grass (*Panicum sanguinale*), and breeds readily in barnyard grass (*Echinochloa crus-galli*). This leaf-miner has quite a wide range of distribution, having been found as far north as Wisconsin, as far east as Washington, D. C., and New England, as far south as Alabama and Florida, and as far west as Salt Lake City, Utah, as well as in Texas, and probably occurs throughout the United States wherever corn is grown.

The author presents a technical description of the several stages of this insect and a somewhat detailed report of its life history and natural enemies. The incubation period of the egg may be as short as 80 hours in the latter part of July. In midsummer the larvæ have been found to obtain full growth in 4 days while the pupal stage may be as short as 14 days. From 30 to 60 eggs have been observed to be deposited. Observations show that there are 4 complete generations and a part of a fifth. In the latitude of La Fayette, Ind., at least, it passes the winter in the puparium only. Brief notes are also given on its life history in Florida based on observations by G. G. Ainslie.

The author reports that there are 18 species of hymenopterous parasites which attack *A. parvicornis*, 3 being braconids and 15 chalcidoids. Of these parasites *Derostenus diastatae* is by far the most abundant and probably the most important. *Diaulinus websteri* and *D. begini* have also been reared quite plentifully and are probably next in importance. Notes are presented on the

18 parasites, the life history of none of which has been worked out completely. It is stated that on no occasion have remedial measures been required.

A bibliography of 12 titles is appended.

A new species of grass grub.—A serious pest of seedling forest trees, A. H. COCKAYNE (*Jour. Agr. [New Zeal.]*, 6 (1913), No. 3, pp. 295–298, fig. 1).—A new scarabæid pest, a description of which under the name *Odontria puncticollis* by Broun is appended, is said to be the source of considerable loss in the seedling beds at the state forest nurseries at Whakarewarewa through the destruction of the roots of the young trees by the larvæ.

The life history and bionomics of *Cryptorhynchus lapathi*, F. SCHEIDTER (*Naturw. Ztschr. Forst u. Landw.*, 11 (1913), No. 5–6, pp. 279–300, figs. 6).—A report of the biological studies of the poplar and willow borer.

On the biology of *Tropinota turanica*, N. N. TROÏTZKY (*Reprint from Jour. Agr. Turkest. [Tashkend]*, No. 6 (1913), pp. 18, figs. 2; *abs. in Rev. Appl. Ent.*, 1 (1913), Ser. A, No. 11, pp. 437, 438).—This cetoniid beetle is a prominent and regular pest of orchards in Tashkend, injuring the blossoms of apricots, cherries, thorns, apples, pears, strawberries, etc. It attacks only the unfertilized blossoms, eating away the ovaries, pistils, and stamens, but doing no great damage to the petals. The injury is done only by the perfect insect, the eggs being laid in the fields, where the larvæ feed on roots of various plants.

On an egg-eating parasite of *Rhynchites auratus*, N. N. TROÏTZKY (*Reprint from Jour. Agr. Turkest. [Tashkend]*, No. 5 (1913); *abs. in Rev. Appl. Ent.*, 1 (1913), Ser. A, No. 11, pp. 436, 437).—A chalcidid, apparently belonging to the genus *Oophthora*, is said to have parasitized 88 per cent of the eggs of this weevil in Tashkend in 1912.

Contributions to our knowledge of the British Braconidæ.—I, Meteoridæ, G. T. LYLE (*Entomologist*, 47 (1914), Nos. 610, pp. 73–77, pl. 1; 611, pp. 119–125).—The author states that he knows of no instance of a meteorid hibernating in the perfect state. With several species the winter is passed within the body of the host, either as an ovum or young larva, and with a few others as a larva within the cocoon.

Life histories of Indian insects.—IV, Hymenoptera, G. R. DUTT (*Mem. Dept. Agr. India, Ent. Ser.*, 4 (1912), No. 4, pp. 183–267, pls. 4, figs. 22).—This part (E. S. R., 26, p. 654) deals with the life histories of various species of Hymenoptera, including species of the families Mutillidæ, Thynnidæ, Scoliidæ, Pompilidæ, Sphegidæ, Eumenidæ, Apidæ, and Formicidæ.

Spider enemies of bees, R. J. LEVANDOVSKY (*Russ. Pchelovod. Listok [Moscow]*, 1913, Nov., pp. 378–387; *abs. in Rev. Appl. Ent.*, 2 (1914), Ser. A, No. 2, pp. 64, 65).—A report of personal observations with a list of the spiders implicated.

Bryobia prætiosa, I. TRÄGÅRDH (*Meddel. Centralanst. Försöksv. Jordbruk-sområdet*, No. 17 (1914), pp. 24, figs. 7).—A review of the literature leads the author to conclude that the different species described under the names of *prætiosa*, *speciosa*, *nobilis*, *gloriosa*, *ribis*, and *pratensis* must be referred to *prætiosa* K., being mere variations and different instars of that species. This pest is said to be found all over Europe, southward as far as Egypt, northward to the arctic regions, and in the United States.

Transmission of *Trypanosoma cruzi* by *Rhipicephalus sanguineus*, A. NEIVA (*Abs. in Bul. Inst. Pasteur*, 12 (1914), No. 1, pp. 45, 46).—Five male ticks (*R. sanguineus*), detached after death from a dog that had been inoculated with *T. cruzi* and was also infected with *Piroplasma vitali*, were placed upon a healthy dog and 19 days later the latter dog was found to be infected with *T. cruzi*.

Rocky Mountain spotted fever, L. D. FRICKS (*Pub. Health Rpts. [U. S.]*, 29 (1914), No. 17, pp. 1008-1020).—This progress report, dealing with investigations made during 1912 by the late T. B. McClintic, relates to infective ticks in nature, the discovery of immune ground squirrels (*Citellus columbianus*), susceptibility and immunity experiments with woodchucks (*Marmota flaviventer*), etc.

The experiments seem to indicate that a tick attaching itself to a woodchuck at any time within a period of 11 days after its inoculation would become infected. In a series of experiments with rock squirrels (*Callospermophilus lateralis cinerascens*), which had been injected with spotted fever virus, four transmitted the infection to guinea pigs through the injection of 0.75 cc. of heart blood on the fifth day.

It is stated that there is no evidence to support the belief that the mountain goat can acquire or transmit Rocky Mountain spotted fever infection.

FOODS—HUMAN NUTRITION.

On certain changes in the composition of the nitrogenous constituents of meat extracts, A. M. WRIGHT (*Trans. New Zeal. Inst.*, 43 (1910), pp. 7, 8).—Analyses are reported of extract liquor before concentration, of extract prepared in an open pan, and of extract prepared in a partial vacuum, and the differences in the chemical composition between the resulting product and the original substance discussed.

In the case of the extract made by the vacuum method, "the proportion of the organic matter decreases, while the mineral salts increase; otherwise the composition of the vacuum-evaporated extract is very nearly that of the original liquor calculated to a 20 per cent moisture content, the acidity, insoluble and coagulable proteids, proteoses, and total meat bases being present in about the same amounts in each case. In the original liquor there were no peptone-like bodies, whereas in the vacuum-concentrated extract there were found 0.31 per cent of these substances.

"The extract concentrated in the open pan is very different in composition from either the original liquor or the vacuum extract: The proportion of the organic matter has decreased, and the mineral salts increased considerably; the total nitrogen remains about the same, but the forms in which the nitrogen is present have undergone considerable change; about three-fifths of the insoluble and coagulable proteids have been rendered soluble and converted to other nitrogenous substances; there is a decrease in the amounts of proteoses and meat bases; while against these decreases there is found 8.69 per cent of peptone-like bodies which are absent in the original liquor, and present in the vacuum extract to only 0.31 per cent. The acidity has increased by over 3 per cent.

"The peptone-like bodies and polypeptids are bitter in taste, and it is found that extracts containing relatively large amounts of these bodies have a decidedly bitter taste. . . .

"As but very small amounts of peptone-like bodies are present in vacuum-concentrated extract, and but little change in the composition of nitrogenous bodies is found, it is probable that the prolonged action of heat on the nitrogenous material in the presence of the normal flesh acids and salts, the amount of which increases as the evaporation proceeds, is the cause of the marked change in composition found in the open pan concentrated extract. The so-called 'burned' flavor sometimes found in meat extracts is doubtless due to the same cause, for in vacuum-concentrated extract no such undesirable flavor is noted."

The chemical composition of meat extract, A. M. WRIGHT (*Trans. New Zeal. Inst.*, 43 (1910), pp. 1-6).—Analytical data are reported of meat extract, including mineral matter as well as other constituents, and a yeast extract, and the results discussed. The meat extract, the author points out, has little food value, but he regards it as "most valuable as a dietary adjunct."

The food value of skim milk and the nutritive value of condensed skim milk (*Riv. Sci. Lattc.*, 3 (1913), No. 5, pp. 71-78).—The relative cost and nutritive value of skim milk and a number of other common food materials are compared. A comparison is also given of the nutritive ratios of several brands of condensed skim and whole milks.

Eggs considered from the point of view of food value, L. DELAYE (*Bul. Soc. Salubrité, Prov. Liège*, 16 (1913), pp. 67-85; *Bul. Soc. Chim. Belg.*, 27 (1913), Nos. 8-9, p. 236; 12, pp. 310, 311).—The nutritive value of eggs is discussed and statistics regarding egg production, particularly in Belgium, are given.

Lard, A. MCGILL (*Lab. Inland Rev. Dept. Canada Bul.* 272 (1913), pp. 21).—Out of 182 samples purchased in Canada, 169 were found to be genuine. Eight of the remainder were adulterated and three contained an excess of water. The adulteration in all cases consisted of added foreign fat of vegetable origin.

Vegetable foods; their distinctive characteristics and classification, H. H. RUSBY (*Jour. N. Y. Bot. Gard.*, 15 (1914), No. 169, pp. 1-5).—A summary of a lecture delivered at the New York Botanical Garden calling attention, among other things, to the similar nutritive value of foods derived from the same general botanical family. The author outlines briefly a system of calculating the nutritive value of rations, employing a method which involves the expression of the nutritive value of foods by their equivalents in carbohydrates, but does not take into account the twofold function of nitrogenous foods.

The digestion of vegetable foods, W. J. GIES (*Jour. N. Y. Bot. Gard.*, 15 (1914), No. 169, pp. 5-9).—In this abstract of a lecture delivered at the New York Botanical Garden the author summarizes in schematic form data regarding digestibility.

Gastric digestion of the proteins of bread and raw meat in man, E. ZUNZ and M. CERF (*Bull. Acad. Roy. Med. Belg.*, 4. ser., 27 (1913), No. 6, pp. 552-581).—The problem was studied with normal men and women, with subjects with cancer of the stomach, and with laboratory animals (dogs and a cat). Horseflesh was used in the experiments with man and beef or horseflesh in the tests with laboratory animals. In the tests with man the stomach contents were removed and examined an hour after the ingestion of raw meat, raw meat and bread 3:1, and raw meat and bread 1:1. Data are given regarding the kind and proportion of the different proteids found in the stomach contents in each test.

The authors conclude that in normal individuals about 60 per cent of the protein was unchanged (i. e., was still coagulable). Of the remainder, or incoagulable portion, acid albumins made up from 7 to 14 per cent; proteoses, from 60 to 65 per cent; and peptones and polypeptids, a little over 25 per cent. Judging by the results obtained, gastric digestion does not proceed so far in normal man as in the dog.

The chemical composition of a number of corn-meal products and the digestibility of the nitrogenous material by pepsin and hydrochloric acid, in comparison with the digestibility of protein substances in certain other cereals and legumes, O. RAMMSTEDT (*Arch. Hyg.*, 81 (1913), No. 6, pp. 286-306).—Proximate analyses are reported as well as more detailed analyses of the protein, carbohydrate, and phosphorus content of different samples and also the results of artificial digestion experiments. A feature of this work was the

comparison of corn, wheat, and rye products cooked in water and in milk with similar products uncooked, with reference to the digestibility of protein substances and with respect to changes in the total sugar and other water-soluble material.

According to the author's summary, corn-meal products as compared with other vegetable foodstuffs are relatively rich in protein, fat, and carbohydrates, and in respect to the digestibility of their constituents are directly comparable with other cereals and with legumes. The corn products are cheaper than similar products from wheat and rye. Furthermore, a very great variety of palatable dishes can be prepared from corn meal in relatively simple ways without waste. As is the case with other foods, the protein is rendered somewhat less soluble by cooking. On the other hand, the carbohydrates are naturally rendered more soluble. The latter is more conspicuously the case with the carbohydrates of wheat and rye than with the carbohydrates of corn products. However, one can obtain as good results with corn meal by longer cooking, and in the end the foods made from corn are equally palatable and are cheaper than those made from wheat and rye.

The influence of artificial drying on the quality of grains for bread making, II, M. P. NEUMANN (*Ztschr. Gesam. Getreidew.*, 5 (1913), No. 12, pp. 329-341, figs. 3).—In continuation of work previously noted (E. S. R., 30, p. 257), the author reports the results of investigations on the artificial drying of wheat with reference to bread making quality. The conclusions drawn were in effect as follows:

Natural drying, such as results when the grain is cut in the "yellow ripe" stage can be replaced within limits by drying with artificial heat. When artificial drying is resorted to, the temperature of the grain should not exceed 45° C. When the harvest is normal, artificial drying has no practical importance but is to be recommended if the weather conditions at the time of cutting and harvesting the grain are unfavorable for complete ripening. Additional experiments are needed to determine whether or not higher temperatures can be used in the case of the drier grains without lowering bread-making quality. Experience already gained indicates that this is not the case. The experiments clearly show that the method of harvesting, and especially the way the wheat dries out in the field, has a decided influence on baking quality and its commercial value.

The effects of nitrogen peroxid on the constituents of flour in relation to the commercial practice of bleaching flour with that reagent, B. MOORE and J. T. WILSON (*Jour. Hyg. [Cambridge]*, 13 (1914), No. 4, pp. 438-466).—Extended investigations led the authors to the following conclusions:

"Bleached flour is not known to be bleached by the great majority of those who consume it.

"There does exist a demand for whiteness in flour, and previously to the advent of bleaching this was based on a real difference between white superfine flour and the cheaper yellower flour called 'household' or 'bakers' flour. The difference consists in this, that the superfine contains the ripest and best part of the flour or 'cream of the wheat,' while the lower grade consists of less ripe or less developed endosperm and is richer in oil which contains the coloring matter carotene, and so is yellow in color. Bleaching by decolorizing the carotene removes a criterion of quality between the two grades of flour and allows the cheaper quality to be admixed with the dearer, and the whole to be sold as first quality.

"That this admixture is made possible is shown in two ways: First, the sellers of the bleaching apparatus advertise in milling journals that the process enables the miller to increase his 'divide,' and secondly, there are

minute microscopic particles of offal in the products of the lower machines which are not bleached or altered in the process, and which serve the microscopist as a guide to how the flour has been blended. Examination of commercial flours shows clearly that a large number of high-priced flours are such mixtures and could not be sold as such unless previously bleached.

“Bleaching confers no advantage in nutritive properties or flavor upon the flour, and the large sum spent upon bleaching flour is really a national waste.

“Bleaching flour with considerable amounts of nitrogen peroxid alters both fats and proteins by nitrating them. Although the changes at the level of commercial bleaching are small, there is no knowledge as to how the small amounts of organic nitro-bodies formed may affect the human body in prolonged use for years, and as there is no counterbalancing advantage, and an addition also to the price obtained by simulating a superior article, it is suggested either that bleaching should be prohibited, or regulated and notified clearly by label to the purchaser.

“Bleaching by nitrogen peroxid is not a more rapid achievement of a slowly occurring natural process, but is essentially distinct. For while natural whitening in pure air consists in an oxidation of the coloring matter, bleaching consists in the formation of additional compounds between nitrogen peroxid and the coloring matter.”

The chemical composition of paddy mill products, F. J. WARTH and D. B. DARABSETT (*Dept. Agr. Burma Bul. 10 (1913), pp. 11*).—Rice milling is described and analytical data including mineral constituents reported of the different milling products and by-products. Some data are also reported regarding pounding rice by hand as compared with commercial milling. The hand process, the authors point out, is clearly wasteful, since none of the hand-milled, broken rice is used for cooking but for cattle food. The marked preference of the natives for the polished rice is commented on.

According to the authors, “the two foods polished rice and wheat flour may be considered equally good when they form part of a mixed diet in which the extra proteid required is supplied from some other source. Where, however, rice forms the complete diet the nutritive ratio (proteid to carbohydrates) is very low and a small increase in proteids would considerably alter it. It is just possible, therefore, that a part of the ill effects of a diet of polished rice may be due to the very low proteid content.

“For the rice miller, however, the phosphorus content has become a much more urgent problem since it has been shown that an inadequate supply of this element is a predisposing cause of beri-beri. . . . It is important to notice that wheat flour is, if anything, poorer in phosphoric acid than our best polished Rangoon rice. However, wheat flour consumers invariably live on a mixed diet, whilst some rice eaters do not. This explains why no complaint has been raised against the low phosphoric acid content of wheat flour.”

Discussing the matter from the Burmese native standpoint, the authors state that “the more perfect the polish the better does the rice cook, and therefore the preference for highly polished rice is not merely due to its clean white appearance but to the good cooking quality indicated by its appearance.

“It is doubtful whether we have as much reason for preferring white bread as the rice eater has for preferring well polished rice. The question of cooking quality in relation to extent of polishing is one that deserves some study by the millers. It may just be possible to produce a good cooking rice without polishing quite as much as is the custom. . . .

“A chemical test bearing on the question of cooking quality may be mentioned here. By means of dilute alkali rice grains can be disintegrated and

eventually gelatinized, but this action does not take place at all until the outer layers of the grain have been removed."

On the powdered sugar of commerce, E. H. S. BAILEY and H. L. JACKSON (*Trans. Kans. Acad. Sci.*, 26 (1912), pp. 27, 28).—The authors point out that although there are about 30 different grades of sugar on the market, only a small number are ordinarily handled in retail trade.

Over 20 samples of "the finest grade of powdered sugar, namely, the XXXX," were examined with reference to adulteration. Of the 20 samples analyzed, 5 contained starch, the maximum quantity being 4 per cent. In one sample, in which the label stated that 2 per cent of starch was present, none was found. "It is not uncommon, however, to find that the label does not truthfully describe the contents of the package. There was no indication of the presence of other substances than pure cane sugar in the samples examined."

The authors' commentary on the use of starch follows: "As one requirement for powdered sugar is that it should be fine and free from lumps, some of the manufacturers have been putting a little starch into the sugar during the process of grinding. This can hardly be called adulteration, however, as it is not put in with the object of cheapening the product, but to improve its quality for a particular purpose. Starch is, furthermore, a food product, although less expensive than sugar. A mineral substance, if added to the sugar, would be considered an adulteration, as mineral substances are especially forbidden for use in sugar or confectionery."

With reference to the cost of some grades, it is pointed out that "those sugars upon which most work has been done in the process of manufacturing sell for a higher price, but the cost to the consumer of such grades as cube sugar and powdered sugar is entirely out of proportion to the increased cost of manufacture. In fact, these grades are to be classed as luxuries, or foods to be purchased only if the consumer has sufficient income so that he can afford to buy them."

The chemistry of a cup of coffee (*Lancet [London]*, 1913, II, No. 22, pp. 1563-1565).—In this paper data are given regarding caffeine in tea and coffee, the chemical composition of hot and cold coffee infusions, and some of the factors affecting the quality of coffee, together with a discussion of its food value.

Tea contains from 3 to 4 per cent of caffeine and coffee seldom more than 1 per cent, but infusions of tea and coffee as commonly prepared contain practically equal amounts of caffeine in equal volumes of liquid, since a much smaller quantity of tea is used. Since cold water extracts all the caffeine in coffee and only a little of that in tea, it appears that the caffeine in coffee has different chemical associates from the caffeine in tea. According to the authors, "the caffeine in tea is for the most part combined with tannin in the form of caffeine tannate, which is not very soluble in cold water, but is easily soluble in hot water. . . . Subsequent experiments showed that the caffeine in coffee is combined with a peculiar acid allied possibly to tannic acid, but exhibiting different properties from the tannin present in tea."

From the fact that the caffeine tannate of tea is precipitated by weak acids, and therefore probably precipitated by the gastric juice, it is assumed that the caffeine is not absorbed until it reaches the alkaline alimentary tract. The caffeine of coffee, however, is soluble in both alkaline and acid fluids, and is therefore probably absorbed in the stomach.

If this is true, coffee, and its physiological action is for the most part due to caffeine, should act more promptly than tea as a stimulant and restorative. This is borne out by the fact that coffee is generally regarded as a more powerful restorative than tea.

Studies of the chemical composition of hot and cold water infusions of several types of coffee revealed the fact that cold water extracted from coffee the same weight of materials as boiling water, but the cold water infusion is somewhat less palatable than the latter. There was little chemical difference between them, and the physiological effect of the cold water extract of coffee was presumably the same as a hot water infusion, except for esthetic considerations. According to the report, "it is probable that cold water fails to extract certain oily bodies or fats which contribute attractive taste and aroma. The total extract is frequently higher in cold than in hot water. . . . Cold water extracts from tea only 17.5 per cent of its total caffeine, while from coffee it extracts the whole. Similarly, cold water extracts from tea 13 per cent of its total tannin, while coffee under the same treatment yields practically the whole of its caffetannic acid."

An infusion of unroasted coffee has a disagreeable taste, the roasting process being necessary to render the coffee palatable. The chemistry of roasting consists largely of a caramelization process, with the formation of certain oils and aromatic principles. Little caffeine is lost in the process, but the amount of caffetannic acid is diminished considerably, a greater reduction taking place in the preparation of the "high roasted" coffee than in the "pale roasted" coffee.

In this investigation no relation could be traced between the esthetic quality of coffee and the chemical composition of the infusions. No important difference in the amount of caffeine was found between the common and the finest varieties. The flavor, body, and aroma of the coffee are probably due to small amounts of oil bases or aromatic principles which are formed during the roasting process. The esthetic quality of coffee depends in a great degree upon the care spent in the roasting process. Pyridin was also found, but not in sufficient quantities to estimate.

From these observations, the following conclusion as to the food value of coffee is drawn: "The infusion of coffee presents practically very little material that is of direct nourishing value, but by diminishing nervous fatigue, by virtue chiefly of the caffeine present, it may increase muscular power. It is not itself a builder of tissue. The use of coffee after dinner, it is of interest to note, is justified in a large number of cases by the fact of its stimulating effect upon the vital centers, and it is said to serve to some extent as an antidote to alcohol. It is commonly claimed to remove drowsiness; as a matter of fact, in many subjects it produces drowsiness, but this is usually followed quickly by marked wakefulness. The practice of drinking coffee after a meal for the sake of the stimulus which is experienced has much to be said in its favor dietetically. There is no reason for supposing that coffee possesses any value as a food."

On the composition of the essence of coffee—the presence of pyridin, G. BERTRAND and G. W. WEISWEILLER (*Bul. Sci. Pharmacol.*, 20 (1913), No. 12, pp. 705-707).—In several samples of freshly roasted and ground coffee amounts of pyridin were found, varying from 200 to 400 mg. per kilogram. Experiments were carried out which would indicate that the aroma of coffee is due to pyridin. Methods of analysis are described, and the suggestion is advanced by the authors that pyridin may possibly play an appreciable rôle in the physiological effect of coffee infusion.

Commodities and provisions (*Ann. Statis. Paris*, 32 (1911), pp. 242-306).—Statistics are given regarding the meat trade, dairy products, eggs, grains, and other food supplies entering into commerce.

Municipal laboratory of chemistry (*Ann. Statis. Paris*, 32 (1911), p. 307).—According to the summary presented, 27,282 analyses were made during the year 1911, the bulk of them of food products and beverages.

Construction, equipment, and operation of public slaughterhouses and markets, O. SCHWARZ and H. A. HEISS (*Bau Einrichtung und Betrieb öffentlicher Schlacht- und Viehhöfe. Berlin, 1912, 4. ed., enl., pp. XVI+1065, figs. 499*).—This exhaustive work is designed as a handbook for slaughterhouse officials, slaughterhouse veterinarians, and sanitary and other inspectors.

The school lunch system [in the Philippines] (*Ann. Rpt. Bur. Health P. I., 14 (1912-13), pp. 21-24*).—An account is presented of the school lunch system which has been established in Manila schools and which forms a part of the school work in domestic science.

Menus are given as well as information regarding the prices at which the different foods are sold and some general data regarding the expenses of maintaining the project, which is designed simply to be self-supporting. The school lunch project was started in order that wholesome foods might be provided at moderate cost in place of those the children were accustomed to buy outside of school.

“To one who has worked any time in the city schools there is no doubt as to the utility and benefit of the lunch system. For many of the pupils it is the only breakfast that they get, while generally it is also the most wholesome meal of the day. A medical inspector who was formerly detailed in the city schools stated that a medical examination of the pupils made about a year after the lunch system was established showed an improvement of 90 per cent in their health.”

The ship's commissary officer, G. P. DYER (*Annapolis: U. S. Naval Inst., 1913, pp. 66, figs. 7*).—This publication deals with the general subject of food purchase, preparation, and service on vessels of the U. S. Navy.

As the author points out, “a ship's efficiency is largely dependent on contentment, and contentment, in turn, on the fare. Variety of fare [is] more a function of contentment than quantity. Given contentment, economy in food cost is an object.”

Food service, it is pointed out, involves cleanliness, “mainly a question of equipment,” and celerity, “mainly a question of mess men.” The equipment is fully described and the routine of food service.

The galley, its personnel, and equipment are discussed, as are also bill-of-fare making, galley cooking and service, and the ship's bake shop and butcher shop.

In an appendix are given specimen bills of fare with quantities (800 men for 1 week) and costs for vessels at sea, in port, in summer, and in winter.

Directions are given for preparing some of the foods enumerated. A partial list is also given of the dishes which can be served in a general mess based on experience on two ships during five years' cruising, and examples are quoted of typical bake shop and galley orders with outlines of the day's routine. Some of the data are of general interest, as the sort of yeast suitable for the Tropics.

The work involved in the combustion processes of the body: The physiology of muscular work, R. HÖBER (*Ztschr. Elektrochem., 19 (1913), No. 19, pp. 738-746; abs. in Chem. Zentbl., 1913, II, No. 21, p. 1814*).—This paper, delivered at the meeting of the Bunsen Society of Applied Physical Chemistry, Breslau, August, 1913, is a summary of the advance made in the knowledge of the chemodynamics of muscle from the time of Fick to the present.

According to the author, a muscle is to be regarded as a chemodynamical and not a thermodynamical machine, since it has so high an effectiveness that

one would have to take into account extremely high temperatures if a thermodynamical explanation were offered.

The chief work reaction which causes contraction depends upon the formation of lactic acid. As yet the origin of the lactic acid is not known. Probably it does not come directly from glycogen or from dextrose. When muscle is stimulated and fatigued, the lactic acid disappears, oxygen being taken up and carbon dioxide given off, not, however, by means of simple combustion but through the regeneration of the lactic-acid-yielding substances coupled with an oxidative process. Muscular contraction is apparently brought about by a swelling which is itself brought about by the presence of the acid. The laws of the increased volume phenomena are the same as those for the dilution of concentrated solutions. In this case, as in the case of the muscle, practically all the energy changes can be noted as work.

A discussion follows the paper.

Protozoan protoplasm as an indicator of pathological changes.—III, In fatigue, F. P. UNDERHILL and L. L. WOODBUFF (*Jour. Biol. Chem.*, 17 (1914), No. 1, pp. 9-12).—From the experimental data which they report, the authors believe that "it is justifiable to conclude that the character of the chemical changes occurring in fatigued muscle must differ only slightly from the normal."

ANIMAL PRODUCTION.

Live stock on farms and elsewhere (*Thirteenth Census U. S.*, 5 (1910), pp. 327-472, pls. 7, figs. 10).—The total value of all live stock on farms in the United States on April 15, 1910, was \$4,925,174,000. Of this total, domestic animals represented 96.6 per cent and poultry most of the remainder.

During the decade 1900-1910 the value of live stock on farms increased 60.1 per cent. The increase was shared by every geographic division. The largest absolute increases were in the West North Central and the East North Central divisions, though with respect to percentages of increase the Pacific division ranked highest, closely followed by the South Atlantic division. The highest percentage of increase was in the West. The North reported in 1910 a little over three-fifths of the total value of all live stock on farms in the United States, the South somewhat over one-fourth, and the West about one-eighth. The average value of live stock per farm for the United States as a whole was \$774 in 1910, for the North \$1,029, for the South \$428, and for the West \$1,673.

In value of domestic animals Iowa outranked all other States in 1910, followed in order by Texas, Illinois, Missouri, Kansas, and Nebraska, each reporting over \$200,000,000. In value of poultry Iowa also ranked first, followed by Missouri and Illinois, each with over \$10,000,000.

Data are given in detail for cattle, horses, mules, swine, sheep and goats, poultry, and bees on farms, and of domestic animals not on farms.

Live stock products and domestic animals sold or slaughtered on farms (*Thirteenth Census U. S.*, 5 (1910), pp. 473-529, figs. 3).—There were on April 15, 1910, 598,047 farms, or 9.4 per cent of all farms in the United States, with sheep of shearing age, the number of such sheep being 39,644,000.

The value of the wool clipped was \$45,670,000 in 1899 and \$65,472,000 in 1909. The average value per fleece increased from \$1.04 to \$1.55, and the average value per pound from 17 to 23 cts. Of the three principal wool-producing divisions, the East, North Central, and Pacific each reported a smaller proportion of the total wool clip in 1909 than in 1899, and the Mountain division a larger proportion. The most important State in the production of wool was Wyoming, with Montana, New Mexico, Ohio, California, Idaho, Oregon, and Texas ranking in order named.

The average weight of fleece increased from 6.3 lbs. in 1899 to 6.8 lbs. in 1909. The highest average weight was in the Mountain division, 7.3 lbs. per fleece.

The total reported production of mohair in 1909 was 1,683,000 fleeces and the value \$902,000. A decrease in the average value of mohair per pound is noted.

The total production of eggs in 1909 was estimated at 1,591,311,000 doz., an apparent increase of 23 per cent over that of 1899. The value of eggs is given as \$306,689,000, or an increase of 112.6 per cent over 1899. The average value of eggs per dozen as reported by the farmers increased from 11.1 cts. in 1899 to 19.3 cts. in 1909. The number of fowls reported as sold in 1909 was 153,600,000, or about one-third of the number raised. In 1909, 28 per cent of the total number of eggs produced and 25.4 per cent of the total number of fowls raised were accredited to the West North Central division, and 24.7 and 21 per cent to the East North Central. The average value of all fowls raised in 1909 ranged from 66.1 cts. each in the New England division to 29.9 cts. in the West South Central division, while the value of those sold ranged from 70.9 to 34.5 cts.

Feeding corn silage to farm animals, W. H. PEW, J. M. EVVARD, and H. H. KILDEE (*Iowa Sta. Circ. 6 (1913), pp. 6*).—In this circular general instructions are given for the feeding of corn silage to the breeding herd of beef cattle, fattening lambs, yearling sheep, horses, hogs, fattening cattle, wintering ewes and lambs, and to dairy cattle.

[Analyses of feeding stuffs] (*Off. Bul. Ohio Agr. Com., 4 (1913), No. 3, pp. 56-58, 80-97*).—Analyses are reported of cotton-seed meal, malt sprouts, linseed cake, blood meal, meat scraps, tankage, dried beet pulp, molasses feed, distillers' grains, middlings, oat hulls, gluten feed, bran, hominy feed, alfalfa meal, germ oil meal, and various mixed and proprietary feeds.

[Animal husbandry], T. L. HAECKER (*Minnesota Sta. Rpt. 1913, pp. 25-30, fig. 1*).—Four or 5 dry-brood sows representing the principal breeds were placed on each of 6 different lots of forage crops, stocking each pasture to its capacity, but not overstocking. Under these conditions it was estimated that a 5-acre plat of rape would have a net value of \$70.85, of oats, peas, and rape \$58.75, of oats \$9.49, of corn \$20.60, and of sorghum \$4.20. The first two lots were the only two in which any individual sows gained consistently during the experiment. Young sows showed more gains and less losses in weight than old sows. No breed showed superiority over other breeds in making gains on pasture. The sows that had been on grain without pasture proved as good breeders as those on pasture without grain for the same period.

Data secured on the composition of the body of a steer at all stages of growth indicate that there is a rapid increase in protein in the early stages of life, which is followed by a marked slowing up when the animal reaches a weight of about 800 lbs. This is just opposite to the results secured for fat, in which the increase is slow during the early stages, but shows rapid gain from about the 600-lb. stage. It was found that disturbances ordinarily not thought of as important cause a decrease in the rate of gain and in some cases an actual loss of weight.

The brains of the domestic animals, H. KRAEMER (*Mitt. Deut. Landw. Gesell., 29 (1914), No. 4, pp. 55-58*).—Data are given on the brain capacity and weight of brains of various breeds of horses, mules, cattle, sheep, hogs, and dogs, and the relative weight of brain to body weight is compared for the various animals.

The importance of measurements in the improvement of the breeds, C. VOITELLIER (*Ann. Sci. Agron., 4. ser., 3 (1914), No. 1, pp. 1-13*).—This reports

body measurements taken of prize cattle of various ages. The measurements included are height at the withers, back, sacrum, and chest; size of the chest, quarters, and trochanter; length of the pelvis and trunk; and perimeter of the chest and anterior cannon.

From this, the relation of selection and improvement of cattle to their body measurements is clearly shown and it is suggested that a systematic method of measurement be adopted which shall furnish a basis for selection and improvement.

The red cattle of Flanders, H. RAQUET (*Ann. Gembloux*, 24 (1914), No. 2, pp. 81-102, pls. 9).—This is an account of the origin, development, distribution, body characteristics, and utility value of this breed of cattle.

[Cattle of northern Spain], J. R. CODINA (*Rev. Hig. y Sanidad. Vet. [Spain]*, 3 (1914), No. 10-11, pp. 627-723, figs. 31).—A description and account of the breeds of cattle in the north of Spain.

Winter steer feeding, 1912-13, J. H. SKINNER and F. G. KING (*Indiana Sta. Bul.* 167, popular ed. (1913), pp. 2-15).—A popular edition of the bulletin previously noted (E. S. R., 30, p. 767).

Raising and fattening beef calves in Alabama, D. T. GRAY and W. F. WARD (*U. S. Dept. Agr. Bul.* 73 (1914), pp. 11, pl. 1).—Continuing cooperative work with the Alabama Station (E. S. R., 25, p. 72) a test was made with a herd of 80 cows, mostly grade Aberdeen-Angus, and headed by two Aberdeen-Angus bulls. From this herd 64 calves were raised during the year 1911. The calves were born during the spring months and ran with their mothers on pasture until late fall, when they were weaned and 49 prepared for the fattening period, which began January 17, 1912, and continued until April 1, 1912. The remaining 15 calves were retained for breeding purposes.

At 9½ months of age the average weight of the calves was 460 lbs.; the cost of raising each calf \$14.36 or \$3.12 per hundredweight. After 2½ months fattening they weighed 560 lbs., making an average daily gain of 1.37 lbs. per head. Each calf during the fattening period ate daily 4.4 lbs. of cotton-seed meal, 23.9 lbs. corn silage, and 2.76 lbs. broom-sedge hay. The cost per pound of gain was 7.31 cts., the cost per hundredweight to raise and fatten \$3.61. The profit on the entire herd, crediting the calves retained for breeding purposes at \$15 each, was \$436.19, or an average of \$6.81 for each calf.

Pig feeding, F. C. GRACE (*Jour. Dept. Agr. Victoria*, 12 (1914), No. 1, pp. 44-50).—Results of pig feeding experiments conducted at the Warrnambool Agricultural High School Farm are reported. Pollard and skim milk with a little bran was found to be the most economical ration under Australian conditions for pigs of all ages. Rape pasture reduced the cost of production.

A rotation of grazing crops for hogs (*Prog. Farmer*, 29 (1914), No. 9, p. 286).—There is outlined a combination of crops for the cotton belt which will furnish practically 12 months' grazing for hogs. Crops included are alfalfa, Melilotus, red clover, crimson clover, bur clover, cowpeas, soy beans, velvet beans, Spanish peanuts, Lespedeza, vetch, oats, wheat, barley, rye, chufas, sweet potatoes, and rape.

Management and breeding of horses, M. W. HARPER (*New York and London*, 1913, pp. XIX+466, figs. 187).—After discussing the judging, anatomy, and history of the horse, the author of this book treats of the various breeds of roadsters, saddle, and draft horses, ponies, the ass, and the mule. Methods of feed, care, and management are treated, together with chapters on horse training, harnessing, ailments, and stallion laws and regulations.

Whole world buying our fast horses (*Amer. Horse Breeder*, 32 (1914), No. 7, p. 97).—It is stated that it is only in the last 25 years that the foreign demand

for American trotting stallions, mares, and colts has assumed important proportions, and that the beginning of the present movement can be traced to the winning of the European championship by the American-bred mare Bosque Bonita at Vienna, in 1890. Since 1894, 63 stallions, together with 51 mares in the select 2.10 list, have gone abroad and most of them are now in the stud in Europe.

Austria has taken more of our 2.10 trotters than any other country, but the Russians have paid the highest prices and have acquired some of the greatest trotters ever foaled. It is thought that exports to Austria-Hungary number upward of 1,000 head. Italy has bought several prominent American stallions and mares. Germany is at present taking many high class trotters. France, Holland, Denmark, and other countries are occasional buyers of American breeding and racing stock. Australia and New Zealand are furnishing an extensive market at the present time.

The Welsh pony, OLIVE T. DARGAN (*Boston, 1913, pp. XIII+52, pls. 24*).—This book furnishes an account of the origin, development, and qualities of the Welsh pony.

Poitou mule breeding (*Live Stock Jour. [London], 79 (1914), No. 2077, p. 81*).—This is an account of mule breeding operations at Poitou, France. The mares used are of northern origin, powerfully built, and heavy animals, with a height at the withers of from $15\frac{1}{4}$ to $16\frac{1}{4}$ hands, the head long and thin, the lips overhanging, the ears pointed and long, the neck and chest flat, the legs powerful, coarse and very hairy, and the color of the coat various. The best mares are mostly found in the moor districts of La Vendée and of the Department of Deux Sèvres, and are the result of improved breeding methods and the introduction of outside stock since 1860.

The jacks used have powerful heads, long and large ears, small eyes, and deeply built bodies, with round cruppers and coarse legs with small hoofs. A dark color is preferred; light coats and black muzzles are avoided. It is thought that jacks with long and curly hair produce better fleshing offspring than others. The breeding of jacks or "baudets" is limited exclusively to private studs in the district of Melle, in Poitou.

It is stated that the mule of Poitou is especially suited for heavy work. Its neck is broad and muscular, its back is straight, the chest broad and deep, the loins broad, the croup round, the legs very powerful with broad joints and small cylindrical hoofs. It stands from $14\frac{1}{4}$ to $15\frac{1}{4}$ hands high. Its hair is short, rough, and generally dark colored.

Studies on the physiology of reproduction in the domestic fowl.—VI, Double- and triple-yolked eggs, MAYNIE R. CURTIS (*Biol. Bul. Mar. Biol. Lab. Woods Hole, 26 (1914), No. 2, pp. 55-83, figs. 4*).—Observations made on the frequency of the occurrence of double- and triple-yolked eggs, the relation of their production to the age of the bird, and the nature of the processes involved in their formation, are summarized as follows:

"During the last six years more than 3,000 different domestic fowls, which have been kept at least one year at the Maine Agricultural Experiment Station, have laid but three triple-yolked eggs. Each of these eggs was laid by a different individual and in each case the triple-yolked egg was one of the first eggs produced by a young pullet.

"Young pullets also show a decided tendency to produce double-yolked eggs when they first begin to lay. About 20 per cent of the pullets which lay before they are seven months old lay among their first eggs one or more with two yolks. Nearly 80 per cent of the individuals of the flock never lay a double-yolked egg. Mature birds also sometimes produce double-yolked eggs; but

most such birds have also produced one or more when they were young pullets. There has been no bird in the experiment station flock with which the laying of double-yolked eggs was 'habitual' although there are some which have produced several such eggs.

"The production of an egg with two or three yolks represents the extreme of rapid egg production, other forms of which are found in the production of two eggs united by a membranous tube; two eggs at the same time; two eggs at different times on the same day, and a daily egg production where the eggs are laid earlier on each successive day. The two yolks of a double-yolked egg may have all the egg envelopes in common, indicating that they have passed the entire length of the duct together; or each may possess one or more separate envelopes. There are also all the possible intermediate forms indicating that the two yolks in a common shell may unite at any point between the mouth of the funnel and the isthmus. When two eggs come together after the first has entirely passed the anterior end of the isthmus the result is the production of two eggs at the same time.

"Various disturbances of the processes of egg production may bring two yolks together in the oviduct. Double-yolked eggs evidently do not always represent simultaneous ovulations. The assumption is simultaneity or abnormally close succession of ovulations is necessary to account for the production of a succession of double-yolked eggs or of a double-yolked egg immediately following a long series of normal daily eggs.

"The double-yolked eggs contain more albumin and have a heavier shell than single-yolked eggs, and in triple-yolked eggs these parts are heavier than in double-yolked eggs. Yet these parts do not increase in direct proportion to the increase in the weight of yolk. That is, the percentage of albumin and shell is less in double- than in single-yolked eggs and is still smaller in triple-yolked eggs. The yolks of the multiple-yolked eggs of mature birds are not consistently smaller than the yolks of the normal eggs produced during the same period. Multiple-yolked eggs are longer in proportion to their breadth than the normal eggs of the same individual."

Previous studies have been noted (E. S. R., 26, p. 670).

The bacteriology of the hen's egg, with special reference to its freedom from microbic invasion, L. F. RETTGER (*Connecticut Storrs Sta. Bul.* 75 (1913), pp. 191-213).—Bacteriological tests were made of more than 10,000 eggs of different ages under various degrees of incubation.

Yolks from fresh eggs showed a positive test for bacteria other than *Bacterium pullorum* of 9.5 per cent. The yolks of artificially incubated eggs showed 2.75 per cent positive test during the first week of incubation, 1.3 per cent the second, and 3.6 per cent the third week.

The small percentage of positive results for eggs which have been incubated from 1 to 3 weeks is considered a noteworthy fact. A more exact method was employed in testing the yolks of fresh eggs and in this case the test was reduced to 3.86 per cent. It is believed that even this test is in all probability considerably above the actual figures, could accidental invasion of bacteria in the tests be entirely prevented. The tests with eggs incubated 1 and 2 weeks indicate that fertilized eggs do not become more subject to bacterial invasion of the yolk than the infertile.

In examinations of the whites of 582 eggs only 1.2 per cent gave positive bacteriological results, although many of the tests were made during the summer months. No *Bacterium pullorum*, the organism of white diarrhea, was detected in the white, although it was recovered from the yolks. Undoubtedly there was some contamination in these tests and it is believed to be safe to

say that the whites of fresh normal eggs are as a rule sterile. Fermentation tests made of the whites of 105 eggs for *B. coli* were negative. In noting the kinds of micro-organisms found in the yolks of fresh and incubated eggs it was observed that a large percentage in both cases were staphylococci, usually *Staphylococcus albus* or *S. aureus*, indicating that there was considerable contamination in the examination. Also the occurrence of a large number of members of the subtilis group would suggest the same thing.

The author reviews the results obtained by earlier investigators, which are not in harmony with those obtained in these tests. He suggests that the methods employed in making previous tests may have been at fault and that it is "highly improbable that normal fresh eggs contain bacteria and molds in such large proportions as various investigators have indicated." It is stated that the developing ova in the ovary of a laying hen are, as a rule, sterile unless the ovary is infected with the organism of bacillary white diarrhea. In 200 bacteriological examinations the author was unable to detect bacteria, molds, or other micro-organisms except *B. pullorum*. It is not thought possible that the blood is a source of infection, and examinations of the oviducts showed them as a rule to be sterile except at or near the cloaca. The views of Horowitz substantiate those of the author. It is believed that autosterilization of the oviduct is due to the following: (1) Phagocytosis, (2) mechanical action of the walls of the oviduct, and (3) bactericidal action of the secretions.

The success in preserving eggs with sodium silicate is cited as an indication that sound fresh eggs are as a rule sterile. The fact that many market eggs are decomposed is accounted for by their storage under unfavorable circumstances, i. e., filthy conditions and warm temperature and the fact that bacteria are given an opportunity to enter when the gelatinous coating is removed from the eggs during washing and handling.

Carbon dioxide in incubation, G. H. LAMSON, JR. and H. D. EDMOND (*Connecticut Storrs Sta. Bul. 76 (1914), pp. 219-278, figs. 13*).—The purpose of the investigation reported in this bulletin, which continues studies previously noted (*E. S. R.*, 20, p. 472), was to determine the presence of carbon dioxide in natural incubation and the relative requirements as to ventilation and carbon dioxide during artificial incubation. A specially constructed incubation apparatus that would hatch eggs and at the same time allow for an accurate control of all factors was used. This experimental incubator consisted of four essential parts, the incubator, humidifier, gas meter, and air pump. Two commercial incubators were also used to determine the carbon dioxide in these types, and nests for sitting hens were prepared in such a way as to enable the drawing of samples of air from under the hen. The work extended over five years, nearly 10,000 eggs being used.

The results of these studies indicated that the chief source of carbon dioxide in incubation is the embryo, with the egg shell, hen, nest material, and room air as minor sources. After the third day the increase of carbon dioxide is proportionate to the increase in weight of the developing embryo.

The amount of carbon dioxide under sitting hens at the beginning of the period of incubation is much higher than for the room and increases to 50 or 60 parts in 10,000, while in the commercial incubators tested it increased to from 30 to 50 parts in 10,000. From this it appears that carbon dioxide is not a limiting factor in commercial incubation. However, ventilation is necessary in incubation in order to remove a portion of the respired carbon dioxide and prevent asphyxiation of the embryo. It was found that the normal embryo is able to withstand a wide variation of carbon dioxide during incubation. Little effect was noted on the percentage hatch where the carbon dioxide

occurred in from 30 to 60 parts per 10,000, but as the amount rises above 150 parts there is a marked decrease in the number of chickens hatched.

It is concluded that in all incubators carbon dioxid will be found, and that while its presence is not essential to successful incubation its occurrence up to 60 parts in 10,000 is not prejudicial to incubation. Factors influencing the amount of carbon dioxid in the egg chamber of an incubator are rate of ventilation, number of embryos, period of incubation, size of egg chamber, temperature, and carbon dioxid in the air of the incubator room.

Natural and artificial incubation of hens' eggs, H. M. LAMON (*U. S. Dept. Agr., Farmers' Bul. 585 (1914), pp. 16, figs. 3*).—This bulletin gives directions for the incubation of eggs, both natural and artificial; describes the several types of incubators; and discusses their selection and care.

The problem of moisture and ventilation requirements in incubation is discussed and the methods of testing eggs described.

Electro-cardiogram for embryo chicks, J. K. A. WERTHEIM-SALOMONSON (*Pföüger's Arch. Physiol., 153 (1913), No. 11-12, pp. 553-573, figs. 23*).—This article reports observations made of the electro-cardiogram of the embryo chick.

DAIRY FARMING—DAIRYING.

Dairying, J. P. SHELDON (*London, New York, Toronto, and Melbourne, 1912, pp. XII+465, pls. 33, figs. 21*).—A comprehensive book treating of the principal breeds of dairy cattle and the feeding, care, and management of dairy animals, and including chapters on soils and climates suitable for dairying, land and its betterment, manuring and treatment of soils, butter making, cheese making, and cooperative dairying in England.

Dairying in Nova Scotia (*Halifax, N. S., 1912, pp. 172, pls. 11, figs. 8*).—This is a reprint of the annual report of the Secretary of Agriculture of Nova Scotia for 1908, revised to date, and is a compilation of articles on general dairying topics, with special reference to Nova Scotian conditions.

[Dairy husbandry] (*Rpt. Dept. Agr. N. S. Wales, 1913, pp. 5, 7, 30-36*).—This report deals with the production and consumption of dairy products in New Zealand, the quality and price received for butter, oleomargarine competition, the cheese industry, and general dairy statistics.

[Dairy husbandry], T. L. HAECKER (*Minnesota Sta. Rpt. 1913, pp. 22-25, 30*).—From feeding trials conducted with dairy cows it appears that 11 lbs. of mangels or 9 lbs. of ruta-bagas are equivalent to 1 lb. of mixed grain, carrying about 10 per cent digestible protein with a nutritive ratio of 1:6 or such a mixture as would result from using equal parts of wheat bran and corn meal.

Studies made of the protein requirements of the animal body and for milk production have demonstrated the importance of long-time experiments. "The animal body can stand shortage of protein for several months, and then show the bad effect only to the trained observer. It was found necessary to continue the cows on low-protein diet for three years before it was possible to state the effect with certainty. When the change does come, it comes quickly, and the results are marked."

Manuring of grass land for milk and meat, B. F. DAVIS (*Field Expts. Harper-Adams Agr. Col. and Staffordshire, Rpt. 1913, pp. 4-7, fig. 1*).—In 1911, three plats of 3½ acres each were drained and treated with ground limestone at the rate of 15 cwt. per acre. Manures were applied as follows: Plat 1, superphosphate 2½ cwt. per acre; plat 2, superphosphate 2½ cwt. and sulphate of potash ½ cwt. per acre; and plat 3, no manure. During 1912 and 1913 the manurings were repeated.

Three lots of 2 cows each, equal in milk yield, period of lactation, etc., were maintained for 20 weeks on the respective plats and data kept on their production. Yearlings were added as the plats needed heavier pasturing and removed during light pasture. Data were collected on increase in weights, etc.

The total milk production for the two years' trials was for plat 1, 1,510 gal., plat 2, 1,489 gal., and plat 3, 1,168 gal. The total value of products, including milk and grazing, was £43 13s. 1d., £43 14s., and £31 16s. 11d. for the respective plats, while the net value per acre after deducting the cost of manures for plats 1 and 2 was £11 13s. 10d., £11 2s. 9d., and £9 1s. 9d., respectively.

Feeding of cattle on phosphatic pasture, C. SELTENSPERGER (*Vie Agr. et Rurale*, 2 (1913), No. 48, pp. 569, 570; *abs. in Indus. Lait.* [Paris], 39 (1914), No. 5, p. 91).—The author records his observations in the feeding of cattle on phosphate-fertilized pastures. He concludes that such fertilizing favors the growth of the legumes and other flora rich in phosphorus content, that the phosphorus is more easily assimilated by the animal body in this form than when fed as bone meal and mineral phosphates, and that in turn the phosphorus content of the milk products is correspondingly increased.

Dairy herd records for fourteen years, J. H. FRANDSEN and A. L. HAECKER (*Nebraska Sta. Bul.* 139 (1914), pp. 3-30).—In summarizing the herd records for the past 14 years at the Nebraska Station it is shown that the average production per cow was 7,020.8 lbs. milk and 341.71 lbs. of butter, which yield is nearly three times the amount produced by the average dairy cow of the State, and indicates the great increase that may be attained by proper breeding and feeding. The rations were made of Nebraska-grown crops and feeds, and the principal roughage was corn silage and alfalfa hay. The herd from a financial standpoint yielded a handsome profit during all the years of the test.

In studying the individual records it is noted that a large flow of milk is generally accompanied with a low milk fat test, while a small flow has a high milk fat test.

A new Holstein record (*Kimball's Dairy Farmer*, 12 (1914), No. 6, p. 163, figs. 2).—An account of a Holstein cow which at 3½ years produced 30.1 lbs. butter from 588.6 lbs. milk in 7 days; 123.88 lbs. butter from 2,522.2 lbs. milk in 30 days; at 4½ years 32.72 lbs. butter from 613.3 lbs. milk in 7 days; 135.31 lbs. butter from 2,632 lbs. milk in 30 days; at 5½ years 35.43 lbs. butter from 750 lbs. milk in 7 days; and 144.64 lbs. butter from 3,090.06 lbs. milk in 30 days.

It is stated that while these figures have not been officially authorized they are essentially correct.

Nourishment of young animals with self and foreign milk, W. SCHRAPE (*Experimentelle Beiträge zur Ernährung tierischer Säuglinge mit artemgener und artfremder Milch.* Inaug. Diss., Univ. Leipsic, 1912, pp. 82).—In trials with lambs, young rabbits, and guinea pigs it was found that the value of the mother's milk is greater than of foreign milk, that mother's milk in the raw state is as healthful as the cooked, and that in the feeding of foreign milk to young animals it is advisable to heat the milk.

There are appended 87 references to works on milk feeding and milk hygiene. The etiology of epidemic septic sore throat (*Jour. Amer. Med. Assoc.*, 62 (1914), No. 11, p. 853).—Evidence is presented to show that "the cause of the infection in septic sore throat is the streptococcus which is discharged from the inflamed udder of the dairy cow into the milk, through which it is transferred to the throats of milk consumers." Animals suffering from garget are thought to be a frequent source of infection in man. It is pointed out, however, "that in addition to the primary infection of milk, pathogenic organisms may be accidentally introduced into it through its being handled by persons suffering from streptococcal infection."

Provision of the agricultural law relating to dairy products, 1913 (N. Y. Dept. Agr. Circ. 88 (1913), pp. 1888-1914).—This circular is a reprint of the laws relating to dairy products for the State of New York as revised to 1913.

Sanitary inspection of market milk, G. L. J. GOOREN (*Hygienische Untersuchungen der Handelsmilch. Inaug. Diss., Univ. Bern, 1912, pp. 22*).—The author comments on the use of the freezing point of milk for detecting adulteration. It was found that the freezing point is not higher than -0.54° C. in normal whole milk and remains fairly constant. The thinning of milk lowers the freezing point, although the influence of thinning is not altogether regular. Homogenizing and sterilizing lowers the freezing point as does also a lower temperature, such as in pasteurizing. Hence the value of this method of detecting adulteration is uncertain.

The isoelectric point of man, cow, goat, dog, and guinea pig milk casein, A. YLPPÖ (*Ztschr. Kinderheilk., Orig., 8 (1913), No. 3, pp. 224-234; abs. in Zentbl. Physiol., 27 (1913), No. 22, p. 1202*).—The isoelectric point of various kinds of milk is given.

Electric sterilization of milk (*Sci. Amer., 110 (1914), No. 8, p. 155*).—It is stated that a process has been developed at the University of Liverpool for the electric sterilization of milk, consisting in a brief exposure to a high-tension electric current. The exact details of the method have not been made public. No difference in taste, aroma, or nutritive qualities could be detected between treated and untreated samples. Acidity did not increase; there was no coagulation; the heating was trifling; and all the pathogenic bacteria were killed.

Ozonization of milk, E. WIENER (*Abs. in Cream. and Milk Plant Mo., 2 (1914), No. 7, p. 18*).—This is a brief comment and description of a process for ozonizing milk which is claimed to be superior to pasteurization. The milk is atomized so fine as to constitute practically a vapor, and the ozone is produced by a high-tension electric current. After treatment the milk is collected in a vessel constructed for that purpose and compressed air is forced through, removing such small quantities of ozone as may remain after the treatment. It is said that the bacteria are destroyed without affecting the organic matter of the milk.

On the free fatty acids and the volatile fatty acids of fresh butter fat, A. BURE and H. WEISE (*Molk. Ztg. [Hildesheim], 28 (1914), No. 16, pp. 291, 292*).—In a study made of the acidity of fresh butter fat it was found that the degree of acidity ranged between 0.6 and 1.4, expressed as tenth-normal alkali; that the lowest occurred in the month of October, the average and highest in May and April, respectively. There was no direct relation between the acidity of fresh butter fat and the content of water-soluble and water-insoluble volatile fatty acids. Butter samples of 2 and of 5 per cent salt content showed no variation in acidity over unsalted butter.

The Polenske number of fresh butter fat ranged between 1.12 and 3.1, the highest being in November and December, when the high water-insoluble volatile fatty acid content at this time is accounted for by the heavy feeding of beets. The Reichert-Meissl number also was highest during these two months.

The variability of *Bacillus bulgaricus*, E. CHRISTELLER (*Ztschr. Hyg. u. Infektionskrank., 77 (1914), No. 1, pp. 45-48*).—In studies made of *B. bulgaricus* it was found that this bacillus propagates rapidly after 24 hours in ordinary agar medium, but does not grow in milk agar. It grows practically as well on a sugar medium as upon bouillon. In milk it grows very poorly and remains in Gram-positive form. Coagulation of milk had no influence. Growth on agar caused it to lose its Gram-positive character.

The keeping quality of sweet cream butter (*Cream. and Milk Plant Mo., 2 (1914), No. 1, p. 21*).—Tests made by the Dairy Division of this Department

of sweet cream butter held in storage for a period ranging from 7 to 9 months are reported. The butter was made as prescribed by the Department from May 1 to August 20, from pasteurized cream containing not more than 0.234 per cent of acid for butter scoring 95 points, and had a water content of 13 per cent or less and a salt content between $2\frac{1}{2}$ and $3\frac{1}{4}$ per cent. The butter was packed in hermetically sealed tins and stored at a temperature of zero or below.

For the 219 samples examined the average loss of points on scoring was approximately 2.5. The results show that for storage purposes butter made in this way has exceptionally good keeping qualities.

Preservation of butter by means of sodium bicarbonate and sodium nitrate, F. BORDAS (*Ann. Falsif.*, 7 (1914), No. 63, pp. 45-49; *abs. in Jour. Soc. Chem. Indus.*, 33 (1914), No. 4, p. 214).—"The results of an investigation, in which quantities of 100 gm. of butter were mixed with 0.857 gm. of sodium bicarbonate or with this quantity of bicarbonate and 0.143 gm. of sodium nitrate, and then kept for 14 days, showed that, although the alkali prevented the acidity of the butter from increasing, it modified the color and taste. The addition of the sodium nitrate was without effect."

Nut butter (*New Zeal. Dairyman*, 18 (1914), No. 5, p. 24).—Attention is directed to the increased consumption of nut butter. At first coconut oil only was used in its manufacture, but now other substances, such as peanut oil and palm-kernel oil are employed. It is stated that nearly 50,000 tons are produced in England each year and that the consumption overtakes the supply.

The ripening of mold cheeses and the ferments involved therein, P. MAZÉ (*Jour. Agr. Prat.*, n. ser., 27 (1914), No. 2, pp. 44-47).—A description is given of the ripening process of such cheeses as Camembert, Brie, and Coulommier, together with notes on the different groups of organisms involved in the production of desirable flavors. The necessity of controlling the ripening process and especially of eliminating undesirable organisms is emphasized.

Oleomargarine, H. VAN VOORNVELD (*Die Margarine. Trier, Germany*, pp. 131, pls. 2, figs. 33).—A complete treatise on the manufacture of oleomargarine, butter, and cheese.

Bibliography of references on milk and milk products received during 1912, C. HUYGE (*Ann. Sta. Agron. Etat Gembloux*, 2 (1913), pp. 253-352).—The 757 references in this bibliography are classified under the following headings: (1) Milk: Production, city supply; hygiene; abnormal milk; diseases of the udder; influence of feeding on the milk and its products; milk of man, sheep, and goats, milk products and substitutes, chemistry of milk; adulterants and preservatives; bacteriology; and ferments. (2) Butter and cheese: Production; chemistry and bacteriology. (3) Milk trade and statistics.

There are included indexes to authors and to publications.

VETERINARY MEDICINE.

Report of the veterinary director general for the year ending March 31, 1913, F. TORRANCE (*Rpt. Vet. Dir. Gen. Canada, 1913*, pp. 110, pls. 4).—Following the main part of this report (pp. 3-29), which consists of a general account of the work of the year, 13 appendixes are presented among the more important of which are the report of the pathologist (pp. 67-73), by C. H. Higgins; report of the pathologist in charge of the veterinary research laboratory at Agassiz, British Columbia, including protocols on the work with hematuria; Notes on the Life History of *Dermacentor venustus*, and a note on the *Ornithodoros megnini* collected on jack rabbits at Lethbridge, Alberta (pp. 74-80), by S. Hadwen; report of the pathologist in charge of the veterinary

research laboratory at Lethbridge, Alberta, including an account of laboratory work and field investigations in connection with outbreaks of dourine and preliminary studies and experiments with swamp fever (pp. 81-87), by E. A. Watson; Special Report on Contagious Abortion (pp. 88-92), by F. Torrance; and The Serum Reactions and Serum Diagnosis of Dourine (pp. 102-108), by E. A. Watson.

Report of the territorial veterinarian for the biennial period Jan. 1, 1911, to Dec. 31, 1912, V. A. NØRGAARD and L. N. CASE ([*Bien.*] *Rpt. Bd. Comrs. Agr. and Forestry Hawaii, 1911-12*, pp. 160-220, pls. 8).—This report deals with the occurrence of diseases of live stock, tuberculin testing in dairy herds in the city and county of Honolulu, the intradermal tuberculin test, glanders in the Territory, the intradermal mallein test, a peculiar disease among sheep on the island of Lanai, etc.

Annual report by the chief veterinary officer for the year 1912, S. STOCKMAN (*Bd. Agr. and Fisheries [London], Ann. Rpt. Chief Vet. Off., 1912*, pp. 41).—This report first discusses in detail the outbreaks of foot-and-mouth disease which occurred in 1912 (pp. 3-36), then, briefly, the occurrence of hog cholera, glanders, and anthrax.

Annual report of the Bengal Veterinary College and of the Civil Veterinary Department, Bengal, for the year 1911-12, F. RAYMOND and A. SMITH (*Ann. Rpt. Bengal Vet. Col. and Civ. Vet. Dept., 1911-12*, pp. 5+7+VIII+2+3).—The first section includes reports on the epizootic diseases department in Calcutta and its vicinity and of the Raymond Research Laboratory. The second section deals with veterinary instruction, the occurrence and treatment of diseases, breeding operations, etc.

Annual report on the civil veterinary department, Burma, for the year ended March 31, 1913, G. H. EVANS (*Ann. Rpt. Civ. Vet. Dept. Burma, 1913*, pp. 3+13, pl. 1).—This, the usual annual, report deals with veterinary instruction, occurrence and treatment of animal diseases, breeding operations, etc.

Veterinary diseases, A. BALFOUR, R. G. ARCHIBALD, ET AL. (*Rpt. Wellcome Research Labs. Gordon Mem. Col. Khartoum, 4 (1911), Sup.*, pp. 395-404).—This is a review of progress in work with diseases of animals, including rinderpest, horse sickness, bovine pleuro-pneumonia, etc.

Practical bacteriology, microbiology, and serum therapy, A. BESSON, trans. by H. J. HUTCHENS (*London, New York, and Bombay, 1913*, pp. XXX+892, figs. 416).—A translation and adaptation from the fifth French edition of the work, the second edition of which has been previously noted (E. S. R., 13, p. 889).

A compend of parasitology, E. BRUMPT (*Précis de Parasitologie. Paris, 1913*, 2. ed., pp. XXVIII+1011, pls. 4, figs. 698).—This is a revised and enlarged edition of the work previously noted (E. S. R., 24, p. 479).

Investigations of scabies and scab mites, particularly scabies of the chamois, J. FIEBIGER (*Ztschr. Infektionskrank. u. Hyg. Haustiere, 14 (1913), No. 6*, pp. 341-365, figs. 8).—This paper includes a discussion of the pathology and pathological histology of the disease; location of the mites; other forms of scabies, including that of the capybara (*Hydrochaerus capybara*), rabbit, and fowl; transmission experiments; and biological studies.

The author finds that the goat can be artificially infected with the chamois mite, a variety of *Sarcoptes scabei*, and that it may be spontaneously transmitted to other goats. Thus it appears that a natural transmission of scabies from chamois to goats is likewise possible. A spontaneous transmission of this mite to sheep does not appear to take place.

Chemotherapy, P. EHRLICH (*Nature [London], 91 (1913), No. 2285*, pp. 620-626).—An address delivered before the Seventeenth International Congress of

Medicine at London on August 8, 1913, which deals especially with the work of the author and others engaged in the same line of research.

The relation of the leucocytic bacteriolysin to body fluids, W. H. MANWARING (*Abs. in Science, n. ser.*, 38 (1913), No. 978, p. 453).—It is pointed out that a substance can be extracted from the leucocytes of the horse which, when dissolved in distilled water, is strongly bactericidal. When dissolved in physiological salt solution it also possesses considerable bactericidal power, but when mixed with sera, cerebro-spinal fluid, products of tissue, or leucocyte autolysis, it is without bactericidal power.

It is stated that the antibactericidal action of body fluids and tissue products depends upon three factors: "(1) The antibactericidal power of the colloids they contain, (2) the antibactericidal power of their neutral salts and other neutral diffusible components, and (3) the antibactericidal power of their diffusible alkalis. Diffusible acids are apparently without antibactericidal effect. An extract from horse leucocytes can have little or no antiseptic action when injected into body cavities and tissue spaces."

Toxic action and disinfecting agents, H. KÜHL (*Chem. Ztg.*, 37 (1913), No. 12, pp. 113-115).—This is a discussion of the methods used at the present time for determining the toxicity of certain disinfecting agents against bacteria and other micro-organisms. It is pointed out that in certain concentrations disinfectants act as stimulators of growth.

Technical errors in protective vaccination, S. LAUFER (*Állatorvosi Lapok*, 36 (1913), No. 12, pp. 139-143; *abs. in Berlin. Tierärztl. Wchnschr.*, 29 (1913), No. 36, p. 645).—This is a criticism of some of the preparatory and vaccination methods utilized at the present time for immunizing animals.

Synthetic antigens for the meiostagmin reaction when used for malignant growths, G. IZAR (*Wiener Klin. Wchnschr.*, 25 (1912), No. 33, pp. 1247, 1248; *abs. in Centbl. Bakt. [etc.]*, 1. Abt., Ref., 56 (1913), No. 17, pp. 520, 521).—On successively precipitating pancreas antigens in a methyl alcoholic solution with acetone, ethyl alcohol, ether, benzol, and petroleum-ether, the preparation obtained was found not to be any more stable than the original crude methyl alcohol extract. The crude extract is insoluble in acetone and the purified product is soluble.

The following antigens, prepared with myristic acid according to E. Fischer's method, were found utilizable in the test: Witte peptone, albumose from Witte peptone, albumose from trypsin digestion and also from pepsin digestion of calf's pancreas, edestin, casein, elastin, and kyrin. Instead of myristic acid, oleic and palmitic acids obtained from the fats of the pancreas, from human sarcomas, carcinoma, and from cacao butter can be employed. Which of these compounds is preferable from the standpoint of stability and the number of positive results obtained, the author was unable to say.

Complement fixation obtained with the purified antigen and with all the combinations mentioned above was as marked with inactivated normal serum as with the sera obtained from subjects affected with tumors. By bringing together blood serum with some of the synthetic antigens hemolytic substances were produced in large amounts. The tumor sera furnished the greatest amount of these substances.

An improvement in the meiostagmin reaction, R. KÖHLER and A. LUGER (*Wiener Klin. Wchnschr.*, 25 (1912), No. 29, pp. 1114, 1115; *abs. in Centbl. Bakt. [etc.]*, 1. Abt., Ref., 56 (1913), No. 3, pp. 77, 78).—The principal purpose of this work was to find a method for preparing more stable extracts of the organs used in the test. Tests with aqueous and alcoholic solutions of lecithin and cholesterol yielded unsatisfactory results, while an extract prepared from lecithin in a finely divided state from various sources and obtained by extracting

the preparation for 24 hours with acetone at a temperature of 50° C. and then filtering the extract through paper gave good results. The extract obtained was diluted with water, and the technique followed was that described by Ascoli.

The results of some tests with the sera of normal subjects and subjects affected with tumors and other diseases are given.

Autoserotherapy in pleuritis, P. HAAN (*Rev. Gén. Méd. Vét.*, 21 (1913), No. 251, pp. 621-625; *qbs. in Berlin. Tierärztl. Wchnschr.*, 29 (1913), No. 35, p. 628).—Although the application of the autoserotherapeutic method for serofibrinous pleuritis is not new, it seems to be very little used by the practicing veterinarian. In addition to the classical methods which use caffenin, digitalis, and other diuretics, and vesicants, the author used autoserotherapy directly after the fluid was drawn from the thoracic cavity as suggested by Teppay (E. S. R., 26, p. 684). The day following the administration of the thoracic fluid, improvement usually set in, which manifested itself by a restoration of the appetite.

A considerable amount of fluid must be withdrawn from the thoracic cavity because 40 cc. must be injected in the subcutaneous tissues of the same animal. The dose may be repeated if a reaccumulation of the fluid in the cavity takes place. If the method is used early, almost two-thirds of the horses affected may be saved.

A dry placenta powder and its use in Abderhalden's dialysis method for diagnosing pregnancy, V. L. KING (*München. Med. Wchnschr.*, 60 (1913), No. 22, pp. 1198; *abs. in Berlin. Klin. Wchnschr.*, 50 (1913), No. 26, p. 1227).—A preparation designed for use in the dialysis method (E. S. R., 28, p. 777) instead of the wet placenta protein.

The biological diagnosis of pregnancy, E. ENGELHORN (*München. Med. Wchnschr.*, 60 (1913), No. 11, pp. 587, 588; *abs. in Berlin. Tierärztl. Wchnschr.*, 29 (1913), No. 26, p. 472).—The dialysis method was studied with human sera. The conclusion drawn is that a reaction does not warrant the diagnosis that the subject is pregnant.

The serum diagnosis of pregnancy, C. C. W. JUDD (*Jour. Amer. Med. Assoc.*, 60 (1913), No. 25, pp. 1947, 1948).—A very general description of the test previously discussed (E. S. R., 27, p. 577), with a statement in regard to the satisfactory results obtained by its use.

The serodiagnosis of pregnancy, K. JAWORSKI and Z. SZYMANOWSKI (*Wiener Klin. Wchnschr.*, 26 (1913), No. 23, pp. 922-924; *abs. in Berlin. Klin. Wchnschr.*, 50 (1913), No. 26, p. 1227).—The Abderhalden method, when conducted strictly in accordance with the rules set down by the originator, gave satisfactory results in every instance. It was positive in the early days of pregnancy and it was still present 14 days after parturition. In extra-uterine pregnancy the reaction was positive when the ectodermal plates were still in contact with the reproductive system. In hyperemesis or eclampsia (women) the reaction was generally very faint. Sera from subjects suffering with carcinoma did not cleave placenta protein.

The diagnosis of pregnancy with the optical method and the dialysis procedure, R. FREUND and C. BRAHM (*München. Med. Wchnschr.*, 60 (1913), No. 13, pp. 685-690).—This is a study of the value of both the optical and the dialysis method. In all there were 135 cases examined, and 6 of these were eclampsia cases and examined twice. The optical method was tried 134 times and the dialysis method 99 times. The subjects were normal pregnancies, extra-uterine pregnancies, adnex tumors, and other nongravid cases.

The clinical findings were parallel with the optical method in 97 out of 134 cases (72.4 per cent), and with the dialysis method in 66 out of 99 cases (66.7

per cent). The reason that variant results were obtained with the optical method lies principally in the inability of the sera to produce a uniform cleavage of the peptone at different times, since some protective ferments will cleave a certain kind of peptone while others will attack this peptone only slightly. In the dialysis method, dialysis thimbles were used. The method was controlled by the optical procedure 92 times and conducted 7 times alone. Agreement was noted in 61 cases, 43 positive and 18 negative, showing that the results from 31 cases did not harmonize. A very high cleavage power was noted with the sera of eclamptic patients.

Experiences with the Abderhalden pregnancy reaction (dialysis procedure and ninhydrin reaction), H. SCHLIMPERT and J. HENDRY (*München. Med. Wchnschr.*, 60 (1913), No. 13, pp. 681-685; *abs. in Chem. Abs.*, 7 (1913), No. 13, p. 2242).—The findings of Abderhalden were verified in 79 cases, of which 40 were absolute cases of pregnancy. In all cases of pregnancy the reaction was positive and the rest of the sera gave negative reactions.

“A total of 316 cases were examined but not with satisfactory results until all the important points in the technique had been worked out. Especially significant was the fact that placenta not blood-free gave inaccurate results. For washing the placenta tissue sodium chlorid below 0.5 per cent proved undesirable; above this concentration to 0.9 per cent the blood was readily removed and clear white placenta tissue was obtained. The procedure finally adopted was to wash out the placenta tissue with 0.9 per cent sodium chlorid until colorless, then wash 10 minutes in running tap water to remove the sodium chlorid, and proceed further as directed by Abderhalden. Other less important details of the technique are discussed.”

Abderhalden's reaction with placenta and serum, H. SCHLIMPERT and E. ISSEL (*München. Med. Wchnschr.*, 60 (1913), No. 32, pp. 1758-1760; *abs. in Berlin. Tierärztl. Wchnschr.*, 29 (1913), No. 37, p. 665).—The tests were conducted with the object of determining whether animals during the period of pregnancy developed certain ferments and to elicit to what extent the ferments are specie specific. It was considered of great importance in the investigations to separate sharply the fetal and maternal parts of the placenta in order to get a substrat which was subject to better control. From theoretical considerations it was also deduced that a migration of chorion villi in the blood stream of the mother is without reasonable foundation. For the tests sheep and horse placentas were used.

Ferments were noted in the blood stream which were not only specific for homologous placenta protein but also for the heterologous protein, e. g., the strongest serum was from man and its action was stronger for horse protein than for human placenta protein. Sheep serum also acted more strongly on horse protein than on sheep placenta protein. The fetal as well as the maternal parts of the placenta were cleaved.

Serology of eclampsia, B. STANGE (*Zentbl. Gynäkol.*, 37 (1913), No. 9, pp. 298-300; *abs. in Jour. Amer. Med. Assoc.*, 60 (1913), No. 14, p. 1117).—Abderhalden's reaction for pregnancy was found especially intense with an eclamptic placenta obtained from a woman. The changes in the blood in eclampsia are similar to those of a normal pregnancy.

Abderhalden's dialysis method, a means of determining whether or not a cow is in a new period of lactation, H. FALK (*Berlin. Tierärztl. Wchnschr.*, 29 (1913), No. 8, pp. 129-132).—The author gives his experience with the Abderhalden dialysis method (*E. S. R.*, 28, p. 777), which was previously proposed for diagnosing pregnancy. It was found that the blood contained proteolytic enzymes 21 days after calving, and in some cases on the twenty-third

day. Apparently positive reactions were obtained some days later than the twenty-third.

The method is considered essentially a laboratory method, and can not be used by the average veterinarian unless he has good laboratory facilities.

Some tests made by E. Abderhalden are also included in the data.

Valuation of precipitating anthrax serum, W. RICKMANN and K. JOSEPH (*Berlin. Tierärztl. Wchnschr.*, 29 (1913), No. 33, pp. 591-593).—It is shown that a standard antigen made from diseased organs is not necessary for the valuation of precipitating anthrax serum. For this purpose the authors propose the use of bacterial extracts in which a determination is made of the total solids or dry substance. The total solids were found to be an index as to the amount of precipitating substances present.

Symptomatic anthrax and diseases resembling it.—I, (a) **Symptomatic anthrax,** F. WULFF (*Deut. Tierärztl. Wchnschr.*, 20 (1912), Nos. 40, pp. 609-614; 41, pp. 625-629).—It is shown that blackleg occurs with and without pathologic changes in the muscle tissue. A suspicion of blackleg may be awakened if the cadaver emits the characteristic rancid or rancid acid odor, or by the presence of a splenic tumor, liver spots, pleuritis, and serofibrinous pericarditis. A microscopic examination of the original material hardly ever presents anything which is characteristic, and consequently a test of this kind is of no practical value for diagnostic purposes. A diagnosis is only certain with the cadaver when the pathologic process is more or less extensive in nature and the changes are not related in any way to some disease of the productive system.

Blackleg may be suspected (a) if small, apparently unimportant, blackish red, dry or wet patches of diseased muscle are present, (b) by external hemorrhagic infiltration of the muscle, or (c) by the same findings in the organs.

Blackleg and diseases resembling symptomatic anthrax.—II, (b) **Diseases resembling symptomatic anthrax,** F. WULFF (*Deut. Tierärztl. Wchnschr.*, 20 (1912), No. 45, pp. 689-693).—A discussion of the author's findings with cases which, in many respects, resembled blackleg. In some instances bacteria were isolated which at first sight appeared to be the typical *Bacillus anthracis symptomatici*; consequently the process of diagnosing cases of symptomatic anthrax must be carefully conducted, and such aids as serum tests and animal experiments must be utilized.

Diagnosis of blackleg by examining the bile, III, F. WULFF (*Deut. Tierärztl. Wchnschr.*, 20 (1912), No. 46, pp. 705-709; *abs. in Centbl. Bakt. [etc.]*, 1. Abt., Ref., 56 (1913), No. 12, p. 367).—Out of 30 cases, undoubtedly symptomatic anthrax, the causative organism was noted 18 times in the bile, and in the remaining subjects the edema bacillus was observed. By injecting the muscle tissue from these 30 animals into guinea pigs, the typical symptoms of blackleg were produced in every case, consequently at the present state of our knowledge the bile is of no absolute value for diagnosing the presence of this disease.

Additional data in regard to the precipitation diagnosis in tuberculosis, F. MORELLI (*Ann. Ist. Maragliano*, 6 (1912), No. 4, pp. 290-297; *abs. in Ztschr. Immunitätsf. u. Expt. Ther.*, II, Ref., 6 (1913), No. 15, pp. 1107, 1108).—As a continuation of previous work (E. S. R., 28, p. 377) the results of examining 46 sera by the precipitation method are reported. It is believed that the method is a satisfactory one for diagnosing tuberculosis.

The intradermal reaction in bovines, M. DALKIEWICZ (*Przegl. Weterynarski*, 27 (1912), Nos. 5, pp. 195-199; 6, pp. 228-237; *abs. in Ztschr. Immunitätsf. u. Expt. Ther.*, II, Ref., 6 (1913), No. 15, p. 1063).—The reaction is deemed a good one, especially as a repetition will always give the same result.

Is tuberculin nontoxic for the healthy organism? P. GEIBEL (*Ztschr. Hyg. u. Infektionskrank.*, 73 (1912), No. 1, pp. 13-30; *abs. in Centbl. Bakt. [etc.]*, 1. Abt., Ref., 56 (1913), No. 7, pp. 212, 213).—The author states that the question as to the therapeutic value of tuberculin for human medicine and its value as a diagnostic agent in veterinary medicine has been decided in favor of tuberculin. On the other hand, very little is known about the toxic effect of tuberculin upon the healthy organism and very divergent views have been presented in this direction.

The author studied this problem with some tables placed at his disposal by Landmann. He believes that Koch's tuberculin can not be used for determining the effect of this product on the organism, since it contains in large amounts substances which are nonspecific such as glycerol and beef extract. With Landmann's tuberculin, however, the interfering factors are not present, and as a result of work with it he concludes that tuberculin to some extent affects the healthy organism. No grounds exist for believing that the toxin of the tubercle bacillus possesses only a relative toxicity.

The relation of bovine tuberculosis to human tuberculosis, B. MÖLLERS (*Arch. Wiss. u. Prakt. Tierheilk.*, 39 (1913), No. 4-5, pp. 465-472).—The author recognizes three types of tubercle bacilli, namely, human, bovine, and avian. He believes that all measures for preventing this disease must be directed against both the human and bovine sources of the malady. The most probable source of infection in man is from man.

Tuberculosis of food animals and its relation to the public health, W. JOWETT (*Agr. Jour. Union So. Africa*, 5 (1913), Nos. 1, pp. 89-99; 2, pp. 205-214).—A discussion of the causes of the disease, symptoms, udder tuberculosis, the post-mortem appearances in tuberculosis, the tuberculin test and its limitations, the methods of controlling tuberculosis, sanitation, relation of animal tuberculosis to public health, sterilized and pasteurized milk, tuberculosis from the standpoint of meat inspection, and tuberculosis of swine.

Tuberculosis of the tonsils in a heifer, P. CHAUSSÉ (*Bul. Soc. Cent. Méd. Vét.*, 90 (1913), No. 16, pp. 313-316).—A description of a case of primary tuberculosis in the tonsils of a cow.

Tuberculous orchitis in a horse, C. DARMAGNAC (*Bul. Soc. Cent. Méd. Vét.*, 90 (1913), No. 16, pp. 316-318).—A description of a case in an 8-year-old stallion. After ablation of the testicles the animal, so far as could be noted by clinical signs, returned to its normal condition.

Concerning the pure cultivation of Bang's bacillus, A. ASCOLI (*Ztschr. Hyg. u. Infektionskrank.*, 75 (1913), No. 1, pp. 172-184, fig. 1).—This relates to the biology of *Bacillus abortus*.

Addresses to the general assembly on tick eradication (*South Carolina Sta. Circ.* 24 (1914), pp. 35).—This circular presents addresses delivered by E. M. Nighbert, A. F. Lever, W. M. Riggs, and B. H. Rawl, respectively, before the general assembly of South Carolina on January 26, 1914, urging the advisability of an appropriation to be used in ridding the State of the Texas fever tick.

Onchocerca gibsoni: The cause of worm nodules in Australian cattle, J. A. GILBETH and GEORGINA SWEET (*Rpt. Austral. Assoc. Adv. Sci.*, 13 (1911), pp. 316-345, pls. 17).—Previously noted from another source (*E. S. R.*, 26, p. 183). See also another note (*E. S. R.*, 28, p. 680).

Anthrax in hogs, with a contribution to the Ascoli anthrax precipitation reaction, E. SEIBOLD (*Ztschr. Fleisch u. Milchhyg.*, 23 (1913), No. 7, pp. 150-153).—A description of the findings with the spleen, appendix, kidney, and bladder of a pig which died presumably of acute hog cholera, although some of the pathologic lesions pointed to the presence of hog erysipelas. The animal was fed on beet tops and leaves.

In the small nodules present in the spleen anthrax bacilli were detected, and the findings were verified by plating and animal tests. Precipitation tests were then made with the regular extract prepared according to the Ascoli procedure and with a chloroform sodium chlorid extract. The precipitating sera used were those of Ascoli, and Schütz and Pfeiler. With extracts made with the pulp of the spleen no reaction was obtained, but with those made from the nodules present in the spleen, a positive reaction resulted.

Investigations in regard to thermoprecipitation for detecting hog erysipelas, K. GAUSS (*Untersuchungen über die Thermopräzipitation zum Nachweis des Schweinrotlaufs. Inaug. Diss., Tierärztl. Hochsch. Stuttgart, 1912; abs. in Centbl. Bakt. [etc.], 1. Abt., Ref., 56 (1913), No. 22, p. 679.*)—The precipitation method is deemed satisfactory for detecting erysipelas in hogs. The specific reaction occurs instantaneously, or at least in from 2 to 3 minutes, when extracts of the kidney or heart are used. It takes a somewhat longer time with extracts of the spleen, liver, muscle, skin, and lung. The method of preparing these extracts has very little effect upon the reaction nor does it make very much difference whether fresh or putrefied material is used. When the specimens, organs, etc., have been conserved in alcohol or formaldehyde, the reaction is not affected, but glycerol affects the reaction somewhat, and a solution of Septoform or corrosive sublimate can not be used for preserving the diseased organs. Drying and heating the material to 130° C. have no effect upon the reaction.

In conducting the test it is always necessary to have a fresh antiserum.

Have reliable observations been made in regard to the spread of hog epizootics through protectively vaccinating against erysipelas? JAKOB ET AL. (*Abs. in Berlin. Tierärztl. Wchnschr., 29 (1913), No. 36, p. 653.*)—Hog cholera occurred from 10 to 12 days after vaccinating against erysipelas in 3 establishments where the animals were treated by the same veterinarians. In the first establishment, which contained 22 hogs, 20 were vaccinated and the other 2 were segregated but not vaccinated. All of the vaccinated animals died 10 days following the vaccination. On necropsy it was found that some of the hogs were affected with a septic form of plague, i. e., hog cholera, and the others with acute swine plague; and in another group chronic hog cholera was noted. The two segregated animals not vaccinated were then slaughtered and found to be affected with chronic hog cholera.

In the second establishment, containing 30 hogs, the animals also died from 10 to 12 days after vaccination. Here also the diseases mentioned above were noted on necropsy. The hogs of the third establishment behaved in a similar manner.

The above cases were treated with Gans's serum and cultures for vaccination purposes. Other experiences of the same kind are also reported by Ziegart, Fritsch, Kussman, and Ott.

Testing the vaccinating substances against swine plague, and some investigations with bacteria killed by heat, F. DÜERKOP (*Prüfung der Impfstoffe gegen Schweineseuche nebst Untersuchungen über die Immunisierung mit thermisch abgetöteten Bakterien. Inaug. Diss., Tierärztl. Hochsch. Hannover, 1912; abs. in Berlin. Tierärztl. Wchnschr., 29 (1913), No. 36, pp. 644, 645.*)—The vaccinating substances examined included (1) sera, (2) bacterial extracts, and (3) vaccines or curative lymphs. Among the sera the polyvalent variety seemed to give the best results. Klett and Braun's sera was especially satisfactory. The bacterial extracts (Gans, Schreiber, Rheinisch Serum Company, Piorkowski, Suptol-Burow, and Kraft's vaccine), while prepared by different methods and various strains of organisms, have some characteristics in common.

The author prefers bacteria killed by heat to bacterial extracts, as the former yield a more active and lasting immunity.

Vaccines (Höchst's vaccine, Gans and Schreiber extracts, and porcine), are suspensions of swine plague bacteria. In all probability these organisms are killed according to Wright's directions for preparing vaccines by heating them to about 60° C. With some of the lymphs, however, the bacteria, in addition to being treated in this manner, are disintegrated by special methods, while others have an addition of swine plague serum, which is added for the purpose of aiding in the solution of the organism after injection into the animal and for the purpose of preventing a negative phase. The Euman lymph also has an addition of swine plague bacilli.

Mammary botryomycosis in the mare, W. PLÖTNER (*Monatsh. Prakt. Tierheilk.*, 23 (1912), No. 6-7, pp. 279-304, pl. 1, figs. 2; *abs. in Vet. Rec.*, 26 (1914), No. 1338, p. 559).—"Early extirpation of the mammary gland is the best treatment for botryomycosis of the udder. Iodids are not advisable as agents for curative treatment, as the tumor, which is fibrous and not well supplied with blood vessels, is but little influenced by their internal administration. Iodid of potassium, however, may be used in small and recent botryomycotic tumors, and is also serviceable before and after the operation of extirpating the mammary gland. Before the operation it disperses the phlegmonous swelling surrounding the botryomycotic tumor, and thus facilitates surgical interference. Afterwards it encourages the absorption of postoperative edemas and swellings."

A bibliography of 42 titles is appended.

In regard to protectively vaccinating against the pectoral form of equine influenza (Brustseuche), D. KONEW (*Berlin. Tierärztl. Wchnschr.*, 29 (1913), No. 33, pp. 589-591).—In order to determine the immunizing properties of blood containing the specific micro-organism isolated by the author, tests were made with 80 sound horses present in a stable in which there were horses affected with equine influenza. The injection was given subcutaneously in the side of the neck in amounts ranging from 1 to 2 cc., the dose given being gauged according to the size and age of the animals. Following the injection the animals were not worked for 3 days and only one-third of the time for the next 4 days.

None of the horses vaccinated became sick. On the other hand, the disease occurred continually in other horses which were apparently sound at the time the group was vaccinated.

Following the above experiments vaccinations were made in the field and in regions where outbreaks occurred, and to date about 667 animals have been successfully treated.

About protective and curative vaccination for the pectoral form of equine influenza, BROMBERGER (*Berlin. Tierärztl. Wchnschr.*, 29 (1913), No. 33, p. 591).—A description of cases of the disease treated with Pfeiler's vaccine and serum, serum alone, or with Bengen's Ozonal. The results obtained were satisfactory.

Nematodes of the genus *Acuaria Brems.* (*Dispharagus Duj.*) parasitic in domestic fowls, A. HENBY and P. SIZOV (*Arch. Vet. Nauk [St. Petersburg.]*, 43 (1913), No. 7, pp. 609-637, pls. 9; *abs. in Rev. Gén. Méd. Vét.*, 23 (1914), No. 270, pp. 303-306).—A report of systematic and biological studies. A bibliography of 58 titles is appended.

Parasitism in relation to birds, H. V. JONES (*Zoologist*, 4, ser., 18 (1914), No. 206, pp. 41-53, pl. 1).—This paper deals chiefly with the Cestoda, Acanthocephala, and Nematoda found in the alimentary canal of some of the common birds. A table is given which shows the month, locality, food of bird, and position of the parasite when found. A list is also given of 24 species of birds ex-

amined, showing the average number of ectoparasites and endoparasites per individual.

Thirty-two per cent of the birds were found to be infested by cestodes and 25 per cent by nematodes.

RURAL ENGINEERING.

[Agricultural engineering] (*Agr. Student*, 20 (1914), No. 5, pp. 345, 346, 350-352, 355-365, figs. 6).—Special articles on agricultural engineering are included as follows: Agricultural Engineering as a Profession, by J. B. Davidson (pp. 345, 346); Fresh Water Systems, by S. E. Brown (pp. 350-352); Farm Implements, by W. E. Taylor (pp. 355-358); The Place of Agricultural Engineering in the Agricultural College Curriculum, by P. S. Rose (pp. 358, 359); Farm Lighting Plans, by J. P. Stout (pp. 360-362); and The Harvester Expert—His Training and Work, by C. O. Reed (pp. 363-365).

Rural engineering (*X. Cong. Internat. Agr. Gand*, 1913, *Compt. Rend.*, pp. 261-291).—This section reports the rural engineering proceedings at this congress (E. S. R., 29, p. 101).

Water conservation and irrigation (*Off. Yearbook Aust.*, 6 (1901-1912), pp. 569-583, fig. 1).—Statistical data are given regarding water supply works, including the development of artesian supplies, and irrigation systems of Australia.

The wet lands of southern Louisiana and their drainage, C. W. OKEY (*U. S. Dept. Agr. Bul.* 71 (1914), pp. 82, pls. 4, figs. 19).—This bulletin, intended for land owners, engineers, and others interested in drainage by pumping, especially in the wet prairies along the Gulf coast, includes all the salient features of the information so far published on this subject (E. S. R., 24, p. 287), and gives also the results of later investigations.

A description of general conditions in the Gulf coast section of Louisiana is followed by a statement and brief consideration of some of the larger drainage problems encountered, and emphasizing the need of more complete cooperation between various interested parties in the study and solution of such problems. The results of detailed examinations of a number of drainage districts reclaimed or in process of reclamation are reported with a summary of such results. The bulletin closes with a consideration of the problems involved in land drainage by means of pumps in Louisiana, which is a continuation of work previously reported (E. S. R., 26, p. 589).

Better roads, E. T. TANNATT (*Mont. Farmers' Bul.* 2, pp. 29, pls. 3, fig. 1).—This is a popular discussion of the general factors entering into and affecting the good roads problem in Montana.

Forest road construction, H. STOETZER (*Waldwegebunkunde. Frankfort on the Main*, 1913, 5. ed., pp. 251, pls. 3, figs. 112).—This is a reference book for engineers in charge of the design, location, construction, and maintenance of forest roads. The three main divisions are (1) the location and design of forest roads; (2) construction, maintenance, and cost; and (3) forest railroads and cable roads.

The cause and the prevention of cracking in concrete roads, H. S. SPACKMAN (*Concrete-Cement Age*, 3 (1913), No. 6, pp. 261-263, figs. 3).—The author gives curves of test data showing the extent to which the drainage of water from the concrete may cause shrinkage within the first few hours after being placed. He concludes from his own and other tests "that the change in volume due to climatic influences after the concrete has hardened is not sufficient in itself to cause the cracking noted in concrete roads," and that "the concrete slab is not a continuous structure, but consists of a number of pieces of various

sizes in close contact, but without bond, the cohesion between the several pieces having been broken by microscopical hair-cracks, formed by shrinkage. . . . These natural lines of cleavage form lines of weakness, along which the concrete is easily fractured by external force, which ordinarily would not cause sufficient stress to overcome the cohesion of a solid concrete slab."

Approximate stresses produced by a concentrated load on a continuous slab supported on earth or other yielding foundation, J. W. PEARL (*Engin. and Contract.*, 41 (1914), No. 6, pp. 186-188, figs. 3).—The author derives formulas with diagrams to determine the stress produced by a concentrated load on concrete pavement slabs supported on earth or other yielding foundation. He discusses the formulas and illustrates their application to pavements and to flat concrete slabs on columns.

Strength of large pipes, D. R. COOPER and E. R. WEINMANN (*Engin. Rec.*, 69 (1914), No. 5, pp. 133-137, figs. 16).—This is a mathematical discussion of stresses in circular conduits, with or without internal pressure, and with various widths of support at bottom.

Reinforced concrete construction, G. A. HOOL (*New York and London, 1912, vol. 1, pp. X+254, figs. 88; 1913, vol. 2, pp. 659*).—The first volume of this work deals with the fundamental principles of reinforced concrete design and includes numerous tables and diagrams to facilitate the calculation and designs of reinforced concrete structures. The work "presupposes a knowledge of the elements of structures." The chapters included are as follows: Concrete; steel; concrete and steel in combination; rectangular beams; slabs, cross-beams, and girders; columns; slab, beam, and column tables; slab, beam, and column diagrams; and bending and direct stress.

Volume 2 covers in some detail the subjects of retaining walls and buildings. The first part is subdivided into chapters on theory of stability, design, and construction of retaining walls. The second part deals with buildings, the first section including chapters on floors, types of reinforcement, roofs, columns, foundations, walls and partitions, stairs, contraction and expansion, shear and moment considerations in continuous beams, eccentric load consideration in columns, and wind stresses. The second section contains chapters on materials, forms, bending and placing of reinforcement, proportioning, mixing, and placing of concrete, finishing concrete surfaces, and waterproofing of concrete. The third section covers estimating unit costs, estimating quantities, and an example of an estimate for a concrete building.

[Farm power and machinery] (*Prairie Farmer*, 86 (1914), No. 3, pp. 123, figs. 8).—Special articles on farm power are included as follows: Tractor *v.* Horse as a Source of Farm Power, by H. J. Sconce (pp. 81, 82); Shall I Buy a Farm Tractor? by I. W. Dickerson (p. 82); [The Work of the Gas Engine], by F. M. White (pp. 83, 95); Points on the Purchase and Care of Farm Machinery, by C. O. Reed (pp. 83, 84, 96); The Windmill as a Source of Power on the Farm, by E. A. White (pp. 85, 96, 97); [Household Power Conveniences], by L. W. Chase (pp. 87, 105, 106); and [Farm Machinery Review for 1914], by F. M. White (pp. 85-87, 100, 101, 103, 106, 107, 111, 119).

Farm motors, A. A. POTTER (*New York and London, 1913, pp. IX+261, figs. 278*).—This book is intended to include the fundamental principles governing the construction, working, and management of motors which are suitable for farm use, including steam engines, gas, and oil engines, traction engines, automobiles, water motors, windmills, and electric motors. The method followed in each chapter is to give (1) the fundamental principles underlying the particular motor, (2) the principal parts of the motor, (3) the auxiliary parts, (4) the uses to which the particular type of motor is adapted, and (5) the selection, erection, and management of the different machines. Practical

information is given regarding steam, gas, and electricity, and some space is devoted to the more refined methods used in engineering practice for improving the economy of various motors. It is the opinion of the author that a knowledge of the best engineering practice is not only of considerable educational value but will lead to the more perfect manipulation of the simple farm motors.

“While this book was prepared primarily as a text-book for students in agricultural engineering, the subject matter is so presented that it will be of equal value to farmers and to operators of various kinds of engines and motors.”

The adaptation of kerosene to gasoline engines, G. A. RICHTER and B. L. PIERCE (*Sci. Amer. Sup.*, 77 (1914), No. 1984, pp. 22, 23, figs. 5).—The experimenters confined themselves to the utilization of kerosene with special reference to water injection methods. A single cylinder 4-cycle engine rated at $5\frac{1}{2}$ horsepower at 650 revolutions per minute was used. The method of water injection consisted of a jacketed intake pipe terminating below in a T connection, which was fitted with elbows. A carbureter was fitted into each of the two elbows, with the idea of injecting both the kerosene and the water by means of respective vaporizers.

Kerosene when used alone caused excessive cylinder carbonization, but the injection of water with the kerosene cooled the cylinder walls, removed carbon and tended to prevent its deposit to an objectionable degree, and reduced the violence of the explosions. The injection of water also appreciably increased the thermal efficiency, the maximum efficiency being observed when the ratio of water to kerosene was 22:100 by weight. Absolute control of this ratio was not necessary as this maximum efficiency remained practically constant for several points to either side. Cylinder carbonization was decreased 82 per cent by injecting water with kerosene, and an oxidizing solution of ammonium nitrate increased this value to 88 per cent, but its use was not warranted. Spark plugs with long points were more satisfactory than those with short points when kerosene was used.

The water jacketed intake heated to a temperature of 60° C. is considered sufficient to give satisfactory carburetion with kerosene. “The field advantageously affected in efficiency by water injection is limited from one-third to full load for the engine in question.”

The use of internal-combustion motors in Danish agriculture, C. L. FELLBERG (*X. Cong. Internat. Agr. Gand. 1913, Sect. 4, Question 1, pp. 8*).—A review of statistical data indicates steady progress in the use of internal-combustion power in Danish agriculture. The 2-cycle crude oil motors of domestic manufacture are said to be preferred. Private electrical systems are usually installed on the larger estates using crude oil motors for power. On medium sized estates portable and stationary internal-combustion motors are more used, with various methods of mechanical transmission of power. The smaller agriculturists rarely use internal-combustion motors but often belong to electrical associations and use small portable electric motors.

The science of laying out and the art of plowing with power (*Peoria, Ill., 1913, pp. 8, figs. 7*).—This work is diagrammatically illustrated.

Recent tests of mechanical cultivation in France, G. COUPAN (*X. Cong. Internat. Agr. Gand. 1913, Sect. 4, Question 1, pp. 13*).—A discussion and comparison of the more recent mechanical cultivation experiments in France, in which the conclusion is drawn that the different tests have not given sufficiently concordant results regarding the direct purpose of the tractor. This is attributed to the extreme difficulty of eliminating all the causes of error. For

this reason it is thought that all such tests should be conducted before the judges only and that the general public should be excluded.

Motor cultivation by tractors or rotating cultivators, K. DE MEYENBURG (*X. Cong. Internat. Agr. Gand, 1913, Sect. 4, Question 1, pp. 10*).—This is a comparative discussion of tractor-drawn plows and motor scarifiers or rotating cultivators in which the author favors the latter type.

Basis for the testing of mechanical cultivating implements, F. GIORDANO (*X. Cong. Internat. Agr. Gand. 1913, Sect. 4, Question 1, pp. 9, pls. 2, figs. 5*).—In the testing of soil cultivating machinery the importance of first determining the tenacity or cohesive properties of a soil and the frictional resistance of the soil particles to a metal wedge is pointed out, and a device for determining these physical characteristics of the soil is described.

Motor-drawn and motor-operated grain binders, M. RINGELMANN (*Jour. Agr. Prat., n. ser., 78 (1914), No. 2, pp. 54-57, figs. 3*).—The author reviews the results of dynamometer tests of grain binders and shows by curves of data the tractive power required for drawing the binder and for operating the mechanism. He concludes that the average binder in average wheat or oats with a 1.5 meter sickle and a speed of about 1.2 meters per second will require a 4-horsepower motor for operating the mechanism alone, and a 14 to 15-horsepower motor for both locomotion and operating the mechanism, due allowance being made for possible grades and obstructions.

Experiments with an electrically-driven thrashing machine, G. COUPAN (*X. Cong. Internat. Agr. Gand. 1913, Sect. 4, Question 1, pp. 14-16*).—These experiments show that the hulling, cleaning, etc., of grain require only a small part of the total power utilized by the thrasher, the greater portion being consumed by the friction of the mechanism.

Operating characteristics of centrifugal pumps, A. B. MORRISON, JR. (*Power, 39 (1914), No. 5, pp. 166-168, figs. 2*).—Centrifugal pumps are discussed from the standpoint of operation, taking up particularly the effect of speed and head on the capacity, and the influence of throttling *v.* some form of speed control on the efficiency.

The author is of the opinion that wherever feasible some form of speed control should be used. "It is almost impossible to determine accurately beforehand the head against which the pump will work, and with a fixed speed any change in piping or operating conditions may make a great difference in the amount discharged and in the power required." Curves and data are included.

The cost of pasteurizing milk and cream, J. T. BOWEN (*U. S. Dept. Agr. Bul. 85 (1914), pp. 12, fig. 1*).—This bulletin deals with the cost of pasteurization by the "holder" and "flash" processes from an engineering point of view, and contains information for proprietors of creameries and milk plants and for designers and manufacturers of pasteurizing apparatus. Tests are reported on the milk pasteurizing equipment of five city milk plants and on the cream pasteurizing equipment of four creameries, the latter covering both the flash and holder processes.

In the milk pasteurization test, live steam was used taken direct from the boiler, but reduced in pressure to from 3 to 5 lbs. while the cream pasteurization was accomplished by using (1) live steam direct from the boiler, (2) exhaust steam from the engine or from steam-driven pumps, and (3) hot water heated by the exhaust steam from the steam-driven auxiliaries.

Data of the tests relative to heating, cooling, heat balance, temperature balance, and costs are given in tabular form. The average cost of pasteurizing 1 gal. of milk was found to be 0.313 cts., and the average cost of pasteurizing 1 gal. of cream, 0.634 cts.

The conclusions drawn from the test are as follows: The flash process of pasteurization requires approximately 17 per cent more heat than the holder process and there is a correspondingly wider range through which the milk or cream must be cooled. The proper design and arrangement of the heater, regenerator, cooler, piping, and refrigerating apparatus have much to do with the efficient operation of the plant. With poorly arranged apparatus and leaky piping the loss in heat may reach approximately 30 per cent of that required to pasteurize, which it is practicable to reduce to a negligible amount. It is practicable to use exhaust steam from the engine and steam-driven auxiliaries, or water heated by exhaust steam, to furnish heat with which to pasteurize both milk and cream. Usually there is sufficient heat in the exhaust steam which is allowed to waste in milk plants and creameries to do the pasteurizing. For every 400 lbs. of milk pasteurized per hour with exhaust steam, approximately one horsepower is taken off the boiler plant.

Electric stimulation of plant growth, W. D. PEASLEE (*Jour. Electricity*, 32 (1914), No. 4, pp. 69-72, figs. 8).—Studies of stimulation of plant growth by electrical methods are reported.

A direct current passing through the soil containing the seeds or roots of plants caused a gain in root structure, and the electrified plants after transplanting were more hardy and grew faster than the nonelectrified. Similar tests with alternating currents gave positive results only at very low power values.

The application of a voltage stress to the atmosphere around plants caused good results only when the stress was applied on cloudy days and at night. Two important points brought out are (1) that no difference in stimulative effect was found when using the ground as positive or negative, and (2) that there is some tendency to show for all plants a curve approximating a straight line within certain limits, the slope of this curve being different for each plant. Practically the same results were secured when using a Tesla coil as when using a Wimshurst machine.

It is concluded in general that indirect stimulation of the root or plant increases the functional activity of the organs if they are far enough from the point of application of the stimulus to avoid the effect of direct stimulation. Though the immediate effect of direct stimulation is to retard growth, it increases the internal energy of the plant and the after effect is to increase the growth rate. Plants are very sensitive to fatigue and the stimulation must be of such degree and duration that fatigue is avoided if the net result of the treatment is to be beneficial.

The dissolving of zinc from pure zinc and galvanized iron pipes by water supplies, K. B. LEHMANN (*Jour. Gasbeleucht.*, 56 (1913), pp. 717-722; *abs. in Wasser u. Abwasser*, 7 (1914), No. 10, pp. 423, 424).—Investigations by the author and others on the action of both hard and soft water on galvanized and pure zinc water pipes show that under the best conditions the zinc content of the water was always moderate, and greater amounts were obtained from the galvanized than from the pure zinc pipes as long as zinc remained on the galvanized pipe. It is concluded that the use of pure zinc water pipe is hygienic and unobjectionable.

The hot water supply plant for private houses, C. A. GULLINO (*Gasndhts. Ingen.*, 37 (1914), No. 2, pp. 24-28, figs. 6).—The author discusses in detail the design of private hot water supply plants for both city and farm houses, economy and efficiency being the chief considerations.

Elements of heating, E. N. IRWIN (*Power*, 39 (1914), No. 3, pp. 89-92).—This article gives practical information regarding air, steam, and water as media for the distribution of heat, including tables of data for computing the heat losses from a building and the radiating surface required.

Some suggested designs for sewage treatment plants for residences and small institutions, P. HANSEN (*Abs. in Engin. and Contract.*, 41 (1914), No. 5, pp. 169-172, figs. 3).—This article gives data on the cost of installing a plumbing system, the design and operation of simple septic tanks, a modified Imhoff tank adapted to the use of a household of 10 persons, a subsoil irrigation system, an intermittent sand filtration plant to handle the sewage from 25 persons, and a double contact filtration plant.

A combination cesspool and septic tank, J. F. DULING (*Engin. News*, 71 (1914), No. 6, p. 305, fig. 1).—A combination cesspool and septic tank, which is recommended for use in porous sandy soils underlaid by gravel in localities where the domestic water supplies are taken from shallow wells, is illustrated and described.

A new suggested method of water testing for plumbing fixtures, H. F. SHADE (*Dom. Engin.*, 66 (1914), No. 7, pp. 200, 201, figs. 2).—A new method of water testing of plumbing fixtures to take the place of the usual air or water tests is described and its application illustrated.

Plumbing practice as seen by the inspector (*Dom. Engin.*, 66 (1914), No. 7, pp. 198-200, figs. 9).—This report illustrates and describes recent developments in plumbing fixtures and in arrangements of plumbing, including faucets, connection of vent lines, traps with concealed partitions, and grounding of electric fixtures in bathrooms.

RURAL ECONOMICS.

The agricultural outlook (*U. S. Dept. Agr., Farmers' Bul. 584* (1914), pp. 22).—This bulletin contains statistical data showing by States the estimated stocks on farms and in interior mills and elevators, price per bushel March 1, and percentage of crop which moves out of the county where grown for wheat, corn, oats, and barley; wages of male farm labor per month with and without board, and at harvest season and at other times per day with and without board; percentages of increase in wages from 1893, 1899, and 1909 to 1913; the average length of time per day required of hired labor; prices of agricultural products March 1, 1913, and 1914 for rye, buckwheat, potatoes, hay, flax, cotton, butter, eggs, and chickens; and the aggregate value per acre of the 12 leading crops.

Accompanying these tables are a short discussion and two articles, one on preparing seed corn for planting, by C. P. Hartley, and the other on the preparation of seed grain for spring planting, by M. A. Carleton.

It is reported that the money wages of farm labor increased about 2.5 per cent during the past year and about 11 per cent during the past 4 years. The average length of time required per day of hired labor on farms is reported by correspondents at 9 hours 48 minutes.

The value per acre of crop production in 1913 is estimated at approximately \$16.31, the highest average thus far recorded.

Agricultural production in West Virginia, O. M. JOHNSON (*West Virginia Sta. Bul. 144* (1914), pp. 37-68, figs. 33).—The author, by means of county outline maps, shows graphically the localization of farm crops and animals, the average yields, the number of mature horses per farm, the total value of all farm property, the percentage of tenants on farms, and the percentage of farms with mortgages. By the use of census and other data he has estimated, by counties, the income and expenses per farm in order to obtain the labor income per farm family, and estimates the average labor income per farm family for the State as a whole as \$181. The highest for a single county was \$402. On this basis, there were two counties which even failed to produce enough to pay

5 per cent interest on the investment. He found those counties more prosperous which have a large investment in live stock.

One-half of the rural section of the State shows a decrease in population. The farms are somewhat smaller than 10 years ago and most of the staple crops are decreasing in their total acreage and production. The planting of young orchards is increasing rapidly.

Some indications of the economic and agricultural progress of Argentina (*Internat. Inst. Agr. [Rome], Mo. Bul. Econ. and Soc. Intel., 4 (1913), No. 10, pp. 104-132*).—After describing the natural and agricultural resources of the country it is shown that the total cultivated area increased from 580,008 hectares (1,432,620 acres) in 1872 to 2,459,120 hectares in 1886, and to 21,838,689 hectares in 1911. The production of wheat increased from 1,263,000 tons in 1895-96 to 5,400,000 tons in 1912-13, flax from 232,000 tons to 1,130,000 tons, and corn from 2,240,000 tons to 5,000,800 tons. During practically the same period the number of plows imported increased from 10,660 to 83,483, reapers from 2,723 to 11,534, seeders from 719 to 21,962, and threshers from 299 to 1,127.

It is also shown that there has been a marked increase in the number of live stock, the number of native bred live stock decreasing and the number of half-bred and thoroughbred increasing. Between 1896 and 1912 the value of the exports of agricultural produce and live stock increased from 113,666,625 pesos (\$109,688,293) to 466,402,528 pesos.

Attention is called to the fact that, although there are many holdings of extremely large sizes, the number of small holdings is increasing rapidly.

[Agricultural statistics of British India] (*Agr. Statis. India, 28 (1907-1912), I, pp. III+420*).—This is the annual statistical statement showing the areas devoted to different agricultural purposes, irrigated, in fallow, and in specified crops; the number of live stock, plows, and carts; and the number of transfers of land and areas transferred.

[Land tenure and settlement; agriculture and live stock in New Zealand], M. FRASER (*New Zeal. Off. Yearbook 1913, pp. 481-587, pls. 2, fig. 1*).—This annual report contains information concerning the distribution of crown and native lands, land transfer and deeds registration, occupation and ownership of land, area and yields of farm crops, and number of live stock.

[International statistics of agriculture] (*Statis. Aarbok Konger. Norge, 33 (1913), pp. 249-252*).—This statement contains data showing for a large number of countries and for the latest year available the area and production of wheat, rye, barley, oats, corn, rice, potatoes, and sugar beets, and the number of horses, mules, asses, cattle, sheep, goats, and swine.

Is scarcity to be preferred to plenty? L. R. JOHNSON (*Breeder's Gaz., 65 (1914), No. 9, pp. 461, 462, figs. 3*).—The author concludes that large crops mean prosperity to the many and small ones prosperity to the few, and that even though the farmer may get less for the large crop its influence reaches into all the channels of business and produces in the aggregate greater national prosperity.

History and description of a farm in the valley of the Unstrut, M. SCHÖNE (*Landw. Jahrb., 45 (1913), No. 4, pp. 597-608*).—This article describes the changes that have taken place since 1863 in a farm belonging to the same family. After noting the climate and topography of the region the author shows, for 5-year periods beginning with 1872-1876, the area devoted to the different crops, yield and value per morgen, fertilizers used, number of work animals and other kinds of live stock, price per pound and quantity of milk used in making butter, agricultural machinery used, and number of laborers and their wages.

The division of capital in agriculture as between landlord and tenant, R. PAGET (*Jour. Farmers' Club [London], 1914, Mar., pp. 23-30*).—According to the present system of leasing farm land it is the produce of the farm and not the profit that is divided between landlord and tenant. The author outlines a system which "is based on the assumption that in the average case it would be fair that the farmer should have as much of the profits in respect of his skill and management (apart from any capital he may invest) as the landlord gets in respect of the use of his land and buildings, and that whoever puts in the capital should get a further share of profits in respect of this investment."

Landed proprietors and agriculture in Norway (*Statist. Aarbok Konger. Norge, 33 (1913), pp. 39-45*).—Statistical data are given showing for 1907 the total number of landed proprietors and their distribution by areas cultivated. Data are also presented for 1907 showing the area devoted to the principal agricultural purposes and for 1912 the area and production of the principal farm crops. For the latter item comparative data are given for earlier years.

Farm credit conditions in a cotton State, L. H. HANEY (*Amer. Econ. Rev., 4 (1914), No. 1, pp. 47-67*).—The author describes the farm credit situation in Texas as determined by a special investigation. He shows the type of credit furnished to the farm owners by the banks and to the tenants by the storekeeper and landlords and indicates the inability of the present system to supply adequate credit at reasonable rates. He advocates that a cooperative organization be formed which should seek to become an effective credit middleman between the present latent and ill-used bases of credit among farmers and the funds held in commercial banks.

Helping the farmer to keep his farm, E. N. BREITUNG (*Business America, 15 (1914), No. 3, pp. 210-212*).—According to the author, one of the worst features of the present system of mortgaging farms is that if the farmer is unable to meet the payments, because of some disaster unforeseen, he may lose his farm at once. To prevent this he would have the farmer under such conditions contract to keep his property up to a certain standard and would form a company with a large credit capital to work the farm in order to pay off its indebtedness and meet the obligations out of the company's surplus. If the farmer is competent he could remain on the land, and as soon as the farm is out of debt it will come back to him.

Special report of New York State delegates on the American Commission for the study of agricultural cooperation in Europe, compiled by F. H. ALLEN and C. C. MITCHELL (*N. Y. Dept. Agr. Bul. 56 (1914), pp. 747-1048, pls. 32*).—This report notes the most striking facts observed in European agriculture and contrasts them with conditions in New York, describes the business organization and agricultural conditions in Europe and points out that the raising and transportation of products constitutes the farmer's part in feeding the nation while marketing and agencies of delivery come within the sphere of the consumer.

Among the greatest needs of the State of New York are considered a readjustment of the existing methods of distributing farm crops, cooperation among the consumers in purchasing, the commercializing of agricultural business, simpler and cheaper means of borrowing money, better roads in the country and particularly the side roads, and practical demonstration on the farm of what it is possible to do under average conditions in farming for profit.

Instruction in marketing (*Daily Cons. and Trade Rpts. [U. S.], 17 (1913), No. 60, pp. 961-970*).—This report consists of a general description of the various methods employed to give instruction in cooperation and marketing in Germany, Netherlands, Denmark, France, and England.

The story of the C. W. S., P. REDFERN (*Manchester: Coop. Wholesale Soc. Ltd.* [1913], pp. VIII+439, pls. 83, figs. 9).—This book contains a very complete description and history of the Cooperative Wholesale Society Limited beginning with 1863.

The organization and present status of the Prussian Chamber of Agriculture, A. OBERG (*Über die Organisation und Zuständigkeit der Preussischen Landwirtschaftskammern. Inaug. Diss., Univ. Greifswald, 1913, pp. 116*).—The author discusses the history, establishment, organization, and efficiency of the Prussian Chamber of Agriculture.

AGRICULTURAL EDUCATION.

Rural life and education, E. P. CUBBERLEY (*Boston, New York, Chicago, [1914], pp. XIV+367 pls. 22, figs. 81*).—The first part of this book sets forth the rural life problem in its historical development and shows the origin and present status of the rural school problem. The second part sets forth more specifically the present rural school problem and points out the fundamental remedies which must be applied for its solution.

Among the legitimate functions prescribed for the redirected school are the conservation of soil fertility, the improvement of farm methods, the dissemination of agricultural and general knowledge, the improvement of home life, etc. There should be added to the course of study of every rural school, in place of much that has been and often still is taught, instruction in nature study, school gardening, agriculture, manual training, domestic science, music, and play. The work in agriculture, home economics, and manual training should be extended and carried on in the high school and rural teachers should be trained in agriculture. Appended to each chapter is a list of questions for discussion, and to the end of the book a bibliography of 80 titles of recent literature bearing on the rural problem.

Educational resources of village and rural communities, J. K. HART (*New York, 1913, pp. X+277*).—This book discusses the great main lines of community interest, activity, and resource and their part in the education of the child and the community. Two chapters are devoted to the sort of school that is needed to meet the changed needs of our times.

“Since agriculture is our chief primary industry, the redirected education for the open country must be agricultural in its nature . . . must aim to make better farmers and better helpmeets for these farmers, must make the occupation more remunerative, and the whole life more satisfactory and free from city domination.”

“Nature study should form the background for the greater part of the rural school curriculum.” It is suggested that nature study in the first 5 years be followed in the last 3 years with nature study and agriculture. “The entire 8 years’ course may be considered as an accumulative growth unmarked by any break to show where nature study ends and agriculture begins.”

Each subject is followed by questions directing students to specific phases of the subject which should be looked for and thoroughly studied in each local community, and by a brief bibliography.

Rules and regulations [governing the instruction in agriculture and domestic science], T. H. HARRIS (*Baton Rouge, La.: State Supt. Pub. Ed., 1913, pp. 11*).—This pamphlet contains the rules and regulations adopted by the state board of education to govern departments of agriculture and domestic science, and suggestive lists of implements, equipment, etc., to be used in such departments.

The agricultural instruction act (*Agr. Gaz. Canada, 1 (1914), No. 1, pp. 31-38*).—The text of the act, approved June 6, 1913, appropriating \$1,000,000 for the advancement of agricultural instruction in the provinces of Canada (E. S. R., 29, p. 198) is given, together with the form of agreement of provincial governments under the act, and an itemized statement of federal appropriations to provinces in 1913-14.

[Progress in agricultural education in Canada in 1913] (*Agr. Gaz. Canada, 1 (1914), No. 2, pp. 69-139, figs. 16*).—This number is devoted largely to progress in agricultural education in Canada, including the following articles: The Ontario new field husbandry building, work of the department of agriculture in Prince Edward Island, progress of agricultural education in Nova Scotia, agricultural education in New Brunswick, agriculture in the Province of Quebec, acre profit competition in Ontario, agricultural instruction in Manitoba, agricultural extension work in Alberta, boys' potato growing contests in Carleton and Russell Counties in 1913, and the rural school problem and its relation to agricultural teaching.

Agricultural organization in Belgium (*Notice sur l'Economie Rurale et l'Organisation Administrative de l'Agriculture. Brussels: Min. Agr., 1913, pp. 86, pls. 9*).—This publication, prepared for the 1913 exposition at Ghent, gives brief accounts of the organization of the ministry of agriculture, veterinary instruction, and affairs, official and private agricultural associations, agricultural and horticultural education and research institutions, agricultural courses in nonagricultural institutions, agricultural home economics schools, elementary and popular agricultural instruction, the service of state "agronomes" and horticultural advisers, agricultural statistics, special phytopathological service, etc.

Nature-study and the teaching of elementary agriculture, ANNA B. COMSTOCK (*Nature-Study Rev., 10 (1914), No. 1, pp. 1-6*).—In the author's opinion, the only way to make the teaching of elementary agriculture "of permanent value is to ground it in nature study, because in nature study the child finds the answer to the why of agriculture and the following up of this why broadens out in so many directions that there is no chance of the agricultural processes becoming an old story." She considers how and why nature lessons on the soil, seed testing, form, growth, and function of roots, leaves, and flowering plants, fertilization of flowers, weeds, insect pests, birds, and live stock add permanency of value and interest to elementary agriculture.

Some students' work (*Nature-Study Rev., 10 (1914), No. 1, pp. 24-29*).—These observations by normal school students consist of field work in the identification and study of the general habits of a number of birds, and a nature calendar of birds, flowers, trees, shrubs, insects, farm activities, and other observations.

The present status of nature-study in the elementary schools, ALICE J. PATTERSON (*Nature-Study Rev., 9 (1913), No. 8, pp. 239-244*).—In an investigation of nature-study methods in the schools of this country, based on a study of the state courses of 20 States and those of 30 large cities and representing the 4 geographical regions of the country, the author finds that (1) nature study is recognized as a school subject in both state and city courses in all parts of the country; (2) there is considerable unity of purpose in the courses offered, namely, to bring children into intelligent and sympathetic touch with daily life and to train them in a scientific attitude of mind; and (3) the material suggested is that found in the environment of the schools. The biological phase receives greatest emphasis. State courses give a decided agricultural trend to the work of the grammar grades. Gardening, making collections, setting up apparatus, and other hand work constitutes a fair proportion

of the courses, and definite correlation with other school subjects is suggested in the majority of the outlines.

The school gardens of Saginaw, KATE M. PASSOLT (*Nature-Study Rev.*, 10 (1914), No. 2, pp. 53-56).—The development of school gardens in Saginaw, Mich., which were commenced in 1903, and the course in gardening are outlined.

Should school gardens survive? A. D. CROMWELL (*Nature-Study Rev.*, 10 (1914), No. 1, pp. 30-32).—The author discusses the kinds of school gardens which should and should not survive, and in view of the greater popularity of the city over the country school garden suggests how plant breeding can be made a very promising field for the latter.

Supervising a community garden in summer, ELIZABETH M. WATERS (*Nature-Study Rev.*, 10 (1914), No. 2, pp. 65-68).—The author gives an account of her experience in supervising a community garden in Chicago in the summer. In conclusion she suggests that this kind of work be put on an industrial basis, that the gardening be done so well and so systematically that it shall yield a profit, that it is wiser that the children should not have all the profit but learn to share the profits, and that getting some pin money in this way lessens the temptation to steal, while estimating the commission gives real practice in percentage.

The lay of the land, J. G. NEEDHAM (*Nature-Study Rev.*, 10 (1914), No. 1, pp. 14-18).—A discussion of the natural lay of the land is followed by a lesson of the natural fields of the farm, taken from the author's field course on the natural history of the farm now being given to freshmen in Cornell University.

Farmers' institute and agricultural extension work in the United States in 1913, J. HAMILTON (*U. S. Dept. Agr. Bul.* 83 (1914), pp. 41).—This is the annual report of the Farmers' Institute Specialist of this Office for 1913 concerning the work of the Office in promoting farmers' institutes and the development of the farmers' institute movement in the different States and Territories. It includes also, among other things, an account of the growth of the institutes during the last decade, administrative methods in use, extension work by the agricultural colleges, the annual meeting of the American Association of Farmers' Institute Workers, a meeting of the section on extension work of the Association of American Agricultural Colleges and Experiment Stations, correspondence schools, aid to agriculture by transportation companies, and agricultural extension work in foreign countries; a list of the state officials in charge of farmers' institutes; and the usual statistical tables covering various lines of institute effort.

MISCELLANEOUS.

Annual Reports of the Department of Agriculture, 1913 (*U. S. Dept. Agr. Rpts.* 1913, pp. 370).—This contains the reports of the Secretary and heads of bureaus and other administrative officers. The various reports are also issued as separates.

Twentieth Annual Report of Minnesota Station, 1912 (*Minnesota Sta. Rpt.* 1912, pp. XLVI+186+V, pls. 5, figs. 83).—This contains the organization list, a list of the publications of the year, a financial statement for the fiscal year ended June 30, 1912, a report of the director summarizing the work of the station and its substations, and reprints of Bulletins 125-128, previously noted.

Twenty-first Annual Report of Minnesota Station, 1913 (*Minnesota Sta. Rpt.* 1913, pp. 92, figs. 3).—This contains the organization list, a financial statement for the fiscal year ended June 30, 1913, and a report of the director summarizing the work of the station and its substations. Portions of the report relating to dairy and animal husbandry have been abstracted elsewhere in this issue.

Report of the director, 1913, J. G. LIPMAN (*New Jersey Stas. Bul.* 263 (1913), pp. 57).—This contains the organization list, a report on the work and problems of the station during the year ended October 31, 1913, and a discussion of its opportunities and needs.

Finances, meteorology, index (*Maine Sta. Bul.* 222 (1913), pp. 319–325+XX, pls. 2, figs. 3).—This contains the organization list of the station; meteorological observations noted on page 117 of this issue; a financial statement for the fiscal year ended June 30, 1913; an index to Bulletins 209–222, which collectively constitute the twenty-ninth annual report of the station; a list of the publications issued during the year; and announcements and notes on the work, personnel, and equipment of the station, including a description of the station building.

The relation of the experiment station to the agricultural college and to university extension, S. B. DOTEN (*Better Farming [Univ. Nev.]*, 1 (1913), No. 7, pp. 1–8).—A discussion designed to give “a clear idea of the differences between the experiment station work and the work of the agricultural college and work in extension.”

[Annual Report of the Rothamsted Experimental Station, 1913], E. J. RUSSELL (*Rothamsted Expt. Sta., Harpenden, Ann. Rpt. 1913*, pp. 32).—A progress report for the year.

The organization of experimental work in agriculture in the German colonies, W. BUSSE (*Bul. Imp. Inst. [So. Kensington]*, 11 (1913), No. 3, pp. 462–478).—An account of the experimental work undertaken in the German colonies in Africa and Samoa with a discussion of its opportunities and needs.

Laws and regulations relating to the work of the department of agriculture of the State of Washington (*Olympia, Wash.*, 1913, pp. 127).—A compilation of the statutes governing the work of the Washington State Department of Agriculture and the rules and regulations promulgated for their enforcement.

New Jersey handbook of agriculture, compiled by A. L. CLARK (*N. J. Handbook Agr.*, 1912, pp. 43, pls. 20).—Part 1 of this handbook discusses the agricultural resources of New Jersey; part 2, its agricultural industries; and part 3, agricultural education. Much of the material was prepared by members of the staff of the New Jersey College and Stations.

The farmers' ready reference book (*St. Joseph, Mo.* [1913], pp. 186, figs. 36).—A collection of articles on various farm topics, based largely upon the publications of this Department, the state experiment stations, and the experience of individual farmers.

Bibliography of scientific writings by the late William McMurtrie, E. M., Ph. D.—Agricultural chemistry, textile fibers, industrial chemistry, technical education, and sanitation, compiled by D. C. McMURTRIE (*New York*, 1913, pp. 6).

NOTES.

Arkansas University and Station.—J. S. Knox, who received the M. S. degree from the University of Idaho at its recent commencement, has been appointed instructor in horticulture in the college and assistant horticulturist in the station.

Illinois University.—The trustees have included in the annual budget an item of \$374,000 for the purchase of agricultural land and building sites for the college of agriculture.

Purdue University.—Clayton R. George has been appointed assistant in dairying in the extension department.

Kansas College and Station.—A corps of extension workers has been holding meetings and demonstrations on typical farms of Bourbon and Cowley counties. Four meetings were held daily and a total of about 1,500 farmers was in attendance. It is planned to conduct similar field campaigns in at least 12 counties next year.

W. L. Blizzard, assistant animal husbandman, resigned July 15 to accept a position with a Kansas syndicate of farm publications.

Massachusetts College.—The construction of the new agricultural building for which the legislature granted \$210,000 is under way. The plans call for a modern fireproof structure of brick and concrete with 166 feet frontage and 156 feet in depth, making the structure the largest on the campus. It will contain lecture rooms, offices, a library, two large laboratories, and an auditorium seating nearly 1,000 people.

Mississippi Station.—J. K. Morrison has resigned as poultryman and has been succeeded by E. P. Clayton, superintendent of education for Lee County since 1908.

Missouri University.—The university celebrated on June 3 the seventy-fifth anniversary of its founding. Secretary of Agriculture D. F. Houston was among those delivering addresses and subsequently received the degree of LL. D.

New Mexico College and Station.—H. S. Hammond, professor of biology and botany, resigned July 1.

Cornell University.—The new forestry building was opened May 15 in connection with the meeting of the Society of American Foresters. It is a four-story brick structure, 142 by 54 feet, costing \$120,000 and constituting the first of the proposed plant industry group. The ground floor contains wood technological and timber testing laboratories, and those above laboratories, classrooms, etc., for mensuration, utilization, silviculture, and dendrological work. For the present it will also house the department of plant breeding.

Ralph S. Hosmer, superintendent of forestry in the Territory of Hawaii since 1903, has been appointed head of the department of forestry vice Walter Mulford, who has accepted a similar position at the University of California. G. W. Peck, instructor in pomology, has resigned to become manager of a large orchard in Ohio. David Lumsden, instructor in floriculture and landscape gardening and superintendent of greenhouses and grounds at the New Hampshire College,

and assistant in floriculture in the station, has been appointed assistant professor of floriculture, beginning June 1, Miss Clark L. Thayer has been appointed assistant in investigation.

Ohio State University.—Walter C. O'Kane, entomologist of the New Hampshire College and Station, has been appointed professor of applied entomology, beginning September 1.

Oregon College and Station.—Director Cordley is spending much of the summer in a study of the various substations with a view to securing closer coordination of the various lines of college and station work and their closer relationship with several new phases of agricultural development. Claude I. Lewis, for the past 8 years head of the department of horticulture, has been appointed vice director of the station. Carl N. Kennedy, instructor of animal husbandry at the Texas College, has been appointed professor of animal husbandry, his duties including the work with horses and the secretaryship of the State Stallion Registration Board. Ralph Reynolds has been appointed extension professor of animal husbandry to have charge of the extension work with all classes of live stock except dairy cattle.

Pennsylvania College and Station.—The new horticultural building was dedicated June 10, Prof. F. A. Waugh of the Massachusetts College delivering the principal address on The Arts of Peace. The Students' Horticultural Association presented to the college at that time a portrait of the late Gabriel Hiester, president of the State Horticultural Association and a most active member of the board of trustees.

J. D. Harlan, assistant in experimental agronomy, resigned May 1 to become agronomist with a chemical manufacturing firm of Pittsburgh, which is operating a test farm of 130 acres near Cleveland, Ohio. It is announced that special attention is being given to work on the effect of radium on the growth of crops under field conditions.

R. S. Maddox, instructor in forestry, has been appointed state forester of Tennessee beginning September 1. Walter B. Nissley, instructor in horticulture, has been appointed head of the department of vegetable gardening at the New York State School of Agriculture recently opened on Long Island.

Clemson College and Station.—S. W. Evans has been appointed secretary and treasurer of the college and treasurer of the station, vice Dr. P. H. E. Sloan resigned.

Texas College.—Short courses of from three to six days duration are to be offered in 18 towns representing 17 counties of the State. Members of the faculty are to be in charge of the various schools, in close cooperation with the county and district agents of the farmers' cooperative and demonstration work of this Department.

Vermont University and Station.—G. S. Fassett, for nearly 25 years connected with the governing board of the university and station, has resigned to take effect July 1. Z. M. Mansur, also a trustee, died in April. Warren R. Austin of St. Albans and Guy W. Bailey of Essex Junction, both alumni of the university, have been appointed to fill the vacancies.

Washington College and Station.—The station is establishing an arboretum in which it is proposed to grow a group of each of the important timber trees of the Temperate Zone. W. D. Hislop, assistant professor of animal husbandry at the Ohio State University, has been appointed professor of animal husbandry and animal husbandman.

West Virginia University and Station.—E. W. Sheets of the extension division has been appointed professor of animal husbandry and animal husbandman. D. C. Neal and Oliver Smith, assistants in plant pathology and agronomy, respectively, are no longer connected with the institution.

Wyoming Station.—A. D. Faville, animal husbandman, and Frank E. Hepner, research chemist, have been granted leave of absence beginning September 1 and October 1, respectively, for a year's further study. Their work will be carried on by J. E. McWilliams, assistant in wool, and E. N. Roberts, recently appointed assistant chemist.

American Association of Agricultural College Editors.—This association was formally organized at a conference held at the Kentucky Experiment Station, June 25 and 26. Delegates were in attendance from the colleges and stations of 13 States, as well as this Department, as follows: Georgia, Illinois, Iowa, Kentucky, Maryland, Massachusetts, Michigan, Minnesota, Ohio, South Carolina, Tennessee, West Virginia, and Wisconsin.

The conference was called to order by the executive secretary, Dr. B. E. Powell of the University of Illinois. An address of welcome was given by Director Kastle of the Kentucky Station, who drew attention to the enormous increase in publicity agencies within recent years and especially the large amount of space now being given to agriculture by the daily press. He cited some of the difficulties to be avoided in publicity work, and suggested ways in which an association could be effective in bringing about an improvement in conditions.

Data derived from a questionnaire as to The Relations of the Editor and the Bulletin Author and Their Respective Rights were presented by J. O. Rankin of Minnesota. Great diversity of practice was reported from the various States, but there seemed to be a general agreement that while the substantial integrity of the author's contribution must be preserved considerable discretion in handling the material should be vested in the editor, either directly or through the director or a committee on publications.

In a discussion of Editorial Standards for Agricultural Bulletins, F. W. Beckman of Iowa made a plea for simplicity in these publications and for making them as widely useful as possible. In the subsequent discussion, the potential permanent value of many publications was also brought out, as well as the need of giving attention to bibliographical considerations.

W. H. Beal of this Office presented a summary of data showing Results of the United States Department of Agriculture's Survey of Bulletin Reading. This survey indicated that the bulletins were being quite generally read and utilized, either by the farmer directly or ultimately through the use of the material by the agricultural press and the various extension agencies.

An illustrated talk on Bulletin Illustration in Black and White and in Color was presented by A. G. Eldredge, photographer of the University of Illinois. The history of illustrative work was briefly reviewed and some of the more recent processes described in considerable detail.

Much interest was manifested by those in attendance in the various forms of publicity work being conducted. C. A. Whittle, of Georgia, described the system followed in that State, which he estimated to be reaching several hundred thousand readers a week through plate matter furnished the press. The methods in vogue in several other States were more briefly outlined by those in charge. O. M. Kile, of West Virginia, proposed a plan for cooperation in the preparation and use of plate matter and similar material by groups of States.

A tentative draft of a constitution was prepared under which annual meetings are provided and membership is open to those doing editorial work in the agricultural colleges and experiment stations or this Department. Officers were selected as follows: President, C. A. Whittle of Georgia; vice president, O. M. Kile of West Virginia; secretary-treasurer, B. E. Powell of Illinois; and

as additional members of the executive committee, E. H. Forbush of Massachusetts and Reuben Brigham of Maryland. Committees were also provided on cooperation with other organizations and on standards and exhibits. The executive committee is to serve as the program committee and to investigate the feasibility of publishing the proceedings. The next meeting is to be held at the University of Wisconsin in June, 1915.

Fifth International Congress on Rice Culture.—This congress met at Valencia, Spain, May 16 to 24, under the patronage of the King of Spain. The work was divided into eight sections dealing with such topics as rice varieties and their improvement, manures for rice, cultural operations and machinery, rice diseases, the rice trade, cooperation as applied to rice, and the relations of rice growing and malaria.

Fifth International Congress of Genetics.—It is announced that this congress will be held in Berlin in 1916, beginning with the first week in September. The subcommittee in charge of the preliminary arrangements consists of Professors von Rümker and Baur, their addresses being the Royal Agricultural High School, 4 Invalidenstrasse, Berlin.

Necrology.—Felix Wahnschaffe, an eminent authority on soils, died at Berlin, Germany, January 20, 1914, in the sixty-third year of his age. His life and services, especially to agriculture, deserve more than passing notice.

In his thirty-nine years' connection with the Royal Prussian Geological Land Office he made notable and valuable contributions to the knowledge of soils, the more important and permanent results of which are embodied in his *Anleitung zur Wissenschaftlichen Bodenuntersuchung* published first in 1887 and revised in 1903 and 1914 (in collaboration with F. Schucht).

Wahnschaffe identified himself especially with investigations in glacial geology, the study of soils on a broad geological basis, the application of improved methods in the mechanical and chemical analysis of soils, and the agronomic and geological mapping of soils. He specialized particularly in the study of the geology and agricultural value of the flat lands of north Germany. In this, as in most of his work, he had in mind not only the elucidation of the scientific problems involved but also the utilization of the lands for agricultural purposes and especially for home building. He was influential in the founding of the *Internationalen Mitteilungen für Bodenkunde*, and was active in the work of the International Agrogeological Congress.

New Journals.—*Revista del Ministerio de Industrias* is being issued monthly in Uruguay. The initial number contains an account of the Institute of Agronomy and Model Farm, an article on Impotence and Sterility in Domestic Animals, statistical and other data regarding various agricultural industries, brief popular articles, etc.

Die Naturwissenschaften is a weekly devoted to the natural sciences, medicine, and technology. The initial number contains, among others, an article by Dr. N. Zuntz on The Significance of the Micro-organisms in Digestion, and one by Dr. Rudolf Ditmar on The Way to Artificial Rubber.

Boletín de la Sociedad Forestal Argentina is being published trimonthly by the Forestry Society of Argentina and consists largely of short popular articles of interest to foresters and horticulturists.

EXPERIMENT STATION RECORD.

VOL. XXXI.

ABSTRACT NUMBER.

No. 3.

RECENT WORK IN AGRICULTURAL SCIENCE.

AGRICULTURAL CHEMISTRY—AGROTECHNY.

Biochemistry, C. L. ALSBERG (*Jour. Indus. and Engin. Chem.*, 5 (1913), No. 12, pp. 1019, 1020).—The address of the chairman of the section on biological chemistry of the American Chemical Society, as given at the Rochester meeting, Sept. 8–12, 1913. The progress of the science and some of its opportunities are briefly reviewed.

Chemistry of fats, lipoids, and waxy substances, W. GLIKIN (*Chemie der Fette, Lipoide, und Wachsarten. Leipsic, vols. 1, 1912, pp. XVI+789, figs. 91; 2, 1913, pp. XI+788, figs. 10*).—The first volume of this work deals with the general, physical, physiological, and analytical chemistry of fats; the second with the description, preparation, and examination of natural fats, oils, waxy substances, and chemical-technical fat products.

Distribution of alkaloids in the belladonna plant, A. F. SIEVERS (*Amer. Jour. Pharm.*, 86 (1914), No. 3, pp. 97–112, fig. 1).—The investigations reported have been previously noted from another source (*E. S. R.*, 30, p. 44).

The leaf oil of Douglas fir, A. W. SCHORGER (*Jour. Amer. Chem. Soc.*, 35 (1913), No. 12, pp. 1895–1897).—"The constituents of the leaf oil of Douglas fir with their approximate percentages are as follows: 1- α -pinene, 25; 1- β -pinene, 48; *i* or *l*-limonene, 6; furfural; ester as bornyl acetate, 6.1; free alcohol as borneol, 6.5; 'green oil,' 3; and losses by polymerization, 5 per cent."

Aroma of hops: A study of the volatile oil with relation to the geographical sources of the hops, F. RABAK (*U. S. Dept. Agr., Jour. Agr. Research*, 2 (1914), No. 2, pp. 115–159, figs. 14).—A systematic comparison of the physical and chemical properties of oils distilled from hops obtained from California, Oregon, Washington, and New York was made with those from imported hops from Saaz, Bohemia.

The average yield of oil from the California hops during 1907, 1908, and 1909 was 0.32 per cent, while during the four years 1906–1909 the Oregon hops showed an average oil content of 0.29, the New York hops 0.192 per cent, the Washington hops, distilled only during 1909 and 1910, 0.37 per cent, and the imported hops distilled from the crops of 1906, 1907, 1908, and 1909, 0.31 per cent. When distilled for a period of more than two seasons, all the hops showed considerable fluctuation in the yield of oil.

The color of the various oils ranged from a golden yellow to a dark brown, but the first runnings of all the distillates were nearly colorless. The predominant color seemed to be red or brown. A golden yellow oil was obtained only when the hops were distilled on a small laboratory scale.

The oils from the American hops were all strongly aromatic, and in most cases agreeable. "The oils from the foreign hops seemed to be distinctly different from the American oils, possessing a very pronounced flowery odor, combined with a fatty odor, the effect being most agreeable." All of the oils had a decidedly aromatic taste, and in some bitterness, fattiness, and acidity were pronounced. All of the California oils were characterized by bitterness and pungency with slight fattiness, while the oils from the imported hops were fatty and only slightly pungent and bitter.

The oils having the highest specific gravities were from New York State hops and averaged 0.8554 at 24° C. "The refractive property of the Oregon, New York, and Washington oils, as compared with the California oils, was not greatly different. However, the oils from the imported hops showed a higher refractive index than any of the other oils." The oils most soluble in alcohol come from the Oregon hops, one volume of the oil dissolving completely in three volumes of 94 per cent alcohol. The solubility varied with the seasons.

In the chemical examination the following average constants were determined: Acid number (for California hop oil 1.45, Oregon hop oil 2.7, New York 3.25, Washington 1.25, and Saaz 2.02), ester number (California hop oil 45.56, Oregon 58.8, New York 50.9, Washington 52.8, and Saaz 23.5), and saponification number (California hop oil 47, Oregon 61.5, New York 54.2, Washington 54, and Saaz 21). "The high and low acid numbers were significant of nothing important as far as the aroma was concerned, as the free acidity did not perceptibly affect the odor of the oil. The ester numbers revealed most striking similarities and dissimilarities, not only during one season but for several successive seasons. The oils from the imported hops were conspicuous because of the fact that the data for the several seasons showed the ester content to be only about one-half as great as the ester content of the oils from the California, Oregon, Washington, and New York hops." That the low ester content is responsible for the generally acknowledged superior aroma of imported hops could not be positively stated, but it is thought probable since other oils, like lavender and peppermint, are more fragrant than oils with a high ester content.

In the fractionation of the various oils, the data show that as a general thing, the oils from the California, Oregon, and Washington hops during the several seasons had a high content of low-boiling constituents, while the oils from the imported hops were invariably poorer in the low-boiling constituents. On the other hand, the oils from the imported hops seemed, generally speaking, to contain much higher percentages of the high-boiling compounds. The oil of the 1908 crop, however, was unique in that it appeared to be similar to the other oils during that particular season. The curves of the imported oils followed those of the New York oils the most closely, the general direction being similar. The California oils also followed very similar directions, as did the Oregon and Washington oils.

The fractions having the lowest specific gravities in all cases were those boiling below 185° C. This portion of the oil is usually supposed to contain most of the terpene constituents. The optical rotation of the various fractions of hop oil was very low. "The most noticeable feature was the tendency of the New York oil to follow the same course as the imported oil during each season. The curves of rotation, as well as the curves of fractionation, show some differences in the various oils, though perhaps in a lesser degree." The acid, ester, and saponification numbers of the fractions during each year were very variable.

From the results it is obvious that the oils which, in their original conditions, possess free acids (as indicated by the high acid numbers) show much more decomposition of ester with the liberation of free acids than do the oils

with less acidity or with none. With the acid values the ester numbers were very regular from year to year.

The approximate composition of hop oil is considered to be as follows: "Free acids.—Chiefly valerianic, with traces of formic, butyric, and heptonic acids; combined acids (in form of esters), chiefly heptonic (œnanthyllic) and nononic (pelargonic) and somewhat smaller quantities of octonic (caprylic), some decylic (caprinic) and undecylic acids, with traces of formic and acetic acids; aldehydes, formaldehyde in the lowest boiling fraction; hydrocarbons, myrcene (olefinic terpene), 30 to 50 per cent, humulene (sesquiterpene), 15 to 25 per cent; esters, chiefly heptonic, octonic, and nononic acid esters of the alcohol myrcenol, to the extent of 20 to 40 per cent (from the ester number (44) of the oil in question the amount of esters calculated as the heptonic-acid ester of myrcenol was found to be 21 per cent); . . . alcohols, probably myrcenol and a small proportion of sesquiterpene alcohols."

"From the data presented it is clearly evident that the geographical source of hops has a pronounced effect upon the volatile oil and hence also upon the odor of the hops." The ester content is thought to be the most influential factor in modifying the odor of the oils and consequently that of the hops.

A review of previous chemical investigations is followed by a bibliography of cited literature.

About the occurrence of adenin and asparaginic acid in mulberry leaves, Z. MIMUROTO (*Jour. Col. Agr. Imp. Univ. Tokyo*, 5 (1912), No. 1, pp. 63-65).—Adenin and asparaginic acid were obtained from young air-dried mulberry leaves. In all probability the asparaginic acid is present as asparagin, as ammonia was evolved during the working up of the free ester. A peptone-like substance was obtained from the phosphotungstic acid precipitate.

About the occurrence of histidin betain in *Boletus edulis*, E. WINTERSTEIN and C. REUTER (*Hoppe-Seyler's Ztschr. Physiol. Chem.*, 86 (1913), No. 3, pp. 234-237).—In work previously noted (E. S. R., 28, p. 501), a base having the formula $C_6H_{15}N_3O_2$ and found in the arginin fraction of *B. edulis* was discussed. The dipicrate of the histidin betain was compared with another dipicrate obtained by Barger and Ewins from ergothionin, and a study was also made of the monopicrate and gold salts of this compound. The two compounds are identical and represent histidin betain.

On some conditions affecting the activity and stability of certain ferments, J. H. LONG and W. A. JOHNSON (*Jour. Amer. Chem. Soc.*, 35 (1913), No. 7, pp. 895-913).—It is suggested in this paper that starch paste for diastatic comparisons should be made from laboratory-prepared potato starch, sound and fully ripe potatoes being employed. Long washing and boiling of commercial starch will not always be sufficient to secure a suitable product. The amylolytic activity of pancreas preparations is best exhibited in a mixture containing about 25 mg. of sodium bicarbonate to 100 cc. of paste and ferment solution. Larger amounts of bicarbonate retard the reaction somewhat but do not appear to destroy the ferment, since the full rapidity of conversion may be recovered by the partial neutralization of the soda by weak hydrochloric acid. The addition of enough acid to convert all the soda to salt at once destroys the ferment, however.

"Glycerol extracts of the pancreas retain their amylolytic power through many months, but by dilution with water this activity is speedily lost. The loss of digesting power is very marked after a short incubation of the diluted extract at 40°, but if salt is present the destructive effect of incubation is much diminished. The effect of incubation of commercial preparations is much the same as with the glycerol extracts, and the presence of salt lessens the disturbing action of alkalis here, also.

"The pancreatic diastase is extremely sensitive to the action of traces of strong acids, which was shown by experiments with glycerol extracts and hydrochloric acid. Salt is a protection here, as before. The action of the acid is much more marked than is that of weak alkali, and neutralization with soda does not bring about recovery. Destruction of the enzym probably follows the contact with acid. The weak inorganic and organic salts present in all pancreas preparations are important factors in modifying the action of added acids, and doubtless, also, of added alkali. The behavior of phosphates may be of the first importance in this regard, especially in the commercial pancreatins, which are largely pancreas powders. Without the presence of these salts the addition of the slightest trace of acid would be doubtless much more marked and possibly destructive."

Inhibition of enzym action by lime-softened waters, O. BERGEM and P. B. HAWK (*Jour. Amer. Chem. Soc.*, 35 (1913), No. 8, pp. 1049-1056).—"Water softened by the use of lime was found to exert a pronounced inhibitory influence on the action of salivary and pancreatic amylases. This was due largely to the adsorption of the enzymes by colloidal magnesium hydroxid present in these softened waters.

"That the two enzymes used in these tests, salivary and pancreatic amylases, are not identical is indicated by differences shown in their response to the action of various ingredients contained in hard and softened waters."

The occurrence of maltase in cereals, Z. WIERZCHOWSKI (*Biochem. Ztschr.*, 57 (1913), No. 1-2, pp. 125-131).—In some previous work it was shown that corn contains most of its maltase in an insoluble form. The investigation has now been extended to wheat, rye, barley, oats, millet, and buckwheat, corn being used for a comparison. All of the cereals were extracted with water until freed from diastase.

As regards the maltase content, the cereals can be conveniently divided into two groups. The first contains only small amounts of maltase and consists of rye, barley, wheat, and oats; the second group contains the cereals which have a large quantity of maltase and is made up of millet, corn, and buckwheat. Buckwheat and millet yield only small amounts of maltase when extracted with water.

The enzymes of the tobacco plant, J. DU P. OOSTHUIZEN and O. M. SHEDD (*Jour. Amer. Chem. Soc.*, 35 (1913), No. 9, pp. 1289-1309).—A study is reported from the Kentucky Experiment Station as to the occurrence of enzymes in the Burley tobacco, from the Burley region, and the dark types grown in western Kentucky.

"It appears that invertase, diastase, emulsin, and reductases are present in appreciable amounts in the tobacco seed and in the leaf in all stages of its growth and after curing. Lipase, inulase, and a proteolytic enzym also seem to be present in small amounts, although in some cases the results are doubtful. The tests for enzymes in the soil were negative with one or two exceptions. Oxidases were found in the green leaf in all stages of its growth, gradually decreasing in amount from the topping stage to maturity, but no definite tests were obtained for this enzym in the cured leaf. A fairly good test, however, was obtained with guaiacum in the leaf cured with a green color, but here, as well as in the other cured samples, no tests were obtained with phthalin. This may be due either to the fact that the enzym has been used up in the cured leaf for oxidation purposes or that some interfering color prevented a positive test from being obtained.

"The fact that the quantitative tests for the amount of oxidase reaction show the smallest amount in the leaf at about the matured stage, taken in connection with the fact that the active extracts of the cured leaf which gave

no oxidase test with phthalin developed a deep red color on the addition of a drop of phenolphthalein, leads to the conclusion that the enzym has been used up in the curing process and is practically absent in the cured sample. The above is in harmony with Loew's work [E. S. R., 11, p. 727; 12, p. 545], since in several samples he obtained no test and in others only a slight test for oxidase in the different varieties of cured tobacco which he used in his work."

During the fermentation process losses occur which often amount to 15 per cent, and about one-fourth of this is considered dry matter. Among the gases formed during the fermentation period ammonia is easily detected in the fermentation room. During the fermentation process practically all the starch is hydrolyzed by diastase and the resulting sugar is changed into other substances by oxidation. The fact that good invertase reactions were noted led the authors to believe that possibly sucrose may be present and that this may be stored in the root and afterward translocated to the leaf and other parts of the plant during photosynthesis and growth. The protein content of the leaf decreases during the maturation period and this is due to proteolytic enzymes. Amino compounds are formed and the nitrate and nicotin contents of the leaf are decreased. A decrease in nitrates is brought about by the reductases which are present.

"Some enzymes perhaps have a rôle in the decrease of the resin and gums in fermentation. If this is true, such enzymes are very necessary, for it is believed that the aroma of a tobacco is partly due to the products formed from the gums and resins after these are broken down. The aroma may partly be due to the breaking up of the glucosids in the tobacco by the glucosid ferment forming an aromatic substance. It is of interest to note, in this connection, that some experiments have been made in this work using emulsin to prove the presence of a glucosid in the green and cured leaf . . . The results proved that there was a small amount of glucosid present. Furthermore, there is no doubt but that positive tests were obtained for a glucosid-splitting ferment.

"If there is a large amount of fat or protein present in the leaf these will create products during combustion which will injure the flavor and aroma of the tobacco. It is due to lipase and the proteolytic enzymes that these objectionable compounds are largely done away with, provided, however, that they have favorable conditions under which to accomplish their work.

"During the process of smoking an ethereal oil is formed from certain products of the sweat and from this may be due a portion of the flavor. Citric, malic, and oxalic acids are present in the cured leaf, although in smaller quantities than in the green leaf. Part of the citric and malic acids are perhaps transformed in the fermentation to acetic and butyric acids. Thus we see that there are many highly complex chemical changes taking place in the plant during its growth and these continue in the curing and fermentation periods. That the enzymes play a very important part in these changes can not be denied."

Micro-organisms in commercial lime-sulphur, C. A. PETERS and A. W. BROOKS (*Jour. Indus. and Engin. Chem.*, 5 (1913), No. 12, pp. 1013, 1014).—Manufacturers of commercial lime-sulphur wash have been troubled for some time by the occasional thickening of their product. The consistency of the spoiled product resembled thin catsup and the precipitate consisted almost entirely of sulphur. When examined under the microscope, the mixture showed long threads which were identified as vegetable parasites closely allied to the group *Beggiatoa*. The use of secondhand wooden barrels is supposed to be the source of the contamination.

Comparison of the Kjeldahl-Gunning-Arnold method with the official Kjeldahl and official Gunning methods of determining nitrogen, T. C.

TRESCOT (*Jour. Indus. and Engin. Chem.*, 5 (1913), No. 11, pp. 914, 915).—This is a comparative study of the Gunning-Kjeldahl and Kjeldahl-Gunning-Arnold methods for nitrogen. The materials studied were hair waste, dried blood, bone meal, leather, leather waste, cotton-seed meal, linseed meal, gelatin, cyanamid, beef extract, desiccated meat, flour, bread, gluten bread, macaroni, ground rye hay, shorts, bran, molasses feed, milk, condensed and evaporated milk, and cheese.

The conclusion reached from the results is "that the Kjeldahl-Gunning-Arnold method with $1\frac{1}{2}$ hours' oxidation, except in the case of cyanamid, which requires $2\frac{1}{2}$ hours, gives more concordant and reliable estimation of nitrogen than do the official Gunning or official Kjeldahl methods, both of which require from 3 to 4 hours for oxidation, depending upon the material."

The aluminum reduction method as applied to the determination of nitrates in "alkali" soils, P. S. BURGESS (*Univ. Cal. Pubs. Agr. Sci.*, 1 (1913), No. 4, pp. 51-62, fig. 1).—In this paper the following points are emphasized:

"The aluminum reduction method^a for the determination of nitrates in soils yields the most accurate results of all methods now commonly in vogue. Alkali salts do not in any way interfere with the successful operation of the method. The presence of extraordinarily large amounts of soluble organic materials (soluble humus and dextrose) have little effect on the method.

"A temperature of 20° C. for from 11 to 15 hours has been found the optimum for the reduction of large quantities of nitrates. The proper amount of NaOH to be employed in the reduction was found to be 2 cc. of a 50 per cent solution, with an aluminum strip weighing approximately 1 gm."

Mineralogical soil analysis, W. J. McCAUGHEY (*Jour. Indus. and Engin. Chem.*, 5 (1913), No. 7, pp. 562-564).—In this paper it is pointed out that the mineralogical analyses of soils are not usually made from the standpoint of the soil investigator. The value of such analyses is shown by numerous examples.

Determination of manganese in the soil, M. J. STRITAR (*Ztschr. Analyt. Chem.*, 52 (1913), No. 6, pp. 337-345).—For soils containing a medium amount of calcium, the following method is proposed:

An extract is first made by treating 100 gm. of the soil with 25 per cent hydrochloric acid for 2 hours at 100° C. and then making up to 500 cc. Fifty cc. of this extract, is placed in a 200 cc. Kjeldahl flask with 25 cc. of concentrated nitric acid (preferably fuming). This is concentrated as far as possible by slow boiling, transferred to a porcelain dish, and evaporated to sirupy consistency on a sand or water bath. From 10 to 20 cc. of concentrated nitric acid is added to the residue and evaporated, this operation being repeated 3 successive times. The residue is then transferred with dilute nitric acid and water to a 100 cc. flask, cooled, and 1 to 2 drops of a sulphocyanid solution added (and when necessary 2 cc. of iron-alum solution) until a definite red coloration is present. The color is discharged with tenth-normal silver nitrate solution and restored with sulphocyanid solution. The solution is heated slightly, cooled, filled to the 100 cc. mark, and filtered.

Next, 25 cc. of the filtrate (free of chlorin and silver ions) is mixed with 17 cc. of nitric acid, cooled to 17 to 18°, shaken for 15 minutes with from 1 to 1.2 gm. of bismuth peroxid, cooled for from 2 to 3 minutes with cold water, filtered through an asbestos filter tube containing a porcelain filter disk into a 250 cc. flask, and the residue washed on the filter with cold water. The colored solution is then rapidly oxidized with about tenth-normal hydrogen peroxid solution and brought to a pink tint by the addition of tenth-normal potassium permanganate solution.

^aAmer. Jour. Pub. Hyg., 19 (1909), No. 3, pp. 536-544.

Where n equals the titer of the hydrogen peroxid solution, t the amount of potassium permanganate in 1 liter, h the number of cubic centimeters of hydrogen peroxid used, and p the number of cubic centimeters of tenth-normal potassium permanganate used, the percentage of manganese in the soil is as follows:

$$X = \frac{40 \times 50}{1,000 \times 158.2} (h.n-p).t = 0.0139 (h.n-p).t.$$

When the manganese content of the soil is very low, or when very great accuracy is necessary, from 50 to 75 cc. of the filtrate can be concentrated to 30 cc., and after adding 20 cc. of concentrated nitric acid oxidation can be accomplished with bismuth peroxid. The above concentrations must be changed accordingly.

Further investigations with reference to the extraction process (the effect of cold, warmth, the use of hydrochloric acid or nitric acid, etc.) and the use of the method for soils rich in lime and for plant ashes are to be made.

Potash in mixed fertilizers, T. E. KEITT (*South Carolina Sta. Bul. 173 (1913), pp. 3-16*).—Some of this material has been noted (E. S. R., 28, p. 508).

The rendering insoluble of the potash when muriate of potash or kainit is mixed with slag is due to the formation of a compound which is almost entirely soluble in hydrochloric acid, sp. gr. 1.115. Some of the potash, as well as silica, ammonia-precipitable substances, and lime was dissolved by citric acid and ammonium citrate solution, sp. gr. 1.09. Potash was most soluble in the ammonium citrate solution, and the remaining substances were most soluble in the citric acid solution. Probably there is a substitution of the ammonia radical for potassium in the compound. There was no definite relation between any one of the other elements and the potash dissolved by the same solvent. The operation of separating the potash soluble in hydrochloric acid from other substances dissolved by the same solvent and precipitable by ammonia was found to be very tedious. The separation, however, may be accomplished by using large dilutions and making many precipitations.

“Basing our work on the difficulty of separating the potash present from the ‘ammonia precipitate,’ a study was made of the influence of the large ‘ammonia precipitate’ always present in the determination of potash in mixed fertilizers by our Official Method for solution.

“The results of this investigation show that there are two partially compensating sources of error in our Official Method of solution:

“(a) The volume is decreased by the bulk of the precipitate in the flask, which would tend to increase the percentage of potash present.

“(b) The potash is decreased by occlusion of potash by the heavy precipitate formed on addition of ammonia and ammonium oxalate. These two sources of error tend to balance to some extent.

“It is impossible to wash out the potash occluded within the precipitate with hot water.

“The occluded potash can be separated to a certain extent by repeatedly dissolving the precipitate in hydrochloric acid, diluting to a volume of about 400 cc., precipitating with ammonia and ammonium oxalate, and filtering to determine potash in the filtrates.

“The use of pure salts in making the solutions shows that both iron and calcium phosphate, when precipitated with ammonia, occlude potash, and that a combination of the two is even more effective to produce occlusion.”

The detection of organic poisons (toxins and the like) in food, G. BARGER (*Pharm. Jour. [London], 4. ser., 37 (1913), No. 2609, p. 572*).—A paper read at the International Congress of Pharmacy at The Hague, 1913.

According to a summary, the author concludes "that the available chemical methods are of little value for this purpose. The isolation of putrefaction bases may be attempted, but it is very difficult. The ordinary methods for vegetable alkaloids are useless, as putrefaction bases are almost always insoluble in ether or chloroform. Special methods, such as precipitation with silico-tungstic acid, may be adopted, but the physiological action is the best test."

The quantitative estimation of gliadin in flour and gluten, G. A. OLSON (*Jour. Indus. and Engin. Chem.*, 5 (1913), No. 11, pp. 917-922).—After reviewing the literature on this topic the author states that the methods which are used for the estimation of proteins in wheat flour are far from satisfactory. The strength of alcohol most suitable for the extraction of gliadin has never been determined.

"The gliadin nitrogen obtained by the indirect method is much lower than that obtained by the direct method, but agrees remarkably closely with the results obtained for nitrogen in the coagulum in the alcohol-soluble. Of the two methods for the estimation of gliadin, the coagulation method is the shorter and is more suitable to use for this reason than the indirect method. Alcohols ranging between 50 to 65 per cent, inclusive, by volume extract equivalent amounts of coagulum nitrogen. Above 65 per cent alcohol by volume there is a rapid falling off in the amount of coagulum nitrogen obtainable. Alcohol of 50 per cent by volume has been adopted by the writer for the determination of gliadin nitrogen. About 68 per cent of the total alcohol-soluble nitrogen is coagulable.

"Alcohol-soluble, incoagulable nitrogen is precipitated by phosphotungstic acid. This, together with the coagulable nitrogen, equals the total alcohol-soluble nitrogen. In the same flours as much coagulable nitrogen is obtained in specially prepared gluten as in case of the flour. The easiest and shortest method for the estimation of the gliadin in flour is to estimate the nitrogen in the uncoagulable portion of the alcohol-soluble and deduct this result from the total alcohol-soluble nitrogen."

The detection of chicory in decoctions of chicory and coffee, C. H. LAWALL and L. FORMAN (*Amer. Jour. Pharm.*, 85 (1913), No. 12, pp. 535-538).—While at present there is no satisfactory specific test for detecting the presence of chicory in roasted coffee, it is possible by inferential tests to note this substance when present.

"A number of samples of roasted coffee of authentic origin were obtained covering all of the important commercial varieties. In these samples were determined, (1) the amount of extractive, and (2) the percentage of reducing sugars calculated in the extractive previously determined. The amount of extractive matter alone is inconclusive, of course, as no knowledge is usually obtainable concerning the ratio of ground coffee in the decoction." When, however, the ratio of the extractive substances to the reducing sugars present in the decoction is considered, a sharp line of demarcation exists by which it is possible to prove conclusively the presence of 5 per cent of chicory in ground coffee.

A coffee containing more than 3 per cent of reducing sugars in its extractive matter is looked upon as adulterated with chicory or with a similar product high in reducing sugars.

The detection of cane sugar in honey, C. H. LAWALL (*Amer. Jour. Pharm.*, 85 (1913), No. 8, pp. 376-378).—"It is not possible to detect cane sugar in honey in the sense of a qualitative test. As cane sugar is normally present in small amounts, its quantitative determination, preferably by means of the polariscope, becomes necessary. The form in which sugar is added usually is

that of invert sugar which can be readily detected in honey which has never been subjected to heat."

Browne's test (E. S. R., 19, p. 1058) may serve as an aid but is not considered infallible.

Estimation of the fat content of milk with the aid of trichlorethylene, D. P. ROSS VAN LENNEP and J. D. RUYLS (*Chem. Weekbl.*, 9 (1912), No. 32, pp. 654-657; *abs. in Chem. Zentbl.*, 1912, II, No. 11, p. 962).—The method is as follows: Boil 19 gm., or 9.7 cc., of milk for 2 minutes with 10 cc. of hydrochloric acid (specific gravity 1.19); cool, add 50 cc. of trichlorethylene, shake, allow the curd to settle, and draw off the supernatant trichlorethylene layer; and filter through a dry filter. Twenty-five cc. of the filtrate is evaporated in a tared beaker, and the residue dried for 45 minutes at 100° C. and weighed.

The properties of watered milk, E. W. LONG and C. E. MAY (*Jour. Indus. and Engin. Chem.*, 5 (1913), No. 7, pp. 573-575).—The results indicate that the Zeiss immersion refractometer method for examining milk serum is very practical for the detection of added water, but that when used alone it is not infallible. For every 10 per cent of water added to milk, the serum when prepared by the acetic acid method gives a refractometer reading about 2.9° lower than the unwatered milk, but the addition of 1 gm. of granulated sugar to 100 cc. of milk, watered or unwatered, will raise the refractometer reading of the serum about 4°. The adulteration of milk by watering and sugaring can therefore be carried on by adjusting the amounts of the adulterants and adding them to milk that is well above the standard in solids and fat. It therefore seems that "in examining commercial samples of milk it is well worth the chemist's trouble to look out for the presence of this form of adulteration."

The examination of the sediment obtained in the leucocyte test, with a description of a new leucocyte tube, V. BRUDNY (*Österr. Molk. Ztg.*, 21 (1914), No. 1, pp. 1-3, fig. 1; *abs. in Cream. and Milk Plant Mo.*, 2 (1914), No. 6, pp. 25, 26).—Milk samples which yield more than 0.1 per cent of sediment should be titrated for acidity, because it often happens that samples of this kind contain precipitated casein. The alizarol test of Morres is best for this purpose. It is also well to consider the presence of tubercle bacilli in the sediment and to make an animal test for the purpose of differentiating between non-pathogenic and pathogenic acid-fast bacteria. The presence of streptococci should also be considered, but it is often difficult to differentiate the pathogenic from the nonpathogenic forms.

The leucocyte test is considered the only simple method which we have for detecting mastitis in cows, but when noting the leucocytes the epithelial cells must not be counted as leucocytes.

A description and illustration are given of a special form of sedimentation tube, provided with a clamp which holds a removable cover at each end of the tube. This allows for the proper cleaning of the tube, especially at its capillary end.

Is the reductase test a valuable method for controlling the milk supply? H. M. HÖYBERG (*Ztschr. Fleisch u. Milchhyg.*, 24 (1913), No. 5, pp. 107-112).—The test is not considered one with which the bacterial content of a milk can be determined with any degree of accuracy. The reduction of the dyes may be due to the formation, by abnormal or pathologic cellular metabolism, of certain substances which are secreted with the milk.

The fluidity of butter fat and its substitutes, G. F. WHITE and R. H. TWINING (*Jour. Indus. and Engin. Chem.*, 5 (1913), No. 7, pp. 568-573, figs. 4).—In this article are presented the results of a series of viscosity measurements of various butter and oleomargarine samples and of mixtures of known composition. In addition to this the iodine number, saponification number, and

volatile acids were determined. The viscosimeter devised by one of the authors and Bingham, with some modifications, was used in the investigation.

"Oleomargarine fats are always more viscous than butter fats except, of course, where the viscosity of the former is greatly lowered by the introduction of large amounts of liquid fats as indicated by a chemical analysis. On standing, the viscosity of butter probably increases to a maximum due to a loss of volatile acids, and then becomes less viscous as putrefaction sets in.

"Although the viscosities for both fats vary somewhat in products from different sources, the fluctuation is always about a mean value which might be assumed without great error as a standard. The viscosities of the mixtures are not strictly additive. The fluidities are practically linear functions of the temperature. The fluidities of the mixtures are additive, so that these, and not viscosities, should be the basis for any comparison.

"Assuming that the fluidity of butter does not vary more than 5 per cent in value, an adulteration of 10 per cent oleomargarine can be detected with assurance."

The detection of gelatin in sour cream, A. SEIDENBERG (*Jour. Indus. and Engin. Chem.*, 5 (1913), No. 11, pp. 927, 928).—The usual method for detecting gelatin in milk and cream consists in removing the proteins with acid mercuric nitrate and the precipitation of the gelatin in the filtrate with picric acid. It often occurs, however, that with a sweet cream no precipitate is noted. "It has been frequently noticed that a sweet cream which gave no precipitate with picric acid would, after souring, show quite a perceptible turbidity on its addition, often heavy enough to lead to the assumption that gelatin was present. It seems most probable that this is due to protein decomposition products not precipitated by the acid mercuric nitrate."

The picric acid precipitate from sour cream is flocculent and settles quite rapidly, while that due to gelatin is small and granular and on shaking in the tube will coalesce in large lumps and leave the solution almost clear. A marked difference was found between the precipitates as regards solubility in hot, neutral water; only the gelatin picrate is soluble in hot water.

A modification of the Official Method based on these findings is presented.

Sampling ice cream, J. O. HALVERSON (*Jour. Indus. and Engin. Chem.*, 5 (1913), No. 5, pp. 409, 410).—It is shown that ice cream, as a rule, is not uniform in composition throughout the can, although this may not be noticeable except on the paddles of the freezer.

"In taking charges from preserved ice cream samples which have stood in a cooler so that the cream rises, perfectly uniform charges can not be obtained. This, it appears, causes a slightly greater variation in the fat reading with a tendency to run somewhat lower. The mixing of ice cream samples should be carefully performed, especially when they have stood so that the cream has risen to the top."

The modified Babcock for fat in sweetened dairy products—ice cream, J. O. HALVERSON (*Jour. Indus. and Engin. Chem.*, 5 (1913), No. 5, pp. 403-409, figs. 2).—It is stated that the Babcock and the Adams-Soxhlet methods can not be used for determining fat in ice cream. The same is true of the modifications of the Babcock test, e. g. that of Leach and Farrington, used for sweetened condensed milk. Various volumetric and gravimetric methods (Röse-Gottlieb and Paul's gravimetric methods and Holm's and Howard's volumetric methods) suggested for this purpose are also deemed unsatisfactory, and the following modification of the Babcock method is proposed:

"To an 18 gm. charge add the usual sulphuric acid (specific gravity 1.82 to 1.83) in small portions of 3 cc. at a time, shaking after each addition with a slight pause. Continue adding acid in portions until a light amber brown color

or the color of coffee with cream in it, is obtained. Stand a few moments; then check the action of acid with 5 cc. of cold water with shaking. (This should be done before the solution becomes a deep dark brown or blackish color, which shows charring action on the sugar, which precipitate, if formed, is difficult to dissolve.)

“The solution having the color of coffee with cream in it, centrifuge 5 minutes; then add 5 cc. of boiling water, whirl one-half minute longer. Drain off the acid through the glass stopcock carefully by tilting the bottle (approximately 5 cc. of solution will be left). Dilute with cold water up to 10 cc. and shake; add acid in small portions as above, with shaking (approximately 8 to 10 cc.) until the remaining curd is dissolved or an almost coffee-black color, as in testing milk, is obtained. Add 3 cc. excess of acid and shake. Whirl 4 minutes; dilute to the neck with an acid solution, 3 parts of the sulphuric acid to 5 of water, at a temperature of about 60 to 70° C. Whirl 1 minute; then add boiling water up to zero or above and again whirl 1 minute more. Read the percentage of fat.”

The results obtained were on the average 0.6 per cent low. “The percentage of residual fat in the drained portion averages the same as that lost in cream testing. The maximum variation in fat readings is not great considering that the variation is somewhat greater on samples which have stood some time and hence are not perfectly uniform. The variation with the modified Babcock compares favorably with the Röse-Gottlieb method. This method can be used in international centrifuges in food control laboratories if preferred, by using a separatory funnel with a graduated cream tube at the top. This method is also applicable to ice cream plants using the ordinary commercial sulphuric acid on hand. Likewise, a similarly modified 10 per cent milk test bottle can be used for determining fat in sweetened condensed milk.”

A rapid method for the determination of fat in ice cream, H. F. LICHTENBERG (*Jour. Indus. and Engin. Chem.*, 5 (1913), No. 9, p. 786).—The method is as follows:

“Weigh into a 10 per cent Babcock milk bottle 9 gm. of melted sample. Add 20 cc. of glacial acetic acid (specific gravity 1.049). Mix well and add 10 cc. of sulphuric acid (specific gravity 1.83). Mix again and proceed as in the regular Babcock test. With the aid of a pair of dividers read the fat column (from one extreme to the other; in other words, read the highest part of the meniscus which appears as a straight line when the bottle is held on the level of the eye and away from the source of light) at a temperature of 130° F. The result times 2 equals the percentage of fat.”

A micro-chemical method for the determination of α - and β -amino acids and certain derivatives in proteolysis, bloods, and urine, P. A. KOBER and K. SUGIURA (*Jour. Amer. Chem. Soc.*, 35 (1913), No. 10, pp. 1546–1584).—“The method (E. S. R., 26, p. 107) of forming copper complexes of amino acids, peptids, and peptones in neutral or slightly alkaline solution ($C_H = 10^{-7.07}$ to $10^{-8.3}$) has been improved so that quantitative results can be obtained in very dilute solution (1 part in 500,000). The ‘precipitability’ of the copper in the complexes of 19 amino acids, 27 dipeptids, 18 tripeptids, and 4 tetrapeptids is given, when in equilibrium with 0.06 normal $Ba(OH)_2$, and it is shown that the amount of copper dissolved by the free amino acid, as well as the amount dissolved by the peptids and peptones, can be separately determined, thus estimating these substances in micro-chemical mixtures.

“Experiments are given to show that under the conditions of this method very few other substances react with the reagent, and that these can easily be removed without interfering with the estimation of amino acids and their homologues. The method is applied to proteolysis, blood, and urine, and it is

shown that amino acids, peptids, and peptones can be estimated accurately and quickly in small amounts of material. It may, therefore, be called a 'clinical' method.

"Two very insoluble copper complexes, η -amino caproic acid and phenyl glycin copper, are found which may be useful in analytical work with copper. Ammoniacal lead acetate (5 cc. strong ammonia, specific gravity 90, to 25 cc. 10 per cent lead acetate) is shown to precipitate sugars, dicarboxylic acids, such as oxalic, citric, tartaric, and in moderate dilutions (1 part to 5,000) the amino acids, histidin, tyrosin, and tryptophan. Under the same conditions none of the other amino acids and [some] of the peptids are precipitated. In very dilute solution (1 to 25,000) this reagent does not seem to precipitate any amino acids.

"By means of the amino acids, η -amino caproic acid and phenyl glycin, the copper of all the other complexes, including those of the amino acids and all the polypeptids thus far studied with the exception of histidin, can be thrown down quantitatively. Therefore, by means of these reagents, we can determine histidin in very small quantities accurately and quickly."

METEOROLOGY—WATER.

Report of the Chief of the Weather Bureau, 1913 (*U. S. Dept. Agr., Weather Bur. Rpt. 1913, pp. 252, pls. 4*).—This contains an administrative report on work during the fiscal year ended June 30, 1913, and includes also tables giving a general summary of the weather conditions in the United States by months during the year 1912, annual summary of climatological data at the Canadian stations for 1912, list of observing stations and changes therein during 1912, sunshine in 1912, details of excessive precipitation in 1912, monthly and annual meteorological summaries for 1912, monthly and annual amounts of precipitation in 1912, and monthly and seasonal snowfall in 1912-13.

Monthly Weather Review (*Mo. Weather Rev., 42 (1914), No. 1, pp. 1-74, pls. 8, figs. 22*).—This is the first number of the Review under the reorganized plan of issuing this publication.

In accordance with this plan this number contains material classified as follows: (1) Aerology—data and discussions relative to the free atmosphere; (2) general meteorology—special contributions by any competent student bearing on any branch of meteorology and climatology, theoretical or otherwise; (3) forecasts and general conditions of the atmosphere; (4) rivers and floods; (5) bibliography—recent additions to the Weather Bureau library, and recent papers bearing on meteorology; and (6) weather of the month—summary of local weather conditions, climatological data from regular Weather Bureau stations, tables of accumulated and excessive precipitation, data furnished by the Canadian Meteorological Service, and monthly charts . . . as hitherto.

Such papers as have heretofore been published in the Bulletin of the Mount Weather Observatory will be incorporated in the Review, but "the voluminous tables of data and text relative to local climatological conditions that have during recent years been prepared by the twelve respective 'district editors' will be omitted."

This number contains articles on Atmospheric Transparency for Radiation, by F. E. Fowle; Pressure in Absolute Units, by W. N. Shaw; The Winds in the Free Air (illus.), by C. J. P. Cave; Meteorology as an Exact Science, by V. Bjerknes; Peculiarities of the California Climate (illus.), by G. F. McEwen (see p. 213); Lorin Blodget's Climatology of the United States, an Appreciation, by R. DeC. Ward; Is There an Auroral Sound? by J. Oxaal; The Mete-

orological Aspect of the Smoke Problem, by H. H. Kimball; New Daily Weather Map; The Weather Map on the Polar Projection; Winslow Upton, 1853-1914; The Drift of a Train of a Bright Meteor (illus.); Annual Meeting Royal Meteorological Society; Evolution of the Meteorological Kite; Results of the Koch Expedition Across Greenland, 1912-13; and Freshets in the Savannah River and the Forecasting of High Water at Augusta, Ga. (illus.), by E. D. Emigh.

Monthly Weather Review (*Mo. Weather Rev.*, 42 (1914), No. 2, pp. 75-136, pls. 8, figs. 34).—In addition to notes on weather forecasts for February, 1914, river and flood observations, lists of additions to the Weather Bureau library and of recent papers on meteorology, notes from the Weather Bureau library, the weather of the month, a condensed climatological summary, and climatological tables and charts, this number contains the following articles:

Italian Twilights of 1913, by I. Galli; Twilight Colors at Mount Weather, Va., in 1913, by H. H. Kimball; Recent Balloon Experiments, by C. G. Abbott; The Effect of Weather upon the Yield of Corn (illus.), by J. W. Smith (see p. 229); Unpublished Contributions to the International Meteorological Congress Held at Chicago, August, 1893; On the Theoretical and Practical Importance of a Series of Daily Weather Charts of the Northern and Southern Hemispheres, by H. Wild; A Classification of the Methods of Transition from Rain to Blue Sky (illus.), by W. I. Milham; Squalls and the Prediction of Tornadoes (illus.), by E. Durand-Gréville; Evaporation from Snow and Errors of Rain Gage when used to Catch Snowfall (illus.), by R. E. Horton; Daily Synoptic Charts of the Northern Hemisphere and Absolute Units, by W. N. Shaw; The Japan Current and the Climate of California, by W. G. Reed; [Artificial Snowfall in a Train Shed]; [Mild Winter of 1913-14 in England]; On the Amount of Evaporation, by Y. Horiguti; Prevention of Fog; Do Clouds Yield Snow Easier than Rain? by D. F. Manning; and The Value of Weather Forecasts in the Problem of Protecting Forests from Fire (illus.), by E. A. Beals.

Climatological data for the United States by sections (*U. S. Dept. Agr., Weather Bur. Climat. Data*, 1 (1914), Nos. 1, pp. 238, pls. 2, figs. 4; 2, pp. 248, pls. 2, figs. 7).—In accordance with the new plan of publication of meteorological and climatological data noted above these volumes contain brief summaries and detailed tabular statements of climatological data for each State for January and February, 1914.

Meteorological observations at the Massachusetts Agricultural Experiment Station, J. E. OSTRANDER and E. K. DEXTER (*Massachusetts Sta. Met. Buls.* 303, 304 (1914), pp. 4 each).—Summaries of observations at Amherst, Mass., on pressure, temperature, humidity, precipitation, wind, sunshine, cloudiness, and casual phenomena during March and April, 1914, are presented. The data are briefly discussed in general notes on the weather of each month.

Peculiarities of the California climate, G. F. McEWEN (*Mo. Weather Rev.*, 42 (1914), No. 1, pp. 14-23, figs. 13).—The peculiarities of the California climate are discussed on the basis of general principles of atmospheric and oceanic circulation. It is stated that "the climate of that part of California lying between the coast and the mountains is largely controlled by the surface temperature of the adjacent ocean, and consequently agrees at any place with the normal marine climate of that latitude in winter. But in summer, when the upwelling is so pronounced as to reduce the surface temperature of the inshore water much below the normal, a coast climate, peculiar in many respects, is produced, the remarkably low summer temperature being the most striking peculiarity."

A bibliography of references to literature relating to the subject is given.

The floods of 1913 in the rivers of the Ohio and lower Mississippi valleys, A. J. HENRY (*U. S. Dept. Agr., Weather Bur. Bul. Z (1913), pp. 117, pls. 22, figs. 3*).—This bulletin reports on the floods of March and April, 1913, in the States of Ohio and Indiana and on the resulting floods in the Ohio and Mississippi rivers, compares these with floods of previous years, and gives a number of tables, diagrams, and illustrations.

The March, 1913, flood is attributed to the existing meteorological conditions previously reported (*E. S. R., 29, p. 510*) which show that in the space of 72 hours 7.5 in. of rain fell. Conclusions as to flood frequency in the Ohio River are that it "is primarily due to the distribution of precipitation as regards both time and space, and that there is urgent need of accurate measurements both of precipitation and stream flow for the next 50 years or longer before conclusions the one way or the other may be reached."

Detailed reports on the 1913 floods by districts are as follows: Precipitation and Floods in Ohio, March, 1913, by J. W. Smith; The Flood at Dayton, Ohio, by H. C. Alps; The Flood at McConnellsville, Ohio, by C. H. Morris; Flood in the White River of Indiana, March, 1913, by C. E. Norquest; Flood in the Wabash River of Indiana, March, 1913, by W. R. Cade; Flood in the Illinois River, by M. W. Hayes; The Flood in the Ohio River in the Louisville District, by F. J. Walz; The Flood in the Ohio River in the Evansville District, by A. Brand; The Flood in the Mississippi River in the Memphis District, S. C. Emery; The Floods in the Mississippi River in the Vicksburg District, W. E. Barron; Floods in the Arkansas and White Rivers of Arkansas, by H. F. Alciatore; Floods in the Mississippi River below Vicksburg, and in the Atchafalaya River in the Spring of 1913, by I. M. Cline; The Flood in the Hudson River, March, 1913, by G. T. Todd; Floods in New York State, by R. E. Horton; Supplemental Note on Frequency of Recurrence of Hudson River Floods, by R. E. Horton; and Floods in the Connecticut Valley and in Vermont, March, 1913, by W. W. Neifert.

The weather of the past agricultural year, F. J. BRODIE (*Jour. Roy. Agr. Soc. England, 74 (1913), pp. 430-439*).—The character of the season is described and meteorological data relating to rainfall, temperature, and sunshine for different parts of the British Isles are reported.

The effect of climate and weather on the soil, E. J. RUSSELL (*Jour. Roy. Agr. Soc. England, 74 (1913), pp. 1-21, pls. 3, fig. 1*).—This article discusses the effect of climate on the formation of the mineral framework of the soil and on the organic matter of the soil; soil losses; the correlation of soil belts and climatic zones; the effect of weather (seasonal variations) on the soil and the crop; and the means of overcoming the effects of a bad season.

It is shown that climate plays a great part in determining the general character of the soil as regards both its mineral framework and its organic constituents, but that the general character may be modified considerably from year to year by variations of season or weather. The ways in which this is done are considered in some detail. The three groups of injurious effects of a bad season considered are (1) injury to the texture of the soil, (2) interference with the preparation of available plant food, and (3) loss of nitrate. Systematic catch cropping or green manuring is suggested as a hopeful method of overcoming these difficulties.

Water conservation, W. McCULLOH (*New Haven, Conn., and London, 1913, pp. X+99, pls. 22, figs. 18*).—This consists of a set of lectures on water storage conservation, discussing (1) basic data essential to a comprehensive study of water storage, (2) water power, (3) water storage for water supplies, sanitation, and irrigation, and (4) the water resources of New York State.

SOILS—FERTILIZERS.

The natural scientific basis for agricultural technique, E. FEIGE (*Naturwissenschaften*, 1 (1913), No. 52, pp. 1305-1307; *abs. in Chem. Zentbl.*, 1914, I, No. 8, p. 806).—This is a brief discussion of factors in soil cultivation, physical properties of soil, importance of humus and of fertilizers, and the food requirements of crops, which points to the importance of a thorough knowledge of natural occurrences in connection with cultural measures for improving growth conditions.

Testing soils in the laboratory and field, W. H. STEVENSON and P. E. BROWN (*Iowa Sta. Circ.* 15 (1913), pp. 2-16, fig. 1).—This circular gives a list of questions for the farmer to answer regarding the lay of his land, the crops grown, fertilizers added, etc., to enable the station to advise him as to the proper treatment of the soil; describes the litmus paper test for soil acidity and the hydrochloric acid test for carbonates; presents the details of field tests to determine the fertilizer requirements of soil for both live stock and grain farming; and gives miscellaneous information regarding commercial fertilizers.

Composition and agricultural value of the arable lands in Argentina, P. LAVENIR (*Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases*, 5 (1914), Nos. 1, pp. 9-18; 2, pp. 145-154).—The physiography and representative soil types of the agricultural area of Argentina are described, physical and chemical analyses of soils reported, and the soils discussed as regards fertility and crops.

This area is an immense plain, a large part of which is arid. The soils are deep, rather fine alluvial beds with a variable clay content and range in texture from heavy to very light. They are usually well supplied with fertility constituents except lime. In one or two localities, however, the soils are high in lime and low in organic matter and nitrogen, and in some cases phosphoric acid. The subsoils are more or less impervious except where the soils are very light and contain much lime. The soils of many of the more arid localities contain injurious amounts of alkali, and irrigation is a quite frequent and necessary practice.

Alkali lands, L. T. SHARP (*Better Farming [Univ. Nev.]*, 1 (1913), No. 4, pp. 4-8).—This is a brief discussion of the subject containing analyses showing fertilizing constituents and alkali salts in 50 samples of Nevada soils.

[Nitrogen supply of the Indian soil], C. M. HUTCHINSON (*Ann. Rpt. Bd. Sci. Advice India, 1912-13*, pp. 123-126).—Azotobacter was found in all Indian soils examined. Pure cultures of *A. chroococcum* from soils of widely different character "exhibited nitrogen fixing power very similar to that recorded from European strains, its physiological activity depending upon appropriate supplies of water, air, lime, and especially of carbohydrate food."

In experiments with green manures it was found that the successful use of such manures depended almost entirely upon the moisture conditions following the turning under of the crops. "Laboratory experiments showed that the nitrate formed from the buried plant tissues increased in amount up to the end of eight weeks from the time of turning into the soil, provided the water supply was kept up to at least 16 per cent of the soil weight, but after this period a steady diminution took place, so that after twelve weeks a smaller quantity of nitrate than that present at the end of the eighth week was invariably found."

To avoid the loss due to insufficient moisture in the soil and to hasten the initial stage of decomposition the crops were cut, steeped in water, and allowed to ferment in heaps, the fermented material being used in the same way as barnyard manure. "The advantages of this method, in addition to the principal

one of eliminating the uncertainty of the rainfall as a factor in decomposing the buried green material, include the possibility of applying the fermented manure at the best rate per acre and at the best time for producing its optimum manurial effect; at the same time it is not necessary to grow the green manure crop on the land which is to carry the . . . crop intended to benefit by its manurial effect."

Brief reference is made to a modified method of biological analysis of soil in which the biological activities are studied with large samples (400 to 1,200 gm.) of soils instead of with 1 gm. samples as is the method commonly employed.

Experiments on the lateral percolation of contamination in soil, O. BAIL and F. BREINL (*Arch. Hyg.*, 82 (1914), No. 1, pp. 33-56, figs. 7).—Experiments on the lateral percolation of contaminated liquids in soils of different mechanical and physical structures are reported.

Percolation was more or less influenced by the soil structure as regards size of soil grain, pore space, permeability, nature of stratification, and moisture content. In tests of both short and long duration, using small and large apparatus and correspondingly large and small soil samples, the soil section being dampened assumed the shape of a more or less irregular triangle, whose base was the wall at the entrance of the liquid to the soil, and whose apex was the most distant point of lateral percolation. Where downward infiltration was unhindered the lateral percolation attributed to the pressure head was small, but when constantly hindered by an impervious layer a horizontal sheet of contaminated liquid was formed. With increasing depth of downward infiltration, due to gravity, the lateral spread of the contaminated surface due to capillarity was very marked. Contaminated liquids were purified to a limited degree through filtration and absorption by soils.

It is concluded that if downward infiltration is unhindered the danger of pollution of the ground water lies in the resulting lateral spread of the contaminated surface due to capillarity.

The effect of hydroxyl ions on clay and clay soils in marling, J. G. MASCHHAUPT (*Landw. Vers. Stat.*, 83 (1914), No. 5-6, pp. 467-470, pl. 1).—The author maintains that the flocculating effect of calcium hydroxid on clay suspensions is due principally to the calcium ion rather than to the hydroxyl ion. He found that both sodium hydroxid and sodium carbonate solutions had a flocculating effect on clay suspensions only in strong concentrations and when very dilute had a stabilizing effect, while calcium hydroxid had a flocculating effect when both dilute and concentrated. He concludes, therefore, that the flocculating effect of calcium hydroxid and sodium hydroxid can not be attributed entirely to the same causes.

Studies of plant growth in heated soil, G. W. WILSON (*Biochem. Bul.*, 3 (1914), No. 10, pp. 202-209, pls. 3).—Pot experiments with buckwheat, wheat, rye, and barley, using a very poor loam soil which had previously been heated to 95, 135, and 175° C., are reported.

The growth and vigor of all the crops, particularly the buckwheat, were accelerated on soil which had been heated to 95°, but were retarded on soils heated to 135 or 175°, especially the latter. Plants grown on heated soil were more susceptible to attack by parasitic fungi than those grown on unheated soil, and soil fungi grew more abundantly on soils which had been subjected to high temperatures.

It is concluded that "the effect of heating soils upon the crop grown varies with the temperature to which the soil is subjected, the kind of soil used, and the nature of the crop grown upon it."

See also a previous note by Bouyoucos (*E. S. R.*, 29, p. 618).

The determination of the fertilizer needs of soils by the aid of chemical soil analysis, O. LEMMERMANN (*Landw. Vers. Stat.*, 83 (1914), No. 5-6, pp. 345-358; *abs. in Ztschr. Angew. Chem.*, 27 (1914), No. 37, *Referatenteil*, p. 298).—The author is of the opinion that the available plant food in soils, and consequently their fertilizer needs, is not exactly indicated by the amount of plant food soluble in water saturated with carbon dioxide according to the Mitscherlich method of chemical soil analysis. He maintains that this is influenced by other factors such as organic acids, soil bacteria, climate, etc.

The determination of the fertilizer needs of soils by the aid of chemical soil analysis, E. A. MITSCHERLICH (*Landw. Vers. Stat.*, 83 (1914), No. 5-6, pp. 401-408).—The author defends his views regarding the value of chemical analysis of soils in determining the fertilizer needs of soils, but emphasizes the importance of a plant physiological basis for all such analyses.

Estimating the fertilizer need of soil, E. A. MITSCHERLICH (*Fühling's Landw. Ztg.*, 63 (1914), No. 3, pp. 75-78).—The author points out the inaccuracy of Liebig's law of minimum as applied to the results of fertilizer experiments, in that the increase in crops due to fertilizing is not an exact indication of the fertilizer need of soils owing to the fact that all other environmental factors exert an influence on the increase in crop and must be kept constant in order to determine the effect of varying amounts of a particular element. To obtain constant factors of environment in pot experiments the different soils were kept at their full water capacity during the entire vegetation period. Of 8 samples of each kind of soil, 4 were treated with a 1 to 2 per cent nutritive solution without phosphoric acid, and 4 with a 1 to 2 per cent nutritive solution containing phosphoric acid. The success was very limited, owing to the tenacity of the soils, but where successful the phosphoric acid deficiency was indicated by the reddening of the oats plants, it being greater the deeper the color.

The behavior of common and improved varieties of plants toward artificial fertilization, F. MASS (*Kali*, 7 (1913), p. 611; *abs. in Chem. Abs.*, 8 (1914), No. 7, p. 1322).—"The experiments were carried out on stony ground which was fertilized as follows: 0, 3, 6, and 8 kg. superphosphate; 0, 1, $\frac{1}{2}$, 3, and 4 kg. potassium salts; 1, 0, 2, and 3 kg. Chile saltpeter per 100 square meters. Four varieties of barley, 3 of oats, and 2 of summer rye were used in the experiments. The results show that on land that is wanting in plant food the common varieties yield better crops, while with fertilized land the improved varieties are more productive."

Maintenance of soil fertility: Plans and summary tables (*Ohio Sta. Circ.* 144 (1914), pp. 63-97, *fig. 1*).—This is one of the annual statements on the subject (*E. S. R.*, 29, p. 213), bringing the data for the experiments at Wooster and Strongsville up to the end of 1913 and summarizing the results for 20 years (1894-1913) at Wooster and 19 years (1895-1913) at Strongsville.

Soil fertility, G. ROBERTS (*Kentucky Sta. Ext. Circ.* 11, pp. 16).—This is a popular discussion of the fertilizer requirements of crops and soils and of the best methods of using fertilizers. Reference is made to an experiment which indicated "that in beginning the restoration of a badly worn soil deficient in phosphorus, it is best to use an application of acid phosphate in growing a cowpea crop to be turned under with a liberal application of raw ground phosphate rock, to be followed with clover as soon as possible. Clover seems especially able to utilize the rock phosphate. The clover turned under, pastured, or fed, and the manure returned, furnishes available phosphorus, as well as nitrogen, for succeeding crops. On soils fairly well supplied with organic matter, rock phosphate may be used to begin with."

Pot culture experiments, 1913, J. A. VOELCKER (*Jour. Roy. Agr. Soc. England*, 74 (1913), pp. 411-422, pls. 5).—These included experiments in continuation of those of previous years (E. S. R., 29, p. 520) on the influence of various metallic salts (zinc, copper, manganese, and cerium) on wheat and on the relation of lime to magnesia in soils, as well as experiments with sulphur as a fertilizer and on the effect on tomatoes of adding lithium phosphate and magnesia to natural and heated soils.

From the results of the pot experiments to test the influence of zinc salts it was concluded "that the addition of zinc up to 0.01 per cent will have, on the whole, a stimulating result and produce better tillering, but that above this amount the influence will be one of a toxic nature. In the form of nitrate the metal will be more active than in that of carbonate or of phosphate."

In studying the influence of copper salts on wheat it was found in pot experiments that "when sulphate of copper was used 0.1 per cent of the metal was absolutely destructive of the plant and 0.05 per cent nearly so; 0.02 and 0.01 per cent, however, showed stimulating action, more corn and more straw being alike produced. In smaller amounts copper appeared to have no action. With the carbonate the results were much the same, though not quite so strongly marked. . . . With the heavy dressing of copper, as sulphate, the roots went down only 1½ in. into the soil. With 0.05 per cent they were but little better, but with 0.02 per cent there was a great change visible, and an extensive and very fibrous root growth was produced. With 0.01 and lower quantities the root was much like that of the untreated plants. Carbonate of copper gave similar results, though not so marked."

Manganese and cerium salts are reported to have shown no indication of stimulation or of toxic effect with wheat plants.

Experiments upon the relation of lime and magnesia in soils showed an injurious effect when magnesia predominated, but when lime was in excess no such effect was produced.

No influence could be detected with mustard, rape, and clover by the application of flowers of sulphur at the rates of 3, 6, and 12 cwt. per acre as a fertilizer.

The results of the experiments with tomatoes indicated that lithium phosphate in amounts of from 0.0025 to 0.005 per cent and magnesia in amounts of from 0.792 to 1.584 per cent were toxic to the plants, the toxic effect being much more decided with tomatoes than with wheat. It was not clear from the results whether the effect of these substances was due to their action upon the bacterial nature of the soil.

Manurial experiments (*Bd. Agr. and Fisheries [London], Misc. Pub. 17 (1914), pp. 22*).—In this publication directions, originally drawn up in 1903 by the Agricultural Education Association of England, for making simple fertilizer experiments are given.

The plans include experiments to show the manurial necessities of the soil as well as the fertilizer requirements of meadow land, permanent pasture, rye grass and clover hay, ruta-bagas, mangolds or cabbages, potatoes, wheat, oats, and barley. Directions are also given for the use of lime in the prevention of finger-and-toe disease, and a method of reporting results is outlined. Duplicate plats are arranged for each treatment, these duplicates being as widely separate in the plan of experiment as possible.

The mixing of fertilizers, K. DIEM (*Meded. Deli-Proefstat. Medan*, 8 (1914), No. 4, pp. 112-117, pl. 1).—This article discusses the mixing of fertilizers and shows how to prepare mixtures of a given composition, explaining also what substances may and what should not be combined in a fertilizer mixture.

The topographic features of the desert basins of the United States with reference to the possible occurrence of potash, E. E. FREE (*U. S. Dept. Agr.*

Bul. 54 (1914), pp. 65, pls. 6.—The location, topography, and extent of the undrained basins of the United States are discussed with reference to conditions indicating the possible occurrence of workable deposits of potash in accordance with the "desert basin" or "dry lake" potash theory which is based upon three simple propositions, viz: "(1) Rocks and soils give up various salts, including those of potassium, to drainage waters which flow over them. (2) In areas of inclosed drainage these salts, still including those of potassium, are concentrated wherever the waters evaporate. (3) In this concentration the salts of potassium may have been sufficiently segregated from other salts to form a workable deposit."

The bulletin deals in general with the Great Basin and its development, and discusses in detail the following groups of undrained basins: The Lahontan Basin and its tributaries, the Bonneville Basin and its tributaries, the basins of the Lava Plateau, the trough valleys of Nevada and the basins of the Transition Zone, the trough valleys of California and the Mojave Desert, the Salton Basin, the basins of the New Mexico-Texas trough, the trough valleys of Arizona and Sonora, the Lordsburgh-Membres region (New Mexico) and the Chihuahua bolsons, the Rocky Mountain basins, the Great Valley of California, the filled lakes of the California ranges, the basins and ponds of the Colorado Plateau, the ponds and coulées of eastern Washington, the ponds of the Great Plains, and local basins of unusual origin.

Nearly 200 basins are referred to but in only the following are all the known conditions favorable to the accumulation of potash deposits: Lahontan, 45,730 square miles; Death Valley, 23,560; Railroad Valley, 6,340; Searles, 4,850; Alvord, 3,200; Diamond, 2,800; Surprise, 2,350; Dixie, 2,290; Warner, 2,000; Panamint, 1,950; Hualpai, 1,450; Columbus, 1,350; Gabbs, 1,280; Edwards Creek, 990; Kane, 900; Ivanpah, 900; Saline, 845; Eureka, 775; Mono, 770; Frenchman Flat, 740; Gold Flat, 640; Opal Mountain, 580; and Clayton, 550.

In the following some of the known conditions are unfavorable to the accumulation of potash but they can not be definitely rejected: Salt Basin, 8,600 square miles; Owens, 2,825; Estancia, 2,100; Spring Valley, 1,550; and Chewaucan (Albert Lake), 1,500. The following are classified as doubtful: Salton, 8,000 square miles; Danby Lake, 4,150; Red Desert, 3,600; Christmas Lake, 2,750; Bristol Lake, 2,520; Catlow, 2,000; Penoyer, 1,000; Guano Lake, 1,000; Emigrant (Timpahute), 1,000; Madeline, 900; and Rhodes, 670.

Presumed luxury consumption of potassium and phosphoric acid, J. LENDE-NJAA (*Separate from Meddel. Norske Myrselskap, 1912, No. 5, pp. 65; abs. in Zentbl. Agr. Chem., 42 (1913), No. 12, pp. 816-824; Chem. Abs., 8 (1914), No. 7, p. 1322*).—"In general the percentage of a constituent in plants is increased if the plants are fertilized with the particular fertilizer. For every soil and every plant there is a limit of fertilizing beyond which there is luxury of consumption. The limit generally agrees with the limit for the profitable employment of the fertilizer.

"The danger of luxury consumption is greatest in case of one-sided fertilizing. It may occur for potassium and phosphoric acid in complete fertilizing but only when the quantities are used in much greater amounts than in one-sided fertilizing. The amounts of valuable plant food which the ordinary culture plants take from the soil in luxury consumption are considerably greater in case of potassium than for phosphoric acid. A moderate amount of potassium nitrate used in addition to dipotassium phosphate lessens the percentage composition of potassium and phosphoric acid in the harvest and also the danger of luxury consumption. If potassium nitrate is increased until the plant tends to lodge there occurs a luxury consumption of potassium and phosphoric acid."

The brown and blue phosphate rock deposits of south-central Tennessee, J. S. Hook and L. P. Brown (*Resources Tenn.*, 4 (1914), No. 2, pp. 51-86, pl. 1, figs. 12).—This paper discusses "the extent of individual fields, the methods of mining, and the preparation of the phosphate for market, its uses, etc. . . . There are three distinct varieties of phosphate rock in Tennessee, known commercially as: (a) The 'brown' rock; (b) the 'blue' rock; and (c) the 'white' rock. Of these, only the first two are being exploited at the present time, and are here given attention."

The total production in 1912 was 423,331 long tons. The phosphate is sold under guaranty of from 70 to 80 per cent of tricalcium phosphate with not more than from 4 to 6½ per cent of combined iron and alumina.

The influence of lime in the form of caustic lime and carbonate on the physical properties of different kinds of soil, O. ENGELS (*Landw. Vers. Stat.*, 83 (1914), No. 5-6, pp. 409-466, fig. 1; *abs. in Ztschr. Angew. Chem.*, 27 (1914), No. 37, *Referatenteil*, p. 298).—From the investigations reported the author concludes that on the addition of lime to the soil the colloids are precipitated and a crumbly structure is produced. The water capacity and the permeability of the soil for water is at the same time increased, and to a greater extent in heavy soils than in light.

The capillary rise of water in the soil as well as the hygroscopicity were decreased by liming, the reduction in the latter case being greater the larger the proportion of clay and fine particles.

The ease of cultivation was decidedly increased by liming, the effect in this respect increasing with the compactness of the soil and the amount of clay and fine particles present. The shrinkage of the soil was very decidedly reduced by liming, particularly in the case of soil containing a large amount of clay and fine particles.

Injurious effect of heavy applications of lime on upland moor soils, DENSCHE and ARND (*Centbl. Bakt. [etc.]*, 2. *Abt.*, 40 (1914), No. 1-8, pp. 83-87).—Investigations in continuation of those already noted (*E. S. R.*, 29, p. 832) gave results confirming the authors' previous conclusions, and further emphasized the fact that the formation of nitrite when heavy applications of lime are made on moor soils is due to biological rather than chemical action since only traces of nitrite were found when the soil and the lime were carefully sterilized.

The action of sulphur on plant production, as well as the agreement of the results of field experiments with Gauss's law of probability, T. PFEIFFER and E. BLANCK (*Landw. Vers. Stat.*, 83 (1914), No. 5-6, pp. 359-383, fig. 1; *abs. in Ztschr. Angew. Chem.*, 27 (1914), No. 37, *Referatenteil*, p. 298).—Investigations by others on the fertilizing effect of sulphur are reviewed and field experiments in which sulphur was applied at the rate of from 267 to 524 lbs. per acre to oats on a heavy loam soil are reported.

The results indicated that the applications of sulphur increased neither the plant growth nor the utilization of the soil nitrogen; in fact, in many cases the opposite result was obtained in both respects. In the author's opinion the very favorable results following fertilizing with sulphur reported by other investigators are to be accepted with caution in view of the faulty methods of experimenting used.

The applicability of Gauss's law of probability to the results of field experiments is discussed and in the authors' opinion confirmed.

Manganese in the living organism and its agricultural applications, LEPERCQ (*Mém. Acad. Sci. Lyon*, 3. *ser.*, 13 (1913), pp. 177-192).—This article discusses the diffusion of manganese in plants and animals, the relation of manganese to enzymes, and manganese fertilizers, incidentally referring to some

of the more recent theories of soil fertility and especially to the possible beneficial effect of manganese salts in aiding the functioning of the oxidases.

Compensation for the unexhausted manurial values of feeding stuffs and fertilizers, J. A. VOELCKER and A. D. HALL (*Jour. Roy. Agr. Soc. England*, 74 (1913), pp. 104-119; *abs. in Mark Lane Express*, 111 (1914), No. 4306, p. 539).—A revision of tables, last published in 1902 (E. S. R., 14, p. 1057), is reported and discussed. The revision was rendered necessary by the recent rise in prices of fertilizing materials, more particularly of those furnishing nitrogen, and by the growing conviction that the spreading of compensation over a period of four years is alike inconvenient and not borne out by recent investigations nor in actual agricultural practice. In the revision, therefore, the unit value of nitrogen is taken as 15 s. (\$3.65) instead of 12 s. (\$2.92) as formerly, and the compensation extends only to one crop after the fertilizing material is applied. The prices for potash and phosphoric acid as used in the computation of the table remain unchanged.

AGRICULTURAL BOTANY.

Studies in plant physiology, P. MAZÉ (*Ann. Inst. Pasteur*, 25 (1911), No. 10, pp. 705-738, pl. 1, figs. 12; 27 (1913), Nos. 8, pp. 651-681, pl. 1; 12, pp. 1093-1143, pls. 2, figs. 6; 28 (1914), No. 1, pp. 21-68, pls. 4, figs. 8).—This is a series of memoirs in which the author attempts to establish the normal behavior of the roots of the higher plants and the mineral nutrition of plants in relation to a rational system for the use of fertilizers. Most of his experiments were carried on with maize, but various phases of the study were extended to other plants to confirm the results obtained. Among the various topics discussed are absorption and excretion of mineral substances by the roots and leaves of plants, excretion of organic materials, relation of the constitution of nutrient solutions to the mineral content of maize, storing mineral substances in different parts of the plant, effect of incomplete solutions on the ash of maize, absorption of organic matter and its use by the plant, the law of minimum in its physiological relations, the rôle of water in plants, the mechanism of absorption, the function of root secretions, conditions for fruiting of maize grown in aseptic solutions, influence of various compounds on the development of maize, chlorosis in maize, etc. Some of these topics have already been reported upon (E. S. R., 25, p. 224; 27, p. 721; 29, p. 826).

Notes on the technique of the determination of the depression of the freezing point of vegetable saps, R. A. GORTNER and J. A. HARRIS (*Plant World*, 17 (1914), No. 2, pp. 49-53).—A description is given of a method devised by the authors for the rapid study of the depression of the freezing point of vegetable saps. This method was successfully used in determining specific gravity, total solids, freezing point depression, and electrical conductance of more than 800 samples in about 2 months' time.

Utilization of solar energy by green plants, A. PÜTTER (*Naturwissenschaften*, 2 (1914), No. 8, pp. 169-175).—Results are given of experiments in which the utilization rate of solar energy by various plants is said to have ranged from 0.27 to 5.24 per cent of that incident on the green leaves employed.

The influence of humidity and dryness on the anatomical structure of two tropical plants, P. CHOUX (*Rev. Gén. Bot.*, 25 (1913), No. 292, pp. 153-172, figs. 16).—Giving results of a study regarding the external appearance, internal structure, etc., as related to seasonal humidity in case of *Ipomœa reptans* and *Neptunia prostrata*, the author states that the differences are marked as regards dimensions, color, and resistance. It is noted that in dry seasons the vascular

and fibrous systems are little developed, and the medullary lacunæ are smaller and thicker walled than in wet seasons.

Recent studies on respiration in tropical plants and on coloration of organs, F. TOBLER (*Naturwissenschaften*, 2 (1914), No. 9, p. 215).—Noting recent results of investigations as reported by Kuyper, Plester, and Hill, jr. (E. S. R., 26, p. 822; 28, p. 728; 29, p. 538), the author holds that while a direct parallel between respiration rate and chlorophyll content has not been established, a relation doubtless exists between respiration and assimilation.

A method of studying transpiration, F. DARWIN (*Proc. Roy. Soc. [London]*, Ser. B, 87 (1914), No. B 595, pp. 269-280, figs. 9).—The author describes and gives an account of experiments on transpiration, the investigation being conducted with leaves of the cherry laurel, the stomata of which had been blocked by a coating of cacao butter or vaseline and communication with the intercellular spaces of the leaves taking place through incisions made in the leaves. The rate of transpiration was estimated by a potometer.

The relation between transpiration and humidity in a number of experiments is shown by curves which indicate that transpiration for different degrees of relative humidity is roughly in a straight line. From this it is inferred that a definite relation exists between transpiration and relative humidity. Another characteristic brought out by the curves is the fact that transpiration in saturated air is not zero.

The effect of light on the transpiration of leaves, F. DARWIN (*Proc. Roy. Soc. [London]*, Ser. B, 87 (1914), No. B 595, pp. 281-299).—Employing the method described above, the author has studied transpiration in leaves and shoots of cherry laurel and ivy. The results of the studies are tabulated.

It appears that a remarkable degree of variability was observed between transpiration in light and darkness. On certain dates there was no difference, while at other times the transpiration in light was double that taking place in darkness. The average rate of transpiration in light and darkness in the ivy was 136 to 100 and in the laurel 132 to 100. Discussing the reason for increased transpiration in light, the author says it may be due either to the fact that the chloroplasts are warmed by the absorption of radiant energy, or that light produces an increased permeability of the plasmic membrane to water.

The influence of light and temperature changes on the germination of *Chloris ciliata*, G. GASSNER (*Jahrb. Hamburg. Wiss. Anst.*, 29 (1911), Beiheft 3, pp. 1-121, figs. 3).—This article gives in greater detail substantially the same statement of results as does a contribution already noted (E. S. R., 27, p. 219).

The action of light on chlorophyll, H. WAGER (*Proc. Roy. Soc. [London]*, Ser. B, 87 (1914), No. B 596, pp. 386-407).—An account is given in this paper of some of the effects produced by light on chlorophyll.

When chlorophyll is exposed to light at least two substances are formed, one of which is an aldehyde and the other an active chemical agent capable of liberating iodine from potassium iodide. The author claims that, so far as experiments on dead chlorophyll extracts can be taken as an indication, the aldehyde produced is a product of the photodecomposition or photo-oxidation of chlorophyll, and is not a result of the direct photosynthesis of carbon dioxide and water, as claimed by Usher and Priestley (E. S. R., 25, p. 634).

Formaldehyde as an oxidation product of chlorophyll extracts, C. H. WARNER (*Proc. Roy. Soc. [London]*, Ser. B, 87 (1914), No. B 596, pp. 378-385).—A study was made of chlorophyll obtained from grass by extraction with alcohol, the extract being exposed to electric light and sunlight in glass jars.

Where the film of chlorophyll was in contact with air containing carbon dioxide and water vapor, the development of formaldehyde is said to be due to

the decomposition of the films under the action of the oxygen of the air. Formaldehyde was not produced when the films were illuminated in a moist atmosphere of nitrogen or of carbon dioxid. The author claims there is no evidence of the photosynthesis of the aldehyde from carbon dioxid by chlorophyll outside of the plant. An extract of carotin was also investigated and the bleaching of the films of carotin extract was found to be associated with the formation of formaldehyde.

The direct assimilation of free atmospheric nitrogen by plants, E. MAMELI and G. POLLACCI (*Ann. Sci. Agron.*, 4. ser., 3 (1914), No. 3, pp. 123-142).—The various theories regarding the assimilation of free atmospheric nitrogen are reviewed, particular attention being paid to that of Jamieson regarding absorption through special trichomes (E. S. R., 19, p. 127). The authors criticise the methods by which Jamieson conducted his experiments and find nothing to substantiate his claim.

In the second part of the paper accounts are given of experiments with a large number of plants, ranging from fungi to phanerogams, grown under controlled conditions in the absence of combined nitrogen. As a result of their investigations the authors conclude that the capacity to absorb free atmospheric nitrogen is one possessed by many or all plants, although some, through their long dependence on combined nitrogen, may have lost this power. They are unable to say definitely in what manner or by what special organs the nitrogen is absorbed, but are disposed to think that it is a physiological function of plants that may be in some way connected with the chemical reactions taking place within the cell.

The influence of organic substances on nitrification and denitrification in cultivated soils, C. BARTHEL (*Ztschr. Gärungsphysiol.*, 4 (1914), No. 1, pp. 11-48, fig. 1).—Referring to the claim of Winogradski and Omelianski (E. S. R., 11, p. 424) that the presence of small proportions of organic substances checked the activity of nitrifying bacteria, and of others said to have obtained results with soils opposed to those given by solutions, the author holds, as the result of his own studies, that the influence of organic substances upon nitrification, if not present in too large proportions, is usually rather favorable than otherwise, because of their ready solubility.

Assimilation of inorganic nitrogen compounds by plants, O. BAUDISCH (*Naturwissenschaften*, 2 (1914), Nos. 9, pp. 199-204; 10, pp. 229-232).—This is mainly a synthesis and discussion of results presented by several investigators named, as bearing upon the influence of different wave lengths in nutritive processes in plants. The waves of high frequency are thought to be peculiarly influential as chemical factors in high regions, where the thin dry air allows them freer passage and access to plant foliage.

Assimilation of nitrates by mold fungi, II, A. KOSSOWICZ (*Ztschr. Gärungsphysiol.*, 3 (1913), No. 4, pp. 321-326).—Reporting further investigations on the fungi formerly studied (E. S. R., 29, p. 29), the author states that all nine species were able to attain fair development when limited to nitrates as a nitrogen source in the medium, some however requiring considerably more time than others. These mold fungi appear to utilize directly the nitrous ion without the formation of ammonia, the presence of the latter, when noted in the medium, being attributed to the activity of the older fungi acting upon nitrogenous organic compounds.

Protein transformations in yeast.—I, Influence of fermentation on protein formation, W. ZALESKI and W. SCHATALOFF (*Biochem. Ztschr.*, 55 (1913), No. 1-2, pp. 63-71).—Among the conclusions reached as the result of these experiments the authors state that acetic aldehyde does not greatly influence proteo-

lysis in yeast, also that the conditions attending constructive processes therein exert considerable influence on the later proteolytic changes.

Protein formation in plants.—I, In bulbs of *Allium cepa*, W. ZALESKI and W. SHATKIN (*Biochem. Ztschr.*, 55 (1913), No. 1-2, pp. 72-78).—As part of a more general study on the mechanism of protein formation in different portions of higher plants, the authors report on experiments with sprouting or injured bulbs of *A. cepa*. It is stated that protein formation during sprouting, as also after wounding, is dependent upon a supply of monamino acids.

Relation of some Saccharomycetes to inulin, V. GRAFE and V. VOUK (*Ztschr. Gärungsphysiol.*, 3 (1913), No. 4, pp. 327-333).—Discussing detailed results of further studies on inulin metabolism (*E. S. R.*, 30, p. 432), the authors state that as noted in yeasts utilization of inulin appears to be a complicated process, depending not upon the presence of inulin alone but also upon that of certain other components of the nutritive medium, more particularly that of certain hydrolyzed products.

Investigations on the substitution of zinc by other chemical elements, M. JAVILLIER (*Ann. Inst. Pasteur*, 27 (1913), No. 12, pp. 1021-1038).—The author has investigated the possibility of substituting cadmium and glucinium for zinc in culture solutions for the growth of *Aspergillus niger*, and has come to the conclusion that such substitution can not take place. The action of zinc culture solutions for the growth of molds is said to be that of an active catalyzer.

Loss or injury of leaves as related to head and grain formation in rye, O. SCHLUMBERGER (*Arb. K. Biol. Anst. Land u. Forstw.*, 8 (1913), No. 5, pp. 515-551, figs. 14; *abs. in Deut. Landw. Presse*, 40 (1913), No. 64, pp. 770, 771).—

This work was carried out with summer rye, various forms and degrees of injury to the leaves being employed.

It was found that injury inflicted at the inception of flowering affects the formation of both head and grain in degrees corresponding somewhat to its severity. The abnormality produced, which is usually less marked about the central portion in case of the head, is both qualitative and quantitative, the latter modification being the greater. This work is regarded as preliminary.

The chemical interpretation of some Mendelian factors for flower color, MURIEL WHELDALE and H. J. BASSETT (*Proc. Roy. Soc. [London]*, Ser. B, 87 (1914), No. B 595, pp. 300-311).—According to the authors flower color in *Antirrhinum majus* is due to the presence of at least six factors. In the present paper four of these are considered, particular attention being paid to the yellow pigment. As a result of their studies they conclude that the yellow pigment in *Antirrhinum* is luteolin.

A discussion is also given of the red and magenta anthocyanin obtained from this flower, and the authors, from their experimental investigation, claim that the reduction and oxidation hypothesis (*E. S. R.*, 30, p. 129) is opposed to the experimental facts. It is believed that the original production of anthocyanins in the plant is either partly or wholly due to the action of an oxidase on a chromogen, most likely a flavone or xanthone.

Inheritance of xenia in beans, J. DANIEL (*Compt. Rend. Acad. Sci. [Paris]*, 158 (1914), No. 6, pp. 418-420).—In continuation of a study of xenia in beans, the occurrence of which was previously noted (*E. S. R.*, 28, p. 431), the second and third generations of the hybrids have been grown.

It was found that xenia in these plants varied considerably, the influence of the staminate parent on the color ranging from total to almost nothing. The hybrids between *Phaseolus multiflorus* and the black Belgian bean did not conform to any interpretation of the Mendelian law regarding heredity. The increase from seed that were thought to be identical gave very diverse descendants in different instances and in different years.

Mutation in *Penicillium glaucum* and *Aspergillus niger*, H. J. WATERMAN (*Ztschr. Gärungsphysiol.*, 3 (1913), No. 1, pp. 1-14, fig. 1).—Concluding a discussion of the causes of mutation and the metabolism of these mutants, the author states that mutation is related in both cases to the same factors limiting development, these including poisons, narcotics, etc., as listed.

A possible mutant in the bellwort (*Oakesia sessilifolia*) which prevents seed formation, A. F. BLAKESLEE and A. F. SCHULZE (*Science, n. ser.*, 39 (1914), No. 1008, pp. 621, 622, figs. 2).—The authors describe a form of the sessile-leaved bellwort in which the pistil is shorter and thicker than in normal flowers and the three stigmas are transformed into functional stamens, each with a pair of pollen sacs. The stigmatic anthers are said to be well formed and filled with perfect pollen, and on account of the transformation it seems that the possibility of fertilization is completely prevented.

A study of semisterility, J. BELLING (*Jour. Heredity*, 5 (1914), No. 2, pp. 65-73, figs. 7).—The results of a study of hybrids of several species of *Stizolobium* are given, from which the author concludes that accurate knowledge of the degree of sterility of some hybrid plants may be obtained by microscopic examination of the pollen of healthy flowers and sections of the ovules. The explanation of the random abortion of half the pollen grains and half the embryo sacs is apparently due to the segregation of Mendelian factors and not to the action of these factors on the zygotes. Semisterility resulting from crossing is apparently one of the simplest cases of sterility, and a knowledge of its inheritance, it is believed, will help in the investigation of more complicated problems of sterility found in many first-generation hybrids.

Partial barrenness in Lübeck currants, E. ZACHARIAS (*Jahrb. Hamburg. Wiss. Anst.*, 29 (1911), Beiheft 3, pp. 129-149).—This work was carried forward, after the author's death in 1911, by W. Himmelbaur, testing the capability, as regards pollination, of several varieties of *Ribes pallidum*. Detailed results are given. It is stated that good results were obtained as regards fertility of the resulting forms by crossing Lübeck with Afsmiter. The normally low fertility of the latter is ascribed to faulty pollen.

Notes on the life history of *Ribes pallidum*, W. HIMMELBAUR (*Jahrb. Hamburg. Wiss. Anst.*, 29 (1911), Beiheft 3, pp. 151-245, figs. 69).—Reporting further studies with *R. pallidum*, carried out in considerable cytological detail at different stages in its early life history in relation to the fertility of this form (considered to be a hybrid of *R. petraeum* and *R. rubrum*), which while only 20 to 40 per cent is still higher than that of either parent, the author states that *R. pallidum* is probably identical with Lübeck currant. Individuals of the latter variety are said to show sudden sterility associated with other alterations of habit which are mentioned.

This work concludes with a bibliography.

FIELD CROPS.

Farm crop surveys, E. G. MONTGOMERY (*Jour. Amer. Soc. Agron.*, 5 (1913), No. 4, pp. 232, 233).—This paper relates to methods and gives some results of a potato survey in which about 700 records were taken in a county in New York. It is noted that "certain problems came to be outstanding as the inquiry progressed. It now appears that if experimental work has been undertaken previous to the survey we should not have hit on the principal problems in all cases. Also some grower, somewhere, has worked out in practice an answer to many problems, making investigation unnecessary. I am convinced that it would be very profitable, before an extensive line of investigation is undertaken with a crop, to first make a survey of this crop."

New work on methods for variety tests, D. LEHN (*Bl. Zuckerrübenbau*, 20 (1913), Nos. 3, pp. 33-39; 4, pp. 52-55).—This is a discussion of the application of the formula $c = \pm \sqrt{\frac{\sum v^2}{n-1}}$ (E. S. R., 30, p. 33), and other formulas in calculating the probable experimental error in variety tests, and similar experiments.

The Hamilton County Experiment Farm.—Second annual report, for the year 1913 (*Ohio Sta. Bul.* 272 (1914), pp. 263-276, fig. 1).—In this bulletin is described the plan of management of this county experiment farm, and some results are given of tests to determine the present state of soil fertility. This involves a rotation of corn, soy beans, wheat, and clover with fertilizer applications that included chemical fertilizers, yard manures, and shed manures. It is noted that "at the computed prices the cost of treatment has in most cases been greater than the value of the increase. This, however, has not been an unexpected outcome, as the first application of fertilizers or manure is largely absorbed by the soil, and it is not until the treatment is repeated that its full effect is manifest."

Results of variety tests with corn, oats, and soy beans as grain crops, and of silage corn are given, and comparisons made with results in other counties of the State. Yields of soy beans, cowpeas, rape, and millet as forage crops are given for Hamilton County.

[Report of] the professor of field husbandry and director of field experiments, C. A. ZAVITZ (*Ann. Rpt. Ontario Agr. Col. and Expt. Farm*, 38 (1912), pp. 112-170).—In addition to notes on the soil and climatic conditions, the author gives general results of continuous growth for from 18 to 24 years of each of 34 varieties of farm crops that include cereals, root crops, and legumes.

It is noted that the influence of seed selection has been shown in the increased yields by the use of large, plump seed. Especially was this marked in the case of oats.

[Field crop experiments] (*Rpt. Agr. Dept. St. Vincent*, 1912-13, pp. 5-10).—Results of seed selection, hybridization, and cultural experiments with cotton, and cultural experiments with arrowroot, cassava, and sugar cane are given.

Further experiences with the use of so-called stimulants, A. STUTZER (*Deut. Landw. Presse*, 41 (1914), No. 1, pp. 1, 2, figs. 2).—After discussing similar work by English and German investigators the author gives results of his own with sugar beets, previously noted (E. S. R., 30, p. 529). In water cultures with maize 0.5 gm. of lead nitrate per liter of nutrient solution seemed to be the optimum amount to stimulate growth, although 1, 2, and 0.25 gm. per liter were tried.

Effect of kainit and forty per cent potash salt as a top-dressing for fall and spring cereals, A. STUTZER (*Ztschr. Landw. Kammer Schlesien*, 18 (1914), No. 7, pp. 278-280).—The results of seven experiments are here given in which the 40 per cent potash salt seemed to be the more efficient.

Straw as a fertilizer under various conditions, A. BISCHOFF (*Jour. Landw.*, 62 (1914), No. 1, pp. 1-95, pls. 5).—In pot experiments conducted at Göttingen chopped straw was turned under shallow and deep at 10 weeks, 4 weeks, and immediately before planting in both sand and clay soils. Mustard and buckwheat were grown.

From his observations the author concludes that on sandy soil the use of straw practically always was followed by a smaller yield of dry matter and of nitrogen, and that the injurious effect of the straw was less in the presence of sodium nitrate. When deeply covered it seemed to have an injurious effect on the yield of nitrogen. The shallow straw application just before seeding was always more injurious than the others, while the deep straw application was

always most injurious when made 10 weeks before planting. With an increased yield of dry matter there was usually a decrease in nitrogen yield.

On clay soils the application of straw did not uniformly decrease the yields. In the presence of alkaline fertilizers and nitrate of soda the straw showed a greater injury to dry matter and nitrogen yields than in the presence of acid fertilizer and nitrate of soda. In the presence of alkaline fertilizers without nitrate of soda the injury was less than with the nitrate, while in the presence of acid fertilizers without nitrate of soda the effect of the straw was similar to that in the presence of alkaline fertilizers with the nitrate. Where there was injury with the deep application of straw it was always greater than with the shallow application. In the presence of nitrate of soda the early (10 weeks) application of straw seemed to produce greater injury to the crops than the late application, while in the absence of nitrate of soda the late application of straw apparently caused the greater injury. With an increase in yield of dry matter, the nitrogen yield decreased.

The data are given in tabular form.

On the details of development of cereals, O. SCHMIDT (*Landw. Jahrb.*, 45 (1913), No. 2, pp. 267-324, pl. 1).—This reports results of experiments to discover characteristics that may be used to determine different varieties.

It is noted that with the exercise of great care varietal differences in the root systems or in the leaf and spike arrangements may be detected, especially in the seedling cereal. Great differences were observed in the length of the vegetative period and the lateness or earliness of the shooting of the spike, but these differences could not serve as variety characteristics as they were so much influenced by climate, and in the young plant by size, specific weight of the seed, and morphological characters. From the results of the investigation, therefore, the author concludes that the observed characteristics of any variety may vary.

The normally formed cereal stalk and its significance, H. PLAHN-APPIANI (*Ztschr. Pflanzenzücht.*, 2 (1914), No. 1, pp. 27-37, figs. 2).—This article discusses the relations of length, thickness, and weight of internodes.

It is pointed out that these relations are not influenced to any considerable extent by heredity, and should not be considered a factor in selection breeding, since they were more influenced by environmental factors such as stand, weather, and mechanical injury, as by insects, animals, or wind. The correlations of these structure factors of the internodes seemed to have no bearing on the yield.

Experiment to determine the influence of age and light on the germination of grass seeds, H. REILING (*Keimversuche mit Gräsern zur Ermittlung des Einflusses, den Alter und Licht auf den Keimprozess ausüben. Inaug. Diss., Univ. Jena, 1912, pp. 87*).—Experiments are reported with *Holcus lanatus*, *Poa pratensis*, *Alopecurus pratensis*, and *Festuca pratensis*.

It is noted that the smaller seeds of these species are not at an optimum condition for germination immediately after harvest, but approach that condition in about 6 months. Light is a favorable factor to germination, but with increased age of the seeds seems to be less important. Good ventilation and dryness of the seeds during storage favored the germination process. The data are given in tabular form.

Some practical hints in breeding grasses, RAUM (*Ztschr. Pflanzenzücht.*, 2 (1914), No. 1, pp. 39-50).—This article discusses methods of stock and seed propagation, transplanting seedlings, prevention of cross fertilization, and harvesting the mature plants.

Alfalfa and sweet clover, G. ROBERTS, E. J. KINNEY, and H. B. HENDRICK (*Kentucky Sta. Bul. 178 (1914), pp. 3-34, figs. 10*).—This bulletin contains in-

structions for the production of alfalfa and sweet clover and gives results of the application of lime to alfalfa. "From these yields it appears that an application of 4 tons of limestone per acre gives larger yields than 2 tons per acre, but that increasing the application to 6 tons per acre does not give a further increase. . . . Sulphate of potash, used with 2 tons of limestone, gave an increase for the first cutting, as compared with the yield of the corresponding plats on which 2 tons of limestone were used without sulphate of potash, but for the second cutting the reverse was true, with the exception of two of the plats. . . .

"Another fact to be noted is that the difference between limed and unlimed plats is not so great for the second as for the first cutting, the unlimed plats all showing an increase for the second cutting, while the limed plats all show a decrease. . . . The unlimed alfalfa contained only 2.06 per cent of nitrogen, whereas the average for the limed alfalfa was 2.6 per cent. . . . The analyses were made on the first cutting, and are calculated on the basis of 12 per cent moisture content in the hay. As the best limed plats yielded 4 times as much hay as the unlimed plats it will be seen that the limed soil produced 5 times as much protein as the unlimed soil."

Some characteristics of barley kernels as variety constants, OPITZ (*Fühling's Landw. Ztg.*, 62 (1913), No. 24, pp. 866-875).—Conclusions are based upon data collected on several varieties that were grown at numerous centers during the period 1908-1912. It is noted that absolute weight was found to be a type character, that protein content did not seem to be a type character, and that percentage of glume was a type character of 2-row barley.

Spineless cactus unsuited to Arizona, J. J. THORNER (*Cal. Cult.*, 42 (1914), No. 4, p. 104).—Notes are given showing the nonhardiness of the spineless cactus under the temperature and moisture conditions of Arizona, and mention is made of a Mexican variety that is much hardier than the Burbank varieties.

A new forage plant, L. MISSON (*Criador Paulista*, 8 (1913), No. 78, pp. 1694-1700, figs. 8).—Descriptive and cultural notes are given for *Chloris virgata*, and its value as a forage plant is discussed.

On the application of vegetative propagation in the breeding of forage plants, J. VASTERS (*Fühling's Landw. Ztg.*, 62 (1913), No. 23, pp. 809-821, fig. 1).—After discussing the different methods of vegetative propagations, the author gives results of experiments in the propagation of red clover by root, stalk, and tip cuttings from which 26 per cent sent out rootlets. The root cuttings were the most propitious.

On hard seed coats and fractured seed coats in the germination of clover seeds, B. STEGLICH (*Landw. Vers. Sta.*, 79-80 (1913), pp. 611-622).—Results are given of a study of hard-coated red clover seeds germinating under various conditions, and of the effect on the seedling during germination in seeds that fracture the seed coats during the germinating process.

It is noted that germination in general took place in the field more slowly and less energetically than in an artificial seed bed. The data show that up to the fourteenth month after planting in the field 51 per cent of the hard-coated seeds of a normal sample germinated, and that germination took place more readily in clay and humus soils than in sand soils. When the hard-coated seeds were separated and planted by themselves germination followed to only 30 per cent, due, it is maintained, to the lack of shading that was furnished in the former case by the plants from the normally coated, early germinating seeds.

Filter paper kept saturated at 40, 60, and 80 per cent proved a satisfactory medium for the germination of hard-coated clover seeds for the purpose of observing the fracture of the seed coat caused by much moisture. This, it is claimed, produces an uneven turgidity resulting in a fracture which often

leads to an injury or a complete breaking off of either the cotyledons or radicle. Brick dust, which allowed for too rapid evaporation, was not suitable for this work.

The number of seeds whose seed coat became thus fractured within 10 days ranged from 7 to 9.75 per cent. With an extension of the period of germination the percentage of fractured seeds became less.

It is noted further that seeds taken from the filter paper just as the germ pricked the seed coat and placed in garden soil in pots showed a very much lower percentage of fractured seed coats and consequently fewer crippled plants.

The author notes that herein lie variations and discrepancies in reports of germination tests in general, inasmuch as the seed is left to lie undisturbed in an unfavorable moisture condition. In sowing the seeds in soil it was found that the optimum conditions for germination as found in the artificial seed tests did not exist and that seeds with fractured seed coats or otherwise weakened germs could scarcely survive.

The effect of weather upon the yield of corn, J. W. SMITH (*Mo. Weather Rev.*, 42 (1914), No. 2, pp. 78-87, figs. 4).—On the basis of the assumption that there is a critical period in the growth of every crop during which the weather conditions exert a determining influence upon the yield, the author conducted a series of studies, the results of which in regard to the corn crop are here given as follows:

“The controlling weather factor in the great corn-growing districts of the United States is rainfall. The critical period of growth of corn during which favorable weather will cause a large crop and unfavorable weather a short crop is comparatively brief. If the rainfall for calendar months be considered, that for July has a far greater effect upon the corn yield than rainfall for any other month. The rainfall from about the middle of July to the middle of August has a far greater effect upon the corn yield than that for any other period of similar length. The rainfall for the 10 days following the date of blossoming has an almost dominating effect upon the yield of corn, the larger the rainfall the larger the yield.

“If the rainfall is small during the 10 days after blossoming a high temperature has a very unfavorable effect upon the yield. Rainfalls of one-half inch or more have a greater effect upon the development of corn than falls of less amount. It seems possible to give a close estimate of the probable yield of corn by August 10, by careful study of the weather conditions that have prevailed up to that time.

“The importance of shallow cultivation after each rainfall in July and after August 1 for the purpose of forming a dust mulch and thus preventing the loss of water by evaporation can not be overestimated. The science of agricultural meteorology can be advanced, and the results of these investigations be made of more practical value to the farmer, by a detailed study of the critical periods of growth and the weather factors most affecting the yield of other field and garden crops.”

The frequency of low temperatures in the Sudan and its effect on the cotton crop, H. E. HURST (*Cairo Sci. Jour.*, 7 (1913), No. 87, pp. 265-268, pl. 1).—This article gives tabulated data and discusses the frequency of low temperature in certain districts as a preliminary to research work on the effect on the cotton crop.

The effect of water on the cultivation of cotton, H. T. FERRAR and H. E. HURST (*Survey Dept. Egypt Paper 24* (1912), pp. VIII+53, pls. 1).—In studying by means of bore holes the relation between the height of the water table or level of the subsoil water and the yield of cotton, it was found that there

was a steady increase in yield as the thickness of the layer of soil above the water table increased and that the rise of the water table at the end of the summer caused a diminution of the crop. It is noted that "from the close connection between the yield of cotton and the height of the water table found in these cases, it seems probable that the latter is one of the most important of the causes which determine the magnitude of the cotton crop." In irrigation experiments "the rise of water in bore holes situated in the experimental plat was usually about seven times the thickness of the layer applied to the land."

The effect of water on the cultivation of cotton, H. E. HURST and HUGHES (*Survey Dept. Egypt Paper 31 (1913), pp. 23, pls. 3, figs. 2*).—In a further study on the effect of water on cotton in Egypt (see above), experiments in irrigation showed that "on land where the level of the subsoil water was low the yield of cotton increased as the amount of water applied to the land increased, though there were signs of a maximum yield having been reached. On the other hand, the maturing of the cotton was delayed by increase of the water applied."

Some defects in *Crotalaria* seeds used in Deli, J. A. HONING (*Meded. Deli-Proefstat. Medan, 7 (1912), No. 9, pp. 395-418, figs. 2*).—The tests indicated that *Crotalaria* seeds seldom germinate more than 50 per cent; that mold readily attacks the seed in germination; that hard-coated seeds reach to 43 per cent or even to 70 per cent if the seeds are dried; that there is a correlation between color and hardness of seed coat, light colored seeds being harder than dark colored ones; and that *C. striata* seed consists of a mixture of seeds of varying colors and degrees of hardness.

Green manuring with sanai in Bihar, A. and G. L. C. HOWARD (In *The Improvement of Indigo in Bihar. Calcutta, 1914, pp. 26-28, pl. 1*).—Experiments with sanai (*Crotalaria juncea*) as a green manure for tobacco in the botanical area at Pusa have shown that drainage is essential to success on the highlands. To get the maximum benefit it is noted that the interval between the plowing in of the sanai and the transplanting of the tobacco should be 8 weeks. A longer or shorter time would lead to loss.

Fertilizer experiment with flax, F. WINDIRSCH (*Deut. Landw. Presse, 41 (1914), No. 10, p. 116, fig. 1*).—In these tests a complete fertilizer (500 kg. Thomas slag, 500 kg. kainit, and 100 kg. ammonium sulphate per hectare) gave greater yields than any two forms only, and also gave the greatest length of stem, 105 cm., in comparison with 70, 80, and 90 cm. by the use of a one-sided fertilizer.

Eight-year variety tests of horse beans, A. ZIFFER (*Arb. Deut. Landw. Gesell., No. 249 (1913), pp. 153*).—Results of variety tests conducted in various centers in Germany from 1905-1912 are reported.

New researches with oats, DENAÏFFE and SIRODOT (*Jour. Agr. Prat., n. ser., 27 (1914), No. 4, pp. 111-114, figs. 5*).—Historical and descriptive sketches are given of several varieties of oats classed under side oats and hull-less oats or "naked oats."

Origin of cultivated oats, L. TRABUT (*Jour. Heredity, 5 (1914), No. 2, pp. 74-85, figs. 10*).—A study is reported of the following points: Whether a difference in ancestry has a vital bearing on the adaptability of varieties, forms derived from *Avena sterilis* best suited to southern countries, possibilities of hybridization, indications that environment is a factor in causing variation, and the influence of culture and the results of mutations which include *A. sterilis segetalis*, *A. sterilis maxima*, *A. sterilis calvescens*, *A. sterilis pseudovilis*, *A. sterilis byzantina*, *A. sterilis parallela*, *A. sterilis algeriensis*, *A. sterilis culta*, *A. sterilis ludoviciana*, *A. sativa*, *A. fatua*, *A. hybrida*, *A. strigosa*, *A. barbata*, *A. brevis*, and *A. abyssinica*.

"At least three wild species of *Avena* under the influence of culture may acquire characters fitting them for cultivation. These three species preserve the ancestral characters by which they are adapted to different climates. *A. fatua* gives rise to oats adapted to temperate and mountainous regions; *A. sterilis*, to oats adapted to the southern countries, and to saline soils; *A. barbata* to races adapted to dry countries."

Influence of nitrates on the germinative period of oats, F. PLATE (*Atti. R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat., 5. ser., 22 (1913), II, Nos. 11, pp. 598-607; 12, pp. 728-733*).—This reports the use of neutral electrolytes in several series of experiments to determine their influence on oat seedlings.

In the first series, nitrates of caesium, rubidium, potassium, sodium, lithium, and ammonium were used, made up into solutions of varying concentrations as follows: N/50, N/100, N/200, N/400, N/800, N/1,600, and N/3,200. The plants grown in the culture solutions were compared by weight with plants grown on moistened filter with no other nourishment than that furnished by the seed. The oats were taken at a certain stage of development, usually attained at the age of 15 days.

Except in the case of rubidium the two highest concentrations of all the cations produced a growth below the normal, and as a rule the development of the plant increased as the strength of the nutrient solution decreased. Other results are expressed as follows: As to weight of entire plant Rb>K>Na>Li>Cs; in root growth Na>K>Rb>Li>Cs; in shoot growth Li>Na>K>Rb>Cs; and in correlation in development Rb>K>Na>L>Cs.

In the second series the nitrates of barium, calcium, strontium, magnesium, zinc, cadmium, and mercury were used in water solutions. The general action of this group upon the development of the oat seedling is expressed as follows: As to weight of entire plant Ca>Sr>Zn>Ba>Mg, Cd, Hg; in root growth Sr>Ca>Zn>Ba>Mg, Cd, Hg; in shoot growth Ca>Ba>Zn>Sr>Mg, Cd, Hg; and in correlative growth Sr>Ca>Zn>Ba>Mg, Cd, Hg.

Experiments with peanuts, A. C. TONNELIER (*Bol. Min. Agr. [Buenos Aires], 15 (1913) No. 5, pp. 586-589*).—The results of seed selections at Córdoba are shown in the following table:

Percentage of different sized pods from selected seed.

Number of kernels per pod in seed.	Kernels per pod in the harvest.			
	4 kernels.	3 kernels.	2 kernels.	1 kernel.
	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>
4 large, shelled before planting.....	6.20	49.70	37.20	6.90
4 small, shelled before planting.....	6.60	45.35	41.05	7.00
3 large, shelled before planting.....	7.12	47.40	38.12	7.36
1 large, shelled before planting.....	11.20	48.20	33.40	7.20
1 small, shelled before planting.....	10.40	48.60	33.97	7.03
3 whole pods planted.....	7.00	47.60	38.10	7.30

Potato culture (*Idaho Sta. Bul. 79 (1914), pp. 67, figs. 14*).—This bulletin consists of four papers, and an introduction by W. L. Carlyle.

Potato culture for northern Idaho, F. L. Kennard (pp. 5-16).—This paper gives notes of culture, varieties, and marketing and results of seed selections. Selections from high-yielding hills gave better yields than those from low-yielding hills or from bulk selections, although the seed tubers used were of the same weight and cut to the same size in each case.

Potato culture under irrigation, J. S. Welch (pp. 17-27).—This paper gives general directions for potato culture under irrigation under the soil and climatic

conditions found at Gooding, variety tests, and some results of experiments on time to irrigate. Better success was obtained by commencing the irrigation about the time the tubers began to form, making about four irrigations and applying about 1½ cu. ft. per acre in deep furrows, than in commencing when the plants are 4 or 5 in. high or when the tubers are the size of an egg.

Dry land potato culture for southern Idaho, L. C. Aicher (pp. 28-39).—This article surveys the dry land potato industry in southern Idaho and gives notes on cultivation and harvest methods.

Diseases and insect pests of the potato, C. E. Temple (pp. 40-67).—This paper describes the fungus and physiological diseases and insect pests of the potato and offers suggestions for treatment for such as may occur in Idaho.

Potatoes, L. GREENE and T. J. MANEY (*Iowa Sta. Circ. 13 (1913)*, pp. 2).—This circular describes 5 early and 6 late varieties of potatoes that have been found to compare favorably with Early Ohio and Rural New Yorker in Iowa. Planting, seed treatment, and spraying directions are given.

Report on the progress and recent work in sugar beet culture, M. HOFFMANN (*Bl. Zuckerrübenbau*, 20 (1913), No. 1, pp. 1-7).—This article reviews and summarizes the results of recent work of investigators on nitrogen content of sugar beets, cultural methods, excrescent growths, weight and sugar content of roots, influence of water, quality and quantity of yield, composition of large beets, defoliation, nematodes, influence of light on the seed production, changes of the beet during storage, germination of dried seeds, and Mendelian studies.

Progress and developments in the culture and selection of the sugar beet and sugar-beet seed (*Sucr. Indig. et Colon.*, 82 (1913), Nos. 23 pp. 534-539; 24, pp. 561-564; 25, pp. 580-584; 26, pp. 605-607; 83 (1914), Nos. 1, pp. 7-11; 2, pp. 32-36; 3, pp. 58-61).—This reviews and summarizes the recent literature relating to the cultivation, anatomy, physiology, composition, fertilization, seed selection, by-products, tools and machines, uses of sugar, by-products as feed, insect enemies, and diseases of sugar beets.

On the physiology of beet seeds, H. PLAHN-APPIANI (*Bl. Zuckerrübenbau*, 21 (1914), No. 1, pp. 1-5).—This article reports an experiment to test the value of the size factor in beet seeds and in beet seed balls. The following table shows the results obtained from a single plant, both with seed balls allowed to mature naturally and those in which one-half of the plant had been pruned back to allow the seed balls on that side to grow to a larger size.

Germination of beet seeds of different sizes and from different sized seed balls.

Seed balls maturing naturally			Seed balls from pruned portion.		
Weight of 100 balls.	Number of seeds germinated.	Number of balls germinating seeds.	Weight of 100 balls.	Number of seeds germinated.	Number of balls germinating seeds.

¹ Unsifted.

² 5.5-mm. sieve.

³ 4-mm. sieve.

⁴ 3-mm. sieve.

⁵ 2-mm. sieve.

Influence of certain stimulants on the development of sugar beets, O. MUNERATI, G. MEZZADROLI, and T. V. ZAPPAROLI (*Staz. Sper. Agr. Ital.*, 46 (1913), No. 7-8, pp. 486-498; *abs. in Sucr. Indig. et Colon.*, 83 (1914), Nos. 10, pp. 231-234; 13, pp. 305-309; 14, pp. 323-327).—The sulphate, chlorid, dioxid, and carbonate of manganese, sulphate and nitrate of aluminum, sulphate of magnesium, boric acid, borate of soda, and sulphate of uranium were used in various quantities and combinations in growing sugar beets on over 100 small plats.

The data show that the largest yield, at the rate of 611.2 kg. of sugar per hectare (544 lbs. per acre), was obtained on a control plat without any of the above-mentioned chemicals; the lowest yield, 343 kg. per hectare, was obtained from the plat receiving 100 kg. of nitrate of aluminum per hectare. The highest percentage of sugar, 15 per cent, was obtained from the plat receiving 50 kg. of carbonate of manganese per hectare, on which the yield was at the rate of 374 kg. per hectare with a purity coefficient of 83.73 per cent. The lowest percentage of sugar, 12.63 per cent, was from the control plat from which the yield was 611.2 kg. and the purity coefficient 83.16 per cent. The highest purity figure was 85.6 from the sulphate of magnesia plat where the yield was 455 kg. per hectare and the percentage of sugar 14.51, and the lowest purity coefficient was 79.62 per cent from the manganese dioxid plat where the yield was 533 kg. per hectare and the percentage of sugar 12.99.

Excessive foliage in sugar beets, M. A. VIVIEN (*Bul. Assoc. Chim. Sucr. et Distill.*, 31 (1914), No. 7, pp. 501-505).—Analyses of juice from beets that developed leaves and crowns in different degrees showed that those beets with a larger proportion of foliage yielded less sugar than those with a low percentage of foliage, 11.5 against 12.75 per cent in one series, and 12.2 against 14.65 per cent in another series.

Analyses of tops and of trimmed beets are given in tabular form.

Dry matter content of stock beets, H. NEUBAUER and G. HILLKOWITZ (*Landw. Ztschr. Rheinprovinz*, 13 (1912), No. 1, pp. 32-34; 14 (1913), No. 2, pp. 20, 21; 15 (1914), No. 7, pp. 117, 118).—Data are given showing percentage of dry matter in numerous varieties of stock beets grown at several centers, in 1911-1913, as related to the weights of individual beets. In 1911 the weight decreased from 2.19 kg. for beets with less than 9 per cent of dry matter to 0.66 kg. for those with over 13 per cent. In 1912 and 1913 the weights were highest, 2.12 and 1.96 kg., respectively, for beets with from 10 to 11 per cent of dry matter, and showed other irregularities.

Dorsiventral structure of the cane stem, C. E. B. BREMEKAMP (*Meded. Proefstat. Java-Suikerindus.*, 4 (1914), No. 18, pp. 309-313, fig. 1; *Arch. Suikerindus. Nederland, Indië*, 22 (1914), No. 2, pp. 41-45, fig. 1).—Notes regarding the manner in which the leaves overlap are given.

Buying cane by test; some suggestions, C. J. BOURBAKIS (*La. Planter*, 52 (1914), No. 4, p. 57).—This article offers suggestions on the advantages of buying sugar cane at the mill on valuation shown by tests of juice. It is pointed out that the advantages to the producer would be a stimulus to improve the sugar content of the cane by fertilization and cultivation rather than merely the weight of foliage.

Green manures for tobacco, D. VIGIANI (*Coltivatore*, 59 (1913), No. 34, pp. 502-504).—Results of green manuring for tobacco in the Arezzo Province, Italy, show the weight of 1,000 cured plants following beans to have been 138.88 kg., following mustard 94.44, following lupines 100, following turnips 98.23, following goat's rue 70.57, and following manure 90.9 kg.

A new method with the tobacco crop, A. ROMÁN (*Bol. Ofic. Sec. Agr. Cuba*, 16 (1914), No. 1, pp. 1-4, fig. 1).—Successful attempts at planting tobacco seed directly in the field to avoid transplanting are noted.

The progressive development of the wheat kernel, R. W. THATCHER (*Jour. Amer. Soc. Agron.*, 5 (1913), No. 4, pp. 203-213, figs. 2).—A report of progress, mostly dealing with methods.

The results, presented in tables, show a fairly regular decrease of mineral matter, ether extract, and fiber as the kernels develop. The percentage of protein decreased during the earlier periods of growth and later increased again.

From actual weights in milligrams of material per kernel of Turkey and Blue Stem wheats at successive stages of development it is shown that regardless of variations in the percentage produced by variations in the relative rate of gains of the several constituents, there is a steady gain in the actual amount of each of those materials in the kernel throughout the period of kernel formation. The relative increase was greatest in the quantity of carbohydrate materials.

"It became a matter of interest, then, to determine whether the statement by Brenchley and Hall that the plant 'continually moves into the grain uniform material . . . possessing always the same ratio of nitrogenous to nonnitrogenous materials and ash' is substantiated by our results. We, therefore, calculated the amount of actual gain in material of the average kernel per day. These data are surprising. On this account, we prefer to regard them as a progress report, subject to later confirmation or modification of the conclusions to be drawn from them. It appears to be quite clear that the composition of the kernel when it is first formed, called by Brenchley and Hall the 'mould,' is more highly nitrogenous than the material which is moved into it, at least during the earlier stages of the filtering-in of the endosperm. But the ratio of carbohydrates to protein in the material gained by the kernels in the later periods of endosperm-filling seems to be lower than at earlier periods, just the reverse of our former ideas based upon general conceptions of plant physiological processes and the quantitative work of Deherain and Dupont. . . ."

"It appears from the progress of our work thus far, that the real facts with reference to the conflicting opinions mentioned above are probably as follows: Pericarp material, which in the first stages of development constitutes a comparatively large proportion of the kernel, is probably relatively richer in protein than is endosperm material. Hence, any condition which results in increased proportion of endosperm in the kernel is likely to produce low-protein grain."

Influence of external conditions on heredity, C. FRUWIETH (*Ztschr. Pflanzenzücht.*, 2 (1914), No. 1, pp. 51-63).—As a result of 3-year trials with winter and spring varieties of wheat, no direct influence due to planting the varieties out of their respective seasons could be detected as inherited. A slight modification in flavor and ripening time was observed, due, the author believes, to an indirect influence of resulting variations in nourishment.

Comparison of spikes in a mutation variety of wheat, N. PASSERINI (*Bol. Ist. Agr. Scandicci*, 2, ser., 7 (1913), No. 4, pp. 303-305, fig. 1).—Two forms of spikes are noted and described, one bearded and the other smooth.

Production of new varieties [of wheat] by crossing, N. PASSERINI (*Bol. Ist. Agr. Scandicci*, 2, ser., 7 (1913), No. 4, pp. 330-348, pls. 4).—This article gives methods employed and some results in wheat breeding at Scandicci since 1888.

Some new or little-known oil seeds and oils (*Bul. Imp. Inst. [So. Kensington]*, 11 (1913), No. 4, pp. 559-574).—The following are some seeds mentioned as coming from the British tropical dependencies and being exploited for their oil content: *Carthamus tinctorius*, which yielded 29.6 per cent of oil; *Amoora rohituka*, 43.5; *Eruca sativa*, 30.8; *Calophyllum inophyllum*, 71.4; *Mesua ferrea*, 49; *Telfairia pedata*, 62.9; *Bassia latifolia*, from 45 to 55 per cent; and *Acrocomia sclerocarpa* (grugru nuts and kernels) from Grenada 56.2 and from Trinidad 57 per cent of oil. Other seeds mentioned as containing oil of com-

mercial value are *Bassia longifolia*, *B. butyracea*, *B. mottleyana*, and *Pentadesma butyracea*.

On the variations in weight of stored seeds, A. MORETTINI (*Staz. Sper. Agr. Ital.*, 46 (1913), No. 7-8, pp. 499-524, pls. 2).—The author reports the results of studies on the weight of grain as affected by insects, rats, birds, respiration, oxidation, and hygroscopic moisture.

It is noted that the weight of wheat with less than 10 per cent of moisture at the time it is placed in storage may oscillate from 18 to 25 per cent during the autumn and spring, but that if it contains from 11 to 12.5 per cent of moisture there will be little variation and if it contains over 12.5 per cent of moisture it will decrease in weight toward spring. With beans it is noted that the increase in weight varied as much as 35 per cent. Lupines showed some increase in hygroscopic power, while corn on the ear varied about 10 per cent. The variations, it is observed, fluctuated according to climate and time of storage, but these results applied in the district of Umbria.

Oxalis on tea estates (*Planters' Chron.*, 9 (1914), No. 1, p. 4).—This notes the appearance of *Oxalis violacea* as a troublesome weed in some parts of Nilgiri Hills, British India.

A cover crop as a factor in restricting certain weed seeds, ZADE (*Fühling's Landw. Ztg.*, 62 (1913), No. 22, pp. 777-785).—This is a discussion of the influence of shading and crowding by oats, barley, wheat, peas, vetch, turnips, and mustard on the germination and growth of weeds, and gives results of experiments in which small plats of rye and wheat were seeded with 500 seeds each of wild mustard and wild oats.

Results in the spring showed that in a thick stand of rye 0.8 per cent of wild oats had germinated, but no mustard. In a thin stand of rye the corresponding percentages were 15 and 17.9, in a thick stand of wheat 6.6 and 10, in a thin stand of wheat 39.8 and 40.6, and on fallow land 48 and 42.8 per cent.

HORTICULTURE.

Colonial plants, H. JUELLE (*Les Cultures Coloniales. Paris, 2. rev. ed.: Plantes à Féculé et Céréales, vol. 1, 1912, pp. 108, figs. 35; Légumes et Fruits, vol. 2, 1913, pp. 122, figs. 33; Plantes à Sucre, Café, Cacao, Thé, Maté, vol. 3, 1913, pp. 127, figs. 42; Plantes à Condiments et Plantes Médicinales, vol. 4, 1914, pp. 120, figs. 30*).—The earlier two-volume edition of this work (E. S. R., 13, p. 1043), which deals with the culture, preparation, and utilization of tropical and subtropical plants, has been revised and redivided into 8 parts. Of those here noted, part 1 deals with starch plants and cereals, 2 with vegetables and fruits, 3 with sugar plants, coffee, cacao, tea, and maté, and 4 with condimental and medicinal plants.

Names of the field and market garden crops and of the principal fruit and timber trees of the United Provinces of Agra and Oudh (*Dept. Land Rec. and Agr. United Prov. Agra and Oudh, Agr. Ser., Bul. 30 (1913), pp. 95*).—This comprises a list of synonyms of the field and market garden crops and of the principal fruit and timber trees of the United Provinces of Agra and Oudh. The vernacular names have been classified under six different divisions, with regard to the different dialects prevalent in them.

Recent observations on the value of carbon dioxide in organic fertilizers, E. REINAU and R. KLEIN (*Gartenwelt*, 18 (1914), No. 16, pp. 214-218).—The authors review the literature dealing with the assimilation of carbonic acid from organic manures and from the air and present data secured in some tests conducted in a commercial sized greenhouse.

The following plants were grown in two compartments, containing 40 cubic meters of space (1,412.6 cu. ft.) each: *Aspidistra*, *philodendron*, *nephrolepis*,

pteris, and begonia. One compartment was treated with 150 liters (39.6 gals.) of pure carbon dioxid twice a day at 7 a. m. and at 12 m. The other compartment was used as a check. Observations taken at the end of a 4- and a 7-week period showed an increased growth from carbon dioxid assimilation ranging from 24 to 152 per cent. The leaves were a much fresher green and the colorings of the begonia leaves were more intense. From a commercial standpoint the increased production from two kinds of plants paid for the cost of the carbon dioxid.

A test was made relative to the rapidity of assimilation. The amount of carbon dioxid in the greenhouse was reduced from 5.2 per cent to about 2 per cent in 30 minutes time, and to about 0.26 per cent in 80 minutes. The plants were removed from the house and the test repeated, but in this case the carbon dioxid content was reduced only from 2.33 to 1.43 per cent in 55 minutes. Shading the greenhouse appears to have no material effect on the rapidity of assimilation.

The authors are of the opinion that these experiments indicate that the carbon dioxid content of organic manures is of considerable importance as a fertilizer ingredient.

The home vegetable garden, A. KRUHM (*New York and London, 1914*, pp. IV+105, pls. 23).—In part 1 of this popular treatise the author discusses the general principles of gardening. In part two specific directions are given for growing various vegetables, together with suggestions relative to improved varieties.

A radish-cabbage hybrid, F. GRAVATT (*Jour. Heredity, 5 (1914), No. 6*, pp. 269-272, figs. 2).—The author here describes a cross between two genera which shows extraordinary vigor but absolute sterility.

Strain tests of tomatoes, C. E. MYERS (*Pennsylvania Sta. Bul. 129 (1914)*, pp. 139-150).—In the present bulletin the author gives a brief summary of a test of a large number of strains of six varieties of tomatoes, conducted from 1908-1911 inclusive. Data secured for the various strains are reported in tabular form and discussed.

The principal fact brought out by these tests is that variations in yield of more than 13 tons per acre of marketable fruit occurred between different strains of the same variety. In some cases considerable variations in earliness of the strains were also observed. The author concludes that these variations may be attributed to hereditary rather than environmental conditions. It is suggested that, whenever practicable, seed should be given a preliminary cultural test a year in advance of the time when it will be needed for general planting.

Garden notes on new trees and shrubs, W. J. BEAN (*Roy. Bot. Gard. Kew, Bul. Misc. Inform., No. 2 (1914)*, pp. 49-54, pls. 3).—A descriptive account is given of a number of new trees and shrubs that have been under observation in the Kew Gardens. Among these plants are a gooseberry-black currant hybrid, two horse chestnuts, a Japanese cherry, and several Chinese shrubs.

The improvement of tree fruits, E. B. BABCOCK (*Univ. Cal. Jour. Agr., 1 (1913), No. 5*, pp. 11-14; 1 (1914), Nos. 6, pp. 14-19, figs. 2; 7, pp. 17-24, figs. 5; 9, pp. 3-8, figs. 2).—The author discusses the various applications of selection in plant production and reviews recent investigations in the improvement of different tree fruits by selection and breeding. Special attention is given to the question of improvement through bud selection.

Apple growing in Delaware (*Bul. Bd. Agr. Del., 3 (1913), No. 2*, pp. 15).—A popular bulletin containing the 1910 census statistics of apple production for the United States, information relative to varieties adapted for Delaware, and brief cultural directions.

Origin of the banana, P. B. POPENOE (*Jour. Heredity*, 5 (1914), No. 6, pp. 273-280, figs. 2).—A popular review of the literature of the subject, including reference to vagaries of pollination and irregularities in the behavior of the banana under cultivation.

Relation of bacterial transformations of soil nitrogen to nutrition of citrus plants, K. F. KELLERMAN and R. C. WRIGHT (*U. S. Dept. Agr., Jour. Agr. Research*, 2 (1914), No. 2, pp. 101-113, figs. 7).—The present paper comprises a contribution to the knowledge of decadence in citrus trees, with special reference to citrus malnutrition, chlorosis, or mottle leaf.

An examination of the soluble-salt content of soil samples taken throughout southern California confirmed the results of other investigators in showing a wide variation in the percentage of carbonates, chlorids, nitrates, and sulphates. Diagrams are given showing the relative nitrogen-fixing power, nitrifying power, and salt content of soil samples taken from good and poor areas in a productive orange grove and in unproductive and chlorotic orange groves. These data indicate that when adjacent areas are compared the soils from the vicinity of deteriorating trees are richer in nitrate nitrogen. The quantities of other salts show no constant relationship to good or poor areas. The nitrate content of poor areas was not excessive except during irrigation, at which time the shallow lateral roots are exposed to a solution which is temporarily stronger than during the intermediate periods. Extensive greenhouse experiments with grapefruit and sour-orange seedlings growing in greenhouse soil and in California soil at Washington, D. C., here described, indicate that nitrate nitrogen in excess produces the typical symptoms of malnutrition. These results are corroborated by reports that in some cases applications of fertilizers high in nitrogen to orange groves showing symptoms of malnutrition have accelerated instead of retarded the deterioration.

The experiments indicate that nitrates are more toxic than chlorids, that nitrates and chlorids together intensify the symptoms of injury, and that moderate quantities of lime—less than 10 per cent of calcium carbonate—exert a more or less pronounced protective action. The range of toxic limits for nitrates in the pot experiments is given as between 0.05 and 0.01 per cent as compared with 0.005 to 0.015 per cent in the field, exclusive of crusts.

Although records are available which show at least temporary benefit from the application of nitrate fertilizers to chlorotic orange groves, it would appear that this benefit may be due to the previously excessive depletion of nitrate nitrogen through the denitrifying action of substances such as mature straw turned under to maintain the humus. The authors' greenhouse experiments show that seedling citrus plants were actually forced by the addition of cellulose and of straw into an apparently typical state of malnutrition through nitrogen starvation caused by the unbalancing of the soil flora and the utilization of all of the nitrate by the organisms which decompose straw and cellulose. Green manures, on the other hand, while causing some actual loss of total nitrogen do not materially disturb the ratios of the nitrogenous compounds.

The evidence tends to show that the total nitrogen content of the soil is of less importance than the control of the rate of nitrification. In pot experiments a normal rate of nitrification was secured with a green crop turned under, hence this practice is recommended for maintaining the humus supply of the soil. The experiments indicate that the extensive use of mature straw is to be avoided, though light applications of straw to fields too high in nitrate, probably also with the liberal use of ground limestone, might be advantageous.

A bibliography of cited literature is appended.

Eremocitrus, a new genus of hardy, drought-resistant citrus fruits from Australia, W. T. SWINGLE (*U. S. Dept. Agr., Jour. Agr. Research*, 2 (1914),

No. 2, pp. 85-100, pl. 1, figs. 7).—An examination of the material of the Australian desert kumquat preserved in the herbaria of Europe and America and a study of living plants now growing in the greenhouses of this Department lead the author to conclude that this plant is out of place in the genus *Atalantia*, being much more closely related to *Citrus*. The author here proposes the name *Eremocitrus* for this genus, which, as far as known, includes only one species, *E. glauca*.

This species is described with reference to its distribution, hardiness, drought resistance, uses, and value for breeding purposes. Attention is also called to the general need for taxonomic study of the wild relatives of cultivated plants. A review of the literature cited is given.

The Australian desert kumquat can be readily grafted or budded on all of the commonly cultivated species of *Citrus* and the various species of *Citrus* graft easily on this plant. It is also believed that the desert kumquat will hybridize with different species of *Citrus*. Hence its value for breeding new types of hardy citrus fruits is suggested.

Babylonian dates for California, P. B. POPEHOE (*Pomona Col. Jour. Econ. Bot.*, 3 (1913), No. 2, pp. 459-477).—This comprises a descriptive list of the varieties of dates grown in Babylonia. The list is prepared both with reference to the utilization of these varieties in California and also as a guide to future visitors to Babylonia. The author considers this region as the most promising from which to draw a large supply of high-grade offshoots for the United States.

Statistics on the production of grapes and olives in 1913 (*Estadística de las Producciones Vitícola y Olivarera en el Año 1913*. Madrid: Govt., 1914, pp. 8).—This is the usual statistical review relative to the production of grapes, wine, olives, and olive oil in the various regions and Provinces of Spain (E. S. R., 29, p. 439).

Study of the influence of various grape stocks on the quality and quantity of the harvest, H. FAES and F. PORCHET (*Étude de l'Influence de Divers Porte-Greffes sur la Qualité et Quantité de Récolte*. Lausanne, 1914, pp. 46, figs. 29).—An account of this work has been noted from another source (E. S. R., 30, p. 43).

The direct bearers, G. VERGE (*Prog. Agr. et Vit.*, (Ed. l'Est-Centre), 34 (1913), No. 50, pp. 757-759; 35 (1914), Nos. 1, pp. 15-27, figs. 2; 2, pp. 48-53; 3, pp. 84-89; 5, pp. 153-156; 6, pp. 175-180, fig. 1; 7, pp. 215-218, fig. 1; 8, pp. 247-251; 9, pp. 268-275, figs. 2; 10, pp. 307-309; 11, pp. 340-347, figs. 2; 12, pp. 359-365, fig. 1; 13, pp. 408-412, fig. 1; 14, pp. 440-443; 15, pp. 468-474; fig. 1; 17, pp. 520-527, figs. 2; 18, pp. 563-567).—The author here summarizes observations made during the past 15 years on direct-producing hybrid grapes growing in the Montpellier experimental vineyard.

Summing up his observations as a whole, the author concludes that there is a considerable choice of direct-bearing hybrid grapes to meet for the most part conditions of climate, production, etc., but in order to secure longevity all of these hybrids should be grafted.

Forcing strawberries with ether and with warm water, G. BULTEL (*Jardin*, 28 (1914), No. 652, pp. 120, 121, fig. 1).—In continuation of previous investigations (E. S. R., 27, p. 145) the author made in 1912 a comparative test of ether vapor and the warm water bath (E. S. R., 23, p. 40) for forcing strawberries. Both processes were satisfactory in producing early fruit. The test was repeated in 1913 with similar results; hence both processes are recommended for the production of early strawberries.

Some of the more important varieties of almonds grown at Andria, L. VIVARELLI (*Coltivatore*, 60 (1914), No. 14, pp. 431-434, figs. 3).—A brief descrip-

tive account of a number of varieties of almonds grown in the vicinity of Andria, Italy.

All about coconuts, R. BELFORT and A. J. HOYER (*London, 1914, pp. XII+201, pls. 26*).—A treatise on coconut culture in which consideration is given to the selection of a plantation site, nursery and plantation practices, the control of coconut diseases and pests, the coir fibre industry, the preparation of copra, the coconut oil, desiccated coconut, and nut butter industries, marketing coconuts and copra, the cost of a coconut estate, the activities of various countries in relation to the coconut industry, and coconuts as an investment.

Native and exotic plants of Dade County, Florida, C. T. SIMPSON (*Washington, D. C. [1913], pp. 46, figs. 12; Proc. Fla. State Hort. Soc., 25 (1912), pp. 166-207*).—In this paper the author gives a descriptive account of the more prominent ornamental trees, shrubs, and plants, both native and exotic, that seem to be especially adapted to the soil and conditions of Dade County, Florida.

History of gardening, MARIE L. GOTHEIN (*Geschichte der Gartenkunst. Jena, 1914, vols. 1, pp. VII+446, pls. 2, figs. 309; 2, pp. 506, pl. 1, figs. 325*).—This two-volume work comprises a history of gardening and garden design.

In volume 1 consideration is given to the gardens of Egypt, western Asia, Greece, the Roman Empire, Byzantium, and Mohammedan countries, and of the middle-age Occident, Italy, Spain, and Portugal during the Renaissance. Volume 2 deals with the gardens of France, England, Germany, and Holland during the Renaissance, gardens during the reign of Louis XIV, the spreading of French gardens in Europe, the gardens of China and Japan, the English landscape garden, and the trend of garden design in the nineteenth century up to the present time. The text is fully illustrated and bibliographies of cited literature are appended.

The horticultural record, R. CORY (*London, 1914, pp. XV+500, pls. 164*).—This volume consists of colored and half-tone reproductions of the most interesting and valuable flowers, plants, shrubs, groups, and rock gardens exhibited at the Royal International Horticultural Exhibition in 1912, accompanied by contributions on the progress of horticulture since the first great International Horticultural Exhibition of 1866. These contributions deal with rock gardens and garden design, the rose, trees and shrubs, sweet peas, tropical garden plants, orchids, greenhouse plants, carnations and pinks, British and foreign ferns, fruit, and vegetables.

Information is also given relative to the arrangements, rules and regulations, awards, etc., for the 1912 exhibition, together with reports on horticultural education and legislation in connection with plant diseases.

International Congress of Horticulture at Ghent (*Cong. Internat. Hort. Gand, Raps. Prélim., 1 (1913), pp. 15+273, figs. 2*).—This comprises abstracts and papers by various reporters dealing with different phases of the following subjects: Floriculture, market gardening, horticultural investigations and education, commerce, transportation, tariffs, and landscape gardening.

FORESTRY.

The Bradley bibliography.—IV, Forestry, A. REHDER (*Cambridge, Mass., 1914, vol. 4, pp. XIII+589*).—The present volume of the Bradley Bibliography (E. S. R., 27, p. 846) aims to contain the titles of all publications relating to forestry and silviculture, including the more important articles published in periodicals and other serials. Volume 3 of this work has not thus far appeared.

Report of the forest branch of the Department of Lands for the year ending December 31, 1913, H. R. MACMILLAN (*Brit. Columbia Rpt. Forest*

Branch Dept. Lands, 1913, pp. 61, pls. 17, figs. 4).—This comprises the report of the chief forester of the Department of Lands of British Columbia for the year ended December 31, 1913. The report deals with the organization of the forest service, forest revenues, importance of the lumber industry, logging inspection, scaling, timber sales, railway permits, products, forest insect damage, exports, land examination, forest reconnaissance, forest reserves, grazing, forest protection, and improvements.

A preliminary forest map of British Columbia is given.

Annual progress report of forest administration in the Western, Eastern, and Kumaun Circles of the United Provinces for the forest year 1912-13, H. B. BILLSON, P. H. CLUTTERBUCK, and F. F. R. CHANNER (*Ann. Rpt. Forest Admin. West., East., and Kumaun Circles [India], 1912-13, pp. 21+19+13+LX+5*).—This is the customary review relative to the administration and management of the state forests in the Western, Eastern, and Kumaun Circles of the United Provinces, including financial statements for the forest year 1912-13. All the important data relative to alterations in forest areas, surveys, working plans, forest protection, silvicultural operations, revenues, expenditures, etc., are appended in tabular form.

Annual progress report of the forest administration in Ajmer-Merwara for the year 1911-12, HUKAM CHAND (*Ann. Rpt. Forest Admin. Ajmer-Merwara, 1911-12, pp. 3+26*).—A report similar to the above relative to the administration and management of the state forests of Ajmer-Merwara for 1911-12.

Progress report on forest administration in the Province of Assam for the year 1912-13, R. M. WILLIAMSON and W. F. PERREE (*Rpt. Forest Admin. Assam, 1912-13, pp. 2+34+53+3, pl. 1*).—A report similar to the above relative to the administration and management of the state forests in the Eastern and Western Circles of Assam for the year 1912-13.

Progress report of forest administration in Coorg for 1912-13, H. TIREMAN (*Rpt. Forest Admin. Coorg, 1912-13, pp. 3+11+13*).—A report similar to the above relative to the administration of the state forests in Coorg for the year 1912-13.

Conservation of the forest (*Rpt. Conserv. Com. La., Sept., 1912-Apr., 1914, pp. 33-45, figs. 3*).—A brief summary of forest conditions in Louisiana, including recommendations for their conservation, based upon a survey made by the Forest Service of the U. S. Department of Agriculture (E. S. R., 28, p. 146).

The text is also given of a timber conservation contract entered into between a large lumber company and the Conservation Commission of Louisiana.

On afforestation and the planting of fruit trees in the dry lands of Chile, S. IZQUIERDO (*Jour. Roy. Hort. Soc. [London], 39 (1914), No. 3, pp. 581-589, pls. 4*).—A brief account of methods of planting forest and fruit trees in the dry lands of Chile.

Forest fires, W. G. HOWARD (*N. Y. Conserv. Com. Bul. 10 (1914), pp. 52, pls. 8, figs. 2*).—In this bulletin the author reviews the most serious forest fires in the past; discusses the nature and causes of forest fires, protective and preventive measures, fire fighting, and progress in legislation; and describes the present fire protective system maintained by the state conservation department, including cooperative assistance under the Weeks law (E. S. R., 24, p. 498).

Some Irish larch plantations, J. H. WADDINGHAM (*Jour. Bd. Agr. [London], 21 (1914), No. 2, pp. 116-123, pls. 2*).—The statistics here presented were collected with the object of determining the volume of timber produced by larch at different ages and the effect of density on the volume. Sample plats of

woods of different ages and density were carefully laid out and accurately measured.

Increase in the flow of latex from *Manihot glaziovii* as a result of peeling off and scraping the outer layers of the bark, A. ZIMMERMANN (*Pflanzer*, 10 (1914), No. 4, pp. 180-188).—Data are given on tapping experiments conducted by Fickenedy at the Kamerun experiment station and by the author and Lommel at the Amani station in German East Africa.

The results of these experiments led to the conclusion that the flow of latex can be increased by either peeling or scraping the outer bark. Scraping the bark gives a much greater yield than that secured by peeling the bark off entirely. It is also less costly in practice and is less apt to injure the trees. The employment of this method, especially on old and much tapped trees, appears to be advisable.

Report on an inspection tour of the rubber industry in Ceylon, the Straits Settlements, and Deli, P. ARENS (*Meded. Proefstat. Malang*, No. 8 (1914), pp. 83, pls. 7).—This embraces the results of a survey of the rubber industry in Ceylon, the Straits Settlements, and Deli, which was conducted with the view of securing information of value for the development of the industry in Java. The information secured deals with various planting operations, cultural practices, tapping operations, preparation, grading, and packing of crude rubber, etc.

Creosoted piling in Galveston Bay bridge, F. B. RIDGWAY (*Engin. News*, 71 (1914), No. 22, pp. 1176-1182, figs. 12).—Data secured from an examination of bridge piling, the first lot of which was set in 1875 and removed in 1913, are here reported.

The results of the examination of these piles show that the 38-year-old piles which received a very light treatment of creosote are mostly destroyed. Over 90 per cent of about 3,000 18-year-old piles which were given a heavy treatment of creosote are still in good condition.

A fence post test progress report, F. G. KRAUSS (*Hawaii. Forester and Agr.*, 11 (1914), No. 4, pp. 87, 88).—The results for the third season's test of eucalyptus fence posts (E. S. R., 29, p. 443) show the creosoted posts to be in the best state of preservation, the tarred posts being the second best preserved. The posts set in concrete are showing rapid disintegration.

DISEASES OF PLANTS.

The diseases of tropical plants, M. T. COOK (*London*, 1913, pp. XI+317, pl. 1, figs. 85).—This book, by the plant pathologist of the New Jersey College Station, is primarily intended for the planter, but it will doubtless prove of service to the student of tropical economic botany as well, as the author has brought together a large amount of data scattered through many publications.

After introductory chapters on the nature and symptoms of plant diseases, the classification of fungi, and a description of other causes of plant diseases, the diseases of many of the tropical economic plants are described at considerable length, the arrangement being according to the host plants. The subjects of prevention and control and fungicides and spraying apparatus are treated in separate chapters, although under many of the descriptions of diseases specific recommendations are given for combating them.

The author recognizes the limitations under which this work was prepared, and he invites correspondence and suggestions from plant pathologists of the tropical world.

Outline of administration in controlling insects and fungi injurious to agricultural plants in Japan (*Tokyo: Bur. Agr., Dept. Agr. and Com., 1913*,

pp. 32, fig. 1).—This pamphlet deals with methods of administration in controlling diseases and insect pests of agricultural plants, entomological and pathological arrangements at agricultural experiment stations, measures for controlling diseases and insect pests of agricultural plants adopted by public communities, and education and practice upon insect pests and plant diseases.

Report of the mycological section, C. J. J. VAN HALL (*Jaarb. Dept. Landb., Nijv. en Handel Nederland. Indië, 1911, pp. 37-39*).—The author briefly reports on some of the investigations in progress in the mycological laboratory, the principal studies being on the canker of cacao, downy mildew of maize, root rot of Hevea (probably due to *Fomes semitostus*), and the rot of cacao caused by *Phytophthora faberi*.

From diseased cacao trees three forms of *Fusarium* have been isolated, and studies are reported in progress with these organisms to determine their relations with the canker disease. The *Peronospora* disease of maize is said to be due to *P. maydis*.

The genus *Atichia*, A. D. COTTON (*Roy. Bot. Gard. Kew, Bul. Misc. Inform., No. 2 (1914), pp. 54-63, fig. 1*).—The author describes *A. dominicana* n. sp., an aberrant species of Ascomycetes found on lime leaves in the West Indies. The genus to which this fungus belongs was formerly grouped with the Collemaceæ, but it is now placed in the family Atichiaceæ. A conspectus of the eight known species of the family is given.

Studies on Nectriaceæ, I, J. WEESE (*Ztschr. Gärungsphysiol., 1 (1912), No. 2, pp. 126-155, figs. 4*).—Claiming that the fungus described as *Nectria rubi* n. sp., by Osterwalder (*E. S. R., 26, p. 450*), is not a new species, but a variety of *N. mammoidea*, and discussing further *N. galligena* on fruit and other trees (*E. S. R., 26, p. 448*), the author describes as new species several fungi which are named, respectively, *N. pseudogrammicola* (on leaves of *Calamagrostis arundinacea*), *N. flammeola* (on *Populus canadensis*), *N. incrustans* (on *Betula* and *Alnus*), also as new varieties *N. inundata minor* and *N. cinnabarina veneta*. The systematic position of *N. platyspora* is also critically discussed.

Remarks concerning Weese's studies on Nectriaceæ, A. OSTERWALDER (*Ztschr. Gärungsphysiol., 3 (1913), No. 2, pp. 212, 213*).—A brief discussion is given of the article noted above.

A reply to Osterwalder's remarks concerning studies on Nectriaceæ, J. WEESE (*Ztschr. Gärungsphysiol., 3 (1913), No. 2, pp. 214-223*).—This is a further discussion of the author's previous publication (see above).

A review of the genus *Phytophthora*, G. W. WILSON (*Mycologia, 6 (1914), No. 2, pp. 54-83, pl. 1*).—This is mainly a historical review, with bibliography, of work recently published on the genus *Phytophthora*, containing descriptions and discussion of 13 species as established and of 3 considered as yet of doubtful classification.

Corrosive sublimate and sublimoform for rust and *Fusarium* on grains (*Prakt. Bl. Pflanzenbau u. Schutz, n. ser., 12 (1914), No. 2, pp. 16-19*).—Results of treating seed grain with sublimoform or with corrosive sublimate were not quite uniform with those of the previous year. The use of these two fungicides jointly is suggested.

Causes of mycelium formation in *Ustilago jensenii*, E. HILS (*Ursachen der Mycelbildung bei Ustilago jensenii. Diss., Tübingen, 1912, pp. 42, figs. 10; rev. in Mycol. Centbl., 3 (1914), No. 7, pp. 338, 339*).—Summarizing conclusions drawn from this study, the author claims it to be highly probable that the formation of mycelium in barley by *U. jensenii* is favored by an excess of oxygen in the interior of the host plant as well as by the presence of alkaline products of metabolic changes in the fungus itself.

"Grey leaf" or "dry leaf" on oats (*Edinb. and East of Scot. Col. Agr. Rpt. 30 (1913), pp. 22, 23; abs. in Jour. Bd. Agr. [London], 20 (1914), No. 11, p. 1010*).—This disease, noted recently as attacking certain varieties of oats named, is said to cause early decoloration, without yellowing, however, of the leaves along the margins and near the bases, these effects spreading upward with the growth of the plant. The upper leaves may show a healthy color or else red stripes. Heads are absent, or late and small, grains being few or poorly developed. Some varieties, as Polish White, show only slight attack. While the disease is regarded as due to some condition not yet fully understood, it is thought to be favored by fertilizers which produce an alkaline soil, as sodium nitrate and basic slag, and to be lessened by such fertilizers as ammonium sulphate and superphosphate. Manganese sulphate is also credited with a beneficial influence.

Leaf cut, or tomosis, a disorder of cotton seedlings (*Agr. News [Barbados], 13 (1914), No. 312, pp. 126, 127*).—The occurrence in St. Croix is reported of a serious infection of cotton closely resembling that which has been previously described by Cook as occurring in the United States (E. S. R., 29, p. 47).

Tikka disease and the introduction of exotic groundnuts in the Bombay Presidency, E. J. BUTLER (*Agr. Jour. India, 9 (1914), No. 1, pp. 59-70, figs. 4*).—Reviewing briefly circumstances connected with the decline in yield of the peanut ascribed to *Septoglæum arachidis* in the period from 1895 to 1902 in parts of India and the progress toward recovery since 1903, the author discusses the apparent influence of the introduction of foreign and the possible development of resistant native varieties, suggesting, however, that probably not all the factors involved have as yet received full recognition.

Potato scab and potato canker, G. KÖCK (*Ztschr. Landw. Versuchsw. Österr., 16 (1913), No. 10, pp. 1005-1008, figs. 2*).—Noting from specimens sent to the station as supposed cases of potato canker, the existence of an apparent confusion of this disease due to *Chrysophlyctis endobiotica* with scab ascribed to *Oospora scabies*, *Spongospora solani*, etc., the author gives illustrated descriptions of each disease in typical form.

Powdery scab of potatoes, W. J. MORSE (*Maine Sta. Bul. 227 (1914), pp. 89-104, pls. 4*).—An account is given of the history and distribution of the powdery scab of potatoes due to *Spongospora subterranea*, the occurrence of which in the United States has been previously noted (E. S. R., 29, p. 448). While the fungus has not been present in this country long enough to secure exact data regarding its behavior, the author describes its principal characteristics, and some diseases for which it may be mistaken, discusses its economic importance, and gives suggestions relative to means to be employed for the prevention of its spread, the information being largely drawn from the work of Pethybridge (E. S. R., 29, pp. 448, 549) and Güssow (E. S. R., 29, p. 448).

[Orders regarding plant diseases] (*Jour. Bd. Agr. [London], 20 (1914), No. 11, pp. 1020-1024*).—This article covers substantially the same ground as that previously noted on wart disease of potatoes (E. S. R., 31, p. 149).

Yellowing of sugar beets, A. MALAQUIN and A. MOITIÉ (*Engrais, 29 (1914), No. 9, pp. 241-243*).—Giving a brief discussion of the history, characters, and effects of beet yellowing, the authors state that the disease may be spread by the mother beets, by seed, and by débris left in the soil. To recommendations as given by Delacroix (E. S. R., 16, p. 479) in connection with his description of the alleged cause, *Bacillus tabificans*, are added their own suggestions, namely, drying the seed at from 40 to 55° C. to a water content of from 5 to 7 per cent, also rigorous selection of roots to be used for production of seed.

The past history and present position of the bitter pit question, D. MCALPINE (*Prog. Rpt. Bitter Pit Invest. [Australia], 1 (1911-12), pp. 197, pls. 34; abs. in Bot. Centbl., 122 (1913), No. 18, p. 431*).—This is the full report (E. S. R., 29, p. 246) of these investigations to date.

It is stated that the delicate skeleton of vessels which remains, preserving a model of the fruit after the softening and removal of the flesh, normally functions in the distribution and regulation of the food supply to the periphery of the fruit, where the most rapid growth takes place. Bitter pit is said to be an internal disease found in association with discoloration of the vascular bundles and probably not due to an organism. The brown spots are generally first found in the subcutaneous zone occupied by the vascular network. Bitter pit may be noted when the fruit is about the size of a walnut, but most generally after it is half grown, and it most commonly occurs in the upper half, where the openings in the skin are more numerous and water is less abundant owing to evaporation.

This injury appears to stand in relation with intermittent weather conditions at a critical period of growth; the amount and rapidity of transpiration and sudden checking thereof at night while the roots are still active owing to heat in the soil; a failure of supplies at the periphery of the fruit, followed by spasmodic and irregular recovery; an inequality of growth resulting in irregular formation of the vascular network controlling the distribution of nutritive material; fluctuations of temperature in stored fruit; and the specific nature of the variety in question. The relation of each of these factors to the development of bitter pit is under investigation.

It is stated that pitting may be noted in case of fruit on young, rapidly growing trees, as also in the case of light crops with abnormally large fruit. The quince is less liable to pitting than is either the apple or pear. In stored fruit the safest temperature is that at which respiration is practically suspended, that is, 30 to 32° F. The delicate structure of the apple and its supply of vessels show the necessity of careful handling and skilled packing for transportation.

An extensive bibliography is appended.

The diseases of the banana, J. E. VAN DER LAAT (*Las Enfermedades del Banano. San Jose, Costa Rica: Dept. Agr., 1914, pp. 19, figs. 3*).—Some diseases of bananas in Costa Rica are described, particular attention being given to that known as the Panama disease.

Two species of *Fusarium* are said to attack bananas, one of which is the cause of the so-called Panama disease. The difference in susceptibility of varieties of bananas to this disease is pointed out and the author suggests more rational methods of cultivation as factors in its control. The disease is said to be favored by an unbalanced condition of the nitrogen in the soil, a lack of soluble potash, and the accumulation of excretions from the banana plant.

Report on some of the diseases of citrus fruits, C. ROSS (*Queensland Agr. Jour., n. ser., 1 (1914), No. 1, pp. 48-54; noted in No. 2, p. 107*).—Reporting on a tour of investigation on diseases and pests affecting citrus fruits, the author states that collar rot (*Fusarium limonis*), was found in two places. The common rough lemon, now abundant in a wild state and practically immune to this disease, is recommended for use as a stock. In addition to thorough cultivation, judicious manuring, good drainage, and close planting as preventive measures, cutting and burning affected parts, aseptic treatment, etc., are insisted upon.

Root rot (*Phoma omnivora*) is reported at one locality and is distinguished from somewhat similar fungi. Lemon bark blotch (*Ascochyta corticola*) was observed in one instance. Scabbing of fruit and leaves was abundant and highly injurious in some places named. Anthracnose (*P. citricarpa*) was

not very prevalent and was not here associated with melanose, which was elsewhere noted in one instance. The latter disease was sometimes associated with Maori on fruit, weak lime-sulphur wash being recommended in such cases. Some other troubles of fungus or insect origin are discussed, and numerous fungicidal formulas or other treatments are given.

The pathological significance of the endocellular fibers in the tissues of grapevines, L. PETRI (*Atti R. Acad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat.*, 5. ser., 22 (1913), II, No. 4, pp. 174-179, fig. 1).—Referring to the contribution of Mameli (E. S. R., 29, p. 551), the author states that the formation of endocellular fibers always precedes by one or more years the external manifestations characteristic of roncet, but that their presence is not always followed by the appearance of this deformation in chronic form. It is considered inadmissible to conclude without adequate experimentation that vines showing these endocellular fibers are really free from incipient roncet.

Reply to L. Petri regarding endocellular fibers and roncet of grapevines, EVA MAMELI (*Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat.*, 5. ser., 22 (1913), II, No. 11, pp. 604-607).—Discussing the above article, the author states that she has found the endocellular fibers in question in perfectly sound individuals representing numerous species of dicotyledons, including normal grapevines under very diverse conditions of cultivation and climate.

More on the pathological significance of the endocellular fibers in tissues of grapevines, L. PETRI (*Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat.*, 5. ser., 23 (1914), I, No. 3, pp. 154-161, fig. 1).—This is an argumentative review of the articles above noted and of other contributions cited.

Diseases affecting pecan trees, H. K. MILLER (*Amer. Fruit and Nut Jour.*, 7 (1913), No. 99, pp. 12-14, figs. 2).—The author, giving the results of experience with pecan diseases in Florida, states that the blight causing leaf fall of young seedlings can be controlled by spraying with Bordeaux mixture every 10 or 15 days during foliation. Pecan scab (*Fusicladium effusum*), attacking nuts, leaves, and twigs, is said to be worse on pecan stock from Texas, and in wet than in dry seasons, also probably on trees weakened by cutting for grafts and bud wood. The application of lime sulphur to dormant trees and of Bordeaux mixture to trees in foliage is recommended, and sanitary cultivation is insisted upon.

Rosette is considered as due to malnutrition, perhaps in most cases caused by soil acidity or the character of the fertilizer employed. The use of ground limestone or Thomas slag has corrected the conditions and given good results in cases mentioned. Other factors and other remedies are suggested.

Winterkilling is considered as caused by sudden cold in autumn or spring, by cutting away too severely in taking bud wood, or by defoliation in early fall in case of attack by webworms. Orchard practice tending to induce early dormancy in autumn or late foliation in spring is recommended.

Immunization of hollyhock against rust, J. ERIKSSON and C. HAMMARLUND (*Compt. Rend. Acad. Sci. [Paris]*, 158 (1914), No. 6, pp. 420-423).—Results of previous work by Eriksson on hollyhock rust (*Puccinia malvacearum*) (E. S. R., 25, p. 850) having raised the question as to the possibility of weakening more or less the internal mycelium by the use of fungicidal solutions in watering the plants, tests were carried out with copper sulphate of from 1 to 10 per cent strength in 1912 and 1 to 5 per cent in 1913.

From the tabulated results it appears that a strength of even from 1 to 3 per cent is sufficient to limit greatly the development of the fungus, all of the new leaves in many cases proving to be free from rust. It is therefore claimed that this parasite may be greatly checked or controlled by the application of a fungicide through the roots.

Observations on the life history of *Ustilago vaillantii*, IVY MASSEE (*Jour. Econ. Biol.*, 9 (1914), No. 1, pp. 9-14, pl. 1).—The author states that *U. vaillantii*, found only on Liliaceæ, permanently infests its host in the seedling stage. The fungus grows up from the bulb each year with the stem and produces in the anthers and ovary spores which, after being dried, retain vitality for at least three months.

Phytopathological notes from North American forests, C. VON TUBEUF (*Naturw. Ztschr. Forst u. Landw.*, 12 (1914), No. 2, pp. 89-91, fig. 1).—Reporting briefly a study of two species of Uredineæ noted on a recent American tour, the author names these *Cæoma pseudotsugæ douglasii* and *Uredo chamæcyparidis nutkænsis*, respectively.

The morphology and life history of the chestnut blight fungus, P. J. ANDERSON (*Penn. Chestnut Tree Blight Com. Bul.* 7 (1913), pp. 44, pls. 17).—The results are given of a study on the morphology and life history of the chestnut-blight fungus (*Endothia parasitica*).

Among the observations reported it is stated that the ascospores germinate readily in water, while the pycnosporos require a nutrient medium. The pycnosporos germinate on the twigs of a large number of forest trees and also in humus about the base of the trees. At summer temperatures the pycnosporos germinate in from 12 to 36 hours, while the ascospores germinate in from 2 to 12 hours. Lower temperatures retard germination. The ascospores in the perithecia and the pycnosporos in the "horns" are said to retain their germinative power for at least a year. The longevity of the spores is diminished when they are separated from each other or exposed to the air. Winter weather conditions were found not to affect the vitality of either kind of spores or of the mycelium. The author states that the mycelium does not invade the living tissues as individual hyphæ, but in flat fan-shaped mats. It continues to grow in the bark even during the winter months, but with much more rapidity in the summer season. The fungus, it is said, may be carried over in the bark for a year or more by the mycelium even when the bark is kept quite dry.

A bibliography is given.

The death of chestnuts and oaks due to *Armillaria mellea*, W. H. LONG (*U. S. Dept. Agr. Bul.* 89 (1914), pp. 9, pls. 2).—The results are given of a study of chestnut and oak trees in New York and in North Carolina, from which the author claims that chestnut timber in these two regions is deteriorating, as shown by the small annual increment during recent years, by the thin sapwood, by the large percentage of diseased and stag-headed tops, as well as by the number of dead and dying trees. The decline is considered probably due to several factors, one of which is the root rotting fungus *A. mellea*. This fungus, it is claimed, can become an active parasite under favorable conditions, especially on oaks and chestnuts, killing not only suppressed trees in the forest, but those growing under more favorable conditions. The prevalence and apparent destructiveness of this fungus seem to point to it as a very important factor in the gradual recession of the chestnut timber in North Carolina.

The chestnut bark fungus (*Endothia parasitica*) was not found present in either of these localities.

A preliminary contribution on the receptivity of oak for *Oïdium*, V. RIVERA (*Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat.*, 5. ser., 22 (1913), II, No. 4, pp. 168-173).—Reporting a study of *Oïdium* on *Quercus robur* in relation to attack from *Oïdium* as affected by temperature, age, turgidity, and functional activity of the leaves, and rapidity of root absorption, the author concludes that while mature leaves are resistant to this disease, rapidity of growth favors attack. Young leaves kept in a very humid atmosphere in a constant state of high turgidity are not very susceptible to attack. High temper-

ature appears to influence susceptibility of leaves to attack through its effect on turgidity. Both pure water and very concentrated nutritive media are unfavorable to attack on the leaves, as also is complete etiolation thereof, partial etiolation showing diverse results in this respect. Mineral nutritive materials do not appear to influence attack directly.

The yellow spot disease of cork oak, A MAIGE (*Bul. Sta. Forest. Nord Afrique*, 1 (1912), No. 1, pp. 10-27).—A description is given of a disease of the cork oak which is characterized by the occurrence of yellow spots on the bark. The trouble seems to be due to the presence of micro-organisms, which are unable to attack the sound bark but develop following the presence of other fungi, particularly some of the molds such as *Aspergillus*.

Various methods are suggested for the control of this trouble, which is said to be rather serious in some portions of northern Africa.

An enemy of the western red cedar, W. A. MURBILL (*Mycologia*, 6 (1914), No. 2, pp. 93, 94, fig. 1).—Giving a description of a fungus recently noted, claimed to be new and named *Fomitiporia weirii*, the author states that the species is abundant throughout northern Idaho and Washington, being the principal fungus found in connection with decay of red cedar. It is said to continue its destructive ravages in the heartwood and sapwood after the tree has fallen, and it may even attack the bark. Separation of the annual layers in initial stages is followed by a characteristic and easily recognizable brown friable rot. Special investigation of this disease is contemplated for the field season of 1914.

Cone bearing and cauliflory in witches' broom, P. JACCARD (*Naturw. Ztschr. Forst u. Landw.*, 12 (1914), No. 3, pp. 122-128, fig. 1).—The author describes a very large witches' broom on a larch tree showing male flowers on the stems, and numerous cones, apparently normal, along with other peculiarities of an anatomical or chemical nature. The witches' broom noted showed a healthy green, contrasting strongly with surrounding foliage which was discolored, following a general attack by *Tortrix (Steganoptycha) pinicolana*.

A preliminary note on a new bark disease of the white pine, A. H. GRAVES (*Mycologia*, 6 (1914), No. 2, pp. 84-87, pl. 1).—Attention is called to a disease spreading in circular areas in white pine groves in several localities in New England.

The bark shows a degree of contraction at or near the surface of the ground, or in bad cases a girdling due to death of the bark. Of several organisms isolated from the diseased areas since the discovery of the trouble in 1911, a very common one, believed to be a *Fusarium*, is thought to be an important factor. Up to this time inoculations have apparently been unsuccessful, but investigations are in progress and further results are to be published. Pending further study, the removal and destruction of all affected trees or parts are insisted upon.

White pine blister, W. C. O'KANE (*Country Gent.*, 79 (1914), No. 6, p. 251, figs. 3).—This is a popular account of this disease as far as known in the United States.

Fairy rings, E. MÜNCH (*Naturw. Ztschr. Forst u. Landw.*, 12 (1914), No. 3, pp. 133-137, figs. 2).—The author discusses a fairy ring fungus, supposed to be *Agaricus maximus*, and kept under observation for three years, stating that attempts to extend the organism by transferring sward containing the mycelium have not succeeded in spreading it beyond the original limits of the portions of turf that were transferred.

Two new wood-destroying fungi, J. R. WEIR (*U. S. Dept. Agr., Jour. Agr. Research*, 2 (1914), No. 2, pp. 163-167, pls. 2).—Technical descriptions and economic notes are given on two new species of wood-destroying fungi, *Fomes putcarius* and *Trametes setosus*, both of which are found on dead coniferous

wood throughout the white pine timber belt of the northwestern United States and adjacent regions.

Studies in dry rot.—III, IV, C. WEHMER (*Mycol. Centbl.*, 2 (1913), No. 7, pp. 331-340, figs. 3; 3 (1914), No. 7, pp. 321-332, fig. 1).—Continuing this series (E. S. R., 27, p. 654), the author reports infection tests with *Merulius lacrymans* under varied conditions on a number of woods more or less commonly used in buildings, furniture, packing cases, etc., giving details as to behavior of each under various conditions of temperature, moisture, etc., continued for several months.

It appears, from the results detailed, that the woods entirely unchanged by the fungus were those of *Tectona grandis*, *Swietenia mahagoni*, *Robinia pseud-acacia*, *Juglans nigra*, and *Cedrela odorata*; slightly attacked, *Quercus pedunculata*; severely attacked, *Ulmus campestris*, *J. regia*, *Fagus sylvatica*, *Tilia parvifolia*, *Betula alba*, and *Picea vulgaris*.

Numerous laboratory infection studies with pure cultures indicated that *Merulius* apparently does not seriously attack mature fir wood under conditions employed, even when other organisms are present. Studies carried out in the moist atmosphere of a cellar gave almost the same negative result. Further reports are promised.

Soil disinfection with carbon bisulphid, A. ROLET (*Jour. Agr. Prat., n. ser.*, 27 (1914), No. 3, pp. 89-91).—This article discusses briefly the manner and amount of dosage with bisulphid of carbon as used for the purpose of controlling various subterranean insect and cryptogamic enemies of cultivated plants.

ECONOMIC ZOOLOGY—ENTOMOLOGY.

A history of British mammals, G. E. H. BARRETT-HAMILTON (*London*, [vol. 2], 1912, pts. 11, pp. 217-264, pls. 4, figs. 5; 12, pp. 265-312, pls. 3; 1913, pts. 13, pp. 313-360, pls. 2, figs. 4; 14, pp. 3+361-408, pls. 5, figs. 11).—This continuation of the work previously noted (E. S. R., 27, p. 51) deals with the Leporidae, or hares and rabbits; the Muscardinidae, or dormice; and the Muridae, or mice and rats, of the Rodentia.

Use and value of wild birds to Texas farmers and stockmen and fruit and truck growers, H. P. ATTWATER (*Texas Dept. Agr. Bul.* 37 (1914), pp. 61, figs. 17).—A compilation from various sources.

The growth and organization of applied entomology in the United States, P. J. PARROTT (*Jour. Econ. Ent.*, 7 (1914), No. 1, pp. 50-64).—This, the address of the president of the American Association of Economic Entomologists, deals with the utilitarian development of entomology, history of state aid in applied entomology, the prominence of entomology in federal aid to agriculture, extension of scope of applied entomology, promise in new broad projects, etc.

A simple and economical method of filing entomological correspondence, W. NEWELL (*Jour. Econ. Ent.*, 7 (1914), No. 1, pp. 87-91, pl. 1).—A description of the author's method.

Ninth annual report of the state entomologist and plant pathologist for 1913, G. M. BENTLEY (*Ann. Rpt. State Ent. and Plant Path. Tenn.*, 9 (1913), pp. 120, figs. 32).—In addition to the details relating to nursery inspection work, etc., brief accounts are given of the insects doing the most damage in 1913, poultry pests and how to control them, destructive melon, cucumber, and cantaloup insects, insecticides, etc.

Ninth report of the state entomologist and plant pathologist of Virginia, W. J. SCHOENE (*Rpt. State Ent. and Plant Path. Va.*, 9 (1912-13), pp. 66, figs. 23).—The first part of this report, relating to details of inspection work, etc.,

is followed by accounts of the round-headed apple tree borer (pp. 28-40), the fruit tree bark beetle (pp. 41-48), and plant lice (pp. 49-66) by E. A. BACK.

List of insect pests of cultivated plants in southern India, T. B. FLETCHER (*Dept. Agr. Madras Note No. 1 (1913)*, pp. 15).—This paper lists 275 insect enemies of crops in southern India.

The enemies of chicory (*Cichorium*), P. NOEL (*Bul. Lab. Régional Ent. Agr. [Rouen]*, No. 3 (1913), pp. 5, 6; *abs. in Rev. Appl. Ent.*, 1 (1913), Ser. A, No. 7, p. 256).—A list is given of the insect pests of varieties of this plant.

Tobacco insects in Hawaii, D. T. FULLAWAY (*Hawaii Sta. Bul. 34 (1914)*, pp. 20, figs. 9).—This paper supplements the information contained in the bulletin on tobacco insects by Van Dine, previously noted (*E. S. R.*, 17, p. 785). It deals with the distribution, life history, habits, means of control, and natural enemies of the more important tobacco pests. The principal insects dealt with are cutworms, splitworms, pod borer, hornworm, flea beetle, and cigarette beetle.

The larvæ of 8 of 35 species of Noctuidæ known to occur on the island are said to be commonly found in cultivated fields, *Caradrina reclusa* being the species most commonly found in the tobacco fields in Hawaii. The parasites of cutworms are said to be fairly efficient. The injury caused by the splitworm in the field is said to be slight on well-conducted plantations, only the two or three lower leaves being injured. It is, however, a source of injury in the seed bed. The braconid *Chelonus blackburni* and the ophionid *Limnerium blackburni* are important parasitic enemies.

The cotton bollworm (*Heliothis obsoleta*), known in Hawaii as the tobacco pod borer, does not attack corn or cotton on the island, and is not generally considered a serious pest of tobacco. The tobacco hornworm is extremely uncommon and has never been observed by the author on tobacco. The tobacco flea beetle does not seem to be much of a pest on the commercial plantations, except late in the growing season, but in neglected tobacco it becomes very numerous.

The minor pests briefly mentioned include *Plusia chalcites*, *Amorbia emigratella*, *Pseudococcus citri*, *P. virgatus*, *Siphanta acuta*, *Pulvinaria psidii*, *Elimæa appendiculata*, *Xiphidium varipenne*, *Nysius detectus*, and *Xyleborus* sp.

The bulletin concludes with a brief account of the cigarette beetle.

Grasshopper control work in western Kansas, G. A. DEAN (*Jour. Econ. Ent.*, 7 (1914), No. 1, pp. 67-73, pls. 2).—In describing the work as carried on in western Kansas the author estimates that the farmers fed almost a thousand tons of poisoned bran mash to grasshoppers in 1913. A close examination of the grasshopper situation made at the close of the season convinced the entomologists and farm demonstration agents that there were fewer grasshoppers in western Kansas than for many years. It is stated that from 60 to 80 per cent of the grasshoppers were killed by the poison bran mash and the remainder were so left to the mercy of the parasitic and predaceous enemies that only a few escaped.

Thrips injury to tobacco, H. JENSEN (*Jaarb. Dept. Landb., Nijv. en Handel Nederland, Indië, 1911*, p. 248, pl. 1).—This article relates to a leaf injury of the tobacco plant in Java by *Thrips* sp.

A little-known lantern fly injuring corn (*Peregrinus maidis*), W. A. THOMAS (*South Carolina Sta. Bul. 174 (1913)*, pp. 7, figs. 3).—During the course of investigations of the cotton root louse, conducted in cooperation with the Bureau of Entomology of this Department, for the past 3 years, observations have been made of *P. maidis*, which is becoming recognized as a serious pest of late corn in the Pee Dee section of South Carolina.

The injury occasioned by the insect is caused through puncturing and sucking the juices from the leaves and tender stalks. The first appearance of the injury is usually noticed on the upper surface of the midribs, near their junction with the stalks, the punctures in these tissues appearing as small whitish spots. Within a few days after the attack the leaves on these stalks become parched and dry and the entire stalk has the appearance of having been killed by a heavy frost. In cases where the infestation is lighter only the buds and upper portion of the stalks are killed, leaving some of the lower leaves still green, and where it is very light the foliage turns yellow.

At Marion eggs deposited September 5 hatched 9 days later, and the nymphs, after molting 5 times, became mature on September 30, thus completing the life cycle from egg to maturity in 25 days.

A 10 per cent kerosene emulsion or whale-oil soap at the rate of 1 lb. of soap to 5 gal. of water is recommended as a control measure.

Since it is a habit of this insect to pass the fall and early winter under shucks on the old cornstalks remaining in the fields and gardens, cutting and plowing under all the stalks immediately after the corn has been harvested is found to be an important control measure.

The rose aphid, H. M. RUSSELL (*U. S. Dept. Agr. Bul. 90 (1914), pp. 15, pls. 3, figs. 4*).—This bulletin reports the results of studies that were commenced in Los Angeles in 1910 and later carried on to some extent at Washington, D. C.

The rose aphid is said to be distributed over the entire United States and also occurs in Europe, from which country it was first described. Observations of its life history, both at Los Angeles and in a greenhouse at Washington, D. C., are reported. It is estimated that in greenhouses there are from 25 to 30 generations annually and in the open 12 or more.

Under natural control mention is made of rains, heat, birds, and parasitic and predaceous insects. A braconid (*Ephedrus incompletus*) was reared from the aphid at Washington, D. C., in 1912. During the year 1910 five different species of Syrphidæ were reared from the larvæ feeding on this aphid, namely, *Syrphus ribesii*, *S. opinator*, *Allograpta frocta*, *Eupeodes volucris*, and *Lasiophthicus pyrastris*.

In the experiments reported nicotin sulphate at a dilution as high as 1:1400 was much more effective against the rose aphid when used in combination with whale-oil or other soap, since the spreading action thus induced is much more favorable. It was found that in the greenhouse lower strengths of nicotin sulphate can be used, and that 1 part to 2,000 of water will not injure the rose plant if applied on a dark day or late in the afternoon so that the plants will not be exposed to reflected sunlight through the glass.

The cotton root louse (*Aphis maidi radialis*), W. A. THOMAS (*South Carolina Sta. Bul. 175 (1914), pp. 3*).—A brief popular account of this cotton pest.

On the biology of aphidid pests of tree and bush fruits, V. V. DOBROVLIANSKY (*K Biologii Tlëi Plodovykh Derevev i Iagodnykh Kustov. Kiev: Kiev Ent. Stantsiâ Iazh. Russ. Obshch. Pooshch. Zeml. i Selsk. Promysh., 1913, pp. 48; abs. in Rev. Appl. Ent., 2 (1914), Ser. A, No. 2, pp. 79-82*).—A report of studies made in the vicinity of Kiev in 1914, particularly of *Aphis pomi*.

Plant louse notes from California, W. M. DAVIDSON (*Jour. Econ. Ent., 7 (1914), No. 1, pp. 127-136, figs. 8*).—Descriptive notes on a number of species, including several new to science.

The life history of the sugar beet root louse (*Pemphigus betæ*), J. R. PARKER (*Jour. Econ. Ent., 7 (1914), No. 1, pp. 136-141*).—"Wingless viviparous females are found in the ground the year around upon the roots of beets, weeds, and grasses. In the fall winged individuals are produced which fly to cottonwood trees and deposit the true sexes. The sexes mate and the female

deposits a single winter egg in the crevices of cottonwood bark. The following spring the young louse hatching from the egg ascends the trees, forms a gall, in which a single generation of lice is produced, all of which are winged and become the summer migrants. The summer migrants fly to beets, weeds, and grasses and upon the leaves of such plants give birth to young which descend to the roots and start new colonies of winged viviparous females."

The San José scale in Nova Scotia, R. MATHESON (*Jour. Econ. Ent.*, 7 (1914), No. 1, pp. 141-147, fig. 1).—A discussion of the present status of this pest in Nova Scotia where it was first discovered in the spring of 1911 on nursery stock planted the preceding year, thus proving that it can survive the winter there.

A new cotton scale from Panama, T. D. A. COCKERELL (*Jour. Econ. Ent.*, 7 (1914), No. 1, p. 148).—A new species from cotton is described as *Icerya zeteki*.

Outline of the work on the gipsy moth and brown-tail moth conducted by the Bureau of Entomology, U. S. Department of Agriculture, A. F. BURGESS (*Jour. Econ. Ent.*, 7 (1914), No. 1, pp. 83-87).—A brief summary of the work now under way.

What Massachusetts has accomplished for science in her fight against the gipsy and brown-tail moths, F. W. RANE (*Proc. Soc. Prom. Agr. Sci.*, 34 (1913), pp. 59-63).—A paper presented before the annual meeting of the Society for the Promotion of Agricultural Science, held at Washington, D. C., November 11, 1913.

The parasitism and reproduction of *Empusa elegans* n. sp., B. MAJMONÉ (*Centbl. Bakt. [etc.]*, 2. Abt., 40 (1914), No. 1-8, pp. 98-109, pls. 5).—This is a report of studies of a new species of *Empusa*, found to attack and cause the death of caterpillars and pupæ of the brown-tail moth in the Province of Campobasso, Italy, which is described as *E. elegans*. This fungus is said to have been so abundant in the fall of 1909 that it caused the brown-tail moth to disappear largely from the Province the following spring.

A bibliography of 35 titles is appended.

Infection experiments with eggs of the nun moth, J. MEVES (*Centbl. Gesam. Forstw.*, 39 (1913), No. 1, pp. 18-25).—The author finds that nun moth caterpillars which emerge from eggs, the shells of which have been infected by caterpillars which died the previous year from wilt disease, consume the infection with the shell and die within a period of 11 days after emergence. The infection can be transmitted by these caterpillars during their lifetime to other caterpillars with which they come in contact. The virus can also be transmitted from those which died the same or the previous year to healthy caterpillars occurring in the vicinity without direct contact. Individual caterpillars may be immune to the disease.

The *Sporotrichum* fungus and *Arctia caja* caterpillars, J. PASTRE (*Bul. Agr. Algérie et Tunisie*, 19 (1913), No. 13, pp. 283, 284; *abs. in Rev. Appl. Ent.*, 1 (1913), Ser. A, No. 11, p. 419).—It is reported that in the vineyards of Hérault the young larvæ of this lepidopteran are often found dead or in a swollen and flabby condition as a result of the attack of *Sporotrichum globuliferum*, which supplements the work of the insect parasites, *Apanteles caja*, *Degeeria funebris*, and *Erynnia vibrissata*. Artificial propagation experiments have given poor results, the fungus apparently affecting only the first generation of the larvæ.

A contribution to the study of the chemical composition of the silkworm at different stages of its metamorphosis, R. INOUE (*Jour. Col. Agr. Imp. Univ. Tokyo*, 5 (1912), No. 1, pp. 67-79).—"The chemical composition of the silkworm is greatly changed in producing the cocoon, while the difference be-

tween the pupa and moth is not so striking. The silkworm never loses its nitrogen in gaseous form while metamorphosing. Fat is accumulated when the silkworm pupates, but during the pupal and moth stage the greater part of it is consumed."

The amount of nitrogen in the phosphotungstic acid precipitate is much smaller in every stage of the metamorphosis than the nitrogen in the filtrate therefrom. In the cocoon the amount of nitrogen precipitable by phosphotungstic acid is very small. "In the pupal and moth stage the waste of body protein is repaired with amino acids, and a part of the latter is further transformed into ammonia. Splitting of the protein in the silkworm is caused by the action of some proteolytic enzyme."

The maize pyralid (*Pyrausta nubilalis*), A. VUILLET (*Rev. Phytopath. Appl.*, 1 (1913), No. 8, pp. 105-107, fig. 1; *abs. in Rev. Appl. Ent.*, 1 (1913), Ser. A, No. 11, pp. 409, 410).—The caterpillars of *Chloridea obsoleta*, *Laphygma exigua*, and others, particularly *P. nubilalis*, are said to be the chief enemies of corn plants in southwestern France. It appears that *P. nubilalis* has but few or no parasitic enemies.

Biological and economic notes are presented.

The control of the codling moth in the Pecos Valley in New Mexico, A. L. QUAINANCE (*U. S. Dept. Agr. Bul.* 88 (1914), pp. 8, figs. 4).—This bulletin reports the results of experiments with control measures carried on during 1912 and 1913 by the late A. G. Hammar and his assistants under the direction of the author. The results of work carried on in an orchard at Roswell, N. Mex., are presented in detail.

The plat which received a total of 3 applications of an arsenate of lead spray gave 95.13 per cent sound fruit. The plat with 4 applications yielded 98.72 per cent of sound fruit, and that which received 5 spray applications, 99.39 per cent. The unsprayed plat showed only 40.77 per cent of the fruit free from codling moth injury. It has been found that in New Mexico the calyx lobes of the small fruit may remain open in suitable condition for calyx spraying for a period of from 2 to 3 weeks, thus differing somewhat from the East where a period of only about 10 days follows the dropping of the apple blossoms before the calyx lobes close.

The results have led the author to recommend that the first application, consisting of 6 lbs. of arsenate of lead to 200 gal. of water, be made as soon as the petals have fallen; the second application, consisting of 8 lbs. of arsenate of lead to 200 gal. of water, about 2 weeks after the falling of the petals; and the third application at the same strength 8 or 9 weeks after the falling of the petals.

Lesser bud moth, E. W. SCOTT and J. H. PAINE (*U. S. Dept. Agr., Jour. Agr. Research*, 2 (1914), No. 2, pp. 161, 162).—The occurrence of the lesser bud moth (*Recurvaria manella*) was noted during the spring of 1912 while the authors were engaged in apple spraying experiments at Benton Harbor, Mich. The injury caused is said to have been severe in a neglected orchard at that place, this insect being the most important factor in the destruction of the entire crop of fruit. The character of the injury, the attack on the swelling buds, and the tying together of the growing leaves led the authors to attribute the damage to the eye-spotted bud moth, but studies the following year led to the identification of the pest and the discovery of an insect the economic importance of which had not previously been recorded in the United States.

The authors' observations of the life history of this pest are said to correspond in detail with those of Houghton in England in 1903 (*E. S. R.*, 15, p. 787). A brief review of the literature consisting of 6 titles follows.

The so-called tobacco wireworm in Virginia, G. A. RUNNER (*U. S. Dept. Agr. Bul. 78 (1914), pp. 30, pls. 2, figs. 5*).—This is a report of studies of the tobacco Crambus (*Crambus caliginosellus*) conducted during the last 4 years largely at a field station at Appomattox, Va.

This pest occurs throughout the eastern United States from Canada south to the Gulf Coast States, and in most, if not all, of the tobacco-growing districts of the Eastern States, but appears to be most destructive in certain sections of Maryland and Virginia, and especially in the famous "dark tobacco district" of the Piedmont section of middle Virginia. In Virginia the damage to the tobacco crop alone by the insect is estimated to average at least \$800,000 annually, and it is also the source of considerable injury to the corn plant.

Tobacco is attacked soon after planting, and feeding by the larvæ continues until the first or second week in July. As feeding continues the larvæ, which commence operations just below the surface of the ground, frequently enter the stalk and tunnel upward, the burrows often extending to the base of the first leaves. Although the plants often partially recover they do not attain full growth. In their attack upon corn the larvæ commence near the surface of the ground and burrow into the base of the stalks, the outer portion of the stalk being frequently girdled. Injury to corn has been noted in many localities where little tobacco is grown and its damage to this crop probably amounts to more than that to tobacco.

Technical descriptions are given of the several stages of this species and a detailed report of life history studies.

At Appomattox the moths which emerge during the summer appear in greatest numbers during the first and second weeks in August. There appears to be but a single generation a year.

The eggs, which are deposited in weedy fields during July and August, hatch in a few days. The larvæ remain in the soil over winter and complete their growth during June and July of the following year, feeding most actively at the time the tobacco or corn is planted. The injury to these crops occurs when they are planted on land which was weedy during the previous season, crops planted on land which has been under clean cultivation being immune. Buckhorn plantain, oxeye daisy, stickweed, and whitetop are the weeds which have been found to be the most common natural food plants of the worms.

Several carabid beetles are mentioned as natural enemies. The subterranean habits and the protection afforded by the loose web in which the worms usually lie when not feeding appear to protect them largely from parasites. The investigations show that the worms when once established in land where their natural food plants are abundant are difficult to control. Various insecticides and repellents have been tested but without satisfactory results. Fall or winter plowing has been found to reduce the injury but is only partially effective, as most of the weeds remain alive and furnish food for the larvæ until the tobacco or corn is planted. "Damage is best prevented by crop rotations, or by cultural methods that prevent growth of the weeds which are food plants of the worms, thus making conditions unfavorable for egg deposition by the moths the summer before tobacco or corn is planted. Summer plowing, thorough preparation of weedy land, and the growing of crops of cowpeas or crimson clover, preferably cowpeas, the year before crops subject to injury are planted, have been found to be most satisfactory and practical means of control."

A bibliography of 19 titles is appended.

A new fruit boring caterpillar of bananas occurring at Tweed Heads (*Heteromicta latro*), E. JARVIS (*Queensland Agr. Jour., n. ser., 1 (1914), No. 4, pp. 280-284, fig. 1*).—This lepidopteran, hitherto unrecorded as of economic

importance, is said to have caused damage to green Cavendish bananas in the locality of Tweed Heads.

Disease-bearing mosquitoes of North and Central America, the West Indies, and the Philippine Islands, C. S. LUDLOW (*War Dept. [U. S.], Off. Surg. Gen. Bul. 4 (1914), pp. 97, pls. 30, figs. 30*).—Following a brief introduction descriptions are given of 11 species of Anopheles, 7 of Myzomyia, 3 of Pyretophorus, 4 of Myzorhynchus, 3 of Nyssorhynchus, 4 of Cellaia, and 1 each of Cyclolepteron and Stethomyia, of the Anophelinæ; and of 4 species of Culicinae. This is followed by a brief account of breeding places, life history, collecting and collections, and a discussion of dissecting and staining.

American black flies or buffalo gnats, J. R. MALLOCH (*U. S. Dept. Agr., Bur. Ent. Bul. 26 (1914), tech. ser., pp. 71, pls. 6*).—This is a synopsis of the Simuliidæ, a group of flies of considerable economic importance as direct enemies of man and domestic animals and, indirectly, through the rôle that they may play in the transmission of disease.

Five species of Prosimulium, 1 of Parasimulium n. g., and 31 of Simulium are recognized as occurring in North America and Central America, of which 14 species are characterized for the first time.

A list of the principal papers dealing with the life histories of American Simuliidæ is appended.

The reproductive organs and the newly hatched larva of the warble fly (*Hypoderma*), G. H. CARPENTER and T. R. HEWITT (*Sci. Proc. Roy. Dublin Soc., n. ser., 14 (1914), No. 19, pp. 268-289, pls. 6, fig. 1*).—This is an anatomical study of the genitalia and larva of *Hypoderma*. A bibliography of 21 titles is included.

Mahogany borers of the Gold Coast, T. F. CHIPP (*Roy. Bot. Gard. Kew, Bul. Misc. Inform., No. 2 (1913), pp. 72-75, figs. 6*).—A brief account of injury by a borer belonging to the genus *Xylotrya*.

The Colorado potato beetle migrating to the Pacific coast, F. H. CHITTENDEN (*Jour. Econ. Ent., 7 (1914), No. 1, p. 152*).—The author reports the receipt of specimens of *Leptinotarsa decemlineata* from Colton, Wash.

The biology of *Rhynchytus auratus*, N. N. TROITZKY (*Materialy po Biologii Vishnevago Slonika. Tashkend: Turkest. Ent. Stantsiia, 1913, pp. 49, pls. 2; abs. in Rev. Appl. Ent., 1 (1913), Ser. A, No. 11, pp. 438-441*).—A detailed description is given of this weevil, which occurs in the southern and southeastern parts of European Russia, in the Crimea and the Caucasus, and in the territories of Middle Asia.

The pest appears in orchards at Tashkend at the beginning of April after having hibernated in the adult stage. The weevils stay on the lower parts of stems of cherry trees, from whence they gradually spread over the crown of the tree, feeding on the blossoms and buds and later on the fruit. In the governments on the Volga they feed on plums, apricots, apples, pears, prunes, thorns, and even gooseberries. Various methods of control are suggested.

The biology of *Bruchus chinensis*, R. SCHANDER and K. BOSS (*Mitt. Kaiser Wilhelms Inst. Landw. Bromberg, 6 (1914), No. 2, pp. 125-132, pl. 1*).—Studies of the cowpea weevil are reported.

Apiary inspection (*Sess. Laws Colo., 1913, pp. 24-27*).—The text of an act establishing a division of apiary inspection and investigation under the state entomologist is presented. Its duties will include the protection of bees from contagious diseases, the prevention and spread of bee diseases, the employment of county apicultural inspectors, the transfer of bees from box hives, the prevention of the poisoning of bees by fruit tree sprays, etc.

The temperature of the honeybee cluster in winter, E. F. PHILLIPS and G. S. DEMUTH (*U. S. Dept. Agr. Bul. 93 (1914), pp. 16, figs. 2*).—This pre-

liminary report presents the results of the first season's work on the behavior of bees during the winter. The authors have eliminated a source of error, through the use of electrical thermometers in place of mercury thermometers, thus being enabled to take the readings of the temperature of various parts of the hive without opening the hive, or going near to disturb the bees. In all 161,617 temperature readings were made during the winter of 1912-13.

The authors find that "when the temperature of a colony of undisturbed broodless bees is above 57° F. and below about 69° the bees are quiet and their temperature drifts with the outer temperature; at lower temperatures they form a compact cluster, and the temperature within it is raised by heat generated by the bees." While the lower critical point, 57°, appears rather well established, it is stated that the observations up to the present do not justify too definite a statement as to the upper limit of quiescence. These conditions do not apply when the colony has brood, since the rearing of brood in winter causes a marked increase in heat production and constitutes a condition which may become one of the most disastrous that can befall a confined colony.

The studies indicate that dextrin can not be digested by bees. Thus honeydew honey causes a rapid accumulation of feces which usually results in the condition known as dysentery, in bad cases of which the feces are voided in the hive. "The accumulation of feces acts as an irritant, causing the bees to become more active and consequently to maintain a higher temperature. We are therefore justified in believing that the cause of poor wintering on honeydew honey is due to excessive activity, resulting in the bees wearing themselves out and ultimately in the death of the colony. . . . The accumulation of feces due to confinement causes increased activity and this in turn is the cause of excessive heat production, resulting in a reduction in the vitality of the bees. . . . While the activity of the cluster is greater at some times than at others, there are not, as has been held, regular intervals of activity at which the colony rouses itself to take food. At no time is a colony kept at a room temperature of 45° or less in a condition which can be characterized as inactive. . . . Poor food is evidently a more serious handicap than low temperature."

The authors state that it is clear that the heat for the warming of the cluster is produced by muscular activity. "It is at least evident from the records obtained in this work that colonies of bees in winter, either in cellars or out of doors, should be disturbed as little as possible. This appears to apply especially to cold weather out of doors or in the cellar, especially after the colony has been confined for some time."

Destruction of germs of infectious bee diseases by heating, G. F. WHITE (*U. S. Dept. Agr. Bul. 92 (1914), pp. 8*).—In this bulletin the author summarizes the results of 55 heating experiments carried on during the last two years.

When maintained for 10 minutes the minimum temperatures that can be used for destroying the germs of the four bee diseases now known to be infectious apparently are approximately 63° C. (145.4° F.) for European foul brood, 98° for American foul brood, 58° for sacbrood, and 57° for Nosema disease.

"It is probable that future experiments may cause slight changes to be made in these conclusions. Nothing more than a comparatively slight variation is to be expected, however. In practice the beekeeper, in destroying these germs by heating, will naturally use a quantity of heat somewhat in excess of the minimum amount that is absolutely necessary."

Dipterous enemies of the Melipona bees, R. RAMIREZ (*Bol. Dir. Gen. Agr. [Mexico], Rev. Agr., 2 (1912), No. 6, pp. 533-535, pls. 2*).—*Phora incrassata* and *P. aterrima* are mentioned as enemies of the immature stages of Melipona bees.

Occurrence of the Argentine ant in Texas, W. NEWELL (*Jour. Econ. Ent.*, 7 (1914), No. 1, p. 153).—*Iridomyrmex humilis* was found throughout a considerable portion of the business and residential sections of Beaumont, Tex., on January 5, 1914.

A natural enemy of the Argentine ant, W. NEWELL (*Jour. Econ. Ent.*, 7 (1914), No. 1, p. 147).—*Eciton (Acamatus) schmitti* has been found to be very active in raiding colonies of *Iridomyrmex humilis*, destroying the adults and carrying off the larvæ and pupæ in the Louisiana citrus growing section.

Calliephialtes in California, H. S. SMITH and E. J. VOSLER (*Mo. Bul. Com. Hort. Cal.*, 3 (1914), No. 5, pp. 195-211, figs. 15).—This is a report of studies of this codling moth parasite in California which were commenced in the spring of 1913. The information presented is supplementary to that by Cushman in an article previously noted (*E. S. R.*, 30, p. 360).

“On account of the wide differences in handling the apple crop in California and that of the native habitat, the physical limitations of the parasite, the fact that the birds destroy a large percentage of the codling moth larvæ, and the habits of the codling moth larvæ seeking hibernating quarters, we believe that *Calliephialtes* sp. will be of no practical value in controlling the host.”

Some information on the parasites of the eggs of *Eurygaster integriceps*, N. A. DOBROVOLSKI (*Ent. Viestnik [Kief]*, 1 (1913), No. 2, pp. 229-236; *abs. in Rev. Appl. Ent.*, 1 (1913), Ser. A, No. 11, pp. 450, 451).—The proportion of eggs parasitized in the Government of Kharkof was found to vary from 88 to 96 per cent, from 37.5 to 68 per cent being parasitized by *Telenomus semistriatus*, 26.7 to 50 per cent by *T. sokolovi*, and 1.3 to 8.8 per cent by a new species.

The Tenthredinoidea of Argentina, P. JÖRGENSEN (*An. Mus. Nac. Hist. Nat. Buenos Aires*, 24 (1913), pp. 247-288, pls. 3, fig. 1).—This paper includes descriptions of 3 genera and 13 species new to science.

Ammonia gas as a fumigant, D. E. FINK (*Jour. Econ. Ent.*, 7 (1914), No. 1, pp. 149, 150).—Three oz. of concentrated ammonia, placed in a fumigation box of 8½ cu. ft. capacity with 6 qt. bags of cowpeas containing living weevils, resulted in 100 per cent mortality. The same amount placed in the same box with a 50-lb. bag of cowpeas and an exposure of 48 hours gave from 75 to 85 per cent mortality.

FOODS—HUMAN NUTRITION.

The milling and baking qualities of Victorian wheat, A. E. V. RICHARDSON, P. R. SCOTT, and F. H. WINSLOW (*Jour. Dept. Agr. Victoria*, 11 (1913), Nos. 9, pp. 521-533, figs. 6; 10, pp. 625-639, figs. 6; 12, pp. 755-765, figs. 2).—In the first of these papers the small milling plant and electric baking oven and the laboratory equipment installed in the Victoria Department of Agriculture, for use in milling and baking tests with Victorian wheats and flours, are described, the structure of wheat discussed, and some analytical data reported.

A representative composite sample of Victorian wheat (1911-12) of “fair average quality” had, according to the authors, the following percentage composition: Water, 10.43; protein, 11.26; crude fiber, 2.32; nitrogen-free extract, 71.97; ether extract, 2.79; and ash, 1.23. As shown by the average of 10 typical Victorian wheats, the total ash was made up as follows: Ferric oxid, 0.5; alumina, 0.58; brown oxid of manganese, 1.62; lime, 3.72; magnesia, 14.61; potash, 29.93; soda, 3.24; chlorin, 0.9; sulphuric anhydrid, 3.02; phosphoric anhydrid, 40.87; and silica, 1.51 per cent; a total of 100.5 per cent, or 100 per cent when 0.5 per cent oxygen (=chlorin) is deducted. The chemical testing of flour is described in detail.

In the second paper the methods followed in milling wheat and testing flour are described at length, the descriptions being elucidated by data comparing Victorian with New South Wales and South Australian wheats.

"The New South Wales sample was intermediate in bushel weight, gave slightly less flour than either of the other wheats, but the quality of the flour was superior to either Victorian or South Australian. The protein content of both wheat and flour were comparatively high, the gluten content and water absorption higher than either of the other samples. The flour on baking gave an excellent loaf of good texture and color, and the volume and pile were very good.

"The Victorian sample gave the highest bushel weight, and yielded the greatest quantity of flour, but the flour contained slightly more moisture than the other samples. It had the lowest protein and gluten content and the lowest ratio of soluble nitrogen to total nitrogen. On the other hand, the yield of bread was good, and the volume and texture excellent.

"The South Australian sample was lowest in bushel weight, intermediate in yield of flour, moisture, protein, and gluten content. The dough did not rise to the same extent as either Victorian or New South Wales, and the volume and pile of the loaf were slightly poorer than either of the other flours."

In the third paper milling and baking tests made with 32 samples of typical Australian varieties of wheat grown at two experiment stations during the season 1912-13 are discussed.

According to the authors' summary, "the percentage of straight grade flour produced from the samples, and this in a large measure determines the value of the grain, varied from 68.7 per cent in the case of King Early to 73.5 per cent with Yandilla King. The break flour varied from 1.4 per cent with Huguenot to over 12 per cent with White Tuscan and Dart Imperial. Break flour, as a rule, has a determining effect in the color of the flour, the more break flour the poorer the color.

"Similar variations were noted with respect to the amount of water required to bring the grain into condition for milling. The maximum, 9 per cent, was required for the flinty durum varieties—Kubanka and Huguenot—while the minimum, 3 per cent, was required by soft varieties like Dart Imperial and Yandilla King."

Considerable differences were noted with respect to the volume of the loaf, and the authors consider it questionable whether the best results are obtained from high strength flours by baking them under the same conditions as low strength flours, which formed the bulk of the types tested. "The yield of bread varied from 461 to 480 gm. per standard loaf, and the volume from 1,310 cc. to 1,710 cc. What is more important still, the texture and quality of the loaves varied very considerably in the different varieties."

As pointed out, the moisture absorbed in the process of conditioning is ultimately retained in the milling products, and so the amount absorbed by different varieties is of some importance to the miller. The moisture content of Australian wheats is low, and a considerable amount is absorbed in storage in a grain shed or during transportation to Europe. The amount so gained is of direct value to the wheat exporter.

"The amount gained during storage or transportation to England largely depends, of course, on the locality in which the wheat is grown. From evidence submitted to the South Australian Royal Commission on the marketing of wheat, it would appear that the increase of weight accruing from storage for a period of 6 months amounted to from 0.75 to 3.5 per cent of the total weight of wheat."

In addition to the milling and baking tests, a special study was made of the protein and gluten content of the wheats under consideration. The protein varied from 10.31 per cent with Marshall No. 3 to 14.68 per cent with Thew, and a similar range was noted in the case of the protein content of the flour,

the extremes being 9.43 per cent with Kubanka and 13.31 per cent with Thew. "The figures for dry gluten range from 7.79 per cent to 10.44 per cent. The gluten content of the standard sample was 7.81 per cent. The variations in strength or water absorption capacity of the flour range from 42 in the case of King Early to 57.2 per cent in the case of Cedar."

The effects of climatic conditions, soil, and variety are discussed with reference to the wheats under consideration.

Wheat and flour, R. HARCOURT (*Ann. Rpt. Ontario Agr. Col. and Expt. Farm*, 38 (1912), pp. 48-50).—A brief account is given of the year's work in wheat and flour, together with the numerical data of baking tests of spring wheats grown on the college experimental plats in 1911, in comparison with earlier work.

Rice polishings or tiqui-tiqui (darac) (*Ann. Rpt. Bur. Health P. I.*, 14 (1912-13), pp. 20, 21).—A brief summary is given of a study of the possible use of rice polishings as porridge.

As obtained from the mill the sample contained grit, insects, and other foreign substances, of which the coarser portions could be removed by sifting. "In this condition the product could no doubt be eaten without actual damage, though the possible presence of insect remains is revolting. If clean, tiqui-tiqui could doubtless be prepared in the same manner as corn meal and other non-glutinous farinaceous products."

The study was undertaken because of the importance of rice polishings in combating beri-beri. The conclusion reached was that "in view of the difficulties that would be encountered in making tiqui-tiqui a palatable food, it is . . . better to make a trial of yeast, which recent laboratory work seems to show possesses the same properties as tiqui-tiqui as a cure or preventive for beri-beri, and as yeast could be more easily administered, trials with the latter are soon to be made."

Analyses of two samples of chick peas (*Cicer arietinum*), N. PASSERINI (*Bol. Ist. Agr. Scandicci*, 2. ser., 7 (1913), No. 4, pp. 311-314).—Proximate and ash analyses are reported.

A study of the ripening and putrefaction of meat, D. OTTOLENGHI (*Arch. Farmacol. Sper. e Sci. Aff.*, 16 (1913), Nos. 9, pp. 403-482, figs. 3; 10, pp. 433-451, figs. 3).—Full analytical data are presented and the results given of a chemical and bacteriological study of the changes which meat undergoes during the process of ripening and during incipient putrefaction. Methods of chemical analysis are described which, together with bacteriological examination, serve, in the opinion of the author, as a practical means of judging the state of preservation of the meat.

Twenty-sixth annual review of the frozen meat trade, 1913 (*Ann. Rev. Frozen Meat Trade*, 26 (1913), pp. 22, pl. 1).—Statistical and other data are summarized.

Medicated milk, L. GRANATO (*Bol. Agr. [Sao Paulo]*, 14. ser., No. 6 (1913), pp. 345-362).—Various medicated milks are described together with their methods of preparation, use, and physiological importance. Tables are given showing the analysis of human milk as compared with that of various animals.

Preliminary report of the dairy and food commissioner for the year 1912, J. FOUST (*Penn. Dept. Agr. Bul.* 240 (1913), pp. 56).—An account is given of the judicial construction of the Pennsylvania state pure food laws, together with a summary regarding a number of foods examined and information regarding the legal work carried on.

Fourth annual report of the board of pure food and drug commissioners, presented to the general assembly at its January session, 1913 (*Ann. Rpt. Bd. Pure Food and Drug Comrs. [R. I.]* 4 (1913), pp. 9).—A brief account of the work carried on during the year.

Pure food and drugs (*Ann Rpt. Comr. Agr., Com. and Indus., S. C., 10 (1913), pp. 195-210*).—A brief account is given of the year's activities in this line of work, together with the report of A. C. Summers, which shows the extent of the analytical work carried on under the state pure food and drug law.

Food and drugs inspection (*Ann. Rpt. Bur. Health P. I., 14 (1912-13), pp. 16-20*).—Out of a total of 369 samples of imported food products and beverages collected at the customhouse, 32 were declared adulterated or misbranded and 80 were rejected. In addition, many examinations were made of food and drugs obtained in the local market.

"An investigation of the coffee sold in the Philippine Islands resulted in establishing the fact that some of the articles sold as coffee contained adulterants such as chicory, cereals, beans, peanuts, etc. Some of these products would have the word 'imitation' printed on the English label, but nothing to indicate the fact in the Spanish or other label. To correct this a circular was issued."

Other work of the board is briefly referred to.

The dairy and pure food laws of the State of Connecticut ([*Hartford, 1913*], pp. 56).—A full text of the laws, corrected to the close of the legislative session of 1913.

Pure food and drug laws of Florida (*Tallahassee, Fla., 1913, pp. 42*).—A full text of the amended laws of Florida as approved June 13, 1913.

Standards of purity for food products, department of agriculture, State of Florida (*Tallahassee, Fla., 1913, pp. 35*).—The standards as approved June 13, 1913, are included.

Food and oil laws of the State of Wyoming, with the rules, regulations, and standards of purity for food products (*Cheyenne, Wyo., 1913, pp. 74*).—The full text is given.

Unsterilized vessels in restaurants (*Brit. Food Jour., 16 (1914), No. 181, pp. 3, 4*).—In a discussion of data collected by the *London Times* the dangers which may attend the use of washed but unsterilized silver and table utensils in restaurants is insisted upon and the installation of sterilizers recommended.

Unearthing cellar bakeries in the capitals of Europe, G. M. PRICE (*Survey, 31 (1914), No. 20, p. 615*).—According to the author's investigations, unclean cellar bakeries were common in Paris, but this was not the case in London or some other European cities, so far as his observations went.

The American cook book, JANET MCK. HILL (*Boston, 1914, pp. 8+255, pls. 16*).—A large number of recipes are brought together for preparing meat, fish, fruits, vegetables, and other foods for the table. The author points out that in the case of recipes "it is well to note the essentials and the nonessentials that make up its content. Nonessentials are usually added for variety in flavor or appearance, and if not agreeable may be eliminated without detriment to the dish; at the same time let no one forget that flavor in food is a prime requisite and it must be brought out or retained in the viand as the case may demand."

The oriental cook book, A. H. KEOLEIAN (*New York, 1913, pp. 349, pl. 1*).—The author states that he has collected at first-hand the recipes from which were selected those presented in this book, which cover the preparation of meats and fish, vegetables, eggs, salads, pickles, pastry, and so on. The oriental order of service is described, some menus are suggested, and a special list of the ingredients for oriental dishes is given.

In this introduction the author points out that there is little regular literature of oriental cookery, which means that the very numerous recipes and culinary procedures have not been standardized. He believes that oriental cookery is valuable not only because it is economical in its methods and use of materials but also because of its nutritious qualities, "and although it is solid and substantial it is often dainty as well." Its good qualities are claimed not to

be dependent upon the extravagant use of numerous and expensive materials, which increase the cost, but upon the use of economical materials with great attention paid to seasoning and flavoring and to careful methods of cookery.

Easy meals, CAROLINE F. BENTON (*Boston, 1913, pp. VII+325, pls. 8*).—The author makes a plea for simple dishes and for their combination into simple meals. Recipes are given and menus illustrating her point of view, including menus for 7 weeks for the different seasons of the year. Among the subjects considered are school luncheons, invalid meals, and catering from a country market.

A one-portion food table, F. A. REXFORD (*[Brooklyn, N. Y.], 1913, 2. ed., pp. 29, pl. 1*).—The table, which is preceded by some general discussion of diet and dietetics, gives the weight and the protein, fat, and carbohydrate content in ounces and the energy content in calories of individual portions of a large number of animal and vegetable food materials. Charts are also included designed to show the relative economy of different food materials as sources of protein and of energy.

Enameled utensils used in the preparation of food, F. BORDAS (*Ann. Falsif., 7 (1914), No. 63, pp. 49, 50*).—This article calls attention to the possible danger in the use of enameled ware in which meat is chopped, in that small particles of the enamel may become detached and thus find their way with the food into the digestive tract, causing damage to its walls.

A study of the diet and metabolism of Eskimos undertaken in 1908 on an expedition to Greenland, A. and MARIE KROGH (*Meddel. Grönland, 51 (1914), No. 1, pp. 52, figs. 13; rev. in Zentbl. Biochem. u. Biophys., 16 (1914), No. 3-4, pp. 97, 98; Jour. Chem. Soc. [London], 106 (1914), No. 615, I, p. 106*).—The results are reported of an investigation carried on at the Danish Arctic Station for Biological Research in West Greenland. A native man and woman were the subjects, and a respiration chamber of the Jacquet type was used. Among the conclusions reached were the following:

The normal diet of the Eskimos contains extremely large quantities of animal protein (280 gm.) and much fat (135 gm.), with very small quantities of carbohydrates (54 gm.), more than half being obtained in the form of glycogen in the flesh eaten. The Eskimos greatly resemble carnivorous animals in that their meals are few and irregular and when food is eaten it is taken to their fullest capacity. Nevertheless, the diet exercises no bad effect, except occasionally skin eruptions and often nosebleed after food has been taken in large quantities. The physical strength of these Eskimos and their resistance to the unfavorable climatic conditions are very great. It is especially to be noted that uric acid diseases are of extremely rare occurrence.

In the metabolism experiments (which were controlled by respiration experiments), the maximum daily food taken was 1.804 gm. of boiled seal meat (supplying 85 gm. nitrogen and 218 gm. fat), a quantity which is said to be much less than the usual amount of meat taken by Eskimos in the open. This quantity of meat was well assimilated, the loss of nitrogen in the feces being at most 3 to 5 gm. per day. The largest amount of nitrogen excreted in the urine in a day was 53 gm. When under experimental conditions an abundant meat diet was taken after a diet lacking nitrogen or a low-nitrogen diet, only about 60 per cent of the nitrogen was excreted in 24 hours, while the remaining 40 per cent was retained.

Long-continued metabolism experiments were not carried out, but the authors believe that the protein which the retained nitrogen represents is held in the body and later used with little loss as a source of energy. These conclusions are rendered the more probable by the fact that the specific dynamic effect of the protein was low, as shown by the respiration experiments.

The relation of the renal excretion of nitrogen to water secretion is very noticeable when such large quantities of protein are taken.

The respiratory metabolism was always higher in the afternoon than in the forenoon. During the night it was practically constant and in general uninfluenced by the food taken.

Rearing an imperial race: Report of the Second Guildhall School Conference on Diet, Cookery, and Hygiene, edited by C. E. HECHT (*London, 1913, pp. XLVIII+508, pls. 12, fig. 1*).—A full report is given of this conference, which had to do with diet, cookery, hygiene, dietaries, children's food requirements, clothing, and similar topics. Especial attention is paid to the teaching of home economics topics, to malnutrition, to school luncheons, and to similar subjects, particularly with reference to Great Britain, while one section is devoted to a summary of data regarding work along such lines in other countries.

Among the papers presented may be mentioned **Food Values, Catering, and Cookery—An Account of the Teaching of These in Connection with the Other Domestic Subjects in Primary Schools under the London County Council**, by Catherine R. Gordon; **Diet, Cookery, and Hygiene in Philanthropic Residential Institutions for Children and Adolescents**, by Edith Butler; **How the Family of the Agricultural Laborer Lives**, by R. T. Herdman; **The Diet of Country School Children**, by E. B. Smith; **Remarks on the Food Requirements of Children**, by C. Watson; **The Bradford Feeding Experiment—Report on a Course of Meals Given to Necessitous Children from April to July, 1907**, by R. H. Crowley and Marian E. Cuff; and **How Edinburgh Feeds and Clothes Her School Children**, by J. W. Peck.

An exhibit of material bearing upon the subjects under consideration was also arranged. The volume as a whole contains a large amount of data with respect to the general question of work in home economics in England.

For the previous conference, see an earlier note (E. S. R., 29, p. 363).

The cost of living of the laboring classes in the important industrial countries: England, Germany, France, Belgium, and the United States, C. VON TYSZKA (*Die Lebenshaltung der arbeitenden Klassen in den bedeutendsten Industriestaaten: England, Deutschland, Frankreich, Belgien und Vereinigte Staaten von Amerika. Jena, 1912, pp. 69*).—A comparison is made of the wages paid in a number of the principal cities of each country in the building, metal working, shipbuilding, and printing trades, and in the mining, textile, and wood working industries. The prices of rents and food materials are compared together with the budgets of the families of working people in the various countries.

[Cooperative buying for] **the Home Hospital experiment**, J. A. KINGSBURY (*Survey, 31 (1914), No. 19, pp. 583-588, figs. 8*).—A cooperative store is maintained as a part of the home for families made dependent by tuberculosis, which was established by the New York Association for Improving the Condition of the Poor, as a 3-year demonstration experiment for the combined treatment of this disease and poverty. The institution is a combination of home and hospital. The well members of the families work and the sick are given treatment.

The average cost of food under the plan of cooperative buying has been reduced during the first year of operation from \$1.30 to 93 cts. per day. The administration and supervision charges amount to 20 cts. per person per day for all members, both sick and well. Details are given of the other expenditures.

The budget of the Home Hospital "furnishes a fair basis for computing the cost of maintaining a decent home and providing a comfortable living

for an average family of 5 persons, father, mother, and 3 children under 14 years of age, in New York City at the present time." It indicates that such a family can live under ordinary conditions fairly comfortably in New York on from \$1,050 to \$1,150 per year, and "that an income of between \$1,100 and \$1,200 is probably necessary for an average family to maintain unaided a normal standard of living . . . —that is to say, for a family to live in such a way as to preserve health, mind, character, self-respect, and proper conditions of family life."

Advantage is taken of the diet kitchen of the hospital to give instruction to the women in the preparation of food, and instruction has also been given in personal and home hygiene and in the care of children.

The summary gives details of the success of the project as a sociological experiment and information of interest in connection with the general subject of institution management.

[Cooperative grocery of the New York Association for Improving the Condition of the Poor] (*Survey*, 31 (1914), No. 21, pp. 636, 637).—A brief description is given of the project recently instituted by this society for the purchase and distribution of the groceries required for its relief work.

"The new method is simply that of buying wholesale, and of running a store of the association's own, where the visitor orders her food instead of getting it at the corner grocery." In the first 10 weeks a net saving of 22.8 per cent was effected, the total expenditure being \$6,866.22. Each association visitor makes out her food orders daily, using the association dietitian's guides, which indicate the supplies needed in a unit of time for families of different sizes and circumstances. Orders are filled and delivery made on the following day.

Emergency demands are still met by purchase in the ordinary way, cases requiring haste being under 10 per cent of the total. "The store is serving also as a laboratory in experimenting with problems relating to the purchase and distribution of food."

It is stated that this enterprise grew out of the success of the association's cooperative project described above.

The fundamental basis of nutrition, G. LUSK (*New Haven, Conn., and London, 1914*, pp. 6+62).—Following a historical introduction, the author discusses the body's constant need for fuel and protein; habits of diet; and beriberi, which is classed as a nutritional disease due to a deficiency in the diet of a substance or substances for which the name "vitamin" has been proposed.

In the final chapter, on the monetary value of foods, data collected by F. C. Gephart regarding the cost and nutritive value of the portions of various foods sold from the counter of a well-known chain system of restaurants in New York and other cities are included which serve to emphasize the extreme variability of the purchasing power of money when expended for food. In general, the author proposes that foods should be sold on the basis of their energy value and of the proportion of the total energy contributed by proteins. "The proteins of the foodstuffs could be labeled A, B, and C according to their physiological value, and to group D might belong gelatin and some other proteins which can not replace the body protein that is continually wearing away." The relative value of different proteins, as determined by the products which they yield on hydrolysis, as well as other recent work on the nature and functions of protein, are discussed.

As the author points out, "since the efficiency of labor depends upon its energy and constant repair, it is certainly of no small moment that the citizen should know how best to maintain the machine at a maximum of efficiency. Not only that, but in times of trouble he should know where to turn to find nourishment in the form which is best and cheapest. . . . If, through the

medium of the schools and the press, everyone knew that a man of sedentary occupation required 2,500 calories and a laboring man 3,000 calories and more, no one suffering from want would spend his money for a can of tomatoes which is little else than flavored water.

"It has been estimated that a family of 5, including the father, a clerk, the mother who does the housework, and 3 children, 9 and 6 years and 1 month old, respectively, requires 7,750 calories per day." Data are presented showing the cost of a diet sufficient to supply this energy, 5 per cent of the total coming from animal proteins of grade A and 10 per cent from vegetable proteins of grade C (bread). The necessary protein to supplement the bread would be supplied by $\frac{4}{5}$ lb. salt codfish, $\frac{3}{8}$ lb. smoked ham, $\frac{4}{5}$ lb. cheese, 2 $\frac{1}{2}$ lbs. milk, 1 $\frac{1}{2}$ lbs. loin pork, 1 $\frac{1}{2}$ lbs. of mutton, 1 $\frac{1}{2}$ lbs. cod steak (fresh), 1 $\frac{1}{2}$ lbs. sirloin beef, or 1 $\frac{1}{2}$ lbs. turkey. According to the prices of foods in the New York markets January 28, 1913, the cost of the ration would vary from 47 cts. with bread and salt codfish to 78 cts. with bread and turkey.

"If corn meal, oatmeal, dried beans or rice had been used instead of bread, these prices would have been lower, whereas potatoes would have slightly increased them.

"These figures are for the great staples of diet. . . . It is obvious that when more than an average of 8 cts. is expended for 1,000 calories of nutriment, the diet must include luxuries."

The author estimates that three servants will double and six servants treble the food bill given above. "Whatever is spent above these amounts is paid for waste or for nonessentials in the form of flavors of high price. High cost may also be due to carnivorous indulgence approximating that of the Eskimo. . . . It is not probable that the food values actually consumed are very different in the various well nourished families. Only the cost can vary enormously."

The value for man of the different constituents of food, L. HIRSCHSTEIN (*Ztschr. Phys. u. Diätet. Ther.*, 17 (1913), No. 8, pp. 453-471; *abs. in Zentbl. Physiol.*, 27 (1913), No. 19, p. 1036).—The elementary components of the diet have different value, the author points out. For instance, in the case of common salt, more sodium than chlorin is retained, and in the case of protein, more sulphur than nitrogen.

In almost every case, there is a tendency to excrete phosphorus. Indeed, chlorin, phosphorus, and nitrogen are the food constituents which the body easily gives up as soon as the intake is sufficiently lowered. On the other hand, if the supply is lowered, sodium and sulphur are generally held on to and are excreted in diminished quantity.

The author states that general observations on different persons were supplemented by extended experiments, which led to the conclusion that losses of chlorin, phosphorus, and nitrogen have been observed to continue under certain conditions for months and years and that they are associated with the occurrence of nervous and other diseases. This leads to the conclusion that the daily diet does not meet man's ideal requirements when it is too poor in sulphur and alkalis or too rich in chlorin, phosphorus, and nitrogen.

Protein and nutrition, M. HINDHEDE (*London, 1913, pp. X+201, pls. 8*).—In this book the author summarizes the results of his own experiments with a low protein diet and also discusses the experiments carried out by other investigators regarding the protein requirement in nutrition. From the fact that the subjects of his experiments were able to maintain a good physical condition upon a low protein diet, the author believes that many of the common ills can be avoided and much better physical condition secured by a reduction of protein, and especially of meat, in the diet.

Experiments on the effects of a limited diet.—VI, The nutritive value of zein, gliadin, and egg albumin in experiments with white rats, S. BAGLIONI (*Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat., e Nat., 5. ser., 22 (1913), II, No. 12, pp. 721-728, fig. 1*).—From these experiments, carried on with laboratory animals, the author concludes that zein, gliadin, and egg albumin are not only capable of maintaining the nitrogen balance in the case of both adult and growing animals, but if given in sufficient quantity will allow a storing up of nitrogen in the body.

Animals maintained on a diet in which egg albumin was the sole source of protein showed a gain in weight. In the majority of cases those maintained on diets in which zein and gliadin were the sole sources of protein showed a loss of weight, both in the case of adult and growing animals. In the latter case the increase of weight could be restored by the addition of egg albumin or meat and bread to the diet.

Utilization of the proteins of cotton seed by man, J. B. RATHER (*Jour. Amer. Chem. Soc., 36 (1914), No. 3, pp. 584-586*).—An abstract of Bulletin 163 of the Texas Station, previously noted (*E. S. R., 31, p. 65*).

Influence of water on the digestion of solid substances, F. GROBBELS (*Hoppe-Seyler's Ztschr. Physiol. Chem., 89 (1914), No. 1-2, pp. 1-21, figs. 3*).—The experiments reported were made with laboratory animals (dogs).

According to the author, of the materials experimented with, water left the stomach soonest. Bread with water taken 5 minutes after required twice as long a time as water alone. However, the material remained in the stomach a shorter time than was the case with bread alone. The longest time was required for bread and water mixed. With water, the largest amount of liquid had left the stomach at the end of an hour, and with bread, the lowest amount, and the amount was greater when bread and water were taken in succession than when they were taken mixed.

The minimum amount of gastric secretion was noted with water and was only slightly lower for bread alone than in the other cases. When the dogs were made to thirst, an increase in the total amount of liquid which left the stomach in an hour was noted in one test without any special diminution of the gastric secretion or the length of the period of gastric digestion. In two other series both of these factors were diminished. Coffee, on the other hand, increased the period of gastric digestion without changing the percentage values.

The author, in discussing his experiments, notes that his work has a bearing upon the length of time that food remains in the stomach, but not upon the amount of work required of the secretory glands in digestion. He believes that his results support the common theory that dry food leaves the stomach less quickly than moist food, and that with respect to the time that food remains in the stomach, the best results are obtained when water or similar liquids are taken after food rather than when they are mixed with it, and that mixing solid or liquid foods is not desirable from a physiological standpoint.

In the case of taking bread or cake at the same time as coffee, he is of the opinion that the increase in the time the food is retained in the stomach is an advantage, since it prolongs the feeling of satiety and delays diuresis.

Influence of some inorganic salts on the action of the lipase of the pancreas, C. A. PEKELHARING (*K. Akad. Wetensch. Amsterdam, Proc. Sect. Sci., 15 (1912), pt. 1, pp. 336-347*).—From his experiments the author concludes that calcium, barium, magnesium, and sodium salts play a part with regard to the activity of lipase totally different from that of the bile acids. In his opinion one may conclude that these salts "separate fatty acid from the solution as soap, and for that reason increase the fat-splitting power of the enzyme."

The rôle of caffenin in the effects exercised by coffee on the heart, kidneys, and nervous system, H. BUSQUET and TIFFENEAU (*Bul. Soc. Sci. Hyg. Aliment.*, 3 (1913), No. 6, pp. 577-587, figs. 4).—The results are reported of experiments carried out to determine the rôle of caffenin in the cardiac, renal, and nervous effects of coffee.

These experiments and those carried out by other investigators show, in the opinion of the authors, that it is the caffenin in the coffee which is responsible for the pharmaco-dynamic effects of coffee infusion. It is deduced from these conclusions that coffee which is sufficiently deprived of caffenin may be considered as an almost negative substance. Caffenin-free coffee may be substituted for ordinary coffee or not, according to whether one wishes to avoid or obtain the effects of caffenin.

Physiological and pathological chymology, together with some experiments on chymotherapy, E. S. LONDON (*Physiologische und pathologische Chymologie. Nebst einigen Versuchen über Chymotherapie. Leipsic, 1913, pp. X+284; rev. in Zentbl. Biochem. u. Biophys.*, 16 (1914), No. 5-6, p. 180).—This volume is not a systematic exposition of the phenomena of the stomach and digestive tract, but rather a useful summary of the investigations of the author and his pupils which have been published in recent years. Such a summary is convenient for those interested in the subject of digestion, not only because it brings material together but also because the reports contain the full data of the author's experimental methods. In his discussion of the results of the investigations the author presents simple, mathematical generalizations with respect to the power of secretion and digestion.

Metabolism and vitality, J. B. NICHOLS (*Med. Rec. [N. Y.]*, 85 (1914), No. 7, pp. 289-291).—A digest of data regarding ventilation, humidity of the air, and similar topics, chiefly with reference to disease.

ANIMAL PRODUCTION.

Soiling crops to supplement Iowa pastures, H. H. KILDEE (*Iowa Sta. Circ. 12 (1913), pp. 4*).—This circular discusses the advantages of providing soiling crops for dairy cattle and gives instructions for the growing of soiling crops, such as oats and Canada field peas, fodder cane, cowpeas, millet, alfalfa, soy beans, etc., suitable to Iowa conditions.

It is stated that at the station an increased production from decreased acreage has been the result secured from this system of soiling crops. In 1911, 37 cows were kept on 19½ acres of pasture and the soiling crops from 8 acres. In 1912, 45 cows were kept on a 19½-acre pasture and 6 acres soiling crop, at a cost for each cow of \$6.62.

The worth of cactus for feeding (*Cal. Cult.*, 42 (1914), No. 8, pp. 227, 242).—This article is a compilation of reports of investigations and the opinions of various authorities on the feeding value of cactus and pie melons. Analyses show cactus to be of low feeding value, but as an appetizer fed with dry feeds it may prove of worth. The analyses indicate that spineless and spiny varieties contain about the same amount of nutriment.

Nitrogen assimilation in the feeding of sodium nitrate, E. GRAFE and H. WINTZ (*Hoppe-Seyler's Ztschr. Physiol. Chem.*, 86 (1913), No. 4, pp. 283-314).—Experiments in the feeding of approximately 1 gm. per day of sodium nitrate to dogs and pigs indicate that there is a nitrogen retention in the body of from 10 to 15 per cent. Larger amounts had a toxic effect.

Nitrogen retention in the feeding of ammonium salts and urea, E. GRAFE (*Hoppe-Seyler's Ztschr. Physiol. Chem.*, 88 (1913), No 6, pp. 389-424).—The

results of trials with swine fed ammonium salts and urea indicate that there is an increased nitrogen retention with these substances.

It is concluded that the form in which the nitrogen is retained must be as protein or protein-like substances.

Live stock and dairy produce (*Ann. Reg. Agr. Expts. [London], 1913, pp. 88-98*).—This is a résumé of British feeding experiments conducted during 1911-12 and previously reported from other sources.

[Austrian live stock statistics] (*Österr. Statist., n. ser., 5 (1910), No. 1, pp. 20-190, pls. 4*).—This is a compilation of statistics relating to cattle and live stock production in Austria for the decade 1901-1910, as prepared by the Royal Statistical Commission.

Heredity of unpigmented hair and of hide peculiarities in cattle and horses, A. R. WALTHER (*Ztschr. Induktive Abstam. u. Vererbungslehre, 10 (1913), No. 1-2, pp. 1-48, pl. 1, figs. 2*).—This reports studies made of the inheritance of color markings of Shorthorn cattle and of horses in the Trakehnen stud.

A bibliography of American and foreign works is appended.

Heredity of color in cattle, RICHARDSEN (*Deut. Landw. Tierzucht, 18 (1914), No. 6, pp. 61-65, figs. 10*).—A number of breeding trials indicated that the single coloring (reddish brown) of the Netherland breed of cattle dominates over the double coloring of the black and white sires. However, this dominance was incomplete as the white color markings were in evidence. The degree of coloring in the first cross was intermediate between the two parents. The color markings in year-old animals were less distinct than in the calves.

Estimating the age of calves, J. SCHWARZ (*Beiträge zur Altersbestimmung des Kalbes. Inaug. Diss., Univ. Leipsic, 1912, pp. 144, pls. 6*).—Observations were made on the growth of the eyeteeth, the retraction of the gums, the drying of the navel cord, and the occurrence of hoof rings to determine the age of calves.

Feeding of calves on skim milk and cassava porridge, A. GOVIN and P. ANDOUARD (*Bul. Soc. Nat. Agr. France, 74 (1914), No. 1, pp. 40-42*).—Successful trials are reported in feeding skim milk and cassava flour as a substitute for whole milk. Whole milk is fed the first week and the skim milk and cassava porridge thereafter.

Beef production, E. S. BAYARD (*Penn. Dept. Agr. Bul. 235, pp. 250, pls. 33*).—A somewhat complete popular treatise on the general phases of the feed, care, and management of beef cattle, embodying many feeding experiments previously reported from other sources, and including chapters on summer feeding, silage for fattening cattle, show steers, cattle farms, computing rations, cattle crops, slaughtering cattle on the farm, marketing cattle, and diseases of cattle.

The cattalo.—Crossing of American bison with domestic cattle (*Mark Lane Express, 111 (1914), No. 4301, p. 339*).—An account of Canadian trials in crossing the American bison with domestic cattle. The term cattalo is used to designate the mixed blood in all proportions including the hybrids. By using domestic bulls it was possible to get away from all resemblance to the buffalo, and vice versa by using the pure buffalo bull an animal was soon graded up indistinguishable from the pure buffalo.

The best results were obtained from a Hereford bull and a buffalo cow. Various other breeds, such as Angus, West Highland, Sussex, and Devon were tried, the object being to learn which sort would yield the choicest pelt, but no marked difference could be distinguished in the length and quality of hair on the hybrids. Where the Hereford was used, the white face characteristic dominated, but otherwise the whole color of the buffalo dominated.

It is stated that "experience seems to warrant the expectation that in later generations, after there has been time for selection, there may be seen on cattaloes having say 10 per cent or less of bison blood, as good fur as is now seen on the half and three-quarter buffaloes." There is also some prospect of improving the beef carcass by this hybridizing, for the bison carries an exceedingly high percentage of beef on the back, and the inheritance of this quality may be encouraged by selection. While there was some irregularity in the fertility of the hybrids it is believed that both males and females will be fairly fertile, and that complete fertility if not found at once will doubtless come through selection, as will early maturity.

Sex determination in sheep, compiled by P. B. POPENOE (*Jour. Heredity*, 5 (1914), No. 2, pp. 46-57, figs. 4).—Observations were made by A. G. Bell on his flock on Cape Breton Island during 1899-1901 on the effect of nourishment of the mother on the sex of offspring and on the production of twins. Earlier observations had led to the conclusion that "three conditions favorable to the production of twins revealed themselves: (1) Maturity in the ewes (ewes 4, 5, and 6 years old yielding a larger percentage of twins than younger or older ewes), (2) mating in October (with consequent lambing in March), and (3) a rapid increase of weight at the time of mating with subsequent loss of weight."

The results obtained in 1899 were inconclusive as to whether the extra feeding given the ewes in the fall had caused them to produce a larger percentage of twins than ordinary. However, it is noted that "no less than 72 per cent of the March-born lambs were females—a circumstance quite unprecedented in the history of the flock."

Believing that possibly climatic conditions were involved, an inquiry was made as to the flocks on the whole island of Cape Breton, the result of which showed that there had been a majority of males. The female percentage was therefore a local matter. Data were then collected as to the treatment during the preceding year of one flock which had produced 88.5 per cent males. Mating occurred at a time when the ewes were beginning to lose weight, after which they remained in reduced condition until their lambs were born. These results were in contrast to those obtained with the experimental flock and seemed to indicate that special feeding in the fall may have been responsible for the large proportion of females born in 1900. A study of the weight of the ewes shows that "at the beginning of October, before mating had been accomplished, the average weights of the two classes of ewes (male-bearing and female-bearing) were the same. The average male-bearing ewe increased in weight up to the end of October, after which there was a decline; the average female-bearing ewe, on the other hand, continued to gain in weight all through November so that by the end of that month the average female-bearing ewe outweighed the male-bearing—a superiority retained during the subsequent decline." Similar observations had been noted in earlier trials, 1890-1899.

It was further observed that the mothers of twins were above the average of the flock in weight and the mothers of single lambs were below the average. "Among the twin-bearing ewes there were none who had male lambs exclusively. Those which had male as well as female lambs were losing in weight at the time of mating and immediately after; whereas those which had female lambs alone were increasing in weight at the time of mating, and, though the weight dropped afterwards, did not continue to drop but remained substantially on a level for several weeks." It was found that the mothers of males were losing in weight at the time of mating, whereas the mothers of females retained their weight. From these observations it is concluded that "variations of weight occurring at or about the time of mating may have great significance.

They reflect changes in the condition of nutrition of the mother, at a critical period in the formation of the unborn young, and suggest the possibility of affecting the fertility of sheep and controlling the sex of their offspring by suitable feeding for a short period of time before and after the time of mating."

Feeling that the absolute number of ewes involved was too small to give certainty to the averages, further observations were made and a table prepared combining all the records. The weight of over 100 mothers of male lambs, taken in the autumn preceding birth of lambs was for September 30, 90.3 lbs.; October 31, 96.2; November 30, 95.6; and December 31, 94 lbs.; and for mothers of female lambs 91.2, 96.4, 95.2, and 94 lbs., respectively. Here it is shown that the average weights were practically the same and would evidently discountenance former conclusions. It is thought that this inconsistency may be accounted for by the fact that the male-bearing ewes increased in weight at a greater rate than the female-bearing ewes during the month of October. They started lower and reached the same point by the end of the month. A marked difference was found to exist between the weight curves for the two classes of ewes, twin-bearing and single-bearing. However, the author hesitates to draw a conclusion from these observations.

Annual report, 1912: Sheep division, A. G. MICHAELIAN (*Union So. Africa Dept. Agr. Rpt. 1912-13, pp. 71-135*).—A statistical report of the sheep and goat industry in the Union of South Africa.

Wool carding and combing, A. F. BARKER and E. PRIESTLEY (*New York, London, Toronto, and Melbourne, 1912, pp. XII+264, pls. 45, figs. 34*).—The chapters included in this book are on wool and hair-producing animals; sheep breeding and Mendelism; wools, hair, and the manufactured materials; commerce in wools and hairs; wool classing and sorting; the physical and chemical properties of wools, hairs, etc.; wool steeping, scouring, and drying; types of yarns generally considered; the preparation of long wools (English, cross-bred wools, and Merino wool for combing); and combing, recombining, and finishing.

A chemical study of the nutrition of swine, E. B. FORBES, F. M. BEEGLE, C. M. FRITZ, and J. E. MENSCHING (*Ohio Sta. Bul. 271 (1914), pp. 225-261, figs. 3*).—Five pigs from the same litter were used in a metabolism experiment involving eight 10-day periods, separated by 7-day intervals. The feeds used were corn alone in two periods; corn supplemented by soy beans, linseed-oil meal, wheat middlings, meat meal, and skim milk; and a ration of rice polish and wheat bran.

It was demonstrated that as sources of calcium for growing swine, corn, wheat middlings, linseed-oil meal, soy beans, wheat bran, and rice polish are unsatisfactory and will not maintain normal growth of bone. From 9 to 10 times as much calcium was retained from rations containing milk and meat meal as from the best one of the grain rations, which emphasizes the need of supplying those feeds rich in calcium, such as pasture and forage crops, especially the leguminous plants.

Corn was deficient in calcium, phosphorus, and nitrogen. Phosphorus was stored on all the rations but was insufficient for maximum growth in the ration of corn alone. In the ration of rice polish and wheat bran, which contained 12 times as much magnesium as calcium, the excess of magnesium appeared to cause a loss of calcium from the animal. Although the remaining rations contained an excess of acid over basic mineral elements, it did not affect calcium retention.

The ammonia of the urine was found to increase with the excess mineral acidity and the total protein of the ration.

One part of sodium chlorid to 256 parts of other feeds seemed to be more than sufficient for growing swine. It was found that the balances of sodium

and chlorin were largely controlled by the amount of water drunk. There was an extensive metabolism of sodium apart from chlorin. The feces may contain an abundance of sodium but are nearly free from chlorin.

Magnesium tends to deflect the phosphorus excretion from urine to feces, and excessive phosphorus content of the ration limits the absorption of magnesium. With an intake of 2.17 gm. of magnesium and 5.4 gm. of phosphorus there was a storage of magnesium, but with an intake of 9.28 gm. magnesium and 20.17 gm. phosphorus there was a loss of magnesium, combined with phosphorus, through the feces.

The potassium of these rations was more than sufficient in all cases. With the maximum intake, however, on the ration of wheat bran and rice polish, there was a loss of potassium, apparently through an excretion of previously stored excess. The urinary potassium varied inversely as the retention.

Nitrogen and sulphur balances were all positive. Sodium, potassium, sulphur, and chlorin were excreted in larger proportion in the urine than in the feces, while calcium, magnesium, and phosphorus left the body more largely in the feces.

The digestibility of the starch of corn was increased by the feeding with it of soy beans, tankage, and milk. Tankage and milk also increased the digestibility of the fat, and decreased the digestibility of the crude fiber of corn. Creatinin excretion in the urine was shown to be entirely independent of the feed, and to vary among the several individuals in the same order as live weight and weight dressed carcass, flesh, bone, and blood.

The metabolism crates used in the experiments are briefly described.

Pork that is made at home, P. F. TROWBRIDGE (*Country Gent.*, 79 (1914), No. 7, pp. 298, 299, figs. 14).—An account of the slaughtering, cutting up, and curing of pork for home purposes.

Productive horse husbandry, C. W. GAY (*Philadelphia and London*, 1914, pp. XV+331, pl. 1, figs. 173).—This book is a comprehensive treatise on the structure and function of the horse, the types and breeds of horses, the principles of horse breeding, the feed, care, and management of the horse, stables, equitation, and markets and shows.

Weights and measurements of horses, H. W. WYNN (*Live Stock Jour.* [London], 79 (1914), No. 2082, p. 199).—There are given the average weights and measurements of 370 horses, representing the cavalry, mounted infantry, artillery, bus, light vanner, and hunter classes.

Origin of Argentina wild horses, W. D. MATTHEW (*Nature* [London], 92 (1914), No. 2311, p. 661).—The author presents evidence to show that the theory that the existing wild horses of South America are descended either wholly or partly from any surviving native stock is erroneous. He points out that the infertility of crosses between zebras or asses and domestic horses is based upon a separation dating back at least to the late Pliocene age, and since the species native to Argentina, if they continued to exist down to modern times, would have evolved in complete isolation from any northern species since the early Pleistocene, they should be equally infertile when crossed with the domestic stock. However, this is not the case. Assuming that the native horses may have survived in Argentina until the time of the Spanish settlement, the stock would not be able to interbreed with domestic stock and would remain separate and unmixed until exterminated.

The great producing brood-mare families, J. C. MCCOY (*Amer. Horse Breeder*, 32 (1914), No. 9, p. 129, figs. 3).—After commenting on the ancestry and attributes of several of our principal brood-mare families the author points out that to-day "our best results are coming from blending several crosses of the top of the Hambletonian family with several crosses of the great brood-

mare families. The more top crosses we get from both sides, the more certain it seems to be that the produce will be of high standard."

[International review of Percherons] (*Percheron Soc. Amer. Internat. Rev.*, 1 (1914), pp. 50, figs. 38).—A review of the Percheron showing at the International Live Stock Show, 1913, together with photographic illustrations of the first and second prize winners in each class, and other data.

Farm poultry, G. C. WATSON (*New York and London, 1913, 11. ed., pp. X+369, figs. 104*).—This book, which is one of the Rural Science Series, is a complete treatise on breeds of poultry and the breeding, feed, care and management of poultry, ducks, geese, and turkeys.

Productive poultry husbandry, H. R. LEWIS (*Philadelphia and London, 1913, pp. XIX+536, pl. 1, figs. 217*).—A complete and practical treatise on the breeding, feed, care, and management of poultry, together with chapters on fattening, killing, and preparing for market.

New breeds of poultry (*Agr. Jour. Union So. Africa, 6 (1913), No. 5, pp. 826-828, figs. 3*).—An account of the Bustin Black Pretors breed of poultry which originated in an attempt to outbreed "liver disease" which is so prevalent among poultry in South America. There are two varieties, the single and the rose-combed. The former is a large bird, greenish black in appearance, with dark feet, black eyes, white ear lobes, red comb, upright carriage, and broad chested. From 178 to 200 eggs are laid per hen in 12 months, the eggs being large, round, and brown or tinted. The rose-comb variety was produced as the result of a freak, the outcome of a cross from the single-comb variety. Both breeds are said to be free from disease of a tubercular nature.

Some factors affecting the weight, composition, and hatchability of hen eggs, H. ATWOOD (*West Virginia Sta. Bul. 145 (1914), pp. 73-102*).—Earlier experiments (E. S. R., 23, p. 76) are cited showing that there is a relation between size of eggs and weight and thrift of chicks hatched from them, and that as previously shown (E. S. R., 13, p. 276) there appears to be a seasonal variation in the weight of eggs, the weight being greater from November to April and lightest from May to October.

During the season 1911-12, three lots of fowls were fed liberally and three lots scantily. While the former showed a fairly uniform increase in weight, the latter showed little, if any, increase. The lots fed liberally produced during the year 8,062 eggs while the scantily fed lots produced 5,144 eggs. The pullets of the liberally fed lots averaged 38.7 eggs each while the corresponding yearling hens produced an average of 125.6 eggs each. The heaviest eggs were laid during February, March, and April. During March the eggs of the liberally-fed lots averaged 60.3 gm. in weight while the scantily fed averaged 57.6 gm., indicating that quantity of feed slightly affects the size of eggs. The results of five hatches indicated that in general eggs from liberally-fed hens are more fertile than those from scantily-fed hens, but that the percentage hatch is practically the same among those eggs that are fertile. There appeared to be no great difference in the vigor of the chicks from the two lots of fowls.

Duplicate experiments conducted during 1912-13 gave results similar to those of 1911-12. It was noted that the average weight of eggs from the fowls of the first year of test was 57.5 gm. and of the second year 58.92 gm. or 1.4 gm. increase, apparently due to increased age of the fowls. Likewise eggs from yearling hens showed greater weight than those from pullets. Further hatching tests showed practically no difference in the average fertility or hatchability of the eggs from the fowls fed heavily or scantily. There was considerable variation, however, in the results from the different pens, due, probably in large measure, to variations in the vigor of the males. Mortality tests were inconclusive.

Analyses made to determine the seasonal variation in the composition of eggs showed that the average percentage of the total egg that is dry yolk was 13.85 in October and 15.56 in April; that the phosphoric acid in the dry yolk was 2.607 in October and 2.653 per cent in April; and that the percentage of dry white in the total egg was 8.395 in October and 7.39 in April. However, it is believed that the analyses were too few to justify definite conclusions. The indications are that during the spring when hens are laying well and when the eggs are heavier than at any other time of the year the dry matter of the yolk constitutes a greater percentage of the total weight of the egg than in the fall when the fowls are laying less liberally. This fact presumably accounts for the larger and more perfectly nourished chicks in the spring than in the fall.

In comparing two lots of pullets, one fed on granulated bone in addition to the regular grain mixture, and the other oyster shell, it was found that the former lot laid practically twice as many eggs. The yolks of lot 1 constituted a larger proportion of the total egg substance than did those of lot 2, indicating that a lack of sufficient phosphorus in the ration results in diminished size of yolk. There was also slightly more phosphorus in the dry matter itself when the fowls received abundant phosphorus supply in the ration. The whites of the eggs of lot 2 constituted a greater percentage of the total weight of the egg than did those of lot 1, but the percentage of phosphorus in the whites was identical in both cases. The shells of the eggs laid by fowls fed granulated bone were somewhat heavier in proportion to the total weight of the eggs than the shells of eggs from oyster shell-fed fowls, and contained 6.66 per cent more phosphoric acid, indicating that some of the tricalcium phosphate of the granulated bone was used for shell material. It is not known whether this phosphorus can be assimilated by the developing embryo as is done in the case of calcium carbonate. It was found that the ordinary grain ration fed to laying hens contains several times as much phosphorus as is found in the eggs produced.

Rearing chicks successfully, R. M. SHERWOOD (*Iowa Sta. Circ. 17 (1914)*, pp. 5-15, figs. 6).—In this circular general instructions are given for the rearing of chicks, including natural and artificial brooding, feeds and methods of feeding, and sanitary precautions.

[Turkeys], MARGARET MAHANEY (*Boston, 1913*, pp. XIII+132, pls. 12).—A general treatise on the breeding, care, feeding, management, and diseases of turkeys.

On a case of unilateral development of secondary male characters in a pheasant, with remarks on the influence of hormones in the production of secondary sex characters, C. J. BOND (*Jour. Genetics, 3 (1914), No. 3*, pp. 204-216, pls. 5).—In the case under observation, on careful dissection no trace of a sex gland could be found on the right side. The sex gland on the other side is described as an ovotestis, which probably functioned originally as a female gland. The ovarian portion subsequently atrophied while the tubular gland or male portion became functionally active. Male secondary characters developed on one side of the body only and the hormonal explanation is given as a partial although not a complete solution of the problem.

It is shown that the "presence of male sex gland elements is necessary for the development of secondary male characteristics in every individual whether the female sex gland be present or not, [and that] the essential point is the presence of a stimulating factor rather than the absence of an inhibiting factor." In this particular case "not only are the somatic characters different on the two sides but the sex gland is also a dual gland composed of male and female elements. The bird is in fact a true genetic as well as a somatic hermaphrodite."

In accounting for this abnormal case it is assumed that "the fertilized egg from which this zygote developed was a female egg, i. e., heterozygous in respect of sex, [and that] at the stage of blastomeric segmentation at which the division of the body into two halves was laid down, the sex factor (instead of passing in equal portions to each half of the germ) divided unevenly, the factor for maleness passing into the left half and the factor for femaleness into the right half of the body."

Studies of inheritance and evolution in Orthoptera, I, R. K. NABOURS (*Jour. Genetics*, 3 (1914), No. 3, pp. 141-170, pl. 1, figs. 3).—After a study of more than 5,000 recorded individuals resulting from the crossing of species, the inbreeding and crossing of hybrids, and the crossing of hybrids with species, it is concluded that "the inheritance behavior of the color patterns in these orthopterous insects shows clearly the Mendelian type of inheritance, and the essential result of these experiments has been the extension of this principle to a considerable number of types of a phylogenetically low group of ametabolous insects."

Peat-moss litter; some of its uses; its manufacture and its future on this continent, W. F. TODD (*Jour. Amer. Peat Soc.*, 6 (1913), No. 4, pp. 161-166).—This article treats of the advantages accruing from the use of peat moss as a litter.

It is stated that the moss must be in a finely powdered state to give the best results. Among the advantages claimed for the moss are its disinfecting and deodorizing properties, and its absorbing powers for all liquids and gases. It is also claimed that it keeps away flies, is dustless, free from danger of fire, is from 2 to 3° warmer in winter than straw bedding, is conducive to a healthy growth of the hoof, and adds to the value of the manure. It is claimed that 1 ton of good peat moss will last as long as 2½ tons of straw and that in a box stall one bedding properly handled can be made to last three months. Although but 8,000 tons of peat moss is used annually in this country, Great Britain uses 180,000 tons.

DAIRY FARMING—DAIRYING.

Care, feed, and management of the dairy herd, H. H. KILDEE (*Iowa Sta. Circ.* 16 (1914), pp. 3-39, pl. 1, figs. 9).—The subjects discussed in this circular are the general advantages of dairy farming, the selection of cows and bulls, feeding stuffs, and soiling crops, preparing the cow for her year's work, encouraging persistency of large milk flow, influencing butter-fat production, rearing the calves, feed and care required by dairy heifers, feed and care of the dairy bull, herd records, essentials in dairy buildings, and diseases common in the dairy herd.

The effect of pituitary extract on the secretion of milk, J. HAMMOND (*Quart. Jour. Expt. Physiol.*, 6 (1913), No. 1, pp. 311-338, figs. 2).—From the results of these studies it is concluded that the "injection of pituitary extract has an immediate action on milk secretion, but the effect soon passes off. During the period after injection there is a rather rapid decrease in the milk flow, but this decrease is gradual and there is no sudden drop followed by increasing secretion to normal. This indicates that the effect of the extract is not muscular. The daily yield is only slightly increased as a result of injection. This shows that the extract acts rather by setting free than by causing the formation of the milk constituents.

"From the composition of the milk obtained as a result of injection, together with other facts, it is concluded that the action of the pituitary extract is not effected through rise of blood pressure. The amount of milk secreted as

a result of injection depends on the period of lactation and also on the state of nutrition. This together with other considerations supports the view that it is not variations in the conditions of the pituitary gland which give rise to the cycle of changes which occur in the mammary gland. Histological evidence points to a direct action of the extract on the glandular epithelium. The flattened appearance of the cells of the full alveolus is caused by the expansion which they have to undergo when the lumen becomes filled with milk.

“The milk obtained as a result of injection is normal in composition except for a higher percentage of fat; in the following milkings, however, there is a drop in the percentage of fat although that of the other constituents remains normal. While the solids-not-fat (proteins, lactose, and ash) are secreted in close connection with the water of the milk, the amount of fat secreted is in no wise connected with the amount of water. The ratio ‘nitrogen to lactose’ is relatively constant throughout. These facts suggest the theory that the pituitary extract causes the combination of the precursor of milk protein and lactose (possibly a glycoprotein) with water and salts of the blood, and so by a purely secretory action produces this part of the milk. The suddenly altered tensions so set up in the epithelial cells cause the fat globules which have accumulated at the ends of the cells to be discharged and to produce milk which is rich in fat. It is because of the relatively large amount of the pituitary extract injected and because of the suddenness of the change that the fat percentage goes up. The act of milking, which also causes rapidly altered tensions, has the same effect.

“Although there is considerable variation, yet the average results on varying the dose of pituitary extract injected show that the smaller doses give less milk with a lower percentage of fat. When the doses are relatively large it does not matter how much is injected, for only a certain amount of milk can be obtained. There is some indication that a goat in the early stages of lactation is more sensitive to small doses than one in a later stage. Experiments with fractional milkings show that while the percentage of fat rises from start to finish in normal milk, yet in milk obtained as a result of injection the percentage remains constant throughout.”

Carotin, the principal natural yellow pigment of milk fat: Its relations to plant carotin and the carotin of the body fat, corpus luteum, and blood serum, L. S. PALMER and C. H. ECKLES (*Jour. Biol. Chem.*, 17 (1914), No. 2, pp. 191-249, fig. 1).—This work comprises 5 papers.

I. *The chemical and physiological relation of the pigments of milk fat to the carotin and xanthophylls of green plants* (pp. 191-210).—The object of the investigation here reported was to classify the milk-fat pigment, not only as a true lipochrome, but also with respect to its relation to the carotin and xanthophylls of green plants, and to determine the relative influence of certain factors, such as character of ration and breed of cow, upon the color of the butter. It was observed that “the fat of cow’s milk owes its natural yellow color to the pigments carotin and xanthophylls, principally carotin, the well-known, widespread, yellow vegetable pigments found accompanying chlorophyll in all green plants. The carotin and xanthophylls of milk fat are not synthesized in the cow’s body, but are merely taken up from the feed and subsequently secreted in the milk fat.

“When feed practically free from carotin and xanthophylls, such as the cow usually receives during the winter months, is given to a milk-giving cow, the immediate supply of these pigments in the organism is greatly depleted and may be entirely used up, on account of the constant drain upon the supply by the milk glands. The butter fat accordingly approaches a colorless condition in proportion to the supply of carotin and xanthophylls in the system, the length of

time these pigments are kept out of the feed, and also very probably in proportion to the amount of milk fat being produced.

"If feed rich in carotin and xanthophylls is given to a milk-giving cow whose milk fat has become practically colorless by reason of the above conditions, the organism will at once recover its lost pigments and the milk fat will increase in color in proportion to the amount of carotin and xanthophylls, especially carotin, in the feed. Fresh green grass probably being the richest in carotin of all natural dairy cattle feeds, accordingly produces the highest colored butter.

"There is some difference among the different breeds of dairy cows in respect to the maximum color of the milk fat under equally favorable conditions for the production of a high color. Each breed of cows, however, will undergo the same variation in color of the milk fat which follows a withdrawal or addition of carotin and xanthophylls, especially carotin, to the feed. Under some conditions, also, the apparent breed characteristic largely disappears. The popular opinion in regard to the breed characteristic has been overemphasized, and statements in regard to it should in the future be qualified with a statement of the conditions of the feed, etc. Under normal conditions cows of all breeds produce very high colored milk fat for a short time after parturition. The pigments of the fat at this time are identical with the normal pigments of the fat. Their increase at this time is probably due to the physiological conditions surrounding the secretion of the milk of the freshening animal."

II. *The pigments of the body fat, corpus luteum, and skin secretions of the cow* (pp. 211-221).—In these studies it was found that "the yellow lipochrome of the body fat, corpus luteum, and skin secretions of the cow, like the lipochrome of butter fat, is composed principally of carotin, which sometimes has associated with it one or more minor xanthophyll constituents. The carotin and xanthophyll pigments of the body fat are derived from the feed of the cow. The body fat of Jersey cows formed on a ration deficient in carotin and xanthophylls is devoid of color.

"The body fat of Jersey and Guernsey cows is usually characterized by a higher yellow color than the body fat of other breeds. This is of great importance in explaining why Jersey and Guernsey cows sometimes show a much slower elimination of pigment from the milk fat on a nonpigmented ration, as during the winter months. In these cases the body fat furnishes a supplementary source of carotin and xanthophylls for the milk fat. The yellow body fat of the Jersey and Guernsey cows should not be a point against the use of these animals for beef. The pigments here are the same as those for which the consumer will pay a higher price when present in butter.

"The breeders of Jersey and Guernsey cattle are no doubt correct in their belief that the yellow skin and skin secretions of these animals are characteristic of these breeds. It is not correct, however, that this characteristic is indicative of the ability of the breeds to secrete yellow milk fat under all conditions. The only indication of this is whether the feed contains an abundance of carotin and xanthophylls. The blood serum of the new-born Jersey calf is free from carotin and xanthophylls. The small amount of fat on the body is tinted faintly with these pigments."

III. *The yellow lipochrome of blood serum* (pp. 223-236).—"The well-known lipochrome of the blood serum of the cow is, like the lipochrome of the milk fat, body fat, etc., of the same animal, composed principally of carotin, the widespread hydrocarbon pigment of plants. Associated in small quantity with the carotin of the serum, probably dissolved in the fat of the blood, are one or more xanthophyll pigments which are always found in more or less variable quantity associated with the carotin of plants. The carotin and xanthophylls

of the blood serum are derived from the feed and furnish the normal source for these pigments in the milk fat and body fat, etc. A variation in the quantity of these pigments in the feed results in a corresponding variation in the amount found in the blood serum and milk fat. Body fat formed during this time will also be affected.

"The carotin is carried by the blood serum in combination with an albumin. The combination is a very firm one. Lecithin and cholesterol are probably a part of the combination. We propose the name caroto-albumin for the new chromo-protein of the blood. The caroto-albumin of the blood serum of the cow is probably of importance in the formation of milk fat, body fat, and the corpus luteum of the cow. It is doubtful if this new pigmented protein is of importance in the oxygen respiration of the body. The lactalbumin of cow's milk may, among other factors, be related to the color of the milk fat. There appears to be a special relation here in connection with the high color and high albumin content of colostrum milk."

IV. *The fate of carotin and xanthophylls during digestion* (pp. 237-243).—"Carotin is assimilated from the feed of the cow in preference to xanthophylls partly because of its greater stability toward the juices of the digestive tract. Xanthophylls are much more soluble in bile than carotin, which probably accounts for their appearance in the fat of the blood.

"It is probable that carotin forms by far the greater part of the lipochromes of the cow's body chiefly on account of its ability to form a compound with one of the proteins of the blood. The xanthophylls, being of a different composition, probably are not capable of forming such a compound."

V. *The pigments of human milk fat* (pp. 245-249).—"The fat of human milk may be tinted by carotin and xanthophylls, the pigments which characterize the fat of cow's milk. The relative proportions of carotin to xanthophyll in human milk fat is much more nearly equal than in the fat of cow's milk. The colostrum fat of human milk is characterized by a very high color, as is the case with the fat of the colostrum milk of cows. The pigment of human body fat is no doubt identical with the pigment of human milk fat."

Improvement of the milk supply (*Ann. Rpt. N. Y. Milk Com., 7 (1913), pp. 7-34, pls. 8*).—Part 1 of this report relates to the character and scope of the work of improving the city milk supply; the standards prescribed by the commission and indorsed by the milk dealers; bacterial standards; the resolutions as adopted by the conference of the delegates appointed by the governors of the Eastern and Middle States, called by the New York Milk Committee, to consider the improvement of state laws for the control of milk industry and for the suppression of bovine tuberculosis; investigations conducted on the icing of milk in transit; short-measure milk bottles; transfer of milk on street; milk served at school lunches; hospital milk supply; typhoid and septic sore throat epidemics; and the findings of the conference to consider the fixing of the market price of milk.

Pasteurization in bottles and the process of bottling hot pasteurized milk, S. H. AYERS and W. T. JOHNSON, JR. (*Jour. Infect. Diseases, 14 (1914), No. 2, pp. 217-241, figs. 6*).—The general object of this investigation was to compare on a laboratory scale pasteurization in bottles with the process of bottling hot pasteurized milk.

It was found that pasteurization in the bottle at a temperature of 145° F. for 30 minutes causes satisfactory bacterial reductions, but that bottles should be steamed for at least 2 minutes before being filled with milk. When milk at an initial temperature of 50° is heated in bottles without agitation in water at about 146°, the temperature of the milk in the top of the bottle will reach 140°

in about 9 minutes before that in the bottom. Bottles with chipped or otherwise imperfect tops should not be used, since the seal caps may allow leaks during the process of pasteurizing.

The advantages claimed for pasteurizing in bottles are that the danger of recontamination is lessened and there is a saving in milk losses due to handling and evaporation over coolers. However, greater expense is incurred through the necessity of water-tight caps. The process of bottling pasteurized milk while hot into hot steamed bottles causes equally good bacterial reductions as does pasteurization in bottles and eliminates bottle infection. It was demonstrated that milk may be pasteurized, bottled hot, capped with ordinary cardboard caps, and cooled by a blast of cold air.

It is thought that "if milk is cooled from 145° to 50° within 5 hours no more bacterial increase will take place during the slow cooling than would take place if the milk were cooled immediately to 50°. Whether or not this will be true under commercial conditions can be determined only by future experiments. As far as laboratory experiments indicate, when milk is heated to 145° for 30 minutes, bottling hot pasteurized milk followed by slow gradual cooling has no more appreciable effect on the cream line or flavor of milk than does the ordinary process of pasteurization. This is true for cooling periods of less than 5 hours' duration.

"Since milk contracts on cooling, a quart bottle filled with milk at 145° does not hold a full quart when the milk is cooled to 50°. It is about 0.62 of an ounce short. Therefore slightly oversized bottles should be used.

"The advantages of the process are: (1) That bottle infection can be eliminated, (2) that milk losses are saved, owing to evaporation over the cooler, and (3) that ordinary cardboard caps can be used. The principal disadvantage is that the air-cooling process requires several hours. This, however, would be a disadvantage only in the few plants where milk is delivered directly after pasteurization."

It is concluded from these investigations that the process of bottling hot pasteurized milk followed by air-blast cooling is an entirely feasible modification of the "holder" system of pasteurization. It is proposed to conduct further experiments to test the efficiency of this method on a commercial scale.

The Lobeck biorisator, NEVERMANN (*Berlin. Tierärztl. Wchnschr.*, 29 (1913). No. 48, pp. 862-864).—A description of a recently invented apparatus for heating milk for which is claimed the quality of killing all micro-organisms, including intestinal catarrh of children, cholera, typhus, and tubercle bacilli without destroying the flavor or nutritive value of the product.

The milk is subjected to pressure in a chamber, from whence it is conveyed to a large cylindrical vessel, which it enters in the form of a fine spray and is at the same time subjected to a temperature of 167° F. From the cylinder it passes through a cooler where its temperature is rapidly lowered to at least 50°. The milk is therefore subjected for only a short time to the sterilizing temperature and while in the form of a spray. An advantage of this method is that no milk is lost by evaporation.

Johnson's standardizing computer, C. A. JOHNSON (*Norway, Mich.*, 1913, pp. [44]).—A book of practical standardizing tables for creameries, ice cream factories, dairymen, city milk supply concerns, etc.

VETERINARY MEDICINE.

Results of research in the general pathology and pathologic anatomy of man and animals, edited by O. LUBARSCHE and R. VON OSTERTAG (*Ergeb. Allg. Path. Mensch. u. Tiere*, 16 (1912), pt. 2, pp. VII+845).—The first part of this

annual has been previously noted (E. S. R., 28, p. 178). The contents of the present volume are as follows: Pathology of Cancer, by G. Herxheimer and F. Reinke (pp. 1-343); Regeneration, Transplantation, and Parabiosis, by M. Goldzieher and E. Makai (pp. 344-759); and the Histological Detection and Biochemical Significance of Oxidizing and Reducing Substances Within the Cell, by W. Loele (pp. 760-806).

A large bibliography accompanies each topic.

Studies from the Rockefeller Institute for Medical Research (*Studies Rockefeller Inst. Med. Research*, 18 (1914), pp. VII+596, pls. 77, figs. 22).—This is a collection in one volume of the studies which have appeared from time to time in the literature from the departments of pathology and bacteriology, physiology and pharmacology, chemistry, experimental surgery, experimental biology, and the hospital of the Rockefeller Institute.

The Lister Institute of Preventive Medicine (*Lister Inst. Prev. Med., Collected Papers*, No. 9, pt. 2 (1912-13), pp. [VI+540], pls. 20, figs. 34).—This is a collection of reprints of articles on physiology, zoology, and biochemistry published in various scientific journals.

Blood sugar, I. BANG (*Der Blutzucker. Wiesbaden, 1913*, pp. VIII+162, figs. 13).—This exceptional volume deals with the physiological sugar content of the blood of man, bovine, horse, sheep, goat, pig, rabbit, cat, and other animals, the reducing substances in blood and their distribution, physiological variation of the sugar content of the blood, experimental hyperglycemia and hypoglycemia, the origin of sugar in the blood, and historical facts relating thereto.

Anaphylaxis, C. RICHET, trans. by J. M. BUGH (*Liverpool and London, 1913*, pp. XII+266).—An English translation of this work. Among the topics discussed are the history of anaphylactic phenomena, duration and symptoms of anaphylaxis, anaphylactizing substances, passive anaphylaxis, anaphylaxis in vitro, the relation of anaphylaxis to the precipitin and the complement deviation reactions, antianaphylaxis, anaphylaxis in medicine, and local, chronic, alimentary, and general anaphylaxis.

Studies on the complementary and antihemolytic properties of normal sheep serum, F. M. SURFACE and G. C. ROUFT (*Jour. Med. Research*, 28 (1913), No. 3, pp. 441-463).—"Fresh normal sheep serum contains a complement capable of dissolving sensitized sheep corpuscles. Sheep serum is relatively poor in hemolytic complement. It rapidly loses its complement ability upon standing. Fresh normal sheep serum is able to prevent the action of guinea pig complement. In the fresh serum this inhibiting property is partially masked by the native complement in the sheep serum. If the sheep serum is heated just sufficiently to destroy its complement the inhibiting property remains and can be clearly demonstrated.

"Heating the sheep serum to temperatures below 52° C. increases its inhibiting properties. Heating at temperatures higher than this tends to destroy this property. If the serum is heated to 60° or beyond, both its complement and its antihemolytic property are destroyed. There is an apparent auxilytic action of the guinea pig complement upon the complement of the sheep serum. This inhibiting property of sheep serum is not due to complement fixation by antibodies in the hemolytic rabbit serum. It is probably not due to any precipitate which may be formed by the mixture of guinea pig and sheep serum.

"The evidence indicates that there is a true anticomplement (against guinea pig complement) in fresh normal sheep serum. This is present in relatively small amounts, and most of its action is masked by the sheep complement. If the complement is removed from the sheep serum the anticomplement becomes manifest. The anticomplement is destroyed by heating at 60° and higher.

Defensive ferments of the animal organism, E. ABDERHALDEN (*Abwehrfermente des tierischen Organismus. Berlin, 1913, 3. ed., rev. and enl., pp. XV+229, pl. 1, figs. 11*).—This is the third revised and amplified edition of this work (E. S. R., 30, p. 77) in regard to the ferments which appear in the body and blood plasma as the result of injecting substances foreign to the organism. The diagnostic significance of these factors is discussed in minute detail and the practical application of these principles for the serodiagnosis of pregnancy and infectious diseases is described. The apparatus used for these purposes is pictured.

Protective (defensive) ferments and the serodiagnosis of pregnancy, L. W. FETZER (*Amer. Jour. Vet. Med., 9 (1914), Nos. 2, pp. 79, 80, 96, 122; 3, pp. 149, 150, 203, 204, fig. 1; 4, pp. 248-250*).—This gives an account of the principles underlying the elaboration of the protective ferments in the body (see above), with a detailed description of the technique necessary for conducting the Abderhalden test for diagnosing pregnancy in man and animals. The apparatus necessary is illustrated and criterions for judging the results of the reaction are included.

Preliminary communication on a complement deviation reaction exhibited in pregnancy, G. H. S. CLOWES, F. C. GOLDSBOROUGH, and F. WEST (*Abs. in Proc. Soc. Expt. Biol. and Med., 10 (1913), No. 3, pp. 107, 108*).—Both heated and unheated sera of 25 normal pregnant women in which lues could be excluded were examined, also the blood of the infants taken from the umbilical cord at the time of birth.

The unheated sera invariably contained antibodies capable of causing a well-marked deviation of complement when used in conjunction with an antigen obtained by extracting human blood clots with alcohol. The unheated infants' sera tested under the same conditions gave negative results. Other tissues (antigens) gave a less marked reaction with the unheated mothers' sera and no reaction with the infants' sera.

"The deviation body concerned in this reaction is destroyed by heating for one-half hour at 58° C. The mothers' sera tested after heating were negative to the antigens enumerated above, and those of the infants either negative or very slightly positive, but exhibiting on the whole a somewhat greater capacity to deviate than that possessed by the heated mothers' sera. The deviating capacity of unheated mothers' sera varies greatly, certain cases exhibiting a complete deviation only when employed in concentrations as high as 0.05 to 0.075 cc. of serum, others giving a complete deviation when amounts as small as 0.001 cc. of serum were employed. . . .

"Similar nonspecific immune bodies destroyed by heating at 58° have been observed in cancer and other pathological conditions, and to a certain extent in supposedly normal individuals. The entire absence of these bodies in the blood of newborn infants and their invariable occurrence in the blood of pregnant women at term indicates that in this case at least they probably bear some relation to the reaction of the body against detached fetal cells or proteid or enzymatic bodies of fetal origin. The occurrence of this reaction to a marked extent in cancer, particularly in those cases in which tumors are absorbing under treatment, lends further support to this point of view."

On the antitryptic reaction exhibited in pregnancy, G. H. A. CLOWES and F. C. GOLDSBOROUGH (*Abs. in Proc. Soc. Expt. Biol. and Med., 10 (1913), No. 3, p. 109*).—The antitryptic index was determined in the sera of 25 pregnant women and their infants. "The antitryptic index of the mother's serum was found to range from 1.5 to 2.5, averaging about 2, while that of the infants was found to range from 0.9 to 1.2, averaging slightly over 1. The antitryptic index of a series of cancer cases previously reported shows a range of varia-

tion from 1.2 to 3.5 and gives an average over 2. It will thus be seen that the blood of this series of 25 infants appears to be practically normal. On the other hand, the blood of the mothers contains an extremely high percentage of antibodies to trypsin, averaging over twice the normal, a characteristic also exhibited by cancer blood."

The antitryptic reaction is destroyed by heating the serum for one-half hour at 60° C. and in this respect it resembles the complement fixation as noted in the abstract above. These two reactions may have a common origin.

Abderhalden's biological test of pregnancy, P. F. WILLIAMS and R. M. PEARCE (*Abs. in Proc. Soc. Expt. Biol. and Med.*, 10 (1913), No. 3, p. 73).—"The use of Abderhalden's test for pregnancy [*E. S. R.*, 28, p. 777], employing the dialysis method and the ninhydrin color reaction, has given positive results with each of 28 sera from pregnant women and with 8 from women in the post partum period, including one abortion. The test has never been negative in a known pregnancy. On the other hand, the serum of pregnancy reacts with tissues (kidney, heart, uterus) other than placenta. Also sera of two cases of nephritis, one of tabes and one of infection (carbuncle), and occasionally of some individuals in apparent perfect health, have given the reaction with placenta and other tissues."

The ninhydrin reaction was superior to the biuret test and the small dialysis thimbles (S. & S.) are preferred to the fish-skin membranes originally recommended. Results as satisfactory as those obtained by dialysis are obtained by mixing tissues and serum in tubes, incubating for 24 hours, and testing the filtrate obtained after treatment by heat and acetic acid with ninhydrin.

"As the result of the studies [the authors] feel that this test can not be accepted as an accurate clinical method until it has been more thoroughly investigated and the possible sources of error corrected. This conclusion, however, applies only to Abderhalden's dialysis method and not to his optical method, with which [the authors] have had no experience."

Diagnosis of pregnancy according to Rosenthal, H. SCHOLZ (*Berlin. Tierärztl. Wchnschr.*, 29 (1913), No. 48, pp. 858, 859).—A description of a method which determines the antitryptic index of the serum of the patient with a solution of trypsin and casein. The principle upon which the method is based is Fuld's.

Bactericidal action and chemical constitution with special reference to basic benzol derivatives, C. H. BROWNING and W. GILMOUR (*Abs. in Jour. Path. and Bact.*, 18 (1913), No. 1, pp. 144-146).—In this investigation certain general principles were established, namely "(1) *Staphylococcus aureus* and *Bacillus anthracis* are more susceptible to the action of basic benzol derivatives than are organisms of the coli-typhoid group. This result has been obtained with triphenylmethan derivatives (triamido-triphenylmethan compounds—parafuchsin, fuchsin, hexamethyl and hexaethyl violet, methyl green; diamido-triphenylmethan compounds—Döbner's violet, malachite green, brilliant green, glacier blue, setoglauclin, setosyanin; naphthalin compounds—victoria blue, new victoria blue, night blue), acridin compounds (3.6 diaminoacridin, acridin yellow, and other diaminoacridin derivatives containing CH₃ groups substituted either in the benzol rings or in the amino groups), indamins (Bindschedler's green), azin dyes (toluylene red, safranin), the thinazin group (methylene blue, new methylene blue), thiopyronin; also with tetrachlor-ortho-biphenol, tetrabrom-*α*-kresol. (2) It is not possible to differentiate generally the Gram-positive organisms as susceptible to hexamethyl violet and the Gram-negative group as insusceptible; thus *Vibrio cholerae*, *B. cholerae gallinarum*, *B. B. faecalis alcaligenes* were found to be all comparatively nonresistant to this dye. (3) Salts

of the heavy metals do not act less powerfully on the coli-typhoid group than on *S. aureus* and *B. anthracis*, e. g., mercury perchlorid, silver nitrate, gold chlorid."

Ehrlich and Bechhold have previously pointed out that the action of powerful antiseptics such as mercuric chlorid and tetrachlor-ortho-biphenol was greatly diminished by the presence of serum. In these tests it is shown that sheep's serum heated at 57° C. and unheated serum diminished the antiseptic action for the *S. aureus* only slightly in the case of hexamethyl violet and to a greater degree with brilliant green, while the depression was very marked with tetrachlor-ortho-biphenol. The antiseptic action of diaminoacridin increased for the *S. aureus*, *B. anthracis*, *B. coli*, and *B. typhosus* when serum was present.

The volatile nature of the toxic constituent of poison ivy, C. E. BESSEY (*Amer. Jour. Pharm.*, 86 (1914), No. 3, pp. 112-114).—An account of the personal experiences of the author, who became poisoned by simply looking at the flowers and foliage of poison ivy contained in a box some distance away.

While the author does not deny Pfaff's statement that ivy contains a fixed poison, he emphasizes the fact that a volatile poison must be present also.

Some observations on the pollen of poison sumac, L. E. WARREN (*Amer. Jour. Pharm.*, 85 (1913), No. 12, pp. 545-549).—The alcoholic extract made from the pollen of sumac (*Rhus vernix*) when tested physiologically upon 4 human subjects according to Tschirch and Stevens's method showed no toxic properties. "The evidence that *Rhus* poisoning may be wind-borne is materially weakened by the results, and the theory that poisoning can take place only by contact with the plant receives additional support."

The cause of fagopyrism and some notes on the fluorescent coloring matters in the hulls of buckwheat seeds, K. FESSLER (*Hoppe-Seyler's Ztschr. Physiol. Chem.*, 85 (1913), No. 1-2, pp. 148-155; *Berlin. Tierärztl. Wchnschr.*, 29 (1913), No. 28, pp. 497-499).—Buckwheat, when fed to animals, especially those with unpigmented skins, is often toxic when the animals are exposed to sunlight. Researches by Fischer and others led to the detection of a fluorescent substance which was noted to a large extent in the hulls of buckwheat.

In this investigation the solvents used were alcohol (95 per cent), acetone, ether, chloroform, benzin, and carbon disulphid. The color of the solution obtained varied from a light to a dark green and from a brown red to a red fluorescence. Benzin was colored only slightly and the color of the carbon disulphid solution was olive to light brown and showed no fluorescence. On long standing the color of the solution was changed and the fluorescence lost. Alcoholic solutions became brownish green and ethereal solutions yellow green. Drying also destroys the fluorescence. The green coloring matter was identified as crude chlorophyll; the yellow coloring matter was considered a xanthophyll.

The crude chlorophyll extract contained a brown coloring matter to which the seeds owe their yellow color and which probably belongs to the phlobaphenes of the pyrocatechin group. It is without pathological significance.

Other substances noted were pentoses, mucin, and phytosterol.

As the green coloring matter is strongly photodynamic and as Hausmann has ascribed to it toxic properties, it might be of interest to study the pharmacological action of the various components of the crude chlorophyll extract.

The pathology of growth: Tumors, C. P. WHITE (*London, 1913, pp. XII+235, figs. 89*).—This book deals with the subject under the following headings: Variations in development, growth, and functional activity; regeneration, transplantation, etc.; tumors—introduction; organomata; histiomata; cytomata; the general morphology and relationships of tumors; the origin of

tumors; the growth and life history of tumors; the physiological aspects of tumor growth; the biological aspects of tumor formation; and the causation of tumors.

Biological detection of parasites, I. BARIT (*Über den biologischen Nachweis von Parasiten. Inaug. Diss., Univ. Königsberg, 1912, pp. 31; abs. in Zentbl. Biochem. u. Biophys., 14 (1912), No. 3-4, p. 150*).—No specific complement fixation reaction could be obtained with tapeworm extracts. This is contrary to the findings of Meyer (*E. S. R., 28, p. 880*).

Further note on the growth of filarial embryos in vitro, F. M. JOHNS and P. L. QUERENS (*Amer. Jour. Trop. Diseases and Prev. Med., 1 (1914), No. 9, pp. 620-624, pl. 1*).—In dextrose defibrinated blood from the dog; prepared and inoculated at a temperature of 37° C., the embryos of *Filaria immitis* exhibit growth and motility for a period of about 15 days, when the media and organisms begin to disintegrate.

Investigations on precipitating anthrax serum, W. PFEILER and L. DRESCHER (*Mitt. Kaiser Wilhelms Inst. Landw. Bromberg, 5 (1913), No. 4, pp. 281-305; abs. in Berlin. Tierärztl. Wechschr., 30 (1914), No. 2, pp. 31, 32*).—In the preparation of highly potent precipitating anthrax sera it is necessary to use a strain of bacteria which will become encapsulated when grown on agar medium and the proper kind of animal. No discharge of anthrax bacilli with the feces of the serum animal took place. It was found advisable to draw the blood from the animal 12 days post-injection. Rapidly and highly immunized animals were found to lose in titer after a short time, but the sera from animals immunized slowly but intensely retrogress only slowly.

The precipitating sera do not lose their activity when held at a temperature of 37 to 45° C. for several days, but when temperatures of 56 to 60° are employed they lose their precipitating powers. In other words, the precipitins are converted into precipitoids.

The addition of complement will not reactivate the sera. Freezing once does not affect the precipitation; centrifuging at 13,800 revolutions has likewise no effect. Repeated freezing and thawing, however, affects the precipitating powers of the upper strata of the sera held in tubes, but there is no noticeable increase in precipitins in the lower layers. Concentration of the volume in a desiccator does not increase the activity of the sera nor does slight dilution affect the titer.

Drying the sera and then mixing them with water results in a cloudy solution which can not be used for tests. Drying on filter paper renders the precipitins insoluble, and only a very weak reaction results with the fluid obtained by dissolving the serum solids on the paper. Precipitins, when dried, will stand a greater degree of heat than when in the liquid state and they are not destroyed by alcohol, ether, and chloroform.

The precipitins of anthrax sera belong to the globulins and in most cases they are distributed in this group among the eu- and pseudoglobulins. According to Ascoli the antigen substances of anthrax bacilli give a biuret reaction but none of the other protein reactions. These authors doubt if the biuret test is satisfactory for determining whether bacillary extracts contain proteins.

Viability of the anthrax bacterium, M. J. HARKINS (*Amer. Vet. Rev., 45 (1914), No. 1, pp. 76-78*).—Experiments made with pieces of suture silk which had been immersed in a liquid culture or suspension of anthrax bacteria and then dried and placed in a glass test tube, sealed with a cotton plug and tight fitting rubber stopper, show that anthrax spores are able to propagate for at least 13 years and 11 months, and that the spores under these conditions retain some virulence, if not all, for the same length of time.

Bacteriological diagnosis of anthrax by dried swabs from the blood, and by examination of the skin, J. M. BEATTIE and U. R. PHADKE (*Abs. in Jour. Path. and Bact.*, 18 (1913), No. 1, pp. 115, 116).—"An examination of the skin of infected animals is too uncertain to be of any value as a means of diagnosis. Spores are not formed in dried swabs or in dried skin, and therefore heating the swab or the skin to 70° C. renders a diagnosis still more uncertain; in our experiments it destroyed all chance of a diagnosis. Small quantities of dried, infected blood may give a negative result on examination, and therefore in the examination of hides considerable areas and those taken from different parts of the body should be examined."

The curability of dourine, MONOD (*Rev. Vét. Milit.*, 1912, Dec.; *abs. in Rev. Vét. [Toulouse]*, 39 (1914), No. 3, pp. 164, 165).—The author finds the form of dourine that occurs in North Africa to be curable through the administration of atoxyl and of orpiment (arsenic trisulphid), on alternate days, until five doses have been given. A 10 per cent solution of atoxyl is administered subcutaneously, the dose varying from 4 to 5 gm. The orpiment is administered in boluses of 30 gm.; three cases of poisoning, two ending fatally, have been observed to follow. After an interval of 10 days the treatment is repeated.

Progress and results in transmission experiments by the Imperial Health Department with cytoryctes cocci recorded by Siegel as the cause of foot-and-mouth disease, and with the bacteria said by von Niessen to be the cause of this disease, WEHRLE and ZWICK (*Arb. K. Gsndhtsamt.*, 45 (1913), No. 4, pp. 522-583, figs. 29; *abs. in Rec. Méd. Vét.*, 91 (1914), No. 3, pp. 102-104).—The commission composed of a number of veterinarians appointed to investigate the subject find that the cytoryctes cocci of Siegel (*E. S. R.*, 28, p. 376) while pathogenic are not of etiologic importance in foot-and-mouth disease, and that the microbe of von Niessen does not represent the infective agent, nor is it of etiologic importance, in this disease.

Experiments with Tryposafrol in foot-and mouth disease, SEILER (*Berlin. Tierärztl. Wchnschr.*, 30 (1914), No. 13, pp. 219-224).—The author's work indicates that Tryposafrol has no protective or curative value in foot-and-mouth disease.

Notes on complement fixation in glanders, L. FROTHINGHAM and S. O'TOOLE (*Jour. Med. Research*, 28 (1913), No. 2, pp. 333-344).—The results show that complement may be obtained directly from the heart of a guinea pig without injury to the animal. This allows a series of high titer guinea pigs to be kept for this purpose only, and these can be bled in rotation. The complement may be kept in an ordinary ice box for 3 days with but little deviation of titer in either direction.

"Hemolytic amboceptor kept in a dark room averaging 45 to 50° F. for more than 6 months still holds its original titer. Rabbits may be immunized by the intraperitoneal injection of washed undiluted sheep corpuscles. The immunized rabbit may be bled from the heart without injury and be kept for the future production of amboceptor. Antigen must be titrated against a known positive glanders serum, and again titrated (as a control) without positive serum. Univalent and polyvalent glanders antigens have been kept in a dark room at 45 to 50° for more than 15 months without loss of titer. They have also been kept in an ordinary ice chest for 4 months, and probably can be kept longer under these conditions without deterioration. Titration and the test proper may be much hastened by placing the tubes in a water bath at 37 to 40° C.

"Clear horse serum, rarely needing centrifugalizing, may be obtained by allowing the blood to clot in an inverted test tube against a cork stopper; the clot adheres to the cork and is removed with it. Positive and negative (glanders) horse sera, inactivated, have been kept in a dark room at 45 to 50° F.

for more than a year without deteriorating, and are still occasionally used as controls in the test. Unactivated positive and negative sera have been kept in an ordinary ice chest for 4 weeks, and undoubtedly can be kept longer under these conditions without deterioration. Naturally occurring hemolytics in a serum may be detected in a test by running a hemolytic control."

Further experiments on the biology of Johne's bacillus, F. W. TWORT and G. L. Y. INGRAM (*Centbl. Bakt. [etc.]*, 1. Abt., Orig., 73 (1914), No. 4-5, pp. 277-283).—The results obtained indicate that the animal's food may be the source of the essential substance for the bacillus rather than any substance metabolized by the animal itself, but there is no definite proof that this is so.

A case of Johne's disease successfully treated, J. M'FADYEAN (*Jour. Compar. Path. and Ther.*, 27 (1914), No. 1, pp. 76-78, figs. 2).—A Devon cow about 7 years old suffering from Johne's disease, which came under observation on August 8, is reported to have recovered from the disease. The treatment consisted in the daily administration from August 12 to September 30 of an ounce of a preparation consisting of ferrous sulphate 5 oz., dilute sulphuric acid 5 oz., and water 1 pint, in a pint of water.

Serodiagnosis of rabies, C. A. ZELL (*Amer. Jour. Vet. Med.*, 8 (1913), No. 12, pp. 637-640, figs. 2).—In the experiments animals were infected with street virus and the serum obtained from these animals was tested according to Wassermann's technique (complement fixation reaction), using an antigen made from the submaxillary glands. In all of the animals in which a positive reaction was obtained, i. e., those which came to autopsy, Negri bodies were detected in the brain.

The experiments were conducted with dogs, rabbits, goats, and cats. "Negative reactions were obtained in the following controls: Normal rabbits, dog, cat, dog with distemper, man." "By means of this reaction a diagnosis can be made immediately, without destroying the animal, and further, a test after the completion of the Pasteur treatment will determine whether or not immune bodies are present in the patient's serum whereby a greater degree of assurance can be given the patient."

Rinderpest: Further investigations on questions connected with the economical production of antiserum, J. D. E. HOLMES (*Mem. Dept. Agr. India, Vet. Ser.*, 2 (1913), No. 2, pp. 33-80).—The results of some experiments obtained in the laboratory of the Agricultural Research Institute at Pusa, India, made it imperative that the methods in use for immunization should be abandoned. The newer methods, which have been employed during the past 2 years, have given good results.

The first experiments reported in this work dealt with the value of serum prepared from bulls hyperimmunized by injections of blood from hill bulls during the progress of a modified attack of rinderpest produced by simultaneous injections of serum and virus. The data show that it is possible to modify the attack of rinderpest in these animals by an injection of serum without destroying the value of their blood as an antigen and without sacrificing the animals.

In studying the value of the serum obtained after a natural recovery or after an immunizing reaction only, it is pointed out that the serum is little inferior in potency to that taken after the process of hyperimmunization. Successive bleeding of plains bulls, hill bulls, and buffaloes brought out the fact that the potency of the serum decreases more rapidly in the plains bulls than in the other animals mentioned. The first and second bleeding of all three kinds of bulls yielded a sufficiently potent serum to maintain the standard protective dose. "The third bleeding of hill bulls and buffaloes is about the standard dose and that of plains cattle is below the required potency."

"As a result of the experiments the volume of virus used for injections in the process of hyperimmunization has been further reduced to 2.5 cc. per pound body weight in the case of plains cattle. For hill bulls and buffaloes a volume at the rate of 3 cc. per pound body weight is now used. Further, it has been found unnecessary to increase the volume of virus in each successive injection, as was generally practiced. Animals reinjected several times with the same volume continue to produce a serum of value equal to that obtained after the first injection."

Some further contributions in regard to the chemotherapeutic action of antimony preparations for spirochete and trypanosome diseases, P. UHLENHUTH and G. HÜGEL (*Deut. Med. Wehnschr.*, 39 (1913), No. 50, pp. 2455-2457).—Among a number of organic antimony preparations the following were found to be active against spirillosis in fowls: The sodium salts of acetyl-p-aminophenylantimonic acid, benzolsulphon-p-aminophenylantimonic acid, p-urethanophenylantimonic acid, m-amino-p-urethanophenylantimonic acid, m₁ m¹-diamino-p-oxy-pi-chlorarsenostibiobenzoldihydrochlorid, and m₁ m¹-diamino-p-oxyarsenostibiobenzol. The first three named substances also gave good results in curative tests for rabbit syphilis, and the first two and last two, as well as p-anisylantimonic acid, in experimental dourine in mice. Acetyl-p-aminophenylantimonic acid was also effective in mouse nagana.

In addition to these metallo-organic compounds experimental tests were made with stibium arsenicosum, a colloid preparation with antimony hydroxid, Sb(OH)₃.

The inorganic preparations were of no value in fowl spirillosis.

The present status of our knowledge of the trombidiasis of man and domestic animals and a new trombidiasis of the goat, B. GALLI-VALERIO (*Centbl. Bakt. [etc.]*, 1. Abt., Ref., 56 (1913), No. 5-6, pp. 129-145, figs. 4).—The author states that he has been unable to find any report of the occurrence of this disease in the goat prior to his study of a very grave affection among goats in the Valtelline region, which is here reported upon. The parasite concerned was *Microtrombidium pusillum*, a species which the author had previously found in the same region on the dog.

About the formation of protein and mucin by tubercle bacilli, F. WELEMINSKY (*Berlin. Klin. Wehnschr.*, 49 (1912), No. 28, pp. 1320-1322; *abs. in Chem. Zentbl.*, 1912, II, No. 16, p. 1386).—In cultures of the tubercle bacillus, mucin was repeatedly detected; coagulable albumin was also noted. The mucin does not seem to originate from the dead tubercle bacilli and must consequently be a product of metabolism. The methods used which predispose to mucin formation diminish the virulence of the organism.

A new contribution to the pathology of tuberculosis infection, A. CALMETTE and C. GUÉRIN (*Compt. Rend. Acad. Sci. [Paris]*, 156 (1913), No. 1, pp. 34-37; *abs. in Rev. Gén. Méd. Vét.*, 21 (1913), No. 246, pp. 323-325).—Some authors believe that tuberculosis in cattle, especially the pulmonary form, is due to the ingestion of tubercle bacilli, and others think it caused by the inhalation of tuberculous particles. In order to determine which of the above theories is correct, some experimental tests with cows were conducted. Five adult cows affected with pulmonary tuberculosis were placed in a barn and faced toward the wall. The excrement of all of these animals was infectious for rabbits.

About 3 meters behind these animals ten 10-months-old heifers were quartered but separated from the other animals by a wooden barrier. The barn was so arranged that the urine flowing from the tuberculous cattle would run into the pens of the healthy animals and consequently soil their litter. The cattle were left together in this building for 11 months and then tested with

tuberculin. Five, or one-half of the healthy animals, reacted to tuberculin after this time, 4 showing infection of the lungs and none of the lung cases being free from tuberculosis of other areas. One of the animals showed an infection of all the lymphatic glands; another was infected in the mesenteric, mediastinal, and retropharyngeal glands; another in the bronchial and retropharyngeal glands and lungs; the fourth in the mediastinal glands and the lungs; and the fifth had all glands except the retropharyngeal affected.

The authors are inclined to believe that tuberculosis, like glanders, emanates from the ingestion of the pathologic material.

[Tuberculosis in man and bovine], WAWRINSKY (*Off. Internat. Hyg. Pub. [Paris], Bul. Mens., 5 (1913), No. 8, pp. 1348-1351*).—This reviews the findings of the Swiss commission for the investigation of tuberculosis.

[Tuberculosis in man and bovine], BENTZEN (*Off. Internat. Hyg. Pub. [Paris], Bul. Mens., 5 (1913), No. 8, pp. 1343-1348*).—This discusses the possibility of infecting man from bovine sources, and the Norwegian literature pertaining to this topic is briefly referred to.

The statistics which are given seem to show that the number of cases of the disease in man are the highest in those regions where the greatest number of cases in bovines exist as detected by the tuberculin test. In Norway the use of the tuberculin test is not obligatory, and in localities where the population is less than 4,000, the meat inspection service is not rigid. The author maintains that in order to prevent the disease in man it is necessary to control both the human and the bovine sources of the disease.

Tuberculin, W. G. RUPPEL (*Deut. Med. Wchnschr., 39 (1913), No. 50, pp. 2462-2466*).—A discussion in regard to the various tuberculin preparations and the chemical composition of tuberculin.

Information on "huaicú," J. S. ACOSTA (*Bol. Min. Agr. [Buenos Aires], 16 (1913), No. 5-6, pp. 649-659*).—This paper relates to a disease of domesticated Herbivora, known as "hucú" or "huaicú," which occurs in certain regions of Patagonia. It is caused by the ingestion of a grass that the natives know by the name "coirón blanco." The disease is said to be similar to the tembladera of Rivas and Zanolli (*E. S. R., 23, p. 288*), and to the pataleta of Quevedo (*E. S. R., 30, p. 783*).

[Infectious vaginal catarrh and contagious abortion of cattle] (*Arch. Wiss. u. Prakt. Tierheilk., 40 (1914), No. 3, pp. 193-244; abs. in Cornell Vet., 4 (1914), No. 1, pp. 45, 46*).—Two articles are here presented, the first (pp. 193-211) by P. Schumann on Clinical Investigations of Infectious Vaginal Catarrh and Sterility of Cattle; the second (pp. 212-244) by E. Hieronymi on Bacteriological Investigations of Infectious Abortion of Cattle.

The investigation by Schumann included the examination and study of 2,715 animals in 43 herds. "The determination of the presence or absence of infectious vaginal catarrh in a herd can not be done, as many believe, through the examination of the vagina of a few animals but only through a careful study of the whole herd and the sexual life of each animal. The presence of an acute case alone determines a diagnosis. The mere presence of yellowish-red nodules in the vaginal mucosa should only be considered with the greatest caution as a diagnostic sign. Infectious vaginal catarrh should be considered as existing in a herd if a large number of the animals are affected with nymphomania, without extensive alteration being present in the internal generative organs of these animals.

"Infectious vaginal catarrh should be regarded as healed if the nodules become pale or disappear and the number of nonpregnant animals not due to organic derangement has become small. It should be kept in mind that the nodules do not always completely disappear but may persist for a long time

and as such are harmless. The number of animals which become sterile after affection with infectious vaginal catarrh is relatively large. Sterility, however, does not bear a direct relationship to the number of nodules present in the mucous membrane of the vagina of these cases. Most of the sterile cases have well marked changes in the ovaries, uterus, or cervix.

"Infectious vaginal disease is often combined with infectious abortion. Abortions, however, are not to be attributed to the vaginal disease but are due to the presence of the Bang abortion bacillus. Abortion is often followed by transitory sterility due to retained placenta. On the other hand, the number of cases becoming permanently sterile following abortion is relatively small."

In the bacteriological investigations the author made use of 8 aborted fetuses. In investigations of methods of diagnosing the infection 259 tests were made. "The cause of infectious abortion in cattle is the abortion bacillus of Bang. The abortion organism can be recovered from aborted fetuses. Aborted fetuses show pathological changes which are characteristic of infectious abortion. The agglutination and complement fixation tests are of great help in the diagnosis of this disease. The precipitation test is not reliable for the diagnosis of contagious abortion. Abortion, likewise, is not a reliable agent in the diagnosis of this infection. In the serum of aborted fetuses agglutinins, precipitins, and bacteriolytic amboceptors of the abortion bacilli are not present. The results of the complement fixation or the agglutination test can not be considered as reliable data upon which to base a prognosis. These tests simply indicate whether the animal has been infected with the Bang organism. An infection may not be followed by an abortion. Immune bodies may simply be formed in the body of the infected animal. These antibodies can be found in the blood in undiminished quantities, 2 years and 10 months after abortion. Infectious vaginal disease has no casual relation to infectious abortion."

A bibliography accompanies each account.

Polyarthritis in sheep caused by the swine erysipelas bacillus (*Bacillus rhusiopathiæ suis*), J. POELS (*Folia Microbiol. [Delft]*, 2 (1913), No. 1, pp. 1-9, pl. 1).—In the course of his investigations the author found nine sheep which were suffering from polyarthritis caused by *B. rhusiopathiæ suis*, and thinks that this organism is frequently the cause of the disease.

Pleuro-pneumonia of goats in the Kangra District, Punjab, India, G. K. WALKER (*Jour. Compar. Path. and Ther.*, 27 (1914), No. 1, pp. 68-71).—"The pleuro-pneumonia of goats met with in Kangra appears to be identical with the enzootic pleuro-pneumonia of goats described by Nocard and Leclainche as occurring in Algeria, the Pyrenees, and the Thuringian mountains. The symptoms and lesions are similar, and the failure to transmit the disease from animal to animal is coincident.

"The value of the above experiments is depreciated, no doubt, from the fact that plains animals had to be used. If possible further investigations with hill goats will be made with the object of proving the possibility of transmission by means of intrapulmonary inoculation."

Some common internal parasites (worms) of hogs and their treatment, C. H. STANGE (*Iowa Sta. Circ. 14* (1913), pp. 4, figs. 4).—A brief popular account.

The present status of the hematology of domestic animals, with a report of blood investigations in diseases of the nervous system of the horse, P. SCHRÖPFER (*Der jetzige Stand der Haematologie der Haustiere sowie einige Bluntuntersuchungen bei nervösen Erkrankungen des Pferdes. Inaug. Diss., Univ. Leipsic, 1912, pp. 60*).—The first part of this paper (pp. 7-28), consisting of a review of the subject, is followed by a report of personal investigations, including methods, and studies of nine cases of contagious cerebro-spinal menin-

gitis (Borna disease), and of cases of congestion of the brain, subacute leptomeningitis, subacute encephalitis, purulent meningomyelitis, subdural abscess, and chronic hydrocephalus.

The investigations led to the conclusion that there is no regularity in the blood findings in these cases. A bibliography of 37 titles is appended.

Recent investigations of contagious pneumonia of horses and the salvarsan treatment of this disease, O. SCHWARTZKOFF (*Amer. Vet. Rev.*, 44 (1914), No. 5, pp. 634-641).—This is a review of the subject.

Streptococcic infections of the deep air passages of the horse, J. EGGINK (*Streptokokken-Infektionen der tiefen Luftwege beim Pferde. Inaug. Diss., Univ. Bern, 1912, pp. 33*).—It is very certain that in inflammation of the deep air passages of the horse the streptococci play an important etiological rôle. These streptococci possess a strong hemolytic action. In most cases they possess the power to encapsulate on weak coagulated horse serum.

A malignant catarrhal fever of horses and mules, R. GRAHAM (*Kentucky Sta. Ext. Circ. 12 (1913), pp. 16, pls. 8*).—This circular relates to an acute, febrile, contagious disease of solipeds that made its appearance in a rather virulent form in several counties of Kentucky. The paper deals with the history, cause, symptoms, complications, methods of combating the spread of the disease, treatment, etc.

Investigations of the occurrence and clinical importance of sarcoma in domestic fowls, K. ELSNER (*Untersuchungen über das Vorkommen und die klinische Bedeutung der Sarkome beim Hausgefügel. Inaug. Diss., Univ. Leipsic, 1912, pp. 41, pls. 2*).—This paper includes reports of 18 cases personally observed.

Nematodes of the pharynx and esophagus of the chicken, J. CIUREA (*Ztschr. Infektionskrank. u. Hyg. Haustiere, 15 (1914), No. 1, pp. 49-60, pls. 2, figs. 3*).—This paper deals with *Trichosoma strumosum* and *Gongylonema ingluvicola*.

RURAL ENGINEERING.

The mechanical engineer's reference book, H. H. SUPLEE (*Philadelphia, 1913, pp. 964; rev. in Engin. Rec., 69 (1914), No. 7, pp. 202, 203*).—This book gives in condensed form much of the data required in mechanical engineering.

List of references to publications relating to irrigation in the public library of New South Wales, G. H. GIFFORD (*Sydney, N. S. Wales: Public Library, 1913, pp. 32*).—This list includes not only references to irrigation in Australia but to such works in all countries where irrigation is practicable.

The question of agricultural hydraulics in Tunis (*Bul. Dir. Gén. Agr. Com. et Colon. Tunis, 17 (1913), No. 70, pp. 225-380, pls. 13, figs. 24*).—This publication takes up in some detail the question of the conservation and utilization of the hydraulic resources of Tunis, particularly for irrigation. Reports and studies relative to projected work of this nature, which include rainfall, runoff, and geological data and maps and charts, are as follows: Archaeology and Hydraulics in Tunis, by D. L. Carton (pp. 227-248); The Dam and Reservoir of Hamman-Zriba near Zaghuan, by J. Coignet (pp. 249-265); The Legal Management of Water in Tunis, by G. Barrion (pp. 267-275); How to Improve the Management of Water, by L. Delaporte (pp. 277-283); Method Permitting the More Abundant Use of Wells and Water Sources, by M. Malcor (pp. 285-302); Rainfall of Tunis and Agricultural Hydraulics, by G. Ginestous (pp. 303-345); Agricultural Hydraulics in Tunis, by R. Gagey (pp. 347-355); Prosperity of Irrigated Crops in Algeria, by R. Marés (357-369); and Particular Features of Oasis Irrigation, by P. Penet (pp. 371-380).

Report of public works of Dutch India (*Verslag Burgerl. Openb. Werken Nederland. Indië, 1910, pt. 4, pp. 269, pls. 31*).—This report deals with irrigation and with the conveyance, diversion, and storage of water supplies including both projected and finished works. Detailed plans, maps, charts, and hydraulic and other data accompany the report.

Behavior of cup current meters under conditions not covered by standard ratings, F. C. SCOBEX (*U. S. Dept. Agr., Jour. Agr. Research, 2 (1914), No. 2, pp. 77-83, pls. 2, figs. 2*).—Tests made to determine the applicability of standard ratings when the meter is held near the water surface, near the sides or bottom of the channel, or out of horizontal, and to determine the effect of the movement of the meter in the water when the "integration" method is used, and of dulling the pivot bearing of the meter, are reported and discussed, the results obtained being compared with those of a standard rating.

The main point brought out is that the cup current meter should be actually rated at the surface and bottom of the channel if it is to be operated at these points. The importance of keeping the meter horizontal is also clearly indicated. The added friction due to dulling the pivot bearing had more influence at low velocities, and for velocities greater than 1 ft. per second the sharpness of the pivot was immaterial. When held close against the vertical concrete wall of the channel so that the open and closed sides of the turbine were brought next to the wall alternately, the meter ran true to the standard curve but disregarded the cycloidal motion of the water.

All vertical movement of the meter when the vertical integration method was used tended to turn the wheel in the same direction as did the flowing water. For slower movements of the meter this tendency was insufficient to overcome the internal friction in the meter, but when it was operated in running water the water overcame the internal friction and the force due to the vertical movement of the water was still available to turn the wheel and cause it to overregister. "It appears that a cup meter underregisters at all points nearer the surface than about 0.3 ft., and also while very near the bottom. Therefore, in a process of vertical integration with a cup meter there is a tendency to overregistration at all times due to the vertical motion, and a tendency to underregistration while the meter is passing from 0.3 ft. below the surface up to the surface and back to that point and while near the bottom."

Cost and methods of clearing land in the Lake States, H. THOMPSON and E. D. STRAIT (*U. S. Dept. Agr. Bul. 91 (1914), pp. 25, figs. 10*).—This bulletin gives detailed cost data and discusses land clearing in Michigan, Wisconsin, and Minnesota by explosives alone, by explosives used in connection with stump pullers or block and tackle, by stump pullers alone, and by power machinery. In addition data of the work of clearing 20 different tracts are presented.

There are said to be approximately 11,954,628 acres of logged-off land in Michigan, 10,792,100 acres in Wisconsin, and 11,768,000 acres in Minnesota, a large part of which will make good agricultural land if cleared and properly managed.

"Cutting and burning the second growth, pasturing for several years, and keeping down all sprout growth is the most economical method of handling all logged-off lands before stumping them. Explosives play an important part in clearing land. On the heavier soils dynamite, with 20 to 30 per cent of nitroglycerin or its equivalent, is to be preferred. Cooperative buying in large quantities is recommended. Stump pullers reduce the cost of stumping on lighter soils. On the heavier soils the difference between the cost of clearing by explosives and by the use of stump pullers is very slight.

"The cost of clearing the better grade of white-pine logged-off land will average \$10 per acre for disposing of the brush and \$25 to \$30 per acre for disposing of the stumps. Some green hardwood lands and unburned swamp lands will cost as much as \$100 per acre. Some of the poorer jack-pine lands can be cleared for \$5 per acre or less. The cost of disposing of the stumps after pulling practically equals the cost of pulling. A tripod or a boom piler is recommended to facilitate piling and burning."

It is concluded that the settler with little capital and no experience will meet with serious difficulties in attempting to make a farm out of a tract of logged-off land, and it is recommended that "in all localities where land companies are selling lands to settlers, no tract of land be sold unless it contains at least 10 acres of land cleared ready for the plow."

A manual of the law of roads and highways in the State of Kansas, W. R. ARTHUR (*Topeka, Kans., 1913, 13. ed., pp. 126*).—This handbook includes the laws relating to roads and highways passed by the legislature of the State up to and including the session of 1913, and is intended as a text-book and compilation of the duties and powers of highway officials.

History of road legislation in Iowa, J. E. BRINDLEY (*Iowa City, Iowa, 1912, pp. XIII+422*).—This volume deals with road legislation in Iowa from the year 1838.

Bibliography of road-making and roads in the United Kingdom, DOBOTHY BALEN (*London, 1914, pp. XVIII+281*).—The contents of this bibliography are classified under the general headings of (1) history and description, (2) administration, (3) engineering, and (4) traffic.

An investigation of sand-clay mixtures for road surfacing, J. C. KOCH (*Proc. Amer. Soc. Civ. Engin., 40 (1914), No. 2, pp. 269-296, figs. 9; abs. in Engin. and Contract., 41 (1914), No. 11, pp. 321-324, fig. 1*).—The author presents the results of two years' studies in both field and laboratory of sand-clay mixtures for road surfaces and describes an approximate field method for the examination of sand-clay mixtures and methods of construction with natural and artificial mixtures.

The conclusions from the laboratory tests are as follows:

"The content of sand smaller than No. 60 is of little value in the mixture, that smaller than No. 100, except in very small quantities, is detrimental. The greater the proportion of coarse to fine sand the harder and more durable will the road surface be. For the best possible results with sand-clay mixtures, the sand smaller than No. 10 and larger than No. 60 should not be less than 45 per cent nor more than 60 per cent, by dry weight, of the entire sample. In addition, the sand smaller than No. 10 and larger than No. 60 should be composed of about equal parts of Nos. 20, 40, and 60. The total sand content should in no case exceed 70 per cent by weight of the total sample.

"Test cylinders of the sand-clay mixture, 1 in. in diameter and 3 in. long, should, when thoroughly dried in air bath at 100° C., take at least 2 minutes, when immersed in water at 21°, to crumble down to the natural slope of the material, and preferably should take 6 minutes. If the cylinder fails in this test, it should be regarded with suspicion. If the sand analysis is poor and the cylinder test is also poor, the material is not worth using."

Similarly, test cylinders made from the clay removed from the sample should take at least 2 minutes to crumble. If the material fails in this test but passes that of the preceding paragraph it may be used, but indicates a poor quality of binder.

Standards of concrete road construction (Engin. Rec., 69 (1914), No. 8, pp. 214-216).—A résumé of committee reports at the National Conference on

Concrete Road Building bearing on standard practices in concrete road construction includes recommendations as to specifications, construction, maintenance, and cost.

The contraction and expansion of concrete roads, R. J. WIG, N. H. TUNNICLIFF, and W. A. MCINTYRE (*Abs. in Engin. and Contract.*, 41 (1914), No. 8, pp. 257-262, figs. 4; *Engin. News*, 71 (1914), No. 9, pp. 446-449, fig. 1).—Experimental data are reported relating to the effect on expansion and contraction of concrete in concrete roads of changes in the temperature and variations in the moisture content of the concrete, variation in the condition and character of the sub-base, and excessive loading by traffic. These data "indicate that the effect of moisture content is very much greater than the effect of temperature change, and may be sufficient to cause a stress in the concrete opposite to that which would be caused by a normal temperature change. A variation in the quality of the concrete will cause a variation in the tendency to expand and contract with change in moisture content."

It is concluded that a proper combination of change in temperature, change in moisture content, and friction have made possible the construction of long slabs which have remained free from cracks. "With a proper understanding of the physical phenomena . . . and a proper application of engineering principles it is believed . . . that all expansion and contraction of concrete in roads can be so controlled as permanently to avoid cracking."

Design of reinforced concrete, C. AUBRY (*Calcul du Beton Arme. Paris, 1913; rev. in Sci. Amer.*, 110 (1914), No. 8, p. 168).—This is a compilation of formulas, tables, and diagrams in compact form for use in designing and estimating reinforced concrete.

Concrete destruction by ground water containing sulphates (moor water), SCHEELHAASE (*Abs. in Wasser u. Abwasser*, 7 (1914), No. 11, p. 464).—Investigations on the effect of moor water on concrete led to the conclusion that water containing gypsum, such as moor water, is able to destroy concrete, this destruction being produced by increase in volume. The effect on concretes made from different makes of cement was entirely different and the age of the concrete had little influence on the processes of destruction. Concrete made with certain cements was not destroyed.

How to calculate the losses in gas engines, G. W. MUENCH (*Power*, 39 (1914), No. 7, pp. 248, 249).—Simple calculations are given showing how to figure the heat balance of a gas engine with a degree of accuracy which is considered close enough for ordinary purposes.

Notes on power variation with atmospheric changes, H. CHASE (*Gas Engine*, 15 (1913), No. 11, pp. 627, 628).—Tests of an internal-combustion motor showed appreciable power variations with marked changes in barometric pressure.

Power losses due to tardy ignition, R. TRAUTSCHOLD (*Gas Engine*, 15 (1913), No. 11, pp. 604-607, fig. 1).—The author points out by data, curves, and discussion that tardy ignition in an internal combustion engine decreases the power output by reducing the mean effective pressure and by causing inefficient expansion of the products of combustion in the engine cylinder.

Elementary machine design, W. C. MARSHALL (*New York and London, 1912, pp. VIII+320, pls. 3, figs. 193; rev. in Science, n. ser.*, 39 (1914), No. 999, p. 288).—This is a book of information and instruction on machine details, and is intended for students who have not studied mechanics and mechanism, although considered to be of service to draftsmen who are already familiar with the principles and methods of machine design. It contains chapters on machine drawing, rivets and riveted joints, piping, screws and bolts, shafting

and shaft couplings, stuffing boxes, bearings, journals, hangers, pistons and piston rods, connecting rods, pulleys, belting, gearing, and valves.

Methods for calculating the accomplishment of the motor plow, O. KASDORF (*Rev. Min. Indus. Uruguay, 1 (1913), No. 6, pp. 105-111*).—The author describes and illustrates the use of formulas for calculating the accomplishment of traction plows per unit of time. Tables of test data show the relation between the draw bar pull and the weight of the tractor and the relation between the effective motor horsepower and effective draw bar horsepower. The author considers the resistance of the soils per unit area to be of prime importance in his computations.

Sawing ice by electricity (*Elect. World, 63 (1914), No. 8, p. 427, figs. 2*).—The use of electrically driven ice saws is briefly described and illustrated.

The plant consists of two sets of 36-in. saws installed in an artificial channel 20 ft. wide, each set being belt-driven by an induction motor. The ice is floated in 12 by 18 ft. cakes to the artificial channel where it is cut into 20 by 28 in. blocks. This method is claimed to effect a great saving in time and labor.

Farm structures, K. J. T. EKBLAW (*New York, 1914, pp. VIII+347, figs. 159*).—This book, written for both the teacher and the progressive farmer, is intended to impart a working knowledge of the construction of practical and economical farm structures. A description of building materials is followed by a discussion of farm building location and the basic methods employed in simple building construction, including designing and estimating. The application of the methods is illustrated by typical plans of various farm buildings and structures. Descriptions of the more essential requirements in the way of equipment and farm life conveniences, including heating, lighting, and ventilation of buildings, and water supply, plumbing, and sewage disposal are appended.

Modern farm buildings, A. HOPKINS (*New York, 1913, pp. 206, pls. 47, figs. 77*).—This work suggests approved designs for the cow barn, dairy, horse barn, hay barn, sheepcote, piggery, manure pit, chicken house, root cellar, ice house, and other buildings of the farm group, based on practical, sanitary, artistic, and financial considerations.

Farm buildings, C. J. WHILLAS (*Jour. Dept. Agr. So. Aust., 17 (1914), No. 6, pp. 654-659, figs. 6*).—Plans are given of farm buildings, including the stable, barn, and machine shed, with a discussion.

The fool-proof poultry house, T. E. QUISENBERRY and R. SEARLE (*Missouri Poultry Sta. Bul. 4 (1914), pp. 61, figs. 44*).—This bulletin illustrates and describes a number of poultry houses which "are the result of several years of very careful testing and experimenting with practically all of the styles of poultry houses found in the country to-day." The types dealt with are recommended to farmers and the poultry raisers of Missouri as being peculiarly adapted to the conditions of that State.

Separation of horses in the stable, M. RINGELMANN (*Jour. Agr. Prat., n. ser., 26 (1913), No. 35, pp. 273, 274, figs. 2*).—This article describes and illustrates devices for easily and safely separating horses in stalls.

Farm conveniences, W. H. DAY (*Ann. Rpt. Ontario Agr. and Expt. Union, 34 (1912), pp. 81-89*).—Farm water systems, farm sewage disposal, farm power, and the theory of the hydraulic ram are briefly discussed.

Estimating the cost of modern improvements (*Dom. Engin., 66 (1914), No. 9, p. 268*).—A table of approximate figures is given showing the cost of water supply, plumbing, sewage disposal, hot air or hot water heating, gas and electric lighting, laundry and dairy equipment, gasoline storage, vacuum cleaner, and refrigerating plant for country houses in proportion to the cost of the house. The houses used range from a 5-room cottage costing \$2,000 to a

15-room country residence costing \$15,000. "Generally, as the basic cost of the house is greater, the percentage that expresses the cost of equipment for same becomes less."

Water supply for farm or cottage (*Jour. Soc. Agr. Suisse Romande*, 55 (1914), No. 2, pp. 29-34, figs. 3).—An automatic water elevator for use in obtaining rural and residential water supplies is described and illustrated which is claimed to be more efficient and convenient than the hydraulic ram. This machine consists essentially of an impulse cylinder below and a compression cylinder above. Besides the impulse cylinder is placed a governor which regulates the entrance and escape of the impulse water. The piston of the compression cylinder is directly connected to that of the impulse cylinder by an iron bar. The disadvantages of this system are said to be its higher cost and the necessity of special construction for each installation.

Rural water supply, C. A. OCOCK (*Country Gent.*, 79 (1914), No. 8, pp. 376-378, figs. 3).—The author briefly describes the gravity, compression, and pneumatic systems for supplying running water to farm homes and gives hints as to installation, operation, and cost.

Disposal of sewage from isolated country houses, mansions, and public institutions, T. W. STAINTHORPE (*Agr. Jour. Union So. Africa*, 7 (1914), No. 1, pp. 60-62).—In a discussion of sanitary conditions in rural South Africa, the author gives a brief description of a small "bacterial" installation for a country house, mansion, or institution with an average population of 15 or 20.

Prevention of malaria, R. H. VON EZDORF (*Pub. Health Rpts. [U. S.]*, 29 (1914), No. 9, pp. 503-508, pls. 2).—Suggestions on how to screen the home to keep out effectively the malarial mosquito are given, these dealing principally with material, screening of doors, windows, and other openings where mosquitoes enter, care and repair of screens, and the economic value of screening.

The best size of mesh for all purposes is said to be the 18 mesh, that is, 18 strands of wire to the linear inch in either direction. A 16 mesh is said to be quite efficient and if carefully painted will practically be equal to an 18 mesh. "Even copper or bronze wire should be treated with some varnish or paint, as it is likely to oxidize and corrode when exposed to a damp climate, particularly near the seashore. . . ."

To be of proper construction, a doorframe should be made of cypress or other seasoned wood 1 to 1½ in. thick, well braced and painted. The wire should be of 16 or 18 mesh. The lower panel should be covered on the inner side with a one-fourth inch mesh wire guard to protect the screening. . . . An easy fitting door, fully one-fourth inch clear all around the edge is best, and to make it mosquito proof it will be necessary only to tack a strip of light canvas 1 in. wide around the top and one side of the door facing on the outer side. . . .

"The most efficient method of screening a window is to screen the entire opening. A well-fitting screen frame which is screwed into place so that it can be removed at the end of the season is probably the best. . . ."

"Other places to be absolutely screened are the fireplaces, openings into chimneys for stove pipes, drain holes, ice-box drips through floors, and the like. . . . If the porches are screened, the holes at the bottom for draining off water should also be screened. . . ."

"In repairing torn wire screening, a small piece of wire netting cut to size should be placed over the torn opening and fixed into place by sewing or lacing with a strand of the wire."

The economic value of screening is illustrated by a typical example and numerous cost data are given.

Modern practice in heating and ventilation.—XIII, Various devices for forcing circulation in domestic hot water heating plants, A. G. KING (*Dom.*

Engin., 66 (1914), No. 8, pp. 231-234, figs. 8).—This article describes and illustrates devices including generators, accelerators, heat retainers and intensifiers, etc., "all of which are designed to allow an increase in the temperature of the water in a hot water heating system by sealing it to the atmosphere and by the maintenance of a small pressure within the apparatus quicken or accelerate the circulation."

Planning lighting installations, J. B. JACKSON (*Jour. Electricity*, 32 (1914), Nos. 8, pp. 164, 165; 9, pp. 184, 185, fig. 1).—The author presents by means of tables of data, diagrams, and discussions, a simple method of calculating illumination for residences which though approximate is considered applicable to the majority of lighting installations.

Housing and town planning, edited by C. ARONOVICI (*Philadelphia*, 1914, pp. VI+270).—This collection includes papers dealing with the new and old house and with town planning. Topics of rural interest are Housing and the Housing Problem, by C. Aronovici; The Workingman's Home and Its Architectural Problems, by F. A. Bourne; The Old House as a Social Problem, by Mildred Chadsey; Fire Waste, by P. Evans; and Rural Housing, by E. S. Forbes.

RURAL ECONOMICS.

Farmers' law, L. V. KOOS (*St. Paul, Minn.*, 1913, pp. 156, figs. 18).—The author has attempted to prepare a concise manual of such common and statute laws as bear most closely upon the farmer in his everyday affairs. This edition applies primarily to conditions in Minnesota.

Handbook of agricultural laws, compiled by E. O. LUTHER (*Nashville, Tenn.: Dept. Agr.* 1912, pp. 89).—There are given in this handbook the laws relating to the bureau of agriculture, fertilizers, agricultural seeds, food control, state board of entomology, apiaries, department of immigration, state fairs, live stock control, and legal weights and measures.

The problem of double entry farm bookkeeping, B. LAMBERGER (*Beiträge zu den Problemen der Doppelten Landwirtschaftlichen Buchführung. Diss. Univ. Giessen*, 1913, pp. 106).—The principal part of the author's discussion is devoted to the various methods that may be used to determine the value of the crops which are produced and consumed on the farm and to determine their profitability or unprofitability.

Agricultural credit.—Personal or short-term credit (*U. S. Senate*, 63. Cong. 2. Sess., Doc. 380, pt. 3 (1914), pp. 32).—This report contains an analysis of the findings of the United States Commission (E. S. R., 28, p. 301) in regard to the uses of personal or short-term credit as found in European countries. The Commission believes that although it is within the power of Congress to pass laws providing for credit unions or cooperative credit associations and make them fiscal agents of the National Government yet the conditions of agriculture differ so widely, the needs of the farmers vary so greatly, and the status of the different classes of people in rural communities are so unlike that laws relating to short-term credit can best be enacted by the various state legislatures. See also a previous note (E. S. R., 30, p. 792).

Agricultural credit in the French colonies, L. GAMARD and L. TARDY (*Ann. Sci. Agron.*, 4. ser., 3 (1914), No. 2, pp. 57-83).—The author outlines the organization of agricultural credit in France and the principal French colonies, and concludes that the only system which can be a success is a mutual credit organization from underneath, that is to say it must be based on local institutions where the members know each other and can observe what is being done with the loans.

The cooperative movement, G. KEEN (*Amer. Coop. Jour.*, 9 (1914), No. 5, pp. 358-362).—The author points out that the weakness of the cooperative plan as advocated by Robert Owen was the absence of democratic control and the sense of individual responsibility by the members themselves in the initiation and management of the societies, but that cooperative societies formed upon the plan of the Rochdale system or the Cooperative Wholesale Society of England have been very successful and have also helped to solve the problem of the trusts. He believes that there is no force strong enough to destroy or even to injure seriously the property, power, or influence of a body of intelligent people who organize their own demand for the necessaries of life and proceed to satisfy it by production under their own control. To be successful, however, a cooperative movement must have an educational department to propagate knowledge concerning itself.

Manual on cooperation (*N. Y. Dept. Agr. Circ. 94* (1914), pp. 33).—Included in this circular are the following articles: A Primer of Cooperation, by M. W. Cole; The Citizens' Cooperative Supply Company, Schenectady, by J. C. Bellingham; One Cooperative Success, by L. C. Tuckerman; The Extent to which Cooperation in Europe is Adaptable to American Conditions, by F. H. Allen and C. C. Mitchell; and Cooperative Buying by Consumers, by E. P. Harris. In addition there is a model form of by-laws for cooperative societies.

"Grand View," a rural experiment in medical cooperation, W. H. BROWN (*Survey*, 31 (1914), No. 26, pp. 797, 798, fig. 1).—The author describes the methods used to establish a hospital in the rural districts of Bucks County, Pennsylvania. This hospital is so organized that any reputable physician can take his patient to it and give him treatment. The nurses are recruited from the rural districts, and after a year's experience in the hospital are sent out to nurse cases under the supervision of the hospital. By means of this scheme it is hoped that the whole countryside will be given the benefit of the best in medical science.

A social survey for rural communities, G. F. WELLS (*New York*, 1911, pp. 23).—The author outlines a scheme for making a social survey and gives a list of 225 items to be included in the questionnaire.

Our recent immigrants as farmers, L. STEINER (*Amer. Rev. of Reviews*, 49 (1914), No. 3, pp. 342-345).—The author shows that most of the immigrants coming to the United States come with the expectation to save enough money from their earnings to return to their native country to buy land. He advocates that an organization be formed to encourage, assist, and direct qualified immigrants to purchase and cultivate farms in the United States instead of migrating to foreign countries to engage in agriculture.

The German-American farmer, J. OCH (*Der Deutschamerikanische Farmer*, Columbus, Ohio, 1913, pp. XIX+248, pl. 1).—The author discusses the migration of Germans to the United States, the coincidence of the spread of grain production to the North Central States with the coming of the Germans, the relation of the first and second generation of Germans to agriculture, and the influence of the Germans upon our social and economic institutions. The book also contains a bibliography and a considerable number of statistical tables.

The question of agricultural population, A. D. WEEKS (*Pop. Sci. Mo.*, 84 (1914), No. 3, pp. 251-256).—Among the conclusions reached by the author is that the number of persons engaged in an occupation bears a very close relation to the economic attractions offered. The steady and rapid drift of the agricultural population to the cities implies the economic dominance of the occupations of the city. With an increase of purchasing power the prosperous consumer wants but little if any more of the direct farm products while his desire for other values increases. It is deemed unreasonable to urge a larger

relative agricultural population without simultaneously urging organization among farmers to regulate farm products and to hold prices to a level which would enable them to approximate the standard of living characteristic of cities unless cheap farmers are desired as well as cheap food.

The rural population, T. G. CHAMBERS (*Jour. Farmers' Club [London], 1914, Apr., pp. 45-55*).—Among the general conclusions reached by the author from his study of the changes in the rural population of England and Wales between 1901 and 1911 are that each rural district must be considered by itself, so that it is impossible to generalize for the country as a whole. Some of the causes influencing the rural population are improved traction, better means of communication, intrusion of mining and manufacturing into the rural districts, and increase of residential population. He believes that as a whole the rural population of England and Wales will continue to increase.

The rural problem, H. D. HARBEN (*London, 1913, pp. VIII+169*).—The author discusses the decline in the rural population of England and Wales and its relation to the problem of wages and the housing of farm laborers. He also calls attention to the problems of small holdings, tenancy and ownership, agricultural education, and organizations, and submits a number of recommendations for improving the condition of the farm laborer.

Development of agriculture in the United States and its influence on prices of agricultural products, M. AUGSTIN (*Schr. Ver. Sozialpolit., 141 (1914), pt. 2, pp. 149, pl. 1*).—The author discusses the relative variations in the increases in population, land in farms, improved land, rural population, values of farm property, farms by sizes, and farm mortgages; agricultural associations; transportation facilities; the farm labor question; the use of machinery, manure, and irrigation; the extensive character of American agriculture and importance of the single crop system; and relative changes in the number of live stock and their geographic distribution. He concludes that the agricultural development of the United States has reached a climax and that never again will its exports become sufficiently important to cause a depression in the prices of cattle or grain on the world's market.

Crop yields and prices, and our future food supply, G. F. WARREN (*New York Cornell Sta. Bul. 341 (1914), pp. 185-211, figs. 3*).—Statistical data are summarized from publications of the U. S. Census and the Department of Agriculture, and discussed.

Some of the conclusions reached by the author are that prices that the farmer now receives for animal products are higher than the average for the past 73 years, but that prices received for crops are generally as low or lower. Crop yields east of the Mississippi River have been rapidly increasing in the last 10 to 15 years. It is believed that farmers raise larger crops when they are convinced it will pay. More land also will be brought into use when the prices of farm products will guarantee a profit on the extra expense of clearing, draining, irrigating, etc. There is a tendency for the people in the United States to use more plant foods and less animal foods. To reduce the size of farms and to import cheap labor to help farm is deemed likely to result eventually in more expensive rather than cheaper food. The machinery of distribution after products leave the farm is considered unnecessarily expensive.

An investigation of the phosphorus supply in this country, with a view to restriction of exports, is advocated.

The history of the grain trade in France, 1400-1710, A. P. USHER (*Harvard [Univ.], Econ. Studies 9 (1913), pp. XV+405, pls. 2*).—The author outlines with considerable detail the changes that took place in the systems of marketing grain in the different parts of France during this period. Among

the features discussed are the history of the Parisian markets, the *Chambre d'Abondance* at Lyon and the wholesale merchants, Lyonese merchants and dearth in the producing regions, royal and local regulation of the grain trade 1500-1660, Colbert's place in the history of the grain trade, and regulation of the domestic grain trade, 1683-1709.

The condition of agricultural production in Argentina, E. A. J. PFANNEN-SCHMIDT (*Schr. Ver. Sozialpolit.*, 141 (1913), pt. 1, pp. V+89).—The author discusses the physical characteristics, immigration, system of land ownership, areas and distribution of the principal crops, cost of producing crops, trade in agricultural products, number of live stock and changes in proportion of those native bred, and the trade in meat products.

Production in the French colonies in 1911-12, E. BAILLAUD (*Inst. Colon. Marseille Notice 10* (1913), pp. VIII+85).—This report shows by statistical tables the quantity and value of agricultural products imported and exported for practically all the French colonies, as well as the number of live stock in several of the colonies.

[Agriculture in Victoria], A. M. LAUGHTON (*Victorian Yearbook*, 33 (1912-13), pp. 619-733, pl. 1).—Included in this annual statement is a discussion of the following subjects relating to agriculture: Land settlement, irrigation, rainfall, number of holdings by sizes, land occupied and cultivated, number of live stock, number of persons engaged in agricultural pursuits, area and production of farm crops, fertilizers used, machinery and implements on farms, number of dairy cows, butter and cheese made, number of cream separators in use, number of live stock slaughtered, and wool production. In most instances the subjects are accompanied by statistical tables.

Prices and wages in India (*Prices and Wages India*, 30 (1913), pp. VI+218).—Contained in this report are statistical tables showing for 1873 and from 1888 to 1912 the average annual retail prices of the principal farm crops at certain selected districts and stations, wholesale prices of staple articles of import and export at Calcutta and Bombay, and average monthly wages of skilled and unskilled laborers for certain selected districts and stations.

AGRICULTURAL EDUCATION.

Report on agricultural education, L. C. COLEMAN (*Dept. Agr. Mysore, Gen. Ser. Bul. 3* (1913), pp. 72).—The author gives an account of the systems and methods of secondary, elementary, and popular instruction in agriculture in Germany, Switzerland, England, Canada, the United States, Japan, and the Philippines, the information having been gained by personal visits supplemented by the perusal of literature on this subject. He also discusses the adaptation of some of these agencies and methods of agricultural instruction to conditions in Mysore. Outlines of the courses of study of the Dunn County School of Agriculture, Menomonie, Wis., the La Crosse County School of Agriculture, Onalaska, Wis., and the University of Minnesota School of Agriculture; conclusions of the committee of the National Council of Education on industrial education in schools for rural communities; and the syllabus of the elementary course in agriculture of the committee on instruction in agriculture of the Association of American Agricultural Colleges and Experiment Stations are appended.

Annual report of the director of education [of the Philippines] (*Ann. Rpt. Dir. Ed. P. I.*, 1913, pp. 149, pls. 22).—This report shows that in 1912-13 there were 5 agricultural schools (grades 1 to 7, inclusive) with a total enrollment of 287 pupils. All of these schools, except the Central Luzon Agricultural School at Munoz, Nueva Ecija, which is much more advanced and better

equipped, enroll non-Christian pupils only. These schools are boarding schools where pupils are maintained by the government. They had a total area of 984 hectares (2,430 acres) of which 131 hectares were under cultivation. There were also 6 farm schools of intermediate grade (grades 5 to 7, inclusive) with a total enrollment of 633 pupils. Schools of this type must have at least 10 hectares of land and the maintenance of pupils is not provided for. Statistics are also given of the animals and value of products at these schools, as well as of the number of pupils in farming, housekeeping and household arts, settlement farm schools, school and home gardens, school nurseries, and corn contests in the various elementary and intermediate grades of the Philippine schools.

The tropical agricultural college, C. F. BAKER (*Philippine Agr. and Forester*, 2 (1912), No. 4-6, pp. 98-103).—The author discusses the development of tropical agriculture and the organization and mission of the agricultural college in this direction.

Twentieth annual report of the inspector of state high schools of Minnesota (*Ann. Rpt. Insp. State High Schools Minn.*, 20 (1913), pp. 67, figs. 3).—This report for the year ending July 31, 1913, shows that there were 94 state high schools which received a total state aid of \$133,646 for instruction in agriculture. Agriculture was taught in 123 high schools to 3,631 students, cooking in 130 high schools to 4,795 students, sewing in 154 high schools to 5,637 students. The total expenditure for agricultural equipment was \$37,016 and for cooking and sewing equipment \$45,020. An outline is given of the home economics instruction, as well as notes on agricultural instruction and statistical tables of enrollment in agriculture and home economics in regular and short courses, expenditures for salaries, real estate, agriculture, home economics, etc., for the high schools receiving state aid for agriculture.

The usual course in agriculture consists of general agriculture taught from an elementary text-book once a week in the seventh and eighth grades, a freshman class in farm crops, and a sophomore class in live stock. A few of the stronger schools have a third and fourth year's work in soils and farm management.

Correspondence courses, O. H. SELLERS (*Tex. Agr. and Mech. Col. Ext. Bul.* 9 (1913), pp. 15).—This is an announcement of general information concerning correspondence courses in agriculture offered by the Texas College.

Report of the bureau of children's school farms for 1912 (*Rpt. Bul. Children's School Farms* [N. Y. City], 1912, pp. 20, pls. 12).—This is a report of the work and influence of the Thomas Jefferson and DeWitt Clinton Park children's school farms in New York City for 1912.

The school as a social center, G. H. EDWARDS, JR. (*Bul. Univ. S. C.*, No. 35, pt. 2 (1913), pp. 73).—This is a dissertation on what this movement is, its relation to other social movements, its value and extent in South Carolina, and what should be done in the State. A bibliography is appended.

How can the girls' industrial club work be made a part of the rural school work? SUSIE V. POWELL (*Proc. Conf. Ed. South*, 16 (1913), pp. 78-81).—The following methods are suggested: Examination questions for teachers based on club activities, instruction at normal colleges and summer normals and institutes, demonstration and club meetings at the school, as well as in the homes, cooperation of the county superintendent and his teachers, correlation of the common school studies with club activities as centers of interest, and careful choice of a county supervisor who can procure the cooperation of the rural school teachers.

Boys' agricultural clubs, W. H. KENDRICK (*W. Va. Univ. Agr. Ext. Dept. Circ.* 8 (1914), pp. 14, figs. 4).—The purpose and present status of agricultural

clubs in West Virginia are outlined and directions given for organizing and conducting club work.

[Instructions for boys' and girls' clubs,] J. C. HOGENSON (*Agr. Col. Utah Ext. Div., 1914, Circs. 16, pp. 4; 17, pp. 8, figs. 1; 18, pp. 7; 19, pp. 8*).—Instructions are given for growing sugar beets and tomatoes, raising poultry, bread making, and flower gardening.

Collegiate Country Life Club of America (*Urbana, Ill., 1913, pp. 12*).—The constitution and by-laws of this organization (E. S. R., 29, p. 199) is given.

Country life club, A. W. NOLAN (*Agr. Col. Ext. Univ. Ill. [Circ.], 1913, pp. 15*).—Outlines are given of the activities of organization of a country life club as a local chapter to the Collegiate Country Life Club of America (see above) and of the constitution and by-laws of boys' and girls' country life clubs.

Agriculture [in Utah high schools] (*In Circular of Information and State High School Course of Study. Salt Lake City, Utah: State Bd. Ed., 1913, pp. 43-52*).—An outline is given of agricultural work for Utah high schools, definitely correlated with the agricultural activities of the neighborhood, and the arrangement and length of courses related to the needs of the community. All high schools outside of cities of the first and second class and mining districts are required to offer one-half unit of elementary agriculture in the first year.

Elementary agriculture (*In Course of Study for the Rural Schools of Kansas. Topeka, Kans.: State Bd. Ed., 1913, pp. 86-97*).—This is an outline in elementary agriculture by months for the eighth grade for the use of Kansas teachers.

Teaching agriculture in rural and graded schools, E. C. BISHOP, R. K. FARRAR, and M. H. HOFFMAN (*Iowa State Col. Bul., 12 (1913), No. 8, pp. 164, figs. 27*).—This bulletin consists of three parts, viz. (1) the correlation scheme and 1-year course of study in agriculture outlined by weeks and months with the topics and subtopics arranged in seasonal and sequential order, and with corn forming the principal topic; (2) development of the topic corn through 42 classroom and field lessons, and (3) supplementary work arranged by months in the study of corn from the standpoint of its final preparation and value as a human food, together with correlation work in agriculture and home economics as related to home and school interests.

Agriculture [in rural land graded schools] (*In State Course of Study for the Rural and Graded Schools in the State of Missouri. Jefferson City, Mo.: State Supt. Pub. Schools, 1913, pp. 101-119, fig. 1*).—Notes and suggestions are given on school garden aims and work, as well as an outline for the study of seeds and corn, corn judging, soils and soil experiments, animal husbandry, seed testing, pruning, chickens, and fruits for the seventh grade, to alternate with the work in farm management, physiology, and road building outlined for the eighth grade. A list of references is appended.

Corn Day annual for the schools of Illinois, 1913 (*Ill. Dept. Pub. Instr. Circ. 73 (1913), pp. 52, figs. 21*).—This circular outlines lessons on corn, following the sequence of the season from planting to harvest. Each lesson consists of a simple discussion of the subject matter followed by review questions and problems, practical exercises being grouped at the end of the circular.

Foods and household management, HELEN KINNE and ANNA M. COOLEY (*New York, 1914, pp. XV+401, pl. 1, figs. 80*).—This volume is intended for use in household arts courses in high and normal schools, as well as in the home. It treats specifically of foods, their production, sanitation, cost, nutritive value, preparation, and serving, these subjects being closely interwoven with the practical aspects of household management, and they are followed by a study of the household budget and accounts, methods of buying, housewifery, and laundering. It includes about 160 carefully selected and tested recipes, together

with a large number of cooking exercises of a more experimental nature designed to develop initiative and resourcefulness.

The house and the art of living in it, JESSIE CAREY (*Contemporary Rev.*, 104 (1913), Sept., pp. 395-403; reprinted in *Littell's Living Age*, 7. ser., 62 (1914), No. 3627, pp. 109-116).—Methods of housekeeping, household conveniences, and similar topics are discussed, in part on the basis of personal experience.

Principles of bread making, HENRIETTA W. CALVIN (*Oreg. Agr. Col. Bul.* 83 (1913), pp. 8).—This bulletin discusses the qualities and ingredients of good bread, and gives recipes for making bread, rolls, buns, and zwieback.

Principles of cake and jelly making, AVA B. MILAM (*Oreg. Agr. Col. Buls.* 84 (1913), pp. 7; 85 (1913), pp. 7).—The author discusses the various principles involved in the preparation of cake and jelly.

Care of food in the home, DOROTHEA BEACH (*Timely Helps for Farmers* [*Col. Agr. Univ. Maine*], 7 (1914), No. 5, pp. 25-32).—The author discusses bacteriology, yeasts and molds, and methods of preserving food.

Syllabus of illustrated lecture on the homemade fireless cooker, MRS. K. C. DAVIS and ANGELINE WOOD (*U. S. Dept. Agr., Office Expt. Stas. Syllabus* 15 (1914), pp. 15).—This syllabus, which was prepared for farmers' institute and other extension lecturers, describes a homemade cooking box and discusses its special uses and advantages, the temperature inside the box, cooking different kinds of food in it, devices for keeping liquids hot or cold, and the cooking box as a refrigerator, and gives directions for a demonstration with a box. A list of 36 lantern slides and a list of references to literature on the subject are appended.

The cow, M. J. ABBEY (*W. Va. School Agr.*, 4 (1914), No. 4, pp. 16, figs. 5; *Sup. Chart*, figs. 4).—This article gives directions for using the supplementary unmounted paper schoolroom charts enumerating different breeds of cattle and characteristics of dairy and beef cows, with suggestions on the care and feeding of a dairy cow and on rearing the young calf.

Mann's agricultural bookkeeping instructor, J. D. MANN (*Galena, Ohio*, 1914, pp. 55).—This book is designed for self-instruction and schoolroom use. The transactions employed will be familiar to the ordinary farmer conducting a general or specialized farm or engaged in business such as selling fences, fertilizer, farm implements, etc., and at the same time illustrate the fundamental principles of bookkeeping.

NOTES.

Arizona University and Station.—Dr. R. H. Williams, formerly of the Minnesota University and Station, has been appointed professor of animal husbandry in the university and animal husbandman in the station.

Connecticut Storrs Station.—Leslie E. Card has been appointed assistant in poultry husbandry.

Illinois University and Station.—Louis D. Hall, assistant professor of animal husbandry in the university and assistant chief in animal husbandry in the station, has been appointed specialist in live stock and meats in the Office of Markets of this Department, and has entered upon his duties.

Kansas Station.—Albert G. Hogan, Ph. D. (Yale, 1914), formerly professor of agriculture and chemistry at the Marysville (Missouri) State Normal School, has been appointed assistant in animal nutrition and has entered upon his duties.

Maryland College and Station.—*Science* notes that the extension and demonstration service has been formally organized, with T. B. Symons as director, Nickolas Schmitz as agronomist, W. T. L. Taliaferro in charge of farm surveys and management, G. E. Walcott in charge of dairy extension work, C. L. Opperman poultryman, and Reuben Brigham in connection with publications. The college has been reorganized into the following divisions: Agronomy and animal husbandry, W. T. L. Taliaferro acting dean; applied science, H. B. McDonnell dean; horticulture, T. B. Symons dean; and engineering T. H. Taliaferro dean. Recent promotions include E. N. Cory to be professor of zoology, L. B. Broughton professor of analytical chemistry, and Grover Kinzy associate professor of agronomy and farm machinery.

Michigan College and Station.—Press reports announce the resignation of President J. L. Snyder to take effect June 1, 1915. J. H. Torrence has resigned to engage in commercial work and has been succeeded by O. F. Jensen, a recent graduate of the college.

New York State Station.—Everett P. Reed, a recent graduate of the Ohio State University, has been appointed assistant agronomist.

Oregon Station.—Dr. H. E. Ewing and V. I. Saftro have resigned as research assistants in entomology, the latter to accept a commercial position in Louisville, Ky. G. F. Mozette, a 1914 graduate of the college, has been appointed assistant in entomology.

Oklahoma College and Station.—Morrill Hall, the substantial agricultural and administration building erected in 1906 at a cost with equipment of about \$75,000, was burned during the night of August 6. A portion of the college records were rescued but practically the entire station property was destroyed, including the stock of bulletins, library, mailing lists, etc. It is understood that the building carried insurance of about \$50,000.

Port Rico Federal Station.—José O. Carrero has been appointed assistant chemist beginning July 1.

South Dakota College.—Dr. E. C. Perisho, professor of geology and dean of the college of arts and sciences at the University of South Dakota since 1903 and state geologist, has been appointed president.

Utah Station.—Recent appointments include Ray Smith as superintendent of the substation farm at St. George, and W. E. Goodspeed as assistant horticulturist, succeeding respectively A. B. Ballantyne and H. B. Sweitzer.

EXPERIMENT STATION RECORD.

Useful minerals of the United States, Sanford and Stone.....	322
The American fertilizer handbook, 1914.....	323
Commercial fertilizers, Jones, jr., et al.....	323
Analyses of fertilizers, fall season, 1913, Kilgore et al.....	323

AGRICULTURAL BOTANY.

Lectures in plant physiology, Jost.....	323
Catalytic effects of light in germinating seeds, Lehmann.....	323
Self-warming by plants in Dewar flasks, Molisch.....	323

	Page.
Transpiration by <i>Viscum album</i> in comparison with other plants, Kamerling.....	324
Transpiration experiments with tropical Loranthaceæ, Kamerling.....	324
Nitrogen transformations in some Actinomycetes, II, Münter.....	324
Reduction of nitrates to nitrites and ammonia by bacteria, Klaeser.....	324
Studies on anthocyanin.—I, Color in the cornflower, Willstätter and Everest....	324
Localization of potash compounds in the sugar beet and their relation, Matoušek.	325
Influence of alkalies and alkaline earths on <i>Lupinus albus</i> , Porodko.....	325
Action of compounds of zinc, arsenic, and boron on plants, Brenchley.....	325
Diffusion and localization of ions in plant tissues, Acqua.....	325
Experimental production of hyperplasia in plants, Petri?.....	326
Effect of external stimuli on the sporidia of <i>Puccinia malvacearum</i> , Robinson....	326
Morphological instability, especially in <i>Pinus radiata</i> , Lloyd.....	326
Effect of climatic conditions on rate of growth of date palms, Vinson.....	326
Effect of shading on transpiration and assimilation of tobacco, Hasselbring....	326
Monograph of <i>Penicillium</i> , with special reference to Norway, I, Sopp.....	327
On the lower fungi.—V, <i>Anisomyxa plantaginis</i> n. g. and sp., Némec.....	327
Studies on heads of wheat and spelt as a contribution to classification, Kondo....	327
Inventory of seeds and plants imported from July 1 to September 30, 1912.....	327

FIELD CROPS.

Agricultural researches and the interpretation of their results, Grégoire.....	327
Field experiments and the interpretations of their results, Grégoire.....	327
Some factors which influence the water requirements of plants, Khankhoje.....	327
Irrigated field crops in western Nebraska, Knorr.....	328
Potash fertilizer experiments, Heine and Lindenberg.....	328
Row fertilizing experiments, Ahr.....	328
Study of relation between space and plant growth, Grundmann.....	328
Transmissible variations of chlorophyll characteristics, Nilsson-Ehle.....	329
The effect of previous vegetation—cabbage after sesame, Skinner.....	329
Basing alfalfa yields on green weights, Farrell.....	329
Studies on the anatomy of alfalfa, Wilson.....	330
Growing alfalfa in Iowa, Hughes.....	330
Influence of potash and phosphoric acid on brew barley, Schül.....	330
Investigations on spacing for breeding plants of brew barley, Claus.....	330
Observations on <i>Beta maritima</i> from 1910-1912, Munerati et al.....	330
On breeding and inheritance questions in red clover, Holdefleiss.....	330
Maize, its history, cultivation, handling, and uses, Burt-Davy.....	331
The corn plant and seed selection, Hayes.....	331
Good seed corn for 1913, Hughes.....	331
Fertilizer experiment with maize.....	331
Moisture in maize, Blackshaw.....	331
An interesting new member of the Gramineæ from Tonkin, Crevost and Lemarié.....	332
Industrial fiber plants of the Philippines, Muller.....	332
Nutrient requirements of flax and the influence on its fiber, Csókás.....	332
Hemp, Dewey.....	332
On the appearance of sterile "dwarfs" in <i>Humulus lupulus</i> , Salmon.....	332
The Ruakura oat, McConnell.....	332
An inhibiting factor in awn development in oats, Nilsson-Ehle.....	332
On the continuous violet colored seed of <i>Pisum arvense</i> , Kajanus.....	333
Influence of potash on potatoes, von Eckenbrecher and Hoffman.....	333
The selection and treatment of potato seed, Ramsay.....	333
Report of the German Potato Culture Station in 1913, von Eckenbrecher.....	333
Notes on the culture of sisal in English and German East Africa, Janssens.....	333
The grain sorghums: Immigrant crops that have made good, Ball.....	333
Soy beans.—An important Wisconsin crop, Moore and Delwiche.....	333
Cultural experiments with sugar beets, Demolon.....	333
Spacing experiment in sugar-beet cultivation in Hungary, 1912, von Jancsó.....	334
Catalogue of German library of L. S. Ware on the sugar industry.....	334
Catalogue of the works on sugar and the sugar industry.....	334
The "Stewart Cuban" variety of tobacco, Hayes.....	334

Decorative garden dahlias at Duffryn, near Cardiff.....	340
Garden design, White.....	340
The commuter's garden, edited by Hayward.....	340
Identifying plants without a key, Hamblin.....	340

FORESTRY.

Report of the forestry committee of the Fifth National Conservation Congress..	340
Seventh report of the State forester of Connecticut, Filley.....	341
Forest statistics at the beginning of the nineteenth century, De Coincy.....	341
The administration of a forest experiment station, Pearson.....	341
A proposed method of preparing working plans for national forests, Kircher...	341
Reforestation of cut-over chestnut lands, Richards.....	341
A mechanical tree planter, McLean.....	341
Design of a range finder, Crowell.....	341
A new measuring instrument, Siggins.....	341
Errors in estimating timber, Margolin.....	341
Stem analyses, Bentley, jr.....	341
The scope of dendrology in forest botany, De Forest.....	342
The silvical and economic geographic importance of the valonia oaks, Burk...	342
Tapping experiments with <i>Funtumia elastica</i> at Musa and Kutu, Gisseleire...	342
Hevea in Cochín China, Girard.....	342
Exploitation of cross-ties in northern New Mexico, Korstian.....	342

DISEASES OF PLANTS.

The biological basis of international phytopathology, Orton.....	342
Report of the botany department, Reed.....	342
Report of the central station for plant protection, 1912, Zimmermann.....	343
Heat killing and stem constrictions of plants, von Tubeuf.....	343
The fungus genus <i>Verticillium</i> in its relation to plant diseases, Orton.....	343
Studies on Nectriaceae, II, Weese.....	343
Snow mold and other aspects of attack by <i>Fusarium nivale</i> on cereals Schaffnit..	343
Smut in small grains, Hughes and Taff.....	344
Investigations of timothy rust in North Dakota during 1913, Mercer.....	344
Heart rot of beets, Käppeli and Morgenthaler.....	344
Celery disease.....	344
Cotton anthracnose, Fulton, Winston, and Cromwell.....	344
Fruit rots of eggplant, Wolf.....	344
Is golden seal resistant to the root knot nematode? McClintock.....	345
Report of 1913 infection studies with <i>Fusarium</i> on potato, Himmelbaur.....	345

	Page.
A Phoma rot of Irish potatoes, Melhus.....	345
Inspection and certification of potato seed stock, Orton.....	345
Relation of the mosaic of the pepper, tomato, and tobacco, Schwarze.....	345
A new rust of economic importance occurring on pomaceous hosts, Jackson.....	345
An unusual outbreak of apple blossom blight, Reed.....	345
Collar blight of apple trees in Pennsylvania, Orton and Adams.....	346
The use of sulphur-lime wash as a remedy for apple scab, Beattie.....	346
Control of Cronartium rust on currents, Ewert.....	346
Practical formulas for the treatment of grape anthracnose, Degrully.....	346
Peronospora disease of grapevines and its control, Müller.....	346
Studies with <i>Plasmopara viticola</i> on grapevines, von Istvánffi and Pálinkás.....	346
Identity of the American and French mulberry blight, Smith.....	347
Diseases and pests of cultivated plants in Samoa, Gehrmann.....	347
Cladosporium diseases of <i>Ampelopsis tricuspidatum</i> , Cook and Wilson.....	347
Stem rot and leaf spot of Clematis, Gloyer.....	347
Latent phases of disease following infection of <i>Euphorbia cyparissias</i> , Tischler.....	347
Heat injuries to forest plants, Münch.....	348
Injury from air exclusion and overheating, von Tubeuf.....	348
More on heat injuries to forest plants, Münch.....	348
Notes on diseases of trees in the southern Appalachians, II, Graves.....	348
Notes on Peridermium from Pennsylvania, Orton and Adams.....	348
Notes on the white pine blister rust, Spaulding.....	348
A preliminary note on the cause of "pecky" cypress, Long.....	349

ECONOMIC ZOOLOGY—ENTOMOLOGY.

The American thrushes valuable bird neighbors.....	349
The food of <i>Rana pipiens</i> , Drake.....	349
The dictionary of entomology, Jardine.....	349
The writings of Philip Reese Uhler.....	349
Bringing applied entomology to the farmer, Webster.....	349
Notes on entomological inspection in the District of Columbia, Sasscer.....	349
[Report of the entomological department], Haseman.....	349
The relation of temperature to insect development, Peairs.....	349
Importance of the measure of evaporation in studies of insects, Shelford.....	350
Use of atmometers to measure evaporation in the study of insects, Shelford.....	350
Can insects become resistant to sprays? Melander.....	350
Insecticides, Sayre.....	350
Some properties of various forms of arsenate of lead, Dew.....	350
Notes on the entomology of the Arizona wild cotton, Pierce and Morrill.....	350
Notes on the onion thrips and onion maggot, Fernald and Bourne.....	350
Two new insect pests of currants and gooseberries, Cooley.....	351
Destruction of mosquitoes, fleas, flies, and other carriers of disease, Purdy.....	351
Grasshopper control in the southern division of Kansas, Hunter and Claassen.....	351
The proper generic names for certain Thysanoptera, Hood.....	351
Sterility in oats caused by thrips, Hewitt.....	351
The periodical cicada in 1914, Marlatt.....	351
Some Pemphiginæ attacking species of <i>Populus</i> in Colorado, Gillette.....	351
Natural control of <i>Toxoptera graminum</i> in Africa and United States, Moore.....	352
A lycenid caterpillar reared in Acacia galls by ants, Le Cerf.....	352
The oviposition of two apple pests, Herrick.....	352
Observations of the bee moth, Paddock.....	352
A new destructive cutworm occurring in western Canada, Gibson.....	352
Two Microlepidoptera on <i>Thurberia thespesioides</i> , Busck.....	352
Feeding habits of <i>Phlebotomus vexator</i> , Shannon.....	352
Notes on a wood-boring syrphid, Barber.....	352
Dispersal of <i>Musca domestica</i> , Zetek.....	352
A new tachinid parasite of <i>Diabrotica vittata</i> , Walton.....	352
The cabbage maggot in relation to the growing of early cabbage, Schoene.....	352
A study of the bionomics of the common rat fleas and other species, Bacot.....	353
Survival of bacteria in alimentary canal of fleas during metamorphosis, Bacot.....	353
Effect of the vapors of various insecticides upon fleas and the bedbug, Bacot.....	353
A coleopterous (clerid) larva predaceous on codling-moth larvæ, Merrill.....	353
Studies of the Arizona <i>Thurberia</i> weevil on cotton in Texas, Coad and Pierce.....	353
Reducing insect injury to stored corn, Hinds.....	353
Information relative to bee keeping, Sanborn.....	354

	Page.
Porto Rican bee keeping, Phillips.....	354
A study of <i>Dryophanta erinacei</i> and its gall, Triggerson.....	354
A parasite of the chinch-bug egg, McColloch and Yuasa.....	354
Hymenoptera of South America, Brèthes.....	355
Report on parasites, Howard.....	355
<i>Epimecis willtii</i> and its host, Shannon.....	355
Biological notes on a few rare or little-known parasitic Hymenoptera, Cushman.....	355
Notes on the life history of <i>Rhopalosoma poeyi</i> , Hood.....	355
New Hymenoptera from North America, Gahan.....	355
The parasites of the San José scale in New York, Hodgkiss and Parrott.....	355
Ticks: Diseases which they transmit and their destruction, Van Saceghem....	356
An endoparasitic mite in the lung of <i>Macacus rhesus</i> , Landois and Hoepke....	356

FOODS—HUMAN NUTRITION.

Supplementing our meat supply with fish, Pennington.....	356
Whitefish of Masurian Lakes of east Prussia, Gabriel and Limprich.....	356
Points which aid in determining whether flatfish have died in the water, Jugeat.....	356
Sea mussels—what they are and how to cook them.....	356
The effect of cold upon the larvæ of <i>Trichinella spiralis</i> , Ransom.....	356
Examination of sausage from St. Petersburg, von Karaffa-Korbutt.....	357
Note on judging the quality of lard, Alpers.....	357
Osmotic phenomena of yolk of egg, Osborne and Kincaid.....	357
Supervision and marketing of eggs, Behre and Frerichs.....	357
Emmerich and Loew calcium bread and reasons for it, Loew.....	357
Migration of constituents of maize into water and aqueous solutions, Poppe....	357
Foods from the grain sorghums—Feterita products, Francis.....	357
Meal used for crumbing foods, Dinslage.....	358
Preserved tomatoes, Carles.....	358
Grape juice as a nutritive and remedial agent, Bender.....	358
Investigation of tea, Besson.....	358
Caffein and the other alkaloids found in tea, Hope.....	358
Food and drug section, Rose and Henry.....	358
Foods and drugs.....	358
Enforcement of the food and drugs act for 1910 and 1911, Allen.....	358
[Report of work under the Kentucky Food and Drugs Act], Allen.....	359
Thirteenth report of food and drug commissioner of South Dakota, Frary.....	359
List of the analyses of samples of butter and other food products.....	359
An attempt to standardize oven temperatures for cookery, Van Arsdale.....	359
What the Department of Agriculture is doing for the housekeeper, Langworthy.....	359
Financing the wage-earner's family, Nearing.....	360
How to live on 2d. a day, Cross.....	360
How to live on 3d. or 4d. a day, Cross.....	360
Dietetics in Italian tenements, Gibbs.....	360
Domestic science.—[School lunch work in Gary, Ind.], Krentel.....	360
Sanitary conditions in Alaska.—Food poisoning], Krulish.....	360
The care of the baby.....	360
My dietary, Sherman.....	360
Health through diet, Haig.....	361
Textbook on physiological chemistry.—I. The organic nutrients Abderhalden.....	361
Observations on the processes of resorption in the cellular organism, Rubner...	361
Concerning resorption phenomena in the intestine, Dobrowolskaja.....	361
The rôle of the spleen in digestion, Rusca.....	361
The effect of a one-sided diet, Kleinert.....	361
Effect of long-continued excessive diet of carbohydrate without protein, Grafe.....	361
Absorption and fate of tin in the body, Salant, Rieger, and Treuthardt.....	362
Do foods contain important unknown substances? Abderhalden and Lampé...	362
Influence of atmospheric pressure, temperature, and humidity, Thomson.....	362
The influence of moisture in the air on metabolism in the body, Thomson.....	363
Biochemical studies of expired air in relation to ventilation, Weisman.....	363
Metabolism during mental work, Becker and Olsen.....	363

ANIMAL PRODUCTION.

Factors affecting the handling of wheaten hay, Perkins et al.....	364
Apples for live stock, Truelle.....	365
Acorns and beechnuts as feeding stuffs, Engels.....	365

	Page.
Fish meal as a feeding stuff, Morgan.....	366
[New feeding stuffs], Mann.....	366
[Feeding stuffs], Rose and Greene.....	366
The feeding stuffs inspection for 1911, 1912, Bachelder.....	366
Commercial feeds, edited by Pickel.....	366
Concentrated commercial feeding stuffs, compiled by Sample and Harrison.....	366
Stock-watering places on western grazing lands, Barnes.....	366
Animal husbandry department, Mumford.....	366
The South American meat industry, Melvin.....	367
The production of beef in the South, Ward.....	367
The Bazadais cattle, Lafforgue.....	367
The Garonnais breed of cattle, Herbet.....	367
The distribution of wild sheep, Kowarzik.....	367
Breeding caracul sheep, Young.....	367
Alaska's reindeer industry, Chubbuck.....	368
The preservation of the Arab horse, Edwards.....	368
A study of sex-linked inheritance in poultry.....	368
Studies on the feather formation of domestic fowl, Andreas.....	369
Early development of scale and feather, Schleidt.....	369
Effect of Röntgen rays on organs of chicken, Unzeitig.....	369
Artificial insemination in birds, Ivanov.....	370
Shipping eggs by parcel post, Flohr.....	370
Eggs from China, Anderson, Mansfield, Wilder, and Neville.....	370
Table rabbit production, Wilson.....	370
Economic value of North American skunks, Lantz.....	370

DAIRY FARMING—DAIRYING.

Department of dairy husbandry, Eckles.....	370
New method for determining the production value of feeding stuffs, Hansson.....	371
The protein minimum and the market value of feeding stuffs, Hoffmann.....	371
Breeds of cattle of Switzerland, Gertsch.....	371
The age for breeding dairy heifers, Siha.....	371
World's record for a dairy cow broken.....	372
Hereditary transmission of fat percentage, Dunne.....	372
Cells in milk derived from the udder, Breed.....	372
Bacterial and enzymic changes in milk and cream at 0° C., Pennington et al.....	373
[Dairy laws], compiled by Smith and Duvall.....	373
Is a uniform fat standard for whole milk practical? Mezger.....	373
Principal types of micro-organisms in Baltimore milk, Shippen.....	373
Blue milk, Wolff.....	374
The composition of carabao's milk, Dovey.....	374
Composition of goat's milk, Storch.....	374
Composition of ewe's milk butter, Martin.....	375
Researches during the last few years at the Dairy Institute at Alnarp, Rosengren.....	375
Cheshire cheese, Davies.....	375
Condensed milk and milk powder, Hunziker.....	375
Organisms in condensed milk.....	375
Aluminum milk cans, Winkler.....	375
International Federation of Dairying.....	376

VETERINARY MEDICINE.

Manual of the practice of veterinary medicine, Courtenay, revised by Hobday.....	376
Veterinary State board questions and answers, Kimball.....	376
Ophthalmology for veterinarians, Sharp.....	376
Exercises in bacteriology and diagnosis, Moore and Fitch.....	376
Apparent inconsistencies of biologic diagnostics, Archibald.....	376
Menziesia, a new stock poisoning plant of the Northwestern States, Marsh.....	376
Mold fungi in oil cake, Schneider.....	377
Biological reactions of the vegetable proteins, IV, Lake, Osborne, and Wells.....	377
Biological reactions of the vegetable proteins, V, Wells and Osborne.....	377
About the specificity and other properties of the ectoproteases, Fermi.....	377
The value of leucocytic extract from a therapeutic standpoint, Archibald.....	377
Autogenous vaccine, Lang.....	378
Experiences with the Abderhalden dialysis method, I, Deutsch.....	378

	Page.
Observations on the protective enzymes of the body (Abderhalden), Grey.....	378
Diagnosis of malignant new formations and pregnancy, Von Gambaroff.....	378
The diagnosis of pregnancy by Abderhalden's dialysis method, Naumann.....	378
The need for a means of physical diagnosis of abortion, Williams et al.....	379
A study of the metabiotic action of the ultraviolet rays, Henri.....	379
The efficacy of antitetanic serum, Rogers.....	379
Diagnosis of tuberculosis with Von Pirquet's reaction, Conradi.....	379
Value of the optical and the dialysis procedure, Abderhalden and Andryewsky..	379
Some remarks about Carl Spengler's fragment sputa, Maffi.....	380
Production of artificial immunity against tuberculosis, Gilliland and Marshall..	380
Control of tuberculosis in Minnesota pure-bred herds, Ward.....	380
Some aspects of the tuberculosis problem, Ravenel.....	380
Some common ailments of the horse and cow, Lueder.....	380
"Abortin" as a diagnostic agent in cattle, Meyer and Hardenbergh.....	380
Bush-sickness—Experimental and demonstration work, Reakes and Aston.....	381
Investigations of coital exanthema of cattle, Zwick and Gminder.....	381
Atoxyl in the treatment of malignant catarrhal fever of cattle, Wyssmann.....	381
Pasteurellosis in the reindeer, Magnusson.....	381
Sanitary police measures and hog cholera, Kinsley.....	381
Abortion in mares caused by <i>Bacillus paratyphosus</i> , Van Heelsbergen.....	381
Colics and their treatment, edited by Campbell.....	382
The diagnosis of dourine by complement fixation, Mohler, Eichhorn, and Buck..	382
Equine piroplasmosis: Types of parasites, Carpano.....	382
Culture of equine piroplasms and views of the nature of anaplasmas, Carpano...	382
Contagious pleuropneumonia of the horse, Gaffky and Lührs.....	382
Spirochetosis of fowls, Kiessig.....	383
The staining of microfilariæ, Fülleborn.....	383
The disinfective action of Cresepton, Wolff-Eisner.....	383

RURAL ENGINEERING.

Twelfth annual report of the Reclamation Service, 1913.....	383
Report of irrigation and reclamation works department.....	383
Irrigation studies, Müntz and Lainé.....	383
Quantity of water consumed in the cultivation of sugar cane, Guardiola.....	383
Control of water as applied to irrigation, power, and town water supply, Parker..	383
The area of waterways, Vicars.....	384
Loss of head due to bends in water pipes, Fuller.....	384
Drainage ditch and levee tables for level section, Blaine.....	384
Drainage and irrigation: Linings for small storage reservoirs, Sessions.....	384
Machine for testing drain tile, Abrams.....	384
Street pavements and paving materials, Tillson.....	385
American Good Roads Congress and convention of Builders' Association.....	385
Road laws of the State of Washington.....	385
Practical handbook of gas, oil, and steam engines, Rathbun.....	385
The construction and design of internal combustion motors, Güldner.....	385
A fuel-saving device for oil engines, Adlington.....	385
Fuel consumption and utilization of energy in small power motors, Charbonnier..	385
The possibilities of mixed fuels.....	386
Fuel-briquetting investigations, July, 1904, to July, 1912, Wright.....	386
Mechanics for builders, I, Bates and Charles.....	386
The testing of sand for use in concrete, I and II, Chapman.....	386
Some tests on strength of overwet concrete.....	387
Use of hydrated lime in concrete pavements, Edwards.....	387
Exterior plastering specifications.....	387
Modern practice in heating and ventilation, XIV, King.....	387
Handbook on sanitation, Price.....	387
The new public health, Hill.....	387
Hygiene of rural, suburban, and summer homes.....	387
Determining the probability of decomposition in a sewage effluent, Stokes...	387
Lighting of towns and rural communities, Strache and Eisler.....	387
General discussion on conveniences in the home and on the farm, Monteith....	388

RURAL ECONOMICS.

Factors of efficiency in farming, Spillman.....	388
Reorganizing the farm, Johnson.....	388

	Page.
The organization of rural interests, Carver.....	388
An experiment in marketing under territorial auspices, Wilcox and Longley ..	388
The farmers' cooperative exchange, Cance.....	389
Monographs on agricultural cooperation in various countries.....	389
Agricultural cooperation and rural credit in Europe.—Bibliography.....	389
How to use farm credit, Carver.....	389
The rural credit situation of the United States, Macpherson.....	389
The problem of agricultural credit in Canada, Mitchell.....	390
Loans granted on grain and establishment of grain elevators in Russia.....	390
[Distribution of produce between landlord and tenant], Jenny.....	390
Agricultural distribution of land in different countries.....	390
Farm lands in New Jersey, Dye et al.....	390
Uses of land in Denmark, July 15, 1912.....	390
Agriculture in Argentina, Van den Bosch.....	390
[Agriculture in Guiana], edited by Leechman.....	391
Rural development in Burma, Clayton.....	391
Contry life conference addresses.....	391
Solving the country church problem, Bricker et al.....	391
The agricultural outlook.....	391
Acreage and livestock returns of England and Wales, Rew.....	391
Agricultural statistics of Netherlands.....	391
World production of cereals in 1913.....	392
Statistics of consumption of cotton, Schmidt.....	392

AGRICULTURAL EDUCATION.

Uniformity in methods of instruction in the lower agricultural schools, Arthold ..	392
[Reports of German horticultural institutions for 1912].....	392
The rural agricultural and housekeeping school at Mährisch-Schönberg, Kolb ..	392
[Agricultural and forestry instruction in Austria and other countries].....	392
Some agricultural education institutions in Hungary and Balkan States, Merkos ..	392
Reforms in agricultural education in the Kingdom of Servia.....	393
The Woodlawn school garden, Joyce.....	393
Lebanon County boys' agricultural and girls' domestic science clubs, Snoko ..	393
Industrial clubs and contests for Oregon boys and girls.....	393
The country home.....	393
The Second International Congress of Home Training at Ghent, Schuppli.....	393
Lesson exercises, Stebbins.....	394
Field trips in elementary agriculture.....	394
Collection and preservation of plant material, Derr and Lane.....	394
Outline of work in agriculture, domestic science, and manual training.....	394
[Reading courses in agriculture and home economics].....	394
Seasonable suggestions, Minear.....	394
Testing seed corn, Smith.....	394
Testing seed corn in rural schools, Evans.....	394
Modern fruit growing, Wilden.....	394
A field lesson on the fuel woods of the farm, Needham.....	394
Instruction in fire extinguishing in the lower agricultural schools.....	394
Expedients in giving instruction in plant protection, Köck.....	395
High school entomology.....	395
Exercises in farm dairying, Larsen.....	395
Educational school gardening and handwork, Brewer.....	395
Suggestions for teaching nature study, Abbey.....	395
Nature study in secondary schools, Drieberg.....	395
Arbor and Bird Day manual for use in West Virginia public schools.....	395
Planning and adorning the farmstead and school grounds.....	396
Back to the farm, Shumway.....	396

MISCELLANEOUS.

Yearbook of the Department of Agriculture, 1913.....	396
Thirty-seventh Annual Report of Connecticut State Station, 1913.....	396
Twenty-sixth Annual Report of Illinois Station, 1913.....	396
Twenty-fourth Annual Report of Kentucky Station, 1911.....	396
Biennial Report of the Director of the Kentucky Station, 1911-1913, Kastle ..	396
Report of the director for the year ending June 30, 1913, Mumford.....	396
Health laws, Caffey.....	396

EXPERIMENT STATION RECORD.

VOL. XXXI.

SEPTEMBER, 1914.

No. 4.

The sixth session of the Graduate School of Agriculture was held June 29 to July 24 at the College of Agriculture of the University of Missouri. As heretofore, the School was conducted under the auspices of the Association of American Agricultural Colleges and Experiment Stations, through its standing committee on graduate study. Since its purpose is not only to give advanced instruction in agricultural science but to acquaint investigators with the latest methods employed and results obtained in special research by their fellows in particular fields, the attendance is by no means confined to beginners in agricultural research. Each session finds an increasing number of seasoned scientific workers enrolled for the sake of its associations and its broadening influence as well as for the practical and special benefit to be derived therefrom. The more advanced phases of the work are being more and more accentuated in the successive sessions, and a considerable portion of the information now being offered in the school is not generally accessible elsewhere for some time, if obtainable at all in so effective a form.

The instruction in the Graduate School for this year was conducted along six main lines, each running through the four weeks' session, as experience has demonstrated the advantage of concentrating attention on a limited number of subjects for the entire period. Those included for this session were genetics, agronomy, horticulture, animal husbandry, immunity and disease resistance, and rural economics and sociology, including farm management.

The number of instructors was twenty-nine, with a considerable number of other speakers at the various conferences and other gatherings. Ten of these were members of the faculty of the University of Missouri, and the remainder were specialists from the U. S. Department of Agriculture, various agricultural colleges and experiment stations, the Carnegie Institution of Washington, the University of Edinburgh, and the Imperial Biological Institute at Dahlem, Berlin. Dr. A. C. True of this Office again acted as dean, with Mr. Arthur J. Meyer of the University of Missouri as registrar. The enrollment of students reached one hundred and fifty, representing about thirty States and Territories, besides the District of Columbia, Porto Rico, Canada, and Scotland.

At its public opening exercises, the School was welcomed to the University of Missouri by Dean Walter Williams of the School of Journalism, as the representative of President Hill who was in Europe, and by Dean Mumford of the College of Agriculture. Dean True of the Graduate School briefly outlined its history and pointed out some of the reasons for its continuance. In this connection he directed attention to the fact that "the desirability and importance of such an agency as the Graduate School of Agriculture, which aims to influence the whole movement relating to agricultural education and research by giving it certain impulses from the top, can not be determined by the number of persons who come directly under its influence. They are rather largely to be found in the character and extent of the movement and the tendencies which are developing in it."

Dean True also briefly summarized some of the important developments of American agriculture and agricultural education and research during the twelve years since the establishment of the Graduate School. Census comparisons of conditions in 1900 and 1910 were quoted, showing an increase in the proportion of improved lands from 49.4 to 54.4 per cent, an increase of land values of 118 per cent, and an increase in the proportion of the total farm investment represented by land from 63.9 to 69.5 per cent. Under these conditions "the farmers, with land much higher in price, are loudly calling for increased knowledge of ways to use their land more economically and with greater returns. But this knowledge can only be obtained by more highly trained men, for the remaining agricultural problems are complex and difficult to solve."

Meanwhile boys from both country and city have been going to agricultural colleges in much larger numbers. During the past decade the number of students taking the full four-year course in agriculture has increased from approximately 2,500 to 12,500, or an increase of 500 per cent. The number of white students registered in short and special courses has doubled, now aggregating about 11,000. Since 1910, the annual number of graduates in agriculture has increased from 708 to 1,384, and the number receiving advanced degrees from 74 to 164. The total revenues of the land-grant colleges have practically tripled and those of the experiment stations have more than tripled, the increase being especially notable from sources other than federal funds. Similarly the number of men on the staffs of the experiment stations has increased from about 750 to approximately 1,600, and the number of these doing no teaching from 375 to 925.

Along with the increase in the activities of the experiment stations and the number of students taking the college courses in agriculture, the number of secondary schools in which agriculture is

taught has vastly increased. In 1903, very few secondary schools were giving instruction in agriculture. At present there are over 2,000.

Ten years ago there was scarcely any agricultural extension work performed outside of the work carried on by the farmers' institutes. To-day there are 1,300 men employed as state, district, and county agents, and as boys' and girls' club workers. The money appropriated under the Smith-Lever Act alone will call for at least 2,500 men for extension work in the next ten years. Even if this number is employed in addition to those already in the field, to reach all the farm operators each extension worker will have to come in contact with at least 2,500 farm operators a year, or over 4,000 farm or agricultural workers.

There are also over seven hundred positions in the U. S. Department of Agriculture for which graduation at an agricultural college is a prerequisite, and doubtless there are many other positions in which the Department would use graduates of agricultural colleges if these colleges were giving more highly specialized and advanced courses of instruction in agricultural lines. As it is, the Department is now often compelled to take men who are well trained in chemistry or biology and give them the special training along agricultural lines required by the work in which they are engaged.

"How different, then, is the condition of these colleges from what it was even twelve years ago! Then they were just beginning to feel the impulse of a more prosperous agriculture and the turn of the tide of popular sentiment in favor of agricultural education. Now they are at a flood tide of popular favor, which is even so strong as to threaten to sweep them from safe moorings. The demand for trained men on the farms and in commercial pursuits allied to agriculture is more than keeping pace with the increase of students and graduates, and is even depleting the faculties of the agricultural colleges. To this must now be added the very large demand for agricultural graduates in extension work. . . .

"Is it any wonder that the friends of higher education and research in agriculture are perplexed and troubled? How shall we meet the incessant demand for agricultural graduates in practical life and in extension work and at the same time strengthen and increase the facilities of our agricultural colleges and the staffs of our experiment stations and great Department of Agriculture? To have well-trained men on our farms and to carry practical information to the multitudes of our farmers is tremendously important. But where are we to get in sufficient numbers the highly trained and efficient college professors who are to teach the thousands of students in our colleges and whence are to come the elaborately equipped men of sufficient originality to conduct thorough and successful researches

in agriculture in order that we may have an adequate fund of knowledge for the use of the college teachers, extension workers, and farmers?

“Evidently the compensations of the trained farmers and extension men in the way of incomes and popular favor are going to be relatively large. Will these occupations, therefore, take our brightest and most capable students and leave the professorships and research positions to be filled by second-rate men? This will depend very largely on the spirit of the men best qualified to be professors and investigators and on the attitude of the universities, colleges, stations, and Department of Agriculture toward such men. . . .

“If we are to have great scholars in agriculture, as we have had them in philosophy or astronomy, we must have men who, having weighed carefully the advantages of commercial success and popular favor, nevertheless decide that they can find their greatest satisfaction only in the attainment of the most profound scholarship through study and research in agricultural lines. Thus they will be unmoved by flattering offers to go out into the broad world of affairs and steadily pursue the scholar’s business in laboratory, library, and classroom whatever happens outside the college campus.

“And we must have college boards and presidents and deans who will have a great appreciation of the value of the great scholar in agriculture and will show this in a substantial way by creating for him a sympathetic environment, and favorable conditions for his work. Even his salary should show some indication of appreciation of his merit. There should be financial rewards for great scholars in the universities and colleges, as well as for able administrators. Above all the atmosphere of the agricultural college should be favorable to learning and research. . . . It should be broadly sympathetic with the men and women on the farms and their immediate problems, but it should also be highly stimulative and encouraging to the scholar who desires to get beneath the surface of things, to know and discover causes that he may be the better able to remedy ills, or devise improvements in practice.

“To encourage high standards and attainments in agricultural scholarship is the main purpose of this Graduate School of Agriculture. It does not attempt to take the place of regular graduate courses in agriculture, which happily are now being maintained at a number of our strongest agricultural colleges. Its aim is rather to promote the wider establishment and greater efficiency of such courses.

“By bringing graduate students together from different points of the United States and some foreign countries and giving them personal contact for a month with eminent experts in agricultural and related sciences, this School hopes to awaken in many of its students

a desire for advanced study which will not be satisfied except by realization. By personal touch with students and experts from widely different regions it is hoped that each student will get a broader and clearer vision of the possibilities in agricultural study and research. Returning to the institutions from which they come it is expected that they will exert a broader influence in raising the standards and expectations of agricultural education and research throughout the United States."

The central feature of the 1914 session was a course in genetics, comprising forty lectures and twelve seminars, which was planned to give a systematic presentation of the present status and outlook of this subject, with special reference to its agricultural relations. This was in response to a somewhat general demand that more comprehensive instruction in at least one subject should be given at the Graduate School. For this purpose the number of lecturers was kept down to four and there was a definite prearrangement regarding the field each lecturer was to cover. The subject chosen was presumably interesting to all students of agricultural science and therefore the hours were so arranged that all members of the School could attend. The course proved very successful and will encourage the development of more definite instruction at future sessions.

This course was opened by Dr. J. A. Harris of the Station for Experimental Evolution of the Carnegie Institution of Washington, who presented the statistical groundwork for research work, including methods of calculation and illustrations of the practical applications of statistical formulas in genetic studies. Prof. M. F. Guyer, of the University of Wisconsin, discussed the physical basis of heredity, including the development of the body and the germ plasm; the chromosomes as related to heredity in the light of Mendelism; sex in relation to heredity; and the ultimate nature of the germ plasm. An account of some pedigree culture investigations and their results as bearing upon heredity and development in plants and as related to Mendel's law was presented by Prof. E. M. East, of Harvard University. Blending inheritance and its interpretation was discussed, as was also the possible application of the present knowledge of heredity to breeding problems and practice. In conclusion, Prof. A. D. Darbishire, of the University of Edinburgh, Scotland, presented results of an attempt to estimate the value of the Mendelian method as an instrument for the improvement of the animals and plants which are serviceable to mankind, discussing the method as applied to practical breeding, and giving illustrations of its application to the improvement of wool and milk. He also developed the philosophical relations of the Mendelian theory in its broader aspects as affecting our conceptions of heredity and of life in general. This was done in a very original and interesting way and drew the atten-

tion of the university community at Columbia, as well as of the members of the Graduate School.

The course in agronomy dealt with special problems in the breeding and nutrition of field crops, with reference to conditions in both humid and arid regions. Dr. H. L. Shantz, of the Bureau of Plant Industry, considered the relation of moisture supply to plant development, and Director C. E. Thorne, of the Ohio Experiment Station, some of the practical aspects of soil fertility investigations. Other factors in crop production were treated by Prof. C. V. Piper, of the Bureau of Plant Industry, and Dr. L. H. Smith, of the University of Illinois, the former dealing especially with the climatic, soil, and biological adaptations of forage plants and the origin of crop varieties, and the latter discussing crop improvement through selection in corn and other cereals.

The work in animal husbandry was largely a presentation of important methods and results connected with the investigations which have been in progress for a number of years at the Missouri Experiment Station. Prof. C. H. Eckles gave the results of studies with dairy cattle, including factors influencing growth, milk secretion, and the composition of milk and milk fat, and the development and composition of the fetus. Dean Mumford discussed age as a factor in animal breeding and the growth curves of animals on different planes of nutrition. H. O. Allison reported on cattle feeding experiments, including nutrition studies on beef-breeding cows. Dr. P. F. Trowbridge discussed the composition of beef animals, changes during growth, fattening and starvation, variations in adipose tissue, and the digestion factors. The account of the Missouri work was appropriately supplemented by discussions based especially on the extensive investigations in animal chemistry conducted by Dr. H. S. Grindley at the Illinois Station. He pointed out the relation of his work and that of other investigators to special problems in animal nutrition such as the specific effects of feeds or rations, particularly protein, upon the nutrition of animals, changes in the animal body during growth, feeding experiments, and the digestibility of feeds and rations.

In the course in horticulture, Prof. J. C. Whitten, of the University of Missouri, reported upon the influence of high-producing and low-producing parent fruit trees upon progeny propagated by bud selection, the influence of the season of transplanting upon the development of fruit trees, and an investigation of factors affecting hardiness. Prof. W. L. Howard, of the same institution, considered the rest period as related to hardiness and some physiological changes accompanying the breaking of the rest period. Prof. H. J. Eustace, of the Michigan Agricultural College, discussed horticultural crop regions of the United States, the holding, moving, and storing of

horticultural products, and fruit selling. E. J. Kraus, of the Oregon Station, reported on the horticultural organization in the Pacific Coast Northwest, orchard economics, the relation of soil moisture to fruit production, and pollination in pomaceous and drupaceous fruits. U. P. Hedrick, of the New York State Station, took for his subjects fertilizers for fruits, the soil treatment of orchards, stocks for fruit trees, orchard ecology, and fruit breeding from the horticulturist's standpoint.

In the course in immunity and disease resistance, an attempt was made to bring the students of plant and animal diseases together to consider some of the general principles underlying this subject and to compare the relative advances made on its plant and animal sides. V. A. Moore, director of the New York State Veterinary College, of Cornell University, reported upon the phenomena of infection and variations in the manifestation of specific diseases, immunity and vaccination, and vaccine therapy. Prof. J. W. Conaway, of the University of Missouri, gave five lectures on immunity and disease resistance in animals. Prof. G. M. Reed, also of Missouri, discussed the influence of external factors on immunity and susceptibility, biologic forms in powdery mildews and rusts, and bridging species. Prof. L. R. Jones, of the University of Wisconsin, discussed problems of immunity and morphological characters of the hosts, theories of immunity, and their possible application, and W. A. Orton, of the Bureau of Plant Industry, the evolution of disease resistance and practical results obtained from a study of the disease resistance factor in general plant breeding.

Taking advantage of the presence in this country of Geheimrat Regierungsrat Dr. Otto Appel of the Imperial Biological Institute at Dahlem, Berlin, Germany, the School was favored with two lectures by him, presenting results of the latest investigations on diseases of potatoes and cereals, and discussing the control of disease through seed certification. Director Moore also, by special request, gave a lecture on bovine tuberculosis, its nature, symptoms, and relation to man.

As at previous sessions, there was general interest in the course on rural economics. Prof. T. N. Carver, of Harvard University and the Rural Organization Service of this Department, under the general head of Organization of Rural Interests discussed marketing and purchasing, rural finance and accounting, communication, education, sanitation, recreation, and beautification. President K. L. Butterfield, of the Massachusetts Agricultural College, took up rural institutions and the community idea and plan, community relationships, and rural leadership, and Prof. S. D. Gromer, of the University of Missouri, the problem of rural tenancy. Along the lines of farm management, E. H. Thompson, of the Bureau of Plant Industry,

gave some results of farm enterprise and management surveys and cost accounting investigations, discussing problems peculiar to certain sections and some profitable types of farming, and O. R. Johnson, of the University of Missouri, discussed the use of the farm diary, giving results of some studies of farm records and surveys.

Some special problems of rural communities in different parts of the country and the relations of the Department of Agriculture to the State agricultural colleges and local organizations in the development of extension work were discussed at evening and Saturday conferences. Methods of instruction relating to soils and crops, the vexed question of requirements in farm practice in college courses in agriculture, the work of traveling professors in Europe, and the relative conditions of agricultural research in Europe and the United States were also considered at these conferences.

Taken as a whole the work of this session of the Graduate School was more generally of a kind and grade appropriate to such a school and the students were more generally such as could appreciate and profit by graduate instruction than ever before. The interest and attendance were maintained to an unusual extent until the close of the session.

The problem of securing a larger representation of States and institutions at this School is evidently not solved. The great increase of summer work in the agricultural colleges and experiment stations is keeping many away. The fact that in many cases attendance at the Graduate School would practically cut off the annual vacation, so much needed by busy workers in these institutions, deters others from coming. It is therefore necessary still to urge that the managers of the institutions from which most of the students at the Graduate School must be drawn would do well to consider more seriously the advisability of more definite and liberal encouragement of attendance on the part of their faculties. An arrangement by which at least three or four men from each college would be enabled to attend each session would greatly enhance the benefits which the agricultural colleges throughout the country might derive from this School.

RECENT WORK IN AGRICULTURAL SCIENCE.

AGRICULTURAL CHEMISTRY—AGROTECHNY.

Organic chemistry, H. D. HASKINS (*New York and London, 1913, 2. ed., pp. XIII+430, figs. 25*).—The second edition of this work, which is intended for medical, pharmaceutical, and biological students, contains practical exercises and some portions of physical chemistry in addition to the organic chemistry. It is the belief of the author that an organic chemistry text-book designed for the use of medical students should consider all the organic compounds of importance that enter into the study of physiology, biochemistry, and pharmacology.

Theories of solutions, S. ARRHENIUS (*New Haven, Conn., and London, 1912, pp. XX+247, figs. 6*).—These are lectures on theories of solutions delivered at Yale University during the spring of 1911 under the Mrs. H. E. Silliman foundation, as follows: Short history of the theory of solutions; the modern molecular theory; suspensions; the phenomena of adsorption; the analogy between the gaseous and the dissolved state of matter; development of the theory of electrolytic dissociation; velocity of reactions; conductivity of solutions of strong electrolytes; equilibria in solutions; the abnormality of strong electrolytes; and the doctrine of energy in regard to solutions.

Some further contributions to simple plant bases, G. TRIER (*Hoppe-Seyler's Ztschr. Physiol. Chem., 85 (1913), No. 5, pp. 372-391*).—The betains are regarded as the simplest alkaloids formed from amino acids by exhaustive methylation.

In this work glycine (glycocoll), betaine, and choline were isolated from an alcoholic extract of oat farina. In the phosphatids from oats amino-ethyl alcohol (colamin) was noted but no betaine. The amino alcohol was found to react quantitatively with nitrous acid and can be determined in this way. Colamin was precipitated by phosphotungstic acid.

In areca nuts secondary bases were studied, and after the removal of the arecolin the bases were freed from choline.

The following formulas, which differ from those suggested by Jahns, are proposed:

Guvacin
 $C_6H_9NO_2$.

Isoguvacin
 $C_6H_9NO_2$.

Arecain
 $C_7H_{11}NO_2$.

About betonicin and turicin, A. KÜNG and G. TRIER (*Hoppe-Seyler's Ztschr. Physiol. Chem., 85 (1913), No. 3, pp. 209-216*).—The betaine mixture obtained from *Betonica officinalis* was resolved into two isomeric bases, one levorotatory

and the other dextrorotatory. The name betonicin (E. S. R., 28, p. 312) is retained for the former and turicin is the suggested designation for the latter. Both must be regarded as betains of natural oxyprolins.

Exhaustion methylation of oxyprolin ($[a]_D = -81.04^\circ$) yielded the same right and left rotatory betains as occur in *B. officinalis*. According to the method of isolation, sometimes one and sometimes the other isomer has been isolated, but in reality, according to the authors, both of these betains are present in the plant.

A description of the properties of betonicin and turicin follows.

Synthesis of betonicin and turicin, A. KÜNG (*Hoppe-Seyley's Ztschr. Physiol. Chem.*, 85 (1913), No. 3, pp. 217-224).—The gamma-hydroxyprolin from gelatin, prepared by Fischer's method, when methylated with potassium hydroxid in methyl alcohol and methyl iodid yields hydroxyprolin betain. This is a mixture of equal quantities of betonicin and turicin.

Gentiobiose, G. ZEMPLÉN (*Hoppe-Seyley's Ztschr. Physiol. Chem.*, 85 (1913), No. 5, pp. 399-407).—Octacetylgentiobiose, which has a high melting point, is not rapidly soluble but crystallizes with ease in a pure state.

These experiments show that acetylation may be conveniently employed to obtain gentiobiose from plant products, especially gentian root. Octacetylgentiobiose, isolated from purified preparations, consisted of almost colorless, silk-like, slender needles and these sintered at 186° C. and melted at 193° . The optical rotation in chloroform at 20° was -5.3 .

Octacetylgentiobiose, prepared from strongly contaminated materials (gentian extract or aqueous alcoholic extract of gentian, sintered at 192° and melted at 195°). It was easily soluble in chloroform, acetone, hot benzol, hot acetone, and hot alcohol, slightly soluble in cold alcohol and ether, and almost insoluble in petroleum ether and in hot water. It was more soluble in dilute than in absolute alcohol. Its rotation at 20° was -5.6 .

Free gentiobiose reduces 130 cc. of Fehling's solution per gram while maltose requires 128.5 cc. and cellobiose 153 cc. The phenylosazone was in the shape of lemon-yellow stellate needles and when obtained from hot water they were short-pointed prisms. The melting point was between 160 and 170° .

Enzymes in the leaves of *Salix caprea*, I. BOLIN (*Hoppe-Seyley's Ztschr. Physiol. Chem.*, 87 (1913), No. 3, pp. 182-187).—The possibility exists that the leaves of *Salix caprea* contain at least three glucosid splitting enzymes, a salicase, an amygdalase, and a β -glucosid-splitting enzym. Salicase is considered specific for salicin and is not active toward β -methyl glucosid. The enzym which acts upon β -methyl glucosid was noted in the leaves in 1911 but not in those from the same tree in 1912.

The partial hydrolysis of cellulose, G. ZEMPLÉN (*Hoppe-Seyley's Ztschr. Physiol. Chem.*, 85 (1913), No. 3, pp. 180-191).—By treating cellulose with concentrated sulphuric acid, products were formed which did not contain cellobiose complexes. Even when this treatment was prolonged, cellobiose acetate was produced on acetolysis and not dextrose pentacetate. Xylan preparations from locust wood, mannan from the seeds of *Phytelephas macrocarpa*, and chitin when partly hydrolyzed gave unsatisfactory amorphous products.

The fermentation of cellulose by thermophilic bacteria, H. PRINGSHEIM (*Centbl. Bakt. [etc.]*, 2. Abt., 38 (1913), No. 21-25, pp. 513-516, fig. 1).—The bacteria were obtained either from soil or manure. From 3 gm. of cellulose 0.2125 gm. of formic acid, 1.15 gm. of acetic acid, and a very small amount of lactic acid were produced. The remainder of the material was converted into hydrogen and carbon dioxide.

Constituents of apples, C. THOMAE (*Jour. Prakt. Chem.*, n. ser., 87 (1913), No. 3, pp. 142-144; *abs. in Jour. Chem. Soc. [London]*, 104 (1913), No. 605, I,

pp. 327, 328).—The compound previously noted (E. S. R., 26, p. 208), which melts at over 200° C., can be separated by treatment of the apple skins with ether into an insoluble substance “of high melting point, and a waxy substance crystallizing in needles, melting point 68.5°. On distillation under diminished pressure, the oil obtained by extracting the skins with ether yields a crystalline substance of low melting point having an odor of apples and a yellow oil which readily solidifies. The behavior of the skins on distillation is also described.”

The study of the ripening of fruit, A. CONTINO (*Staz. Sper. Agr. Ital.*, 45 (1912), No. 5–6, pp. 460–472; *abs. in Chem. Abs.*, 7 (1913), No. 19, p. 3373).—“Kaki plums were used. One sample was analyzed immediately; the second sample was kept in air 1 month; the third sample was preserved in paraffin. Results showed that the second sample had lost in weight through respiration. The constituents, however, remained the same as in the sample preserved with paraffin, except in the case of pectins, of which the third sample contained three times as much as the second sample. The formation of pectins, therefore, has nothing to do with the atmospheric oxygen but is brought about by the internal decomposition of the tannin. The fruit contained no sucrose.”

The constituents of hops, F. B. POWER, F. TUTIN, and H. ROGERSON (*Jour. Chem. Soc. [London]*, 103 (1913), No. 609, pp. 1267–1292).—The material used in this investigation consisted of good Kentish hops, harvested in 1911. The air-dried hops contained 10.48 per cent of moisture, 2.4 per cent of tannin, and 7.919 per cent of ash.

The work emphasizes the fact that the bitterness of hops is not due to a single substance but to a number of products, some of these soluble in alcohol and others soluble in water. One of these, which was a well-defined, crystalline, bitter substance, termed humulol, $C_{17}H_{16}O_4$, was isolated from the resin. It is phenolic in character, melts at 196° C., is fawn-colored, and on hydrolysis with potassium hydroxid yields among other products an acid, $C_{15}H_{14}O_5$, melting point 210°, and p-hydroxybenzaldehyde. Another crystalline compound, designated as xanthohumol, $C_{13}H_{14}O_3$ (melting point 172°), which is tasteless and possesses an orange-yellow color, was also isolated.

That hops contain a yellow coloring matter resembling quercitrin and myricylpalmitate could not be confirmed. It is shown that the alcoholic extract, which consisted of a dark green, oily resin (equivalent to 14.1 per cent of the weight of the hops), contained “ceryl alcohol, $C_{27}H_{56}O$, hentriacontane, $C_{31}H_{64}$; a phytosterol, $C_{27}H_{46}O$; a phytosterolin (phytosterol glucosid), $C_{33}H_{56}O_6$; a mixture of volatile fatty acids, consisting of formic, acetic, butyric, and valeric acids, together with a hexenoic acid, $C_6H_{10}O_2$ (boiling point 204 to 208°), which was identified as B-isopropylacrylic acid, and apparently a little nonoic acid, $C_9H_{16}O_2$, was also present; saturated and unsaturated nonvolatile acids, comprising palmitic, stearic, and cerotic acids, and an acid, $C_{20}H_{40}O_2$ (melting point 62.5 to 63°), which is apparently an isomerid of arachidic acid; furthermore, cluytinic acid, $C_{21}H_{42}O_2$ (melting point 69°), the methyl ester of which melts at 47°, and linolic acid.”

“From the portion of the extract which was soluble in water there were isolated small amounts of cholin, $C_5H_{15}O_2N$, and l-asparagin, $C_4H_8O_3N_2$, both of which had previously been observed to be present, although no evidence of the identity of the last-mentioned substance appears to have hitherto been recorded. The aqueous liquid also contained, besides tannin, a quantity of potassium nitrate and a sugar which yielded d-phenylglucosazone (melting point 208°), together with dark-colored, amorphous material which possessed an intensely bitter taste. A volatile base, having a conin-like odor, was also obtained, but the amount was so extremely small that it could not be further characterized.”

Formation of fat in oleaginous fruits.—IV, Formation of fat in *Phillyrea media*, F. SCURTI (*Ann. R. Staz. Chim. Agr. Sper. Roma*, 2. ser., 6 (1913), No. 1, pp. 29–37; *abs. in Jour. Soc. Chem. Indus.*, 32 (1913), No. 10, p. 542).—The results obtained were analogous to those previously noted (*E. S. R.*, 29, p. 201).

In the *Phillyrea* the fatty acids present are oleic, palmitic, and stearic, and the waxy alcohol from which they originate is fillirol. The latter melts at 290–295° C. and has the same composition ($C_{31}H_{50}O_2$) as oleanol and ligustrol. The fatty substances extracted by petroleum ether from the fruits had an acid number of 25.6 and saponification number of 172.2. The amount of petroleum extract present was 11.93 per cent when calculated on a dry basis.

Formation of fat in cork.—V, Cork from the elder (*Sambucus nigra*), F. SCURTI (*Ann. R. Staz. Chim. Agr. Sper. Roma*, 2. ser., 6 (1913), No. 1, pp. 39–52; *abs. in Jour. Soc. Chem. Indus.*, 32 (1913), No. 10, p. 542).—The methods used for this work were similar to those employed in previous investigations. In the cork a waxy alcohol melting at 278–280° C. and of the same composition ($C_{31}H_{50}O_2$) as those noted in the olive, Japanese privet, etc., was present. The substance has been described as cerin by other investigators.

Formation of fat in cork.—VI, Researches on the leaves of elder (*Sambucus nigra*), F. SCURTI and G. TOMMASI (*Ann. R. Staz. Chim. Agr. Sper. Roma*, 2. ser., 6 (1913), No. 1, pp. 53–59; *abs. in Jour. Soc. Chem. Indus.*, 32 (1913), No. 10, p. 542).—“The portion of the ether extract soluble in petroleum spirit contains stearic acid and other fatty acids which have not been identified. In plants (olive, Japanese privet) of the order Oleaceæ the waxy alcohol is formed in the leaves of the plant, but its transformation into fatty acids takes place almost entirely in the fruit. In the elder, on the other hand, which belongs to the order Caprifoliaceæ, the formation of the waxy alcohol and its transformation (to a considerable extent) into fatty acids both take place in the leaves.”

Formation of fat in cork.—VII, Fellenic acid of Kügler, F. SCURTI and G. TOMMASI (*Ann. R. Staz. Chim. Agr. Sper. Roma*, 2. ser., 6 (1913), No. 1, pp. 67–75).—The constituent of cork designated as fellenic acid by Kügler was isolated and identified as α -hydroxybehenic acid ($C_{22}H_{44}O_2$).

The chemical composition of cork substance, G. ZEMPLÉN (*Hoppe-Seyler's Ztschr. Physiol. Chem.*, 85 (1913), No. 3, pp. 173–179).—Cork substance, isolated by the methods employed for isolating cellulose, when judged by its appearance and solubility is very similar to cellulose but when acetylated does not yield cellobiose acetate.

Cork flour contains in 100 gm., water 6.21, ash 4.12, alcoholic extract obtained after 2 hours 10.5, fatty acids obtained from the alcoholic extract by saponification with alcoholic potassium hydroxid 19, an extract (nonreducing) obtained by a second extraction of the cork residue with alcohol for 3 hours 13.5, a watery extract obtained by extraction for 1 hour on the water bath 14 (the watery solution, when hydrolyzed with normal sulphuric acid yielding 1.24 gm. of a substance calculated as d-glucose), and a 1.5 per cent sulphuric acid extract which showed 1.5 gm. of sugars calculated as d-glucose. The amount of residue remaining after extraction was 24.5 gm. and from this 4.17 gm. of a cellulose-like but not identical product was obtained by hydrolyzation with the Bevan and Cross chlorin method.

The cork used in the experiments was of good quality, and was obtained from Portugal.

Methods for the biochemical examination of soils, J. STOKLASA (*X. Cong. Internat. Agr. Gand*, 1913, Sect. 2, Question 3, pp. 14).—The biological phenomena in the soil are dependent upon climatic factors, the physical and

chemical make-up of the soil, the composition of the soil air, the temperature, the time of year, and the animal and vegetable life contained therein. Methods are briefly discussed under the headings of hygroscopically and mechanically absorbed water in soil; water capacity; water vapor and oxygen in the soil air; air capacity of the soil; whether the organic substance of the soil will serve as a good source of carbon for heterotrophs; the respiratory intensity of soil bacteria, and the cleavage of organic substances in the soil; anaerobic and aerobic respiration of bacteria in the soil; nitrogen requirements of soil micro-organisms; oxidation processes of nitrogenous substances in the soil; putrefaction of nitrogenous organic substances by anaerobic organisms; a biochemical method for determining available phosphoric anhydrid and potassium oxid in the soil; bacteriological soil examination; cellulose-destroying power of the soil; detection of bacteria which decompose carbohydrates in the soil; soil catalase; and biological absorption of the soil. In some cases the interpretation of the results obtained on the basis of the above methods is described.

A full account of the methods mentioned has been previously presented by Abderhalden (E. S. R., 27, p. 107).

Estimation of total carbon in soils, M. E. Pozzi-Escot (*Bul. Assoc. Chim. Sucr. et Distill.*, 30 (1913), No. 10, pp. 618-621; *abs. in Jour. Chem. Soc. [London]*, 104 (1913), No. 609, II, p. 622).—In this method a quantity of soil containing not more than 0.3 gm. of organic matter is mixed in a nickel boat with 0.1 gm. of fused potassium bichromate and 1 gm. of lead chromate, and the combustion conducted in the usual manner.

It is necessary to employ a large excess of oxygen, but the rate at which this gas is passed through the combustion tube must be slow. It is advisable to pack the tube with copper oxid in the form of threads for a length of at least 350 mm. and the copper foil usually employed may be replaced by silvered pumice. The carbon dioxid formed is absorbed in a suitable apparatus and weighed.

The author criticizes the method described recently by Grégoire (E. S. R., 28, p. 708).

Estimation of carbon and carbon dioxid, A. Grégoire, J. Hendrick, E. Carpiaux, and E. Germain (*Ann. Chim. Analyt.*, 18 (1913), No. 1, pp. 1-8, fig. 1; *abs. in Jour. Chem. Soc. [London]*, 104 (1913), No. 605, II, p. 243).—The method proposed has been previously described (E. S. R., 28, p. 708).

The application of Folin's method for the determination of ammonia to fertilizers, O. Folin and A. W. Bosworth (*Jour. Indus. and Engin. Chem.*, 5 (1913), No. 6, p. 485).—This method (E. S. R., 24, p. 703) is now recommended for determining ammonia in fertilizers in lieu of the magnesium oxid method, as follows:

“Two gm. of fertilizer is placed in a 100 cc. graduated flask, about 50 cc. of water added, and then 25 cc. of approximately normal hydrochloric acid. The volume is now made up to 100 cc. with water, the contents of the flask are shaken, and after standing a few minutes are shaken a second time. The flask is now allowed to stand until the heaviest of the undissolved particles have settled. Five cc. of the supernatant liquid is withdrawn by means of a pipette (filtering is not necessary) and transferred to the tube of the Folin apparatus. Two cc. of a saturated solution of potassium oxalate, a few drops of kerosene, and finally 2 cc. of a saturated solution of potassium carbonate are added. The apparatus is immediately closed and air passed through for 10 to 20 minutes. The ammonia is collected in a flask or test tube which contains 20 cc. of seventieth-normal hydrochloric acid. If the air current is produced by a blast the ammonia is collected in a flask and 25 cc. of water is added to

the 20 cc. of acid in order to increase the volume and thus prevent the loss of ammonia.

"After the distillation, the contents of the flask, or test tube, are titrated back with seventieth-normal sodium hydroxid, using alizarin red as indicator. The percentage of nitrogen as ammonia is found by subtracting the number of cubic centimeters of alkali used from the number of cubic centimeters of standard acid used, and dividing the difference by 5."

The method as given has been tried on 22 samples of fertilizers.

Estimation of water-soluble phosphoric acid in ammonium superphosphates, E. BÜTTNER (*Chem. Ztg.*, 37 (1913), No. 66, p. 662; *abs. in Jour. Chem. Soc. [London]*, 104 (1913), No. 609, II, p. 621).—About 0.5 per cent more water-soluble phosphoric acid may be obtained when ammonium superphosphate is shaken for 30 minutes with water at a temperature of 18 to 20° C. than when the temperature is allowed to fall to 16° during the shaking process. The solubility also increases with the fineness of the superphosphate.

The determination of phosphoric acid in Thomas slag powder, M. POPP (*Ztschr. Angew. Chem.*, 26 (1913), No. 71, Aufsatzteil, p. 480).—The results obtained with the Lorenz method agreed with those given by the magnesium precipitation method only when the solution contained large amounts of calcium. Evidently a compensation occurs between the calcium and phosphoric acid. If twice the amount of citrate solution is used, low results are found. Magnesium is also easily precipitated and consequently no uniform ammonium magnesium phosphate is obtained. Satisfactory results are obtained only when the phosphoric acid is precipitated under identical conditions.

The work emphasizes the fact that the citrate magnesium phosphate method is a compensation method. When the results agree with those found by the Lorenz method it is an indication that the latter is yielding low results.

The rapid estimation of magnesia in limestone by means of the hydrogen electrode, J. H. HILDEBRAND and H. S. HARNED (*Orig. Commun. 8. Internat. Cong. Appl. Chem. [Washington and New York]*, 1 (1912), Sect. I, pp. 217-225, figs. 3; *abs. in Jour. Chem. Soc. [London]*, 104 (1913), No. 610, II, p. 727).—The method is based on the fact that if normal alkali is added to a solution consisting of calcium and magnesium chlorids, the magnesium is precipitated first and the end point is observed by a further rise in potential.

The apparatus required is shown in the original.

The hydrolysis of levulosans and its application to plant analysis, P. L. DE VILMORIN and F. LEVALLOIS (*Bul. Soc. Chim. France*, 4, ser., 13 (1913), No. 13, pp. 684-691; *abs. in Jour. Chem. Soc. [London]*, 104 (1913), No. 610, II, p. 736).—This is a study of the behavior of inulin toward hydrolyzing agents.

The use of sulphosalicylic acid (0.72 to 4.3 gm. per liter) at a temperature of 80 to 100° C. is recommended. The acid has no effect on the subsequent estimation of the reducing sugars by Fehling's solution. Sulphuric and oxalic acids are said to give figures which are too variable. Acetic acid in concentrations of from 3 to 10 per cent and hydrolyzing at 80° gives fairly concordant results, but the acid and its salts interfere with the subsequent determination of the sugars.

The anatomical structure of some foreign pod fruits, M. KONDO (*Ztschr. Untersuch. Nahr. u. Genussmtl.*, 25 (1913), No. 1, pp. 1-56, figs. 40).—This is a description of the gross and minute anatomy of *Glycine soja*, *Dolichos melanophthalmus*, *Vigna sinensis*, *D. lablab*, *Canavalia ensiformis*, *Lathyrus sativus*, and *Cicer arietinum*. An analytical key is included.

About the nature and significance of the quantitative precipitin reaction in honey examinations, J. THÖNI (*Ztschr. Untersuch. Nahr. u. Genussmtl.*, 25 (1913), No. 8, pp. 490-493).—The precipitin reaction (E. S. R., 28, p. 22) was

found to differentiate real from spurious honey and further to determine the extent to which a honey has been adulterated. The author, however, does not wish to imply that all other methods suggested for honey examination should be eliminated.

The method has not generally been employed in food-control work except at the Swiss food-control stations, but this is probably due to the difficulty experienced in obtaining the antiserum and normal rabbit serum. For the purpose strong antisera are necessary.

The method of conducting the test is described in detail.

In regard to foreign honeys, K. LENDRICH and F. E. NOTTBOHM (*Ztschr. Untersuch. Nahr. u. Genussmtl.*, 26 (1913), No. 1, pp. 1-11).—Analyses are given of honeys gathered in France, Italy, Hawaii, the United States, Mexico, Jamaica, Guatemala, Cuba, Haiti, Santo Domingo, Peru, Chile, and Australia. The results are compared with German honeys.

About Fiehe's reaction, J. GERUM (*Ztschr. Untersuch. Nahr. u. Genussmtl.*, 26 (1913), No. 2, pp. 102-104).—Some samples of German honey give an orange or reddish yellow coloration with Fiehe's test. This is not due to the presence of invert sugar but rather to the presence of waxy substances in the honey. If such a reaction is obtained, it is advisable to extract a large quantity of honey with ether and then evaporate the extract and examine for the presence of beeswax.

About free and fixed lactic acid in grape and fruit wines, T. ROETTGEN (*Ztschr. Untersuch. Nahr. u. Genussmtl.*, 26 (1913), No. 11, pp. 648-650).—An attempt to simplify existing methods, especially Kunz's, for determining lactic acid in wine and also to note whether the lactic acid extractable by ether represents the free acid present.

The results show that the free lactic acid can be easily extracted by the method prescribed. Grape wine contains only free lactic acid, while apple, pear, and other fruit wines contain both fixed and free lactic acid. Although fruit wines yield only a part of their free acid to ether, the possibility still exists for using a procedure of this kind for determining the addition of fruit wine to grape wine.

Sugar analysis, F. G. WIECHMANN (*New York and London, 1914, 3. ed., pp. XIII+307, figs. 7*).—This is the third edition of this work and has been entirely rewritten.

Examination of sugar-beet chips for the addition of molasses, R. Woy (*Ztschr. Öffentl. Chem.*, 19 (1913), No. 9, pp. 168, 169; *abs. in Ztschr. Angew. Chem.*, 26 (1913), No. 92, *Referatenteil*, p. 699).—The addition of molasses to beet chips can be easily recognized by the odor of the feed. If the chips, after maceration with water, are acidified with phosphoric acid and then heated, a disagreeable odor is evolved which can be noted even when quantities of molasses as low as 2 per cent are present.

About the colorimetric determination of injurious nitrogen in the sugar beet, G. FRIEDL (*Osterr. Ungar. Ztschr. Zuckerindus. u. Landw.*, 40 (1911), No. 1, pp. 274-284, figs. 5).—A continuation of the work previously noted (E. S. R., 23, p. 514). The colorimetric method is described in which the Stammer colorimeter is used and the color of filtrate obtained in the copper hydroxid precipitation is compared with standard colored glasses. The term "injurious nitrogen" is discussed with regard to whether ammoniacal and amid nitrogen should be included in the term.

Bottling and preserving of fruit, T. REDINGTON (*Agr. Jour. Brit. East Africa*, 4 (1912), No. 4, pp. 289-295).—Directions are given for the home canning of fruits, together with recipes for preparation of "fruit-cheese," jellies, jams, and fruit juices.

The unfermentable sugar (pentose) and furfural formation in wines, R. HAID (*Ztschr. Gärungsphysiol.*, 2 (1912), No. 2, pp. 107-109).—The furfural in wines originates from a pentose which is not an arabinose. The formation of this aldehyde is gradual and its production increases with the concentration of the wine.

METEOROLOGY—WATER.

Report of the meteorological station at Berkeley, California, for the year ending June 30, 1913, W. G. REED (*Univ. Cal. Pubs. Geogr.*, 1 (1914), No. 6, pp. 247-306, pls. 3, figs. 8).—Observations on pressure, temperature, precipitation, cloudiness, and wind at Berkeley during the year ended June 30, 1913, are summarized and discussed in this paper. The mean temperature for the year was 57° F.; the precipitation was 15.63 in., or 10.54 in. less than the average. September and November had more than the average rainfall, but all the other months had less.

Meteorological observations made at Berkeley from July 1, 1887, to June 30, 1912, A. O. LELSCHNER (*Univ. Cal. Pubs. Geogr.*, 1 (1914), No. 5, pp. 241-246).—Observations on temperature, pressure, rainfall, humidity, and cloudiness at Berkeley from July 1, 1887, to June 30, 1912, are summarized in this report.

The mean pressure, calculated from these observations, is 30.019, the 25-year range 1.633; the mean temperature 54° F.; maximum temperature, June 6, 1903, 101.1°; minimum temperature, January 14, 1888, 24.9°; the mean rainfall, 26.62 in.; mean relative humidity, 85.5 per cent; minimum humidity, October 28, 1890, 2 p. m., 27.3 per cent; and average number of clear days 156, fair days 88, foggy days 56, and days on which rain fell 71.

Meteorological summaries for the year 1911 (*Kentucky Sta. Rpt. 1911*, pp. 347-350).—Observations at the State University at Lexington on temperature, pressure, precipitation, cloudiness, wind, and miscellaneous phenomena are reported in tables.

The climate of British Columbia, E. B. REED ET AL. (*Bur. Prov. Inform. [Brit. Columbia] Bul.* 27, 2. ed. (1914), pp. 12, pl. 1).—Data, mainly on temperature and precipitation, at different places in British Columbia during 1911 to 1913 are compiled and briefly discussed, the characteristic features of the climate of the Province being indicated.

The weather of Scotland in 1913, A. WATT (*Trans. Highland and Agr. Soc. Scotland*, 5. ser., 26 (1914), pp. 288-300).—"This report consists of (1) a general description of the weather over the Scottish area from month to month; (2) a selection of rainfall returns, in which each county in Scotland is represented by one or more stations. . . . The outstanding feature of the year was perhaps the long-continued spell of dry weather in summer."

Temperature, precipitation, and water-table fluctuations in northern Europe, A. WALLÉN (*Met. Ztschr.*, 31 (1914), No. 5, pp. 209-220, figs. 8).—These fluctuations are shown diagrammatically and briefly explained.

Analyses of mineral and potable waters, A. M. PETER, S. D. AVERITT, and O. M. SHEDD (*Kentucky Sta. Rpt. 1911*, pp. 329-346).—Analyses (mostly partial) of miscellaneous samples are reported.

The fertilizing value of sewage and sewage sludge, H. W. CLARK (*Surveyor*, 45 (1914), No. 1162, pp. 687, 688).—A summary of an article previously noted (*E. S. R.*, 30, p. 621).

SOILS—FERTILIZERS.

Economic waste from soil erosion, R. O. E. DAVIS (*U. S. Dept. Agr. Yearbook 1913*, pp. 207-220, pls. 6).—The author in a general survey of the economic aspects of soil erosion points out that the fertility of the fields in many hilly

sections is being reduced by the bodily removal of the soil material. He particularly draws attention to the relative erosion of forested and cleared lands, and to the relation of erosion to lumbering, mining, power development, navigation, and agriculture. It is pointed out that the main factor in the better utilization of rainfall, the reclamation of eroded soils, and the prevention of soil erosion, is the retention of water where it falls by means of different soil treatments, including terracing, deep plowing, foresting, increasing the humus supply, etc., thus either increasing the porosity of the soil and its absorptive capacity for rain water, or decreasing the velocity of the surface run-off and keeping it within safe limits.

Soil erosion and its remedy by terracing and tree planting, J. R. SMITH (*Science, n. ser., 39 (1914), No. 1015, pp. 858-862*).—The author in discussing erosion of sloping soils, and factors aggravating or retarding this, draws attention to the possibilities offered by the so-called plowless utilization of land, not only for checking erosion, but also for increasing the crop area. This plan includes as main factors (1) forestry by means of crop trees to control erosion and provide forage and food, and (2) moisture and fertility control by means of careful terracing.

The influence of winds in the formation of agricultural soils, A. BENCKE (*Naturwissenschaften, 2 (1914), No. 16, pp. 396-398*).—The author discusses briefly wind erosion, transportation, and deposition of soil-forming materials, relative to the formation and fertility of different types of agricultural soils.

The environment of soil organisms, F. H. H. VAN SUCHTELEN (*Science, n. ser., 39 (1914), No. 1012, p. 763*).—In a study of soil as a culture medium a method was devised for obtaining the soil solution based on its displacement by inactive substances (paraffin oil, vaseline, etc.). The concentration of the soil solution thus obtained was similar to that of the very first portion of drainage water obtained by careful percolation through a large quantity of soil. Physico-chemical and chemical examinations of the liquid obtained by the displacement process showed that different soils, soils closely adjacent, and soils of the different layers, contained soil solutions of different compositions.

Antagonism between salts as affecting soil bacteria, C. B. LIPMAN (*Science, n. ser., 39 (1914), No. 1012, p. 764*).—Experiments dealing with the antagonism between anions of the alkali salts—sodium chlorid, sodium carbonate, and sodium sulphate—showed that both as regards ammonification and nitrification it was possible to improve the soil as a medium after it had been made toxic for the bacteria in question by means of any one of these salts, through the addition of any other of the three. "Thus briefly, it was possible at times to triple and quadruple the total salt content of the soil and still make it a better medium for ammonification and nitrification than it was with one-third or one-fourth of the total salt content consisting, however, of but one salt." The author indicates the great significance of this in regard to the management and control of alkali land.

Studies on ammonification in soils by pure cultures, C. B. LIPMAN and P. S. BURGESS (*Univ. Cal. Pubs. Agr. Sci., 1 (1914), No. 7, pp. 141-172*).—Comparative tests of the power of pure cultures of *Bacillus mesentericus vulgatus*, *Pseudomonas putida*, *B. vulgatus*, *B. megatherium*, *B. mycooides*, *B. subtilis*, *B. tumescens*, *Sarcina lutea*, *B. proteus vulgaris*, *B. icteroides*, *B. ramosus*, *Streptothrix* sp., *P. fluorescens*, *P. vulgaris* (Novy strain), and *Micrococcus tetragenus* to produce ammonia from dried blood, tankage, cotton-seed meal, sheep and goat manure, peptone, fish guano, and bat guano in sandy soil, clay loam, and black clay adobe soil are reported and discussed and the results compared with those obtained by other investigators.

It was found that the nature of the soil, as well as the nature of the nitrogenous matter, markedly modified the ammonifying powers of an organism, there being no regularity or certainty in these variations; but every organism did best with a definite combination of soil and organic matter. *B. tumescens* appeared on the whole to be the most efficient organism tested.

In sandy soil as a medium *B. vulgaris* was the most efficient ammonifier with dried blood; *B. mesentericus* with tankage; *B. tumescens* with cotton-seed meal; *B. vulgaris* with fish guano; *B. mycoides* with bat guano; *B. megatherium* with sheep and goat manure; and *S. lutea* with peptone. Using the clay loam soil as a medium *B. proteus vulgaris* was the most efficient with dried blood; *B. tumescens* with tankage; *Streptothrix* sp. with cotton-seed meal; and *B. megatherium* with fish guano. Using the clay adobe soil as a medium *B. tumescens* was the most efficient with dried blood; *S. lutea* with tankage; *B. tumescens* with cotton-seed meal; and *B. vulgaris* with fish guano.

The highest efficiency in a single culture with a fertilizer was shown by *B. mycoides* in bat guano and in a single culture with peptone by *S. lutea*. A comparison of availability of nitrogenous fertilizers with ammonifiability as a criterion showed tankage, fish guano, and cotton-seed meal to be superior in most or in many cases to dried blood. Some of the organisms tested, particularly *B. icteroides* and *P. fluorescens*, were consistently weak ammonifiers.

Nitrogen accumulation in continuous rye culture, P. EHRENBURG (*Fühling's Landw. Ztg.*, 63 (1914), No. 5, pp. 178, 179).—The author defends his views as set forth in a previous article (E. S. R., 30, p. 424).

Nitrogen and organic matter in dry-farm soils, R. STEWART and C. T. HIRST (*Jour. Amer. Soc. Agron.*, 6 (1914), No. 2, pp. 49-56).—Studies of the nitrogen and humus content of virgin soils, and soils which have been dry-farmed (by continuous cropping or summer fallowing) for different lengths of time, in the Bear River, Salt Lake, and Juab valleys of Utah, yielded results and conclusions similar to those obtained in previous work in the Cache Valley (E. S. R., 24, p. 422). That no marked decrease was shown in the nitrogen and humus supply of the surface-cultivated, dry-farm soils "is probably due to the deep-rooted character of the wheat plant when grown under dry-farm conditions and to the fact that very little erosion takes place by wind or water."

Sulfification in soils, P. E. BROWN and E. H. KELLOGG (*Science*, n. ser., 39 (1914), No. 1012, pp. 764, 765).—In this article it is maintained that soils have a definite "sulfofying power" (power of producing sulphates from other sulphur compounds) which may be determined in the laboratory as follows:

Add 0.1 gm. of a sulphid, or of sulphur, to 100 gm. of fresh, uncontaminated soil, and bring the moisture conditions to the optimum by additions of sterile water. Incubate the soils for from 4 to 5 days at room temperature, after which leach out the sulphates by shaking for 6 hours with water. The sum of the sulphate content of the soil itself and the purely chemical oxidation of the sulphid occurring upon shaking, subtracted from the total sulphate content of the soil after incubation, gives the sulfofying power of the soil, or the physiological efficiency of the sulphur oxidizing bacteria in the soil.

The awakening of the soil, A. MUNTZ and H. GAUDECHON (*Ann. Sci. Agron.*, 4. ser., 2 (1913), II, No. 1, pp. 1-15, fig. 1).—This is a full account of investigations briefly noted elsewhere (E. S. R., 26, p. 722).

The fertility of the soil, B. P. SMOOT (*Missouri Bd. Agr. Mo. Bul.* 12 (1914), No. 3, pp. 31).—It is the purpose of this bulletin to present in popular form the scientific facts underlying the principles of soil fertility and soil management.

The benefits of deep plowing and of maintaining the humus supply in soils are particularly emphasized and the keeping of live stock is discussed in its

relation to maintaining the soil fertility. General information is given regarding commercial fertilizers, soil correctives and stimulants, and their use.

The duration of the action of manures, A. D. HALL (*Jour. Roy. Agr. Soc. England*, 74 (1913), pp. 119-126).—This article is based upon results of experiments begun at Rothamsted in 1904 with an alternating rotation of wheat and root crops on "eight sets of five plats; five for nitrogenous manures—dung made from roots and hay only, cake-fed dung, shoddy (wool waste), Peruvian guano, rape dust, and three for phosphatic manures—bone meal, superphosphate, and basic slag. Once during each rotation a dressing of superphosphate and sulphate of potash was applied equally to all the nitrogen plats; similarly for the corn [grain] crops a dressing of sulphate of ammonia was given alike to all the phosphatic plats. For each manurial series there was one check plat unmanured."

Of the manured plats "one received the manure in 1904, but remained unmanured in 1905, 1906, and 1907; a second plat was manured in 1906, but not in 1907; the third in 1907. Thus in 1907, by which year the experiment was in full swing, there was a plat that had been manured in that year, another that had been manured in the previous year; a third two years previously; and a fourth three years previously. In 1908 it was considered that the manure applied in 1904 to the first plat had been exhausted by the four crops grown with it, and the manuring was renewed on that plat; on the second plat it was renewed in 1909, and so on; the result being that in any year after 1907 there was a crop grown on some plat with the manure; on a second plat with the residue of the manure after one crop had been taken; on a third with the residue after two crops; and on a fourth with the residue after three crops; while there was a further check plat that had never received the manure."

The conclusions reached are summarized as follows: "As regards farmyard manure we can distinguish between the nitrogenous compounds introduced by the consumption of cakes and other concentrated feeding stuff and the compounds derived from the straw and the undigested residues of such coarse foods as hay. The former will have an immediate effect on the first crop, and to a much smaller extent on the second crop, after which they disappear; the latter compounds act slowly, do not waste, and have a measurable value for many years, though for practical purposes we may neglect their action after the fourth year.

"Among nitrogenous fertilizers ammonium compounds and nitrate of soda have no perceptible action after the first year; Peruvian guano, rape cake, and similar fertilizers containing proteins leave very little residue after the first year, and none after the second. On the other hand, nitrogenous fertilizers of the wool, hair, bone class are slowly acting and nonwasting; their effect may be expected to persist for at least four years.

"Phosphatic fertilizers, even when soluble like superphosphate, do not waste in the soil, and their residues continue to be effective until they have been exhausted by the crops.

"To one other point attention may be called, though it does not arise strictly out of these experiments. It is seen that the residues of active nitrogenous fertilizers are wasted; this wastage takes place in the winter, for soils in the autumn after the crop has been removed become very rich in nitrates, which usually disappear before the spring. Hence, especially in rich soils, there will be a great economy if before the winter the land can be occupied by a rapidly growing catch crop which will convert these fugitive nitrates, etc., into insoluble plant material, afterwards plowed in to become available for another crop."

Interpreting fertilizer tests, C. E. THORNE (*Jour. Amer. Soc. Agron.*, 5 (1913), No. 3, pp. 129-137).—A reply to criticisms of the plan of fertilizer

experiments at the Ohio Station contained in an article by Warren, previously noted (E. S. R., 29, p. 213).

Further notes on interpreting fertilizer tests, G. F. WARREN (*Jour. Amer. Soc. Agron.*, 5 (1913), No. 3, pp. 137-140).—A reply to the article noted above reiterating certain points emphasized in the previous articles, viz, that in fertilizer experiments “(1) more attention should be given to the place in the rotation at which fertilizers are applied. (2) The difference between the cost of a fertilizer and the value of the increased crop is not all profit. The extra cost of harvesting, storing, and marketing increased crops must also be considered, particularly in cases where a very expensive treatment gives only slightly greater returns above fertilizer cost than is given by a cheaper treatment. (3) Too little attention is given to the increased value of the land because of the residual effect of fertilizers.”

Fertilizing the rotation, H. O. BUCKMAN (*Jour. Amer. Soc. Agron.*, 5 (1913), No. 3, pp. 157-164).—Conclusions regarding the time and manner of fertilizing a rotation are drawn from data derived from various sources.

Stimulants of plant growth (*Rev. Sci. [Paris]*, 52 (1914), I, No. 21, p. 663).—This is a brief note referring to the use by Payen in 1837 of the term “stimulant” as applied to certain kinds of fertilizing materials now frequently referred to as catalytic.

The fertilizing value of the above-ground parts of cereals and leguminous plants, J. MIKULOWSKI-POMORSKI (*Kosmos [Lemberg]*, 38 (1913), pp. 929-951).—From the large amount of data bearing upon this subject which are reported the conclusion is drawn that the greater value of leguminous plants for green manuring as compared with cereals is due not only to the ability of the former to utilize the free nitrogen of the air but also to the fact that the nitrogen which leguminous plants contain is qualitatively of greater fertilizing value than that of cereals. This is true not only of the stems and leaves but also of the seed.

The nitrogen of Gramineæ in the earlier stages of growth is of greater fertilizing value than that of the maturer plants. The fertilizing value decreases as the plants approach maturity. Thoroughly ripe straw may even be injurious. Such marked changes were not observed in the leguminous plants as they matured. The nitrogen of the seed of leguminous plants was of greater fertilizing value than that of the stems and leaves.

The changes of stable manure during storage and its action in soil, F. LÖHNIS and J. H. SMITH (*Fühling's Landw. Ztg.*, 63 (1914), No. 5, pp. 153-167).—Experiments with fresh stable manure and manure in different stages of decay to determine (1) the numbers and kinds of organisms present, (2) the qualitative and quantitative changes undergone by the solid and liquid constituents when separated and combined, particularly as regards the nitrogen content, and (3) the extent of the activity in soil of the nitrogen content are reported.

The results indicate the importance of preventing the great losses of nitrogen in manure during storage and in distribution and of better utilizing the plant food content. The following conclusions are drawn: Urine may be mixed with peat dust and used in that form, thus decreasing the loss of nitrogen through ammonia evaporation. Excrement and straw mixture and urine when used separately have a better effect and suffer less loss in value. The chief value of excrement and straw mixture lies in its high bacterial content and its richness in humus-forming organic matter. Its fertilizing value is always small and in the most favorable cases the nitrogen action can increase only about 20 per cent in the first year. About one-half of the excrement nitrogen is present in the form of living and dead microbes, the other part being derived from the

indigestible parts of the animal food. A rapid mineralization is in both cases prevented. Likewise the plant food in the straw is only very gradually broken down and made available. In direct contrast to these urine is relatively poor in bacteria and humus-forming matter but rich in active plant food. A mixture of solid and liquid manure often has a better fertilizing effect the first year than the mixture without urine, but the second year shows great losses due to storage of the manure in the soil and imperfect utilization of the plant food content of the urine. Urine used in separate form gives as good results as ammonium sulphate or sodium nitrate. The nitrogen losses from manure during storage are due in part to volatilization of ammonia and in part to the setting free of elementary nitrogen. The losses due to denitrification are unimportant, as the deficiency in nitrates usually make denitrification either impossible or very limited. A determination of the carbon content in manure is of special importance since the quantity and kind of carbon combinations largely determine the extent of the activity of the plant food added in manure. Nitrate-forming bacteria can be found in every manure, but not in noteworthy numbers.

The utilization of peat in Italy, U. ROSSI (*Bol. Quind. Soc. Agr. Ital.*, 19 (1914), No. 10, pp. 356-361).—This article discusses particularly the preparation of ammonium sulphate from peat.

The manufacture of nitrates by direct electrolysis of peat, G. DARY (*Elect. Rev.*, 73 (1913), No. 1882, pp. 1020, 1021, figs. 2; *Jour. Amer. Peat Soc.*, 7 (1914), No. 1, pp. 20-26, figs. 2; *Engrais*, 29 (1914), No. 12, pp. 329-333).—A process of electrolytically extracting nitric acid from nitrifying peat is described.

The present state of the cyanamid industry, E. J. PRANKE (*Jour. Indus. and Engin. Chem.*, 6 (1914), No. 5, pp. 415-419).—It is estimated that the world's production of calcium cyanamid will reach 275,000 tons in 1914. The works at Niagara Falls, Canada, are being increased to a capacity of 64,000 tons. Recent improvements in the manufacture of the product are described and its use as a fertilizer is discussed.

The production of phosphates, MAIZIÈRES (*Engrais*, 28 (1913), Nos. 46, pp. 1274-1276; 47, pp. 1302-1304; 48, pp. 1330, 1331; 50, pp. 1386-1388, fig. 1; 52, pp. 1442, 1443).—This article deals particularly with the production of phosphates in Algeria and Tunis.

The action of guano components on carbonates in phosphoriferous rock on Nauru Island, C. ELSCHNER (*Amer. Fert.*, 40 (1914), No. 10, pp. 25-27, fig. 1).—The probable formation of these phosphate deposits by the infiltration of the dolomitic reefs with solutions of guano deposits is discussed and analyses of the phosphates are given.

Potash salts: Summary for 1913, W. C. PHALEN (*U. S. Geol. Survey, Mineral Resources of the United States, 1913, pt. 2, pp. 85-107*).—A brief account is given of progress in investigations by the Geological Survey and the Bureau of Soils with reference to possible commercial sources of potash in the United States.

It is stated that the activities of the Survey in this direction were more restricted in 1913 than in previous years. Field drilling was carried on to a limited extent and in only two areas, the Columbus Marsh and Black Rock Desert, Nevada. The report deals with the development of saline potash deposits in California (Searles Lake), Oklahoma, and Texas; alunite and kelp as sources of potash salts and as fertilizers; the preparation of potash salts from silicate rocks; and statistics of imports and consumption of potash salts and other fertilizing materials in the United States.

A bibliography of recent papers on the subject is given.

The production of feldspar in 1913, F. J. KATZ (*U. S. Geol. Survey, Mineral Resources of the United States, 1913, pt. 2, pp. 145-151*).—This bulletin dis-

cusses the composition, occurrence, and uses of feldspar and gives statistics of production in the United States and other countries.

"The marketed production of feldspar in the United States in 1913 was 120,955 short tons, valued at \$776,551. Both in quantity and in value this was the largest recorded annual production. Each important producing State—California, Connecticut, Maine, Maryland, New York, North Carolina, and Pennsylvania—showed an increase in both quantity and value. During the year about 50 quarries marketed feldspar. Ten of them were new producers. Notwithstanding the increase in quantity and the production from new sources the average price per ton of the total production was higher than in any other year."

Alunite, a newly discovered deposit near Marysvale, Utah, B. S. BUTLER and H. S. GALE (*U. S. Geol. Survey Bul. 511 (1912), pp. 64, pls. 3*).—This deposit is described and its significance as a source of potash is discussed. Other known occurrences of alunite in the United States, as well as in foreign countries, are also referred to.

"The Marysvale deposit, so far as now known, is not of such magnitude as to afford a source of all the potash salts now consumed in the United States, but it may prove to be an important factor in providing an American supply that will perhaps be especially available to local and western markets, particularly in meeting the demand for higher-grade salts. Possibly also the greatest importance of the commercial development of this deposit will be in the added stimulus it may afford to exploration for other similar deposits of this mineral, especially in this general region, and it is on the discovery of such other deposits that the provision of a home supply from this source must depend."

It is estimated that the Marysvale deposit would yield 30,000 tons of potash for each hundred feet in depth or from one-sixth to one-seventh of the total annual consumption of the United States.

Ground limestone for southern soils, C. G. HOPKINS (*South. Settlement and Develop. Organ., Farm Truth 1 (1914), pp. 38*).—The need and value of liming (use of ground limestone) for southern soils is fully set forth largely on the basis of experiment station work, and practical directions for liming are given.

Soil acidity and liming (*Missouri Bd. Agr. Mo. Bul., 12 (1914), No. 2, pp. 27, figs. 11*).—This bulletin is a partial reprint, with an introductory chapter by M. F. Miller, of those parts of Wisconsin Station Bulletin 230 (E. S. R., 29, p. 623), which are considered applicable to Missouri conditions.

It is stated that the soils in Missouri which are the most strikingly in need of lime are the more level portions of the prairies of northeast and southwest Missouri which are inclined to be wet. Other areas needing it are some of the old farmed lands and high ridge tops of the Ozark border and Ozark region proper. The poorer timber lands of northeast Missouri along the streams in the central and eastern parts of the State are in general more or less in need of lime.

The removal of lime from soil by acid furnace fumes and its effect on plants, A. WIELER (*Jahresber. Ver. Angew. Bot., 10 (1912), pp. 58-74, figs. 6*).—From his experiments with trees and field crops on limed and unlimed soils in the vicinity of smelters the author arrived at practically the same conclusions as in previous work (E. S. R., 28, p. 623).

Useful minerals of the United States, S. SANFORD and R. W. STONE (*U. S. Geol. Survey Bul. 585 (1914), pp. 250*).—This is a list showing the composition, character, and location of deposits of the principal useful minerals in each State.

The American fertilizer handbook, 1914 (*Philadelphia, 1914, pp. 456, figs. 50*).—This handbook contains as usual directories of fertilizer manufacturers and allied fertilizer trades, cotton-seed oil mills, and packers and renderers, as well as special articles, statistics, and miscellaneous information relating to the fertilizer industry. Among the more important articles included are The Sulphuric Acid Industry, by A. M. Fairlie; Tables for Making Fertilizer Formulae, by W. D. Rhea; Digest of State Fertilizer Laws; Available Phosphates by Furnace Treatment, by J. H. Payne; Available Nitrogen in Compounds, by E. P. Verner; Present State of the Cyanamid Industry, by E. J. Pranke; The World-Wide Search for Potash, by H. Wilson; Phosphate Rock Production in 1912, 1913, by W. C. Phalen; Florida Phosphate Rock, 1913, by E. H. Sellards; Mining of Florida Pebble Phosphate Rock, by T. M. Peters; The Western Phosphate Deposits, by M. S. Duffield; The Products of Cotton Seed, by T. C. Law; The Use of Packing House By-Products, by J. B. Sardy; Tankage and Dried Blood, by J. W. Turrentine; and The Western Animal Ammoniate Market, by J. B. Sardy.

Commercial fertilizers, W. J. JONES, JR., ET AL. (*Indiana Sta. Bul. 174 (1914), pp. 477-594, fig. 1*).—This is a detailed report of inspection of fertilizers in Indiana during 1913 including analyses of 1,204 samples.

The results show that the amount of fertilizers sold was greater and the quality better in 1913 than in any previous year. It is estimated that the consumption of fertilizers in the State in that year was 193,899 tons, valued at \$4,516,404.

Analyses of fertilizers, fall season, 1913, B. W. KILGORE ET AL. (*Bul. N. C. Dept. Agr., 35 (1914), No. 3, pp. 93*).—This bulletin contains analyses and valuations of fertilizers collected by the fertilizer inspectors of the state department of agriculture during the fall of 1913, as well as a list of brands of fertilizers registered for sale during the fall season.

AGRICULTURAL BOTANY.

Lectures in plant physiology, L. JOST (*Vorlesungen über Pflanzenphysiologie. Jena, 1913, 3. ed., pp. XVI+760, pls. 2, figs. 193*).—This is a third edition of the author's lectures on plant physiology (E. S. R., 19, p. 529) in which the subject matter is brought up to date and the references to literature given to January, 1913, with occasional later citations.

The general plan of the work is not changed except in the matter of citing literature. By means of a system of abbreviations and placing the citations at the bottom of the page, considerable space has been gained.

Catalytic effects of light in germinating seeds, E. LEHMANN (*Biochem. Ztschr., 50 (1913), No. 5-6, pp. 388-392*).—It is stated that the germination of seeds of *Epilobium hirsutum*, moistened with distilled water and kept in darkness at from 22 to 24° C., was in each case increased or hastened by the addition of papayotin, trypsin, or muriatic acid in a way analogous to the influence of light, which is held to act catalytically upon albumen in the seeds.

Self-warming by plants in Dewar flasks, H. MOLISCH (*Ztschr. Bot., 6 (1914), No. 4, pp. 305-335, figs. 3*).—Tests made by the employment of Dewar flasks on the development of heat by flowers, leaves, or fruits of several dicotyledonous plants, also with mosses, lichens, fungi, and algæ, are given in tabular detail.

Most leaves and flowers develop considerable heat, some however much less. Mosses, algæ, and a number of common fruits develop little heat as a rule. Lichens show considerable differences in this respect, as do some fungi.

Transpiration by *Viscum album* in comparison with that by other plants, deciduous or evergreen, Z. KAMERLING (*Ber. Deut. Bot. Gesell.*, 32 (1914), No. 1, pp. 10-16, figs. 2).—Separated shoots of mistletoe, apple, poplar, conifers, etc., exposed to evaporation showed some striking differences in water loss per unit area of foliage during the early stages of experiment. The relatively larger transpiring surface soon led to wilting and death of the deciduous shoots employed, while the evergreen, presumably through better stomatal control, resisted desiccation for a longer time. The desiccation curves of *V. album* lay between those of the two classes above mentioned, though showing some irregularities which are ascribed to a possible antagonism between the guard and neighboring cells of the stomatal apparatus.

Transpiration experiments with tropical Lorantheae, Z. KAMERLING (*Ber. Deut. Bot. Gesell.*, 32 (1914), No. 1, pp. 17-24, fig. 1).—It appears from experiments with *Loranthus pentandrus* on *Mangifera indica* in Java that the daily loss per unit area of leaf surface of the parasite was about 50 per cent greater than that of the host, this difference being accentuated during the hotter part of the day, owing, presumably, to the observed better control of the stomata by the host. The same general relation was apparent in case of *L. dichrous* and its host *Psidium guajava*. This high evaporation rate is considered as significant in connection with the injury to the host plant noted in case of these growths, sometimes resulting in desiccation and death of the part beyond the location of the semiparasite.

Nitrogen transformations in some Actinomycetes, II, F. MÜNTER (*Centbl. Bakt. [etc.]*, 2. Abt., 39 (1914), No. 23-25, pp. 561-583, figs. 3).—Reporting the completion of work previously given in part (E. S. R., 29, p. 222), the author states that in the present series of studies employing the same organisms as formerly (*Actinomyces odorifer*, *A. chromogenes*, *A. albus*, and three species of *Actinomyces* from German East Africa), it was found that all these are capable of separating ammonia from organic sources. No formation of ammonia compounds from nitrates was noted. The nitrogen which disappeared from nitrates in solution was almost wholly recovered from the organisms. Alkaline media developed a slender mycelium, neutral media a heavier, ranker tissue, and those of acid reaction gave mycelium of a peculiar swollen appearance. These organisms, grown in solutions with *Azotobacter*, checked the activity of the latter and this was true of them in higher degree in connection with other fungi, yeasts, and Actinomycetes tested.

Reduction of nitrates to nitrites and ammonia by bacteria, M. KLAESER (*Ber. Deut. Bot. Gesell.*, 32 (1914), No. 1, pp. 58-61).—Reporting on studies employing 28 species of bacteria in nutritive solutions of varying composition, the author holds that nitrates and nitrites are probably not formed by these bacteria from ammonia or from peptone, but that a number of them do form ammonia from peptone.

Studies on anthocyanin.—I, Color in the cornflower, R. WILLSTÄTTER and A. E. EVEREST (*Liebigs Ann. Chem.*, 401 (1913), No. 2, pp. 189-232, figs. 4; *abs. in Gard. Chron.*, 3. ser., 55 (1914), No. 1419, p. 168).—To a brief discussion of previous work by others on flower coloration, the authors add the results to date of their own experimental studies on problems related to the chemical composition and history of anthocyanin pigments in plants, in particular *Centaurea cyanus*.

It is claimed that the successful isolation and study of anthocyanin shows a close and definite relation between the blue, the violet, and the red pigment, all these representing the anthocyanin glucosid, but depending respectively upon whether this assumes the form of a free acid, such an acid combined with potassium, or occurs in connection with a plant acid. Since each of these forms

may, by isomerism, become colorless, it is suggested that such a change may be instrumental in producing the white flowers, but this has not yet been established.

The localization of potash compounds in the sugar beet and their physiological relation, A. MATOUŠEK (*Ztschr. Zuckerindus. Böhmen*, 38 (1914), No. 5, pp. 235-251, figs. 6).—The author reports that potash salts are to be found in the embryo of the sugar beet seed. In the plant potash is widely distributed, being most abundant in the leaf blade, less so in the petiole, and least in the roots. In the blade of the leaf potash is more abundant in the portions beneath the upper epidermis. The xylem part of the fibrovascular bundles in leaves, roots, etc., has a higher content of potash than the phloëm. In the root the potash content is highest in the upper part, particularly in the corky portions, and tends to increase in the vicinity of any wounds. In water cultures, in the absence of potash in the nutrient medium, potash is found in the blade of the leaf, the roots containing practically none. Etiolated leaves have a very low content of potash, and the general distribution of potassium compounds in etiolated plants, as well as those grown with a limited amount of potash, is similar to that in normal plants.

Comparative studies on tropisms.—VI, Influence of alkalies and alkaline earths on *Lupinus albus*, T. M. PORODKO (*Ber. Deut. Bot. Gesell.*, 32 (1914), No. 1, pp. 25-35, fig. 1).—Previous work, mainly qualitative (E. S. R., 25, p. 632) regarding the effects of solutions on tropisms, has been followed by studies on the responses, quantitatively considered, of white lupine seedlings tested with solutions of alkalies and alkaline earths in different strengths. The results are given in tabular detail.

The action of certain compounds of zinc, arsenic, and boron on the growth of plants, WINIFRED E. BRENCHELY (*Ann. Bot. [London]*, 28 (1914), No. 110, pp. 283-301, figs. 17).—Results are given of water culture experiments of peas and barley in which the action of zinc sulphate, arsenic compounds, and boric acid was tested.

Zinc sulphate in high concentrations was found very toxic to barley and peas and no evidence of stimulation was obtained even when as great a dilution as 1 to 200,000,000 parts was used. Arsenious acid was found more toxic in its action on peas and barley than arsenic acid. This distinction also held good for sodium arsenite and sodium arsenate. No stimulation was observed even with the smallest quantities tested. Boric acid was found less poisonous than zinc sulphate or arsenic compounds, especially with peas. Barley showed some evidence of stimulation with the weaker strengths of boric acid, but this was not borne out by an examination of the dry weights. Peas, on the other hand, were definitely stimulated with relatively high concentrations of boric acid. Where the higher strengths of this poison were used the action was quite evident, the leaves tending to become brown and to die in a characteristic manner.

Recent studies on diffusion and localization of ions in plant tissues, C. ACQUA (*Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat.*, 5. ser., 22 (1913), II, No. 11, pp. 594-598).—In extension of work previously noted (E. S. R., 30, p. 31), the author tested the effects upon development of seedlings exerted by cerium.

It was found that development, especially of the root system, of *Triticum sativum* is quickly checked by cerium chlorid in very dilute solution, no secondary roots being formed in the cases observed. Microscopic examination showed a yellow deposit in the cortical cylinder of the roots, which increased and finally occupied in part the intercellular spaces. These results, agreeing with those previously noted when employing manganese, uranium, and lead,

were also confirmed in essential details in further experiments with *Zea mays* and *Phaseolus vulgaris*.

Experimental production of hyperplasia in plants, L. PETRI (*Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat.*, 5. ser., 22 (1913), II, No. 10, pp. 509-516, figs. 3).—A preliminary report is made showing some results obtained by injecting solutions of peptone, urea, etc., of not over 1 per cent strength into growing cortical tissue of stems and roots.

Comparison of microphotographic views shows that the thickening of the tissue is due mainly to a great enlargement of the cells individually. The cell walls remain thin and tender. These indications of arrested development are compared with effects observed to follow exposure to cold or puncture by insects.

Some experiments on the effect of external stimuli on the sporidia of *Puccinia malvacearum*, W. ROBINSON (*Ann. Bot. [London]*, 28 (1914), No. 110, pp. 331-340, figs. 7).—Cultures were made of spores of *P. malvacearum* in hanging drop cells, in which the effect of various stimuli were tested.

The sporidia were found to be negatively heliotropic. Moisture and contact were also found to affect the germ tubes. In the normal host plant a slender growth from the swollen end of the germ tube penetrated the cuticle and outer wall of the epidermis, bringing about a true infection, but this was not seen to occur in other plants than the normal hosts. In the case of certain leaves, as *Pelargonium*, *Eucalyptus*, and *Primula*, with glandular secretions, a definite toxic effect was exerted on the sporidia and germ tubes in the immediate neighborhood of the fragment of the leaf. The investigations did not disclose why the normal hosts should be infected while other plants were not. They did show, however, that the germ tube is irritable to light, to moisture to a certain degree, and to contact.

Morphological instability, especially in *Pinus radiata*, F. E. LLOYD (*Bot. Gaz.*, 57 (1914), No. 4, pp. 314-319, pl. 1, figs. 2).—A description is given of a proliferation of spur shoots occurring in the Monterey pine, which has also been seen in other species of *Coniferæ*. The tree described was growing near a cess-pool and it is believed that the water relation of the plant was responsible for the proliferation. A somewhat similar occurrence is reported as having been observed in *P. taeda* after injury.

The effect of climatic conditions on the rate of growth of date palms, A. E. VINSON (*Bot. Gaz.*, 57 (1914), No. 4, pp. 324-327, pl. 1).—The results are given of observations of the effect of climate on the rate of growth of date palms made at the cooperative date orchard, Tempe, Ariz.

In these studies comparisons were made between the rate of growth and the temperature. From the platted curves the rate of growth was found to be most active, not at the period of highest maximum, but rather at the highest minimum temperatures, which were warm nights in July, August, and sometimes in September. By far the greater part of the total yearly growth was found to occur in the last half of the year.

The rate of maturing fruit was also investigated. It is thought to be probably influenced by the same factors as the rate of growth of foliage.

The effect of shading on the transpiration and assimilation of the tobacco plant in Cuba, H. HASSELBRING (*Bot. Gaz.*, 57 (1914), No. 4, pp. 257-286, fig. 1).—A report is given of experiments conducted in western Cuba to determine the effect on transpiration and assimilation in the tobacco plant of the cheese-cloth shade, which is frequently used in that region for shading tobacco.

It was found under the climatic conditions of the region that the transpiration of the tobacco plants grown in the open was nearly 30 per cent greater than that of plants grown under cheese-cloth shade. The transpiration per

unit of leaf surface was nearly twice as great in the sun plants as in the shade plants. Shading of tobacco plants by this coarse grade of cheese cloth did not seem to result in a diminished production of total plant substance as compared with other plants not shaded. As the leaves of the shade-grown plants had a much greater total area than those of plants grown in the open, it was evident that the quantity of plant material elaborated per unit of leaf area was greater in the plants grown in the open. Although the cheese-cloth shade was found not to influence in any marked degree the total production of dry matter in the plants, the distribution of this substance was so affected that in the shade-grown plants relatively less material was deposited in the leaves and more in the stems than in the corresponding organs of the plants grown in full light. No evidence was secured to indicate that shade influenced the deposition of material in the roots.

A monograph of the fungus group *Penicillium*, with special reference to the species occurring in Norway, I, O. J. O. SOPP (*Vidensk. Selsk. Skr. [Christiania]*, *Math. Naturv. Kl.*, No. 11 (1912), pp. VI+208, pls. 23, fig. 1).—The author gives an account of the morphology and physiology of the various species of *Penicillium* and related genera known to occur in Norway, discussing their systematic relationships, after which he describes in detail the species of *Penicillium*, *Dactylomyces*, *Acaulium*, *Stysanus*, *Gliocladium*, *Corollium* n. g., and *Aspergillopsis*.

On the lower fungi.—V, *Anisomyxa plantiginis* n. g. and sp., B. NÉMEC (*Bul. Internat. Acad. Sci. François Joseph I*, 1913, pp. 15, pls. 2, figs. 5; *abs. in Riv. Patol. Veg.*, 6 (1913), No. 7, p. 218).—A study is reported of an organism found on roots of *Plantago lanceolata*. It is thought to be new and is named *A. plantiginis*.

Studies on heads of wheat and spelt as a contribution to exact classification, M. KONDO (*Landw. Jahrb.*, 45 (1913), No. 5, pp. 713-817, figs. 3).—This is a detailed account of studies on 62 varieties of winter and 20 of summer wheat, also 16 of spelt, in regard to characters available for use in exact classification of cultivated grains. Some correlations appearing therefrom are also noted.

Inventory of seeds and plants imported by the Office of Foreign Seed and Plant Introduction during the period from July 1 to September 30, 1912 (*U. S. Dept. Agr., Bur. Plant Indus. Inventory No. 32* (1914), pp. 44, pls. 5).—This inventory gives notes on the seeds and plants introduced during the period indicated, about 250 numbers being included. These represent collections secured through collaborators, diplomatic and consular officials, or interested amateurs who have forwarded from different parts of the world plants that they thought might prove valuable in this country. Botanical notes and publication of new names are given of a number of species.

FIELD CROPS.

Agricultural researches and the interpretation of their results, A. GRÉGOIRE (*Ann. Gembloux*, 22 (1912), Nos. 2, pp. 58-173; 3, pp. 130-164; 4, pp. 181-208; *Ann. Sta. Agron. Etat Gembloux*, 2 (1913), pp. 1-86, figs. 12).—This discusses field methods and the interpretation of results by the application of mathematical laws bearing upon probable, systematic, and experimental errors, statistical methods, and the law of minimum.

Field experiments and the interpretations of their results, A. GRÉGOIRE (*X. Cong. Internat. Agr. Gand*, 1913, *Raps.*, Sect. 2, Question 1, pp. 13).—Essentially the same as the article noted above.

Some factors which influence the water requirements of plants, P. KHAN-KHOJE (*Jour. Amer. Soc. Agron.*, 6 (1914), No. 1, pp. 1-23, fig. 1).—In this

article the author describes methods employed by him that involve water and sand cultures in which the pots were sealed with paraffin.

It was observed that the kind of crop, the strength of the soil solution, the age of the plant, and the amount of moisture in the soil were factors influencing the water requirements of crops. In wheat plants grown in nutrient solutions ranging from 0.01 to 0.33 per cent in strength from 621 to 210 gm., respectively, of water was required for each gram of dry matter produced.

In regard to methods, basing the results upon dry matter of stalks only or upon that of stalks and roots together, it is noted that in all cases where only stalks have been used the water requirements have been greater and that differences between the two methods diminished as the strength of the solution increased. With a 0.01 per cent solution 1,018 gm. of water were required to produce 1 gm. of dry matter of stalks alone, and 621 gm. to produce 1 gm. of dry matter of plant, including roots, while with 0.33 per cent solution the amounts were 246 and 210 gm., respectively. This and other data from the experiment show that there was less growth of the roots in proportion to the growth of the stalk in the stronger solutions. "The percentages of ash in the plants grown in the different strengths of solution do not agree with each other, nor do they vary in any regular manner."

In pure quartz sand cultures 422, 362, and 261 gm. of water were used to produce 1 gm. of dry matter in wheat plants 50, 90, and 137 days of age, respectively, in solutions of uniform strength.

The water requirements of a crop were shown to increase with the increase of the soil moisture. Data "show that when there is more moisture in the soil there is a larger growth of the plant. But the growth of the plants does not give an idea of the percentage of dry matter."

Irrigated field crops in western Nebraska, F. KNORR (*Nebraska Sta. Bul.* 141 (1914), pp. 5-32, figs. 5).—This bulletin contains suggestions based on work at the Scottsbluff Substation and designed to be of value to the farmers of western Nebraska in the production of irrigated field crops. These suggestions touch upon the general practice of irrigation; the construction and use of farm irrigation systems; the handling of virgin soils; possible rotations; and methods employed with alfalfa, sugar beets, wheat, oats, barley, potatoes, and corn.

Potash fertilizer experiments, F. HEINE and K. LINDENBERG (*Illus. Landw. Ztg.*, 34 (1914), No. 12, pp. 110, 111).—Applications of potash to both heavy loam and clay soils in the vicinity of Halberstadt and Magdeburg in connection with the production of wheat, potatoes, sugar beets, rye, and peas, gave unprofitable yields, indicating an abundant supply of potash already in these soils.

Row fertilizing experiments, AHR (*Mitt. Deut. Landw. Gesell.*, 29 (1914), Nos. 7, pp. 94-98; 8, pp. 123-125).—From 2 years of experimental work the author concludes that for a heavy clay soil row fertilization with cereals gave no beneficial results over the ordinary method of broadcasting, but that with stock beets, and probably for all crops planted in wide-distance rows, row fertilization was much superior to other methods. If, however, it implies the use of new, costly, and complicated machinery the row method is not recommended for practice.

Study of relation between space and plant growth, K. GRUNDMANN (*Kühn Arch.*, 3 (1913), pt. 1, pp. 199-242, fig. 1).—These experiments were conducted with several varieties of spring wheat, spring barley, and oats, so spaced as to allow 36, 45, 54, 60, 75, 90, 100, and 200 sq. cm. of surface per plant for the several tests. From the resulting data the author made the following conclusions:

Within areas of from 36 (about 5.5 sq. in.) to 100 sq. cm. per plant, the yield of grain per surface unit is the same when soil, fertilizer, cultivation, and climatic conditions remain the same. The development of individual characters is favored by the wide spacing over the narrow, and the number of well-developed elites increases as the size of area per plant increases; a large area per plant insures against lodging and against such other growth suppression as would interfere with experimental results. For select breeding of elites the distance 5 by 20 cm. seemed to be especially good, as the largest number of well-developed plants were secured, a sufficient quantity of kernels was obtained for increase tests, and this distance between plants facilitates plant selection at harvest as well as cultivation. For test plats 3 by 20 cm. seemed to be the best spacing, for with fall-sown rye and wheat it allows for some winterkilling, with winter and spring barley it prevents an unnatural stooling which would tend to increase the protein content, with oats it is a safeguard against damage of frit fly, with all the cereals it allows of cultivation without injury to the plants, and it approaches field conditions and gives a better basis for calculating yields.

Some observations on the transmissible variations of chlorophyll characteristics in cereals, H. NILSSON-EHLE (*Ztschr. Induktive Abstam. u. Vererbungslehre*, 9 (1913), No. 4, pp. 289-300, pl. 1).—It is noted that by selection it was possible to segregate the white (albino) plants of oats, barley, and rye, but not those of wheat, and that breeding showed the white characteristic to be recessive to green.

While the first generation from a single albino plant was all green plants, pure lines from many white plants showed a certain regularity in the appearance of albino plants, half of which would be heterozygous, one-fourth normal green, and one-fourth not viable (a characteristic of albinism as noted by the author). The repeated disappearance of chlorophyll factors is deemed as inexplicable as in the case of the author's experiments with the black factor in the hulls of oats (E. S. R., 29, p. 739).

Illustration of the effect of previous vegetation on a following crop: Cabbage after sesame, J. J. SKINNER (*Plant World*, 16 (1913), No. 12, pp. 342-346, fig. 1).—This article gives the results of an investigation of soil from Middle River, Cal., which show an oily material, apparently left in the soil by the sesame crop, as the cause of an injurious effect on cabbage plants, but not on wheat plants grown in solutions containing extracts from the soil under investigation.

Basing alfalfa yields on green weights, F. D. FARRELL (*Jour. Amer. Soc. Agron.*, 6 (1914), No. 1, pp. 42-45).—This paper presents a plea for basing the yields of alfalfa on green weights rather than on weights of "cured hay," and gives data obtained by investigations conducted at Huntley, Mont., and Fallon, Nev., to determine the constancy of weights of green matter of different crops to be used as a basis for comparisons.

The results showed that of the "28 samples taken on 12 different dates at Huntley the average loss in weight was 76.5 per cent of the green weight. Of the 30 samples taken on 10 different dates at Fallon, the average loss in weight was exactly the same as at Huntley. The highest loss was 81.6 per cent at Fallon and 80.6 per cent at Huntley; the lowest at Fallon was 71.7 per cent and at Huntley 70 per cent; the extreme range was 10.6 per cent at Huntley and 5.9 per cent at Fallon.

"The results fail to show any consistent significant differences in the loss in weight of samples cut on different dates or at different stages of growth; that is, when the range of variation in samples cut on the same date or at the same stage of growth is considered it is seen that the variation in samples cut on

different dates and at different stages of growth is not large enough to be considered significant."

Studies on the anatomy of alfalfa, O. T. WILSON (*Kans. Univ. Sci. Bul.*, 7 (1913), No. 17, pp. 291-299, pls. 5).—Cross sections of roots, stems, and leaves, and the cellular structure of many parts of the alfalfa plant are described and illustrated.

Growing alfalfa in Iowa, H. D. HUGHES (*Iowa Sta. Circ.* 3 (1912), pp. 2-11, figs. 5).—Cultural notes on alfalfa growing for Iowa conditions.

On the influence of potash and phosphoric acid on the quality of brew barley, L. SCHÜL (*Landw. Jahrb.*, 45 (1913), No. 5, pp. 641-712).—Results from field experiments in which potash and phosphoric acid were used singly and combined with nitrogenous fertilizer showed that potash and nitrogen were better appropriated by barley in the presence of phosphoric acid. Potash-phosphatic fertilizers accompanied increased total yields and improved quality. The use of 40 per cent potash salt and of superphosphate as a top-dressing worked favorably. The protein content decreased under the influence of potash and phosphoric acid applications and yield increase. Dry matter increased with considerable regularity with the application of potash and phosphoric acid, regardless of the yield. In general an improvement in 1,000-kernel weight, in size, in percentage of hull, in germination ability, and in germination force was noted as attributive to potash and phosphoric acid. The potash and phosphoric acid-fertilized barley kernels were of a canary yellow.

Investigations on spacing for breeding plants of brew barley, E. CLAUS (*Kühn Arch.*, 3 (1913), pt. 1, pp. 169-197, figs. 8).—From data collected in 1911 from several experiments the author concludes that spacing is correlated with stooling, with individual plant weights, and with grain weight per plant. The optimum distance for brew barley in the climate and soil of Halle Station is 5 by 20 cm. (about 2 by 8 in.). The percentage of grain is independent of distance. With brew barley dry matter and extract content are in inverse ratio to distance, while protein content is in direct ratio to distance. In single plants the protein content increased with the stooling, with weight of head, and with kernel weight, and declined when the percentage of grain and stand increased. No correlation between protein content and kernel weight could be detected.

Observations on *Beta maritima* from 1910-1912, O. MUNERATI, G. MEZZADROLI, and T. V. ZAPPAROLI (*Staz. Sper. Agr. Ital.*, 46 (1913), No. 6, pp. 415-445, figs. 7; *abs. in Österr. Ungar. Ztschr. Zuckerindus. u. Landw.*, 42 (1913), No. 6, pp. 1015-1023, figs. 4).—The authors give results of planting seeds of wild beets collected on the Adriatic coast and on the banks of the river Po in 1910.

It is concluded that although most of the individuals produce seed the first year, many do not until the second year, and that these may continue to produce seed annually up to 6 or 7 years. Whether in a wild state or under cultivation they show a great tendency toward wide variations. Some characteristics were rigidly transmitted while others were not. It is noted that the biennial character of some individuals was transmitted regularly 100 per cent, while others of this character produced only annuals.

The results of 2-year selections from the wild form gave beets that weighed 3 kg. and contained 15 per cent of sugar, with a juice of 81 per cent purity and little fiber. Five years of cultivation, it is noted, brought the wild toward the sugar-beet form but not toward the stock-beet form.

On breeding and inheritance questions in red clover, P. HOLDEFLEISS (*Kühn Arch.*, 3 (1913), pt. 1, pp. 81-115, figs. 3).—From a 2-year study of color characteristics in red clover the author concluded that in general there was a correlation between yellow seeds and light colored or white flowers, the pure-bred white flowering plants always bearing yellow seeds. Dark red flower color and

violet seed color are correlated with large wide leaves, and yellow seed color and light flower color with long narrow leaves. Foreign pollinization occurs but not to the extent of overthrowing inheritance in pure lines. Fertilization by bumble bees could be detected abundantly among flowers of the same plant and between flowers in the same plat, but seldom between flowers of different plats. A retarded development occurred in plants that were white flowered, in some cases as much as four weeks later than the red flowered plants. The violet colored seeds averaged heavier than the yellow.

Maize, its history, cultivation, handling, and uses, J. BURTT-DAVY (*London, New York, Bombay, and Calcutta, 1914, pp. XL+831, pl. 1, figs. 245*).—A very complete treatise with special reference to corn production in South Africa, and including chapters on importance and history, climatic requirements, geographical distribution, botanical characters, inheritance of characters and improvement by breeding, judging and selection for exhibition, varieties and breeds, soils and manures, tillage, planting, and cultivation, diseases and pests, harvesting and storage, commerce, milling, mill products, chemical composition, the maize grain as food, the preservation and use of maize stover, hay, and silage for stock feed, construction of modern silos, and uses of maize products in the arts and manufactures. A bibliography of 430 titles is attached.

The corn plant and seed selection, H. K. HAYES (*Connecticut State Sta. Rpt. 1913, pt. 6, pp. 353-384, pls. 4*).—In this paper the author gives the results of a series of tests during 1912 and 1913 of the commercial value of first generation crosses and a comparison of yields of shelled corn of several of the more important Connecticut varieties when grown in the same season under uniform conditions.

Twenty-two varieties of yellow and white dent and yellow and white flint that were used in the tests are described. Ear-to-row tests were made. Characters which showed dominance are noted as red cob over white cob color, colored pericarp over colorless pericarp, straight rows over irregular rows, light tillering over heavy tillering, and low protein content over high protein. As a variable character endosperm color is mentioned, and as intermediate characters the number of rows, shelling yield, date of maturity, and height of plant.

Eight crosses are noted as being advantageous crosses, producing yields ranging from 9.2 per cent to 17 per cent higher than the better parent. Griswold Early Dent X Brewer Flint gave the greatest increase, while the cross between Hall Tyler Dent and Brewer Flint produced the highest absolute yield of 73 bu. of crib-dried shelled corn. Tables give the yield of crib-cured corn, comparative yields of first generation hybrids and their parents, tests of sweet-corn varieties and crosses, inheritance of protein, inheritance of row number, percentage of shrinkage, and shelling capacity.

Good seed corn for 1913, H. D. HUGHES (*Iowa Sta. Circ. 4 (1912), pp. 3-11, figs. 7*).—This gives directions for selecting, gathering, and storing seed corn, with special reference to Iowa conditions.

Fertilizer experiment with maize (Bol. Soc. Agr. Mexicana, 38 (1914), No. 14, pp. 263-265).—The data show an increased yield over the check plot of 1,794 kg. of grain per hectare (1,596 lbs. per acre) by the use of 50 kg. of superphosphate, 150 kg. of potassium sulphate, and 200 kg. of ammonium sulphate.

Moisture in maize, G. N. BLACKSHAW (*Rhodesia Agr. Jour., 11 (1914), No. 3, pp. 396-398*).—The moisture content is given of 12 samples (sacks) of corn in storage, together with the atmospheric moisture, as determined in 13 periods from October, 1912, to July, 1913.

Tabulated results showed "the maximum variation in moisture recorded during the period of the investigation (mean of 12 samples) was 3.72 per cent, the lowest average being shown in the month of October, 1912, and the highest

in April, 1913. In single bags, the maximum variation in moisture for the same period was 4.6 per cent, and the minimum 3.3 per cent."

An interesting new member of the Gramineæ from Tonkin, CREVOST and C. LEMARIÉ (*Bul. Econ. Indochine, n. ser., 16 (1913), No. 105, pp. 1099, 1100*).—This notes the spontaneous appearance of and describes *Erianthus cây-cong* (*Andropogonæ*). Its use in Tonkin seems to be in the manufacture of blinds and screens.

Industrial fiber plants of the Philippines, T. MULLER ([*Philippine*] *Bur. Ed. Bul. 49 (1913), pp. 157, pls. 43*).—This bulletin contains a description of the chief industrial fiber plants of the Philippines, and their distribution, method of preparation, and uses, considering ferns, pandans, grasses, bamboos, sedges and similar plants, palms, rattans, vines, plants with leaf or petiole fiber of commercial value, miscellaneous industrial fibers, and Philippine bast fibers, including about 100 specimens.

Nutrient requirements of flax and the influence on the quantity and quality of its fiber, C. CSÓKÁS (*Kísérlet. Közlem., 17 (1914), No. 1, pp. 64-120, pls. 8*).—The results of these experiments are noted as showing that flax requires especially large quantities of potash and nitrogen during the early stages of growth. Quick-working nitrogen fertilizers during the entire growth period showed good results. Phosphatic fertilizers were especially useful in seed production rather than in fiber production. Nitrogen and phosphorus collected chiefly in the leaves, while the potash was found more abundant in the stems, in which part of the plant it played a prominent part in the formation of carbohydrates. The percentage of fiber in the stems was less on those plats when potash was lacking; but the fertilizer had no influence upon the strength of the fiber produced.

Hemp, L. H. DEWEY (*U. S. Dept. Agr. Yearbook 1913, pp. 283-346, pls. 7, figs. 5*).—This article gives the history, names, botanical description, relationship, geographical distribution, and introduction into the United States, varieties, methods of improvement by seed selection, and notes on the cultivation of hemp, including climate, soil, rotation of crops, fertilizers, diseases, insect pests, weeds, harvesting, seed production, and methods of retting and marketing the fiber, with some commercial aspects.

On the appearance of sterile "dwarfs" in *Humulus lupulus*, E. S. SALMON (*Jour. Genetics, 3 (1914), No. 3, pp. 195-200, pls. 3*).—Seedling hop plants (derived from crossing), the distinguishing features of which are noted as total or almost total inability to climb and complete sterility, are described.

The Ruakura oat, P. MCCONNELL (*Jour. Agr. [New Zeal.], 6 (1913), No. 2, pp. 133-136, figs. 3*).—This article describes a rust-resistant variety of oats derived from a selected spike of Argentina oats in 1908. "It has never been claimed that the new oat is absolutely rust-proof. What can be claimed is that it is the most resistant to disease of all the varieties tested at Ruakura."

A noticeable color factor as an inhibiting factor in awn development in oats, H. NILSSON-EHLE (*Ztschr. Induktive Abstam. u. Vererbungslehre, 12 (1914), No. 1, pp. 36-55*).—In breeding oats the author found that yellow color accompanied awnlessness and that white or black colors and awns were correlated.

By the use of charts the segregation of the color factors in hybrids to F₂ has been graphically shown, together with their relations to the awn factors. The individual plants having the homozygous yellow factor showed a strong suppression in awn development. The yellow color factor not only developed the yellow color, but at the same time had an inhibiting influence on awn development. In the individuals heterozygous for yellow color the inhibiting influence on the awn developments is not so pronounced but still perceptible,

even though the yellow color may be obscured by black, and in such cases it is noted the yellow factor becomes an awn factor.

As an alternative explanation of the appearance of yellow color and awnlessness in oats the author suggests the possible presence of two distinct but accompanying factors.

On the continuous violet colored seed of *Pisum arvense*, B. KAJANUS (*Fühling's Landw. Ztg.*, 62 (1913), Nos. 5, pp. 153-160; 24, pp. 849-952).—Experiments in crossing field peas having more or less of a violet color in the seeds or pods did not result in any regular increase in the amount of colored surface or in establishing any uniformity in this color factor.

Report on the influence of different quantities of potash fertilizer on the yield and starch and protein content of potatoes, C. VON ECKENBRECHER and F. F. HOFFMAN (*Ztschr. Spiritusindus.*, 1914, *Ergänzungsh.*, pp. 60-66).—Areas were fertilized with single (300 kg. per hectare or 267 lbs. per acre) and double (600 kg.) applications of potash salt. Results with several varieties at 7 centers showed both plus and minus yields over untreated areas, but a general average increase with the use of potash. There was a decrease in starch content that was greater with the larger applications, while the protein content increased in some varieties and decreased in others.

The selection and treatment of potato seed, J. T. RAMSAY (*Jour. Dept. Agr. Victoria*, 12 (1914), No. 2, pp. 73-75, fig. 1).—A method of selection which secures the use of immature tubers for seed tubers is described. The results of this system are noted as showing an increase of from 30 cwt. to 5 tons of tubers per acre. Sprouting the tubers before planting gave increased yields and other advantages, including the opportunity to reject weaklings.

Report of the German Potato Culture Station in 1913, C. VON ECKENBRECHER (*Ztschr. Spiritusindus.*, 1914, *Ergänzungsh.*, pp. 3-59).—Results are reported of testing 21 varieties of potatoes in 32 different fields. Starch contents ranged from 16 to 19.8 per cent, yield per hectare from 17,940 to 34,510 kg., and yield of starch from 3,270 to 6,550 kg. per hectare.

Notes on the culture of sisal in English and German East Africa, P. JANSSENS (*Bul. Agr. Congo Belge*, 4 (1913), No. 4, pp. 905-918, figs. 12).—This describes cultural and manufacturing methods. The weights of 100 leaves in the various Provinces of English East Africa are noted to be from 82 to 127 kg. (180 to 279 lbs.), and the weights of fiber per 100 leaves from 2.3 to 3.6 kg.

The grain sorghums: Immigrant crops that have made good, C. R. BALL (*U. S. Dept. Agr. Yearbook 1913*, pp. 221-238, pls. 7, figs. 8).—In this article the author describes the introduction of grain sorghums into the United States, their usefulness as drought resisters, brings out their economic and commercial values for the arid and semiarid sections of the country, which include statistics on value and acreage, and gives characteristics of the durras, Kafir corn, and milo maize.

Soy beans.—An important Wisconsin crop, R. A. MOORE and E. J. DELWICHE (*Wisconsin Sta. Bul.* 236 (1914), pp. 3-20, figs. 6).—This bulletin contains cultural notes on the soy bean crop as grown in Wisconsin and discusses uses to which the crop may be put.

Data show yields of several varieties covering a period from 1902-1913, inclusive. Pedigreed Early Black soy beans gave an average yield for the 3 years, 1911-1913, ranging from 11 to 18.2 bu. per acre.

Cultural experiments with sugar beets, A. DEMOLON (*Bul. Assoc. Chim. Sucr. et Distill.*, 31 (1914), No. 8, pp. 576-582).—Part of this paper is devoted to the discussion of the use of large or small areas as experimental plots.

In giving results of experiments to study the formation of sugar in beets it is noted that the individual root weight and actual sugar content continued to

increase throughout November and December, even though the lower leaves for a distance at 5 or 6 cm. (about 2 in.) on the stem had been removed, but that the average weight of the roots was less in cases when the leaves had been removed. The author concludes, therefore, that the sugar formation takes place regardless of the presence or absence of the leaves, and that this action must take place within the root.

Spacing experiment in sugar-beet cultivation in Hungary, 1912, B. VON JANCSÓ (*Österr. Ungar. Ztschr. Zuckerindus. u. Landw.*, 43 (1914), No. 1, pp. 7-16).—In row spacing varying from 14 to 18 in. and plant spacing varying from 8 to 10 in. the yield results from 19 fields showed a spacing of 10 by 14 in. to be most satisfactory.

Catalogue of the German division of the library of L. S. Ware on the sugar industry (*Katalog der Deutschen Abteilung einer Special-Bibliothek des Herrn L. S. Ware über die Zuckerindustrie. Courbevoie, France, [19-?], pp. 33*).—A bibliography of nearly 550 volumes, comprising the works on the sugar industry in the German language found in the private library of the late L. S. Ware (E. S. R., 29, p. 719).

Catalogue of the works on sugar and the sugar industry (*Katalog der Werke über Zucker und Zuckerindustrie. Locarno, Switzerland, 1914, pp. 70*).—This is an appendix of the above and includes over 400 volumes on sugar and the sugar industry in German, 11 in Danish, 50 in Spanish, 315 in Dutch, 13 in Hungarian, 58 in Italian, 9 in Bohemian, 6 in Latin, 11 in Polish, and 1 each in Roumanian, Russian, and Swedish, found in the library of the late L. S. Ware.

The "Stewart Cuban" variety of tobacco, H. K. HAYES (*Connecticut State Sta. Rpt. 1913, pt. 6, pp. 385-390, pls. 2*).—This article describes a new type of Cuban tobacco (E. S. R., 31, p. 43) which differed from the normal Cuban in having leaves of a somewhat lighter green shade and in being nearly free from basal suckers, the range of leaf counts being from 62 to 80. "This type bred true in 1913, and when compared with the normal Hazlewood Cuban gave an increase in packed yield of about 90 per cent. The quality of the cured leaves was also very satisfactory."

On the nitrogen content of the wheat kernel from trans-Volga districts, N. TULAÏKOV (*Zhur. Opytn. Agron. (Russ. Jour. Expt. Landw.)*, 15 (1914), No. 1, pp. 1-11; *Bezenchuk. Selsk. Khoz. Opytn. Stantsiia*, No. 48 (1914), pp. 11).—Results of analyses show that there was little change in the nitrogen content of wheat varieties at the Bezenchuk station during 4 years of investigations. Difference in the nitrogen content of the wheat kernel is ascribed to the composition and osmotic pressure of the soil solutions under given climatic conditions, botanical variations in varieties playing no part.

Yams (*Dioscorea*), R. DE NOTER (*Agr. Prat. Pays Chauds*, 13 (1913), Nos. 118, pp. 1-18, figs. 9; 119, pp. 146-160, figs. 6; 120, pp. 215-236, figs. 2).—This article gives data on the origin, history, principal species, 23 cultivated varieties, and methods of cultivation of yams in Asia, Oceanica, North and South America, Africa, and Europe, with analyses and culinary preparations.

HORTICULTURE.

[Report of the] department of horticulture, W. L. HOWARD and J. C. WHITTEN (*Missouri Sta. Bul. 117 (1914), pp. 427-430*).—A progress report on horticultural investigations for the year ended June 30, 1913.

Three crops of apples have thus far been harvested from trees part of which were grown from scions selected from high-producing parents and part from trees of low-producing parents. There was practically as much variation in yield, size, and color of fruit between trees from the same parent as there was

between trees of different parentage. Bud selection from high-producing and from low-producing strawberries carried on through 12 previous years showed absolutely no gain in productiveness by selecting runners from high-producing parents.

Bordeaux mixture and lime-sulphur were found to be about equally effective against the ordinary diseases of the apple which occur in spring and summer, although the Bordeaux caused considerable damage from burning the fruit. Where lime-sulphur was substituted for Bordeaux as the calyx spray the injury was comparatively small. Arsenate of lead paste proved to be superior to arsenite of zinc in controlling the curculio and codling moth. The arsenite of zinc used in the quantities recommended by the manufacturers not only failed to control the insect but russeted the fruit and also scalded the leaves to a considerable extent. A demonstration spraying experiment conducted in a commercial orchard near Columbia resulted in a return, less cost of spraying, of \$66.80 per acre for the sprayed fruit as compared with \$5.50 per acre for the unsprayed fruit.

A study was made of fruit bud development as influenced by various treatments. Apple trees girdled in early June set a higher percentage of fruit buds than untreated trees of the same varieties without essentially injuring the growth of the trees. Other things being equal the tendency is for a heavy crop of apples to be followed by a light crop and for a light crop to be followed by a heavy crop. It has been shown that by proper cutting back water sprouts in both pears and apples can in one season be induced to produce both fruit spurs and fruit. In a comparison between fall versus spring planting of trees the increased growth through fall planting has decreased from about 100 per cent in the first season to 50 per cent in the second season and 33 per cent in the third season.

Observations relative to the self-fertility and self-sterility of peaches during the year have shown that all the leading commercial varieties grown on the station grounds are self-fertile. Since these results coincide with those previously secured it is concluded that the grower may safely plant even a single variety like the Elberta and expect the trees to set fruit. The self-fertile trees set as much fruit and the fruit develops as well as where varieties are cross-fertilized.

During the summer and fall of 1912 almost 200 species of seeds, representing 51 genera, were planted to determine whether seeds in general are capable of germinating immediately after ripening if placed under favorable conditions. The seeds of the grass, lily, pink, mallow, legume, and composite families seemed to have no rest period while the sedge, rose, cashew, and vine families have a pronounced rest period. In general seeds of woody plants have a more pronounced rest period and are more difficult to force into growth than seeds of vegetable and other herbaceous plants. Variation in the length and intensity of the rest period is greater between species than within a species. Etherization tended to stimulate seeds into an early growth and to increase the percentage of total germination. Soaked or stratified seeds are more strongly affected by ether than dry seeds. A 12-hour exposure to ether was the most favorable dosage for forcing seeds into germination.

In the orchard nutrition experiments none of the apple orchards responded to fertilizers applied during the past year. Peaches showed a notable response to an application of nitrogen, whether in the form of dried blood or nitrate of soda. Phosphorus and potash showed no appreciable influence upon the yield of fruit.

Report of the experimental work of the Taliparamba Agricultural Station for 1912-13, H. C. SAMPSON (*Dept. Agr. Madras, Rpt. Taliparamba Agr. Sta.,*

1912-13, pp. 12).—This report deals principally with the results of fertilizer and cultural experiments with peppers. Some data are also given on a variety test of sugar cane. An account of the locality and agriculture of the neighborhood of the Taliparamba Agricultural Station together with meteorological data and chemical analyses of sugar cane varieties are appended.

The manuring of market garden crops, B. DYER and F. W. E. SHRIVELL (*London, 1913, rev. ed., pp. 149, figs. 22*).—The present edition of this work (E. S. R., 24, p. 640) has been revised and brought up to date.

Third report on the partial sterilization of soils for glasshouse work, E. J. RUSSELL (*Jour. Bd. Agr. [London], 21 (1914), No. 2, pp. 97-116, pls. 2*).—In continuation of previous studies (E. S. R., 26, p. 815; 28, p. 538) experiments were conducted to determine the value of partial sterilization of soil in forcing houses. The crops worked with were tomatoes, cucumbers, and chrysanthemums. The results of preliminary outdoor experiments with wheat, barley, oats, and Swedish turnips are also reported.

The results as here presented indicate that partial sterilization of soil will give increased crops under the practical conditions of commercial forcing houses. The three heating methods tried out—high-pressure steam, low-pressure steam, and baking—all proved workable in practice and each has its advantages. Low-pressure steam was found to be the simplest method of heating soils in situ.

Partial sterilization effectually stamps out most of the diseases arising from the soil including club root. The supply of plant food is increased by partial sterilization, consequently less nitrogenous manure need be supplied to the plants in the early stages of their growth. Owing to the vigorous growth of tomato plants due to partial sterilization some difficulty was experienced with the setting of the fruit. It appears, however, that this can be avoided by adopting precautions as to varieties selected, size of plant at the time of setting out, withholding water and manure, and keeping on the heat.

It was found that old cucumber soil after being partially sterilized may be used again in making up borders. Since this soil has lost much of its fiber, however, it should be mixed with some new compost. In a similar manner old chrysanthemum compost may be used again after partial sterilization, provided a certain amount of new fibrous material is added.

Vegetable gardens on irrigated farms in western Nebraska, F. KNOBB (*Nebraska Sta. Bul. 142 (1914), pp. 24, figs. 4*).—This bulletin discusses the general requirements for successful gardens under irrigated conditions and gives suggestions relative to the specific culture of different garden crops. The suggestions are based primarily on the results secured in the garden at the Scottsbluff Substation on the North Platte Irrigation Project.

[Culinary peas and miscellaneous vegetables at Wisley, 1913] (*Jour. Roy. Hort. Soc. [London], 39 (1914), No. 3, pp. 674-701, 713, 714*).—Data are given on a variety test of 217 stocks of garden peas, together with data on a number of miscellaneous vegetables tested at Wisley in 1913.

Chicory (*Cichorium intybus*), L. LAPICCIARELLA (*Staz. Sper. Agr. Ital., 46 (1913), No. 11-12, pp. 675-723*).—A monograph on chicory with reference to its history, cultivation, uses, and botany. A bibliography of consulted literature is appended.

Jack bean (*Canavalia ensiformis*), N. O. BOOTH (*Oklahoma Sta. Circ. 29 (1914), pp. 2, fig. 1*).—A descriptive account of this bean with special reference to its adaptation to Oklahoma conditions.

The fruits of Ontario (*Toronto: Ontario Dept. Agr., 1914, pp. 320, figs. 380*).—In the present edition of this work (E. S. R., 19, p. 842) a number of new varieties and new photographs have been included, and the descriptions of varieties and cultural directions have been brought up to date.

A selected list of hardy fruits, W. WILKS and G. BUNYARD (*London: Roy. Hort. Soc., 1914, pp. 20*).—This comprises a selected list of orchard and small fruits for various sections of Great Britain, together with notes on cultivation and planting.

Promising new fruits, W. A. TAYLOR and H. P. GOULD (*U. S. Dept. Agr. Yearbook 1913, pp. 109-124, pls. 8*).—In continuation of similar articles (*E. S. R., 29, p. 436*) historical notes with descriptions and color plates are given of the following new or little-known fruits which are believed to possess valuable characteristics which render them worthy of the attention of fruit growers: Banana, McCroskey, and Opalescent apples; Lizzie peach; Flowers and James grapes; Triumph persimmon; and Lue orange. The Boone chestnut is also described.

New or noteworthy fruits, II, U. P. HEDRICK (*New York State Sta. Bul. 385 (1914), pp. 303-313, pls. 4*).—In continuation of a previous bulletin (*E. S. R., 29, p. 838*) the author describes some of the best recent fruit introductions as tested on the station grounds. These include King David apple, Edgemont peach, Abbess d'Oignies cherry, French plum, Hicks grape, Chautauqua gooseberry, Chautauqua currant, and Indiana and Barrymore strawberries. Each variety is considered with reference to its history, important characteristics, and economic value.

Pollination in orchards.—III, Self-fruitfulness and self-sterility in apples, F. J. CHITTENDEN (*Jour. Roy. Hort. Soc. [London], 39 (1914), No. 3, pp. 615-628*).—In continuation of a previous investigation (*E. S. R., 31, p. 140*), the author here presents the results of some experiments conducted at Wisley during the past few years.

About 5,000 clusters of flowers were bagged during the 3-year period 1911-1913. Data are given for each variety showing for the different seasons the relative amount of bloom and fruitfulness of the tree, number of fruits set in bags, and number of fruits harvested.

The results as a whole indicate that some varieties can form fruit without the aid of foreign pollen, whereas most of them appear to be sterile with their own pollen. Attention is called to the fact that there are many other causes of unfruitfulness in addition to lack of efficient pollination. Further experiments are to be conducted in an orchard house with the object of eliminating some of these disturbing factors. For cases in which apples are formed without the development of the seed, the author proposes the name "self-fruitful," restricting the term "self-fertile" to those cases where seed is produced.

A comparison of tillage and sod mulch in an apple orchard, U. P. HEDRICK (*New York State Sta. Bul. 383 (1914), pp. 249-281, pls. 6, fig. 1*).—This is the second and final report on one of the station's 10-year tillage and sod mulch experiments, the results for the first 5 seasons having been previously noted (*E. S. R., 21, p. 238*).

During the first 5-year period of the experiment here described the orchard, comprising 239 trees, of which 118 were in sod and 121 under tillage, was divided into halves by a north and south line and during the last 5-year period by an east and west line. Hence one-quarter of the orchard has been tilled 10 years; another has been tilled 5 years and then left in sod 5 years; the third quarter has been in sod 10 years; and the fourth quarter in sod 5 years and then tilled 5 years.

The experiment is described in detail. The results as here summarized show an average yield on the plat left in sod for 10 years of 69.16 bbls. per acre as compared with 116.8 bbls. per acre on the plat tilled 10 years. The average cost per acre of growing and harvesting apples in sod was \$51.73 as compared with \$83.48 under tillage. After subtracting these figures from the

gross returns in each case, however, a balance of \$140.67 per acre remains for the tilled plats as compared with \$74.31 for the sodded plats. The fruit from the sod mulch plats was more highly colored and matured from one to three weeks earlier than the tilled fruit. The tilled fruit was found to keep from two to four weeks longer than the sodded fruit and was also better in quality, being crisper, juicier, and of better flavor.

The average annual gain in trunk diameter for the sod-grown trees was 2.39 in. as compared with 3.9 in. for the tilled trees. The tilled trees were uniform in growth whereas the sod-grown trees were lacking in uniformity. There were many more dead branches on the sodded trees and the new wood was not as plump or as bright in color. The leaves of the tilled trees came out 3 or 4 days earlier, they were larger, more numerous, a darker, richer green, and remained on the trees several days longer than those on the sodded trees.

In the quarter of the orchard grown in sod for 5 years and then converted to tillage the beneficial effects to tree and foliage were almost instantaneous. The yield likewise improved after the first year. A change for the worse was almost immediately observed in the quarter of the orchard which had been tilled for 5 years and was then grown in sod. The use of nitrate of soda in the sod plats greatly increased the vigor of the trees and was a paying investment, although for the 5-year period they bore but a trifle more than half as much as the tilled trees. A marked beneficial influence was observed in the case of sodded trees growing adjacent to ground under tillage.

Contrary to the results secured in the 10-year experiment in the Hitchings orchard (E. S. R., 31, p. 45), the quantities of humus and nitrogen in the plat tilled for 10 years were materially increased.

The author enumerates and discusses the following reasons why grass militates against successful apple growing: Lowering the water supply, decreasing some elements in the food supply, reducing the amount of humus, lowering the temperature of the soil, diminishing the supply of air, affecting deleteriously the beneficial microflora, and forming a toxic compound that affects the trees. The general conclusion is reached that grass is the chief cause of unprofitable orchards in New York.

Winter spraying with solutions of nitrate of soda, W. S. BALLARD and W. H. VOLCK (*Prog. Agr. et. Vit. (Ed. l'Est-Centre)*, 35 (1914), Nos. 20, pp. 630-632; 21, pp. 648-653).—A French translation of the authors' investigations which have been previously noted (E. S. R., 30, p. 640).

Citrus fruit handling and storage, A. W. MCKAY (*Proc. Fla. State Hort. Soc.*, 26 (1913), pp. 30-45).—In this paper the author discusses the prevalence of blue mold decay in Florida citrus fruit during the 1912-13 season and concludes, in the light of experimental work conducted by the Bureau of Plant Industry for several years (E. S. R., 30, p. 841), that the decay was due to the unusually large crop with a consequent relaxing from careful methods of handling, combined with temperature and humidity conditions favorable for the development of the fungus in injured fruit.

In the discussion following O. W. Sadler presents some evidence to show that carefully dried fruit will tend to resist blue mold decay, even though injured.

During the season of 1912-13 the Bureau of Plant Industry commenced a cooperative investigation of the factors relating to grapefruit storage. The results for the first season, as here summarized, indicate that grapefruit may be held for 4 months in common storage with over 96 per cent of it in good commercial condition. Grapefruit stored, wrapped, and not washed has kept in the best condition in all the experiments. The quality of grapefruit is improved by storage, the chief attraction of stored fruit being a peculiar mellowness of flavor. Some evidence was obtained which indicated that there is also

an increase in the sugar content of stored fruit. The experiment has not been continued long enough to warrant any definite conclusions relative to a feasible and practical means of holding grapefruit.

Olive culture in Tunis, GUILLOCHON ET AL. (*Bul. Dir. Gén. Agr., Com. et Colon. Tunis*, 18 (1914), No. 77, pp. 268-296).—A cultural and statistical account of olive and olive oil production in Tunis.

A test of commercial fertilizers for grapes, U. P. HEDRICK and F. E. GLADWIN (*New York State Sta. Bul.* 381 (1914), pp. 201-230, pl. 1).—This bulletin reports a number of experiments which were conducted on a leased vineyard near Fredonia, N. Y., and also cooperatively in 6 vineyards in various parts of Chautauqua County in order to determine the value of commercial fertilizers in increasing or restoring former yields of grapes in the Chautauqua grape belt. The vineyards were selected to obtain fair averages of soils and of health and vigor of the grape plantations of this region. The experiments were conducted for a 5-year period, commencing in 1909.

The results of the experiment in the Fredonia vineyard have shown in brief that nitrogenous fertilizers had a marked beneficial effect upon the yield and quality of fruit, as well as upon leaf and wood growth. Lime had no appreciable effect in this vineyard and phosphorus and potassium had so small a beneficial effect that their use was not profitable. Hence it is concluded that nitrogen is the limiting factor.

The cooperative experiments were less conclusive. Commercial fertilizers, stable manure, and green manure crops were all used and the results vary greatly in any one vineyard or in the several vineyards compared with one another. The data obtained indicate that the fertilization of vineyards is so involved with other factors that only long-continued work will give reliable results.

The authors recommend that the following steps be taken in restoring the failing vineyards: Good drainage, control of insects and fungi, improvement in tillage and general care, and the application of such fertilizers as may be found lacking by actual test.

Bibliotheca vinaria, A. L. SIMON (*London*, 1913, pp. VIII+340).—A bibliography of books and pamphlets dealing with viticulture, wine making, distillation, and the management, sale, taxation, use, and abuse of wines and spirits.

The history and development of the strawberry, E. A. BUNYARD (*Jour. Roy. Hort. Soc. [London]*, 39 (1914), No. 3, pp. 541-552, pls. 8).—A review of the literature of the subject, including a bibliography of the most important works on the strawberry.

Classification of the genus *Annona*, with descriptions of new and imperfectly known species, W. E. SAFFORD (*U. S. Nat. Mus., Contrib. Nat. Herbarium*, 18 (1914), pt. 1, pp. XII+68, pls. 41, figs. 75).—This bulletin embraces a synoptical view of the genus *Annona* by natural groups and sections with descriptions of additional new or inadequately known species. Descriptions are also given of two closely allied new genera, *Fusaea* and *Geanthemum*, together with critical notes upon *Rollinia*, *Duguetia*, and *Raimondia*.

Mango crops, and some factors influencing them, A. C. HARTLESS (*Agr. Jour. India*, 9 (1914), No. 2, pp. 141-159).—A survey of mango production at the Government Botanical Gardens, Saharanpur, based upon information found in old reports for a period of 27 years. From these data the author makes deductions relative to factors influencing mango crops.

Control of imported tea seed, C. BERNARD and J. J. B. DEUSS (*Indian Tea Assoc., Sci. Dept. Quart. Jour.*, No. 1 (1914), pp. 1-23, figs. 6).—An English translation of a report previously noted (*E. S. R.*, 30, p. 742).

Analyses of materials sold as insecticides and fungicides (*New York State Sta. Bul.* 384 (1914), pp. 283-302).—This comprises data on the guaranteed and found analyses of samples of materials sold as insecticides and fungicides which were collected in different parts of the State.

Practical tree surgery, J. F. COLLINS (*U. S. Dept. Agr. Yearbook* 1913, pp. 163-190, pls. 7).—In this article the author describes the various parts of the tree and their functions, together with the methods employed in the renovation of injured and decayed trees. Suggestions are also given relative to precautions to be taken by tree owners when employing commercial tree surgeons to attend their trees.

Plants, etc., certificated by the [Royal Horticultural] Society from 1859 to 1910, inclusive (*London: Roy. Hort. Soc., 1911, pp. 195*).—This comprises a list of all the fruits, vegetables, decorative plants and flowers, ferns, daffodils, and tulips to which the Royal Horticultural Society of England has granted certificates from the year 1859 to the end of 1910, with the exception of purely florists' flowers certificated previous to 1890, many of which have been superseded and have become obsolete.

[Antirrhinums and miscellaneous flowering plants at Wisley, 1913] (*Jour. Roy. Hort. Soc. [London], 39 (1914), No. 3, pp. 635-656, 665-673*).—Descriptive notes are given on some 207 stocks of antirrhinums and on a large number of miscellaneous flowering plants tested at the Wisley Gardens in 1913.

Decorative garden dahlias at Duffryn, near Cardiff (*Jour. Roy. Hort. Soc. [London], 39 (1914), No. 3, pp. 657-664*).—Descriptive notes on a large number of varieties of dahlias tested on behalf of the Royal Horticultural Society and the National Dahlia Society of England are given.

Garden design, E. WHITE (*Jour. Roy. Hort. Soc. [London], 39 (1914), No. 3, pp. 559-580, pls. 12*).—This comprises the substance of two lectures on garden design, delivered before the Royal Horticultural Society.

The commuter's garden, edited by W. B. HAYWARD (*New York, 1914, pp. VII+219, pls. 16*).—A popular work dealing with vegetable and ornamental gardening in the suburbs, including suggestions relative to poultry raising, bee keeping, etc.

Identifying plants without a key, S. F. HAMBLIN (*Boston, 1914, pp. 25, figs. 50*).—In this pamphlet the author calls attention to interesting points in botanic difference or relation that apply to the twigs, buds, leaves, flowers, fruit, or specific peculiarities of various trees, shrubs, and herbs, and which will be of assistance in placing the plants in their proper families.

FORESTRY.

Report of the forestry committee of the Fifth National Conservation Congress at Washington, D. C., November 18-20, 1913 (*Rpt. Forestry Com. 5. Nat. Conserv. Cong., 1913, pp. 397, pl. 1*).—This report, which also includes those of the various subcommittees of the forestry section, deals with the following subjects: Publicity, forest planting, state forest policy, forest taxation, forest school education, forest investigations, lumbering, forest utilization, forest fires, and federal forest policy. The resolutions on forestry adopted by the congress are given and the following addresses are also included: Federal Forestry, by H. S. Graves (pp. 360-365); Economic Factors in Private Forestry Work, by E. A. Sterling (pp. 366-377); Public Knowledge of Forest Economics, by E. T. Allen (pp. 378-384); Conservation of Life in the Lumber Camps, by Mabel T. Boardman (pp. 385-389); The Lumberman's Point of View, by J. E. Rhodes (pp. 390-394); Lumbermen and Forestry, by W. Irvine

(pp. 395, 396); and What the Conservation Congress Accomplished, by C. L. Pack (p. 397).

Seventh report of the state forester of Connecticut, W. O. FILEY (*Connecticut State Sta. Rpt. 1913, pt. 6, pp. 391-420, pls. 2*).—In view of the detailed report on the work of the forestry department which appeared in the station report for 1912 (E. S. R., 29, p. 546) the report on the work for 1913, here presented, is confined to a paper on A Preliminary Working Plan for the Portland State Forest, by W. O. Filley and A. E. Moss, and tabular data as to forest fires in Connecticut during 1913. This forest is described in detail and discussed with reference to its silvicultural treatment, administration, fire protection, division of area, and revision of working plan. The compartments and subcompartments of the forest are described in detail.

Forest statistics at the beginning of the nineteenth century, H. DE COINCY (*Rev. Eaux et Forêts, 53 (1914), Nos. 9, pp. 281-288; 10, pp. 313-320*).—The author here presents a statistical account of forest conditions in France during the early years of the nineteenth century.

The administration of a forest experiment station, G. A. PEARSON (*Forestry Quart., 12 (1914), No. 2, pp. 211-222*).—A discussion of this subject based on the author's experience of 5 years as director of the Fort Valley Experiment Station, and here presented with the view of stimulating discussion from other experiment stations and the U. S. Forest Service in general.

A proposed method of preparing working plans for National Forests, J. C. KIRCHER (*Forestry Quart., 12 (1914), No. 2, pp. 145-157*).—The author discusses the main reasons for the failure of past plans of the Forest Service and describes the proposed plan to be tried out on the National Forests during 1914 before being put into effect.

Reforestation of cut-over chestnut lands, E. C. M. RICHARDS (*Forestry Quart., 12 (1914), No. 2, pp. 204-210*).—The author here presents the results of a study of the conditions found on various types of cut-over chestnut lands in northern New Jersey, and offers brief suggestions relative to reforestation of these lands.

A mechanical tree planter, F. T. MCLEAN (*Forestry Quart., 12 (1914), No. 2, pp. 139, 140, figs. 3*).—The author here illustrates and describes a mechanical tree planter which gives promise of planting forest trees more rapidly and as well as a man with a mattock can do it. The machine is specially adapted to plant tap-rooted conifers on rough, brushy lands, and burns.

Design of a range finder, L. CROWELL (*Forestry Quart., 12 (1914), No. 2, pp. 137, 138, pl. 1*).—A description and an illustration is given of a range finder for forest lookout stations which is said to be quite accurate and cheaply and easily constructed.

A new measuring instrument, H. W. SIGGINS (*Forestry Quart., 12 (1914), No. 2, pp. 141-144, fig. 1*).—The instrument illustrated and described consists of a combination of the Biltmore stick, the Christen hypsometer, and the Doyle rule in a single stick. Scales are given for constructing the Biltmore stick and the Christen hypsometer in connection with any log rule which will fulfill the requirements for a particular section.

Errors in estimating timber, L. MARGOLIN (*Forestry Quart., 12 (1914), No. 2, pp. 167-176*).—A discussion of the sources of error in timber estimating, with special reference to errors involved in making an estimate on only a small part of the area.

Stem analyses, J. BENTLEY, JR. (*Forestry Quart., 12 (1914), No. 2, pp. 158-166, fig. 1*).—The object of the present discussion is to recommend a more logical tabulation of the data usually included on a stem analysis blank as recorded in this country.

The scope of dendrology in forest botany, H. DE FOREST (*Forestry Quart.*, 12 (1914), No. 2, pp. 228-237).—The author here presents a short critical analysis of the subject of dendrology.

The silvical and economic geographic importance of the valonia oaks, K. BURK (*Jahrb. Nassau. Ver. Naturk.*, 66 (1913), pp. 1-52, pls. 2).—An account of the distribution, habitat, exploitation, and economic importance of the valonia oaks in the Mediterranean region, with a bibliography of cited literature.

Note on tapping experiments with *Funtumia elastica*, conducted at Musa and Kutu, Belgian Congo, A. GISSELEIRE (*Bul. Agr. Congo Belge*, 5 (1914), No. 1, pp. 95-104, figs. 6).—In the tapping experiments conducted at Musa some 1,696 *Funtumia* trees, ranging from 7 to 9 years of age and tapped for a period of about 3 weeks, yielded an average of 105 gm. of fresh rubber per tree, including the scrap rubber. In the Kutu tapping experiments some 1,368 trees, ranging in age from 6 to 9 years, yielded about 123 gm. of fresh rubber per tree, including the scrap.

Hevea in Cochin China, E. GIRARD (*Bul. Écon. Indochine, n. ser.*, 17 (1914), No. 106, pp. 46-53; *Jour. Agr. Trop.*, 14 (1914), Nos. 154, pp. 97-100; 155, pp. 129-132).—This comprises a general discussion relative to the adaptability of Hevea rubber to the soils and climate of Cochin China, cultural operations, and methods of exploitation.

Exploitation of cross-ties in northern New Mexico, C. F. KORSTIAN (*Forestry Quart.*, 12 (1914), No. 2, pp. 177-192).—Data on the various operations in the exploitation of cross-ties, based on the methods employed by one company which had been operating for the past 6 years in northern New Mexico, are here given and discussed.

DISEASES OF PLANTS.

The biological basis of international phytopathology, W. A. ORTON (*Phytopathology*, 4 (1914), No. 1, pp. 11-19).—An outline is given of what the author considers the fundamental principles upon which successful international action for the control of plant diseases should be based.

Report of the botany department, G. M. REED (*Missouri Sta. Bul.* 117 (1914), pp. 420, 421).—Brief summary reports are given of the investigations carried on during the fiscal year ended June 30, 1913.

The work of the year has conclusively shown that the loose smut of barley and wheat can be completely controlled by the hot water treatment and that when once eradicated from fields it will not reappear unless introduced from the outside. As a result of a manuring experiment about 70 per cent smutted plants were obtained affected with loose smut of oats.

The results of the investigation on the effect of toxic substances on soil organisms are summarized, showing that the detrimental or beneficial effect of toluol or carbon bisulphid upon nitrate accumulation in soils depends (1) upon the acting strength of the chemical in question, and (2) upon whether the soil is exposed for the chemical to evaporate. Toluol in strengths approximating 0.1 cc. per 100 gm. of soil was found to exert no appreciable effect upon nitrification. If the strength exceeds this, it may, and usually does, exert a detrimental or even inhibitory effect upon the process for short periods of incubation. However, if the periods of incubation are extended the harmful effect is overcome with strengths up to and including 1 cc. per 100 gm. of soil. In strengths of less than 1 cc. per 100 gm. of soil carbon bisulphid, even for short periods of incubation, did not show any appreciable effect upon nitrate accumulation. If the strength of carbon bisulphid exceeded 1 cc. per 100 gm.

a temporary retarding effect was observed, but this was soon overcome even when the treatment was as strong as 5 cc. per 100 gm. of soil. It was found that samples of soil treated with either chemical in sufficient quantity to inhibit entirely nitrification for a period of from 4 to 20 weeks may entirely recover from the effect with reinoculation. So far as the laboratory experiments can be applied to field practice, it is thought that neither toluol nor carbon bisulphid as previously used could materially affect nitrate accumulation, since practical applications rarely exceed 0.1 cc. per 100 gm. of soil.

Preliminary to a study of the parasitic flora, the local rusts have been studied and about 400 collections made of 70 different species.

In experimental work with the powdery mildew on oats, it was found that this species will not pass over to wheat, barley, rye, or other grasses tested, although it does infect the tall wild oats (*Avena elatior*). In studying the effect of light, it was found that etiolated plants will not become infected, even though normal green plants of the same varieties are extremely susceptible to the mildew.

Report of the central station for plant protection in Mecklenburg-Schwerin and Mecklenburg-Strelitz, 1912, H. ZIMMERMANN (*Ber. Haupt-sammelstelle Pflanzenschutz Mecklenburg-Schwerin u. Strelitz, 1912, pp. 121*).—Beginning with an account of the weather during each month of 1912 in connection with crops or other vegetation affected thereby, this report then deals in considerable detail with diseases of various field and forest plants and with other enemies thereof, giving in some cases comparisons with data obtained in previous years.

Heat killing and stem constrictions of plants, C. VON TUBEUF (*Naturw. Ztschr. Forst u. Landw., 12 (1914), No. 1, pp. 19-36, figs. 4*).—This is a discussion of notes by the author and others on growth and behavior of woody plants as influenced by parasitic fungi, compression (from binding), extreme dryness, heat, etc., including studies in regions subject to extremes on several continents.

The fungus genus *Verticillium* in its relation to plant diseases, W. A. ORTON (*Abs. in Phytopathology, 4 (1914), No. 1, pp. 40, 41*).—In a previous publication (*E. S. R., 30, p. 649*) the author called attention to a disease of potatoes caused by *V. alboatrum*. It is now reported that a similar fungus occurs on eggplants, causing a serious wilt disease.

Of two wilt diseases of okra, one is said to be due to *Fusarium vasinfectum*, the other to *V. alboatrum*. The *Verticillium* is in general said to be more northern in its range than the *Fusarium* wilt of okra.

Diseases of dahlia in Germany and seedling maples in Schleswig-Holstein are associated with *Verticillium*.

Studies on Nectriaceæ, II, J. WEESE (*Ztschr. Gärungsphysiol., 4 (1914), No. 2, pp. 90-132, figs. 2*).—The report previously noted (*E. S. R., 31, p. 242*) is followed by a critical discussion of *Nectria peziza*, *N. suffulta*, *N. hæmatites*, *N. cucurbitula meizospora*, *N. pityrodes*, *N. erinacea*, and *N. heterosperma*. In connection with the treatment thereof notes by numerous other authors are cited.

Snow mold and other aspects of attack by *Fusarium nivale* on cereals, E. SCHAFFNIT (*Landw. Jahrb., 43 (1913), No. 4, pp. 521-648, pls. 5*).—This is a more detailed account (*E. S. R., 29, pp. 244, 445*) of studies by the author with *F. nivale*, including its relations with the host plant in its three stages (on leaves of young plants in early spring, on stems before maturity, and on grains thereafter). Discussion is given also of its cultural and other characters and behavior in connection with those of other related or other grain infecting fungi, also of measures for its control. The last mentioned include selection

of resistant varieties, dipping of seed grain, field treatment by means of fertilizers, etc.

The results are presented in considerable detail, largely in tabular form, and a critical description of *F. nivale* is also given.

Smut in small grains, H. D. HUGHES and P. C. TAFF (*Iowa Sta. Circ. 11 (1913)*, pp. 4).—A description is given of smuts of small grains, the authors stating that in Iowa loose smut of oats is most prevalent, with covered smut or stinking smut of wheat as second in importance.

For the control of these diseases the authors recommend the formalin treatment for the smut of oats, stinking or covered smut of wheat, and covered smut of barley, and for treatment of loose smut of wheat and barley a modified hot water treatment which consists of soaking the seed for 4 or 5 hours in cold water, after which it is placed in hot water for 10 to 13 minutes.

Investigations of timothy rust in North Dakota during 1913, W. H. MERCER (*Phytopathology*, 4 (1914), No. 1, pp. 20-22).—Timothy rust (*Puccinia phleipratensis*) is said to have become prevalent and very destructive in various parts of North Dakota. Some investigations are reported, in which the author undertook to determine a possible ædial host and the relation of this rust to the rusts on various cereals and grasses. Field observations supplemented by laboratory and greenhouse work were carried on with a number of rusts which showed that there is apparently no relation between grain and timothy rusts and probably none between the rust on the timothy and that on other grasses studied.

Heart rot of beets, J. KÄPPELI and O. MORGENTHALER (*Landw. Jahrb. Schweiz*, 27 (1913), No. 8, pp. 432-435, pl. 1, fig. 1).—An account is given of a case in which it is claimed that dust from passing vehicles, etc., was responsible for a great local increase of injury to beets affected with heart rot (*Phoma betæ*) along a roadside by its effects in clogging the stomata on the upper leaf surfaces and thereby reducing the vitality of the plants.

The employment of less susceptible varieties, also the protection of the beet crop by planting other and nonsusceptible crops between the beet plants and dusty roadside are recommended.

The heart rot is said to be communicated by beets infected in the field to sound roots in storage.

Celery disease (*Gard. Chron.*, 3. ser., 55 (1914), No. 1418, p. 150).—It is stated that the celery crop of 1913 under nearly the same conditions as that of 1912, with the exception that artificial watering was necessary, showed late blight in August. Copper sprays had but little effect except at first. It is held that manuring had little if any influence on the disease, but that dry weather and artificial watering probably are more influential in this regard.

Cotton anthracnose, H. R. FULTON, J. R. WINSTON, and R. O. CROMWELL (*Abs. in Phytopathology*, 4 (1914), No. 1, p. 42).—A description is given of the cotton anthracnose which is said to be a recent introduction into North Carolina. The topics considered by the authors are the introduction of the fungus, its local spread, factors influencing seasonal development, susceptibility of varieties, and the effectiveness of seed selection for the control of the disease.

Fruit rots of eggplant, F. A. WOLF (*Abs. in Phytopathology*, 4 (1914), No. 1, p. 38).—The author reports a study of the morphology and cultural characters of *Ascochyta hortorum*, which causes a rot of the fruit of eggplant.

In addition there is reported an undescribed fruit rot due to a species of *Rhizoctonia*, which cultural studies indicate is identical with *Corticium vagum solani*. The fungus is said to excrete an enzym, pectinase, which causes the dissolution of the middle lamellæ and the consequent disintegration of the tissues.

Is golden seal resistant to the root knot nematode? J. A. McCLINTOCK (*Phytopathology*, 4 (1914), No. 1, p. 33).—An investigation was made to determine the accuracy of the popular belief that golden seal is not liable to attack from root knot nematodes and may, therefore, be grown in infested ginseng beds.

It was found that golden seal plants from Tennessee and from Michigan were badly infected with nematodes, indicating that this plant can not be used to starve out nematodes in infested ginseng beds.

Report of 1913 infection studies with *Fusarium* on potato, W. HIMMELBAUB (*Österr. Ungar. Ztschr. Zuckerindus. u. Landw.*, 43 (1914), No. 1, pp. 1-6).—Reporting detailed results of further studies (E. S. R., 30, p. 539), the author states that wound infection with *Fusarium subulatum*, *F. rubiginosum*, *F. falcatum*, and *Verticillium alboatrum*, also with *Fusarium* taken from several designated varieties of potato, produced disease symptoms similar to those of leaf roll.

A Phoma rot of Irish potatoes, I. E. MELHUS (*Abs. in Phytopathology*, 4 (1914), No. 1, p. 41).—A report is given of a new storage rot observed prevalent on potatoes grown in Maine. The disease is believed to be due to a species of Phoma, which causes depressed circular areas from 0.5 to 3 cm. in diameter and often extend into the center of the tuber. The results so far as reported indicate that the fungus is a wound parasite most destructive on potatoes in storage.

Inspection and certification of potato seed stock, W. A. ORTON (*Abs. in Phytopathology*, 4 (1914), No. 1, pp. 39, 40).—The author outlines a plan for the inspection and certification of potatoes, the certificate to be based on field inspections supplemented by inspection of the tubers prior to shipment. The presence of powdery scab, wart, nematodes, *Fusarium* wilt, *Verticillium* wilt, southern brown rot, and leaf roll should disqualify potatoes from certification. The presence of other diseases should receive special consideration.

Relation of the mosaic of the pepper and the filiform leaf of the tomato to the mosaic of the tobacco, C. A. SCHWARZE (*Abs. in Phytopathology*, 4 (1914), No. 1, p. 42).—The characters of the mosaic disease of the pepper are said to be practically the same as those shown by similarly affected tobacco. On the tomato the disease is less well known. Here it takes a form called filiform leaf, causing the reduction of the size of the leaf and frequently reducing it to nothing but a midrib. The blossoms are also affected, branching is excessive, and the fruit production is greatly reduced. Small portions of diseased pepper and tomato leaves inserted into healthy tobacco plants soon developed the disease. Attention is called to the difference in susceptibility of varieties to this trouble.

A new rust of economic importance occurring on pomaceous hosts, H. S. JACKSON (*Abs. in Phytopathology*, 4 (1914), No. 1, p. 41).—A description is given of the occurrence of an *Æcidium* on the pear and quince in Oregon, foliage, fruit, and stems being attacked and frequently causing considerable distortion. This is believed to be the same rust as that occurring on the apple, crab apple, etc. The *Æcidium* agrees on all the hosts with *Æ. blasdaleanum*. Although cultural proof is lacking, the author believes the *Æcidium* is connected with *Gymnosporangium blasdaleanum*. If this should be true, most of the plants upon which it has been observed are unrecorded hosts for this species.

An unusual outbreak of apple blossom blight, G. M. REED (*Phytopathology*, 4 (1914), No. 1, pp. 27-30).—The author reports an unusual occurrence of blossom blight on apple trees in Missouri in 1913. An examination was made of orchards in the vicinity of Columbia, showing that some varieties were entirely free from the blight while others showed varying degrees of the infection. The

blossom blight was very common on the pear trees in the same orchard and twig blight was also conspicuous. An examination of wild crab and haw trees in the vicinity revealed the presence of a large percentage of blighted flower clusters. This was particularly true of *Crataegus crus-galli*.

As an explanation of the unusual outbreak of blossom blight it is suggested that the absence of severe cold weather may have favored the survival of the blight bacteria in cankers. The trees did not come into bloom until two weeks later than usual. At this time insects were much more abundant than usual and may have served as carriers for the bacteria.

Collar blight of apple trees in Pennsylvania, C. R. ORTON and J. F. ADAMS (*Abs. in Phytopathology*, 4 (1914), No. 1, p. 43).—Collar blight or collar rot, as the disease is said to be locally known, was first reported in Pennsylvania in May, 1907. Since that time it has spread rapidly throughout the State as well as in neighboring States and is considered one of the most serious apple diseases with which the orchardist has to contend. The disease appears distinct from the crown rot in New York, which is due to winter injury. It is considered definitely established that the trouble is due to *Bacillus amylovorus*, and the apple tree borer is considered one of the most active agents in the spread of the causal organism.

The use of sulphur-lime wash as a remedy for apple scab, R. K. BEATTIE (*Abs. in Phytopathology*, 4 (1914), No. 1, p. 42).—A résumé is given of 5 years' spraying experiments at the Washington Experiment Station, in which an attempt was made to overcome the injury following the use of Bordeaux mixture. This, it is said, was secured by the use of lime-sulphur. Experiments showed that if properly applied twice during the season, practically perfect results were given, as high as 99.17 per cent of the fruit being free from scab, while in the unsprayed check not more than 6 per cent of the fruit was unaffected. Attention is called to the necessity for thoroughness in spraying and the value of spraying under heavy pressure for attaining the best results.

Control of *Cronartium* rust on currants, R. EWERT (*Ztschr. Pflanzenkrankh.*, 23 (1913), No. 8, pp. 463-476, figs. 2).—Experiments in 1912 and 1913 are described. It is claimed that while the black currant is ordinarily infected almost exclusively from below, a slight benefit appears to be derived from spraying the upper leaf surface with Bordeaux mixture of 1 per cent strength.

Control of *Cronartium* rust on currants, R. EWERT (*Jahresber. Ver. Angew. Bot.*, 11 (1913), pt. 1, pp. 30, 31).—This gives in condensed form the substance of the article above noted.

Practical formulas for the treatment of grape anthracnose, L. DEGRULLY (*Prog. Agr. et Vit. (Ed. l'Est-Centre)*, 35 (1914), No. 2, pp. 33-38, fig. 1).—It is claimed that a spray containing 8 parts of sulphuric acid and from 10 to 15 of iron sulphate to 100 of water is more adherent and therefore more lasting in its effects than those of the more common composition.

Peronospora disease of grapevines and its control, K. MÜLLER (*Grossh. Bad. Landw. Vers. Anst. Augustenb. Flugbl. 1* (1913), pp. 12, figs. 5; in *Ber. Grossh. Bad. Landw. Vers. Anst. Augustenb.*, 1912).—An illustrated description is given of *P. (Plasmopara) viticola* in relation to leaves, blooms, and berries in connection with other grape diseases or influences producing results somewhat resembling those of this parasite. The history of its development is traced in relation to weather and to effects on the vine stock. Protective measures are discussed, including control of general culture conditions and sprays with their effect on the crop and stock.

Studies with *Plasmopara viticola* on grapevines, G. VON ISTVÁNFFI and G. PÁLINKÁS (*Ztschr. Pflanzenkrankh.*, 23 (1913), No. 8, pp. 449-463).—This contribution is in the form of a report on about 70 investigations with discussion

thereof, relating to the invasion of grape leaves by *P. viticola* and its development therein, and dealing with the incubation period, oil spots, conidiophores, conidia and swarm spores, infection, stomatal relations, etc.

Identity of the American and French mulberry blight, E. F. SMITH (*Phytopathology*, 4 (1914), No. 1, p. 34).—As the result of studies of leaves and stems of mulberry from France and a comparison of the cultural characters of *Bacterium mori*, the author was led to the conclusion that the same organism is responsible for the disease in both America and France.

Diseases and pests of cultivated plants in Samoa, K. GEHRMANN (*Arb. K. Biol. Anst. Land u. Forstw.*, 9 (1913), No. 1, pp. 1-72, figs. 11).—Discussing in general the cultural conditions prevalent in Samoa, more particularly as related to diseases of cacao, the author reviews briefly the history, modes of attack, etc., of cacao canker with an account of studies thereon by others.

He concludes from his own investigations that *Fusarium samoense* n. sp. is the cause of this disease, a *Nectria* and a *Calonectria* being found in connection apparently as saprophytes. The canker is said to be spread largely by surface drainage of the soil. Admission of air and sunshine and employment of radical pruning and fungicides are recommended. Some other diseases of cacao with alleged causal organisms are briefly discussed. Among other injurious agents noted are sulphurous volcanic gases, lightning, etc.

A bibliography is appended.

Cladosporium diseases of Ampelopsis tricuspidatum, M. T. COOK and G. W. WILSON (*Abs. in Phytopathology*, 4 (1914), No. 1, p. 42).—A disease of this ivy due to *C. herbarium* is described. The organism is said to penetrate the stems, causing a hypertrophy and resulting in the death of the vine. It is said that the same fungus has been observed on grapes in California and in Europe. During the past season it was reported common in New Jersey, where it caused a great deal of injury.

Stem rot and leaf spot of Clematis, W. O. GLOYER (*Abs. in Phytopathology*, 4 (1914), No. 1, p. 39).—A description is given of a stem rot and leaf spot of Clematis due to *Ascochyta* sp. The fungus is said to live as a saprophyte on the stem stub of the previous year and to produce numerous pycnidia. It works slowly downward to the new shoots, which become girdled, the portions above suddenly wilting. The same fungus has been observed causing a leaf spot of *C. paniculata*. The disease has been produced artificially by inoculating with pure cultures of *Ascochyta*, and by spraying with spores from pure cultures.

Latent phases of disease following infection of Euphorbia cyparissias with Uromyces, G. TISCHLER (*Bot. Jahrb. [Engler]*, 50 (1914), Sup., pp. 95-110, figs. 7).—Previous work (E. S. R., 26, p. 650) has been followed up by a further study of *E. cyparissias* infected with *U. pisi*.

It is stated that by a treatment preventing the occurrence of the usual winter resting period of the host it is possible to prevent the development of the fungus on the young foliage and stems. The disease remains latent in such plants, ready to break out on reestablishment of the regular resting period, as in the ordinary life cycle of the host. In the latent condition of this fungus thus induced the mycelium appears unable to make its way between the meristematic cells of the growing point, although it may be present between the vacuolated cells into which it sends typical haustoria. The observed variations in activity of the parasite, it is thought, may be related to differences in osmotic pressure in plant and parasite, as noted by MacDougal (E. S. R., 26, p. 433). It is stated that even when the fungus is apparently absent from growing points of the leaves of a given shoot, the parasite may appear in the floral organs later developed, causing a characteristic deformation thereof.

A bibliography is given.

Heat injuries to forest plants, E. MÜNCH (*Naturw. Ztschr. Forst u. Landw.*, 11 (1913), No. 12, pp. 557-562, figs. 2).—In a preliminary statement of studies regarding the injurious effects of heat on young forest trees, descriptions and illustrations are given of injuries to young beeches and pines, as noted in the dry, hot summer of 1911. Fungi found in connection therewith are thought to have played the part of saprophytes merely. Temperatures of from 50 to 55° C. (122 to 131° F.) at the surface of sandy soil are said to have been common during that time. It is thought that such temperatures may prove directly fatal to young plants independently of their drying influence. Protection against direct sunshine is said to prevent this sort of injury. Raw humus is most favorable to heat injury and loose sand almost as much so, the latter being found in one case to be 16° hotter than compact sand, on account of its poor conductivity.

Injury from air exclusion and overheating, C. VON TUBEUF (*Naturw. Ztschr. Forst u. Landw.*, 12 (1914), Nos. 2, pp. 67-88, figs. 2; 4, pp. 161-169).—Detailing methods pursued and results obtained in experiments continued for two years with artificial or solar heat applied to the trunks or roots of *Fraxinus excelsior* or *F. americana*, the author states that stems were usually injured or killed by long exposure to 42° C. (107.6° F.). Exclusion of air by means of paint, etc., seemed to exert less influence than did high temperature.

More on heat injuries to forest plants, E. MÜNCH (*Naturw. Ztschr. Forst u. Landw.*, 12 (1914), No. 4, pp. 169-188).—Following the two contributions noted above, the author gives a fuller discussion of observations made on heat transference by absorption, radiation, conduction, and convection in relation to plants, also of such modifying factors as moisture, nature and state of the soil, etc. The suggestion is made that in these studies more exact means be employed to ascertain the temperature of the plant itself, as this is always lower than that of the adjacent soil at the surface under such circumstances.

Notes on diseases of trees in the southern Appalachians, II, A. H. GRAVES (*Phytopathology*, 4 (1914), No. 1, pp. 5-10, pl. 1, fig. 1).—In continuation of an account of diseases in the southern Appalachians (E. S. R., 29, p. 851), the author gives brief descriptions of the more important fungus diseases observed on the scrub pine (*Pinus virginiana*).

The most prevalent diseases are said to be the burl caused by *Cronartium quercus*, heart rot due to *Trametes pini*, and a leaf cast (*Gallowaya pini*). A second disease of the needles caused by *Coleosporium inconspicuum* is said to be rather rare. Among other injuries to the pine trees a description is given of the damage done by wind, ice, and snow, and unfavorable soil conditions.

Notes on Peridermium from Pennsylvania, C. R. ORTON and J. F. ADAMS (*Phytopathology*, 4 (1914), No. 1, pp. 23-26, pl. 1).—From a recent study of some Peridermiums occurring on various species of pine, the authors conclude that the form associated with *Cronartium comptoniæ* should be called *P. comptoniæ* n. comb., that *C. comandræ* is the alternate stage of *P. pyriforme*, and that the Coleosporium occurring on Aster and Solidago has for its æcidial stage *P. aciculum*. In the course of the investigations *P. aciculum* was found on *Pinus pungens* in addition to the usual host species.

Notes on the white pine blister rust, P. SPAULDING (*Abs. in Phytopathology*, 4 (1914), No. 1, pp. 41, 42).—In continuation of a previous report on this blister rust (E. S. R., 29, p. 554) the author gives an account of its occurrence on white pine in New York, near where it was first reported (E. S. R., 18, p. 747), and also in northern Vermont. In Vermont a large white pine tree fully 75 years old was found badly infected and a number of younger trees were also diseased. The fungus has been definitely reported in Denmark as occurring

on *Pinus excelsa* and during the past year it was found several times on this same host in this country. The author states that inspection records show that in but one case have all the diseased white pines been removed upon the first inspection.

A preliminary note on the cause of "pecky" cypress, W. H. LONG (*Abs. in Phytopathology*, 4 (1914), No. 1, p. 39).—The author reports the discovery of the sporophores of a fungus associated with what is popularly known as pecky cypress. The fungus is apparently *Fomes geotropus*, a tropical species closely related to *F. ulmarius*. It enters through a wound at the butt of the tree and produces hollows which may or may not terminate in a pecky condition further up the tree. The fungus was found directly associated with the diseased condition in five localities in Florida, two in Louisiana, and one in Arkansas. In addition to occurring on the cypress it was found associated with hollows in the butts of living trees of tupelo gum, black gum, sweet gum, elm, maple, and magnolia.

ECONOMIC ZOOLOGY—ENTOMOLOGY.

The American thrushes valuable bird neighbors (*U. S. Dept. Agr. Yearbook 1913*, pp. 135-142, pl. 1).—This article, prepared from data furnished by F. E. L. Beal, calls attention to the economic importance of the robin, bluebird, and other members of the thrush family.

The food of *Rana pipiens*, C. J. DRAKE (*Ohio Nat.*, 14 (1914), No. 5, pp. 257-269).—This report of investigations of the food of the common leopard frog (*R. pipiens*) and its relation to nature in the neighborhood of its habitat is based upon dissections of 209 specimens collected on the peninsula of Cedar Point, Ohio. It is stated that the frog's food consists only of living and moving creatures and that very little vegetable matter was found in its stomach. A detailed tabulation of the findings, including determinations of many of the insects, is presented.

The dictionary of entomology, N. K. JARDINE (*Ashford, England*, [1913], pp. IX+259).—The author has compiled and explained technical and special terms used by writers in entomology from the time of Linné to the present date and has given their derivations. Some 3,000 scientific terms are thus brought together.

The writings of Philip Reese Uhler (*Proc. Ent. Soc. Wash.*, 16 (1914), No. 1, pp. 4-7).—This is a list arranged chronologically of Dr. Uhler's entomological contributions, which largely relate to the Hemiptera.

Bringing applied entomology to the farmer, F. M. WEBSTER (*U. S. Dept. Agr. Yearbook 1913*, pp. 75-92, pls. 6, figs. 4).—This popular article discusses ancient misconceptions regarding insects, early records of insect depredations in America, the primitive state of entomology at that time, first efforts for the protection of plants from insects, beginnings of the application of entomology to grain growing, the introduction and development of entomological field stations, and the practical value of the field stations to the farmers.

Notes on entomological inspection in the District of Columbia, E. R. SASSCER (*Jour. Econ. Ent.*, 7 (1914), No. 2, pp. 240-244).—This is a brief description of inspection work carried on by the author.

[Report of the entomological department], L. HASEMAN (*Missouri Sta. Bul.* 117 (1914), pp. 423-425).—Brief notes on the work of the fiscal year ended June 30, 1913, with insect pests in Missouri are presented.

The relation of temperature to insect development, L. M. PEAIRS (*Jour. Econ. Ent.*, 7 (1914), No. 2, pp. 174-181, figs. 6).—It is stated that the study carried on has seemed to prove the following points which are proposed as tentative laws:

"The rate or velocity of insect development is affected by temperature, and, other factors being constant, this rate increases in direct proportion to the increase in temperature within the normal limits of development. The curve expressing the increase in rate of development is a true hyperbole. The Developmental Zero, or what has been styled the 'critical point,' is at or near the point where the reciprocal curve for the time factor intersects the temperature axis. The thermal constant for an insect or any stage of an insect is the constant for the developmental curve for such insect or stage. The effective temperature for conditions of variable temperature, i. e., the ordinary daily variations, is higher than the mean for the period. (This point is not supported by any evidence in the present paper, but there is little doubt in the mind of the writer that it will be found to be correct.)"

The importance of the measure of evaporation in economic studies of insects, V. E. SHELFORD (*Jour. Econ. Ent.*, 7 (1914), No. 2, pp. 229-233).—The author reports upon a series of experiments conducted.

The use of atmometers to measure evaporation in the study of insects, V. E. SHELFORD (*Jour. Econ. Ent.*, 7 (1914), No. 2, p. 249).—A brief descriptive account.

Can insects become resistant to sprays? A. L. MELANDER (*Jour. Econ. Ent.*, 7 (1914), No. 2, pp. 167-173).—The author states that the data at hand do not permit the determination as to whether resistance and susceptibility are differences of degree and not of kind, or whether they behave as allelomorphs.

Insecticides, L. E. SAYRE (*Trans. Kans. Acad. Sci.*, 26 (1912), pp. 138-141, fig. 1).—The author's experiments with cimicifuga, or bugbane, tend to show that this drug has been greatly overestimated as to its toxic properties toward insects.

Powdered cimicifuga seems to be devoid of insecticidal properties, crickets kept in contact with it for hours showing no ill effects. "As a fumigant cimicifuga proved unsatisfactory, acting more as an anesthetic than as an insecticide. One hundred times as much powdered cimicifuga as the amount of sulphur that proved effective was used, or the fumes from 2 gm. of the drug in a space of 9,000 cc. The insects were removed after a period of 1 hour, apparently dead, but recovered after an hour or 2 hours' time."

A commercial insecticide having the trade name "Vermingo," said to contain 6½ per cent carbolic acid among other ingredients, as a fumigant had one-fiftieth of the toxic power of sulphur, but by contact in an open jar it killed almost instantly.

Pyrethrum was tested as a fumigant but proved no superior to cimicifuga.

Some properties of various forms of arsenate of lead, J. A. DEW (*Jour. Econ. Ent.*, 7 (1914), No. 2, pp. 162-167).—Experiments conducted with the plum curculio in a peach orchard indicate that the killing power of arsenate of lead varies directly with the percentage of As_2O_5 that it contains.

Notes on the entomology of the Arizona wild cotton, W. D. PIERCE and A. W. MORRILL (*Proc. Ent. Soc. Wash.*, 16 (1914), No. 1, pp. 14-23).—The insect enemies of *Thurberia thespesioides* observed by the authors include the boll weevil *Anthonomus grandis thurberiae*, accounts of which have been previously noted (*E. S. R.*, 30, p. 56); cotton leaf worm (*Alabama argillacea*); *Thurberia* bollworm; blister mites; a leaf gall due to a species of *Itonididæ*; a mealy bug (*Pseudococcus* sp.); etc.

Notes on the onion thrips and onion maggot, H. T. FERNALD and A. I. BOURNE (*Jour. Econ. Ent.*, 7 (1914), No. 2, pp. 196-200).—In the first part of this paper the authors present a brief account of the life history and habits of the onion thrips in Massachusetts, investigations of which have extended over a period of about 5 years.

The insecticides experimented with have not given satisfactory results, but it has been found that the destruction of all refuse after the crop is gathered and burning over all strips of grass through and around the fields will give very satisfactory results. Since the adult does not appear to fly far of its own volition unless carried by strong winds, it seems probable that onion fields can, at least to a considerable extent, be kept free from the thrips by running fire over all places near, in which they hibernate.

Most of the data here presented relating to the onion maggot have previously been noted from another source (E. S. R., 30, p. 160).

Two new insect pests of currants and gooseberries, R. A. COOLEY (*Jour. Econ. Ent.*, 7 (1914), No. 2, pp. 193-195).—A small curculio, *Pseudanthonomus validus*, for which the name currant fruit weevil is proposed, has been found at the Montana Experiment Station destroying the fruit of the currant in a manner very similar to that of the currant fruit fly. *Liothrips montanus* is said to have caused a peculiar injury to the tender, terminal growth of gooseberries and red and black currants in Montana for several years past.

The destruction of mosquitoes, fleas, flies, pediculi, and other insect carriers of disease, J. S. PURDY (*Rpt. Austral. Assoc. Adv. Sci.*, 13 (1911), pp. 662-673).—The author describes measures, such as drainage, use of petroleum and disinfectants, fumigation, etc., which he states have been successful in destroying insect disease carriers.

Grasshopper control in the southern division of Kansas, S. J. HUNTER and P. W. CLAASSEN (*Jour. Econ. Ent.*, 7 (1914), No. 1, pp. 73-83, pls. 3).—A detailed report of work carried on in 1913.

On the proper generic names for certain Thysanoptera of economic importance, J. D. HOOD (*Proc. Ent. Soc. Wash.*, 16 (1914), No. 1, pp. 34-44).—The author points out several changes that must be made in the generic names of Thysanoptera and presents a catalogue of the genera Frankliniella, Physothrips, Tæniothrips, Odontothrips, and Scirtothrips. It is pointed out that Euthrips is an absolute synonym of the genus Thrips and therefore can never be used as a generic name in zoology.

A bibliography of 34 titles is appended.

Sterility in oats caused by thrips, C. G. HEWITT (*Jour. Econ. Ent.*, 7 (1914), No. 2, pp. 211-218, pl. 1, fig. 1).—*Anaphothrips striatus*, commonly known as the grass thrips, is a source of considerable injury to oats in Saskatchewan and British Columbia. The author presents a general review of the literature relating to thrip injury to cereal crops in connection with his discussion of the subject.

The periodical cicada in 1914, C. L. MARLATT (*U. S. Dept. Agr., Bur. Ent., Periodical Cicada in 1914*, pp. 3, figs. 3).—This paper gives information on the occurrence of Brood V of *Tibicen septendecim*, which occupies in the main a rather compact territory lying chiefly in Ohio and West Virginia with a few scattering colonies in Pennsylvania and Virginia. It is stated that some of the southern West Virginia records are open to doubt, as are also some of the records in Virginia. It is pointed out that the cicadas may be expected to emerge from the middle to the end of May and scattering individuals may be found up to the middle of June.

A request is made that information be furnished to supplement and complete the knowledge of the distribution of this brood.

Some Pemphiginæ attacking species of *Populus* in Colorado, C. P. GILLETTE (*Ann. Ent. Soc. Amer.*, 6 (1913), No. 4, pp. 485-493, pl. 1; 7 (1914), No. 1, pp. 61-69, pl. 1).—The species discussed in this paper are *Thecabius populimonilis*, *Cornaphis populi* n. g. and n. sp., *T. populiconduplifolius*, *Asiphum sacculi* n. sp., and *Mordwilkoja vagabunda*.

A comparison of natural control of *Toxoptera graminum* in South Africa and the United States, W. MOORE (*Ann. Ent. Soc. Amer.*, 7 (1914), No. 1, pp. 77-85).—A report of comparative studies.

On a lycenid caterpillar reared in *Acacia* galls by ants of the genus *Cremastogaster*, F. LE CERF (*Compt. Rend. Acad. Sci. [Paris]*, 158 (1914), No. 16, pp. 1127-1129).—This is a report of observations made in East Africa.

The oviposition of two apple pests, G. W. HERRICK (*Jour. Econ. Ent.*, 7 (1914), No. 2, pp. 189-192, figs. 3).—This article relates to the green fruit worm and the Palmer worm.

Observations of the bee moth, F. B. PADDOCK (*Jour. Econ. Ent.*, 7 (1914), No. 2, pp. 183-188).—This paper is based upon studies previously noted (E. S. R., 29, p. 859).

A new destructive cutworm of the genus *Porosagrotis*, occurring in western Canada, A. GIBSON (*Jour. Econ. Ent.*, 7 (1914), No. 2, pp. 201-203).—A cutworm identified as *Porosagrotis delorata*, probably synonymous with *P. orthogonia*, has been the source of serious loss to grain crops in southern Alberta since 1911. It is estimated that in the Lethbridge Land District in 1912 33 per cent of the grain sown was destroyed. In inspections of the infested districts it was found that between 30,000 and 35,000 acres of grain were actually being destroyed by cutworms in the southern part of the Province of Alberta.

It appears to be the habit of this cutworm to travel over the surface of the soil and when a suitable plant for attack is found to burrow immediately and feed just below the surface. In experiments with poisoned bran 25 was the highest percentage killed, the underground feeding habit probably being the cause of the failure to get better results. It is stated that in large fields of sugar beets the attack in 1912 was stopped in 24 hours after the bran was applied.

Two Microlepidoptera on *Thurberia thespesioides*, A. BUSCK (*Proc. Ent. Soc. Wash.*, 16 (1914), No. 1, pp. 30, 31).—*Dichomeris deflecta*, the larva of which is a leaf folder, and *Bucculatrix thurbericella* reared from *T. thespesioides*, both from Arizona, are described as new to science.

Feeding habits of *Phlebotomus vexator*, R. C. SHANNON (*Proc. Ent. Soc. Wash.*, 15 (1913), No. 4, pp. 165-167).—This hematophagous dipteran has been found to feed normally upon reptiles rather than upon warm-blooded animals.

Notes on a wood-boring syrphid, H. S. BARBER (*Proc. Ent. Soc. Wash.*, 15 (1913), No. 4, pp. 151, 152).—The syrphid *Temnostoma bombylans* has been found to bore in hickory logs in the early stages of decay.

Dispersal of *Musca domestica*, J. ZETEK (*Ann. Ent. Soc. Amer.*, 7 (1914), No. 1, pp. 70-72, figs. 2).—In experiments in the Canal Zone the house fly and *Hermetia illucens* were found to travel 2,500 ft. from a breeding place and become a menace within 32 hours.

A new tachinid parasite of *Diabrotica vittata*, W. R. WALTON (*Proc. Ent. Soc. Wash.*, 16 (1914), No. 1, pp. 11-14, pl. 1).—A tachinid parasite of the striped cucumber beetle reared at Hyattsville, Md., is described as *Neocelatoria ferox* n. g. and n. sp.

The cabbage maggot in relation to the growing of early cabbage, W. J. SCHOENE (*New York State Sta. Bul.* 382 (1914), pp. 231-247, pls. 6, figs. 5).—A series of preliminary tests which demonstrated that carbolic acid emulsion and tar pads are the most effective of the various protective and remedial measures commonly recommended for the control of this pest led to the laboratory and field experiments here reported in detail.

The tests with carbolic acid emulsion at recommended strengths have demonstrated that it will prevent the hatching of the eggs and is fatal to the younger

stages of the larvæ. It may, however, cause injury to young seedlings and is not a safe remedy for plants recently set in the field.

“The value of tar pads, or hexagonal tar paper collars, for the purpose of preventing the adult of the cabbage maggot from placing eggs about the stems of the plants has been previously demonstrated, but, in spite of its effectiveness, this method of protecting cabbage has not been generally adopted by truck growers. The tests herein described show that tar pads will protect early cabbage from the pest at a cost of about \$1.40 per thousand plants. Truck growers who are subject to losses by the cabbage maggot are urged to test the tar pads experimentally as a basis for more extensive operations against this pest.” “In the employment of tar pads as a means of protecting early cabbage, truckers should arrange to transplant seedlings of good size with rather long stems. Disks can not be satisfactorily adjusted about small plants, for in setting such seedlings it is necessary to place them low in the soil so that only the leaves protrude.”

Descriptions are given of the tar pads and the tool for making them.

A study of the bionomics of the common rat fleas and other species associated with human habitations, with special reference to the influence of temperature and humidity at various periods of the life history of the insect, A. BACOT (*Jour. Hyg. [Cambridge] Plague Sup. 3 (1914), pp. 447-654, pls. 8, figs. 15*).—*Ceratophyllus fasciatus*, *Pulex irritans*, *Ctenocephalus canis*, *Leptopsylla musculi*, and *Xenopsylla cheopis* were experimented with in the studies here reported. The author describes the apparatus and methods employed in making the observations, reports general observations on the bionomics of fleas, and gives accounts of an experimental study of the influence of external conditions and the influence of low temperature on the various stages.

On the survival of bacteria in the alimentary canal of fleas during metamorphosis from larva to adult, A. W. BACOT (*Jour. Hyg. [Cambridge] Plague Sup. 3 (1914), pp. 655-664*).—The results of the experiments here reported show (1) that the alimentary canal of the flea larva may become infected with the following bacteria if mixed with its food, namely, *Bacillus pyocyaneus*, *B. enteritidis*, *Staphylococcus albus*, and *S. aureus*; (2) that an infection of the larval gut may persist until the resting period of the larva in the cocoon, and (3) that there is no satisfactory evidence that such infection can survive the pupal stage. No infection of the larval gut was demonstrated in the experiment with *B. violaceus*.

The effect of the vapors of various insecticides upon fleas (*Ceratophyllus fasciatus* and *Xenopsylla cheopis*) at each stage in their life history and upon the bedbug (*Cimex lectularius*) in its larval stage, A. W. BACOT (*Jour. Hyg. [Cambridge], Plague Sup. 3 (1914), pp. 665-681, fig. 1*).—The results of investigations with the vapor of various insecticides are presented in tabular form.

A coleopterous (clerid) larva predaceous on codling moth larvæ, D. E. MERRILL (*Jour. Econ. Ent., 7 (1914), No. 2, pp. 251, 252*).—The larva of an undetermined clerid beetle is quite an important enemy of the codling moth at Mesilla Park, N. Mex., where the observations were made.

Studies of the Arizona Thurberia weevil on cotton in Texas, B. R. COAD and W. D. PIERCE (*Proc. Ent. Soc. Wash., 16 (1914), No. 1, pp. 23-27*).—The experiments here reported demonstrate the ability of the two varieties of the boll weevil to interbreed and produce fertile offspring. The work has also resulted in the determination of the developmental period for certain seasons of the year.

Reducing insect injury to stored corn, W. E. HINDS (*Jour. Econ. Ent., 7 (1914), No. 2, pp. 203-211*).—This paper deals with some preliminary facts

on the life history of *Calandra oryza*, futile remedial practices, and weevil resistance in corn varieties, and presents recommendations for future practice. A bulletin relating to the subject has previously been noted (E. S. R., 31, p. 58).

Information relative to bee keeping, C. E. SANBORN (*Oklahoma Sta. Circ.* 28 (1914), pp. 2-8).—A popular account prepared for use by the bee keeper.

Porto Rican bee keeping, E. F. PHILLIPS (*Porto Rico Sta. Bul.* 15 (1914), pp. 24, pls. 2).—This is a report of investigations made during May and June, 1913, of bee keeping in Porto Rico, where the industry has grown in the past 5 years from almost nothing to an export trade of \$100,000.

Among the subjects discussed are the present extent of the industry, sources of honey, equipment and methods of manipulation, difficulties encountered, use of bees for pollination, diseases of bees, possibilities of wax production, etc.

The author concludes that the future of the bee keeping industry in the island is full of promise. The problems at hand are (1) the development of the industry as rapidly as is consistent with the experience of the bee keepers, and (2) the keeping out of the brood diseases.

A study of *Dryophanta erinacei* and its gall, C. J. TRIGGERSON (*Ann. Ent. Soc. Amer.*, 7 (1914), No. 1, pp. 1-34, pls. 11).—This is a report of studies of the cynipid gall maker *D. crinacei*, including a discussion of its life history, parasites, guests, and the cause of gall formation.

A parasite of the chinch bug egg, J. W. MCCOLLOCH and H. YUASA (*Jour. Econ. Ent.*, 7 (1914), No. 2, pp. 219-227).—This paper deals with the biology of the parasite previously noted (E. S. R., 29, p. 854), which has been described by Gahan in the article noted on page 355 as *Eumicrosoma benefica*.

In studies of the life history and habits of this parasite in Kansas it was found that for 81 individuals the average time between the collection of chinch bug eggs and the emergence of the parasites in May and June was 13.9 days. The average length of the life cycle for the second generation was 14.3 days; for the third generation 11.9 days; and for the fourth generation 9.9 days. From the last of July to the first of September for 249 parasites, reared from eggs collected in the field, the average time between collection and emergence was 9.8 days. The average length of the life cycle for the sixth generation was 15.2 days; for the seventh generation 17.6 days; and for the eighth generation 27.8 days. Thirteen was the largest number of eggs parasitized by a single female and 29 was the largest and 13 the smallest number of eggs found in 29 females dissected, with an average of 22.8. On an average from 70 to 75 per cent of the parasites obtained in the laboratory were females. It is stated that this parasite can breed parthenogenetically but the number of eggs parasitized per female is usually low and many of the offspring fail to develop. A number of experiments were conducted in which parasites were given eggs of false chinch bugs and other hemipterous eggs, but no parasitism occurred. A hasty survey made in August to determine the distribution in the State showed the parasite to be present in the 16 counties visited, in fact, it was found wherever material was collected, which covers practically all of the chinch bug infested region of the State.

"The average percentage of parasitism over the State of 16 per cent does not represent the actual number of chinch bug eggs destroyed. The period of oviposition of the chinch bug covers about 2 months, while the life cycle of the parasite covers a period of only 2 or 3 weeks. Thus the eggs of a single female chinch bug are exposed to about 3 broods of parasites, while the eggs of one brood of chinch bugs are exposed to 4 or 5 broods of parasites. Therefore, the percentage of parasitism for a brood of chinch bugs is at least 50 per cent. Experiments conducted in the field and in the laboratory show this to be true."

Hymenoptera of South America, J. BRËTHES (*An. Mus. Nac. Hist. Nat. Buenos Aires*, 24 (1913), pp. 35-165, figs. 18).—Two hundred and seventeen species of Hymenoptera, largely from Argentina, are dealt with, many of which are characterized for the first time.

Among the important parasites dealt with are *Parepyris sylvanidis* n. sp. and *Cephalonomia meridionalis* n. sp., which attack the grain pest *Silvanus surinamensis*; *Tetrastichus ceroplastides* n. sp., parasitic on *Ceroplastes bergii*; *Platymesopus erausquinii* n. sp., a parasite of the screw worm; *Pteromalus caridei* n. sp., parasitic on *Papilio thoas thoantiades*; *Signiphora platensis* n. sp. and *Paracharitopus lecanii* n. sp., parasites of *Lecanium* sp.; *Allotropa meridionalis* n. sp., *S. argentina* n. sp., *Paranusia bifasciata* n. sp., and *Philoponectroma pectinatum* n. sp., parasitic on *Dactylopius* sp.; *Trichogrammatoidea signiphoroides* n. sp., parasitic on Diaspis, Aspidiotus, etc.; *Eucercchysius scolytii* n. sp., parasitic on *Scolytus assimilis*; and *Brasemopsis halysidotæ* n. sp., a parasite of *Halisidota tessellaris*.

Report on parasites, L. O. HOWARD (*Ann. Ent. Soc. Amer.*, 7 (1914), No. 1, pp. 86-88).—This is a brief report on the status of some of the more important introduced parasitic enemies of the gipsy and brown-tail moths.

Epimecis wiltii and its host, R. C. SHANNON (*Proc. Ent. Soc. Wash.*, 15 (1913), No. 4, p. 162).—The ichneumonid *E. wiltii* has been found by the author to be an external parasite of spiders.

Biological notes on a few rare or little-known parasitic Hymenoptera, R. A. CUSHMAN (*Proc. Ent. Soc. Wash.*, 15 (1913), No. 4, pp. 153-161, figs. 2).—A braconid parasite of lady beetles (*Perilitus americanus*) is reported to have been very abundant in the region of Vienna, Va., during the fall of 1912, being invariably so far as observed parasitic on *Megilla maculata*. *Paniscus geminatus* was found to be an external parasite of an undetermined lepidopterous larva. *Polysphincta texana* was taken as an external parasite from an adult female spider (*Steatoda borealis*). *Sphæropyx bicolor* was taken under codling moth bands on apple and pear trees as a parasite of *Apatela clarescens*. This parasite is said to be gregarious, as many as 30 having been reared from a single host.

Notes on the life history of *Rhopalosoma poeyi*, J. D. HOOD (*Proc. Ent. Soc. Wash.*, 15 (1913), No. 4, pp. 145-148, fig. 1).—The author records *R. poeyi* as a parasite of the jumping tree cricket (*Orocharis saltator*).

New Hymenoptera from North America, A. B. GAHAN (*Proc. U. S. Nat. Mus.*, 46 (1914), pp. 431-443, pl. 1).—The species here described of economic importance as parasites include *Elis atriventris* n. sp., reared from *Lachnosterina* sp., and *Bracon (Tropidobracon) meromyzæ* n. sp. and *Cælinidea ferruginea* n. sp., at Elkpoint, S. Dak., and *Euphoriana uniformis* n. g. and n. sp., at Hagerstown, Md., all reared from *Meromyza americana*; *Pteromalus eurymi* n. sp. reared from *Eurymus eurytheme*, at Tempe, Ariz.; *Dibrachys meteori* n. sp. and *Eupelminus meteori* n. sp. reared from *Meteorus* infesting the fall army worm at Brownsville, Tex.; *Elasmus apanteli* n. sp. reared from *Apanteles harnedi* at Memphis, Tenn.; *Tetrastichus bruchophagi* n. sp. reared from *Bruchophagus* sp., from alfalfa seed at Corcoran, Cal; *T. (Tetrastichodes) detrimentosus* n. sp. reared from *Coccinella sanguinea* and *Sympiesis agromyzæ* n. sp. reared from *Agromyza parvicornis*, at Lakeland, Fla.; *Gonatocerus eximius* n. sp. reared from jassid eggs at Orlando, Fla.; and *Eumicrosoma benefica* n. g. and n. sp. reared from eggs of the chinch bug, at Manhattan, Kans.

The parasites of the San José scale in New York, H. E. HODGKISS and P. J. PARROTT (*Jour. Econ. Ent.*, 7 (1914), No. 2, pp. 227-229).—It is stated that

parasites of the San José scale were numerous in New York State during 1913. In order to determine the range of the species infested wood was collected from unsprayed trees in the more important fruit districts of the State, including 20 towns representing 13 counties. From the material 5 species were reared, namely, *Prospaltella perniciosi*, *Aphelinus fuscipennis*, *A. diaspidis*, *Signiphora nigrita*, and *Perissopterus pulchellus*, the last two species mentioned being comparatively unimportant. Taking the State as a whole breeding records for September and October, 1913, indicate that *Prospaltella perniciosi* was about the most numerous species during that period, though *A. diaspidis* was numerically greater in two counties, and *A. fuscipennis* ranked first in three counties.

In order to determine the ratio of parasitism numerical counts were made of scales after the rearings of the parasites were completed, some 20,000 individuals being examined of which about 3,500 contained exit holes of the hymenopterans. The percentage of affected scales was variable, and on the average ranged between 12 and 24 for the whole State. Some attention was also directed to the occurrence of parasites in orchards which had been regularly sprayed with lime-sulphur solution, it being found that in some instances 12 per cent of the scales were destroyed by the hymenopterans.

Ticks: The diseases which they transmit and means for their destruction, R. VAN SACEGHEM (*Bul. Agr. Congo Belge*, 5 (1914), No. 1, pp. 73-87).—This is a summarized account.

An endoparasitic mite in the lung of *Macacus rhesus*, F. LANDOIS and H. HOEPKE (*Centbl. Bakt. [etc.]*, 1. Abt., Orig., 73 (1914), No. 6, pp. 384-395, pl. 1, figs. 3).—The name *Pneumotuber macaci* is given to the mite here dealt with. A bibliography of 45 titles relating to the subject is appended.

FOODS—HUMAN NUTRITION.

Supplementing our meat supply with fish, MARY E. PENNINGTON (*U. S. Dept. Agr. Yearbook 1913*, pp. 191-206).—The author points out the similarity of fish to meat in respect to its nutritive value, and summarizes statistical data regarding the fishery industries in this and other countries. Information is given regarding the kind and cost of fish in the American market, and brief statements made as to the preparation of fish for the table.

Concerning whitefish of Masurian Lakes of East Prussia, A. GABRIEL and R. LIMPRICH (*Ztschr. Untersuch. Nahr. u. Genussmtl.*, 27 (1914), No. 1-3, pp. 34-38).—Methods of curing European whitefish (*Coregonus*, sp.) are described and analyses are reported.

Points which aid in determining whether or not flatfish have died in the water, JUGEAT (*Hyg. Viande et Lait*, 8 (1914), No. 2, pp. 57-63, figs. 2).—The data recorded have to do with the detection and marketing of such fish.

Sea mussels—what they are and how to cook them (*U. S. Dept. Com., Bur. Fisheries Econ. Circ.* 12 (1914), pp. 5, fig. 1).—Some statements are made regarding the natural supply, flavor, and nutritive value of sea mussels, their cooking is discussed, and 18 recipes for their use are given.

The effect of cold upon the larvæ of *Trichinella spiralis*, B. H. RANSOM (*Science*, n. ser., 39 (1914), No. 996, pp. 181-183).—A preliminary report is made of experiments carried out to determine the effect of cold storage upon the larvæ of *Trichinella* in pork.

It was found that most of the parasites survive when exposed to a temperature of from 11 to 15° F. for a period as long as 6 days, but when exposed to a temperature of about 0° they succumb quickly. In view of the difficulty of detecting these parasites in pork by microscopical examination, the possible use of refrigeration of pork as a means of preventing trichinosis is suggested.

Further experiments along this line are being carried out and it is expected that additional data will be available soon.

The examination of several kinds of sausage from Petrograd market, K. VON KARAFFA-KORBUTT (*Ztschr. Untersuch. Nahr. u. Genussmtl.*, 27 (1914), No. 4, pp. 330-333).—Analyses of sausage of different sorts and showing a considerable range in cost are reported and discussed.

Note on judging the quality of lard, K. ALPERS (*Ztschr. Untersuch. Nahr. u. Genussmtl.*, 27 (1914), No. 1-3, pp. 142-152).—A large number of analyses are reported and discussed.

Osmotic phenomena of yolk of egg, W. A. OSBORNE and HILDA E. KINCAID (*Biochem. Jour.* 8 (1914), No. 1, pp. 28, 29).—Data are reported regarding the behavior of unbroken egg yolk floated or immersed in ether, chloroform, carbon disulphid, alcohol, olive oil, and other liquids or solutions.

Supervision and marketing of eggs, A. BEHRE and K. FRERICHS (*Ztschr. Untersuch. Nahr. u. Genussmtl.*, 27 (1914), No. 1-3, pp. 38-59).—The weight and specific gravity of eggs kept from 43 to 99 days were determined and the data discussed with reference to defining market quality. Other characteristics of eggs were also studied.

Emmerich and Loew calcium bread and reasons for it, O. LOEW (*Ztschr. Gesam. Getreidew.*, 6 (1914), No. 2, pp. 25-44).—The author discusses the need for calcium in the diet, the possible lack of this element, the desirability of adding calcium if there is a deficiency, and the use in bread making of calcium chlorid and of a commercial preparation called "calcifarin" made from rye flour and calcium chlorid, in which, it is stated, the calcium salt is firmly united to the starch of the grain.

The author considers also the relation of calcium in the diet to arteriosclerosis and other pathological conditions, and here, as elsewhere, brings together many references to work and experience of others as well as his own data.

In a summary he states, among other things, that only those adults who use milk and vegetables in abundance secure a sufficiency of calcium and that those who eat an abundance of meat and secure their carbohydrates in the form of bread, potatoes, and beer have a special need for an increased calcium supply.

In a supplementary note the author refers to some matters pertaining to whole grain bread in comparison with bread made from fine flour. He is of the opinion that it is more rational to add calcium to fine flour than to attempt to change public opinion and substitute whole grain bread for it.

Migration of the constituents of maize grains into water and aqueous solutions, E. POPPE (*Bul. Soc. Chim. Belg.*, 27 (1913), No. 4, pp. 103-109).—The results of investigations are reported on the removal of material when Indian corn is soaked in water or water containing acids, common salt, sugar, etc.

The equilibrium established between the moisture in the grain and the solutions depended solely on the concentration of the latter. When soaked for 48 hours at room temperature (20-33.5° C.), it was found that practically no material had been removed from the grain, owing to the fact that the epidermis cells were unbroken and consequently only semipermeable at the temperature employed. When the corn kernels were boiled in the water, 36.2 per cent of the nutritive material was removed, weak solutions of chlorids, nitrates, phosphates, and sulphates having practically the same effect as distilled water.

The data are discussed with reference to the economy of methods employed by the natives of the Belgian Kongo, in preparing corn for food, it being their custom to discard the water in which the corn is boiled, which involves a loss of nutritive material.

Foods from the grain sorghums.—Feterita products, C. K. FRANCIS (*Oklahoma Sta. Circ.* 27 (1914), pp. 8, figs. 3).—This circular reports data regarding

the chemical composition and food value of feterita as compared with corn, Kafir corn, and wheat. Several recipes for the preparation of foods with feterita meal are given.

Meal used for crumbing foods, E. DINSLAGE (*Ztschr. Untersuch. Nahr. u. Genussmtl.*, 27 (1914), No. 1-3, pp. 173-176).—Analyses are reported and discussed, with reference to quality, of commercial products used for crumbing foods in cookery.

Preserved tomatoes, P. CARLES (*Ann. Falsif.*, 6 (1913), No. 60, pp. 531-537).—A number of different ways for the preservation of tomatoes are described, and definitions given of these products including canned tomatoes, puree of tomato, concentrated tomatoes, and extracted tomatoes, which are further dehydrated than the concentrated.

Analytical data are given and discussed, together with the more common methods of adulteration.

Grape juice as a nutritive and remedial agent, G. BENDER (*München. Med. Wchnschr.*, 61 (1914), No. 8, pp. 424, 425).—Pasteurized grape juice and grape juice condensed in partial vacuum and called "grape honey" are discussed and special grape juice preparations are briefly described. A kilogram of "grape honey," the author states, contains the nutritive constituents of 6 kg. of grapes. He states that this condensed grape juice dissolves albumin, casein, and many other substances and may be used for such purposes in place of alcohol.

Investigation of tea, BESSON (*Mitt. Lebensm. Untersuch. u. Hyg., Schweiz. Gsndhtsamt.*, 4 (1913), No. 4, pp. 213-216).—Data are given regarding the analysis of 30 samples of tea, part of a collection of 90 samples examined 2 years before.

Caffein and the other alkaloids found in tea, G. D. HOPE (*Indian Tea Assoc., Sci. Dept. Quart. Jour.*, No. 2 (1912), pp. 31-41).—Data are given regarding the properties of alkaloids and their presence in various plants, and also in beverages such as tea, coffee, maté, kola, and cocoa.

In addition to caffein the closely related alkaloids of theobromin, theophyllin, xanthin, methyl xanthin, and adenin are found in tea. With the exception of caffein they exist in such small quantities as to be of little importance.

According to the author, the taste of caffein in tea is masked by that of tannin so that it is no factor in the judgment of the quality of tea as determined by tea tasters. In spite of this, however, caffein is undoubtedly an important factor in the quality of tea as a beverage, the best tea containing relatively high percentages of caffein.

A larger percentage of caffein is found in the young leaves than in the older ones. As a rule, China and Japan teas contain less caffein than those of Java, India, and Ceylon. A table is given showing the per capita consumption of caffein in tea and coffee in the principal countries of the world.

Food and drug section, R. E. ROSE and A. M. HENRY (*Ann. Rpt. State Chem. Fla.*, 1913, pp. 93-146).—Results are reported from the examination of a large number of food and drug products, beverages, water samples, and miscellaneous products.

Foods and drugs (*Bul. Ga. Dept. Agr.*, No. 61 (1913), pp. 167, pls. 2).—This publication contains the report of the state chemist and other information regarding the state pure food and drugs act and its operation, including data regarding the examination of miscellaneous foods and beverages, the examination of milk, and the results of sanitary inspection work.

Enforcement of the food and drugs act for the years 1910 and 1911, R. M. ALLEN (*Kentucky Sta. Food and Drugs Rpt. 1910-11*, pp. 35).—General statements are made regarding food and drug inspection, which included the examination of 7,269 samples of food, of which 2,800 were found to be adulterated

or misbranded. The work done in inspection of bakeries, slaughter-houses, cold storage plants, grocery stores, etc., is also reported and discussed, with recommendations.

[Report of work under the Kentucky Food and Drugs Act], R. M. ALLEN (*Kentucky Sta. Food and Drugs Bien. Rpt.*, 7 (1911-1913), pp. 65, pls. 18).—The work done by the department during the fiscal years July 1, 1911, to June 30, 1913, is reviewed. This included the analysis of 10,148 samples, of which 5,269 were found to be adulterated. The results are also given of the work accomplished in the experimental bakery for the instruction of bakers in improving existing conditions. Inspections were made of dairies, slaughter-houses, cold storage plants, grocery stores, food factories, bakeries, ice cream plants, restaurants, hotels, and pop factories.

Thirteenth annual report of the food and drug commissioner of South Dakota, G. G. FRARY (*Ann. Rpt. Food and Drug Comr. S. Dak.*, 13 (1913), pp. 136).—The increased scope of the commission's work is discussed and the year's work described, including general inspection work under the pure food and drug law, the inspection of petroleum products and other work of the department, coal analysis, and the examination of a large number of samples of miscellaneous food products, drug products, and soap.

List of the analyses of samples of butter and other food products (*Penn. Dept. Agr., Mo. Bul. Dairy and Food Div.*, 11 (1913), No. 9-10, pp. 67-102).—Data are reported as to the examination of butter and other food products.

Some attempts to standardize oven temperatures for cookery processes, MAY B. VAN ARSDALE (*Teachers Col. [N. Y.] Bul.* 8, 5. ser. (1913), pp. 15).—The inaccuracy of the usual household methods for determining oven temperature is discussed on the basis of a summary of data and attempts to control such methods by actual test.

The results of a number of experiments are reported on the relation of time and oven temperature to the cooking of a variety of foods. The observed range was from about 250 to 550° F. "It therefore follows that while 400° may be a relatively high temperature it can scarcely be called 'hot' for cooking purposes when so many of the ordinary processes require a much higher temperature."

A number of recipes are given with the temperature and time required for baking the quantities under consideration. A summary of the experimental data secured, the author points out, might yield such a classification of oven temperature as the following: Low temperature (250-350°), custards, meringues; low to moderate, sponge cake, angel food; moderate (350-400°), bread, gingerbread, plain cake, cookies; hot or "quick" (400-450°), Parker House rolls; hot to very hot, baking powder biscuit. Popovers begin at 450°, decrease to 390°, finish at 350°. Pastry (pies) begins at 500°, finishes at 450°.

The use of a thermometer in cookery by the housewife and in the instruction of children is discussed, the author's conclusion being that it will yield more definite and uniformly good results than the usually inaccurate descriptions which accompany recipes.

What the Department of Agriculture is doing for the housekeeper, C. F. LANGWORTHY (*U. S. Dept. Agr. Yearbook 1913*, pp. 143-162).—An account is given of the various activities of this Department which provide information valuable to the housewife, and particularly of the nutrition investigations of the Office of Experiment Stations. Some of the results of the nutrition investigations of interest to housekeepers are cited, the principal topics discussed being the results of experimental studies and their relation to planning meals, laboratory work and cooking problems, food and its care in the home, and the avoidance of waste of materials and time in providing food for the family.

Financing the wage-earner's family, S. NEARING (*New York, 1913, pp. 171, figs. 8*).—This book is an attempt to bring into comparison available figures upon the incomes of wage-earners in the United States and reliable estimates of the cost of maintaining a fair standard of living.

In the matter of the cost of living, the author estimates that between \$450 and \$650, according to locality, is necessary to maintain a minimum standard for an average family consisting of father, mother, and 3 children under 14. This provides only for the barest necessities—food, clothing, and shelter—and not for school books nor for the expenses attending illness or death.

The cost of a fair standard of living is estimated to be from \$700 to \$750 for a family of average size in the individual towns of eastern United States, and \$100 more in cities—significant figures from the author's point of view, since he estimates that three-fourths of the males in the United States are earning less than that amount.

The author urges that local comparisons between wages and the cost of living be made, and for those who wish to undertake such studies his book with its ample bibliographical notes will serve as a guide.

How to live on 2d. a day, F. J. CROSS (*Cassell's Mag., n. ser., No. 23 (1914), pp. 223-228, figs. 3*).—A brief note, based on the author's experience, on the possibility of procuring a day's food for 4 cts.

How to live on 3d. or 4d. a day, F. J. CROSS (*Cassell's Mag., n. ser., No. 22 (1914), pp. 161-170, figs. 8*).—On the basis of his experimental study of the question, the author discusses the possibilities of economical living.

Dietetics in Italian tenements, WINIFRED S. GIBBS (*Pub. Health Nurse Quart., 6 (1914), No. 1, pp. 42-53*).—In connection with this article describing methods followed in teaching Italian housewives how to procure a better diet under American conditions, information is given regarding the kind of diet followed before and after instruction.

Domestic science.—[School lunch work in Gary, Indiana], CALLA KRENTEL (*Mo. Bul. Ind. Bd. Health, 17 (1914), No. 1, p. 7*).—A brief account, with menus, is given of school lunch work designed to be instructive as well as to provide suitable food. The preparation of the lunches is in the hands of the domestic science classes.

Sanitary conditions in Alaska.—[Food poisoning], E. KRULISH (*Pub. Health Rpts. [U. S.], 28 (1913), No. 12, pp. 544-551*).—Water supply, garbage disposal, and other questions are discussed.

The author states that cases of food poisoning are not uncommon among the natives, especially, it is said, in isolated districts where large quantities of canned food are consumed. He states that he has treated 7 cases of poisoning "due to the eating of putrid moose meat." "In some parts of the territory the natives eat fish heads which have been previously buried in the ground until they have undergone putrefaction; this dish they consider quite a delicacy."

The care of the baby (*Pub. Health Rpts. [U. S.], Sup. 10 (1914), pp. 14, fig. 1*).—This paper, prepared by a committee of the American Association for the Study and Prevention of Infant Mortality and presented to the association at its annual meeting held in Washington, D. C., November, 1913, discusses the feeding and care of infants. The publication is designed for popular instruction.

My dietary, S. S. SHERMAN (In *My Autobiography Continued from my 95th to 99th Year of my Age. Chicago, 1913, pp. 11, 12*).—The author, in his ninety-ninth year, describes his dietary. The usual breakfast consists of orange juice, a wheat cereal, an egg, and a cup of coffee; the midday meal, usually of a little soup with simple vegetables and a little meat, some simple dessert, and fruit, with a cup of boiled coffee or weak tea as the usual beverage. A glass of

milk an hour or two before retiring is the usual supper, though this is often omitted.

The principle on which the diet was selected is the use in moderate quantity of simple foods, which experience has shown to agree with the user, and of such a physical character that maceration in the mouth takes the place of mastication, which, in this particular case, is not possible.

Health through diet, K. G. and A. HAIG (*London, 1913, pp. X+227+31*).—The author believes the uric-acid-free diet is desirable and makes a plea for it.

Textbook on physiological chemistry.—I, The organic nutrients and their behavior in cell metabolism, E. ABDERHALDEN (*Lehrbuch der Physiologischen Chemie.—1. Teil, Die Organischen Nahrungsstoffe und ihr Verhalten in Zellstoffwechsel. Berlin and Vienna, 1914, vol. 1, 3. ed., pp. VIII+736, figs. 2*).—This volume, which presents the author's course of class-room lectures, has to do with carbohydrates, fats, protein, nucleo-proteids, and similar topics; the fate of such substances in the body; and other matters having to do with metabolism. The volume, which has been thoroughly revised, is a valuable contribution to the literature of physiological chemistry.

Observations on the processes of resorption in the cellular organism, M. RUBNER (*Arch. Anat. u. Physiol., Physiol. Abt., 1913, pp. 240-258; abs. in Chem. Zentbl., 1913, II, No. 26, p. 2149*).—The author's observations were made with yeast, the experiments having to do with the resorption of protein and sugar.

The resorption phenomena were found to be directly dependent upon the vital properties of living substance. In the case of nitrogen a decided selective function was noted with reference to nutritive material and resorption phenomena. In the case of the yeast cell resorption consists of two parts, namely, adsorption and penetration through the cell wall.

The investigations also report the results of comparative studies regarding the phenomena of resorption in a single cell organism and in a more complicated one.

Concerning resorption phenomena in the intestine, N. A. DOBROWOLSKAJA (*Biochem. Ztschr., 56 (1913), No. 4, pp. 267-290; abs. in Chem. Zentbl., 1914, I, No. 1, pp. 47, 48*).—Experiments are reported on the resorption of protein cleavage products. Contradictory results were obtained.

Contribution to the experimental study of the rôle of the spleen in digestion, C. L. RUSCA (*Gaz. Med. Ital., 63 (1912), Nos. 35, pp. 331-333; 36, pp. 341, 342; abs. in Zentbl. Biochem. u. Biophys., 16 (1914), No. 7-8, pp. 243, 244*).—The experiments, which were made with dogs, did not lead to definite conclusions.

The effect of a one-sided diet upon the composition of the body and upon the respiratory exchange in a subsequent fasting period, F. KLEINERT (*Ztschr. Biol., 61 (1913), No. 8, pp. 342-372, figs. 5*).—The experiments, which were made with dogs, led to the conclusion that the gaseous exchange and the respiratory quotient in fasting are influenced by the food taken during the period preceding the fasting period and by the composition of the body as affected by the food. In reaching such a conclusion, account must naturally be taken of other disturbing factors, such as muscular work and the upsetting of the general condition.

The effect upon the metabolism of man and animals of long-continued excessive diet of carbohydrate without protein, E. GRAFE (*Deut. Arch. Klin. Med. 113 (1913), No. 1-2, pp. 1-91; abs. in Zentbl. Biochem. u. Biophys., 16 (1914), No. 9-10, pp. 307, 308*).—In experiments with man (an insane person and a woman professional faster) and with animals it was found that an exces-

sive diet of carbohydrates without protein did not lead to a gain in weight but rather to a loss.

Absorption and fate of tin in the body, W. SALANT, J. B. RIEGER, and E. L. P. TREUTHARDT (*Jour. Biol. Chem.*, 17 (1914), No. 2, pp. 265-273).—Soluble tin salts subcutaneously injected were found in the contents of the gastro-intestinal canal and in smaller quantities in the urine in tests with laboratory animals. The skin contained from 20 to 25 per cent, and the liver on an average about 5 per cent of the total amount injected.

“After feeding soluble salts of tin to rabbits for from 3 to 4 days, and to dogs for from 2 to 4 weeks, only traces could be detected in the urine. After feeding soluble tin salts to rats for 4 months appreciable quantities were found in the body. Soluble tin salts given intravenously disappeared from the circulation within 2 to 3 hours.

“The above data justify the conclusions that the gastro-intestinal tract is the chief organ for the elimination of tin; that the kidney plays a subordinate though an important rôle. Elimination of the metal is very slow; appreciable quantities are eliminated during the first and second days.

“Absorption of tin from the gastro-intestinal tract may take place under certain conditions.”

Do foodstuffs contain substances at present unknown which are important for the maintenance of life? E. ABDERHALDEN and A. E. LAMPÉ (*Ztschr. Gesam. Expt. Med.*, 1 (1913), pp. 296-354; *abs. in Chem. Zentbl.*, 1913, II, No. 6, pp. 522, 523; *Jour. Chem. Soc. [London]*, 104 (1913), No. 614, I, p. 1409).—A critical study in which the authors contend that the existence of vitamins and similar substances has not been definitely established.

On the influence of atmospheric pressure, temperature, and humidity on animal metabolism, W. THOMSON (*Mem. and Proc. Manchester Lit. and Phil. Soc.*, 57 (1912-13), pt. 3, No. 13, pp. 8, pls. 2).—From the observation that the percentages of carbon dioxid in the air exhaled from the lungs of a number of people were on certain days nearly all low while on other days they were nearly all relatively high, the author was led to conduct a series of experiments in which the carbon dioxid in the air exhaled from the lungs was determined and at the same time observations made of the barometer, hygrometer, and thermometer.

It was shown by experiments that the percentage of carbon dioxid in the exhaled air was greater when the inhaled air had been previously dried with strong sulphuric acid, from which the author assumed that metabolism would be greater when breathing dry air than when breathing damp air. It was observed that the percentage of carbon dioxid in the exhaled air was greater at high elevations than in valleys and also greater in valleys than in a deep coal mine, from which the assumption is made that a low barometric pressure would produce increased metabolism, while high barometric pressure would result in decreased metabolism.

Greater metabolism, as indicated by production of carbon dioxid, was observed when the body was surrounded by cold air than when it was surrounded by warm or hot air, but if the body remained in cold air and warm or hot air was breathed metabolism was greatly increased. It was also noticed that the breathing of pure dry oxygen produced no greater metabolism than that of ordinary dry air. It was found that the metabolism was greatly increased for some time after violent exercise had been taken.

The data of these experiments with human beings and similar ones with laboratory animals are presented in tabular form, from which it appears “that, on all occasions where the barometer, hygrometer, or thermometer alters appreciably, there is a corresponding change in the percentage of carbon dioxid in

the exhaled air of all, or nearly all, the persons or animals tested." A rise in the barometer or marked increase in humidity produced a fall in the carbon dioxid, while a fall in the barometer or decrease in humidity produced a rise in the carbon dioxid exhaled. "The rise of the temperature of the air produced a lowering of the carbon dioxid in the exhaled air, and a fall in the temperature produced a rise.

"The rate of the pulse seems to have no influence on the percentage of carbon dioxid in the exhaled air. The temperature (sublingual) of the body appeared also to have little influence on the carbon dioxid in the expired air."

The influence of moisture in the air on metabolism in the body, W. THOMSON (*Mem. and Proc. Manchester Lit. and Phil. Soc.*, 57 (1912-13), pt. 3, No. 14, pp. 4).—Further experimental data regarding the effect of moisture in the air are reported by the author in confirmation of the observations of the experiments noted above.

In these experiments, three different persons breathed first damp and then dry air at about 56° F. and afterwards both damp and dry air at 98°. An average increase of 4 per cent in the carbon dioxid in the exhaled air was observed when dry cold air was breathed over that observed when damp cold air was breathed. When warm dry air was breathed, an increase of about 7.5 per cent was observed over that noted when damp warm air was breathed.

Biochemical studies of expired air in relation to ventilation, C. WEISMAN (*Easton, Pa.*, 1913, pp. 99, fig. 1).—An extended summary of data relating to the subject is given, and the results are reported of a series of experiments, from which the following conclusions are drawn:

Subcutaneous injection into guinea pigs of either isotonic condensation liquid from human breath, in amounts up to 20 cc. followed by intravenous injection of human blood serum in amounts up to 0.5 cc., or of isotonic condensation liquid from human breath, followed by intravenous injection of the same kind of material in amounts up to 3 cc., with a suitable incubation period between both injections, did not result in anaphylactic shock. Likewise intravenous injection of this liquid into human beings in amounts up to 8 cc. was not toxic. There was no evidence to show that the condensation liquid obtained from males is more toxic than that from females, or that proteins are volatile.

From the fact that the extremely sensitive anaphylactic test failed to show the presence of any sensitizing material in human breath, it is concluded that this material is not a factor to which may be attributed the ill effects of poor ventilation. The results of these experiments are contradictory to those obtained by Rosenau and Amoss, previously noted (*E. S. R.*, 25, p. 866).

Metabolism during metal work, F. C. BECKER and O. OLSEN (*Skand. Arch. Physiol.*, 31 (1914), No. 1-3, pp. 81-197, figs. 13).—The results of extended investigations are reported in which the carbon dioxid excretion was studied in periods of mental rest and activity, the mental work consisting in committing to memory meaningless syllables. Quotations from the authors' summary follow:

"The carbon dioxid percentage of the air expired is approximately constant during rest within each experiment and only the oscillations of the respiratory level furnish an approxi-expression for the oscillations in the carbonic acid eliminated. Moreover on transition to rest the carbon dioxid percentage of the alveolar air will rise, a fact which must probably be understood as an expression for an increased accumulation of carbon dioxid in the organism produced by a less effective ventilation of the lungs.

"In the case of minor muscular work, when the subject takes up the same position during the entire experiment and works with unhindered respiration, the value of the increase of metabolism may approximately be expressed by

the increase of the respiratory volume. While the efficiency, regarding the individually working muscle, reaches its maximum contemporary with the performing maximum work, the efficiency for the organism, as a whole, will reach its maximum long before the muscle reaching maximum of the output of work.

"Variations in the air pressure will influence the magnitude of the respiratory level so that relative maximum points in the level curve correspond to relative minimum points in the air pressure curve and vice versa; thus a rise or a sinking of the air pressure will involve a sinking or a rise of the respiratory level respectively.

"The respiration is reflectorily released with such an amount that the carbonic acid percentage of the alveolar air is kept about constant. Should any changes occur in the carbonic acid percentage of the alveolar air, the respiration will at once appear with a new value, endeavoring to equalize the changes. . . .

"When closing the eyes the respiratory level goes down, and a simultaneous decrease occurs in the carbonic acid eliminated and the oxygen absorbed; these changes being partly attributable to a less effective ventilation of the lungs. The respiration of a subject resting, but awake, has a wavy course, but on entrance of sleep the respiratory level is lowered, whereupon the respiration elapses with a constant level value. The cause of the wavy respiration of the subject, while awake and at rest, must partly be sought in changing states of consciousness.

"During the getting-by-heart of meaningless syllables, an increase of the organic elimination of carbonic acid occurred. This increase which is relatively big at the beginning of the work, is partly attributable to a dilution of the store of carbonic acid in the organism, but may besides, as a whole, be understood as an expression for a contemporary increase of the production of carbonic acid—consequently an increase of metabolism. A fraction of this increase arises from the muscular movements performed during the mental work, whereas the main part is due to psycho-physiological processes upon which the association work depends.

"The magnitude of the metabolic increase arising from mental work will oscillate parallel to the subjectively estimated amount of work performed. The metabolic increase attached to the performance of certain mental work will gradually decrease, according as the subject acquires greater practice in the work in question. Energetically the psychological notion 'concentration of attention' will furnish an expression for the peculiarity that one may voluntarily solve the same problem in the same space of time with a various amount of energy. The check occurring between contemporary energetical transformation in the brain takes in the main the same course as corresponding check effects in the case of simple physical motors."

ANIMAL PRODUCTION.

Further investigations into factors affecting the handling of wheaten hay, including a study of its digestibility, A. J. PERKINS, J. H. PHILLIPS, W. J. SPAFFORD, and N. S. MAY (*Jour. Dept. Agr. So. Aust., 17 (1914), No. 7, pp. 720-755, figs. 3*).—The results of 2 years' study at the Roseworthy Agricultural College of the character and digestibility of wheat hay, cut in various stages of development, indicate that maximum yields will be secured from cuts taken about 3 weeks after full bloom at a time when the grain is just about to leave the milky stage and enter upon the dough stage.

It was noted that hay cut after the milky stage tends to become ill-balanced hay, in which the culms and flag rapidly lose their feeding value, and if the

hay is not cut at least 2 weeks earlier than the ripening of the grain there occurs an actual loss of hay. There is a steady decrease in the percentage of mineral matter and a corresponding increase in that of organic matter with the ripening of the crop. The percentage of protein shows a rise during the first 3 weeks and a steady decline thereafter, that of fat remains practically stationary throughout the whole period, and that of carbohydrates steadily increases throughout the 6 weeks, with a corresponding decrease in the culms and flag, while that of fiber steadily rises in culms and flag and equally declines in the ears. A heavy loss of dry matter was noted in the last 2 or 3 weeks of the development of the wheat crop and it is believed that aside from the loss due to falling off of flag, the occasional shaking out of grain, and the leaching action of rain, there is some sort of migration of the mineral matter towards the root system as maturity advances.

The loss of weight on drying of a wheat crop is represented by approximately three-fourths of the green weight of the crop in the full-bloom stage, and by less than one-fourth of the green weight when the grain is ripe. Generally speaking, early-cut hay retains slightly more moisture than late-cut hay. It is believed that aside from the loss of moisture due to evaporation a crop of hay left to dry in the field undergoes a loss of moisture due to a chemical reaction set up in the drying cells of the plants, which involves a breaking down and loss of carbohydrates. This loss is estimated at $1\frac{1}{2}$ per cent of the original green weight.

"Direct digestion experiments show that hay cut at full bloom is more highly digestible than any hay cut at later periods, and that in general the digestibility of wheaten hay decreases by regular steps as the period of complete ripeness is approached. In this connection there is a difference of over 12 per cent between the digestibility of hay cut at full bloom and that of hay cut a week before the ripening of the grain. This superior digestibility of wheaten hay cut at full bloom holds good all along the line, with the exception, perhaps, of the doubtful case of the mineral matter. The regular decline in the digestibility of hays cut at later periods is most marked in the case of proteins and fiber. Carbohydrates are, on the whole, rather erratic in their behavior, and perhaps on the whole they may be considered more or less stationary in their direct digestibility.

"The albuminoid ratio is narrower and more favorable in character in the earlier cut hays than in those in more advanced stages of development. This arises from the more highly digestible condition of the proteins in the less mature cuts of hay, and the overwhelming preponderance of carbohydrates in the later cuts."

Apples for live stock, A. TRUELLE (*Jour. Agr. Prat., n. ser., 26 (1913), No. 49, pp. 727, 728*).—Suggestions are given for the utilization of apples as a feed for live stock. Rations containing apples are formulated for different animals.

Acorns and beechnuts as feeding stuffs, O. ENGELS (*Landw. Vers. Stat., 82 (1913), No. 1-2, pp. 93-148*).—This article summarizes the results of analyses made by various investigators of acorns and beechnuts and of experiments conducted in feeding these products to farm animals. It is concluded that acorns are protein-poor but high in carbohydrate content; that they are highly digestible, although where fed in large quantities they hinder digestion and are constipating; and that small quantities may be successfully fed to sheep and goats, but are distasteful to dairy cows and horses. The shell comprises approximately 15 per cent of the entire nut.

Beechnut cake is successfully fed to cattle, sheep, hogs, horses, and poultry. In large quantities it is said to have a toxic effect. The shell comprises approximately 34 per cent of the entire nut and contains 2.11 per cent tannic acid.

The kernel contains a high percentage of phosphoric acid, given as 1.25 per cent.

Fish meal as a feeding stuff, H. H. MORGAN (*Daily Cons. and Trade Rpts. [U. S.]*, 17 (1914), No. 76, p. 7).—It is stated that fish guano as a supplementary feed for cattle, hogs, and poultry is coming into more general use in Germany. Fish meal is mixed with hay, chopped straw, turnips, and other fodders. A fish-meal cake is manufactured from herrings which contains from 12 to 25 per cent of wheat bran or oat hulls and from 75 to 85 per cent of fresh chopped herrings.

Extensive importations of fish guano were being made to the United States.

[**New feeding stuffs**], H. H. MANN (*Ann. Rpt. Dept. Agr. Bombay, 1912-13*, pp. 62, 63).—Analyses are given of the seed of the roselle plant (*Hibiscus sabdariffa*) and of the tubers of the Indian plant kudu tondli (*Cephalandria indica*), both of which when properly prepared are said to be of value as feeding stuffs. Safflower cake is another feeding stuff said to be very rich in nitrogen.

[**Feeding stuffs**], R. E. ROSE and E. P. GREENE (*Fla. Quart. Bul. Dept. Agr.*, 24 (1914), No. 1, pp. 66-92).—Analyses are reported of cotton-seed meal, bran, mowrah meal, corn, molasses feed, wheat middlings, shipstuff, hominy meal, linseed meal, and various mixed and proprietary feeds.

The feeding-stuffs inspection for 1911, 1912, N. J. BACHELDER (*Rpt. Bd. Agr. [N. H.]*, 32 (1911-12), pp. 229-267).—Analyses are reported of cotton-seed meal, linseed meal, meat scrap, bone meal, cob meal, buckwheat middlings, dried brewers' grains, malt sprouts, dried beet pulp, gluten feed, hominy feed, wheat bran, middlings, molasses feed, alfalfa meal, and various mixed and proprietary feeds. The text of the state feeding-stuffs law is included.

Commercial feeds, edited by J. M. PICKEL (*Bul. N. C. Dept. Agr.*, 34 (1913), No. 11, pp. 39).—Analyses are given of the following feeding stuffs: Wheat bran, middlings, shipstuff, corn, corn chop, cotton-seed meal, cotton-seed feed, rice meal, rich polish, crushed oats, buckwheat, dried beet pulp, gluten feed, screenings, molasses feed, and various mixed and proprietary feeds.

There is included a summary of the requirements of the state feed law.

Concentrated commercial feeding stuffs, compiled by J. W. SAMPLE and A. L. HARRISON (*Tenn. Agr.*, 3 (1914), No. 3, pp. 101-152, pl. 1, fig. 1).—Analyses are reported of the following feeding stuffs: Bran, shorts, middlings, hominy feed, molasses feed, cotton-seed meal, and various mixed and proprietary feeds. There is included a digest of the Tennessee feed law, together with feed definitions.

Stock-watering places on western grazing lands, W. C. BARNES (*U. S. Dept. Agr., Farmers' Bul.* 592 (1914), pp. 27, figs. 3).—This publication gives suggestions for the development and improvement of stock-watering places. Items treated are natural watering places, including springs, seeps, and swamps, and artificial watering places, including reservoirs, wells, and water from mining tunnels. The types of troughs and their construction are discussed.

Animal husbandry department, F. B. MUMFORD (*Missouri Sta. Bul.* 117 (1914), pp. 418-420).—Five lots, each comprising 6 choice 2-year-old steers, were fed during a 130-day period a ration of alfalfa hay, corn silage, cold pressed cotton-seed cake, and corn in various forms. Lot 1 received broken ear corn, lot 2 shelled corn, lot 3 crushed corn and cob, lot 4 corn and cob meal, and lot 5 corn meal. Deducting the value of pork produced it was estimated that the final cost of grain in producing a pound of beef under these conditions was 7.14, 6.47, 7.31, 8.41, and 7.85 cts., respectively; and the profits realized were \$6.18, \$8.96, \$6.21, \$4.79, and \$6.33, respectively, per steer.

In preliminary studies of the various planes of nutrition in their influence upon breeding cattle, it appears that heifers on a high plane of nutrition reach the breeding period at an earlier age but are more uncertain breeders than those maintained on a lower plane of nutrition.

In comparing the value of various roughages for breeding ewes it was found that "corn stover proved nearly as efficient as timothy hay. The use of silage instead of stover materially reduced the amount of grain required; silage, clover hay, and grain proved the most economical ration; clover hay and grain was the second in economy. Two lbs. of corn silage appeared to be equivalent to 1 lb. of hay in the ration where it was used. Breeding ewes proved to be very susceptible to poisoning from old silage."

In the feeding of animals it was found that warm feed and warm water show no advantage over cold feed and water, which results verify those of earlier trials. Notes on the improvements through the use of pure-bred rams have been reported from another source (E. S. R., 29, p. 870).

In an investigation of age as a factor in animal breeding it has been found by careful measurements that early pregnancy interferes with the rate of growth and the ultimate development of the maternal parent.

The South American meat industry, A. D. MELVIN (*U. S. Dept. Agr. Year-book 1913, pp. 347-364, pls. 8*).—The author reports on his recent tour of investigation made of the South American meat inspection and meat industry, especially Argentina, Paraguay, Uruguay, and Brazil. Data are presented showing the recent imports of food animals into the United States from Argentina, Canada, Mexico, Australia, Uruguay, and other countries.

Methods of freezing and salting of beef products in vogue in South America are discussed. Statistics are given on the supply of cattle and sheep in South America and a comparison made with other countries. It is believed that "while statistics show that Argentina is already slaughtering up to the limit of its present stock of cattle, that country has such great resources for cattle raising that it is easily possible for the stock raisers to bring about a large increase in the meat output if present prices are maintained, which, with the opening of the United States market, seems very probable."

The production of beef in the South, W. F. WARD (*U. S. Dept. Agr. Year-book 1913, pp. 259-282, pls. 4*).—In this article the author discusses the possibilities of the South for beef production, the abandonment of the one-crop system, the growing of forage crops, grasses, and grains in the South, tick eradication, and the most approved methods of cattle production in the South as determined by experiment station results and reported in various station and Department publications previously noted.

The Bazadais cattle, G. LAFFORGUE (*Vie Agr. et Rurale, 3 (1914), No. 12, pp. 322, 323, fig. 1*).—The characteristics of this French breed of cattle are given.

The Garonnais breed of cattle, P. HERBET (*Vie Agr. et Rurale, 3 (1914), No. 12, pp. 324-330, figs. 6*).—This gives a historical sketch, characteristics, and measurements of this French breed of cattle.

The distribution of wild sheep, R. KOWARZIK (*Mitt. Justus Perthes' Geogr. Anst., 60 (1914), No. 2, pp. 70-72, pl. 1*).—An account of the various breeds and types of wild sheep and of their geographical distribution.

Breeding caracul sheep, C. C. YOUNG (*Jour. Heredity, 5 (1914), No. 4, pp. 170-178, pl. 1, figs. 3*).—The author reviews the history of importations and the development of the caracul sheep industry in the United States.

He found a difference to exist in the wooling characteristics of caracul rams and ewes, some having a coarse long wool, others a long coarse gray wool in which was hidden a fine lusterless short reddish wool resembling microscopically that of Merinos. It was found that this fine underwool came into the

strain through the admixture of some fine-wool-bearing Afghans, and it was fully determined that the fine wool in most of the sheep was entirely responsible for their inferior fur-producing qualities. The results of tests in interbreeding these 2 types indicated that "a very small amount of fine wool can be overcome, and considerable fine wool in ewes can be neutralized, where the ram is entirely free from the short fine underwool. Two crosses suffice to breed it out entirely."

Where Merinos and Shropshires were crossed with a pure-bred caracul ram "a very inferior skin was produced in which there was great lack of luster and a very important curl formation, giving the skin a matty appearance, valueless from a fur standpoint, but excellent results were obtained when the same ram was bred to such of our lustrous longwools as Lincolns, and such red Persian fatrumps as were entirely free from short wool and possessed very coarse wool." Where a pure-bred caracul ram was "bred to long-wool ewes, free from fine wool, and the skins of the lambs were obtained the first few days after birth, they showed tight curls uniform in size and possessing the required luster. Such half-blood skins were valued . . . at from \$8 to \$12 per skin. In all cases where the prices ranged from \$3 to \$4 the skins showed lack of luster and curl formation, which was easily traced to fine wool, either in the caracul rams or grade native longwools."

It is stated that in Central Asia there are "6 classes of caracul sheep, all of which owe their black pigment tendency to tight curl formation, and luster to the small black and nearly extinct Danadar sheeep. These breeds are known as (1) Large Arabi or Duzbai, (2) Small Arabi, (3) Intermediate Arabi, resulting from the crossing of the above-mentioned two classes, (4) Gray Shirad, (5) Zigais (of these classes there are very few), and (6) caracul Afghans, which last class unfortunately comprise 90 per cent of all the fur-producing sheep in Bokhara, and while possessing excellent mutton qualities and wonderful hardiness, like all of the other breeds, can hardly produce profitable fur in America, where people demand the best quality of the Persian furs."

The author comments on the difficulties of procuring breeding stock from Bokhara.

Alaska's reindeer industry, L. CHUBBUCK (*Jour. Heredity*, 5 (1914), No. 4, pp. 149-154, figs. 3).—The author comments on the Government's importations of reindeer to Alaska and the opportunities for the extension of the industry. It is suggested that it might be possible to cross the native caribou and the domesticated reindeer, thus preserving the size and vigor of the stock.

The preservation of the Arab horse, C. W. EDWARDS (*Philippine Agr. Rev. [English Ed.]*, 7 (1914), No. 1, pp. 47, 48).—An effort is being made to preserve the pure-bred Arab horse. There is being formed in Cairo an international horse society, the object being the starting of a stud book, the arranging for annual shows and auction sales, and the encouragement of the breeding of Arabian horses. It is stated that at the present time the pure-bred Arab is found only among the different Bedouin tribes of the Arabian and Syrian deserts in Mesopotamia and in the Nedj, in a few private studs in Egypt, and in a very few of the European and American studs.

A study of sex-linked inheritance in poultry (*Missouri Sta. Bul.* 117 (1914), pp. 430, 431).—"In the spring of 1913 matings were made as follows: (1) Barred Plymouth Rock male and Black Minorca female; (2) Barred Plymouth Rock female and Black Minorca male; (3) White Leghorn male and White-crested Black Polish female; (4) White Leghorn female and Whitecrested Black Polish male; (5) Silver Spangled Hamburg male and Brown Leghorn female; (6) Silver Spangled Hamburg female and Brown Leghorn male; (7) Seabright Bantam male and Black Bantam female; and (8) Seabright

Bantam female and Black Bantam male. From all of the above matings, except (7), a large number of birds were obtained in the F_1 generation.

"Matings (1) and (2) gave typical sex-linked results: In (1), both the males and the females are barred, while in (2), the reciprocal cross, only the males are barred, the females being entirely black like their father. In matings (3) and (4), no sex-linked characters have been observed.

"The F_1 birds from matings (5) and (6) show a number of points of interest. The spangled pattern of the Hamburg is evidently sex-linked, but the pattern is not transmitted for the entire body as a unit. In all of the offspring of both crosses, the tail is pure black and shows no spangling whatever, but on the rest of the body the pattern is inherited as a sex-linked character. From mating (5), both cocks and hens are spangled, while from mating (6), the reciprocal cross, only the males are spangled, the females being black with some scattered brown and golden markings.

"The Bantam matings are of unusual importance by reason of the fact that the Seabright male lacks the usual secondary sexual feathers of poultry, and is therefore feathered like the female. The cocks of this breed have no sickle feathers, and the long hackle and saddle feathers are also absent. The crosses in question were made in order to determine the mode of inheritance of this peculiarity. It is known, furthermore, that the Seabright cocks show a greatly reduced fertility, and it is possible that a correlation exists between this condition and the absence of secondary sexual characters. From the mating (7), in which the Seabright cock was used, only 4 birds were obtained, 1 male and 3 females. The cock has the usual sickle feathers and the hackles and saddle. But in the mating (8), in which the reciprocal cross was made, all of the cocks are hen-feathered. A complete analysis of this result will not be possible until the next generation is obtained."

Studies on the feather formation of domestic fowl, K. ANDREAS (*Studien über die Locken- und Struppbildung beim Hausgeflügel. Inaug. Diss., Univ. Bern, 1913, pp. 45, pls. 3*).—A study of the feather formation and characteristics of some unusual types of domestic fowl, and of the effect of domestication and environment upon these characters.

Early development of scale and feather, J. SCHLEIDT (*Arch. Mikros. Anat., 83 (1913), No. 1-2, I, pp. 118-129, pls. 2; abs. in Jour. Roy. Micros. Soc. [London], No. 1 (1914), p. 33*).—The author finds that the scales on the chick's feet have primordia like those of reptilian scales. They consist of a proliferation of epidermis and dermis. It is stated that the "foot of the chick and the fore limb of the blackbird show embryonic down feathers on scales. At a very early stage the down primordia are seen as special differentiations on the scale primordia."

It is concluded that there is no homology between scales, embryonic down feathers, and definitive feathers.

Effect of Röntgen rays on organs of chicken, H. UNZEITIG (*Arch. Mikros. Anat., 82 (1913), No. 4, I, pp. 380-407, pl. 1, figs. 2; abs. in Jour. Roy. Micros. Soc. [London], No. 1 (1914), p. 38*).—It was found that "chickens can stand about 2 hours' exposure to a given intensity of Röntgen rays. For a few days following there is a marked reduction of body weight. Feathers often fall off. The bursa fabricii becomes smaller and lighter, and in one case almost disappeared. The lymphocytes of the cortical substance are destroyed in large numbers, the number of follicles is reduced; after the fifth day or so regenerative processes often set in. The testes are very susceptible; there is marked loss of weight and great destruction of sperm cells. The interstitial cells do not seem to be affected. The spleen loses greatly in weight and there is a marked reduction of lymphocytes."

Artificial insemination in birds, E. IVANOV (*Compt. Rend. Soc. Biol. [Paris]*, 75 (1913), No. 31, pp. 371-374; *abs. in Jour. Roy. Micros. Soc. [London]*, No. 1 (1914), p. 34).—The author has effected artificial insemination of hens and pheasants, and reports that a small percentage of the hens laid fertile eggs which developed.

Shipping eggs by parcel post, L. B. FLOHR (*U. S. Dept. Agr., Farmers' Bul. 594* (1914), pp. 20, figs. 6).—In the experiments reported in this study in cooperation with the Post Office Department approximately 761 doz. eggs were sent through the mails in 466 shipments of from 1 to 10 doz. each. The total breakage was 327 eggs, of which 118 were only cracked or slightly broken and were usable. Of the 209 broken beyond use, 91 were broken because the parcels containing them were handled contrary to postal rules and regulations. Subtracting these, the loss was less than 1.3 per cent.

In the shipment of eggs it is advised that only fresh well-preserved eggs and preferably nonfertile eggs be sent. In trials made of a large number of styles and makes of containers quite a number proved satisfactory.

Complete details of methods of shipment and a suggested form of agreement between producer and consumer are given.

Eggs from China, G. E. ANDERSON, R. E. MANSFIELD, A. P. WILDER, and E. L. NEVILLE (*Daily Cons. and Trade Rpts. [U. S.]*, 17 (1914), No. 71, pp. 1142-1145).—Notes on the Chinese exportation of fresh eggs and egg products, principally egg albumin, to the United States.

Table rabbit production, P. E. WILSON (*Newport (Salop), England*, pp. 45, pl. 1, figs. 10).—This booklet treats of the breeding, feed, care, management, killing, and dressing of rabbits for food production.

Economic value of North American skunks, D. E. LANTZ (*U. S. Dept. Agr., Farmers' Bul. 587* (1914), pp. 22, figs. 10).—This publication discusses the value of skunks to agriculture as destroyers of rodents and injurious insects, their value as fur bearers, and the possibilities of raising them for their fur. Methods of feed, care, and management for commercial purposes are discussed. It is suggested that these animals should be protected everywhere by a close season of at least 9 months, but the right of farmers to destroy predatory skunks should be reserved.

DAIRY FARMING—DAIRYING.

Department of dairy husbandry, C. H. ECKLES (*Missouri Sta. Bul. 117* (1914), pp. 421-423).—Portions of this report, relating to nutrients required for milk production and the characteristics of carotin have been reported from another source (*E. S. R.*, 30, p. 773; 31, p. 273).

Results obtained in experiments made to determine the nutrients required to develop the fetus "confirm those previously reported that the amount of feed required to develop the fetus is so small that it cannot be measured by weighing the animal and taking the weights and analyses of the feed. In other words the fetus may be developed on a maintenance ration. A cow in producing about 200 lbs. of milk produces as much dry matter and of much the same composition, except in regard to the ash, which varies in certain respects, as would be required to develop the fetus."

In feeding cotton-seed products in combination with other grains results as to the composition of the milk and butter were obtained identical with those obtained in feeding cotton-seed meal containing equal quantities of oil. This indicates that the results from cotton-seed meal feeding are due to the oil content.

Results of studies made of the factors influencing the development of dairy heifers indicate that ordinary variations of feed have no measurable effect upon the development of the dairy functions. The tendency to produce milk is apparently an inherited characteristic not subject to much, if any, modification by feeding.

New method for determining the production value of feeding stuffs in the feeding of dairy cows, N. HANSSON (*K. Landtbr. Akad. Handl. och Tidskr.*, 52 (1913), No. 8, pp. 633-647; *Meddel. Centralanst. Försöksv. Jordbruksområdet*, No. 85 (1913), pp. 17; *Fühling's Landw. Ztg.*, 63 (1914), No. 2, pp. 41-53; *abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases*, 5 (1914), No. 1, pp. 84-87).—In feeding trials with dairy cows the Kellner starch value did not prove an exact measure of the feeds used for the production of milk. The difference between this starch value and the Swedish and Danish food-unit values is ascribed to the fact that Kellner's figures are the result of fattening experiments with steers, while the Swedish food-unit values are founded on experiments with milch cows; fats, carbon-hydrates, and crude fiber have the same value in the 2 cases, but protein is more advantageously used in the production of the milk proteins than in the putting on of fat. It was found that by reckoning the digestible protein of fodder at 1.43 instead of 0.94 (Kellner's figure) the calculated values corresponded to those which resulted from the feeding experiments.

A method is proposed for calculating the milk-producing value which differs from Kellner's method for the calculation of the starch value only as regards the factor for the reduction of protein. A table is given showing the value of some of the principal feeding stuffs based upon this method. From this it is seen that one food-unit is generally equivalent to about 0.75 of the new values. By means of the new method a valuation may be made for feeding stuffs of the most varied composition provided their content of digestible matter is known.

The problem of the protein minimum in the dairy ration and of the market value of feeding stuffs, M. HOFFMANN (*Mitt. Deut. Landw. Gesell.*, 29 (1914), No. 11, pp. 162-165).—Answers received to numerous inquiries made in the various Provinces of Germany indicated that but 20 per cent of the dairymen are using the Kellner standard, showing that that standard is not deemed entirely satisfactory. While the Kellner method is based on the assumption that 1 kg. of protein is equal to 0.94 kg. starch value, the equivalents in actual use range from $\frac{1}{2}$ to $\frac{2}{3}$ and $\frac{6}{7}$.

It is suggested that a uniform system of estimating market value of feeds is necessary.

Breeds of cattle of Switzerland, A. GERTSCH (*Rev. Vet. e Zootech.*, 4 (1914), No. 1, pp. 21-48, pls. 9).—This is a discussion of the breed characteristics and milking capacity of the Swiss, Simmental, and Freiberg breeds of cattle of Switzerland.

The age for breeding dairy heifers, E. SIHN (*Kimball's Dairy Farmer*, 12 (1914), No. 8, p. 233).—This article reports the experiences of E. Tesdorpf of Denmark, covering observations for 10 years, in which 206 heifers calved at 2 years of age and 193 calved at 3 years. The average milk yield in the first lactation period was for the 2-year-olds 5,355 lbs. and for the 3-year-olds 5,676 lbs. However, in comparing the yields from the fourth to ninth years in which time the greatest development of the milk-yielding quality takes place, the 2-year-olds fully measured up to the 3-year-olds, and their vitality was equally as good if not better. With regard to abortion and failure to get in calf the 3-year-olds showed no advantage.

It is stated that these records are from one of the oldest and best herds of Red Danish cattle in Denmark, and that this may account in part for the strong showing of the 2-year-olds.

World's record for a dairy cow broken (*Hoard's Dairyman*, 47 (1914), No. 13, p. 480, fig. 1).—An account of a 7-year-old Guernsey cow, May Rilma, which has recently completed a 365-day test in which she gave 19,639.5 lbs. milk, containing 1,059.59 lbs. milk fat. This record is said to surpass that of any cow thus far.

Hereditary transmission of fat percentage, J. J. DUNNE (*Hoard's Dairyman*, 47 (1914), No. 15, p. 553).—Observations made for 12 years on a herd of red Danish cows tend to support the theory that Mendel's law dominates the variations of the fat percentages. It is believed that there are only two constant types in the herd, namely the cows with a tendency to give rich milk, i. e., 4 per cent, and those with a tendency to give poor milk, i. e., 3.3 per cent, while the animals with an intermediate fat percentage might be described as the crossbred product of the two foregoing types.

Cells in milk derived from the udder, R. S. BREED (*New York State Sta. Bul.* 380 (1914), pp. 139-200, figs. 4).—The purpose of this investigation was to determine the normal number of cells present in milk, to discover the reason for variation in the cell content of the milk of individual cows, and to study the influence of the milking machine on the number of cells present in the milk. The method used in counting the cells was the direct microscopical method in which the counting was done under an oil-immersion lens (*E. S. R.*, 26, p. 274). The method of preparing dried milk smears here used gave excellent results and is deemed more accurate than where the cells are counted in centrifuge sediments.

It is pointed out that cells of two entirely different kinds are discharged in the milk of all cows throughout the entire lactation period. The larger number of the cells are leucocytes (white blood corpuscles) while a smaller number are epithelial cells, nuclei, or other fragments of such cells. It was found that the largest average number of the cells present in milk occur in colostrum milk but equally large numbers are occasionally found in milk drawn at any portion of the lactation period. High counts are more common during the latter part of the lactation period than during the height of lactation, although the average total number of cells discharged per milking is less. There are marked daily variations in the number of cells discharged which do not show a close correlation with any of the suggested causes for such variations. No constant relation exists between the number of cells in fore milk and that obtained later, although there is an increase in the number of cells in the strippings which may possibly be due to manipulation of the udder or to other factors.

The four quarters of the udder do not act as a unit in the discharge of the cells but show as wide variations in number and character of the cells discharged as do separate udders.

Of 122 cows whose milk has been examined, 59 gave cell counts under 500,000 per cubic centimeter, 36 gave counts between 500,000 and 1,000,000, and 27 gave counts over 1,000,000 per cubic centimeter. The average cell count was 868,000 per cubic centimeter. The milk of all these cows was apparently normal. In an examination of goat's milk the numbers of cells found were uniformly high, the average count for 11 goats being 7,465,000 per cubic centimeter.

Changes of a considerable amount in the vacuum used to operate milking machines were found to be entirely without effect on the cell content of the milk. The station herd which has been accustomed to machine milking showed a much lower average cell content than the milk of other herds, indicating that the number of cells present in machine drawn milk is somewhat less than that

of hand-drawn milk. The results obtained in the course of the experiments do not indicate that high vacuums or changes in vacuum may of themselves cause the excessive discharge of cells or draw blood from the interior of the udder.

The reasons for the discharge of the two kinds of cellular elements are different. The epithelial cells are presumably discharged because they are worn out in the process of the secretion of the milk. The reason for the presence of the leucocytes is not so clear. By some investigators it is believed that they are attracted to the milk by the presence of bacteria in the udder, especially by the pus-forming streptococci. The investigations here carried out have not demonstrated what relationship exists, if any does exist, between the number of cells discharged and specific infections of the udder. Enough data were secured, however, to make it probable that there are other reasons for the discharge of leucocytes in the milk than the presence of bacteria in the udder. These other reasons undoubtedly have to do with the physiological conditions surrounding the process of milk secretion.

Bacterial and enzymic changes in milk and cream at 0° C., MARY E. PENNINGTON, J. S. HEPBURN, E. Q. ST. JOHN, ET AL. (*Jour. Biol. Chem.*, 16 (1913), No. 3, pp. 331-368).—In some previous work (E. S. R., 20, p. 179) it was demonstrated that raw milk held at or a little below a temperature of 0° C. undergoes marked proteolysis, which is very noticeable at the end of 2 weeks. The function of the present research was to determine which part of the proteolysis is due to bacteria and which part is due to the enzymes of milk, and, finally, what results when both bacteria and enzymes act together.

It is shown that the proteolysis of casein is due primarily to bacterial action, while that of lactalbumin is due to the enzymes of the milk. Bacterial and milk enzymes, when active at the same time, cause a greater degree of proteolysis. In the course of proteolysis the true proteins are broken down to caseoses, peptones, and then to amino acids. The fermentation of lactose is largely, if not entirely, due to bacterial action.

“The digestion of the protein, the fermentation of the lactose, and the increase in acidity are progressive changes, and are accompanied by more or less progressive lowerings of the freezing point of the milk. The depression of the freezing point of the cream is to be ascribed to chemical changes in its protein and lactose. . . . “During the holding at 0°, the organisms of the raw untreated and reinfected sterile milk and cream undergo an increase, which is most striking in the raw untreated milk.”

[Dairy laws], compiled by L. J. SMITH and F. B. DUVAL (Sess. Laws Colo., 1913, pp. 231-245).—This is the text of the Colorado laws relating to the regulation of the production, sale, and shipment of dairy products and oleomargarine, the inspection of dairies, creameries, etc., standards for dairy products, rules for sampling, and other related subjects.

Is the establishment of a uniform fat standard for whole milk practical? O. MEZGER (*Milchw. Zentbl.*, 42 (1913), Nos. 16, pp. 492-499; 17, pp. 522-528; 18, pp. 545-555; 19, pp. 574-580, figs. 4; 20, pp. 609-616, figs. 2).—In commenting on the impracticability of a uniform fat standard for whole milk the author cites a number of earlier investigations showing that milk undergoes wide daily and weekly changes due to feeds, lactation period, and other variable factors.

Principal types of micro-organisms in Baltimore milk, L. P. SHIPPEN (*Bul. Johns Hopkins Hosp.*, 25 (1914), No. 278, pp. 122-123).—It was found that the most frequently encountered organism in the milk examined was *Bacillus lacticus*, or as the author chooses to term it, *Bacterium güntheri*. Certain strains of the bacterium resemble *Streptococcus pyogenes*, but may be dif-

ferentiated from it. Pasteurization at from 60 to 70° C. destroys certain strains of *B. g ntheri*.

B.  rogenes and *B. coli* were frequently found in the milk examined. Other types of micro-organisms were found in lesser and inconstant numbers.

A bibliography of 23 references is included.

Blue milk, A. WOLFF (*Milchw. Zentbl.*, 42 (1913), No. 19, pp. 571-574).—The occurrence of blue milk is ascribed to *Bacterium syncyanum* and *B. cyano-fluorescens*. The former bacterium forms small blue spots on the surface of milk which rapidly increase in size and may extend downward. It is dependent upon the presence of the lactic acid bacterium, without which the formation of pigment can not continue in strongly acid milk. There are also other organisms capable of coloring milk blue. It is thought that though these micro-organisms of blue milk are easily killed by pasteurization, the ordinary temperature of from 68 to 70° C. is too low unless kept up for 30 minutes. Flies and water are common carriers of these organisms and are the sources of infection of milk.

The composition of carabao's milk, E. R. DOVEY (*Philippine Jour. Sci.*, Sect. A, 8 (1913), No. 3, pp. 151-157).—The average composition of 19 samples of carabao's milk is given as follows: Specific gravity at 17.5° C. 1.0364, water 78.46 per cent, total solids 21.55, fat 10.35, solids-not-fat 11.2; protein 5.88, casein 5.35, albumin 0.53, lactose 4.32, and total ash 0.844 per cent. The fat butyrometric reading at 25° was 49.7, the specific gravity of the serum at 20° 1.0345, and the immersion refractometer reading at 20° 45.3.

It was found that whereas in cow's milk the fat is approximately 30 per cent of the total solids, in the case of carabao's milk it reaches nearly 50 per cent. The ratio of lactose, protein, and ash in carabao's milk is given as 5:7:1. The ratio of casein to albumin in carabao's milk is given as 1:10, and for cow's milk 1:55. However, the amount present fluctuates considerably. The ratio of mineral matter to solids-not-fat is approximately the same in carabao's milk as in cow's milk but the ratio of phosphoric acid and calcium to ash is greater in the former than in the latter. It is shown that carabao's milk varies greatly in composition, and it is recommended that a minimum of 8.5 per cent of solids-not-fat and 8 per cent of milk fat be adopted as the standard.

The average composition of cheese made from carabao's milk is given as follows: Water 52.52 per cent, fat 28.47, protein 15.47, acetic acid 0.071, lactic acid 0.337, insoluble ash 1.63, soluble ash 3.91, and sodium chlorid 0.438 per cent, with a fat butyrometric reading at 25° of 50.3.

Composition of goat's milk, A. STORCH (*Ztschr. Fleisch u. Milchhyg.*, 24 (1914), Nos. 12, pp. 269-272; 13, pp. 298-309; *abs. in Milk. Ztg. Berlin*, 24 (1914), No. 14, pp. 159, 160).—On an average goat's milk was found to have a specific gravity of 1.0291, a fat content of 2.87, and a fat-free dry substance content of 8.109 per cent. It was found that the fat and fat-free dry substance in goat's milk varies widely with different individuals. In general goat's milk is lower in fat content than cow's milk. Age and milk yield, green feeding, and pasturing exert no appreciable influence on the composition of the milk, but evening milk is richer in fat and fat-free dry substance than morning milk. No uniform change occurs in the composition with advancing lactations, and the content of fat-free dry substance remains practically constant to the end of the lactation period, although during the first 10 days after kidding the content of fat and fat-free dry substance in the majority of cases increases.

The composition of the milk of the Saane, native, and crossbred goat is similar. The colostrum character of goat's milk is lost very soon after kidding, usually within 12 hours. The end milk is richer than that first drawn.

Composition of ewes' milk butter, M. MARTIN (*Ann. Falsif.*, 6 (1913), No. 62, pp. 662, 663; *abs. in Internat. Inst. Agr. [Rome] Mo. Bul. Agr. Intel. and Plant Diseases*, 5 (1914), No. 3, pp. 403, 404).—Ewes' milk butter is characterized as being very white, soft, and difficult to work and to dry. It is rarely used on the table but is found mixed in various proportions with cows' milk butter. Its chemical composition is said to be very nearly that of cows' milk butter, but the content of insoluble volatile acids and saponification value are much higher.

Summary of the results of researches made during the last few years at the Dairy Institute at Alnarp (Sweden), L. F. ROSENGREN (*Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases*, 5 (1914), No. 1, pp. 121-125).—It was demonstrated that if whey is submitted to a violent motion, such as, for instance, working in a churn for 30 minutes at a temperature of 50° C. (122° F.), the cream could not afterwards be separated to the same degree as if it had not been so treated. Whey containing 0.305 per cent of fat was reduced by separating without previous churning to a fat content of 0.035 per cent, while when churned before separating it was reduced to only 0.235 per cent. It was found that the degree to which milk is capable of separation at the different periods of lactation is variable, being greater in the case of cows recently fresh than in those drying off.

Brief notes are given on the value of ripening cream at low temperatures, keeping of lactic ferment, influence of too acid a ferment on the butter, factors determining the water content of butter, influence of various kinds of concentrated feeds on butter, control of iron salts in wash water for butter, use of cultures of lactic ferments in cheese making, and the coating of cheese with paraffin.

Cheshire cheese, MISS G. N. DAVIES (*Jour. Agr. [New Zeal.]*, 7 (1913), No. 3, pp. 287-293).—Directions are given for the making of Cheshire cheese, which is described as having a texture loose, open, and flaky, strikingly unlike the Cheddar's smooth solidity.

Condensed milk and milk powder, O. F. HUNZIKER (*Lafayette, Ind., 1914*, pp. V+7-239, figs. 62).—This book treats of the various phases of the condensed and powdered milk industry, including the processes of condensing and desiccating milk, skim milk, buttermilk, and whey.

Organisms in condensed milk (*Jour. Amer. Med. Assoc.*, 62 (1914), No. 16, pp. 1257, 1258).—Commenting on the bacteriology of condensed milk, it is shown that this product, contrary to general opinion, is rarely sterile. However, the presence of bacteria or of body cells is no greater than in market milk, even of the certified grade, and in fact, there appears to be a comparative paucity of cells in the cheap machine-skimmed condensed milks, due to the removal of debris and dirt through the centrifugal separators. It is stated that condensed milk may contain the types of bacteria commonly found in fresh milk, *Bacillus coli*, streptococci, a few staphylococci, and *B. enteritidis sporogenes*, together with ordinary air contaminations, such as *B. subtilis* and *B. Mesentericus*.

While there is a tendency to depreciate the importance of these bacteria in condensed milk it is believed that efficient pasteurization before the condensing process would prevent the presence of such organisms in the final product.

Aluminum milk cans, WINKLER (*Österr. Molk Ztg.*, 21 (1914), No. 3, p. 39, fig. 1; *abs. in Cream. and Milk Plant Mo.*, 2 (1914), No. 8, p. 25).—An account of the use of aluminum milk cans. This metal is not attacked by sour milk and the cans are not affected by repeated steaming. The cans are made of corrugated sheet iron or steel, covered inside with aluminum bronze and closed tightly at the junction, and are recommended particularly for certified milk. They should not be cleaned with soda.

International Federation of Dairying (*Bul. Féd. Internat. Lait.*, No. 7 (1913), pp. 144, pls. 3, figs. 5).—This bulletin summarizes the proceedings of the International Federation of Dairying, held in Brussels in April, 1913, gives statistics relating to the dairy industry in Hungary, and outlines methods of cheese control in Holland.

VETERINARY MEDICINE.

Manual of the practice of veterinary medicine, E. COURTENAY, revised by F. T. G. HOBDAV (*London, 1913, 3. ed., pp. 450, figs. 77; rev. in Amer. Vet. Rev., 44 (1914), No. 6, pp. 767, 768*).—The third revised edition of this work (E. S. R., 14, p. 910).

Veterinary state board questions and answers, V. G. KIMBALL (*Philadelphia and London, 1914, pp. VII+395*).—This work, which is intended for the use of those about to take a state board examination, is arranged under the headings of the several subjects covered in such examinations, namely, chemistry, anatomy, physiology, pathology, theory and practice of medicine, surgery, obstetrics, materia medica and therapeutics, sanitary science—meat and milk hygiene, and zootechnics. Through the complete index furnished the work also forms a general reference book on veterinary science.

Ophthalmology for veterinarians, W. N. SHARP (*Rev. in Cornell Vet., 4 (1914), No. 2, pp. 106, 107*).—This is a review by D. H. Udall of the work previously noted (E. S. R., 29, p. 377).

Exercises in bacteriology and diagnosis, V. A. MOORE and C. P. FITCH (*Boston, Chicago, and London, 1914, pp. XIX+154, figs. 10*).—This small book, which is intended for veterinary students and practitioners, is in its fourth edition. It is intended to be used as a laboratory guide and also contains a small appendix dealing with biologic diagnostic methods.

Apparent inconsistencies of biologic diagnostics, R. A. ARCHIBALD (*Amer. Vet. Rev., 44 (1913), No. 1, pp. 58-65; Proc. Amer. Vet. Med. Assoc., 50 (1913), pp. 675-683*).—The purpose of this paper is to demonstrate that biologic diagnostic methods, if properly applied, are absolutely consistent, and that this depends upon the stage of the disease through which the animal is passing at the time at which the tests are applied.

Menziesia, a new stock-poisoning plant of the Northwestern States, C. D. MARSH (*U. S. Dept. Agr., Bur. Plant Indus., Menziesia, A New Stock-Poisoning Plant (1914), pp. 3, pls. 2*).—A rather heavy loss of sheep in the Pend Oreille National Forest in Idaho was brought to attention in the summer of 1912. Preliminary feeding experiments with *Menziesia glabella* showed that it is poisonous to sheep and indicated that the deaths were due to this plant. The Rocky Mountain species grows on moist northern slopes in open woods and about the "balds" at altitudes of 3,500 to 6,000 ft. It is a local species, occurring abundantly in many places, but often many miles may be traveled at the right altitude without coming upon it.

The symptoms exhibited in cases of poisoning by *Menziesia* are much like those seen in poisoning by other plants. Salivation or frothing at the mouth is noticeable, and this is followed by weakness leading to a staggering gait and culminating in a more or less complete paralysis. There is generally pronounced nausea and sometimes difficulty in breathing. It is stated that the plant is not extremely toxic, the experiments showing that a considerable quantity must be eaten before symptoms of intoxication appear. When, however, sheep eat any great quantity of *Menziesia* serious losses may occur. It is deemed important that herders handling sheep in the mountains of Idaho.

Washington, and Oregon become acquainted with the plant and take proper precautions to prevent the sheep from eating any large quantity of it.

Mold fungi in oil cake, E. SCHNEIDER (*Milchw. Zentbl.*, 42 (1913), No. 10, p. 313).—The author finds that draft oxen and young cows which have calved for the first time are not affected by moldy oil cake.

The immunological relationship of hordein of barley and gliadin of wheat as shown by the complement fixation, passive anaphylaxis, and precipitin reactions.—The biological reactions of the vegetable proteins, IV, G. C. LAKE, T. B. OSBORNE and H. G. WELLS (*Jour. Infect. Diseases*, 14 (1914), No. 2, pp. 364-376).—Among the principal conclusions drawn from these experiments, which continue earlier work (E. S. R., 30, p. 778), were the following:

“Carefully purified preparations of vegetable proteins readily produce antisera. The antisera obtained in our experiments differed in their range of reactions, some giving only the complement fixation, some the complement fixation and precipitin tests, while others in addition conferred passive anaphylaxis to guinea pigs.

“Antisera to the same protein obtained from different individual animals differ in their reactions, for some unknown cause. . . . A specific complement fixation reaction in high dilution does not necessarily accompany reactions with the heterologous proteins, nor can such serum always produce the passive anaphylaxis reaction. Both the precipitin and passive anaphylaxis reactions appear later in immunization than the complement fixation reaction, and seem to be closely related to each other in delicacy.”

The anaphylactogenic activity of some vegetable proteins.—The biological reactions of the vegetable proteins, V, H. G. WELLS and T. B. OSBORNE (*Jour. Infect. Diseases*, 14 (1914), No. 2, pp. 377-384).—According to the authors' conclusions the data presented support the assumption “that the severity of the anaphylaxis reactions produced by intraperitoneal injections of dilute, alkaline solutions of vegetable proteins is, approximately, in inverse ratio to their relative precipitability when their solutions are mixed with the peritoneal fluid.

“Proteins like edestin, which are readily precipitated and only slowly redissolved under conditions similar to those presumably prevailing in the peritoneum, rarely produce a fatal intoxication; whereas those that are less easily precipitated and more readily dissolved give fatal reactions in much smaller doses.”

Other conclusions have to do with lethal and minimum intoxicating doses.

About the specificity and other properties of the ectoproteases, C. FERMI (*Centbl. Bakt. [etc.]*, 1. Abt., Orig., 68 (1913), No. 5-6, pp. 433-454; 69 (1913), No. 7, pp. 465-474; *Arch. Farmacol. Sper. e Sci. Aff.*, 15 (1913), Nos. 1, pp. 36-48; 2, pp. 49-65; 3, pp. 131-144; 4, pp. 145-162; 5, pp. 233-240; 6, pp. 241-250).—This deals with the distribution of proteolytic enzymes in the animal and vegetable kingdoms. For this purpose organs of animals belonging to the Mammalia, Aves, Reptilia, Amphibia, Pisces, Mollusca, Insecta, Arachnida, Myriapoda, Crustacea, Echinodermata, Vermes, Spongilla, Coelenterata, and Protozoa were used. The proteolytic enzymes in the plant kingdom were from pathogenic and nonpathogenic bacteria, molds, and imperfect fungi, and the studies were made with autolyzed press juices from animal organs.

In this connection, the time at which the proteolytic enzymes selected for different substrata appear during the development of the animal or plant in question is considered. In addition the results of experiments made on the activation of certain proenzymes, exposing the enzymes (vegetable and animal) to light and heat, filtration through porcelain filters, and dialyzing tests, are recorded.

A preliminary report on the value of leucocytic extract from a therapeutic standpoint, R. A. ARCHIBALD (*Proc. Amer. Vet. Med. Assoc.*, 50 (1913), pp. 451-460).—For preparing the leucocytic extract the blood taken from the jugular

vein of a horse or other domestic animal is drawn into a flask containing a sufficient quantity of 1 per cent sodium citrate solution to prevent coagulation. It is then centrifuged, the sodium citrate solution and serum drawn off, and the corpuscles treated with 0.5 per cent acetic acid solution. It is then centrifuged again and the process repeated several times with acetic acid until the mass of corpuscles is free from red blood corpuscles.

"The leucocytes are then washed with physiologic salt solution 3 or 4 times to remove most if not all trace of the acetic acid, after which they are ground in a mortar with quartz sand. To the washed and ground leucocytes is added about 5 volumes of sterile distilled water to 1 volume of leucocytes. This mixture is exposed to a temperature of 58° C. for 1 hour, when it is placed in the incubator for a period of 12 hours, and again exposed to a temperature of 58° for one hour. This process of exposure to different temperatures is continued for 2 or 3 days or until autodigestion is complete. It is then centrifuged, the supernatant fluid decanted, and sufficient tricresol added for preservative purposes." The extract so prepared, when given parenterally, gives rise to a marked leucocytosis.

"While the total leucocyte counts were intensely interesting, the differential counts were infinitely more so. The polymorphonuclear neutrophils increased about 100 per cent, the small mononuclears decreased about 100 per cent, the large mononuclears decreased about 25 per cent, while the eosinophils increased about 800 per cent. In all our experiments we found that there occurred a marked eosinophilia. In fact, in one rabbit the eosinophils showed by differential count 44½ per cent of the total count."

"The practical therapeutic application of leucocytic extracts has been followed out during the past year, not only in our own practice, but also by other practitioners. Various infections have been treated with, in some types of infections, encouraging results, while in others the beneficial results were not so marked.

"The diseases to which the treatment has been applied, and which have given the most gratifying results are such infections as purpura, influenza, pneumonia, distemper in dogs, etc."

Autogenous vaccines, W. W. LANG (*Vet. Rec.*, 26 (1914), No. 1331, pp. 434, 435).—In this brief article the author relates his experiences with the use of autogenous vaccines, especially for cases of strangles and poll evil. Their use is recommended.

Experiences with the Abderhalden dialysis method.—I, Cleavage of thymus tissue by a normal serum, HELENE DEUTSCH (*Wiener Klin. Wchnschr.*, 26 (1913), No. 33, pp. 1492-1494; *abs. in Zentbl. Expt. Med.*, 4 (1913), No. 12, p. 540).—Thymus-cleaving ferments were noted in 51 out of 55 sera coming from healthy humans varying in age from 4 to 70 years.

Observations on the protective enzymes of the body (Abderhalden), E. G. GREY (*Bul. Johns Hopkins Hosp.*, 25 (1914), No. 278, pp. 117-122).—This reports the results of a study of the Abderhalden (protective enzyme) method, with a view to ascertaining the relationship of these enzymes to epithelial transplants. The ferments are considered specific.

Diagnosis of malignant new formations and pregnancy with the Abderhalden method, G. VON GAMBAROFF (*München. Med. Wchnschr.*, 60 (1913), No. 30, p. 1644; *abs. in Zentbl. Expt. Med.*, 5 (1914), No. 1, p. 17).—In only 3 out of 50 cases of tumor were the findings negative. Serum from cases of carcinoma cleaves carcinomatous tissue but not sarcoma tissue. The inverse holds good also.

Experimental contribution to the diagnosis of pregnancy by Abderhalden's dialysis method, NAUMANN (*Deut. Med. Wchnschr.*, 39 (1913), No. 43,

pp. 2086-2088; *abs. in Berlin. Tierärztl. Wchnschr.*, 30 (1914), No. 2, p. 33).—With bovines it was possible to note by the Abderhalden procedure whether an animal was pregnant or not. At least 2 cc. of serum are necessary and the ninhydrin test is more satisfactory than the biuret test.

The need for a means of physical diagnosis of abortion, W. L. WILLIAMS, J. N. FROST, and R. R. BOLTON (*Proc. Amer. Vet. Med. Assoc.*, 50 (1913), pp. 831-842, *figs.* 4).—This is the original material with discussions, previously noted (E. S. R., 29, p. 500).

A study of the metabiotic action of the ultraviolet rays.—Production of mutation forms of the anthrax bacillus, MME. V. HENRI (*Compt. Rend. Acad. Sci. [Paris]*, 158 (1914), No. 14, pp. 1032-1035, *pl.* 1; *abs. in Nature [London]*, 93 (1914), No. 2321, pp. 193, 194, *figs.* 3).—Through the exposure of an aqueous suspension of sporing anthrax in a quartz tube to ultraviolet radiations for a period varying from 1 to 40 minutes and afterwards subculturing, the author has been able to produce artificial mutations of *Bacillus anthracis*. The majority of the organisms were destroyed by this treatment, but a few survived, and while most of these presented a normal aspect a few showed characters decidedly different from the typical anthrax bacillus. The principal of these were (1) coccoid forms which remained stable during a period of 2 months, and (2) thin filamentous forms not taking the Gram stain, not liquefying gelatin or curdling milk, and producing an affection different from anthrax on inoculation. The second form remained absolutely fixed after daily subcultures for more than 80 days, but, though stable *in vitro*, *in vivo* after passage through an animal Gram-positive coccoid forms made their appearance, and subsequently, after subculture in broth, a certain number of bacillary forms approximating to typical anthrax were obtained.

The efficacy of antitetanic serum, T. B. ROGERS (*Vet. Rec.*, 26 (1914), No. 1330, p. 419).—The mortality from tetanus is much lower since antitetanic serum has been introduced into veterinary therapeutics. In the article a comparison is made with pre-antitoxin days.

Diagnosis of tuberculosis in test animals with von Pirquet's reaction, E. CONRADI (*München. Med. Wchnschr.*, 60 (1913), No. 29, pp. 1592-1594; *abs. in Berlin. Tierärztl. Wchnschr.*, 30 (1914), No. 2, pp. 30, 31).—It is stated that the only certain method of diagnosing tuberculosis is the animal test but this generally requires about 6 weeks. The author proposes to shorten this period by testing the guinea pigs with von Pirquet's cutaneous tuberculin test, and in his experiments, using guinea pigs and rabbits, he has reduced the time to about 10 to 13 days. It is, however, necessary to follow von Pirquet's specifications closely and to use a diluted, old tuberculin.

The value of the optical method and the dialysis procedure in infectious diseases.—Investigations about tuberculous bovines, E. ABDERHALDEN and P. ANDRYEWSKY (*München. Med. Wchnschr.*, 60 (1913), No. 30, pp. 1641, 1642).—The most suitable animals in the preliminary experiments were found to be dogs and rabbits. Guinea pigs which were not infected with tubercle bacilli cleaved a substrat made of tubercle bacilli. Animals receiving finely suspended boiled tubercle bacilli into the blood stream showed protein or peptone cleaving ferments 3 days post injection. The same was noted after injecting tubercle bacilli peptone or living tubercle bacilli.

In the experiments with cattle which came to slaughter the results were less favorable, as out of 50 cases of localized tuberculosis only 10 gave positive reactions. Where cleavage was obtained with the bovine sera it was practically always with a substrat prepared from the bovine type of bacillus and miliary tuberculosis was present. When, however, lung tissue containing caseous areas were boiled out and used as a substrat for the dialysis method or con-

verted into peptone for the optical method, the results showed positive for the pulmonary cases and negative for the milinary cases. The reaction in its present stage is not entirely reliable, especially as 10 sera out of 50 from normal animals gave positive tests.

Peptone was also prepared from glanders bacillus and then mixed with the sera of sound and glandered horses. The optical methods showed cleavage with the glandered sera.

Some remarks about Carl Spengler's fragment sputa, F. MAFFI (*Centbl. Bakt. [etc.]*, 1. Abt., *Orig.*, 69 (1913), No. 7, p. 555, pl. 1).—This short article is accompanied by a plate showing microscopical preparations of the so-called fragment (Splitter) sputa organisms which are found in the sputum of tuberculous subjects. In only one instance were fragmentary, granular, and normal forms of bacilli noted at the same time. The investigations are to be continued for the purpose of determining the significance of acid-fast organisms with reference to ordinary bacilli and Much's forms.

The production of artificial immunity against tuberculosis in domestic animals, S. H. GILLILAND and C. J. MARSHALL (*Proc. Amer. Vet. Med. Assoc.*, 50 (1913), pp. 719-753).—This is a résumé of experiments carried on for several years by the State Live Stock Sanitary Board of Pennsylvania, and deals especially with the Pearson method of immunizing against tuberculosis.

"Intravenous injections of tubercle bacilli from human sources, nonvirulent for cattle, are capable of conferring an immunity in cattle against tuberculosis sufficient to withstand natural infection by association with tubercular cows. The length of the immunity has not been determined accurately, though it is believed to diminish gradually after 2½ years. It is necessary that the animals, during the period of vaccination and for at least 8 weeks following the last vaccination, be kept in a manner that they are in no way exposed to tubercular infection.

"The normal resistance of the animal is apparently lowered during the period of vaccination. The number of vaccinations and the amount of vaccine administered have a direct relation to the degree of immunity conferred. The interval between vaccinations should be of sufficient length to allow the reaction following the previous vaccination to subside entirely.

"The results of the experiments lead us to be hopeful that the day may come when animals can be immunized against tuberculosis in common practice. Until further knowledge is obtained in regard to the destruction or outcome of the living tubercle bacilli injected in the animal with the vaccine, no practical method for the immunization of animals under ordinary conditions can be advocated."

See also other notes (E. S. R., 25, p. 288).

Control of tuberculosis in Minnesota pure-bred herds, S. H. WARD (*Proc. Amer. Vet. Med. Assoc.*, 50 (1913), pp. 824-830).—Previously noted from another source (E. S. R., 29, p. 500).

Some aspects of the tuberculosis problem, M. P. RAVENEL (*Proc. Amer. Vet. Med. Assoc.*, 50 (1913), pp. 88-98).—Previously noted from another source (E. S. R., 29, p. 499).

Some common ailments of the horse and cow, C. A. LUEDER (*W. Va. Farm Bul.*, 1 (1914), No. 5, pp. 16, figs. 5).—This is a popular account.

On the value of the "abortin" as a diagnostic agent for infectious abortion in cattle, K. F. MEYER and J. B. HARDENBERGH (*Jour. Infect. Diseases*, 13 (1913), No. 3, pp. 351-374, figs. 5; *Proc. Amer. Vet. Med. Assoc.*, 50 (1913), pp. 862-876).—"The serum tests, agglutination and complement fixation, are the most reliable methods to determine the existence of infectious abortion in a herd and to detect the bovines which are or have been infected with *Bacillus*

abortus. The abortin test in the form and with the preparation recommended by the English Commission is unreliable and misleading.

"Encouraging results are obtained with a precipitated purified abortin by intravenous application. The reaction is not absolutely specific as a high percentage of healthy animals react to the injection of abortin products. This nonspecificity is more frequently observed with an ordinary plain abortin than with our purified product. By means of the abortin test we can not decide whether an animal has been recently infected and will abort, or whether it is recovering from an invasion with *B. abortus*."

Bush sickness.—Field experimental and demonstration work, C. J. REAKES and B. C. ASTON (*Jour. Agr. [New Zeal.]*, 8 (1914), No. 2, pp. 160-165, figs. 2).—The information gained from investigations carried on in continuation of those previously noted (E. S. R., 30, p. 83) is summarized as follows:

"The most susceptible class of dairying cattle, namely, first calf heifers, can be kept healthy and made profitable for dairying purposes for at any rate a considerable time when grazed upon paddocks suitably top-dressed. . . . Animals of the same age and class will develop bush sickness in a few months when grazed upon similar land not top-dressed even with plenty of feed, good shelter, and access to standing bush. Syrup of phosphate of iron in solution is a valuable curative agent when given daily over a sufficiently long period. Breeding ewes grazed upon suitably top-dressed paddocks will remain healthy over a much longer period than these animals will do when kept upon land not top-dressed."

Investigations of coital exanthema of cattle, ZWICK and GMINDER (*Berlin. Tierärztl. Wchnschr.*, 29 (1913), No. 36, pp. 637-640).—The authors conclude that the cause of this disease is not a filterable virus. The horse, goat, and sheep are resistant to the virus.

Atoxyl in the treatment of malignant catarrhal fever of cattle, E. WYSSMANN (*Schweiz. Arch. Tierheilk.*, 55 (1913), No. 7, pp. 361-371; *abs. in Vet. Rec.*, 26 (1914), No. 1332, p. 450).—The author, who considers the disease to be a bacterial toxemia, recommends the injection of atoxyl following a copious bleeding. He reports having obtained very encouraging results from this treatment.

Pasteurellosis in the reindeer and a contribution to the knowledge of the biological characteristics of the pasteurella, H. MAGNUSSON (*Ztschr. Infektionskrank. u. Hyg. Haustiere*, 15 (1914), No. 1, pp. 61-92, figs. 6).—This is a detailed report of studies conducted at the Government Veterinary Bacteriological Laboratory at Stockholm in which the author finds the disease to be the same as that of deer, known in Germany as "Wildseuche." He finds the pasteurella organism to be resistant to low temperature and to changing temperatures near the freezing point, and to survive putrefaction for 6 months without attenuation.

Sanitary police measures and hog cholera, A. T. KINSLEY (*Amer. Vet. Rev.*, 44 (1913), No. 2, pp. 227-231; *Proc. Amer. Vet. Med. Assoc.*, 50 (1913), pp. 684-703).—A statement in regard to the prevalence of hog cholera in the United States at the present time. The total losses in the United States for 1912 approximated \$100,000,000, and those in Iowa, Nebraska, Kansas, and Missouri over \$30,000,000. So far as can be determined from available statistics these relative losses have never been exceeded or equaled, and have occurred regardless of the fact that large quantities of antihog cholera serum have been used.

The inadequacy of present legislation and sanitary measures in controlling the pest is given as one of the causes of the prevalence of hog cholera.

Abortion in mares caused by Bacillus paratyphosus, T. VAN HEELSBERGEN (*Centbl. Bakt. [etc.]*, 1 Abt., Orig., 72 (1913), No. 1-2, pp. 38-70, figs. 2).—A

detailed report of studies carried on in continuation of those reported by de Jong, previously noted (E. S. R., 28, p. 886).

While the portal of entry has not been positively determined, the bacillus is thought to be ingested by the horse in its feed.

Colics and their treatment, edited by D. M. CAMPBELL (*Chicago, 1914, pp. 137*).—This is the third volume of the Veterinary Medical Series (E. S. R., 27, p. 377; 31, p. 88). Its contents include Differentiation of the Various So-called Colics, by R. P. Lyman, Stomach Lavage in Acute Indigestion of the Horse, by D. O. Knisely, Surgical Treatment of Colics in Horses, by L. A. Merrillat, Impaction of the Cecum in the Horse, by A. T. Gilyard, Colics in the Horse, by D. S. White, and Medicinal Treatment of Colic in the Horse, by E. L. Quitman.

The diagnosis of dourine by complement fixation, J. R. MOHLER, A. EICH-HORN, and J. M. BUCK (*Proc. Amer. Vet. Med. Assoc., 50 (1913), pp. 467-484*).—Previously noted from another source (E. S. R., 30, p. 83).

Equine piroplasmosis: Types of parasites, M. CARPANO (*Centbl. Bakt. [etc.], 1. Abt., Orig., 73 (1914), No. 1, pp. 13-41, pls. 3, figs. 6*).—The author describes two piroplasms which occur in horses in Italy, one a small variety named *Nuttallia equi* by França, and most frequently encountered; the other a large variety, first distinguished by Nuttall as *babesia caballi*. That the two piroplasms are distinct has been shown by inoculation of an animal, which has recovered from or become immune to one, with the other. The author states that there are two ticks which infest Italian horses, namely, *Rhipicephalus bursa* and *Margaropus (Boophilus) annulatus*, that are probably responsible for the transmission of these piroplasms.

A bibliography is appended.

Culture of equine piroplasms and views of the nature of anaplasms, M. CARPANO (*Centbl. Bakt. [etc.], 1. Abt., Orig., 73 (1914), No. 1, pp. 42-53, pl. 1*).—The author describes the artificial culture of the parasites mentioned in the article noted above in blood mixed with a solution of sodium chlorid and sodium citrate. *Babesia caballi* remains alive in this medium for many days, but does not reproduce. *Nuttallia equi* reproduces, as in the blood, by division and ultimately leads to the formation of small Anaplasma forms, regarded as resistant stages.

Further investigations of contagious pleuro-pneumonia of the horse, GAFFKY and LÜHRS (*Ztschr. Veterinärk., 25 (1913), No. 1, pp. 1-11, pls. 5; abs. in Cornell Vet., 4 (1914), No. 1, pp. 49-51*).—This is a report of further investigations (E. S. R., 28, p. 482) conducted in the Imperial Institute for Infectious Diseases.

The authors' conclusions are as follows:

"The local changes in the lungs begin in the finest branches of the air passages. In the beginning of the disease there is secreted a glassy, transparent, slightly gelatinous, yellowish material. This is surrounded by a thick layer of cells and a serous infiltration. In the region of the affected bronchi the alveoli are filled with a fluid rich in cells. In those places where the disease foci are near the pleura there is an infiltration of the subpleural tissue with a transparent, yellowish, gelatinous fluid. The interlobular connective tissue is infiltrated with serum. On the fourth or fifth day, not before, bacteria begin to colonize in the diseased parts of the lung in the form of cocci arranged in chains. These cause inflammatory, often hemorrhagic, changes that may lead to extensive necrosis.

"Transmission from horse to horse is usually direct. The incubation period is at least 16 days, usually from 20 to 40 days, and over. Injection into susceptible horses of the blood or parts of diseased organs from horses affected with

contagious pleuro-pneumonia does not transmit the disease. It may be transmitted, but not always, by placing bronchial secretions on the mucous membranes of the uninjured nasal cavity or mouth. The ciliated epithelial cells in the bacteria-free secretions of the bronchi show peculiar inclosures which seem to be the result of degenerative changes rather than parasites.

"Horses that had been injected with the pulverized parts of diseased lungs, and which did not thus contract this disease, could not afterwards be infected by the usual method. Foci of lung tissue rubbed up with glycerin and preserved for a long time seem to prevent a later infection when injected into the lungs or under the skin."

Spirochetosis of fowls, KIESSIG (*Centbl. Bakt. [etc.]*, 1. Abt., Ref., 61 (1914), No. 7, pp. 193-208).—This review of the literature on the subject includes a bibliography of 59 titles.

The staining of microfilariæ, F. FÜLLEBORN (*Centbl. Bakt. [etc.]*, 1. Abt., Orig., 73 (1914), No. 6, pp. 427-444, pls. 2, figs. 3).—A discussion of the technique.

The disinfective action of Cresepton in comparison with creolin and liquor cresoli saponatus, WOLFF-EISNER (*Deut. Tierärztl. Wchnschr.*, 21 (1913), No. 44, pp. 702-704; abs. in *Berlin. Tierärztl. Wchnschr.*, 30 (1914), No. 1, p. 9).—The author having conducted experiments concludes that liquor cresoli saponatus, creolin, and Cresepton are very similar in their disinfective action, and that their cost is the first thing to be considered.

RURAL ENGINEERING.

Twelfth annual report of the Reclamation Service, 1913 (*Ann. Rpt. Reclamation Serv. [U. S.]*, 12 (1913), pp. 382).—This report relates in particular to work completed and in progress during the fiscal year ended June 30, 1913, with explanatory information regarding previous operations.

Report of irrigation and reclamation works department (*Rpt. Irrig. and Reclamation Works Dept. So. Aust. 1913*, pp. 27, pls. 7).—This report covers the period from August, 1910, to June, 1913.

Irrigation studies, A. MÜNTZ and E. LAINÉ (*Vie Agr. et Rurale*, 2 (1913), No. 48, pp. 557-559).—Studies of module, grade, state of vegetation, permeability of the soil, and unit area of the plat to be irrigated, relative to economy in the use of irrigation water, are briefly noted. It is concluded that a rational choice and consideration of these factors will in a large measure reduce the use of irrigation water in excess of that amount actually required by the crop.

Quantity of water consumed in the cultivation of sugar cane, J. GUARDIOLA (*Bol. Dir. Gen. Agr. [Mexico]*, *Rev. Agr.*, 2 (1912), No. 2, pp. 101-107).—Methods of computing the amounts of water necessary for the irrigation of sugar cane are outlined, as governed by local conditions relating to duty of water, soil, climate, and rainfall.

The control of water as applied to irrigation, power, and town water supply purposes, P. A. M. PARKER (*New York, 1913*, pp. VII+1055, figs. 273; rev. in *Engin. News*, 71 (1914), No. 12, pp. 646, 647).—This is a rather extensive contribution to the literature of applied hydraulics containing a large number of data, formulas, and mathematical demonstrations. The chief topics discussed are the theory of hydraulics, gaging of streams and rivers, weirs and weir formulas, orifices, collection of water and flood discharge, dams and reservoirs, open channels, filtration and purification of water, municipal water supplies, irrigation, and silting in canals.

Under gaging of streams and rivers a novel method called chemical gaging is described. In the remaining chapters of the book are treated such varied

subjects as movable dams, hydraulic machinery, the hydraulics of contracting and expanding pipes, valves and valve motions, water-hammer, ejectors, siphons, the removal of air from siphons, air lifts, air compression, hydraulic rams, resistance of motion of solid bodies in water, impact of water, turbines, and centrifugal pumps. The work closes with a brief treatise on concrete, iron, and other materials used in hydraulic construction.

The area of waterways, J. VICARS (*Rpt. Austral. Assoc. Adv. Sci.*, 13 (1911), pp. 622-629).—The author endeavors to demonstrate the inadequacy of the existing formulas for run-off used in determining the area of waterways for carrying off storm water. In addition he presents his own formula, which he believes embodies the primary essentials governing flood discharge and may be applied to any locality.

Loss of head due to bends in water pipes, W. E. FULLER (*Canad. Engin.*, 26 (1914), No. 11, pp. 441-443, figs. 4).—In this article the loss of head due to 90° bends is considered as that portion of the total loss in excess of the loss which would occur in an equal length of straight pipe. Data from various experiments indicate that the loss is more nearly the same for different sizes of pipe with bends of the same actual radius in feet than for the bends of the same radius in terms of pipe diameters.

Average values of the loss of head for different velocities due to bends of the same radius show that the loss is proportional to $v^{2.25}$, from which the formula $h^b = kv^{2.25}$ is deducted in which h^b is the loss of head, k is a coefficient varying with the radius of bend, and v equals the velocity.

The computations in which the actual lengths of the tangents to the curve were assumed as the straight pipe brought out the following points: The excess loss of head in bends is greater for large pipes than for small ones, and for large pipes a 6-foot radius bend gives the least resistance unless very long radii are used. "For small pipes . . . with long radii the loss of head will be less than it would be in straight pipe of a length equal to the tangents of the curve." For losses due to 45° bends it is suggested that three-fourths of that due to 90° bends of the same radius be used; for 22.5° one-half, and for a Y-branch three-fourths of that due to a T.

Drainage and irrigation: Drainage ditch and levee tables for level section with explanation of method of computation, E. S. BLAINE (*Engin. and Contract.*, 41 (1914), No. 10, pp. 302-306, fig. 1).—A table is given of volumes of excavation in cubic yards per 100 linear feet of ditch in level sections, having side slopes of 1 on 1 and bottom widths of from 4 to 123 ft. The volumes are calculated to correspond to tenths of feet in depth. The method of computation was by use of second differences, calculating them by addition within the limits of the table. A demonstration shows that the second difference not only remains constant for prisms having the same slope, but also that the second differences for other slopes are a multiple of this quantity if the slopes are the same on both sides of the section. If not the same, then it is a multiple of the average of the two slopes.

Drainage and irrigation: Linings for small storage reservoirs, C. R. SESSIONS (*Engin. and Contract.*, 41 (1914), No. 10, pp. 304-306).—The author discusses clay, plastered cobble, concrete, and asphaltum and oil linings for small storage reservoirs, but is of the opinion that of these the clay puddle lining is probably the cheapest and best.

Machine for testing drain tile, D. A. ABRAMS (*Engin. News*, 71 (1914), No. 12, p. 614, fig. 1).—A tile testing machine which is used in the laboratory of applied mechanics of the University of Illinois is illustrated and its construction and operation briefly described.

Street pavements and paving materials, G. W. TILLSON (*New York and London, 1912, 2. ed., pp. XVI+651, pl. 1, figs. 97*).—This book contains chapters on the history and development of pavements; stone; asphalt; brick-clays and the manufacture of paving-brick; cement, cement mortar, and concrete; the theory of pavements; cobble and stone-block, asphalt, brick, wood, broken-stone, and concrete pavements; plans and specifications; the construction of street-car tracks in paved streets; width of streets and roadways, curbs, sidewalks, etc.; asphalt plants; and the protection of pavements.

Fourth American Good Roads Congress and tenth annual convention of the American Road Builders' Association (*Good Roads, n. ser., 7 (1914), Nos. 1, pp. 3-59; 6, pp. 91-126*).—These proceedings include a number of special papers which deal with different phases of the design, construction, maintenance, and repair of different types of roads and with road administration.

Road laws of the State of Washington (*Olympia, Wash., 1913, pp. 263*).—These laws relate to road construction, financing, and administration.

Practical handbook of gas, oil, and steam engines, J. B. RATHBUN (*Chicago, 1913, pp. 370; rev. in Sci. Amer., 110 (1914), No. 10, p. 212*).—This book deals in condensed form with the construction, operation, and repair of all kinds of engines, with the various parts in detail, and with the different kinds of fuel.

The construction and design of internal combustion motors, H. GÜLDNER (*Das Entwerfen und Berechnen der Verbrennungskraftmaschinen und Kraftgas-Anlagen. Berlin, 1914, 3. ed. rev., pp. XX+800, figs. 1282; rev. in Engin. News, 71 (1914), No. 12, p. 648*).—This book is meant primarily for the designer of internal combustion engines. It contains many detailed drawings of parts, assembled drawings of complete machines, and tables of performance, as well as data on the fundamental theory that is necessary in design.

A fuel-saving device for oil engines, E. R. ADLINGTON (*Gas Engine, 16 (1914), No. 2, pp. 84-86, figs. 3*).—Tests of a recarbureting device for remixing and increasing the uniformity of the gasoline and air mixture are reported. The device consisted of a rapidly revolving fan placed in the intake pipe.

Curves of results obtained with and without the recarbureter showing brake horsepower plotted against pounds of gasoline per brake horsepower hour, percentage of thermal efficiency, and revolutions per minute all point more or less favorably toward the use of the recarbureting device. It is concluded that the points in favor of such a device are (1) reduction in gasoline consumption, (2) increased engine capacity, (3) higher speed at maximum loads, and (4) greater thermal efficiency.

Fuel consumption and effective utilization of energy in small power motors, CHARBONNIER (*Maschinen Ztg., 12 (1914), Nos. 1, pp. 4-8; 2, pp. 19-22*).—The author gives tables of data comparing the fuel consumption, effective utilization of energy, and cost of operation per effective horsepower hour for portable saturated and superheated steam engines, gas and crude oil engines, and electric motors of from 5 to 20 horsepower, operating at $\frac{1}{4}$, $\frac{1}{2}$, $\frac{3}{4}$, and full load.

The electric motors showed the least increase in fuel consumption per effective horsepower hour with decrease from full to $\frac{1}{4}$ load, followed in order by the superheated and saturated steam engines, and the crude oil and gas engines. The crude oil engines showed the highest effective utilization of heat units in fuel per effective horsepower hour from full to $\frac{1}{4}$ load, followed in order by the gas engines, the electric motors, and the superheated and saturated steam engines.

Using German prices for coal, gasoline, crude oil, and electricity per 10,000 heat units, it is shown that on the basis of the results obtained for fuel consumption and energy utilization the crude oil engine is the most economical

in sizes from 5 to 20 horsepower when operating at $\frac{1}{4}$ to full rated capacity, followed in order by the superheated and saturated steam engines, the gas engines, and the electric motors. It is stated, however, that utilization by the mechanical means available of the waste heat will place the steam engines ahead of the crude oil engines as regards economy.

The possibilities of mixed fuels (*Gas Engine*, 16 (1914), No. 2, pp. 120, 121).—Tests on a 4-cylinder engine of 3.54 by 5.12 in. bore and stroke, using gasoline, benzol, or mixtures of benzol and methylated spirits 1:1, 1:2, and 1:3 showed that on none of the mixtures of methylated spirits and benzol did the engine run steadily under load unless the temperature of the jacket of the induction pipe was at least 160° F. The benzol took less air than gasoline, and the more methylated spirit in the mixtures the smaller was the quantity of air required.

The engine at 1,000 revolutions per minute gave 1.25 per cent less power and used 15.5 per cent less benzol; 1 per cent less power and used 3.7 per cent less of the 1:1 benzol-methylated spirit mixture; 8 per cent less power and used 8.9 per cent more of the 1:2 mixture; and 8.5 per cent less power and used 24.5 per cent more of the 1:3 mixture than when running on gasoline. Later experiments using the 1:1 mixture in a high speed engine up to 2,000 revolutions per minute "show that with the slightly increased compression obtained in this engine, it was possible to get an explosive mixture which would burn rapidly enough to exert at least as much power as gasoline with a piston speed of about 2,000 feet per minute."

Fuel-briquetting investigations, July, 1904, to July, 1912, C. L. WRIGHT (*U. S. Dept. Int., Bur. Mines Bul. 58 (1913), pp. IX+275, pls. 21, figs. 3*).—This bulletin reports briquet tests made with a large number of fuels from different parts of the United States and also laboratory tests of briquet binders. The advantages of briquetted fuel are noted as more regular, thorough, and smokeless combustion, better draft, little clinkering, less need of care in firing, greater evaporative power, better weather resisting qualities, higher rates of combustion, less breakage during transportation, no spontaneous combustion, less space required in storage, and higher heating values.

Among a large number of other tests were tests of briquets in a kitchen range and in a heating grate. The briquets ignited readily, making a hot fire, and burned freely until consumed. Little shaking or poking of the fire was needed to obtain maximum efficiency from the fuel, and the loss of unburned fuel through the grates was not excessive and could be reduced by using step grates or grates with narrow spaces between the bars. A grate measuring 8 by 24 in. was big enough for heating a large room with briquets. Under the test conditions little smoke was made.

It is concluded that briquets should prove a satisfactory domestic fuel.

Mechanics for builders, I, E. L. BATES and F. CHARLES (*New York, 1913, pp. 201; rev. in Sci. Amer., 110 (1914), No. 10, p. 212*).—This book is meant for students of building construction who desire to perfect themselves in the principles of form and design. It selects from the larger study such subjects as bear directly upon building problems and gives a thorough grounding in strength of materials and theory of structure.

The testing of sand for use in concrete, I, II, C. M. CHAPMAN (*Engin. News, 71 (1914), Nos. 6, pp. 306-310, figs. 7; 11, pp. 554-558, figs. 2*).—Part 1 of this article describes methods of sampling and testing sand for use in concrete, and part 2 gives methods of reducing to useful form the laboratory and field data from such testing of samples.

Some tests on strength of overwet concrete (*Engin. News*, 71 (1914), No. 11, pp. 587, 588, fig. 1).—Data and curves of tests show the effect of variation in water content in concrete and the deleterious effect of using too much water.

Use of hydrated lime in concrete pavements, R. S. EDWARDS (*West. Engin.*, 4 (1914), No. 3, pp. 209–215; *Nat. Lime Manfrs. Assoc. Bul.* 1 (1914), pp. 12).—The author points out that small percentages of hydrated lime when added to concrete mixtures in road work will render the concrete highly plastic and homogeneous, thus producing density and uniformity in the finished concrete, will keep a certain amount of excess moisture in the concrete while setting, will render the concrete mass more nearly watertight, thereby preventing alternate wetting and drying of the finished concrete, and will reduce the labor of spreading and finishing.

Exterior plastering specifications (*Cement and Engin. News*, 26 (1914), No. 3, pp. 70–73, figs. 5).—These specifications include materials, preparation of mortar, structure, mortar coats, finish, and overcoating.

Modern practice in heating and ventilation, XIV, A. G. KING (*Dom. Engin.*, 66 (1914), No. 11, pp. 328–331, figs. 10).—Special fittings and devices for hot water circulation in domestic heating are described and suggestions given for their installation.

Handbook on sanitation, G. M. PRICE (*New York*, 1913, 3. ed., rewritten, pp. 353, figs. 25; *rev. in Sci. Amer.*, 110 (1914), No. 10, p. 212).—The first part of this book covers soil and sites, air, ventilation, heating, water supply, sewage disposal, and plumbing. The second part is devoted to sanitary practice and deals with the problems of housing, of trades and occupations, and of disinfection. The third part relates to sanitary inspection as a profession and includes calculations and tables.

The new public health, H. W. HILL (*Minneapolis, Minn.*, 1913, pp. VI+128; *rev. in Engin. News*, 71 (1914), No. 12, p. 646).—Public health as here considered relates almost wholly to communicable or infectious diseases. It is the aim to control these at the source, which is the infected person, by measures which will prevent infective material from escaping to other people. Among other topics, the author discusses under the general heading of "community defense," the public-health engineer, laboratory, and statistician.

Hygiene of rural, suburban, and summer homes (*Bd. Health Maine Circ.* 100, pp. 44, figs. 23).—This paper points out the essentials in the structure, arrangements, and surrounding of homes to insure their healthfulness, particularly referring to the requirements of farm and suburban houses and summer homes in the State of Maine. The discussion includes such topics as location for the home, relative position of the house and other buildings, relative arrangement of rooms, warming of houses, food supply, water supply, disposal of wastes, water carriage systems, and the typhoid fly.

A rapid method of determining the probability of decomposition occurring in a sewage effluent, E. S. STOKES (*Rpt. Austral. Assoc. Adv. Sci.*, 13 (1911), pp. 679–688).—The author describes tests, gives data of results, and concludes "that a very fair idea may be obtained as to the probability of decomposition occurring in a sewage effluent by calculating the ratio between the oxygen absorbed and the oxygen in nitrites and nitrates." This ratio he states can be worked out by the following formula: Decomposition factor = N (as N_2O_3) $\times 1.71 + N$ (as N_2O_5) $\times 2.86 \div$ oxygen absorbed in 4 hours. For a satisfactory effluent it is thought that this factor should exceed 0.7.

Lighting of medium sized and small towns and rural communities, H. STRACHE and F. EISLER (*Beleuchtung mittlerer und kleiner Städte und Ortschaften. Technische Praxis, Vienna and Leipsic*, 1913, pp. 234, figs. 23; *rev. in*

Gsndhts. Ingen., 37 (1914), No. 7, p. 127).—The authors deal with lighting by coal gas, electricity, gasoline, blau gas, water gas, acetylene, petroleum, and petroleum and alcohol incandescent lamps. The book is written for both the engineer and layman.

General discussion on conveniences in the home and on the farm, N. MONTEITH (*Ann. Rpt. Ontario Agr. and Expt. Union*, 34 (1912), pp. 79, 80).—Some general data are brought together.

RURAL ECONOMICS.

Factors of efficiency in farming, W. J. SPILLMAN (*U. S. Dept. Agr. Yearbook 1913*, pp. 93–108).—The author maintains that on farms that combine a large number of the following factors in production, the profits are greater than on those which are efficient in only a few: The size of the business, whether measured by area of land farmed, amount of working capital employed, or number of days of productive labor determines the size of the income. The system of management of the various factors of production should be such that there is no lost motion or useless work. The enterprises conducted should be adaptable to the local soil and climate, and also to the existing economic conditions. There must be an adequate income both per acre and per animal or the one may offset the other.

Data illustrating these various factors are presented and discussed.

Reorganizing the farm, J. M. JOHNSTON (*Bul. N. C. Dept. Agr.*, 35 (1914), No. 1, pp. 61–65).—The author by using census data computes for four counties the average size and area in crops and unimproved land per farm, as well as the average acreage cropped per work horse, and the number of days of horse labor per year. By a more extensive use of land already in farms and the working of the horses a greater number of days, the author estimates that the farmer's income could be greatly increased with only a small additional investment.

The organization of rural interests, T. N. CARVER (*U. S. Dept. Agr. Yearbook 1913*, pp. 239–258, figs. 8).—The author points out that the improved means of transportation, mechanical inventions, the passing away of common local interests, and the public land policy have tended toward a disorganization of the rural communities. Efforts at reorganization through mutual insurance companies, cooperative creameries and cheese factories, and cooperative elevators are graphically illustrated. It is maintained that the various scattered movements should be brought together by a permanent body, such as the Rural Organization Service. Organization is deemed especially essential in marketing operations, the development of credit facilities, and the protection of the farm home against disease. The method of procedure and principles to be observed are briefly discussed. In cooperative enterprises an accurate system of account keeping and auditing, and a desire to eliminate waste and inefficiency, must be maintained. Organization for marketing purposes calls for the improvement and standardizing of the products and the acquainting the consumer with the goods by a system of labeling. Some of the disadvantages of unnecessary credit to the farmer are pointed out, and it is stated that the function of the cooperative credit organization should be to furnish it only where it can be used to advantage.

An experiment in marketing under territorial auspices, E. V. WILCOX and A. T. LONGLEY (*Hawaii Sta. Press Bul.* 45 (1914), pp. 27).—The territorial marketing division established under the supervision of the station (E. S. R., 30, p. 600) is now handling about 150 shipments of farm products per month. It issues weekly lists of prices and of buyers and sellers of pure-bred stock and of

seeds, and by improving the methods of handling, grading, and packing farm produce has been able not only to increase the profits of farmers but to stimulate them to greater efforts along the lines of diversified agriculture. The consumer has been benefited by having a more even and better graded supply of farm produce. The requirements of the division in the future are noted. The demand, methods of preparing for market, and range of prices are given for a long list of farm produce adapted to Hawaii.

The farmers' cooperative exchange, A. E. CANCE (*Mass. Agr. Col., Ext. Serv. [Pub.], 1914, pp. 34*).—The author outlines the principles that should serve as a guide to farmers desiring to form cooperative societies for buying agricultural supplies or collecting, shipping, selling, storing, and manufacturing farm products. Among the essentials to success pointed out are that a given community should have sufficient material to do a cooperative business, that the cooperative area should be small, that the members be loyal and have but a single purpose in cooperating, that a good manager be employed and be given sufficient money to advertise and to do business on a cash basis, and that incorporation be on the principle of "one man one vote." He also calls attention to some of the possible fields of agricultural cooperation in New England and suggests forms that may be used in establishing cooperative exchanges.

Monographs on agricultural cooperation in various countries (*Inst. Internat. Agr. (Rome), Serv. Inst. Econ. et Soc., 2 (1914), pp. VII+238*).—This is a continuation of the monographs previously noted (E. S. R., 27, p. 590), and contains notes and statistics on the movement of agricultural cooperation in Argentina, the development and actual conditions of agricultural cooperation in Austria, agricultural cooperation in Hungary, Croatia and Slavonia, and Italy, and the organization of agriculture in Switzerland. Accompanying each section is a series of demographic and economic statistics and a bibliography.

Agricultural cooperation and rural credit in Europe.—Bibliography (*U. S. Senate, 63. Cong., 1. Sess., Doc. 214, pt. 2 (1913), pp. 79*).—This document contains a complete bibliography of the literature on the agricultural credit and cooperative systems of European countries collected by the American Commission (E. S. R., 30, p. 492).

How to use farm credit, T. N. CARVER (*U. S. Dept. Agr., Farmers' Bul. 593 (1914), pp. 14*).—The nature and use of capital are discussed, and it is pointed out that with the increase in the value of land and the use of machinery has arisen increased demand for credit or capital. Some of the important rules mentioned as to the use of credit are to make sure that the purpose for which the borrowed money is to be used will produce a return greater than needed to pay the debt, rather than merely pay living expenses, that the length of time a debt is to run has a close relation to the productive life of the improvement for which the money is borrowed, and that for long-time loans arrangements be made for gradual reduction of the principal.

Included in this publication are a series of amortization tables showing the annual payment necessary to pay off a debt of \$1,000 under varying rates of interest and periods of time.

The rural credit situation of the United States, H. MACPHERSON (*Oreg. Countryman, 6 (1914), No. 7, pp. 371-373*).—The author includes among the essentials necessary to afford the farmer proper credit facilities that the credit system should aim at service and not at dividends on stocks, and that it should have local banks with a central bank as a clearing house, a system of repayment on the amortization plan, an effective system of floating the bonds on farm mortgages, and a simplification of the present land registry system. The author points out some of the defects in pending legislation.

The problem of agricultural credit in Canada, H. MITCHELL (*Bul. Depts. History and Polit. and Econ. Sci., Queen's Univ. Canada, No. 10 (1914), pp. 24*).—The author describes the German *Landschaften*, the *Caisses Populaires* of Quebec, and the state government loans in Australia with a view of determining their adaptability to conditions in Saskatchewan. He concludes that the *Landschaft*, modified to suit local conditions, is the most adaptable of the three types mentioned.

Loans granted by the state bank on security of grain and the establishment of grain elevators in Russia (*Internat. Inst. Agr. [Rome], Mo. Bul. Econ. and Soc. Intel., 5 (1914), No. 3, pp. 85-94*).—The lack of funds or the means of obtaining credit formerly made it necessary for the Russian peasant to sell his grain immediately after harvest. Generally at this period of the year the condition of the grain market was very unfavorable. In 1885 banks were authorized to grant loans on grain stored in certain buildings designated by the bank. In 1894 the law was modified so that the peasant could borrow on his grain wherever it happened to be located, and whether thrashed or not. The rate of interest varied from 4½ to 6 per cent, and the loan was required to be repaid within 9 months. In 1896 the term of repayment was limited to 6 months and the granting of loans was somewhat restricted. In recent years the Government has made vigorous efforts to develop the loan business through the medium of the *zemstvos*, cooperative credit societies, private credit institutions, and railways. In 1910 it decided to establish a system of state elevators, and through those in charge of the elevators the rate of loans, the methods used in classifying grains, and the standards are established.

[Distribution of produce between landlord and tenant], E. JENNY (*Staats u. Soz. Wiss. Forsch., No. 171 (1913), pp. XVIII+346*).—The author discusses systems, history, legal status, elements, and social influence of the distribution of farm produce between landlord and tenant, and describes in detail the distribution on a large estate in Russia during the years 1891 to 1910. An extensive bibliography is included.

Agricultural distribution of land in different countries (*Inst. Internat. Agr. [Rome], Pub. Bur. Statis. Gén., No. 5 (1914), pp. IV+310*).—The total land surface is classified as productive and nonproductive, and the productive areas are further subdivided into arable land, natural meadows and pasture land, tree and shrub plantations, woods and forest, and marshes, moors, and uncultivated productive lands. For the arable land there are given the areas devoted to cereals, to grasses and forage crops, and to other arable land crops and fallows.

In addition to the summary tables showing data for 36 countries according to the classification outlined above, data are given for each country showing the area devoted to individual crops so far as the information is available.

Farm lands in New Jersey, F. DYE ET AL. (*Trenton, N. J.: State Bd. Agr., 1913, 2. ed., pp. 53, pls. 12*).—This report contains a detailed description by counties of the natural characteristics and systems of farming and the possible development of agriculture in this State.

Uses of land in Denmark, July 15, 1912 (*Danmarks Statis. Meddel., 44 (1912), No. 2, pp. 175*).—This report contains statistical data showing the areas devoted to the various kinds of farm crops by minor geographic divisions. For the larger geographic divisions comparative data are given for 1896 and 1907.

Agriculture in Argentina, I. G. J. VAN DEN BOSCH (*Dept. Landb., Nijv. en Handel [Netherlands], Verslag. en Meded. Dir. Landb., No. 1 (1914), pp. 140, pls. 13, fig. 1*).—This report contains discussions of the physical features, immigration, live stock, agricultural machinery, crops, dairy and meat industry, and trade of Argentina.

[*Agriculture in Guiana*], edited by A. LEECHMAN (In *Handbook Brit. Guiana, 1913, pp. 153-185, pls. 6*).—The chapter on agriculture gives a description of the methods used in producing sugar, rice, coconuts, cacao, coffee, rubber, and fruits.

Rural development in Burma, H. CLAYTON (*Rangoon, India, 1911, pp. II+IV+114*).—The author outlines briefly the cooperative methods employed by farmers in Europe for the purchase of supplies, sale of farm produce, insurance of live stock, and securing of credit, and the modifications necessary to meet rural conditions in Burma.

Country life conference addresses (Iowa State Col. Agr. Ext. Bul. 18, pp. 94, figs. 14).—Contained in this report are a series of addresses on the economic phases of country life, by T. N. Carver; social phases, by C. S. Adams; and religious phases, by C. S. Adams, W. Hints, and P. A. Johnson.

Solving the country church problem, G. A. BRICKER ET AL. (*Cincinnati and New York, 1913, pp. 296, pls. 2, figs. 60*).—This is a series of articles by 14 authors treating of the various phases of the country church problem.

The agricultural outlook (U. S. Dept. Agr., Farmers' Bul. 590 (1914), pp. 20, fig. 1).—It is estimated that during the past year the losses of live stock from disease and exposure were 7,005,000 hogs valued at \$73,000,000, 1,737,000 cattle valued at \$68,611,000, 2,124,000 sheep valued at \$8,531,000, and 523,000 horses valued at \$59,100,000. It is shown that the monthly variation in the number of sheep and hogs is subject to greater fluctuation than the number of cattle. Directions are included for the use of anti-hog-cholera serum.

Statistics are given showing for Louisiana the cane production for 1911, 1912, and 1913, the condition of the principal crops in Florida and California, and for all the States the condition of winter wheat and rye on April 1, 1913, and 1914, the condition of the various kinds of live stock on the same dates, the estimated losses for the year ended March 31, 1914, and other statistical data relating to prices of agricultural products.

The agricultural outlook (U. S. Dept. Agr., Farmers' Bul. 598 (1914), pp. 21).—This number contains estimates of the conditions on May 1, 1914, of winter wheat, rye, hay, pasture, and honeybees, of the wheat fed to live stock, of the progress of spring plowing and planting, and of the prices of farm products. These estimates are shown by States and with comparative data for earlier years. The production of beet sugar, the sources of sugar supply of the United States, and the production of sugar in Hawaii are shown for 1913 and earlier years. A revised estimate of the acreage and yield of cotton for 1913 and data as to condition of crops in California and Florida are included.

Acreage and live stock returns of England and Wales, with summaries for the United Kingdom, R. H. REW (*Bd. Agr. and Fisheries [London], Agr. Statis., 48 (1913), No. 1, pp. 119*).—This report contains statistics showing the acreage devoted to the principal crops and the number of live stock by counties for 1912 and 1913, by minor subdivisions for 1913, and for England and Wales, Great Britain, and the United Kingdom for 1884 to 1913.

The number of holdings by sizes is given for 1913 by counties and minor subdivisions. Between 1895 and 1913 the number of holdings in England and Wales above 1 and not exceeding 5 acres decreased from 97,818 to 92,302; those above 5 and not exceeding 20 acres increased from 126,714 to 122,117; those above 20 and not exceeding 50 acres from 74,846 to 78,027; those above 50 and not exceeding 100 acres from 56,791 to 59,287; those above 100 and not exceeding 200 acres from 68,277 to 69,431; while those above 300 acres decreased from 16,021 to 14,513.

Agricultural statistics of Netherlands (Jaarc. Konink, Nederlanden, Rijk Europe, 1912, pp. 172-183).—Contained in this report are statistical data show-

ing for 1910 the subdivision of the total land area according to agricultural uses and number of exploitations by sizes and by types of tenure. The area and production of the principal farm crops are shown for 1898-1912 and the number of live stock for 1891-1910.

World production of cereals in 1913 (*Pub. Min. Roy. Hongrois Agr., No. 2 (1914), pp. 318*).—This publication gives the area, production, and imports and exports of cereals for practically all the countries of the world. For many countries the same information is given for other agricultural products.

Statistics of consumption of cotton, A. SCHMIDT (*Internat. Fed. Master Cotton Spinners' and Manfrs. Assocs. [Pub.], 1913, pp. 23*).—Contained in this report are statistical data showing the consumption of cotton in all countries of the world and the stocks on hand August 31, 1906 to 1913. The number of cotton spinning spindles and the visible supply are also given for 1913.

AGRICULTURAL EDUCATION.

Proposals to bring about a uniformity in the methods of instruction in the lower agricultural schools with special reference to schools for vine growers, M. ARTHOLD (*Land u. Forstw. Unterrichts Ztg., 27 (1913), No. 3-4, pp. 182-189*).—The functions of the various categories of agricultural schools for the training of farmers' sons are discussed. In the author's opinion it would be more feasible to improve existing schools than to replace them by new organizations. Their apparent inadequacy in some respects can be traced largely to the small attendance of many of the schools, which, however, is not the fault of the school system but due rather to other circumstances such as a lack of knowledge on the part of the people concerning the functions of the schools and the value of technical training, unsatisfactory labor relations, etc. The best remedy suggested for this is an untiring itinerant instruction and an active contact with the rural population. The author suggests that the utility of a school does not depend entirely on its organization but also on its management, and points out the desirability of the performance of practical work by students, of examinations to control their progress, and of the supervision of the instructors by the director or an inspector.

[Reports of German horticultural institutions for 1912] (*Landw. Jahrb., 45 (1913), Ergänzungsbd. 1, pp. 147+235+158, pl. 1, figs. 111*).—This number consists of the annual reports for 1912 of the royal horticultural institutions at Dahlem, Geisenheim, and Proskau.

The rural agricultural and housekeeping school at Mährisch-Schönberg, K. KOLB (*Land u. Forstw. Unterrichts Ztg., 27 (1913), No. 3-4, pp. 169-174*).—A description is given of the buildings, equipment, and 1-year course of instruction of this school which was opened October 1, 1913, in connection with the Farm and Flax Preparation School.

[Agricultural and forestry instruction in Austria and other countries] (*Land u. Forstw. Unterrichts Ztg., 27 (1913), No. 3-4, pp. V+169-308, figs. 4*).—This number contains special articles noted elsewhere, an account of the Second International Congress of Home Training at Ghent (see p. 393), and a review of agricultural literature and of the activities of agricultural and forestry education institutions in Austria in 1912-13, as summarized from their annual reports.

Some agricultural education institutions in Hungary and the Balkan States, L. MERKOS (*Land u. Forstw. Unterrichts Ztg., 27 (1913), No. 3-4, pp. 222-237*).—An account is given of the organization, equipment, curriculum, and work of the following institutions visited by the author: Royal Hungarian Cellarers' School at Budafok, near Budapest; Royal Hungarian Ampelograph-

ical Institute, at Budapest; Horticultural and Viticultural School, Bukovo, near Negotin, Servia; Horticultural and Viticultural School at Plevna, Bulgaria; Intermediate Agricultural School, Obrassof-Tschiflick, near Rustchuk, Bulgaria; Chemical Agricultural Experiment and Seed Control Station, Bucharest, Roumania; Agricultural High School, Herastran, near Bucharest; and Farm Horticultural and Viticultural School, Mediasch, Hungary.

Reforms in agricultural education in the Kingdom of Servia (*Land u. Forstw. Unterrichts Ztg.*, 27 (1913), No. 3-4, pp. 238, 239).—This is a summary of proposed reforms in agricultural education in Servia, including the introduction of agricultural instruction into normal schools, teacher training institutes, and theological seminaries, to be obligatory in the first-named, the establishment of 17 lower agricultural schools in place of existing agricultural stations, the establishment of a higher agricultural school, and the appointment of 79 itinerant agricultural instructors and 5 agricultural inspectors.

The Woodlawn school garden, ALICE V. JOYCE (*Nature-Study Rev.*, 10 (1914), No. 2, pp. 61-65, figs. 3).—The garden work of the Woodlawn school is described by grades. Each teacher is given a section in which each of her pupils has an individual plat. The last year there were 585 individual plats, those for the primary grades being 5 by 8 ft. and those for the intermediate and grammar grades 8 by 10 ft.

Lebanon County boys' agricultural and girls' domestic science clubs, J. W. SNOKE (*Lebanon Co. [Penn.] Boys' Agr. and Girls' Dom. Sci. Clubs Circ.* 2 (1914), pp. 16).—The objects and plans of work of these clubs in corn and potato growing, fruit canning, bread making, sewing, and vegetable growing contests and the exhibition of products are outlined.

Industrial clubs and contests for Oregon boys and girls (*Oreg. Agr. Col. Buls.*, 1914, Nos. 97, pp. 12; 98, pp. 16; 109, pp. 8, figs. 13; 110, pp. 4, figs. 5; 112, pp. 11, figs. 5).—These bulletins describe respectively (1) the organization of junior club work, by F. L. Griffin, (2) rules governing each of the 10 approved projects for 1914, by F. L. Griffin, (3) directions for making the Babcock test and keeping the records, by W. A. Barr, (4) a suggested list of tools and materials for the manual arts contest, by H. C. Brandon, and (5) hotbeds and cold frames for the gardener in the vegetable gardening contests.

The country home (*Proc. Conf. Ed. South*, 16 (1913), pp. 66, 85-96).—Problems of the country home were discussed as a part of the 1913 conference on the education of women in the country. The papers presented included *How to Relieve the Drudgery of Women on the Farm*, by J. Cook; *Home Economics and Help for the Home Maker*, by B. R. Andrews; *Home Economics, or Help for the Home Manager—What Domestic Science is Aiming to Accomplish by Developing Instruction as to Food, Clothing, Shelter, and Home Management*, by Isabel E. Lord; *The Department of Agriculture and Its Work for the Home*, by C. F. Langworthy; *Social Life in the Country for Women*, by Mrs. M. C. Roark; and *The Awakening of Farm Women*, by Mrs. W. N. Hutt.

The Second International Congress of Home Training at Ghent, IDA SCHUPPLI (*Land u. Forstw. Unterrichts Ztg.*, 27 (1913), No. 3-4, pp. 211-221).—An account is given of the proceedings and resolutions of the sections of the congress with reference to the following topics: (1) Home economics instruction in the elementary school or in connection with it in cities, industrial centers, and rural communities; (2) home economics instruction for adults or in connection with the intermediate school; (3) the training of teachers of home economics; and (4) literature, progress made since the Freiburg congress, and the importance of instruction in home economics in its social relations.

Lesson exercises, C. A. STEBBINS (*Univ. Cal. Syllabus Ser., No. 34 (1912)*, pp. 32, figs. 33).—Twenty-one lessons on the soil and its origin, water and soil, the seed and its needs, propagation of plants, roots, stems, leaves, flowers, fertilizers, weeds, insects, birds, plant diseases, and trees, are outlined.

Field trips in elementary agriculture (*W. Va. School Agr., 4 (1913), No. 1*, pp. 19, figs. 10).—As a means of securing correlation between the schoolroom and the community, outlines for four field trips are presented for the purpose of studying soil formation, forest trees, and insects. Directions for preserving weed specimens and mounting twigs and insects are included.

Collection and preservation of plant material for use in the study of agriculture, H. B. DERR and C. H. LANE (*U. S. Dept. Agr., Farmers' Bul. 586*, pp. 24, figs. 16).—Methods of collecting, preparing, mounting, and preserving plant specimens of various sorts are suggested for the use of teachers of agriculture.

Outline of work in agriculture, domestic science, and manual training (*Cicero, Ind., 1913*, pp. 19, figs. 4).—This is an outline of instruction in agriculture in the high schools of Jackson township, Hamilton County, Ind., and in domestic science and art, manual training as related to the farm, and mechanical drawing in grades five to eight, inclusive, and the high schools.

[Reading courses in agriculture and home economics] (*Cornell Reading Courses, 2 (1913), Nos. 39, pp. 153-184, figs. 16; 41, pp. 185-196; 43, pp. 197-208, figs. 6; 45, pp. 209-218; 47, pp. 221-228, figs. 4; 3 (1913), Nos. 49, pp. 47, figs. 27; 51, pp. 49-72, figs. 28; 54, pp. 45-64, figs. 11; 55, pp. 85-103, figs. 10; 56, pp. 65-95, figs. 15; 58, pp. 97-116, figs. 19*).—These numbers treat of the following subjects: The Farmhouse, by Helen B. Young; Rules for Planning the Family Dietary, by Flora Rose; The Box Luncheon, by Clara W. Browning; Hints on Choosing Textiles, by Bertha E. Titsworth; A Canning Business for the Farm Home, by Claribel Nye and Bessie Earll Austin; Household Insects and Methods of Control, by G. W. Herrick; A Story of Certain Table Furnishings, by Clara W. Browning and Edith J. Munsell; The Dairy Herd, by H. H. Wing; Rice and Rice Cookery, by Miriam Birdseye; Practical Horse-Breeding, by M. W. Harper; and Planting the Home Vegetable Garden, by A. E. Wilkinson.

Seasonable suggestions, S. A. MINEAR (*Rural Educator, 3 (1914), No. 3*, pp. 48, 49).—Directions are given for testing seed corn and making a school garden.

Testing seed corn, A. L. SMITH (*Iowa Agr., 14 (1914), No. 7*, pp. 363, 364, fig. 1).—Directions are given for three lessons in testing seed corn, viz, making the testing box, filling the box, and reading the test.

Testing seed corn in rural schools, AUGUSTA D. EVANS (*Ill. Agr., 18 (1914), No. 6*, pp. 343-346, figs. 2).—The author points out the value of seed corn testing and gives directions for making a germination box, preparing the corn for the tester, reading and recording the test, and making a record blank for community testing.

Modern fruit growing, W. WILDEN (*Neuzeitlicher Obstbau, M[ünchen] Gladbach, Germany [1913]*, pp. 96, figs. 24).—This is a text and reference book in modern fruit growing for self-instruction and use in seminaries and agricultural schools.

A field lesson on the fuel woods of the farm, J. G. NEEDHAM (*Nature-Study Rev., 9 (1913), No. 9*, pp. 282-290, figs. 5).—A consideration of the fuel value of different kinds of woods is followed by an outline for the study of the fuel woods of the farm in which fuel stuffs are gathered from the woodlot and tested in fire making.

The question of the introduction of instruction in fire extinguishing in the lower agricultural schools (*Land u. Forstw. Unterrichts Ztg., 27 (1913)*,

No. 3-4, pp. 206-210).—The author suggests a plan for the introduction of instruction in fire extinguishing into the lower agricultural schools of Austria and outlines a course in this subject.

Expedients in giving instruction in plant protection, G. KÖCK (*Land u. Forstw. Unterrichts Ztg.*, 27 (1913), No. 3-4, pp. 175-181, figs. 4).—In this discussion of the use of illustrative material in instruction in modern plant protection, the author points out the requisites of an efficient wall chart; and describes and illustrates a phytopathological chart showing the injuries by the grape leaf roller (*Cochylis ambiguella*) and methods of combating it, issued by L. Fulmek. Attention is called to the importance of the use of the sciopticon and of biological exhibits illustrating the progress of diseases or injury and of different stages of development of the pest. Seventeen cases of such exhibits have been prepared in recent years by K. Kafka of the Biological Institute of Vienna.

High school entomology (*Agr. Student*, 20 (1914), No. 7, pp. 529-531, figs. 2).—The author calls attention to the economic importance of insects to the farmer, gives directions for making collections, and recommends classifying and studying the insects not according to scientific orders but according to their characteristics, such as parasitic, predacious, beneficial, injurious, herbivorous, etc.

Exercises in farm dairying, C. LARSEN (*New York*, [1913], pp. [75], fig. 1).—This is an elementary loose leaf field and laboratory manual for agricultural high schools and colleges and a practical guide for farmers and dairymen.

Educational school gardening and handwork, G. W. S. BREWER (*Cambridge, England*, 1913, pp. XI+192, figs. 71).—The author considers the aims and ideas that should underlie school gardening, and outlines a method of teaching the subject by which the pupil takes up the suggestions of the teacher, but develops ideas, discovers facts, and forms judgments for himself. The object of the author seems to be the promotion of character building by training boys in habits of industry, cooperation, and broad scientific outlook. Directions are given for making school gardens; correlating the work with drawing, composition, nature study, cookery, arithmetic, and wood and metal work; keeping records; making a school museum; experimental work in the garden; beautifying school buildings and grounds; caring for tools; preparing exhibits; and teaching gardening in evening continuation schools. Lists of suggestive questions and helpful books are added.

Suggestions for teaching nature study, M. J. ABBEY (*W. Va. School Agr.*, 4 (1913), No. 11, pp. 32, figs. 7).—These suggestions are intended as a guide to the selection of subject matter and methods of presenting it. Type lessons on a study of the cow, the weather, preparation of nature for winter, clothing, the heavens, insects, and fur bearing animals are included.

Nature study in secondary schools, C. DRIEBERG (*Trop. Agr. [Ceylon]*, 42 (1914), No. 1, pp. 79-82).—The author discusses the objects of nature study, the style of teaching it, the object of the school garden as a field for nature study, and the range of general knowledge it is best to gain by nature study in association with the school garden. He recommends that a syllabus dealing with the facts and phenomena of common experience, adapted to the seasons and conforming to local conditions for a junior as well as a senior course of nature study, be prepared for the use of teachers, and that pupils complete this course at about the age of 12 years, go on to a 3-year course of experimental science proper in chemistry, physics, and biology, and then specialize in any one or two branches of science according to the future career decided upon.

Arbor and Bird Day manual for use in West Virginia public schools (*W. Va. School Agr.*, 4 (1914), No. 3, pp. 58, figs. 28).—Programs, lessons, and

general suggestions are given for the observation of Arbor and Bird Day on April 3, 1914, in the West Virginia schools.

Planning and adorning the farmstead and school grounds (*Columbus, Ohio: Supt. Pub. Instr., 1913, pp. 36, figs. 13*).—This bulletin, which is intended for seventh and eighth grade and high school pupils of all village and rural schools of Ohio and persons interested in farm and school improvements, offers suggestions for planning and adorning school grounds, homes, and farms.

Back to the farm, M. H. SHUMWAY (*Bul. Univ. Minn., Gen. Ser., No. 12 (1914), pp. 45, figs. 8*).—This play in three acts is intended to illustrate the value of a collegiate agricultural education to the farmer.

MISCELLANEOUS.

Yearbook of the Department of Agriculture, 1913 (*U. S. Dept. Agr. Yearbook 1913, pp. 541, pls. 54, figs. 21*).—This contains the report of the Secretary of Agriculture, previously noted (*E. S. R., 31, p. 195*); 14 special articles abstracted elsewhere in this issue; and an appendix combining a directory of the agricultural colleges and experiment stations and the state officials in charge of agricultural work, and statistics of the principal crops, farm animals and their products, the federal meat inspection, prices of meat in the United States and Europe, legal standards for dairy products, agricultural statistics from the census of 1910, imports and exports of agricultural products, and imports of pure-bred animals.

Thirty-seventh Annual Report of Connecticut State Station, 1913 (*Connecticut State Sta. Rpt. 1913, pp. XVIII*).—This contains the organization list, a report of the board of control, a financial statement for the fiscal year ended September 30, 1913, and a list of corrections to the report.

Twenty-sixth Annual Report of Illinois Station, 1913 (*Illinois Sta. Rpt. 1913, pp. 12*).—This contains the organization list, a financial statement for the fiscal year ended June 30, 1913, brief notes as to additional equipment, and a list of the publications issued during the year.

Twenty-fourth Annual Report of Kentucky Station, 1911 (*Kentucky Sta. Rpt. 1911, pp. XVIII+355, pls. 2, figs. 4*).—This contains the organization list, a financial statement for the fiscal year ended June 30, 1911, a report of the director on the work of the station during the year, reprints of Bulletins 153-158, previously noted, and reports of analyses of mineral waters and meteorological data, abstracted elsewhere in this issue.

Biennial Report of the Director of the Kentucky Station, 1911-1913, J. H. KASTLE (*Kentucky Sta., Bien. Rpt. Dir., 1911-1913, pp. 57, pl. 1, figs. 7*).—This contains the organization list, a list of publications, and a review of the work of the station for the biennium ended June 30, 1913.

Report of the director for the year ending June 30, 1913, F. B. MUMFORD (*Missouri Sta. Bul. 117 (1914), pp. 401-443*).—This contains the organization list, a report of the director on the work and publications of the Missouri Station, including reports of heads of departments, the experimental features of which are for the most part abstracted elsewhere in this issue, and a financial statement for the fiscal year ended June 30, 1913.

Health laws, F. G. CAFFEY (*U. S. Dept. Agr. Yearbook 1913, pp. 125-134*).—This article briefly describes the Food and Drugs Act, Meat Inspection Act, and other health laws administered by the Department, and discusses the need for the exercise of powers by the States.

NOTES.

Arizona University and Station.—Ground was broken July 31 for the new agricultural building which is to cost about \$165,000. The structure will include office and laboratory room for all departments of the station work, for college class work in agriculture, and for extension work. By an ingenious utilization of the patio, or inner court, of the building, audience room is provided for about 1,600 people. It is expected that the building will be completed in July, 1915.

A new farm of 160 acres has been purchased for the station in Salt River Valley at a cost of \$30,000. This farm is expected to afford suitable facilities for experimental work in this representative irrigated district.

Recent appointments include G. W. Barnes as farm adviser in the extension service; W. S. Cunningham, assistant in animal husbandry and dairying at the New Mexico Station, as assistant animal husbandman in the college and station; and Stephen B. Johnson as assistant horticulturist in the college and station.

California University and Station.—A. V. Stubenrauch, in charge of the horticultural and pomological investigations of this Department, has been appointed head of the new division of pomology.

Connecticut College.—A Country Life Conference was held for 3 weeks beginning July 13. The first week was devoted to rural leadership, with conferences of rural ministers, business men, and others. Subsequently, meetings were held by the State Forestry Association, Botanical Club, Pomological Society, Vegetable Growers' Association, Bee Keepers' Association, Farm Managers' and Sheep Breeders' Associations, Dairymen's Association, and Poultry Association.

Connecticut State Station.—H. F. Huber, a graduate of the New Jersey College, has been appointed specialist in market gardening.

Georgia Station.—The legislature recently appropriated \$2,500 to be used for buildings and repairs. This action is encouraging as it is the first money appropriated for the station by the State for over 20 years.

Iowa College and Station.—A plant industry building of the same general type of architecture as the hall of agriculture is under construction. One of its wings is to be a plant laboratory for work in truck crops, floriculture, landscape gardening, and general horticulture. This laboratory is to consist of a cellar containing a cold-storage room for cut flowers, truck crops, and pomology, and rooms for the storage of greenhouse supplies, bulbs, roots, etc.; a basement with three plant propagation laboratories and a packing and shipping room; a main floor with offices, a large truck-crop laboratory and smaller recitation rooms, etc.; and a first floor with offices for the station staff in truck crops and pomology, drafting rooms, and a research laboratory. This laboratory building is expected to be ready for occupancy at the beginning of the second semester.

Immediately adjoining it is being built a range of greenhouses, covering about one-half acre. Eventually there will be ten of these houses, six being 25 by 75 feet, three 25 by 150 feet, and one 25 by 150 feet with a palm house 50 by 30 feet. Eight of these houses are already nearly completed.

Harlan B. Munger, assistant in farm cost accounting in the farm management investigations of this Department, has been appointed professor of farm management in the college and chief in farm management in the station.

Kansas College.—Rev. Walter Burr, of Louisville, Kans., has been appointed director of the rural service department in the extension division beginning about August 1. Otis Earle Hall, a graduate of Wabash College and for the past 8 years a county superintendent of schools in Indiana, has been appointed supervisor of boys' and girls' club work beginning September 1.

Kentucky University.—A demonstration of machinery suitable for preparing agricultural lime was held during the week of June 22, with addresses on soil fertility and the use of lime in agriculture.

Massachusetts College.—Prof. George F. Mills has been made dean emeritus and E. M. Lewis dean of the college. R. J. Watts has been appointed secretary. Miss Helena T. Goessmann has been appointed instructor in languages and literature and will offer a course on rural literature which, it is believed, is not given elsewhere.

Minnesota University and Station.—A week's conference of teachers of agriculture and home economics was held June 20-25, with special instruction by members of the college faculty during the morning and conferences regarding work in the high schools in the afternoon. The first Country Life Conference to be held in the State took place the following week, with special attention to the problems of rural ministers, social workers, and others interested in rural social welfare.

W. F. Lusk has been appointed assistant professor of agricultural engineering beginning August 1, Dr. Howard C. Kernkamp assistant veterinarian in the station, and Mary G. Blythe instructor in clothing in the school of agriculture.

Nebraska University and Station.—R. K. Bliss has resigned as professor of animal husbandry and animal husbandman to become director of the agricultural extension service of the Iowa College.

New Hampshire Station.—J. B. Scherrer has been appointed vegetable gardener.

New Jersey College and Stations.—The new agricultural building has been completed. It will house the departments of botany, plant pathology, soil fertility, extension teaching, horticulture, and seed testing.

The station poultry department has been assigned an area of about 20 acres of land which will be developed for experimental work in poultry husbandry.

A number of research fellowships have been recently established by industrial concerns, among them the Chilean Nitrate Propaganda, and others are anticipated. Thomas A. Edison has also provided an industrial fellowship for the study of ground limestone as a factor in soil improvement. Nicholas Kopeloff and R. C. Cook have been appointed research fellows under two of these grants.

Among other recent appointments are the following: Clarence E. Brett as instructor in poultry husbandry; Frank App, assistant professor of agronomy and assistant agronomist at the New Hampshire College and Station, as assistant professor of agronomy; and Miss M. Anna Houser and C. M. Arthur in charge of extension work in home economics and marketing respectively. Ward C. Pelton, in charge of extension work in market gardening, has resigned

to accept a position at the Delaware College and Station. Arthur J. Farley has been transferred from extension work to an instructorship in horticulture, Warren W. Oley from research to extension work in the same subject, and Alexis L. Clark from extension work to become an assistant state leader in extension work.

Cornell University.—The equipment of the college of agriculture is being augmented by the addition of new buildings for work in soils and animal husbandry, which are approaching completion. The soils building, for which \$100,000 was available, will house the teaching and investigational activities of the department of soil technology. The animal husbandry building provides about 37 rooms for the department of animal husbandry and costs about \$91,000. In connection with this building is a large stock-judging pavilion 160 by 80 feet, accommodating about 500 people.

The summer school of agriculture secured an enrollment of about 360. Several new courses were offered for the special benefit of those teaching agriculture.

The department of home economics is cooperating with various communities in organizing local canning clubs among farm women. These clubs aim to promote a knowledge of the possibilities of canning as a profitable addition to the activities of the farm.

Ohio State University.—The former department of agronomy has been divided by the establishment of a department of agricultural engineering, with H. C. Ramsower in charge and F. W. Ives as instructor. A. G. McCall has been granted a year's leave of absence, during which time George Livingston will be acting head of the department of agronomy, with instruction work in charge of Forrest Semple. M. F. Abel has been appointed graduate assistant in field crops.

Recent promotions include Dr. J. F. Lyman, D. J. Kays, and Vernon H. Davis as professors of agricultural chemistry, animal husbandry, and horticulture respectively. L. M. Montgomery has been made professor of horticulture, and Miss Minna C. Denton professor of home economics. J. R. Wiley and Gilbert Gusler of the department of animal husbandry, W. G. Stover of the department of botany, and R. B. Stoltz and W. L. Clevenger of the dairy department, have been appointed assistant professors. A professorship of farm management in the rural economics department has been established.

C. S. Wheeler has been appointed in charge of agricultural extension work in public schools, vice A. B. Graham resigned to become head of the newly established New York State School of Agriculture on Long Island.

The first Country Life Week was held beginning August 10, with special attention to the needs of rural ministers.

Oregon College and Station.—Recent important additions have been made to the dairy and live stock herds with a view to strengthening both the instruction and experimental work of these departments. It is announced that a pure-bred herd of the four principal dairy breeds is to be built up as rapidly as possible.

Extension work in dairying has been separated from that in live stock and remains under the direct charge of E. B. Fitts. Ralph McBurney, instructor in chemistry in the Oklahoma Station, has been appointed instructor in bacteriology, and Leroy Childs research assistant in entomology.

Pennsylvania College and Station.—H. P. Davis, instructor in dairy husbandry and assistant experimentalist, has resigned to accept a position with the Dairy Division of this Department.

West Virginia University.—President Thomas E. Hodges resigned August 1 to become a candidate for Congressman at Large. Dr. Frank B. Trotter, dean of the college of arts, has been appointed acting president.

G. L. Oliver has been appointed extension instructor in dairying in cooperation with the Dairy Division of this Department. C. L. Hartley has been appointed assistant to the director in agricultural extension.

Agricultural Grants of the General Education Board.—*The Journal of Education* announces that at the spring meeting of the board appropriations aggregating \$1,400,000 were allotted. Among the items were \$36,500 for the maintenance of rural school supervision in the Southern States, \$20,000 for farm demonstration work in six counties in Maine, \$10,000 for similar work in New Hampshire, and \$50,000 for rural school agents to work in connection with state departments of education in 15 States.

Spanish Railways and Agriculture.—A Spanish railway in the Province of Soria, to improve agricultural conditions, has provided its stations with small agricultural museums supplied with various kinds of useful information, such as formulas for fertilizers and their use, methods of buying fertilizing material, addresses of houses selling machinery, seeds, plants, live stock, etc., directions for organizing agricultural societies, the manner of soliciting appropriations from the central government, construction of district roads, and details of different industries which might be introduced with success in the province. Experiment fields showing how to use fertilizers have been established near the different stations by the Central Experiment Station Service of Madrid, and lectures given on their proper use. Demonstrations of agricultural machinery have been made by local agents of manufacturers. As a result Soria has been making noteworthy progress in agriculture.

Agricultural Education in India.—The American Presbyterian Mission is acquiring 53 acres near Allahabad to establish a fully equipped agricultural department for experimental work in connection with the Ewing Christian College at Allahabad. It will be in charge of Samuel Higginbottom, an American missionary, who has already introduced numerous important improvements in agricultural methods among native farmers near Allahabad.

Miscellaneous.—Peter Waite, of Adelaide, has given to the University of Adelaide his house and grounds at Urrbrae, embracing an area of 134 acres, half of the land to be available for the university for agricultural and kindred subjects and the balance as a public park under its control. He has also given to the government of South Australia 114 acres adjoining Urrbrae for the establishment of an agricultural high school.

Officers in the department of rural and agricultural education of the National Education Association were chosen at the St. Paul meeting July 4-11 as follows: President, E. C. Bishop, of the Iowa College; vice president, M. J. Abbey, of the West Virginia University; and secretary, F. L. Griffin, of the Oregon College.

The Italian minister of agriculture has recently authorized the transformation of the Royal School of Agriculture, at S. Ilario Ligure, into a colonial agricultural school with a 3-year course for the training of students in practical farming in the Italian colonies.

Leonard S. Klinck, professor of cereal husbandry at MacDonald College, has been appointed dean of the College of Agriculture of the British Columbia University, now in process of establishment.

EXPERIMENT STATION RECORD.

CONTENTS OF VOL. XXXI, NO. 5.

Editorial notes:	Page.
The United States and Canadian commissions on vocational training and some of their conclusions as to agricultural education.....	401
Recent work in agricultural science.....	407
Notes.....	496

SUBJECT LIST OF ABSTRACTS.

AGRICULTURAL CHEMISTRY—AGROTECHNY.

A report of chemical investigations on the lime-sulphur spray, Tartar.....	407
Reaction between sulphur and potassium hydroxid in aqueous solution, Tartar.....	409
On the valuation of lime-sulphur as an insecticide, Tartar.....	409
Soluble arsenic in mixtures of lead arsenate and soap, Tartar and Bundy.....	409
The present status of the synthesis of plant alkaloids, Bauer.....	409
Solubility of casein in dilute acids, Van Slyke and Winter.....	409
A contribution to the history of corn sugar, De Vilmorin and Levallois.....	409
The chemistry of gums and mucin substances, Schirmer.....	409
In regard to a uniform nomenclature for ferments, Giaja.....	409
Existence of three types of proteolytic vegetable ferments in latexes, Gerber..	409
The lipases of a latex, Gerber.....	410
The rennet of the latex of <i>Calotropis procera</i> , Gerber and Flourens.....	410
In regard to the nature of amylases, Kamecki.....	410
In regard to invertase, I, II, Meisenheimer, Gambarjan, and Semper.....	410
The preparation of neutral ammonium citrate solution, Rudnick and Latshaw..	410
Determination of citric acid-soluble phosphoric acid in Thomas slag, Hausssding.	410
Winkler's method for oxygen in water; effect of nitrite, Hale and Melia.....	411
Estimation of starch and dextrin in sugar products, etc., Auguet.....	412

	Page.
Determination of quercetin in wine, von Fellenberg.....	412
Estimation of the bromin absorption of wines, von Fellenberg.....	412
Practicum of milk chemistry, von Sobbe.....	413
A new method for proteins in milk, De Graaff and Schaap.....	413
Determining fermenting capacity of feeding stuffs, milk, and galactase, Rosam.....	413
The determination of nitrobenzol in peanut oil, Lucas.....	413
Determination of total formaldehyde, Hinman, jr.....	414
The thermal figure of oil of turpentine, Grimaldi and Prussia.....	414
Loganberry by-products, Lewis and Brown.....	414

METEOROLOGY—WATER.

Agricultural meteorology, Stupart.....	415
Comparative agricultural and forestry meteorology, Cuif.....	415
Climatological data for the United States by sections.....	415
Meteorological observations at Massachusetts Station, Ostrander et al.....	415
Meteorological observations, 1913.....	416
Temperature records, Thompson.....	416
American temperatures and European rainfall, Humphreys.....	416
Chemical composition of rain in the Union of South Africa, Juritz.....	416
Electrical hail protection, Angot.....	416
Studies in water supply, Houston.....	416
The utilization of sewage in agriculture, Grossmann.....	417
Sewage disposal, Fowler.....	417
Sewage irrigation and disease organisms, Ciocalteu.....	417

SOILS—FERTILIZERS.

Report of international commission for the examination of soil, Schucht.....	417
New classification of granulation products in mechanical analysis, Kopecky.....	418
Vegetation and agricultural soil, De Angelis d'Ossat.....	418
The radio-activity of some type soils of the United States, Moore.....	418
Olifants River irrigation scheme.—Agricultural survey of the soils, Juritz.....	418
Pakihi lands: Note on their treatment, Aston.....	419
The storage and use of soil moisture, Burr.....	419
Mineral acid soils, Loew.....	419
Some notes on soil protozoa, Martin and Lewin.....	420
Ammonification and nitrification in soil and solution, Lohnis and Green.....	420
Absence of nitrate formation in cultures of Azotobacter, Kellerman, and Smith.....	421
Fertilizers in relation to soils and crop production, Harcourt and Gibson.....	421
Manurial requirements, McConnell.....	421
Inefficiency of fertilizers in dry farming regions, Couston and Garrigues.....	421
Fertilizer experiments in the German colonies.....	421
The plant food content of liquid manure, Liechti and Truninger.....	421
Escape of ammonia from soil treated with liquid manure, Liechti and Ritter.....	421
Sodium nitrate <i>v.</i> ammonium sulphate, Pošpíšil.....	422
Experiments with sulphate containing sulphocyanid, Stutzer and Goy.....	422
Mixing lime nitrogen with Thomas slag and kainit, Gerlach and Tiedemann.....	422
Effects of ensilage on solubility of floats, Forbes and Fritz.....	422
The production of phosphate rock in 1913, Phalen.....	422
The fertilizing value of phonolite, Neumann.....	423
Potash salts and other salines in the Great Basin region, Young.....	423
A plea for the increased use of lime, Hendrick.....	424
Agricultural lime analyses.....	424
Sulphur fertilizer for alfalfa, Reimer.....	424
The world's production and consumption of chemical fertilizers.....	424
State fertilizer tonnage.....	424

AGRICULTURAL BOTANY.

Plants and their uses, an introduction to botany, Sargent.....	425
Some honey plants of Guam, Thompson.....	425
Some new tuberous species of Solanum, Wittmack.....	425
A study of the vegetation of the sand hills of Nebraska, Pool.....	425
Sand plants on lime soils, Büsgen.....	425
A study of nutrient solutions for plant cultures, Tottingham.....	425
The functions of nutritive materials in higher plants, Faack.....	426

	Page.
A review of recent investigations on the mineral nutrition of fungi, Dox.....	426
The carbon nutrition of plants, Ravin.....	426
Formation of anthocyanin in flowers of <i>Cobæa scandens</i> , Rosé.....	427
Physico-chemical properties of vegetable saps, II, Harris and Gortner.....	427
A review of Willstätter's researches on chlorophyll, West.....	427
Study of the constitution of plastids, Buscalioni.....	427
Reply to Kostytschew's articles on respiration of wheat seedlings, Zaleski.....	427
The action of anodic and cathodic solutions on germination, Micheels.....	427
The application of electricity to plant production, Priestley.....	428

FIELD CROPS.

Irrigation and manuring studies, Harris.....	428
Minor dry-land crops at the Nephi Experiment Farm, Cardon.....	429
The Clermont County experiment farm.....	430
The Miami County experiment farm.....	430
The Paulding County experiment farm.....	430
Report on grass-seed mixtures, 1907-1913, Findlay.....	430
Fodder grasses of Java, III-IX, Backer.....	431
The chemical composition of South African maize and other cereals, Juritz....	431
Suppressing the inflorescence and the sugar content of cane and maize, Decock..	431
Composition of maize at various stages of its growth, Jones, jr., and Huston...	431
Corn culture, Kimbrough.....	432
Corn growing in Washington, Severance.....	432
On cotton cultivation, Kimbrough and DeLoach.....	432
The feeding of cotton, White.....	433
A new system of cotton culture and its application, Cook.....	433
The classification and grading of cotton, Earle and Dean.....	433
Helianthus, Rau.....	433
A rapidly growing new forage plant, Denaiffe and Colle.....	434
Oats for New York, Love.....	434
Some varieties and strains of oats in South Dakota, Hume and Champlin....	435
Potato growing in Washington, Morris, Hall, and Yothers.....	435
Effects of defoliation and application of nitrates on the sugar beet, Headden..	435
Sweet potatoes: Culture, storing, and studies in fertilizing, Stuckey.....	436
Tobacco seed beds, Olson.....	437
Wheat investigation.....	438
The culture of winter wheat in the Eastern United States, Leighty.....	438
The quality of clover and vetch seed in Maryland markets in 1913, Smith....	438
Weeds, Coe.....	438

EXPERIMENT STATION RECORD.

VOL. XXXI.

OCTOBER, 1914.

No. 5.

One of the most striking educational developments of recent years has been the increasing interest manifested in the subject of vocational training. Less than a decade ago the term itself was unfamiliar to the general public. To-day we find the desirability of such instruction comparatively well recognized, promising beginnings toward its development in some form already under way in every State of the Union, and an ever deepening realization of its importance to the nation as a whole. Similar conditions have come about in the Dominion of Canada, and in both countries commissions have been appointed to collect information regarding the status of vocational training and to present recommendations for its further development in a comprehensive way. The reports of these commissions have recently become available and bring together a large amount of useful data along these lines. In each case due attention has been accorded to those phases pertaining to training in the trades and industries and to commercial education, but much prominence has also been given to the question of education for farm life and homemaking, and the findings of the commissions regarding this subject are of much interest.

The Canadian commission, known as the Commission on Industrial Training and Technical Education, was appointed in 1910 by the Dominion authorities following a memorandum from the Minister of Labor. Its purpose was to inquire into the needs and present equipment of the Dominion "representing industrial training and technical education and into the systems and methods of technical instruction obtaining in other countries." Dr. James W. Robertson, principal of MacDonald College and well-known for his deep interest in agricultural education, was made chairman of the commission. A thorough study of these questions followed, embracing conditions not only in Canada but also in the United States, Great Britain, Ireland, Denmark, France, Germany, and Switzerland, and extending over several years. The report, submitted for publication in 1913, constitutes four volumes of nearly 2,500 pages, one volume containing a summary of the commission's findings and recommendations, another

quite detailed accounts of the status of vocational education in Canada, and the others similar data pertaining to the remaining countries.

The United States commission was appointed by President Wilson in response to a joint resolution of Congress authorizing a commission of nine to consider the subject of national aid for vocational education. Its personnel consisted of the following: Senators Hoke Smith, of Georgia, and Carroll S. Page, of Vermont; Representatives D. M. Hughes, of Georgia, and S. D. Fess, of Ohio; John A. Lapp, director of the Indiana Bureau of Legislative Information and secretary of the Indiana Commission on Industrial Education in 1912; Miss Florence M. Marshall, director of the Manhattan Trade School for Girls of New York City; Miss Agnes Nestor, of Chicago, president of the International Glove Workers' Union; Charles A. Prosser, secretary of the National Society for the Promotion of Industrial Education; and Charles H. Winslow, of the United States Bureau of Labor Statistics and a member of the Massachusetts Commission on Industrial Education, 1906-1909. This commission organized as the Commission on National Aid to Vocational Education on April 2, 1914, by the election of Senator Smith as chairman, and Ernest A. Wreidt, director of the Public Education Association of New York City, was subsequently appointed secretary.

Inasmuch as the law establishing the commission required it to submit its report not later than June 1, a period of less than two months was available. This time, however, was utilized as fully as possible in meetings of the commission and subcommittees, hearings given to representatives of the Federal Departments and national organizations interested as well as to individuals, questionnaires sent out to superintendents of public instruction, national labor organizations, and others, and the preparation of a bibliography of the subject. A considerable amount of useful data was thereby accumulated, and the two-volume report covers about 500 pages. Much of the time and attention of the commission were necessarily devoted to the specific question of national grants to the States for vocational education and to the drafting of a bill embodying these recommendations, but much information is also contained in the report as to the general subject of secondary agricultural education.

The reports of the two commissions are in most significant agreement as regards the need of developing the vocational aspects of agricultural education at this time. Thus from the economic side, the Federal Commission points out that "a virgin fertility of soil is no longer available for unintelligent exploitation over any considerable area in the United States, and in the future a permanent and increasingly productive and profitable agriculture can be achieved throughout the country only by scientific culture. In agriculture, science has advanced far beyond practice, and it has become essential

for the welfare of our increasing population that the farmer be made an expert." Furthermore, "history records the decline of nations which have failed to maintain their soil fertility, and history will certainly repeat itself in the United States unless we, and not posterity, succeed in inaugurating now a system of agricultural training that is nation wide, which shall achieve a permanent and highly productive agriculture." Similarly the Canadian commission maintains that "it is high time for Canada to recognize the difference between the primitive conditions of the undeveloped country and the complexities of advanced rural life in a democratic civilization," and that "the conservation of a vigorous, intelligent, and prosperous population in the country stands out among the foremost duties of the whole nation. . . . Acceptable instruction, adequate education, capable leadership, and hearty cooperation are necessary means."

Likewise the tendency to rural depopulation is recognized as a serious menace in both countries. Statistics are given showing that in Canada, despite the opening up for settlement of vast areas of virgin land in the western provinces, the rural population of the Dominion increased from 1901 to 1911 but twenty per cent, while the urban population showed a gain of sixty-two per cent. The commission concludes that "nothing can be done by legislation to compel people to stay in the country, but much may be done by education to cause them to prefer to stay there." Moreover, "whether the movement of population at present flowing from rural to urban areas goes on or takes an opposite direction, the rural communities for their own sakes are entitled to and must have education suited to the needs of all their members."

One of the questionnaires propounded by the United States commission and sent out to superintendents of schools in typical rural counties indicated that the popular belief that boys and girls are being drawn from the farms to the cities is generally well founded. Two of the principal explanations advanced were the supposed lack of profit in farming and the absence of suitable education. Of two hundred and fifty-three suggestions of means tending to retain the boys on the farm, eighty-five mentioned the development of demonstration work, seventy-eight the improvement and multiplication of agricultural schools, and thirty-nine the provision of better teachers of agriculture, while in a similar query as to girls, over one-third advocated the provision in high or normal schools of agricultural and home economics instruction. These replies were admittedly few in number, but they may perhaps be interpreted as none the less typical of the increasing belief in the need and efficacy of secondary instruction along these lines.

As would be expected, the details of the plans recommended by the two commissions for a system of secondary agricultural education

vary considerably. The Canadian commission, whose scope, it should be stated, was somewhat wider than that of the United States commission, since it embraced industrial and technical education of the higher and lower as well as the secondary grades, suggests a comprehensive system of agricultural training. This system has as its base, intermediate rural classes or schools for pupils thirteen years of age or over. These institutions would offer two-year courses at the schools, on the farm, and in the home, and would aim to prepare pupils for general farming, housekeeping, and life in a rural community. They would also admit graduates to the rural high schools. These high schools would present a four-year course, the first two years of which would be similar to those of the rural intermediate school, and as a whole would aim to prepare students for rural occupations and housekeeping as well as for admission to the agricultural colleges. There are also recommended resident or traveling county instructors in farming and housekeeping, who would eventually be associated with the rural schools or high schools and in some cases with a system of demonstration farms. Special types of schools, such as apprentice schools for the teaching of ordinary farm practices, short courses to be offered at the demonstration farms, and resident county agricultural and housekeeping schools for young people from seventeen years of age upwards are also suggested to meet certain conditions.

The United States commission recognizes the provisions now being made under the Smith-Lever Act for the education of the adult farmer and his wife, but suggests the need of additional provision for the boys and girls of the rising generation. It believes that "the most opportune time to train the boy is during his adolescent period, when he has already gained much knowledge of farm work and its requirements and is at the age when he is most ambitious, most alert, and therefore most teachable. The agricultural school will awaken interest, turn his attention to the large possibilities of a scientific and businesslike agriculture, and give him an elementary knowledge of right methods of farming which will start him in his career as a farmer and prepare him to use with profit the scientific and practical information which magazines, bulletins, and farm-extension teaching are bringing to his door."

To this end it advocates a system of schools of subcollegiate grade and for pupils over fourteen years of age. The instruction recommended is classified in general as that of all-day schools but with ample provision for correlating the school work with farm operations. Much insistence is placed upon directed or supervised farm practice to be obtained either on the home farm or a farm provided by the school. As regards details, however, either as to types of schools or methods of operations, the commission recognizes the great

diversity of conditions prevailing in the various States and deems the adoption of any arbitrary and inflexible system both impracticable and undesirable.

In no respect are the two commissions more thoroughly in accord than in their realization of the scarcity of well-trained instructors and of the fundamental necessity for providing means for their more adequate preparation. Thus, the United States commission believes that "the development of vocational education along right lines both for agriculture and for the trades and industries will depend largely upon the ability to secure and retain well-trained teachers." The dearth of such teachers and facilities for training them was emphasized by most of those testifying at the various hearings. The commission states that "excellent as has been the technical preparation which the state colleges of agriculture and mechanic arts have given to their students, many of them have not as yet developed departments of education adequate to the task of training prospective teachers either of agriculture or the mechanic arts in the administrative and teaching problems of the vocational school," and it draws attention to the fact that although under the Nelson amendment over \$1,300,000 was provided for the fiscal year ended June 30, 1913, from which an indefinite portion could be expended for the preparation of teachers, but \$34,000 was actually utilized for this purpose. "We can not rightly undertake a program of practical education in this country and carry it through successfully without teachers properly qualified by training and experience for their work and with practically no facilities for their proper training in the future."

So, too, the Canadian commission declares that "at the present time the supply of competent men obtainable as instructors in agriculture is entirely inadequate to meet the demand. It is important that thoroughly trained men should be available. Men for this educational work need liberal education and practical experience of work similar to that of the department which they are to direct. Their general education should give them a good grounding in the natural sciences, particularly in their relation to the science and art of agriculture. They should have a good knowledge of technical and practical agricultural and farm practice, and have sound acquaintance with the important questions in economics and sociology, as applicable to rural communities. It is also important that they should have a good knowledge of the art of teaching and the underlying principles of it. It would seem necessary that the district instructor should be a graduate of an agricultural college or have the education of a rural high school and be a graduate of the science department of an arts college. The qualification for a teacher in a

rural high school or a county or district agricultural school should not be less thorough and wide."

As a means of developing better trained instructors, this commission recommends increased efforts on the part of the agricultural colleges in this direction. It maintains that the Canadian agricultural colleges have aimed to educate young men to go back to the farm, whereas those of Europe definitely profess to train young men for professional service in connection with agriculture and rural life. Inasmuch as "the need for capable and thoroughly trained men is already so great that the present capacity of the agricultural colleges would not suffice to meet it for several years to come," it appears to the commission that "the agricultural colleges maintained by public funds should devote themselves chiefly to the education of those who would serve the rural community. Under present conditions it does not seem probable that any large percentage of the working farmers can be spared from their occupations or can have opportunity to take a full course at an agricultural college. The helpfulness of the agricultural college can be carried to every community through the labors, knowledge, and character of men and women who are trained at the college for professional service; and it can best serve the rural population through the education of such men and women." As a means to that end it recommends the development of courses for the preparation of teachers qualified to carry on the science and practical work in connection with the intermediate rural school, rural high schools, and county or district agricultural schools, and of district instructors who in addition to technical and practical instruction in agricultural work would receive training in the art of teaching and in the administration of affairs in rural communities.

The foregoing summary necessarily covers only a portion of the large amount of material embraced in the extended reports of these commissions, but it is thought that it may none the less prove of service in directing attention to these interesting documents. Although some of the conclusions of the commissions may seem already familiar to many educators, and others may be received with some differences of opinion, the reports as a whole are entitled to serious consideration, especially as representing the views of official bodies appointed for the specific purpose of inquiring into this great question of the development of vocational training. They are also of special importance as the practically contemporaneous expressions of national commissions of two countries with much in common in their educational problems, and they should, therefore, be of unique value in aiding in the solution of some of the intricate problems involved in the development of secondary agricultural education.

RECENT WORK IN AGRICULTURAL SCIENCE.

AGRICULTURAL CHEMISTRY—AGROTECHNY.

A report of chemical investigations on the lime-sulphur spray, H. V. TARTAR (*Oregon Sta. Research Bul. 3 (1914), pp. 28*).—The first investigation reported in this bulletin has been noted previously from another source (*E. S. R., 23, p. 701*).

The primary action between sulphur and calcium hydroxid was studied because the investigations cited in the literature did not include this phase of the subject and the work in general on this topic was imperfect. In the literature it is shown that the products resulting from the reaction of sulphur with the alkali and alkaline earth hydroxids are polysulphids and thiosulphates, but in practically all of the investigations air was not excluded from contact with the products of the reaction. This caused an error due to the rapid oxidation of the polysulphids. Most of the experiments were also made with an excess of sulphur and probably without considering a possible secondary reaction of the sulphur with the products formed by a primary reaction. Previous work was also handicapped by the lack of methods for determining the amount of the hydroxid of a metal present in solutions also containing polysulphids and thiosulphates of the same metal.

“The primary reaction between calcium hydroxid and sulphur in heated aqueous solution takes place as represented by the following equation:

The reaction resembles that occurring with potassium hydroxid and sulphur with the exception that with potassium hydroxid the trisulphid (K_2S_3) is formed. “When sulphur is used in excess, a secondary reaction occurs, in which it combines with the calcium tetrasulphid to form the pentasulphid.”

When considering the theoretical basis for the proportion of lime and sulphur used in the preparation of lime-sulphur solution, it is pointed out that although some difference still exists in the recommendations made by the different experiment stations, the more recent work shows the proper proportion of lime and sulphur to be approximately 1 : 2.

“The compounds formed by the reaction between calcium hydroxid and sulphur, under ordinary commercial conditions of manufacture, are calcium tetrasulphid, pentasulphid, thiosulphate, and sulphite. All of these compounds are readily soluble in water with the exception of the sulphite, which is comparatively insoluble.” The chemical analysis of a lime-sulphur solution, therefore, will show the amount of lime and sulphur which have reacted to form the same, with the exception of these substances necessary to form insoluble sulphites. The equation given above “shows that when calcium hydroxid and sulphur combine, one-third of the calcium is combined as thiosulphate and two-thirds as polysulphid. Since there is no decomposition of the polysulphid, the quantitative estimation of the calcium combined in this form gives a means for determining the amount of thiosulphate which has been formed. The difference

between this total estimated amount of thiosulphate and the amount actually present in the solution, is the quantity that is decomposed; and from these data the amount of sulphite can be easily calculated.

"The initial ratio of lime to sulphur is also easily determined when one knows not only the amounts of calcium and sulphur present in a given lime-sulphur solution, but also the insoluble sulphite produced in the preparation of the same. . . . The data given show that the proportion of lime (CaO) to sulphur which reacts in the preparation of the more concentrated commercial lime-sulphur solutions, is but a mere trifle greater than 1:2. . . . More dilute solutions prepared under commercial conditions [were not examined]. It is evident, however, from the work of Thatcher^a and Van Slyke et al. [E. S. R., 24, p. 663] that the ratio in this case would be somewhat greater than 1:2; in some cases it would be perhaps 1:2.25.

"The theoretical basis given here will not exactly apply to the preparation of small amounts of solution, say 150 gal. or less, where the oxidation of the polysulphids occurs to a considerable extent through contact with the air."

In general, the insecticidal properties of lime-sulphur are due principally to its power to take up large amounts of oxygen, the amount of free sulphur formed in its decomposition, and its ability to soften the newly secreted wax at the margin of scale insects. The question of the correct valuation resolves itself into the quantitative measurement of these factors.

The amount of oxygen consumed depends upon the following reactions: (1) $\text{CaS}_2 + 3\text{O} = \text{CaS}_2\text{O}_3 + 3\text{S}$; (2) $\text{CaS}_4 + 3\text{O} = \text{CaS}_2\text{O}_3 + 2\text{S}$; (3) $\text{CaS}_2\text{O}_3 = \text{CaSO}_3 + \text{S}$; and (4) $\text{CaSO}_3 + \text{O} = \text{CaSO}_4$. Calcium sulphite is formed very slowly on account of the slow decomposition of the thiosulphate. The oxygen required to produce sulphate is absorbed slowly, and it has been found that the sulphite has practically no insecticidal value as far as San José scale is concerned. It may, however, be important to use as a measure for insecticidal efficiency the oxygen required to convert the polysulphid, using Harris's method for monosulphid (E. S. R., 25, p. 414) into thiosulphate. It is suggested that the oxygen-consuming power be expressed as the oxygen number, this term to mean the number of grams of oxygen absorbed by 100 gm. of lime-sulphur solution.

Free sulphur is liberated from lime-sulphur according to (1), (2), and (3) of the foregoing equations.

The reduction of polysulphid takes place rapidly and there is a correspondingly rapid deposition of sulphur. The decomposition of thiosulphate is much less rapid. No good evidence, however, exists which shows that the liberated sulphur is not of equal insecticidal value, and the total free sulphur which would be deposited may be expressed as the available sulphur number.

The insecticidal property of softening the so-called wax of scale insects (E. S. R., 26, p. 753) is not easily estimated and the caustic properties of soluble calcium polysulphid are not explained on the basis of the calcium hydroxid present. "Experience in handling the spray simply verifies the correctness of Shafer's statement that the 'so-called caustic action of the wash on the hands seems rather due to its strong reducing power (power to absorb oxygen) than to the alkalinity of the solution.'" It is possible also that the reducing power may also cause the softening of the so-called wax of the scale insects. If this assumption is found to be true the oxygen number mentioned above would be its quantitative measure. "The power of the spray to soften the so-called wax is evidently due to some property of the polysulphids, and in the light of present knowledge no definite statement can be made regarding its exact nature or its exact quantitative analytical measurement."

^a Jour. Amer. Chem. Soc., 30 (1908), No. 1, pp. 63-68.

On the reaction between sulphur and potassium hydroxid in aqueous solution, H. V. TARTAR (*Jour. Amer. Chem. Soc.*, 35 (1913), No. 11, pp. 1741-1747).—This material has been noted in the abstract above.

On the valuation of lime-sulphur as an insecticide, H. V. TARTAR (*Jour. Indus. and Engin. Chem.*, 6 (1914), No. 4, pp. 313-315).—This material has been adequately noted in the abstract above.

Soluble arsenic in mixtures of lead arsenate and soap, H. V. TARTAR and L. A. BUNDY (*Jour. Indus. and Engin. Chem.*, 5 (1913), No. 7, pp. 561, 562).—“These results show that in the mixtures of the soaps with the acid arsenates large amounts of arsenic are rendered soluble. The results also indicate that when a neutral (ortho) arsenate of lead is used with soap only a very small amount of arsenic is made soluble. Evidently, the use of a mixture of soap with an acid arsenate of lead for spraying purposes would be a dangerous practice, for the amount of soluble arsenic would be sufficient to burn badly the foliage of fruit trees.”

The present status of the synthesis of plant alkaloids, H. BAUER (*Der Heutige Stand der Synthese von Pflanzenalkaloiden. Brunswick, 1913, pp. VIII+144*).—This monograph deals with the synthesis of the alkaloids comprising the pyridin, tropin, isoquinolin, and purin groups, the oxyphenylalkylamin bases, and the synthesis of the cleavage products of alkaloids. An extensive bibliography is distributed throughout the work.

Solubility of casein in dilute acids, L. L. VAN SLYKE and O. B. WINTER (*Abs. in Science, n. ser.*, 38 (1913), No. 983, p. 639).—“Casein, freshly prepared by precipitating skim milk with acetic acid and washing free from acid, was treated with 100 cc. of different acids of known strength for given periods of time at definite temperatures and the undissolved residue determined. The acids used were hydrochloric, sulphuric, lactic, and acetic; strength of solutions, tenth-normal, 1/100-normal, 1/500-normal; time of contact, 1, 5, and 15 minutes; temperatures, 15°, 25°, and 42°. In general, the amount of dissolved casein increases with increase of temperature, time of contact, and concentration of acid. Hydrochloric acid dissolves most, and then come in order, lactic, sulphuric, and acetic.”

A contribution to the history of corn sugar, P. L. DE VILMORIN and F. LEVALLOIS (*Rev. Sci. [Paris]*, 51 (1913), I, No. 13, pp. 396-401).—A résumé of the literature on the subject with a report of some experiments by the authors themselves.

Most of Heckel's findings (*E. S. R.*, 29, p. 409) were confirmed. The fact that the sugar develops and decomposes rapidly in the corn stalk is somewhat of a handicap, but the indications are that some means may finally be devised whereby the biological processes going on in the plant may be controlled.

Contribution to our knowledge of the chemistry of gums and mucin substances, W. SCHIRMER (*Arch. Pharm.*, 250 (1912), No. 3, pp. 230-251; *abs. in Chem. Zentbl.*, 1912, II, No. 3, pp. 195, 196).—This reports investigations with reference to the gums of *Anogeissus latifolius* and *Odina woder* and the mucin-like substances of *Sassafras variifolium*, *Althea officinalis*, and *Ulmus fulva*.

In regard to a uniform nomenclature for ferments, J. GIAJI (*Rev. Sci. [Paris]*, 51 (1913), I, No. 11, pp. 333-335).—A plea for uniform nomenclature for ferments and some suggestions in this connection.

The existence of three types of proteolytic vegetable ferments in latexes, GERBER (*Compt. Rend. Acad. Sci. [Paris]*, 157 (1913), No. 3, pp. 241-243).—The proteolytic enzymes present in latexes from *Ficus carica* and *Broussonetia papyrifera* are of three kinds, rennet (coagulating), casease (digesting), and trypsin. The ferment of *F. carica* will not coagulate nor digest raw milk, casein, and fibrin in the presence of traces of neutral salts of silver, copper,

mercury, gold, platinum, etc., and chlorin, bromin, iodin, and hydrogen peroxid. The enzym from *B. papyrifera*, on the other hand, will coagulate and digest raw milk, casein, and fibrin. It will also act in the presence of traces of the salts of the chemicals mentioned above, even if the doses are comparatively large.

The lipases of a latex, C. GERBER (*Compt. Rend. Soc. Biol. [Paris]*, 74 (1913), No. 12, pp. 718-721).—The saponification of unboiled egg yolk by the latex of *Euphorbia characias* was only feeble when massive amounts of latex were allowed to act upon egg yolk emulsion. The saponification of boiled egg yolk was much more regular than that of the untreated yolk. This latex was in small quantities and obeyed the law of proportion. The difference between the two types of saponification was the same as exists between the two types of caseation which occur in boiled and unboiled milk.

The rennet of the latex of *Calotropis procera*, C. GERBER and P. FLOURENS (*Compt. Rend. Acad. Sci. [Paris]*, 155 (1912), No. 6, pp. 408-410; *abs. in Chem. Zentbl.*, 1912, II, No. 17, p. 1469).—The milky juice of this plant contains a vegetable proteolytic enzym which coagulates boiled milk with greater ease than raw milk. The enzym is very stabile toward heat. While small amounts of metals belonging to the gold group and mercuric chlorid lessen the coagulating power of the enzym, alkalis seem to increase its fermenting power.

In regard to the nature of amylases, S. KAMECKI (*Abs. in Chem. Ztg.*, 37 (1913), No. 47, *Repert.*, p. 220).—The amylases obtained by fractional precipitation of malt extracts have different properties. The first fraction has the greatest starch liquefying power, while the saccharifying power is most intense in the third fraction. In the fourth fraction it is similar to that of the first fraction. Various enzymes seem to take part in the process.

In regard to invertase, I, II, J. MEISENHEIMER, S. GAMBARJAN, and L. SEMPER (*Biochem. Ztschr.*, 54 (1913), No. 1-2, pp. 108-154).—In the preparation of invertase by treatment with acids, the material forming the basis of the tests was Buchner's yeast press juice. Dilute acids were found to precipitate much of the proteins contained in the juice without destroying the activity of the invertase. The precipitate obtained with acetone from the juice which had been previously treated with acid was twice as active as a juice treated with acetone alone.

An investigation of the enrichment of the invertase content of living yeasts (pp. 122-154) showed that the invertase content of lager beer yeast can be increased as much as eight times its original amount by simply propagating the yeast in a saccharose solution.

On the preparation of neutral ammonium citrate solution, P. RUDNICK and W. L. LATSHAW (*Jour. Indus. and Engin. Chem.*, 5 (1913), No. 12, p. 998).—The method recommended by the committee on ammonium citrate solution of the division of fertilizer chemistry of the American Chemical Society and the method proposed by Patten and Marti (E. S. R., 29, p. 718) were studied comparatively. In the first named method, however, the neutrality was determined by the indicator method of Hand (E. S. R., 23, p. 508).

Two ammonium citrate solutions, one slightly acid and the other alkaline, were tested against the same acid phosphate preparation. The alkaline solution, analyzed by the Patten and Marti method, showed a ratio of ammonia to citric acid of 1:3.748, and the acid solution a ratio of 1:3.786. "The results indicate that the variation of these solutions from the ratio given by Patten and Marti [1:3.765] was not sufficient to affect the results obtained on the sample of acid phosphate in question. Further work on this subject is in progress."

The determination of citric acid-soluble phosphoric acid in Thomas slag powder, F. HAUSSDING (*Landw. Jahrb.*, 45 (1913), No. 1, pp. 119-126).—This is

a study of the Lorenz method and the Popp iron citrate method (E. S. R., 29, p. 410).

The Lorenz method was studied with chemically pure salts of known phosphoric acid content and later with additions of calcium and iron salts, and silicates, and the results obtained corresponded well with the theoretical figures. With Thomas slag powders it gave figures which were always lower than those obtained by the Official Method (removal of silica by hydrochloric acid). It also presents many difficulties in the way of manipulation.

The Popp method was studied from the standpoint of time required for precipitation (determination made directly after shaking and after 48 hours), the time for filtration (directly after stirring and 24 hours later), and the effect of time of stirring (one-half hour and one-quarter hour). The results obtained were practically the same in all instances.

In a comparison with the Official Method, the Popp method with 23 samples of slag powder gave slightly higher results, and in 17 cases somewhat lower results. On the whole, the figures obtained by the two methods agreed very well, and in only two cases was there a difference of over 0.2 per cent (0.25 to 0.22 per cent) noted. The Popp method always gave higher results than the Lorenz method, the average results being 16.201 and 15.905 per cent of phosphoric acid, respectively.

Winkler's method for the determination of oxygen in water; the effect of nitrite and its prevention, F. E. HALE and T. W. MELIA (*Jour. Indus. and Engin. Chem.*, 5 (1913), No. 12, pp. 976-980).—Considerable criticism has arisen of late regarding the effect of nitrites upon the results obtained by the Winkler method. The present experiments were undertaken for the purpose of ascertaining the extent of error with varying amounts of nitrite and to find, if possible, a simple method for preventing the error.

The results show that when nitrites are present in quantities below 0.2 part per million in ordinary tap water, the figures obtained for dissolved oxygen are fairly accurate. Winkler showed the danger point to be with 0.1 part per million or over.

“The effect of high nitrite present in any amount ever occurring in water may be counteracted by the use of potassium acetate solution (or sodium acetate crystals) to neutralize the hydrochloric acid before exposure to the air. The procedure then is to add at the bottom of the bottle 2 cc. of manganous sulphate solution (480 gm. per liter) followed by 2 cc. of potassium hydroxid-iodid solution (360 gm. hydroxid and 100 gm. iodid per liter). Shake and settle. Add at the bottom 2 cc. concentrated hydrochloric acid and shake until the precipitate is entirely dissolved. Then add 2 cc. potassium acetate solution (1,000 gm. per liter) at the bottom and mix. Withdraw by pipette 100 cc. into an Erlenmeyer flask and titrate with 1/100-normal thiosulphate, adding a little starch solution at the end. Correction must be made for 6 cc. of water displaced by the first two solutions and by the acetate solution. The acid needs no correction, since it displaces only water from which oxygen has been removed.

“Precautions must be taken (1) to exclude contact with air as much as possible until the solution is ready to titrate, by replacing the stopper as quickly as possible after each reagent is introduced; (2) to get complete solution of the precipitate by the hydrochloric acid; (3) to give the thiosulphate a little more time to react at the endpoint in the acetic acid condition; (4) to use small amounts of starch solution. For introducing the solutions it is advisable to use pipettes with two marks, measuring 2 cc. well up on the pipette so as to give head and not contaminate the upper liquid in the bottle more than necessary while actually displacing liquid from the bottle in proportion to the amount introduced.

"Samples for oxygen may be taken and transported elsewhere for titration in ground glass stoppered bottles with part of the chemicals added, either in alkaline or acid condition, if kept out of contact with air. The alkaline condition is preferable."

Estimation of starch and dextrin in sugar products, confectionery, etc., A. AUGUET (*Ann. Falsif.*, 6 (1913), No. 53, pp. 143-147; *abs. in Jour. Chem. Soc. [London]*, 104 (1913), No. 607, II, p. 448).—In the method 0.5 gm. of the substance under examination is inverted at 70° C. with 1 per cent hydrochloric acid. Another 0.5 gm. portion is inverted by heating with 2 per cent hydrochloric acid for 1 hour at 110°. The reducing sugars are then estimated with Fehling's solution in the usual manner. The difference between the two estimations, expressed in terms of invert sugar, is multiplied by 0.9 to give the quantity of starch or dextrin.

"A preliminary examination of the substance under the microscope, and a test with iodine solution, will show whether starch or dextrin is present, or which of these preponderates."

Determination of quercetin in wine, T. VON FELLEBERG (*Mitt. Lebensm. Untersuch. u. Hyg., Schweiz. Gsndhtsamt.*, 4 (1913), No. 1, pp. 1-14).—In the examination of red wine a yellow coloring matter was noted which gave the reactions applied by Heise to similar substances, i. e., those with lead acetate, iron acetate, ammonia, and concentrated sulphuric acid.

The coloring matter present in wine was found to be more soluble in water than that from other sources and did not give a blood red reaction with silver nitrate. Various wines were then examined for the presence of this substance and the results obtained were compared with those given by standards of wool dyed with authentic quercetin. It colored wool, mordanted with clay, yellow, and wool, mordanted with clay and tin salts, a very pure yellow. When the tin salt was in preponderance the color was more intense. Unmordanted plant or animal fibers were not affected by the coloring matter.

The coloring matter which exists only in traces in white wines and in larger amounts in red and white wines, and red wines made from dregs, is formed during fermentation, especially from the substances which make up the dregs, i. e., skins, stems, and seeds; consequently the detection of this coloring matter is a medium whereby one can often determine wine made from dregs. Heating wine with dilute sulphuric acid was found to increase the coloring matter content of wine.

For the purpose of determining whether Neubauer's conclusions were correct, 1 kg. of grape wine was extracted with 3 liters of water in an autoclave at 130° C. The solution was treated with ether, the ether extract was brought to dryness, and the crystalline residue extracted with water and recrystallized from dilute alcohol. In this experiment 0.17 gm. of the coloring matter was obtained in the form of fine microscopic needles which melted at 250°. The combustion showed a formula similar to that calculated for quercetin. The reactions for the substances were also positive. The green plants, or plant parts green during some stage of their growth, such as skins and hulls of fruits, and flowers, yield on heating with dilute sulphuric acid yellow coloring matters which are considered decomposition products of a substance which accompanies chlorophyll. The yellow coloring matter of wine in all probability consists of quercetin, traces of quercetin, and the decomposition product of an accompaniment of chlorophyll.

Estimation of the bromine absorption of wines, T. VON FELLEBERG (*Mitt. Lebensm. Untersuch. u. Hyg., Schweiz. Gsndhtsamt.*, 4 (1913), No. 1, pp. 14-41, figs. 5).—The results show the possibilities in this determination for detecting adulterations in wines. Sugaring and watering can be easily detected.

Practicum of milk chemistry, O. VON SOBBE (*Milchchemisches Praktikum. Leipzig, 1913, pp. V+162*).—This book is designed for self-instruction and for dairy laboratories, in place of the author's previous work called the A B C des Molkereibeamten (A B C of the Dairy Official). In addition to the usual methods for examining dairy products the chemical and biologic methods employed on the European Continent are described with much detail.

A new method for the determination of the proteins in milk, W. C. DE GRAAFF and Mlle. A. SCHAAPE (*Ann. Falsif., 6 (1913), No. 53, pp. 149-157*).—This is a study and criticism of Steinegger's method.

It was found that with unboiled cow's milk the factor for 1 gm. of protein obtained by the authors agreed well with the figure found by Steinegger, 2.06 (E. S. R., 17, p. 696), but not with that noted by Richmond, 2.23 (E. S. R., 22, 39). Steinegger's claim that no change of the aldehyde index after heating the milk to 120° C. takes place could not be borne out because the figures obtained by these workers were very variable. Ordinary pasteurization or sterilization evidently produces some changes in the protein substances. Dilution did not alter the aldehyde index.

Six samples of women's milk were also studied in this regard, and the aldehyde index for 1 gm. of woman's milk protein was found to be 2.26. The aldehyde index for 1 gm. of the protein of buttermilk was 3.15. The difference in value between the normal proteins and the proteins of buttermilk is not believed to be due to the development of lactic acid but probably to cleavage of protein taking place under the influence of the micro-organisms present.

The addition of lactic acid did not affect the results. See also other notes (E. S. R., 18, p. 8; 27, p. 209).

A simple method for determining the fermenting capacity of various feeding stuffs, milk, and the galactase of milk, A. ROSAM (*Milchw. Zentbl., 42 (1913), No. 7, pp. 193-195, figs. 2*).—Infant foods and feeds for animals often contain micro-organisms which gain entrance to the gastrointestinal tract where they exert a detrimental effect. For determining the fitness of such foods, a method is proposed which is said to be a modification of the author's prior procedure.

The apparatus consists of a tall, tapered, flat-bottomed flask supplied with a rubber cork through which a glass tube passes. The tube dips into the flask 5 cm. below the cork while the outside portion of the tube is from 30 to 50 cm. above the cork. If a food is to be examined, a definite portion is mixed with water and the apparatus with its contents is attempered at 35 to 40° C. The height to which the fermenting mixture rises in the glass tube at the end of three hours is compared with the standard set down. As a basis for the test a rise of 30 cm. in three hours is taken. This fermentation is designated $\frac{30}{30} = 10 = 100$ per cent.

If the effect of feces or other contaminating substances upon milk is to be studied, sterile milk is substituted for the water.

Tests made gave the following figures: Feed beets, 43 to 60 per cent; fresh beet chips, 30 to 50; soured beet chips, 10 to 18; dried chips, 25 to 40; green, dirty cabbage leaves, 40 to 60; bran, 50 to 70; hay, 30 to 45; fresh brewers' grains, 0.5 to 5; unclean straw, 65; feces, 50 to 70; and milk, 4 to 20 per cent.

As the results obtained with the different materials vary, it is necessary to set up a standard for each kind of material to be tested. The fermenting power of feces depends very much upon the kind of feed an animal receives. The feces of animals affected with dysentery yield high figures.

The apparatus described can also be used for catalase determination.

The determination of nitrobenzol in peanut oil, H. J. LUCAS (*Jour. Indus. and Engin. Chem., 5 (1913), No. 7, pp. 576, 577*).—Nitrobenzol is usually added

to peanut oil for the purposes of giving the oil a pleasant odor and deceiving the public into thinking that the product is oil of bitter almonds. A method for determining its presence is given, and some analyses of mixtures of peanut oil and nitrobenzol of known strength and also of two mixtures of lard oil and nitrobenzol are presented.

Determination of total formaldehyde in fumigators and commercial solutions, J. J. HINMAN, JR. (*Jour. Indus. and Engin. Chem.*, 5 (1913), No. 9, pp. 752-755).—"For an occasional analysis, the methods of Haywood and Smith and Seyewetz and Gibello seem to be preferable, while in a plant producing formaldehyde or where a large number of samples are to be analyzed, Kleber's method would be the most desirable. Legler's method gives too low results and Blank and Finkenbeiner's gave the highest ones. Haywood and Smith's method gave slightly lower percentages than Blank and Finkenbeiner's, closely followed by Kleber's and the remaining methods." A bibliography is included.

The thermal figure of oil of turpentine, C. GRIMALDI and L. PRUSSIA (*Chem. Ztg.*, 37 (1913), No. 65, p. 657).—If pinene, of which two optically active forms go chiefly to make up oil of turpentine, is treated with concentrated sulphuric acid, an active exothermic reaction takes place with a simultaneous formation of oxidation and reduction products.

A method has been worked out whereby it is possible to determine the thermal figures characteristic for turpentine. The test is carried out in Tortelli's thermoleometer (*E. S. R.*, 22, p. 311) and as a reagent 1 part of sulphuric acid is dissolved in 7.5 parts by volume of cooled amyl alcohol. The test is conducted as follows: Twenty cc. of the oil of turpentine is allowed to flow dropwise into the vacuum chamber and the temperature noted; then 10 cc. of freshly prepared reagent is run into the turpentine oil, and the mixture is stirred until a constant temperature is obtained. The difference between the two temperatures is the heat evolved, or the thermal number of the oil.

French, Portuguese, Spanish, Austrian, and Greek oils gave figures varying from 77 to 85.7. The same oils by distillation with lime gave similar figures. Fractions boiling at 155 to 156° C., which are comparable to pinene, gave somewhat lower figures. American turpentine oils not prepared in the laboratory also gave figures corresponding to those stated above. Badly stored oils gave an increased thermal figure. The distillation of ozonized oils over sodium gave the characteristic figures of good oils.

The use of the method for detecting adulterations suggested itself.

Loganberry by-products, C. I. LEWIS and F. R. BROWN (*Oregon Sta. Bul.* 117 (1914), pp. 3-32, figs. 9).—This is a preliminary report which deals with the picking, handling, and utilization of the loganberry for the preparation of canned fruit, evaporated fruit, fruit juice, and sirup. Plans and descriptions of systems of evaporation are presented, and practical hints, based on experimental work, are given for the purpose of overcoming many of the causes of failure which have been heretofore experienced in this comparatively new industry. The principles involved in evaporating are much the same for both prunes and loganberries, but climatic conditions are very different during the two seasons. It will not always follow, therefore, that because an evaporator works successfully for prunes it will work equally well for loganberries.

Analyses of loganberry juice from berries at various stages of ripeness are presented. Juice made from very ripe fruit retained a more distinct flavor and had a higher quality. It is pointed out that the fruit juice may be utilized, not only for the preparation of vinegar and wine but also in frozen products (ices and ice creams), gelatin desserts, puddings, and pies, recipes for which are presented. The commercial aspects are also considered.

METEOROLOGY—WATER.

Agricultural meteorology, R. F. STUPART (*Agr. Gaz. Canada*, 1 (1914), No. 3, pp. 210, 211).—A brief account is given of the action of the General Assembly of the Institute of Agriculture at Rome in May, 1913, with reference to the proposed work of the permanent commission for the study of agricultural meteorology.

The questions which this commission should consider are outlined as follows: Statistics of losses occasioned by storms in relation to the possible maximum; importance of daily reports of the weather in order to establish statistics regarding favorable conditions; means of disseminating general meteorological information among agriculturists; the connection existing between the harvest and the various atmospheric elements; establishment of the atmospheric conditions which lead to the best agricultural results in any year; establishment of notes or percentages for the good year and for normal years; special study of the elements of a good year; study of the various elements which contribute to a good harvest—(a) weather, (b) sunshine, (c) heat, (d) quantity of rain required for a good harvest; and the establishment of a Meteorological Information Office for Agriculturists.

In accordance with these suggestions the meteorological service of Canada has established a new division for the study of the connection between weather and the growth of crops and has placed the work in charge of R. W. Mills.

Comparative agricultural and forestry meteorology, E. CUIF (*Bul. Soc. Sci. Nancy*, 3. ser., 14 (1914), No. 3, pp. 225-307, pls. 3, figs. 4; *abs. in Rev. Sci. [Paris]*, 52 (1914), II, No. 2, p. 50).—A continuation and summary of previous investigations (E. S. R., 22, p. 44; 27, p. 816) is given in this article, which deals with (1) influence of forest cover on the temperature of the soil at different depths, (2) influence of the degree of forestation on the amount of rainfall, and (3) the influence of leafy and coniferous forest growth on the temperature and humidity of the air.

The more important conclusions are that forest growth exerts a decided influence on diurnal variations in temperature of the air, the maximum being much lower and the minimum much higher than in the air of unforested areas. The influence on the temperature of the soil, however, is comparatively small and disappears entirely at a depth of 0.2 meter. Forest growth appears to have considerable influence on the frequency of rainfall, although little upon the amount. It appears to increase the number of rainy days and to reduce the number of torrential rains. The absolute humidity is higher and the relative humidity is lower in the forest than in the open country on account of the lower temperature prevailing in the former. This is true to a greater extent in coniferous forests than in those of leafy growth and is most pronounced during the period from April to October.

Climatological data for the United States by sections (*U. S. Dept. Agr., Weather Bur. Climat. Data*, 1 (1914), Nos. 3, pp. 248, pls. 2, figs. 9; 4, pp. 238, pls. 2, figs. 8).—These numbers contain respectively brief summaries and detailed tabular statements of climatological data for each State for March and April, 1914.

Meteorological observations at the Massachusetts Agricultural Experiment Station, J. E. OSTRANDER, E. K. DEXTER, and R. E. McLAIN (*Massachusetts Sta. Met. Buls.* 305, 306 (1914), pp. 4 each).—Summaries of observations at Amherst, Mass., on pressure, temperature, humidity, precipitation, wind, sunshine, cloudiness, and casual phenomena during May and June, 1914, are presented. The data are briefly discussed in general notes on the weather of each month.

Meteorological observation, 1913 (*Agr. Students' Gaz., n. ser., 16 (1914), No. 6, pp. 194-199*).—This article gives summaries of observations on the temperature of the air and soil, rainfall, and sunshine at the Royal Agricultural College, Cirencester, and briefly reviews the weather conditions at this place and of the whole of England.

It is stated that the year was characterized by a wet spring, a dry summer, which was neither sunny nor warm, and a mild autumn, with no very wide fluctuations of temperature over the whole country. The rainfall was generally for the country as a whole slightly below the average. The total rainfall at the college was 30.52 in., measured on 184 days. The average temperature was 47.6° F. The duration of bright sunshine was everywhere considerably less than the average.

Temperature records, J. B. THOMPSON (*Guam Sta. Rpt. 1913, pp. 22-24, figs. 2*).—Records of maximum and minimum temperatures at the Guam Station throughout the year ended June 30, 1913, are shown in charts.

American temperatures and European rainfall, W. J. HUMPHREYS (*Jour. Wash. Acad. Sci., 4 (1914), No. 13, pp. 345-347, fig. 1*).—Data are presented to show that "high annual average temperatures in America must lead to correspondingly heavy precipitation in Europe and, conversely, that persistently low average American temperatures must be accompanied by more or less correspondingly light European precipitation."

Chemical composition of rain in the Union of South Africa, C. F. JURITZ (*So. African Jour. Sci., 10 (1914), No. 7, pp. 170-193, pl. 1; abs. in Jour. Chem. Soc. [London], 106 (1914), No. 621, I, p. 916*).—The results of determinations of nitrogen and chlorin in rain water collected at different places in the Union of South Africa more or less continuously from September, 1910, to December, 1912, are reported. The results for nitrogen are summarized in the following table:

Nitrogen in rain water of South Africa, in pounds per acre.

Locality and period.	Summer: September to February.			Winter: March to August.		
	As ammonia.	As nitrates.	Total.	As ammonia.	As nitrates.	Total.
	<i>Pounds.</i>	<i>Pounds.</i>	<i>Pounds.</i>	<i>Pounds.</i>	<i>Pounds.</i>	<i>Pounds.</i>
Grahamstown (Sept., 1911, to Aug., 1912).....	0.592	0.465	1.057	0.448	0.264	0.712
Bloemfontein (Sept., 1910, to Aug., 1911).....	1.425	.907	2.332	2.233	.713	2.946
Bloemfontein (Sept., 1911, to Aug., 1912).....	3.244	1.077	4.321	1.626	.286	1.912
Durban (Sept., 1911, to Aug., 1912).....	2.739	.780	3.519	1.796	.295	2.091

The chlorin content varied with distance from the sea.

Electrical hail protection, A. ANGOT (*Ann. Soc. Mét. France, 62 (1914), Mar., pp. 82-85*).—The efficiency of various electrical devices which have been proposed for protection against hail is briefly discussed, the general conclusion being that the results have been unconvincing as to the efficiency of these devices. The extension of installations for this purpose is discouraged.

Studies in water supply, A. C. HOUSTON (*Abs. in Chem. News, 109 (1914), No. 2834, p. 143*).—This monograph is practically a summary of papers and articles published by the author, embodying the results of his personal experiences and giving accounts of his investigations. Tables of results and graphical representations are given relating to bacteriological and chemical tests, and processes of purification and sterilization are described. The question of the connection between the purity of water supplies and the prevalence of

disease is treated and routine methods of bacteriological work are described in detail. Methods of collecting and labeling samples, registering results, and decimally diluting samples are first treated, and a chapter is devoted to a detailed description of the exact method followed in the examination of a sample of raw river water. Full accounts are included of each day's work, and the composition of the culture media used for the different tests is also given.

The utilization of sewage in agriculture, J. GROSSMANN (*Rpt. Brit. Assoc. Adv. Sci.*, 1913, pp. 771, 772; *abs. in Mark Lane Express*, 110 (1913), No. 4277, p. 383; *Chem. Ztg.*, 38 (1914), No. 34, p. 373).—Abstracts are given of a paper presented at the Birmingham meeting of the British Association, 1913, describing more particularly the system installed by the author at Oldham for the recovery of grease and the preparation of fertilizer from sewage sludge (E. S. R., 30, p. 19).

Sewage disposal, G. J. FOWLER (*Times [London]*, 1914, Mar. 11, *English Sup.*; *abs. in Jour. Soc. Chem. Indus.*, 33 (1914), No. 7, p. 372).—The extent to which sewage sludge is used as fertilizer in the British Isles is discussed.

It is stated that "at Manchester the 'slurry' from the washing of the contact beds is being dried, powdered, and sold to Canada at a price which covers cost. At Bradford the crude sewage is 'cracked' with sulphuric acid, the resulting sludge hot pressed, the grease recovered and sold at a profit, and the residual sludge cake sent to northern France for intensive gardening. At Oldham the sludge is distilled and the residue sold. At Dublin the sludge is fermented by yeast, which causes a separation of water; the solid sludge is dried and the resulting powder sold for 50 shillings a ton. An organism has been isolated from the water of an old colliery which has the property of precipitating iron in presence of organic matter. When this organism was added to an effluent together with a salt of iron and then air blown in, complete clarification was obtained; the deposit produced had a high nitrogen content."

Sewage irrigation and disease organisms, CIICALTEU (*Compt. Rend. Soc. Biol. [Paris]*, 74 (1913), No. 24, pp. 1411-1413).—A study of the question whether disease organisms applied to the soil in sewage are able to gain entrance into the interior of plants grown on the soil is reported. The results indicate that where there is no injury to the underground parts of the plants the germs do not enter the plant, but that a very slight injury is sufficient to allow the germs to gain entrance.

SOILS—FERTILIZERS.

Report of the meeting of the international commission for the mechanical and physical examination of soil, F. SCHUCHT (*Internat. Mitt. Bodenk.*, 4 (1914), No. 1, pp. 1-31, fig. 1; *abs. in Rev. Sci. [Paris]*, 52 (1914), I, No. 14, p. 439).—This commission of fourteen delegates, representing Germany, Sweden, Brazil, Holland, Hungary, and the United States, discussed methods of mechanical and physical analysis of soils and agreed upon the following:

(1) Group soil particles according to Atterberg's classification: Grains greater in size than 20 mm.—pebbles; those from 20 to 2 mm.—gravel; 2 to 0.2 mm.—coarse sand; 0.2 to 0.02 mm.—fine sand; 0.02 to 0.002 mm.—dust; and grains smaller than 0.002 microns—colloidal particles and raw clay.

(2) Subdivision of groups to be left to the judgment of the analyst.

(3) Preparation of samples for mechanical analysis by sifting through a 2 mm. mesh sieve, soil to be still moist. This applies only to soils rich in humus.

(4) For sedimentation use apparatus similar to Atterberg's in which all particles up to $\frac{1}{2}$ mm. in size are separated by sifting, and then levigate samples into a graduated flask.

(5) In samples poor in clay the clay should be weighed directly, but in samples rich in clay it may be estimated by differences.

(6) The humus content should be computed as one-half of the carbon dioxide obtained in ordinary organic analysis for carbon determination.

(7) Compare the trituration of the sample with the thumb according to Atterberg with that by shaking according to Hissink.

The new classification of the granulation products in mechanical analysis, J. KOPECKÝ (*Internat. Mitt. Bodenk.*, 4 (1914), No. 2-3, pp. 199-202).—The author criticizes the classification of soil grains noted above, compares it with the old classification according to Schöne, and concludes that the modification of the washing process and the rinsing apparatus is not necessary or justified.

Vegetation and agricultural soil, G. DE ANGELES D'OSSAT (*Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat.*, 5 ser., 22 (1913), I, No. 1, pp. 876-878, fig. 1).—The author concludes from his observations of natural soils that the vegetation best adapted to a soil can not be accurately determined from a geological map of the soil area, owing to the many physical, mechanical, and more particularly, chemical changes to which the original rock may be subjected during the transformation into agricultural soil.

The radio-activity of some type soils of the United States, R. B. MOORE (*Jour. Indus. and Engin. Chem.*, 6 (1914), No. 5, pp. 370-374, fig. 1).—The author reports chemical examinations of samples of several type soils of the United States to determine their radium and thorium contents.

Of the 7 types examined for radium, the soil of 4 was more active than the subsoil, while in the other 3 the reverse was true. The average activity of the soils was 1.97×10^{-12} , and of the subsoils 1.52×10^{-12} .

“There seems to be a fairly definite relationship between the activity and the combined amounts of barium and strontium. In the majority of cases the soil or subsoil which has the highest activity also has the largest amount of barium plus strontium. . . . The same reaction holds fairly well with the amount of sulphur present. . . . Since radium has an insoluble sulphate, which precipitates with the sulphates of barium and strontium, the results seem to indicate that radium in the soil is very largely, if not entirely, in the form of sulphate.”

The thorium determinations in five of the types showed small variations and “seem to indicate that soils contain more thorium than most rocks.”

Olifants River irrigation scheme (Van Rhynsdorp division). Flying agricultural survey of the soils of the irrigable area, C. F. JURITZ (*Union So. Africa Dept. Agr. Sci. Bul.* 5 (1914), pp. 30; *Agr. Jour. Union So. Africa*, 7 (1914), No. 4, pp. 541-546).—The prevailing soil types of the Van Rhynsdorp division of the project are described and discussed with reference to mechanical and physical structure and plant food and alkali content. The prevailing types are the so-called Karroo soils, consisting of red sands and sandy loams, and alluvial soils, consisting of drab-colored loams and fine sandy loams. The alluvial soils are generally of finer texture than the Karroo soils. “The average alluvium contains only 31 per cent of material coarser than 1/10 of a millimeter, as against 68 per cent contained by the average ‘Karoo’ soil. On the other hand, no less than 54 per cent of the average alluvium is silt and clay of finer grade than 1/20 of a millimeter, and in the ‘Karoo’ soils this averages only 19 per cent.”

Of the two Karroo soils the sands are classed as much the poorer chemically than the finer-grained sandy loams. Except in phosphorus content the Karroo soils did not appear to differ greatly from the average alluvium in mineral plant food content. The alluvial soils examined were not invariably rich in plant food, and the most marked chemical deficiency found in all the soils

analyzed was in regard to nitrogen. The soils of the northern part of the area were found to be fairly well supplied with lime, while many of those of the southern part were deficient. Comparatively few of the soils examined are classed as deficient in phosphoric acid or potash.

Out of the 45 soil samples analyzed for alkali only 9 samples, 7 of which were Karroo soils, contained sodium carbonate, which occurred in very small amounts and only in the surface soil. Sodium chlorid composed the bulk of the alkali salts.

Pakihi lands: Note on their treatment, B. C. ASTON (*Jour. Agr. [New Zeal.], 7 (1913), No. 3, pp. 295-300, figs. 4*).—The results of field and pot tests indicate that the chief need of these lands, which have been described previously (E. S. R., 23, p. 621) is for lime and phosphorus, and that they may be profitably reclaimed where cheap ground limestone or quicklime and phosphate are available.

The storage and use of soil moisture, W. W. BURR (*Nebraska Sta. Research Bul. 5 (1914), pp. 88, figs. 20*).—The results of field studies of soil moisture accumulation and conservation conducted for 6 years on fairly uniform fine sandy loam soil at the North Platte substation are reported.

Under field conditions the maximum capacity for water of the soil in question was found to be from 16 to 18 per cent of its dry weight, of which above 7 to 8 per cent is available for plant use. The more important findings are summarized as follows:

Summer tillage is the most effective means of storing water in the soil, the annual storage by this means varying from 10 to 33 per cent of the seasonal rainfall, according to the amount and distribution of the rainfall, the effectiveness of the tillage, and the presence or absence of a growing crop. Plowing seems better than disking for accumulating water in the soil, although disking small grain stubble to kill weeds and stir the surface is generally effective. Artificial mulches of straw or hay are more effective than soil mulches in absorbing and retaining rain water, and a 3-in. mulch is more effective than a shallower one. Corn, oats, spring wheat, and barley use water from the first 4 or 5 ft. of soil, winter wheat at a depth of 6 or 7 ft., and alfalfa and grasses when well established at much greater depths. Under normally favorable conditions growing vegetation is a greater factor than surface evaporation in removing water from soil, and weeds are frequently the most effective agents in removing available water from soils and in preventing the storage of water for the use of other plants. Capillary movement is feeble in soils that are dried to any considerable extent below the saturation point, so that in the main the plant roots to obtain water extend themselves into the soil where available water is present rather than depend upon capillarity.

In order to store water in these soils it is necessary that the soil surface should be in condition to catch rains, and kept loose and rough by cultivation to reduce evaporation and prevent blowing. Weeds should be suppressed, as far as possible, before and after seeding. Crops which will withstand considerable drought or escape drought by maturing early should be chosen.

The storage and use of soil moisture, W. W. BURR (*Nebraska Sta. Bul. 140 (1914), pp. 20*).—A popular edition of the above.

Mineral acid soils, O. LOEW (*Landw. Jahrb., 46 (1914), No. 1, pp. 161-164*).—The author reviews his own and other studies on mineral acid soils of several tropical countries, particularly Porto Rico (E. S. R., 29, p. 815), with special reference to the determination and correction of the acidity and the relation of acidity to the biological activities of the soil. Such soils are thought to owe their acidity chiefly to acid clay constituents.

Some notes on soil protozoa, C. H. MARTIN and K. R. LEWIN (*Phil. Trans. Roy. Soc. London, Ser. B, 205 (1914), No. 315, pp. 77-94, pls. 2*).—This paper gives an account of protozoan organisms found in two different kinds of soil by a special method devised by one of the authors. Three new species are described, *Vahlkampfia soli*, *Amœba cucumis*, and *A. gobanniensis*.

“The main purpose of this introductory paper has not, however, been the study of these amœbæ from a specific point of view, so much as the proof which we hope to have brought of the existence of a relatively frequent trophic protozoan fauna in certain soils and the rough indication of some possible methods of dealing with this fauna. How far this fauna under certain conditions exercises a deleterious influence on plant growth is rather a question for the agriculturist than the zoologist.

“The startling success in the Lee Valley of the treatment of sick soils by partial sterilization, introduced by Russell, would seem to present a very strong argument in favor of the view that these protozoa do exercise an important influence on plant growth in these soils. We have, by means of the method described above, been able to establish the occurrence of a trophic protozoan fauna in certain field soils that we have examined, and to this question we hope to return in a future paper.”

A bibliography of 29 references to literature on the subject is given.

Methods in soil bacteriology.—VII, Ammonification and nitrification in soil and solution, F. LÖHNIS and H. H. GREEN (*Centbl. Bakt. [etc.], 2. Abt., 40 (1914), No. 19-21, pp. 457-479*).—A continuation of previous studies of factors effecting ammonification and nitrification in soil and solution (*E. S. R., 30, p. 218*) is reported.

Aeration, the concentration of the material undergoing decomposition, and more particularly, its distribution in the medium, were found to be important factors for ammonification. In certain specimens of blood meal there appeared to be components which very seriously hindered ammonification in solution and in saturated soil, and to a much less extent in well aerated soil or sand media.

In solution or in sand media, higher concentrations of ammonia lowered the nitrification. The alkaline reaction resulting from the use of basic magnesium carbonate to cultivate the nitrite organisms hindered or suppressed the effective conversion of nitrite into nitrate, as did also the adoption of a temperature of from 30 to 35° C. Neutral chalk gave more satisfactory results than did magnesium carbonate. It is pointed out that by varying the conditions in regard to depth of layer analytical figures for nitrification in solution tests may be made to run above, below, or parallel with those of soil tests. “The same solution, if supplied with both sodium nitrate and ammonium sulphate, may give rise to nitrification in shallow layer and denitrification in deep layer; if further supplied with suitable organic compounds, may lead to nitrate assimilation in shallow layer.”

It is concluded that no necessary fundamental difference exists between bacteriological processes in soil and solution media, and that the most important factors in both are: (1) Nature and quantity of material used as substrata; (2) concentration and distribution of the substrata in the medium; (3) aeration; (4) diffusion, absorption, destruction, or evaporation of metabolic products; (5) reaction of the medium; (6) temperature; and (7) duration of the experiment.

“The fact that in soil tests, in consequence of absorption, more perfect distribution of substrata, and superior aeration, the processes in the laboratory may proceed faster than in solution, does not by any means justify the conclusion that soil tests more closely represent field conditions.” Observations concerning the course of decomposition processes in the field are mentioned as indicating

that suitably arranged solution tests may afford equally, if not more, instructive information than soil tests. "By suitable addition of glass-wool, sand, chalk, humus, etc., tests which are primarily 'in solution' may be so arranged as to separate at least partially the conglomeration of factors involved in soil tests."

The absence of nitrate formation in cultures of *Azotobacter*, K. F. KELLERMAN and N. R. SMITH (*Centbl. Bakt. [etc.]*, 2. Abt., 40 (1914), No. 19-21, pp. 479-482, fig. 1).—Studies of cultures of *Azotobacter* indicate that while these strains are capable of fixing appreciable quantities of free nitrogen, they are apparently unable to produce nitrates.

Fertilizers in relation to soils and crop production, R. HARCOURT and A. L. GIBSON (*Ontario Dept. Agr. Bul.* 223 (1914), pp. 30, figs. 2).—This is a popular discussion explaining the use of manures and fertilizers in the improvement of soils.

Manurial requirements, PRIMROSE MCCONNELL (*Jour. Agr. [New Zeal.]*, 8 (1914), No. 1, pp. 43-49).—The results of two years' observations on the experimental farm at Ruakura are briefly summarized in this article, the general conclusions being that the soil of this farm, as in case of New Zealand soils in general, does not need nitrogen if a proper rotation of crops is practiced; that phosphoric acid, particularly in the form of basic slag and guano, gives uniformly good results; that comparatively little result, good or bad, is obtained from the application of potash except in the case of potatoes and mangels; and that liming, particularly on the raw and apparently more sterile parts of the farm, together with draining, is necessary to bring the soil into a profitable state of cultivation.

The inefficiency of fertilizers in dry farming regions, F. COUSTON and B. GARRIGUES (*Rev. Dry-Farming Nord Afric.*, 1912, Nos. 2, pp. 30-36; 3, pp. 59-62; 1913, No. 6, pp. 168-172).—Experiments on the high plateaus of Algeria, where the winter is cold, the summer very hot, and the spring and autumn very dry, and the annual precipitation varying from 180 to 500 mm. and averaging 320 mm., showed almost uniformly no benefit from the use of fertilizers. The failure of the fertilizers to increase the crop yields is attributed to deficiency of moisture in the soils.

Fertilizer experiments in the German colonies (*Düngungsversuche in den Deutschen Kolonien*. Berlin: Kolonialamt, 1913, No. 3, pp. III+64, pls. 6, fig. 1).—An account is given of experiments carried out in German East Africa in 1912 and 1913 and of those planned for 1914. The crops experimented with included cotton, corn, sorghum, rye, wheat, barley, garden beans, mungo beans, peanuts, potatoes, alfalfa, rubber, coffee, cacao, coconuts, sisal, besides various forage plants and vegetables. The general conclusion reached is that as a rule fertilizers produced a profitable increase in yield.

The plant food content of liquid manure, P. LIECHTI and E. TRUNINGER (*Landw. Jahrb. Schweiz*, 27 (1913), No. 8, pp. 459-474).—Analyses of a large number of samples of liquid manure as used by Swiss farmers are reported.

Some of the samples represented liquids obtained without the addition of water. In other cases a certain amount of water had been added in their preparation. All of the samples contained more or less suspended matter. The analyses showed wide variations in composition but the average of all analyses showed 1.7 gm. of total nitrogen, 70 per cent of which was in the form of ammonia, in 1 liter of liquid; 4.37 gm. of potash; and 0.3 gm. of phosphoric acid.

The escape of ammonia from soil treated with liquid manure, P. LIECHTI and E. RITTER (*Landw. Jahrb. Schweiz*, 27 (1913), No. 8, pp. 436-458).—The authors report further investigations (E. S. R., 25, p. 22) from which they

conclude that the addition of superphosphate to liquid manure in the quantities generally used in practice has little or no tendency to prevent the nitrogen losses due to the evaporation of ammonia from the soil, also that the effect of the liquid manure on the superphosphate is to render a part of the phosphoric acid insoluble. Field experiments on the utilization of the nitrogen of liquid manure in the production of green forage verified the results of the previous experiments referred to above regarding the losses of nitrogen through evaporation. They further indicate that the neutralization of liquid manure with superphosphate is not feasible, but that the practice of making relatively large applications of liquid manure in the production of green forage may be followed provided the soil does not become deficient in phosphoric acid.

Sodium nitrate v. ammonium sulphate, K. POSPIŠIL (*Wiener Landw. Ztg.*, 64 (1914), No. 18-19, pp. 163, 164).—Comparative tests of sodium nitrate and ammonium sulphate in field experiments with sugar beets extending over four years, two of which were dry and two wet, showed that the sulphate gave better results than the nitrate in the wet seasons, although the nitrate gave better results in the dry seasons and as an average of the four years.

Pot experiments with ammonium sulphate containing sulphocyanid, A. STUTZER and S. GOY (*Jour. Landw.*, 62 (1914), No. 2, pp. 149-158; *abs. in Jour. Chem. Soc. [London]*, 106 (1914), No. 621, I, p. 916).—Previous investigations on this subject by others are reviewed and a brief bibliography of the subject is given. The author made water culture and pot experiments on corn, mustard, summer rye, oats, wheat, and barley with commercial ammonium sulphate and mixtures of pure salts containing varying amounts of sulphocyanid.

In the water cultures it was shown that small amounts of sulphocyanid were stimulating but larger amounts were toxic. In the soil cultures the results confirm those of Wollny and Böhmer in showing that ammonium sulphate containing as much as 1 per cent of sulphocyanid can be safely used if applied at ordinary rates.

Mixing lime nitrogen with Thomas slag and kainit, GERLACH and O. TIEDEMANN (*Illus. Landw. Ztg.*, 34 (1914), No. 28, p. 273).—Experiments with oiled calcium cyanamid as well as with mixtures of 3 parts of kainit, 2 of Thomas slag, and 0.5 and 1 of cyanamid are briefly reported.

The oiled cyanamid gave somewhat better results as measured by crop yields than the untreated. It was found that the mixtures of kainit, slag, and cyanamid were of good mechanical condition and underwent little chemical change except a small loss of water-soluble potash in 10 days.

The effects of the ensilage process on the solubility of floats, E. B. FORBES and C. M. FRITZ (*Jour. Indus. and Engin. Chem.*, 6 (1914), No. 3, pp. 222, 223).—Floats was mixed with corn in the proportion of 1 part of the former to 250 parts of the latter, and the mixture was ensiled in earthen jars for 6 months.

Determinations of the different forms of phosphoric acid in the original material and in untreated and phosphated silage are reported, and showed that the water-soluble and citrate-soluble phosphorus in the phosphated silage was not higher than in the untreated silage. There was, however, a very considerable increase in inorganic phosphorus soluble in 0.2 per cent hydrochloric acid, the phosphated silage containing more than twice as much as the untreated silage. The authors conclude from these results that "the ensilage of corn will render soluble in 0.2 per cent hydrochloric acid such an amount of the phosphorus of floats added to corn as to constitute a practical consideration in the feeding of live stock."

The production of phosphate rock in 1913, W. C. PHALEN (*U. S. Geol. Survey, Mineral Resources of the United States, Calendar Year 1913, pt. 2, pp. 273-289*).—Statistics of production in the United States and other countries are

presented. The phosphate industry in the different States is also briefly discussed and general information of interest to those engaged in the phosphate trade is given. The marketed production of phosphate rock in the United States in 1913 was 3,111,221 long tons valued at \$11,796,231, representing an increase of 5 per cent in output and 1 per cent in value over the corresponding figures for 1912.

The fertilizing value of phonolite, R. NEUMANN (*Fühling's Landw. Ztg.*, 63 (1914), No. 8, pp. 278-291, figs. 2).—Field and pot tests are reported of a form of phonolite consisting mainly of leucite, which, it is claimed, is more effective as a potash fertilizer than the ordinary forms and promotes nitrogen fixation. The results failed to confirm these claims and showed that while the phonolite had a slight fertilizing value this was in no sense comparable with that of ordinary potash fertilizers.

Potash salts and other salines in the Great Basin region, G. J. YOUNG (*U. S. Dept. Agr. Bul.* 61 (1914), pp. 96, pls. 6, figs. 8).—This is an account of investigations carried on in cooperation with the U. S. Geological Survey and the Mackay School of Mines of the University of Nevada.

The region explored included practically the entire State of Nevada, the southern part of Oregon, the western part of Utah, and certain sections of eastern and southeastern California, and comprised an area of between 208,500 and 210,000 square miles. The report deals fully with the origin, formation, and character of the saline deposits.

It is pointed out that potash deposits similar to those of Stassfurt, Germany, can hardly be expected to occur in the Great Basin. The saline deposits of the Great Basin represent comparatively recent geological activity and are not the result of extreme desiccation even in the older deposits. The present deposits are in process of formation. "It may be said that the basin deposits already discovered represent the initial stages of what in time might result in deposits rather remotely similar to Stassfurt, but of much less magnitude. . . ."

"With the exception of the crusts and efflorescences about hot springs and in soils, no notably high potassium content has been reported from salines taken from beds. The potassium content in material of this nature ranges from less than 1 to 2 per cent. It is not in the salts which have crystallized out, but in the residual brines or mother liquors that concentration of potassium has taken place, and it is to these that we must look for potassium salts. As desiccation approaches completion so will the residual brines increase in proportion of potassium. A near approach to complete desiccation would give a brine high in potash. . . ."

"Two general types in the desiccation phenomena may be distinguished, the Searles type, in which a large, deep lake was evaporated, and the comparatively thick body of saline material, restricted in area and saturated with residual brine, was formed; and a second type, which is best illustrated by Death Valley, in which case we have the building up of a mass of muds and silts with interbedded salines, by the repeated formation and desiccation of a shallow lake. To the latter type belong most of the desert, dry lakes, or playas. The line between the two types is not a sharp one."

The possibility of deep deposits is considered to be uncertain though not completely disproved. In view of this uncertainty deposits such as those occurring in Searles Lake which have resulted from desiccation of the most recent Quaternary lakes seem to be of most significance. Of the various basins examined "Searles is the only one in which the investigation has shown sufficient concentration of potassium salts in the residual brines to be of probable commercial importance. . . . The presence of brines of moderate concentration is shown

in Death Valley and Silver Peak. It is a matter of some doubt whether these brines can be worked. The investigation of the Carson Sink, Railroad Valley, and Columbus Marsh is inconclusive."

A plea for the increased use of lime, J. HENDRICK (*Trans. Highland and Agr. Soc. Scot.*, 5. ser., 26 (1914), pp. 218-232).—This article discusses the extent to which liming is practiced at the present time in Scotland, as compared with its use in former times. It is shown that there has been a marked decline in the use of lime, and the reasons why lime should be more freely used are briefly stated.

It is estimated that the average loss per acre per annum in the drainage water throughout England and Wales is not less than 500 lbs. of calcium carbonate, the loss probably being much higher than this on manured soils. Reference is made to the fact that large quantities of carbonate of lime of excellent quality for agricultural purposes are annually produced in Scotland as a by-product from the causticizing plant of paper works, as previously noted (*E. S. R.*, 30, p. 127).

Comparative field tests of this by-product and ordinary lime shells and gas lime are reported. The results show that the yields of turnips were largely increased by the use of each form of lime, the waste product being especially effective in this respect. It also apparently reduced the amount of finger-and-toe disease.

Agricultural lime analyses (*Md. Agr. Col. Quart. No. 64* (1914), pp. 8).—Chemical analyses of samples of agricultural lime examined from June, 1913, to May, 1914, inclusive, are reported with brief notes on the use of lime. Mechanical analyses are also given of ground limestones and ground oyster shells.

Sulphur fertilizer for alfalfa, F. C. REIMER (*Pacific Rural Press*, 87 (1914), No. 26, p. 717).—Experiments in which flowers of sulphur, iron sulphate, superphosphate, and ground rock phosphate were applied to alfalfa at the rate of 300 lbs. per acre are reported. Largely increased yields where sulphur and sulphur compounds were used are reported.

The world's production and consumption of chemical fertilizers (*Production et Consommation des Engrais Chimiques dans le Monde. Rome: Inst. Internat. Agr.*, 1914, 2. ed., pp. XI+162, pls. 2).—The first edition of this report has already been noted (*E. S. R.*, 30, p. 223). This edition brings the statistics up to the end of 1912.

It is stated that the world's consumption of different classes of fertilizers for 1912 was as follows: Natural phosphates, 6,500,000 metric tons; superphosphates, 11,000,000; Thomas slag, 3,500,000; Peruvian guano, 83,000; potash salts, 4,520,959 (equivalent to pure potash, 904,000); sodium nitrate, 2,530,645; ammonium sulphate, 1,200,000, and synthetic nitrogenous fertilizers, 150,000 metric tons.

State fertilizer tonnage (*Amer. Fert.*, 40 (1914), No. 13, p. 96).—A table is given which shows the consumption of fertilizers in the United States for the years 1909-1913, inclusive, "compiled from the most reliable statistics that are obtainable."

The figures for each State and Territory for 1913 are as follows: Alabama, 474,730 tons; Alaska, 45; Arizona, 600; Arkansas, 52,000; California, 36,000; Colorado, 3,500; Connecticut, 50,000; Delaware, 50,000; Florida, 213,728; Georgia, 1,120,693; Hawaii, 67,000; Idaho, 2,000; Illinois 90,000; Indiana, 193,899; Iowa, 3,500; Kansas, 7,380; Kentucky, 75,000; Louisiana 98,778; Maine, 160,000; Maryland, 169,000; Massachusetts, 125,000; Michigan, 57,985; Minnesota, 3,500; Mississippi, 128,050; Missouri, 60,000; Montana, 800; Nebraska, 1,000; Nevada, 800; New Hampshire, 25,000; New Jersey, 156,661; New Mexico, 1,000; New

York, 460,000; North Carolina, 840,447; North Dakota, 1,000; Ohio, 185,000; Oklahoma, 18,000; Oregon, 4,500; Pennsylvania, 340,000; Porto Rico, 18,836; Rhode Island, 18,000; South Carolina, 918,336; South Dakota, 700; Tennessee, 84,060; Texas, 75,500; Utah, 1,000; Vermont, 25,000; Virginia, 412,434; Washington, 1,500; West Virginia, 31,852; Wisconsin, 4,000; Wyoming, 200; total, 6,868,014 tons.

AGRICULTURAL BOTANY.

Plants and their uses, an introduction to botany, F. L. SARGENT (*New York, 1913, pp. X+610, figs. 384*).—This book is somewhat out of the ordinary in its plan. The author, after an introductory chapter on the study of plants, takes up and describes many species of common usage, grouping them under the headings of cereals, food plants, flavoring and beverage plants, medicinal and poisonous plants, and industrial plants. Chapters are also given on classification and descriptions of the general features of many of the more common plant groups, with discussions on the relations and adaptation of plants, life history, etc. This method, which the author calls the historical method, is thought to be adapted to teaching botany, as it not only helps the beginner to learn at the outset as much about these economic plants as he is ready for, but helps him to classify them scientifically. He will thus be prepared to appreciate the wider view of the life of plants which inspires botany today.

Some honey plants of Guam, J. B. THOMPSON (*Guam Sta. Rpt. 1913, pp. 21, 22*).—Notes are given on some of the more common honey plants occurring in Guam.

Some new tuberous species of Solanum, L. WITTMACK (*Bot. Jahrb. [Engler], 50 (1914), Sup., pp. 539-555, figs. 3*).—Work previously reported (E. S. R., 22, p. 435) on species of Solanum has been continued, and the author herein gives a description with brief discussion of six tuberous forms from Argentina claimed to be new species and named respectively *S. neoweberbaueri*, *S. kurtzianum*, *S. vernëi*, *S. velascanum*, *S. famatinæ*, and *S. æmulans*, the name of Dr. Bitter being added to that of the author in connection with all but the first named species.

A study of the vegetation of the sand hills of Nebraska, R. J. POOL (*Minn. Bot. Studies, 4 (1914), pt. 3, pp. 187-312, pls. 16, figs. 16*).—This thesis gives the results of an ecological study of the sand hill region which occupies a considerable portion of the northwestern part of Nebraska. After discussing the geological and topographical features of the region and the general plant life conditions, the author describes at length the different plant formations and their relations and successions. A bibliography is appended.

Sand plants on lime soils, M. BÜSGEN (*Bot. Jahrb. [Engler], 50 (1914), Sup. pp. 526-538, pls. 2*).—In tests with *Sarothamnus scoparius* and *Digitalis purpurea* on both sandy and limy soil it was found that a good start was made by both plants, but that on limy soil weakening was early apparent in connection with chlorosis. *Calluna vulgaris* showed a decided difference in favor of the sandy substratum as regards development. *Lupinus luteus* is said to have shown no preference between sandy and siliceous soils at first, but finally an increase of 50 per cent in weight in favor of sandy soil. *S. scoparius* in either soil showed no particularly high percentage of lime. It is suggested that the utilization of other elements may have been influenced by the calcium content in these experiments.

A quantitative chemical and physiological study of nutrient solutions for plant cultures, W. E. TOTTINGHAM (*Physiol. Researches, 1 (1914), No. 4, pp. 133-245, figs. 15*).—The author reports an investigation made to study the influence upon the growth of young wheat plants of a wide range of proportions

of the component salts in nutrient solutions and the alterations of this influence produced by different total concentrations.

Preliminary to the investigation a study was made of methods for preparing Knop's nutrient solution. The wheat seedlings were started in water, after which they were grown for 24 days in the above solution containing various concentrations of potassium phosphate, magnesium sulphate, calcium nitrate, and potassium nitrate. It was found convenient to employ the component salts of Knop's formula in stock solutions, one part containing only the calcium nitrate and the other part the remaining three salts. Methods for germinating seeds and mounting seedlings in culture solutions, which were somewhat different from those usually employed, were devised and are described.

The most important factor found to affect the physiological influence of varying proportions of the four salts in the culture solutions was apparently the ratio of the magnesium content to that of calcium. The injurious effect of magnesium and the amount of dry matter produced by the plants were found to depend upon the complex balance between all the salts in solution. The effects upon growth of any given set of proportions of nutrient salts in the medium varied with the total concentration of the medium.

A bibliography is given.

The functions of nutritive materials in higher plants, K. FAACK (*Mitt. Landw. Lehrkanz. K. K. Hochsch. Bodenkul. Wien*, 1 (1913), No. 4, pp. 443-509, fig. 1).—Results are given in considerable detail of studies carried out with wheat plantlets as affected by solutions of salts containing nitrogen, carbon, potassium, iron, phosphorus, and sulphur employed separately, and also as furnished simultaneously by placing portions of the rootlets of a given plantlet in different media. It is thought that the nutritive substances necessary to growth must be first combined in and by the plant body itself after being taken up separately in the transpiration current, since passage from root to root is excluded by the arrangement described.

A short bibliography is appended.

A review of recent investigations on the mineral nutrition of fungi, A. W. DOX (*Biochem. Bul.*, 3 (1914), No. 10, pp. 222-228).—A critical review is given of recent literature pertinent to the nutrition of fungi, most of the articles having appeared within the last two years.

The carbon nutrition of plants, P. RAVIN (*Ann. Sci. Nat. Bot.*, 9. ser., 18 (1913), No. 5-6, pp. 289-451, figs. 24).—A study is reported on the carbon nutrition of radishes grown in Knop's solution, to which were added various organic acids and organic acid and neutral compounds of potassium. The effect of the different compounds on turgescence, respiration, increase in fresh and dry weight, and ash content is shown.

In addition to radishes, the study was supplemented with investigations on the carbon nutrition of some algæ and fungi. For the higher plants it was found that they absorbed and assimilated succinic, malic, citric, tartaric, and probably oxalic acids. The order in which they are mentioned is in a decreasing proportion as to their nutritive action or an increasing ratio of toxicity. If two organic acids, one in a free acid state and the other in the form of a corresponding salt, are added to solutions, the free acid is found more toxic and less nutritive than its corresponding salt.

Some physiological differences were noted in the behavior of the various groups of plants. Phanerogams were found to utilize indiscriminately the free organic acids and their various potassium compounds. Algæ, which are very susceptible to acids, assimilated only the neutral salts of potassium. The molds utilized the organic acids, but not all the organic acid salts.

An extensive bibliography is given.

Gaseous exchanges and variation of sugars and glucosids during formation of anthocyanin in flowers of *Cobæa scandens*, E. ROSÉ (*Compt. Rend. Acad. Sci. [Paris]*, 158 (1914), No. 13, pp. 955-958).—Reporting a study of this flower in its four stages of development, the author states that in the corolla of flowers kept in darkness the intensity of respiration reaches a maximum in the bud stage, decreasing progressively thereafter. The ratio of carbon dioxide given off to oxygen absorbed is nearly constant (lying between 96 and 99 per cent) during floral development, the intensity thereof being less than that of the reverse exchange in light during nearly the whole of this period, and the two approximating equilibrium at floral maturity. Considerable oxygen is taken in at all times by the petals in both white and colored flowers. Pigments in colored petals showed a general relation to light intensity analogous to that noted by Combes (*E. S. R.*, 23, p. 528). In the first three stages (budding, greening, and reddening) the total amount of sugars increases, decreasing, however, in the fourth (violet) stage, in which glucosids increase. It is thought that anthocyanin is formed independently of the preexistence of glucosids, but that the total amount of glucosids present in the petals is related to the presence of anthocyanin therein.

Researches on the physico-chemical properties of vegetable saps, II, J. A. HARRIS and R. A. GORTNER (*Biochem. Bul.*, 3 (1914), No. 10, pp. 196-201, pl. 1).—In continuation of a previous paper (*E. S. R.*, 28, p. 821), the authors give an account of a study of the physico-chemical constants of the juice of apples and pears of varying size and fertility. Comparisons are also made with the fruit of *Cercis* and *Staphylea*.

Summarizing their results, the authors state that in all four cases there is a correlation between the size of the fruit and the number of seeds which it produces. It is thought probable that the relationship is a direct causal one and that the size of the fruit is influenced by the number of seeds rather than conversely. It has been considered that the development of the seed influences the properties of the sap in the development of the fruit, but the authors were unable to demonstrate any sensible differences in the osmotic pressure, mean molecular weight, or electrical conductance of the saps of nearly ripe fruits of different sizes or producing different numbers of seeds.

A review of Willstätter's researches on chlorophyll, C. J. WEST (*Biochem. Bul.*, 3 (1914), No. 10, pp. 229-258).—This is a review of a recent book entitled *Untersuchungen über Chlorophyll*, by R. Willstätter and A. Stoll, together with numerous articles by Willstätter in other publications.

Study of the constitution of plastids, in particular as regards the presence of lipoids and the photosynthetic function of the chloroplasts, L. BUSCALIONI (*Bot. Jahrb. [Engler]*, 50 (1914), Sup., pp. 657-672).—Plants of about 150 species representing different families were kept under controlled conditions for one year and examined at intervals of about one month.

It is stated, among other findings, that lipoids were present almost universally in the green plastids of the cells in case of the older leaves, much less frequently in the younger ones.

Reply to Kostytschew's articles on respiration of wheat seedlings, W. ZALESKI (*Ber. Deut. Bot. Gesell.*, 32 (1914), No. 1, pp. 87-90).—This is a reply to an article by Kostytschew and Scheloumoff and one by these authors and Brilliant (*E. S. R.*, 30, p. 522).

The action of anodic and cathodic solutions on germination, H. MICHEELS (*Acad. Roy. Belg., Bul. Cl. Sci.*, 1913, No. 9-10, pp. 831-887, fig. 1; *abs. in Jour. Chem. Soc. [London]*, 106 (1914), No. 616, I, p. 239).—Experiments are reported on the germination of wheat in the anodic and cathodic compartments of an electrolytic cell containing from 0.001 to 0.01 molecular concentration of sodium

or potassium chlorids. The effect of the electrical treatment as shown by the percentage of germination, length of first leaf, length of roots, and increase in weight was determined.

The author claims that the effect on germination in a given solution is approximately proportional to the quantity of electricity which has been passed through the solution in which the germinating seeds are placed. It is said that the differences between the cathodic and anodic effects can not be accounted for on the basis of the alkali and acid which are formed as a result of secondary decomposition. The feeble development of the roots in the anodic solution is attributed to the coagulation of the colloidal solution under the influence of the cations which readily pass through the membrane of the root cells.

Some recent experiments in the application of electricity to plant production, J. H. PRIESTLEY (*Gard. Chron.*, 3. ser., 55 (1914), Nos. 1424, pp. 245-247, figs. 3; 1425, p. 271, figs. 3).—Recent experiments carried out with potatoes at Garforth and at Dumfries are claimed to show (1) that results of work as heretofore reported by some investigators probably require revision on account of the recent discovery of the large part played by wind in carrying the charge to control plats, and (2) that screens surrounding electrified areas must be higher, the carrying wires lower, and the plats more completely isolated by screening and by location with reference to prevailing winds. Results from experiments under improved conditions in 1913 are thought to have been vitiated by the extreme dryness during much of the growing season, but it is expected that more accurate and instructive results may be obtained from the work as planned for the present season.

FIELD CROPS.

Irrigation and manuring studies, F. S. HARRIS (*Utah Sta. Bul.* 133 (1914), pp. 383-418, figs. 6).—The effect of irrigation on yield of grain and stover was such that "during 1911 and 1912 the highest yield of grain was obtained with 30 in. of irrigation water, while in 1913, and as an average of the 3 years, 20 in. gave a higher yield than any other amount of water. In every case the yield was lower where 40 in. of water were given during the season than where less was applied. The stover yield was greatest in 1911 with 40 in. of water, in 1912 with 30 in., and in 1913 with 20 in." For each inch of irrigation water the yields of grain for 5, 10, 20, 30, and 40 in. were respectively 1.12, 0.46, 0.59, 0.33, and 0.26 bu. per acre. Over four-fifths of the crop was produced by the natural precipitation.

The effects of manuring at the rates of 5 and 15 tons per acre are noted as evident in connection with the irrigations, even on rich soil. "During the first year of the test the yield was raised from 55 to 74 bu. by 15 tons of manure. By comparing the yields of 1911 with those of 1913 it will be noted that the manured plats maintained their original yields of grain, while the yields on the unmanured plats decreased considerably. . . . During the first year of manuring there was a greater increase in yield for each ton of manure where 15 tons were added than where 5 tons were added. During the other years, however, the manure was used more economically with a light than with a heavy application. The figures show that all the value of the manure is not used during the first season, but that it has a residual effect. The average of all treatments show that for each ton of manure applied the yield per acre was increased by 2.32 bu. of grain and 396 lbs. of stover. The manure would, therefore, have a money value to the farmer of something like \$2 per ton during the first year, besides improving the soil for future crops." As a result of

the study of the effect of the manurial treatments in connection with irrigation on the different parts of the plant, it is noted that "the average results for three years show that the relative amount of stover gradually increased with the moisture. There was, however, a very slight falling off when 40 in. of water were used."

In regard to the ratio of grain to cob it was found that "the water applied did not affect the ratio of grain to stover as much as did the manure. On the average the proportion of grain to cob was increased by manure. An increase is also noted with the application of more water, but the difference is slight. The season seems to be the chief factor affecting the ratio." Data show that "the irrigation water did not have any consistent effect on the weight of 1,000 kernels from year to year, but manure increased the weight of kernels in every case. One year's test on the weight of a measured bushel of grain showed it to be heaviest with a medium amount of water. The grain on manured plats was heavier than on the unmanured, and 5 tons of manure gave slightly heavier grain than 15 tons. . . ."

"As an average of the three years, the greatest yield [of leaves] per plat was secured when 20 in. of water were applied. In 1912, however, the highest yield was secured with 30 in. The effect of the manure was more marked on the yield of leaves than it was on the yield of total stover or of grain. About twice as many leaves were produced on plats with 15 tons of manure to the acre as on the unmanured plats." Data also show the effects of the treatments of manure and water on yield of stalks, husks, and cobs, which do not seem to be very marked, especially in regard to water.

"Large amounts of irrigation water cause the corn to have relatively less grain, cobs, and leaves, and more husks and stalks. Manure decreased the percentage of grain, cobs, and husks in the plant, but increased the percentage of stalks and leaves. Soil treatments affected the branching of the corn tassels in the same manner that they affected the production of ears. The time of maturity of corn was delayed by irrigation, but hastened by manure. This is important, since earliness in maturity of corn is very desirable in Utah. The germination of corn was most rapid and complete in a soil containing a medium amount of soil moisture. The number of stomata on a given area of leaf surface was increased by a large amount of soil moisture. This probably causes wastefulness in transpiration. The proportion of roots to tops was increased by lowering the soil moisture. When deep rooting is desired, overirrigation should, therefore, be avoided."

Many tabulated data are included.

Minor dry land crops at the Nephi Experiment Farm, P. V. CARDON (*Utah Sta. Bul. 132 (1914), pp. 349-378, figs. 7*).—This bulletin gives results of trials of crops other than cereals.

Both in the production of seed and hay alfalfa planted in hills 18 by 24 in. apart proved very successful, yielding heavier than several other methods tried. An alfalfa nursery, consisting of 48 selections, is under observation.

Thus far sweet clover and vetch are noted as being of little value under these dry land conditions. *Agropyron occidentalis*, *Bromus inermis*, *B. uniloides*, and *Avena elatior* were of little value as forage crops. Work, which is being continued, with grain sorghum, broom corn, and sugar beets has not yet given satisfactory results.

Drilling corn in rows 3 ft. apart with an ordinary grain drill proved the most profitable method of planting this crop on heavy lands. Several varieties of field peas are reported as being satisfactory, yielding from 384 to 737 lbs. of seed per acre.

Results of variety and cultural tests with potatoes show that "25 varieties of potatoes have been tested since 1908 and most of these have given fair yields during that time. The variety White Peerless has proved most satisfactory from the standpoint of both yield and keeping qualities. The cultural tests with potatoes indicate that sets placed about 24 in. apart in rows 3 ft. apart will give the best results. The depth of planting seems to depend upon the condition of the soil at planting time." Potato yields ranged from 4 to 133 bu. per acre. The source of seed, whether dry-land or irrigated, seems to have little effect on the yield. Small seed was better than large seed, and freshly cut seed slightly better than calloused seed.

The Clermont County experiment farm (*Ohio Sta. Bul. 275 (1914), pp. 309-316*).—This report gives an outline of the general plan of management and results of fertilizer tests in rotations with corn, soy beans, wheat, and clover; of variety tests with corn and oats in 1913; and some results of a 5-year rotation conducted for 20 years at Wooster.

In regard to the fertilizer treatments in a 4-year rotation at Clermont it is noted "that the treatment has produced an immediate and marked increase in yield, and that the complete fertilizer, containing nitrogen as well as phosphorus and potassium, has produced not only the largest total increase but also the largest net gain, notwithstanding the greatly increased cost of the fertilizer."

The Miami County experiment farm (*Ohio Sta. Bul. 274 (1914), pp. 289-307, figs. 2*).—This is a report of progress (E. S. R., 29, p. 31), and gives data on rotations and fertilizer experiments that include corn, oats, wheat, clover, soy beans, and tobacco; variety tests with corn, wheat, oats, tobacco, and soy beans; and feeding trials with pigs (see p. 471).

The data show a much reduced yield the third year on land growing corn continuously as compared with land cropped in rotation. The fertilizer tests indicate a need of potash and phosphorus.

The Paulding County experiment farm (*Ohio Sta. Bul. 273 (1914), pp. 278-288, pls. 2*).—This is a report of progress (E. S. R., 29, p. 137) and gives data on fertilizer tests in rotations that include corn, oats, wheat, clover, soy beans, and sugar beets, and results of variety tests of wheat, corn, oats, and soy beans for 1913.

Report on grass seed mixtures, 1907-1913, W. M. FINDLAY (*North of Scot. Col. Agr. Bul. 18, 1914, pp. 75*).—From grass seed mixtures sown at many centers the following conclusions were drawn:

"There was no direct relation between the weight of hay produced and the quantity of perennial rye grass sown. A small quantity (say $\frac{1}{2}$ bu.) of seed of perennial rye grass produced nearly as much of this grass in the hay as a larger quantity ($1\frac{1}{2}$ bu.). This was due to the greater stocking power and to the stalks being bigger. When a large quantity of perennial rye grass was used, the pasture, during the second and third years, was neither abundant nor prolonged, and pluff grass was encouraged. Neither a small nor a large quantity of Italian rye grass, as part of a seed mixture, increased the hay crop. When the conditions suited it, it competed too severely against red clovers; when the conditions did not suit it, the quantity in the hay was very small.

"The quantity of cocksfoot and timothy in both hay and pasture was increased by increasing the seeding (up to a certain point) and by reducing the quantity of perennial rye grass. Meadow fescue was not able to compete against rye grass the first year or against cocksfoot and timothy the second year. Tall oat grass tended to increase the hay crop, but was not a success in the pasture. Rough-stalked meadow grass had no influence on the hay. Although the plants were small, they helped to fill up spaces in the pasture.

Crested dogtail was present in small quantities in the first and second seasons, but increased considerably by the third. Cattle, however, did not relish the herbage on the plats where it was included. Late-flowering red clover produced more hay than any other kind, but tended to suppress the grasses. On land where white clover did not grow naturally wild white clover was much superior to ordinary white."

Fodder grasses of Java, III-IX, C. A. BACKER (*Teysmannia*, 24 (1913), Nos. 5, pp. 314-320, pls. 3; 6, pp. 366-377, pls. 2; 7, pp. 423-437, pls. 2; 8-9, pp. 495-511, pls. 5; 10, pp. 633-644, pl. 1; 11-12, pp. 721-729, pls. 2; 25 (1914), No. 2, pp. 81-88, pls. 3).—In these articles, containing previous work (E. S. R., 30, p. 525), are described *Paspalum scrobiculatum*, *P. longifolium*, *P. conjugatum*, *P. platycaulon*, *P. distichum*, *P. sanguinale*, *P. royleanum*, *P. minutiflorum*, *P. brevifolium*, *Eriochloa ramosa*, *Isachne australis*, *I. albens*, *I. kunthiana*, *I. pangerangensis*, and *I. firmula*, and their value as fodder plants for Java are discussed, including chemical analyses in some cases.

The chemical composition of South African maize and other cereals, C. F. JURITZ (*Agr. Jour. Union So. Africa*, 6 (1913), Nos. 2, pp. 189-197; 3, pp. 495-501, fig. 1; 5, pp. 806-811).—The chemical composition is reported of numerous varieties of oats, wheat, barley, and maize grown in several Provinces in South Africa, with a special discussion of the content of phosphoric acid.

Influence of suppressing the inflorescence on the sugar content of cane and maize, DECOCK (*Bul. Agr. Algérie, Tunisie, Maroc*, 20 (1914), No. 4, pp. 123-127).—Results are given which show no change or only a slight decrease in sugar content when maize plants were detasseled, while by heading cane the sugar content was in some cases increased nearly 3 per cent.

Composition of maize at various stages of its growth, W. J. JONES, JR., and H. A. HUSTON (*Indiana Sta. Bul.* 175 (1914), pp. 599-630, pl. 1, figs. 12).—This bulletin gives results of chemical analyses of maize made at seven stages of growth.

These results showed that "every ingredient continues to increase uniformly until October 1, and with the exception of potash until October 8. . . . The dry matter, crude fiber, fat, nitrogen-free extract, and starch in the stalks, blades, and husks remain practically constant while they increase rapidly in the ear. The potash increases regularly in the ear, but is depressed in the vegetative parts from August 28 to September 24. This may be due to washing out of potash from the leaves, since there were repeated rains during this period, or it may have been due entirely to transfer to the ear. The potash in the whole plant continued to increase till October 1. On October 2, 4, and 7 heavy rains occurred, which probably account for the marked reduction of potash in both stalks and ears between October 1 and 8.

"The total ash increased regularly in both stalks and ears. After the ear begins to form the nitrogen decreases quite regularly in the stalk, from 53.5 lbs. per acre on August 28 to 31.8 lbs. per acre on October 8, although the nitrogen in the whole plant was rapidly increasing. The amount of amid nitrogen in the ears is too small to be satisfactorily illustrated by curves. But one of the most striking facts shown by the analyses is that the nitrogen in the ear, even in its earliest stages, is practically all in the form of real albuminoids, the amount of amid nitrogen in the ears never exceeding 1.5 lbs. per acre.

"The amount of amid nitrogen in the vegetative parts of the plants decreased from 10.7 lbs. per acre on August 28 to 4.5 lbs. on October 8. No starch was found in the preliminary period, and even at the time when the formation of the ear began, August 28, there were only 335.3 lbs. of actual starch per acre. . . .

"The sharp rise in the potash curve during the period of greatest starch formation, September 24 to October 1, is highly significant. Undoubtedly many maize fields fail to give a satisfactory yield of grain because of a lack of available potash at this period. This lack may be due either to a deficiency of available potash in the soil or to a lack of moisture to bring it to the plant. It is therefore advisable to provide a reasonable supply of available potash if we expect a full formation of starch in the maize. Without complete formation of starch the maize is what is known as 'chaffy.' The same remarks apply to the desirability of furnishing a suitable amount of available phosphoric acid.

"It is to be noted that in this investigation the maize plant, when supplied with a proper amount of water at regular intervals by irrigation, took up about the same amount of phosphoric acid, about 35 per cent more nitrogen, and more than twice as much potash as the authorities usually state that the crop contains."

A large colored chart showing the composition of the plant at five stages of growth is included.

Corn culture, J. M. KIMBROUGH (*Georgia Sta. Bul. 104 (1914), pp. 17-30, fig. 1*).—The results of variety tests with 19 varieties of corn grown in 1913 show an average yield of 36.35 bu. of shelled corn per acre as compared with a little over 15 bu. as a state average in 1912. The best yielder was Weekley Improved, averaging 51.79 bu. per acre.

In a fertilizer test in which the formulas were made to carry equal amounts of nitrogen, sulphate of ammonia at the rate of 99.4 lbs. per acre apparently gave better returns than cotton-seed meal, nitrate of soda, or dried blood as the average of a 4-year test, although nitrate of soda gave slightly the best yield for 1913, followed by sulphate of ammonia, nitrate of lime, dried blood, and cotton-seed meal. In a comparison of cotton-seed meal (285.6 lbs.) and dried blood (189.6 lbs.) the yields per acre were identical.

Better results are shown to have been obtained by applying a complete fertilizer at the time of the second cultivation of the corn than before planting. Subsoiling by the use of dynamite was followed by a yield of 30.35 bu. per acre as compared with 34.3 bu. on soil not dynamited. Applications of complete fertilizers from 200 to 600 lbs. per acre in 100-lb. degrees gave gradually increased yields of corn, but not sufficient to cover costs when more than 200 lbs. was applied.

Corn growing in Washington, G. SEVERANCE (*Washington Sta. Popular Bul. 60 (1914), pp. 14, fig. 1*).—A revision of Popular Bulletin 38 (E. S. R., 25, p. 531).

On cotton cultivation, J. M. KIMBROUGH and R. J. H. DELOACH (*Georgia Sta. Bul. 105 (1914), pp. 33-47, figs. 2*).—In a test of 20 varieties it was found that "the Cleveland Big Boll stands at the head of the list again, with a total yield of 2,852 lbs. of seed cotton per acre."

In fertilizer tests to study the relative efficiency of nitrogen in cotton-seed meal, dried blood, nitrate of soda, sulphate of ammonia, and nitrate of lime in a 9:3:3 formula for cotton, it was found that "on account of the falling off in the yield of the sulphate of ammonia plats in 1913 the five years' average was less with this source of ammonia than with nitrate of soda. The four years previous to this favored the use of sulphate of ammonia." A comparison between cotton-seed meal and dried blood resulted slightly in favor of the latter in yields of 1,754 and 1,852 lbs. seed cotton per acre, respectively. With muriate of potash a yield of 1,679 lbs. was obtained as compared with 1,429 lbs. with kaint.

Dynamiting the land to a depth of 2½ to 3 ft. apparently produced an increase in yield of seed cotton over undynamited land of 126 lbs. per acre.

Brief directions for farm selection of cotton seed to improve the crop are given.

The feeding of cotton, H. C. WHITE (*Georgia Sta. Bul. 108 (1914), pp. 129-144*).—This bulletin gives results of four years' investigation of the composition of the cotton plant at four stages of development during the seasons of 1910-1913, inclusive.

Determinations were made of the nitrogen, phosphorus, sulphur, potassium, calcium, magnesium, ash, and dry matter content for each period.

"Notwithstanding the seasonal differences, which were such as usually obtain in this region, the results for the four successive years exhibit marked agreement. The weight of dry matter of the plant in different periods varied somewhat from year to year, as did also the yield of crop. But the feeding habit of the plant for the mineral foods remained approximately uniform. In only one case is a somewhat wide divergence shown—that of sulphur in 1913. . . .

"Stated roughly, approximately one-third of the total plant food is taken during the first period of 30 days in the life of the plant, terminating with the setting of the first form; a second third is taken during the second period of 30 days terminating with the formation of the first bloom; by the termination of the third period of 60 days, with the opening of the first boll, 85 to 90 per cent will have been taken, leaving only 10 to 15 per cent to be added during the ripening and maturing period of 90 to 100 days. Of the total dry matter of the plant, however, approximately only one-eighth is produced during the first period; another eighth during the second period; one-fourth during the third period; and one-half during the maturing period.

"It may be stated that examination of plants grown in the usual manner in rows 4 ft. apart and plants 12 to 16 in. apart in the row, the cultivation and fertilization being as above recorded, gave results in general agreement with those above reported. The main differences were in the amount of dry matter produced, that is, the weights of the individual plants, which were generally less for the closely spaced plants than for those more widely apart."

A new system of cotton culture and its application, O. F. COOK (*U. S. Dept. Agr., Farmers' Bul. 601 (1914), pp. 12, figs. 2*).—A description of this new system of cotton culture, which is based upon the principle of controlling the formation of the branches, has already been noted (*E. S. R., 28, p. 832*).

Results of additional experiments show an increase in yield due to the new system of 35 per cent in the first picking and 26 per cent in the second picking. No adverse effect on the lint was observed.

The classification and grading of cotton, D. E. EARLE and W. S. DEAN (*U. S. Dept. Agr., Farmers' Bul. 591 (1914), pp. 23, figs. 16*).—This describes the standard grades of cotton established by this Department, with suggestions as to cotton handling and grading.

As factors influencing the grade of cotton, leaf, dirt, sand, notes, neps, gin-cut or stringy fiber, cut seed, and color are discussed. Directions for grading samples by comparing with official standards are given, likewise a comparison of American and European standards. Grade characteristics of Gulf, Upland, and Texas growth, and the relative values of different grades and different lengths are also discussed.

Helianthus, M. RAU (*Illus. Landw. Ztg., 34 (1914), No. 21, pp. 209, 210*).—In giving results of comparative tests the author shows the artichoke to be superior to the potato as a forage crop, as it requires less labor to plant and cultivate, yields more heavily in tubers and straw, is of higher food value, and the tubers have a greater frost resistance.

Grown on adjoining plats and with similar cultural treatment artichokes and potatoes analyzed as follows: Water 74.48 and 71.52 per cent, fat 0.08 and 0.12,

protein 1.84 and 2.53, nitrogen-free extract 22.09 and 23.11, crude fiber 0.52 and 1.17, and ash 0.99 and 1.55 per cent, respectively.

A rapidly growing new forage plant, M. DENAÏFFE and J. COLLE (*Jour. Agr. Prat., n. ser., 27 (1914), No. 10, pp. 300-302, fig. 1*).—This describes *Lolium multiflorum* and gives results of cultural tests in which this grass yielded 4,880 kg. per hectare (4,343 lbs. per acre) in comparison with 3,200 kg. of Italian rye grass and 3,200 kg. of English rye grass.

Chemical analysis shows it to contain less cellulose and more ash than the other two grasses.

Oats for New York, H. H. LOVE (*New York Cornell Sta. Bul. 343 (1914), pp. 363-416, figs. 19*).—This bulletin reports work in cooperation with the United States Department of Agriculture with strains of hybrids, selections, and commercial varieties of oats grown at Cornell in 1911-1913. Some methods and apparatus used in the field and laboratory are described. Tables give yields in bushels per acre, together with gain or loss over the check variety, yields of straw, ratio of straw to grain, weight per bushel, percentage of meat, and weight per 100 kernels.

In regard to transmission of high yield it is noted "that many of the strains under test are not constantly high-yielding. There are some strains, however, which are always among the best in yield."

Some correlations of characters of oats as developed in these tests are noted as follows: Correlation coefficients between a yield of straw and yield of grain for the 3 years, 1911-1913, "are 0.357 ± 0.082 , $0.714 \pm .03$, and 0.5 ± 0.043 , showing that there is a very good correlation between the two characters in question." "When all the varieties that have been grown in 1912 and 1913 are considered, it is found that weight per bushel is correlated with yield per acre. The coefficients for the two years are 0.442 ± 0.05 , and 0.533 ± 0.041 The length of kernel was correlated with weight per bushel for the two years 1912 and 1913, and the correlation coefficients were found to be -0.221 ± 0.059 and -0.5 ± 0.043 , respectively. In other words, as the kernels become longer the weight per bushel became less. The varieties having a long kernel, in general, have a smaller weight per bushel than those having a shorter kernel.

"The breadth of kernel was divided by the length in order to find the ratio between the two characters. The kernels that were broader in comparison to their length would have a higher ratio. This ratio was then correlated with weight per bushel for the two years, and the correlation coefficients were found to be 0.751 ± 0.027 and 0.626 ± 0.035 , respectively, thus indicating that those varieties possessing kernels with greater breadth in comparison to their length gave a higher weight per bushel."

"The highest percentages of meat are obtained from those varieties having a comparatively small kernel. Of 19 varieties having a percentage of meat of more than 70, all but 4 have a kernel weight of less than 2.5 gm. per hundred; while of the 7 varieties whose percentage of meat is 65 or less, 4 have a kernel weight of over 3 gm. This indicates that there is no relation between large kernels and high percentage of meat in the sense that the two are found together.

"All the varieties studied for 1912 and 1913 were arranged in correlation tables with respect to the two characters, weight per hundred kernels, and percentage of meat, and there was found a negative correlation of -0.237 ± 0.058 and -0.188 ± 0.055 . These coefficients are not large, and when one considers their probable errors they are not conclusive other than for the fact that they are negative both years. This indicates that if any relation exists between these characters it is in the direction that large seeds would tend to have a thick hull and therefore a low percentage of meat. For the condi-

tions under which these oats were grown the small- or medium-seeded strains are the more desirable.

"These studies indicate, further, that the varieties tending to produce large quantities of straw give, on the other hand, a large quantity of hull and a comparatively small quantity of meat. The correlation between percentage of meat and yield of straw for the varieties grown in 1913 gave a correlation coefficient of -0.621 ± 0.035 , showing that as the yield of straw increased there was a decrease in percentage of meat. The correlation between length of kernel and percentage of meat was also determined, in order to see whether long kernels gave more meat than short ones. The correlation coefficients were found to be -0.108 ± 0.061 and 0.04 ± 0.057 for the two years, thus showing that there was no relation between length of seed and amount of meat. Correlation tables were made on the percentage of meat and weight per bushel, but no correlation was found. . . . The weight per hundred seeds was correlated with the yield for each of the years 1912 and 1913, and the correlation coefficients for the two years are 0.347 ± 0.054 and 0.23 ± 0.054 . So far as these coefficients are concerned, while they are not conclusive, there is a tendency for the large seed to be associated with large yield."

It is noted in conclusion that some of these hybrids and selections, "such as Silvermine selections 120-9 and 125-20, Welcome selection 123-5, and the Garton Tartar King \times Clydesdale hybrid 27a1-31, have proved to be of value for New York State.

"Place variation tends to operate to such an extent that variety tests should be continued over several years before definite conclusions may be drawn. The later oats, such as the Lincoln or the Silvermine type, have given better results for this locality than have the early oats, such as Sixty Day. The results show that the yield of straw tends to follow closely the yield of grain, and that varieties producing heavy yields of straw usually produce low quantities of meat. The ratio of grain to straw seems to be rather constant from year to year. The weights per bushel for the different years for the same varieties are comparatively high or low, as the case may be.

"Weight per bushel depends considerably on the shape of the kernels. A high weight per bushel does not necessarily mean a high-yielding variety. The weight per hundred kernels was found to vary greatly for the different varieties. There is a slight tendency for heavy-yielding varieties to have larger seed. The percentage of meat differed greatly for the different varieties. Certain varieties give such a low amount of meat that they should not be grown at all commercially."

Some varieties and strains of oats and their yields per acre in South Dakota, A. N. HUME and M. CHAMPLIN (*South Dakota Sta. Bul. 149 (1914)*, pp. 347-372).—Classifications and descriptions are given based upon color, time of maturity, and shape of panicle. Tables report the yield of several varieties grown during 1906-1912, inclusive.

Sixty Day, Swedish Select, North Finnish Black, and Red Algerian were among the best yielders, producing from 23.2 to 43.5 bu. per acre.

Potato growing in Washington, O. M. MORRIS, J. G. HALL, and M. A. YOTHERS (*Washington Sta. Popular Bul. 62 (1914)*, pp. 37, figs. 18).—Cultural notes, including especially methods of treatment for diseases and insect pests.

The effects of defoliation and the application of nitrates on the composition of the sugar beet, W. P. HEADDEN (*Proc. Colo. Sci. Soc., 10 (1914)*, pp. 415-429).—This reports a study subordinate to that previously noted (E. S. R., 28, p. 43).

It is noted that "the defoliation has very radically affected the assimilation and metabolism of the nitrogen compounds in the beets. This is most marked

in the case of the nitric nitrogen, the form in which the plant supposedly takes up its nitrogen supply. In the case of the variety ER the nitric nitrogen in the beet on September 1 was 0.01925, in the normally developed beet on November 8, 0.00827, in the defoliated beets on November 8, it was 0.01367. There is an actual depression in the percentage, but it is not equal to that required to be proportional to the increase in the weight of the beets; in other words, there has been an increase in the amount of nitric nitrogen in these beets instead of a decrease as there was in the normally developed beets, and as there had been in those which had received an application of nitrates up to September 28. The total nitrogen in the beets of the variety ZR harvested November 8 is very low and the nitric nitrogen very high. In this variety we find the size of the beets depressed and the percentage of sugar no higher than it was on September 1 immediately prior to defoliation.

"The amount of mineral matter taken up by the crop of defoliated beets is less than that taken up by the normally developed crop, but the ratio or percentage is scarcely disturbed at all. The most striking feature is perhaps the phosphoric acid, which is the same in the normally developed and the defoliated beets, while it is decidedly depressed in the nitrate beets.

"The complete defoliation of the beets on September 6 caused the production of smaller roots than were produced in the case of the same varieties with normal development. The roots were poorer in dry matter and in sugar than the normally developed beets. These results are in harmony with those previously observed. The effects upon the nitrogen in the beets was to suppress the total amount, but it caused an increase in the nitric nitrogen present in the root while this form was materially reduced (50 per cent) in the normally developed beet. The proteid nitrogen was also depressed, showing that both the intake and assimilation of the nitrogen had been involved.

"The effects of defoliation upon the ash constituents was proportional to the effect upon the size of the roots or crop, and affected the composition of the ash but slightly, or not at all."

It is noted that the attack of the fungus *Cercospora beticola*, which often defoliates beets, produces a similar effect on the resultant crop.

Tabulated data of analyses of various parts of the beet plant are given.

Sweet potatoes: Culture, storing, and studies in fertilizing, H. P. STUCKEY (*Georgia Sta. Bul. 107 (1914), pp. 81-112, figs. 24*).—In this bulletin cultural methods are given which include soil preparation, bedding the seed potatoes in hotbeds and in the open, time and method of setting the plants, methods of keeping and storing sound potatoes, and directions for the construction of a storage house.

Tests of planting dates show a period from May 16 to June 11 to be most favorable for large yields.

Better yields were obtained from pieces of vine about 14 in. long set July 28 in comparison with plants, yields being 36 and 7 lbs., respectively on 1/52 acre plats. Pruning the vines to about 1 ft. in June reduced the yield nearly one-half. Home-grown plants yielded considerably better than commercial plants shipped in from other localities.

Data on the date of digging show that there was a decided financial loss on the Golden Beauty potato by early digging and a gain on the Enormous. "This just emphasizes the necessity of knowing the stage of maturity of the potatoes and the price the market offers for the crop before an early harvest is made." A test of 17 varieties showed a wide range in yields (126.6 bu. to 474.6 bu. per acre) based upon varietal characteristics, the heavy yielders being chiefly of stock feeding quality.

The use of formalin and Bordeaux mixture did not prevent decay of potatoes in storage.

Yields in fertilizer tests are given for the years 1908-1913, inclusive, but indicate that variations due to seasonal conditions are often as great as those due to fertilizer. "Stable manure alone apparently gave a heavy crop of vines and a heavy crop of potatoes, while nitrate of soda alone gave a heavy crop of vines, but a light crop of potatoes. The size and length of the vines, the size and length of the leaf petioles, and the size of the leaves were much greater on those plats receiving nitrogenous fertilizers."

In a study of the cell structure of the vines from different plats it was found that "cross sections of those vines grown on plats receiving heavy applications of nitrogenous fertilizers showed about the same number of cells, but of much larger size than the vines from plats receiving nonnitrogenous fertilizers. The vascular ducts in the vines from the plats receiving nitrogenous fertilizers were also larger than the vascular ducts in the vines from the other plats, but were surrounded by much thinner layers of bast tissue and showed less resistance to the edge of the microtome blade." Analyses of the vines seemed to indicate that their food constituents are only slightly influenced by the kind of fertilizer applied, while analyses of potatoes from the crops of 1909-1913, inclusive, showed considerable variation, but "not sufficient constancy in this variation to warrant any conclusions that the kind of fertilizers used has any marked effect on the chemical composition of the potato." Tests of both raw and baked potatoes for quality and texture for the entire six years showed that the plat fertilized with acid phosphate and the check plat which received no fertilizers gave potatoes of the best quality.

In regard to skin surface the fertilized plats ranked in smoothness as follows: No fertilizer, acid phosphate alone, sulphate of potash alone, complete fertilizer, nitrate of soda alone, and stable manure. In size of tubers the order from large to small was as follows: Complete fertilizer, sulphate of potash, acid phosphate, check plat, and nitrate of soda. With stable manure there were a few extraordinarily large specimens but also a high percentage of very small potatoes.

Notes on the effect of the fertilizers on the mechanical condition of the soil point to an improvement in friability except with nitrate of soda, especially accompanying the application of acid phosphate and barnyard manure. Chemical analyses of the soil of the plats are given.

It is noted that a study to correlate the bacterial nitrification, the chemical composition, and the fertilizers applied with yield of potatoes on the different plats showed little relation. "Plat 1 [barnyard manure] gave a high percentage of plant food, phosphorus, nitrogen, and potash, and a correspondingly high yield of potatoes, but the other plats seem to have no constant variation."

Several hundred measurements of the size of the starch grains showed that they vary slightly, in no constant way, the variation between counts of the same plat often being as great as those from different plats."

Analyses of sweet potato vine hay, alfalfa hay, cowpea vine hay, and timothy hay are reported. The sweet potato vine hay contained 15.5 per cent water, 1.3 nitrogen, 1.7 fat, and 20.8 crude fiber, but it was found impossible to cure and store the hay under ordinary outdoor conditions.

Tobacco seed beds, O. OLSEN (*Pennsylvania Sta. Bul. 130 (1914)*, pp. 151-166, figs. 10).—This bulletin gives results with steam sterilized tobacco seed beds (*E. S. R.*, 24, p. 338; 25, p. 394), the following conclusions being drawn:

"Steam sterilization of seed beds is decidedly beneficial, as it not only effectually kills all weeds and insects when properly done, but also destroys

certain detrimental organisms in the soil. Tobacco seeds should not be sown on the beds until at least 24 hours after sterilization. Seed beds should not be too heavily fertilized, but should be well supplied with nitrogen. . . . The fertilizers should be applied before sterilizing.

"Tobacco seed should be sown without being previously forced to germinate. Seeds should not be sown too thickly, for too heavy seeding results in crowded plants with poor roots. Beds covered with muslin are cheaper and easier to water than glass-covered beds, though the latter cause faster growth. Beds should be ventilated occasionally, and kept moist but not too wet. When weather conditions permit, covers should be removed about a week before planting time, so as to allow the plants to harden."

In fertilizing, the best results were obtained by using at the rate of 20,000 lbs. barnyard manure, 1,600 lbs. cotton-seed meal, 400 lbs. acid phosphate, and 200 lbs. sulphate of potash per acre, and the bed seeded at the rate of 1 oz. per 900 sq. ft.

Wheat investigation (*Nebraska Sta. Rpt. 1913, pp. IX, X*).—This gives results which show about 4.7 bu. increase in yield by the use of selected strains of Turkey Red wheat over local seed, obtained by several farmers throughout the State in 1911-12.

The culture of winter wheat in the Eastern United States, C. E. LEIGHTY (*U. S. Dept. Agr., Farmers' Bul. 596 (1914), pp. 12, figs. 2*).—This gives cultural and harvesting notes for the production of winter wheat in the Eastern States.

The quality of clover and vetch seed found in Maryland markets in 1913, C. P. SMITH (*Maryland Sta. Bul. 179 (1914), pp. 59-88*).—This bulletin gives the results of inspection of samples of red, crimson, white, alsike, and sweet clovers, alfalfa, and hairy vetch found on the market in 1913.

Weeds, H. S. COE (*South Dakota Sta. Bul. 150 (1914), pp. 380-453, figs. 29*).—This bulletin discusses weeds in general, their manner of dissemination, and the losses they cause, and describes in detail, giving methods of eradication of each, about 50 of the more common weeds.

How to rid our farms of weeds, A. L. STONE (*Wisconsin Sta. Circ. 48 (1914), pp. 3-24, figs. 14*).—This circular describes quack grass and Canada thistle and gives means of eradication for large and small areas, besides discussing the detrimental action of weeds in general.

HORTICULTURE.

Vegetable gardening, H. P. STUCKEY (*Georgia Sta. Bul. 106 (1914), pp. 49-91, figs. 17*).—This bulletin contains practical directions for the culture of various vegetables, the subject matter being largely based on data secured from cultural experiments conducted by the station during the past five years. Some brief notes on the results of these experiments are included. The bulletin concludes with a paper on combating insect pests and fungus diseases of garden plants, prepared by B. B. Higgins and H. P. Stuckey.

In 1910 some crosses were made between the cabbage and collard in an effort to obtain new types of collards for breeding strains superior to the common collard. The collard was taken as the seed parent. Data are given on the characteristics of the first and second generation plants. Among these offspring were a number which are considered decided improvements over the ordinary collards. An effort will be made to perpetuate these types.

In a variety test of Irish potatoes it was found on the whole that the early maturing varieties gave the lightest yield. A test was made of the comparative effect on the yield of Irish potatoes from turning under a heavy summer cover

crop and from cutting the crop and raking it off. The results indicate that plowing under large quantities of green vegetable matter during the summer is not deleterious to the potato crop. The yield was slightly higher where the green crop was turned under.

A test of various early strains of tomatoes indicates that Sparks Earliana is about the best foundation stock for breeding early varieties.

Truck farming, H. NESS (*Texas Sta. Circ. 3, n. ser. (1913), pp. 5-50, pls. 3*).—This circular contains practical directions for growing the more important vegetables with special reference to conditions in Texas. Introductory considerations deal with the improvement and conservation of the soil, together with the general principles of vegetable growing.

Regional distribution of fruits and factors controlling it, J. C. CUNNINGHAM (*Proc. Soc. Hort. Sci., 10 (1913), pp. 160-165*).—The author discusses a number of natural and economic forces which have been influential in the distribution of fruits in this country. The factors considered include climate, soil, market, transportation, advertising, labor, and fungus and insect pests.

Some observations on South American fruit production, present and prospective, W. F. WIGHT (*Proc. Soc. Hort. Sci., 10 (1913), pp. 122-133*).—In this paper the author points out some of the more conspicuous features of the fruit industry in South America.

Orchard management (Nebraska Sta. Rpt. 1913, pp. X, XI).—A brief note on the relative efficiency of Bordeaux and lime-sulphur for controlling both apple scab and apple blotch.

Bordeaux was more effective as a fungicide but caused more injury to the fruit, except in the case of the first spraying, which is given before the blossoms open. It is recommended that Bordeaux be used for the first spraying and lime-sulphur for the three subsequent sprayings, except where the weather conditions become extremely dry and hot, in which case Bordeaux should be substituted for the lime-sulphur.

The penetration method of spraying, that is, the application of material in coarse drops at a very high pressure from a Bordeaux nozzle, proved more effective as a control of the codling moth than did the mist spraying in so far as the second or petal-fall spray was concerned. The best results were secured by using the penetration spray at this time and the mist spray for all later sprayings.

Composition of lime-sulphur solutions, A. C. WHITTIER and F. THOMPSON (*Proc. Soc. Hort. Sci., 10 (1913), pp. 71-76*).—Analyses of various commercially-boiled and self-boiled lime-sulphur solutions lead the authors to conclude that the only appreciable chemical difference between self-boiled and diluted commercially boiled lime-sulphur is in the amount of free calcium hydrate, the former containing an amount practically equal to that in a saturated solution of lime water, while that in the diluted commercial product is nearly negligible.

Commercially boiled lime-sulphur solution diluted with lime water to different strengths was applied to peach trees as a summer spray. None of the solutions caused injury, although one contained five times as much polysulphid as did the strongest self-boiled solution analyzed. Although no conclusive experiments have been thus far conducted, the results of the test indicate that the injury usually caused by commercial lime-sulphur solutions may be avoided providing a sufficient amount of free lime is present.

A new spray rig, J. L. STRAHAN (*Cornell Countryman, 11 (1914), No. 9, p. 312, figs. 3*).—The spraying machine here illustrated and described is of the two-wheeled type, the wheels consisting of sheet-metal cylinders $4\frac{1}{2}$ ft. in

diameter and 18 in. high. These are hung on and connected with a 5-in. hollow, stationary iron axle. Vertical suction pipes descend from the axle in each wheel. The engine and pump are carried on a platform between the wheels and connected with the axle. Among the advantages attributed to this machine are its low center of gravity; wide tires; relative lightness as compared with machines now in use; power for agitation supplied by the horses, thereby reducing the necessary engine power; and its short construction, making it easy to turn in the orchard.

Some investigations in grafting, N. O. BOOTH (*Proc. Soc. Hort. Sci.*, 10 (1913), pp. 144-149).—A discussion of the various factors which tend to restrict the art of grafting.

Characteristics of one hundred seedlings of the Northern Spy apple, W. T. MACOUN (*Proc. Soc. Hort. Sci.*, 10 (1913), pp. 76-83).—Data are given showing the similarity or dissimilarity as to various characteristics between 100 Northern Spy seedlings and the Northern Spy parent. Briefly summarized, 35 per cent of the seedlings resembled the Northern Spy in general appearance, 12 per cent in form, 39 per cent in flesh, 19 per cent in color, and 35 per cent in flavor, and 28 per cent showed no marked resemblance. The Northern Spy, which is late in coming into bearing, has given this characteristic to most of the seedlings.

The author concludes that the Northern Spy is one of the best parents to use in crossbreeding, since it has impressed its good characteristics on a large proportion of its progeny, although a self-sterile or partly self-sterile variety.

The effect of pollen of Wagener and McIntosh on the size of and number of seeds in Wealthy apples, J. W. CROW (*Proc. Soc. Hort. Sci.*, 10 (1913), pp. 153-155).—The author used pollen of the Wagener and of the McIntosh apples in fertilizing flowers of the Wealthy apple.

The data secured indicate that McIntosh pollen is more effective in producing a set of fruit on Wealthy than is the Wagener pollen. The resulting fruit is likewise more abundant in proportion to the number of blossoms pollenized, and the average size of the fruits is larger. On the other hand, the average number of good seeds per fruit was greater for the Wagener pollen in spite of the fact that the average number of seeds which had undergone at least partial development was approximately the same in both cases. It appears that the McIntosh pollen may have some effect on fruit setting and the size of fruit entirely separate and distinct from its effect in bringing about actual fertilization.

Some peculiarities of native Georgia apples, T. H. MCHATTON (*Proc. Soc. Hort. Sci.*, 10 (1913), pp. 67-70).—The author here calls attention to a peculiar type of basin, calyx, and calyx tube observed in a large number of varieties of apples grown in the mountains of northern Georgia. The calyx tube is found to be very broad and deep and somewhat between urn and cone shaped. The lobes appear to have fallen away, leaving a very broad and open space at the bottom of the basin. The apples also have a marked oblate shape.

Factors which determine color and size of peaches, M. A. BLAKE (*Proc. Soc. Hort. Sci.*, 10 (1913), pp. 83-88).—A general discussion relative to the various factors influencing color and size of peaches.

Effect of pollination on the fruit of *Diospyros kaki*, H. H. HUME (*Proc. Soc. Hort. Sci.*, 10 (1913), pp. 88-93).—The author's observations relative to the fruiting habits of the Japanese persimmon lead him to conclude that the fruits of *D. kaki* of the same variety and on the same tree often vary greatly in size, shape, color of flesh, quality, taste, and time of ripening. The underlying cause of these variations is attributed largely to the pollination factor. All varieties of Japanese persimmons thus far studied are light-fleshed when

seedless but certain varieties show a dark area in the flesh when seeds are present. Other varieties are always light-fleshed even when seeds are present. Both dark and light fleshed varieties may occur on the same tree.

No conclusions have been reached relative to the physiological causes which underlie the changes in color of the flesh.

Prune growing in southwestern Washington, O. M. MORRIS (*Washington Sta. Popular Bul.* 57^a (1914), pp. 13, figs. 4).—This is a preliminary report on a survey of the soil and orchard conditions in southwestern Washington in conjunction with a study of the weather records. It discusses the cause of the frequent failure of the prune crop in certain localities and suggests certain changes in orchard management for the improvement of these conditions.

Summing up the observations thus far made it appears that unfavorable weather at a critical time during the blossoming or immediately after, together with a weak condition of the trees, has been the greatest cause of crop failure.

Orchard notes, J. B. THOMPSON (*Guam Sta. Rpt.* 1913, pp. 17-19, pl. 1).—This comprises brief notes on the behavior of a number of fruits and miscellaneous plants being tested at the station grounds.

The propagation of the "Saipan" mango (*Mangifera odorata*) on seedling stocks of the ordinary Guam mango (*M. indica*) has been readily accomplished by Oliver's system of inarching seedling stocks (E. S. R., 24, p. 736). In the work at the station inarched plants have flowered within four months from the time of inarching. The results indicate a tendency of this variety to early bearing when inarched.

The jelly plant *Abera gardnerii*, introduced from Florida in 1911, has been successfully fruited and seedlings are being grown for distribution. Thus far the results with citrus trees have been unsatisfactory, due, it is believed, to unfavorable soil conditions. The trees have been lost largely from a disease, probably "gum disease," which is prevalent among citrus trees throughout the island. A further introduction of several varieties was made during the year. Seedlings of the cherimoya (*Annona cherimola*) were found to inarch readily with those of both the bullock's heart (*A. reticulata*) and the sour-sop (*A. muricata*). A list is given of a number of new fruit and other economic plants that were introduced successfully during the year.

Small fruits for Colorado, E. P. SANDSTEN (*Colorado Sta Bul.* 195 (1914), pp. 3-19, figs. 2).—This bulletin contains cultural directions for growing red, purple-cane, and black raspberries, blackberries, dewberries, loganberries, strawberries, currants, and gooseberries, including information relative to varieties adapted to Colorado and insects and plant diseases.

State bog report, H. J. FRANKLIN (*Ann. Rpt. Cape Cod Cranberry Growers' Assoc.*, 26 (1913), pp. 17-32, 43-47).—A report on cranberry investigations presented to the Cape Cod Cranberry Growers' Association, August, 1913. The substance of this report is essentially the same as that noted (E. S. R., 30, p. 142) with the addition of some preliminary observations for the season of 1913.

The "little bogs" at Amherst, T. W. MORSE (*Ann. Rpt. Cape Cod Cranberry Growers' Assoc.*, 26 (1913), pp. 6-9).—The first season's results from fertilizer tests on experimental cranberry plats located at Amherst, Mass., are here reported.

Although no conclusions are thus far drawn relative to a fertilizer for cranberries, the heaviest yields of fruit were secured where potash predominated. Nitrate and acid phosphate fertilizers had a similar effect upon the yield. Potash gave the least vine growth and nitrate the most. The results as a

^a The popular bulletin entitled Sheep for Washington Farms, issued September 13, 1913, and abstracted (E. S. R., 29, p. 870) as Popular Bulletin 57, is evidently now regarded as Popular Bulletin 58.

whole show that of 20 plats receiving fertilizers only 3 bore smaller crops than the average of the 7 unfertilized plats and only one of the unfertilized plats had more berries than the average yield of the fertilized plats.

Some limited experiments dealing with the use of lime for cranberry bogs failed to show either an advantageous or a detrimental effect from lime.

Raspberry breeding, R. WELLINGTON (*Proc. Soc. Hort. Sci.*, 10 (1913), pp. 155-159).—A brief study of the first generation characteristics of a number of raspberry crosses which were made at the New York Geneva Station.

Strawberries under irrigation in south Texas, E. E. BINFORD (*Texas Sta. Circ.* 1, n. ser. (1913), pp. 3-13, figs. 2).—A practical treatise on the culture of strawberries under irrigation, based on data secured by experiments at the Beeville Substation and also on observations of commercial practices in south Texas and on the literature of the subject. The phases discussed include soils and their preparation, transplanting, varieties, sex of plants, spraying, rules for picking and packing, irrigation, picking season, summer treatment, and cost of production.

The varieties that have proved most successful in the extreme south are Saint Louis, Klondike, Lady Thompson, and Buster. Other varieties that have tested well at the Beeville Substation are Brandywine, Marshall, Ben Davis, and Michael Early. The cost of production for the first year, based on data secured from a number of growers by the Office of Farm Management of the U. S. Department of Agriculture, approximates \$200 per acre.

Sterility in the grape, M. J. DORSEY (*Proc. Soc. Hort. Sci.*, 10 (1913), pp. 149-153).—A brief summary of an investigation to be reported on in full at a later date.

Attention is called to the necessity of distinguishing between sterility resulting from differences in essential organs and that due to unfavorable weather conditions occurring at flowering time during many seasons. Sterility is associated with both hybridity and dioeciousness. The native species of our grapes are, generally speaking, dioecious, and fertile pollen borne by the pistillate flower with reflexed stamen is rare. This condition suggests a deep-seated relation between sterility and functional decline. Taking into consideration the fact that there are both fertile and sterile hybrids, the author concludes that the contributory causes of sterility are deep-seated influences operating to produce declinism or dioeciousness. The deep-seated nature of sterility and its relation with dioeciousness indicate that it can not be overcome by cultural conditions.

A bibliography of consulted literature is given.

The fertilizing action of sulphur on the vine, J. CHAUZIT (*Rev. Vit.*, 41 (1914), No. 1052, pp. 175-179, figs. 2).—The author conducted two distinct series of experiments on $\frac{1}{2}$ -acre plats of grapevines. In the first series it was sought to determine what effect sulphur produced on soils which had not received farmyard manure since 2, 3, 4, and 5 years. The second series of experiments dealt with the action of sulphur mixed with manure or sown broadcast and applied in various quantities.

From the work as a whole it is concluded that sulphur acts favorably, both on the growth and yield of the vine. The greater the quantity of organic matter in the soil and the more recently it has been applied the more pronounced is the action of sulphur. To secure the best results the sulphur should be thoroughly mixed with the organic matter on which it is to act. As far as the quantities applied in this test are concerned the yield increased with an increase in the amount of sulphur. The largest amount applied was 360 lbs. per acre mixed with manure. The manure used with or without sulphur was

supplemented by a dressing at the rate of 180 lbs. of muriate of potash and 360 lbs. of superphosphate per acre.

Brief reference is also made to other investigations with sulphur.

How sulphur stimulates plant growth, F. DE CASTELLA (*Jour. Dept. Agr. Victoria*, 12 (1914), No. 5, pp. 289-291).—A review of the above investigation.

Unusual methods of propagating nut trees, R. T. MORRIS (*North. Nut Growers Assoc. Proc.*, 4 (1913), pp. 43-48, fig. 1).—The author discusses a number of unusual methods of propagating nut trees.

When grafting the shagbark hickory with scion wood more than one year old, the author found that if a small side branch from old wood carries a large terminal bud this bud will start promptly, providing care is taken to remove vigorous stock sprouts. Scions 4, 5, and even 6 years of age have been used with success.

An inarch method was recently experimentally employed with success in grafting hickories. In this method the scion is cut free from the parent plant and the part below the inarch is inserted in a test tube or a small bottle containing water. Whereas the use of chemicals in the water prevented the development of unfavorable micro-organisms, they likewise interfered with the union of stock and scion. It was found that the water can be kept in good condition by inserting specimens of bladderwort (*Utricularia*). Two specimens thus grafted in the summer were found to have made a good union in the fall. The successful development of this method will be of special value in extending the grafting season.

The author has also met with success in developing plants of the shagbark hickory, beech, and hazel from adventitious root buds started in sand. With the beech and hazel the buds started from various sized root segments, but with the hickory the buds started best upon root segments more than 6 in. in length and more than $\frac{1}{2}$ in. in diameter. Hazels may be propagated from cuttings similar to rose cuttings, but not so readily as with roses.

Attention is also called to the development of seedlings grown from seed secured from pistillate chinaquapin flowers, which were bagged to prevent pollination. Subsequent check experiments indicate that the chinquapin will develop nuts freely without pollen and that the bitternut hickory, shagbark hickory, and pignut will develop nuts sparingly without pollen. In advance of microscopic examination of the ovules, this phenomenon is attributed to parthenogenesis.

Multiplication of floral parts in the carnation, C. H. CONNORS (*Proc. Soc. Hort. Sci.*, 10 (1913), pp. 93-99).—The substance of this paper has been abstracted from another source (*E. S. R.*, 30, p. 644).

Individuality in rose plants, M. A. BLAKE (*Proc. Soc. Hort. Sci.*, 10 (1913), pp. 133-144).—This comprises a study on the individuality of rose plants based on data secured in a soil experiment with My Maryland roses, conducted for a number of years at the New Jersey Stations (*E. S. R.*, 30, p. 344).

Sweet pea studies.—IV, **Classification of garden varieties of the sweet pea**, A. C. BEAL (*New York Cornell Sta. Bul.* 342 (1914), pp. 217-360, pls. 23, fig. 1).—In continuation of previous reports (*E. S. R.*, 28, p. 641) descriptions are given of a large number of varieties of sweet peas being tested at the station in cooperation with the American Sweet Pea Society. The author briefly reviews the methods which have been previously employed in the classification and description of varieties, and outlines the method of classification employed in the present descriptions.

The results previously noted relative to autumn and spring planting tests (*E. S. R.*, 25, p. 645) are briefly summarized here. A germination test of old seed of a great many varieties conducted in 1910 indicated that white-seeded

varieties lose their vitality in a greater degree than do the black-seeded varieties of the same year's crop. Nearly all varieties from the 1904 crop gave as good results as were obtained in general from the 1909 crop.

FORESTRY.

Tree guide, JULIA E. ROGERS (*Garden City, N. Y., 1914, pp. VIII+265, figs. 244*).—A popular guide to the trees common to the eastern half of Canada and the United States. In addition to the native species the most important cultivated species brought from other countries are also described.

Yellow pine, A. T. NORTH (*St. Louis, Mo., 1913, 4. ed., pp. 130, figs. 22; rev. in Engin. News, 71 (1914), No. 12, p. 649, 650*).—This handbook contains tables of the strength of beams, grouping the timbers in terms of their depth; factors for converting safe loads to other fiber stresses than that on which the tables are based; deflection; properties of actual size instead of nominal size timbers; maximum bending moment; strength of wooden columns; trussed beams; joists, trusses, and nailed and spiked joints; and tests of timbers.

On the conditions for the natural occurrence of spruce, P. E. MÜLLER (*Centbl. Gesam. Forstw., 40 (1914), No. 1-2, pp. 11-27*).—A review of European literature dealing with the factors influencing the natural distribution of spruce trees.

Influence of precocity of thinning on the yield of regular stands of spruce, E. MEE (*Rev. Eaux et Forêts, 53 (1914), Nos. 11, pp. 345-349; 12, pp. 377-386*).—As a result of observations conducted over a period of 30 years and here reported, the author concludes that early thinning undertaken with a view of favoring the development of future trees have accelerated the diameter and volume growth of the trees, and have likewise increased the financial returns.

Can the yield of rubber from Hevea trees be increased by commercial fertilizers? A. W. K. DE JONG (*Teysmannia, 25 (1914), No. 3, pp. 139-144, pl. 1*).—In the experiments here reported potassium, phosphoric acid, and sulphate of ammonia were tried, both alone and in combination, as fertilizers for the Hevea rubber tree. The increased yield of rubber secured by the use of commercial fertilizers, particularly a complete fertilizer, appears to warrant a further thorough investigation of the subject.

[**The rubber industry in Brazil**] (*Min. Agr. Indus. e Com. [Rio de Janeiro] Monograph, 1913, Nos. 9, pp. 47+32, pls. 19; 10, pp. 26, pls. 10; 11, pp. 78, pls. 5; 12, pp. 51; 13, pp. 32, figs. 9; 14, pp. III+118+55, pls. 50, figs. 14; 15, pp. 49, pls. 16; 18, pp. 30, pls. 22; 19, pp. 31+22, pls. 20; 20, pp. 22+12, pls. 4*).—This comprises a series of monographs containing descriptive and statistical accounts of the rubber industry in various regions of Brazil. The monographs given in order corresponding to the numbers above listed are as follows: The Rubber Industry in Pernambuco, by N. C. Pereira de Andrade; in Alagoas, by L. de Moraes; in Sergipe, by A. M. Rabello; in Bahia, by A. Hermenegildo da Silva; in Espirito Santo, by A. A. Campos da Cunha; in Rio de Janeiro, by A. Pereira da Silva; in Sao Paulo, by G. Catramby; in Januaria, State of Minas Geraes, by C. Guimarães junior; in Goyaz, by J. Guedes de Amorim; and balata rubber, by G. Barroso.

Note on a latex hydrometer, B. J. EATON (*Agr. Bul. Fed. Malay States, 2 (1914), No. 9, pp. 224-226*).—The author briefly describes a hydrometer which has proved satisfactory for tropical use in determining the rubber content of latex.

[**The lumber industry in Wisconsin**], MARY DOPP (*Bul. Amer. Geogr. Soc., 45 (1913), No. 10, pp. 736-749, figs. 4*).—A brief historical and statistical review of lumbering and forestry in Wisconsin.

Manitoba, a forest Province, R. H. CAMPBELL (*Dept. Int. Canada, Forestry Branch Circ. 7 (1914), pp. 16, figs. 9*).—An address on the extent, condition, and management of the forest resources of Manitoba, delivered before the Canadian Forestry Association, at Winnipeg, July, 1913.

Trent watershed survey, B. E. FERNOW, C. D. HOWE, and J. H. WHITE (*Toronto: Com. Conserv. Canada, 1913, pp. VIII+156, pls 19*).—This embraces the results of a reconnaissance of the Trent watershed in Ontario. The subject matter is discussed under the following general headings: Conditions in the Trent watershed and recommendations for their improvement, physiographic and forest conditions, and economic and industrial conditions. Information relative to the lumbering industry in the Trent watershed, physical features and geology of the area, mineral occurrences, and other miscellaneous data are appended.

Forest protection in Canada, 1912, C. LEAVITT (*Toronto: Com. Conserv. Canada, 1913, pp. 174, pls. 23*).—This comprises a progress report for the year 1912 relative to methods of forest protection and results secured, together with considerable information on the subject of forest protection based upon observations and methods employed in different sections of the United States.

The subject matter is discussed under the following general headings: Protection from railway fires, forest fires, and the brush disposal problem, the top-logging law in the Adirondacks, the use of oil as a locomotive fuel from a fire-protective point of view, and forest planting in Canada. The report of the committee on forests, Commission of Conservation, 1912, presented at the annual meeting at Ottawa, is also included. Statistical information dealing with the Dominion forest reserves area extensions, a memorandum regarding the country between Sudbury and Port Arthur, by J. H. White, and various opinions on oil fuel are appended.

Cooperative forest fire protection, G. E. BOTHWELL (*Dept. Int. Canada, Forestry Branch Bul. 42 (1914), pp. 28, pl. 1, figs. 10*).—In this bulletin the author describes the development of cooperative forest-fire protective associations in America, particular attention being given to the development and work of the St. Maurice Fire Protective Association in the Province of Quebec.

The care of the woodlot, B. R. MORTON (*Dept. Int. Canada, Forestry Branch Circ. 10 (1914), pp. 16, figs. 11*).—A popular treatise on woodlot management in eastern Canada.

DISEASES OF PLANTS.

The nonvalidity of the genus *Lasiodiplodia*, J. J. TAUBENHAUS (*Abs. in Phytopathology, 4 (1914), No. 1, p. 47*).—The author states that during the past two years his work with *L. tuberculata* and *L. nigra* and upon *Diplodia gossypii* and *D. natalensis* shows that the presence of paraphyses is not of constant occurrence. Under certain conditions it was found that either fungus may dispense with paraphyses or produce the same, and in view of these facts it is believed that the genus *Lasiodiplodia* should be abolished.

Identity of *Peridermium fusiforme* with *P. cerebrum*, G. G. HEDGCOCK and W. H. LONG (*U. S. Dept. Agr., Jour. Agr. Research, 2 (1914), No. 3, pp. 247-250, pl. 1*).—As the result of field and cultural studies the authors claim that *P. fusiforme* and *P. cerebrum* are both æcial stages of the same fungus, *Cronartium cerebrum* n. comb., and that they are not sufficiently differentiated to constitute separate races. In this connection it is further stated that *C. quercus* of Europe is not identical with *C. cerebrum* of the United States.

Biological strains of *Sphæropsis malorum*, L. R. HESLER (*Abs. in Phytopathology, 4 (1914), No. 1, p. 45*).—Studies are reported of *Sphæropsis* taken from 15 different host plants, cross inoculations being made on a large number

of hosts. Pedigreed cultures of a given strain were found to show as wide morphological variation as several strains from different hosts. The results are held to indicate that on several hosts under consideration there is one large species showing many biological races.

Life history of *Sphæropsis malorum*, C. L. SHEAR (*Abs. in Phytopathology*, 4 (1914), No. 1, pp. 48, 49).—In a previous publication (E. S. R., 23, p. 454) the author presented evidence from which it was concluded that the perithecial stage of the apple *Sphæropsis* is a form of *Melanops*, which was found on dead apple branches. Subsequent investigations have confirmed the previous conclusion, and by means of cultures from single ascospores of *M. quercuum* obtained from an old apple tree, *S. malorum* has been obtained.

Grain smuts: Their causes and treatments, M. T. COOK (*New Jersey Stas. Circ.* 36, pp. 4).—Brief descriptions are given of the loose smut of oats, loose smut of wheat, stinking smut or bunt of wheat, and smut of corn, with directions for their control so far as means are known.

Experiments on the control of certain barley diseases, A. G. JOHNSON (*Abs. in Phytopathology*, 4 (1914), No. 1, p. 46).—In connection with investigations on the *Helminthosporium* disease of barley, seed was infested with the covered and loose smuts, as well as by the stripe disease (*H. gramineum*). Seed was treated by the hot water method and also by variations of the formaldehyde treatment.

The control plats averaged from 8 to 10 per cent of covered and loose smut and 20 per cent stripe disease. Where the seed had received the modified hot water treatment, that is soaked for five hours in cold water and 15 minutes at 52° C., the two smuts were perfectly controlled and the stripe disease reduced to less than 1 per cent. Where seed was soaked for two hours in 1 lb. formalin to 40 gal. water, the covered smut was perfectly controlled and loose smut reduced to a bare trace. This treatment was also highly efficient against the stripe disease. The formaldehyde gas treatment proved less efficient than the water solution, and inhibited germination considerably.

Similar tests were conducted with two lots of seed infested respectively with *H. teres* and *H. sativum*, and in both cases the primary infections were reduced but not entirely eliminated.

Some observations and experiments on the blackleg disease of cabbage, M. P. HENDERSON (*Abs. in Phytopathology*, 4 (1914), No. 1, pp. 46, 47).—A report is given of studies to determine the host range of the fungus on the Cruciferæ and whether it may not be disseminated with the seed of cabbage. Inoculations were made on 7 genera, including 15 species and 4 varieties of Cruciferæ, and infections occurred in all but 2 species, *Lepidium virginicum* and *Capsella bursa-pastoris*. In other series of experiments mother seed plants were inoculated by spraying the plants with a spore suspension, after which they were covered with a bell-jar. Infections occurred on leaves, flower stalks, and seed pods. Seeds removed and plated gave pure cultures of the fungus.

The observations and experiments outlined indicate a wide host range for the blackleg organism, thus insuring easy and rapid distribution in the field, and that infected seed may also serve as a means of dissemination.

Progress in developing disease-resistant cabbage, L. R. JONES (*Abs. in Phytopathology*, 4 (1914), No. 1, pp. 47, 48).—In continuation of a report previously given (E. S. R., 29, p. 646), the author gives an account of experiments in developing cabbage resistant to *Fusarium*.

Many of the selected strains of seed tested in 1912 proved equally resistant in 1913, although the weather conditions were considered somewhat more favorable for the fungus in the latter year. The resistant varieties secured in 1912 were all of the Danish ball head or winter types. In 1913 one of the kraut

types, Volga, proved more highly resistant than the best secured in 1912. From the second generation of selected heads sufficient seed was obtained in 1913 for a wider qualitative test of resistance on the part of these varieties.

Decay of celery in storage, D. REDDICK (*Abs. in Phytopathology, 4 (1914), No. 1, p. 45*).—Some experiments are reported upon to determine the keeping quality of celery affected by the late blight disease (*Septoria petroselinæ*) when placed under modern storage conditions. When stored at a temperature of 31° F. from October 15 to December 23, 1912, there was no appreciable spread of the disease.

The author also reports the deterioration of a carload of celery which was stored in November at a temperature of 31 to 32°. A study showed that this lot was infected with *Sclerotinia libertiana*, and cultures of the fungus were obtained which were used for inoculations with positive results.

Some points in the life history of Phytophthora on ginseng, J. ROSENBAUM (*Abs. in Phytopathology, 4 (1914), No. 1, p. 44*).—A disease of ginseng tops due to *Phytophthora* has been previously noted by Hori (E. S. R., 19, p. 752). Some additional observations are reported and it is said that the disease on the leaves and stems, as well as a very serious root disease, is caused by the same organism. The *Phytophthora* organism may first appear on the tops, work its way down by way of the stems, and eventually rot the root. Or it may first appear on the root, and after rotting this, may travel upward into the stem and appear in the tops. The conidia of the fungus may be washed down into the soil and infect the root, provided the latter is not too deep below the surface.

Fusaria of potatoes, C. D. SHERBAKOFF (*Abs. in Phytopathology, 4 (1914), No. 1, pp. 43, 44*).—This is the result of a taxonomic study of the species of fungi of the genus *Fusarium* as they occur in *Solanum tuberosum*.

The author isolated 120 strains which seemed morphologically different, but when grown on artificial and natural media about 70 of them were found to be simply morphological variations. Of the remaining 50, many were identified with the species described by Wollenweber (E. S. R., 29, p. 444).

A study of the annual recurrence of Phytophthora infestans, I. E. MELHUS (*Abs. in Phytopathology, 4 (1914), No. 1, p. 54*).—A large number of potato tubers infected with *P. infestans* were planted in northern Maine under field conditions to determine the possibility of infection through the tuber. This locality is said to be favorable for the annual recurrence of the blight, but the land used in this experiment had not grown a crop of potatoes for at least five years.

Some of the diseased tubers produced plants which became infected by the mycelium in the parent tuber. Above the surface of the soil the fungus produced spores and infected the foliage and neighboring shoots in the same and adjoining hills. It is considered that this experiment demonstrated that seed potatoes affected with *P. infestans* may function in starting an epidemic of late blight.

Some recent studies on new or little-known diseases of the sweet potato, J. J. TAUBENHAUS (*Abs. in Phytopathology, 4 (1914), No. 1, pp. 50, 51*).—In addition to the black rots previously described (E. S. R., 30, p. 150), accounts are given of stem rot due to *Fusarium batatis*, ring rot, which recent studies have shown is a form of soft rot (*Rhizopus nigricans*), a white rust caused by *Cystopus ipomææ panduranæ*, which is said to be of considerable importance, and a new leaf spot, which is attributed to a species of *Septoria* as yet undescribed.

Blossom-end rot of tomato, C. BROOKS (*Abs. in Phytopathology, 4 (1914), No. 1, p. 49*).—The author states that this disease is usually not accompanied by any organism, although bacteria and fungi are present in late stages of the

rot. These organisms, when inoculated into healthy green tomatoes, have failed to produce the disease. The development of the disease is said to be favored by heavy applications of commercial fertilizers and greatly increased by the addition of stable manure. It is decreased by the application of sodium nitrate, and is worse on heavy than on light soil. Its development may be favored by a lack of water and also by excessive watering, depending upon the condition of the plants at the time of the change. Lime has been found to be a partial preventive and it also serves as a remedial agent on plants already predisposed to the disease.

Diseases of tobacco, J. JOHNSON (*Wisconsin Sta. Bul. 237 (1914), pp. 1-27, figs. 7*).—The author gives descriptions of the more common and injurious diseases affecting tobacco in the seed bed, field, and curing house, and suggests methods for their control.

The most serious troubles of the seed bed are said to be the bed rot or damping off and the root rot or black root. The first-named disease is due to *Pythium debaryanum* and Rhizoctonia, while the second is caused by the fungus *Thielavia basicola*. For the control of the diseases of the seed bed sterilization of the soil is recommended, and the steam sterilization by the inverted-pan method is said to be the most efficient and economical of any method tested.

The root rot may also attack tobacco in the field, causing large losses. The author believes that this disease is, in some cases at least, responsible for the so-called running out of tobacco soils rather than a depletion of fertility.

Descriptions are given of rusts of the leaves, which are due to a number of causes, the mosaic disease or calico, shed burn or pole rot, stem rot, wet butts or fat stem, white vein diseases, black rot occurring in sweating tobacco, etc.

For most of the troubles of the curing house, proper attention to ventilation and temperature, it is said, will reduce the loss.

Two new diseases occurring in the field have been observed and studied in a preliminary way. These have been called black leg or canker and hollow stalk. The first is characterized by the decay of the stalks at or above the surface of the ground and seems to be due to the same organisms which cause the damping off of seedlings in the plant beds. The hollow stalk is said to be a decay of the pith of the stalk, which sometimes extends out into the midrib and veins of the leaves, causing them to droop. A bacillus of the soft rot type has been isolated and the disease produced by inoculating healthy plants, which seems to indicate that it is of a bacterial nature.

Disease resistance in tobacco to root rot, J. JOHNSON (*Abs. in Phytopathology, 4 (1914), No. 1, p. 48*).—The root rot of tobacco, due to *Thielavia basicola*, is said to be becoming of economic importance to tobacco growers. In 1913 the author studied the "Burley sick soils" of Ontario and the "deteriorated tobacco soils" of Wisconsin, upon which root rot was found very prevalent. Marked differences in resistance were observed for different varieties, White Burley being very susceptible to root rot, while the variety Little Dutch was found to be very resistant. The Connecticut Havana is approximately intermediate between the other two varieties in resistance to disease. A large acreage was examined for resistant plants and a number were found sufficiently resistant to warrant bagging and preserving for seed. These are to be tested for further selection and breeding in 1914.

Some diseases of nursery stock, M. T. COOK (*New Jersey Stas. Circ. 35, pp. 24, figs. 15*).—A description is given of some of the more serious diseases which are likely to be carried by nursery stock, attention being drawn to them in order that growers and nurserymen may be on their guard concerning their introduction and dissemination.

Among the diseases described are the crown gall, fire blight, apple scab, black rot, peach yellows, little peach, peach leaf curl, black knot, chestnut blight, and anthracnose of berries.

Attention is called to the fact that growers frequently heel in stock that is left over, and this becomes a source of many serious infections. The author recommends that such stock should be either properly reset or destroyed.

Crown gall and hairy root, M. T. COOK (*New Jersey Stas. Circ.* 34, pp. 14, figs. 8).—A description is given of crown gall and hairy root, most of the information being drawn from other investigators, but the author adds a number of his own recent observations concerning these diseases.

The circular concludes with a number of suggestions, the observation of which would tend to reduce the occurrence of the disease to a minimum.

Perithecia in cultures of *Venturia inequalis*, F. R. JONES (*Abs. in Phytopathology*, 4 (1914), No. 1, pp. 52, 53).—The author reports observing perithecia of the apple scab fungus in cultures taken from ascospores in May, 1913, the perithecia appearing in the latter part of November.

Comparative dusting and spraying experiments, F. M. BLODGETT (*Abs. in Phytopathology*, 4 (1914), No. 1, p. 44).—Experiments are reported in which a mixture of sulphur and arsenate of lead applied as a powder and also in suspension in water as a liquid spray were compared with the regular lime-sulphur solution for the control of apple scab.

The dustings with sulphur and sulphur in suspension in water were found to control scab to a large extent, closely approximating that of lime-sulphur solution. The control of insects was best effected by the use of the dust sprays, and the apples from this block were considered commercially the best.

A preliminary report on fruit infection of the peach by means of inoculations with *Cladosporium carpophilum* from peach twigs, G. W. KEITT (*Abs. in Phytopathology*, 4 (1914), No. 1, pp. 49, 50).—The author describes the successful infection of peaches with spores from peach twigs, claiming that the artificial production of peach scab in this manner has not hitherto been recorded.

Gum formation in citrus as induced by chemicals, B. F. FLOYD (*Abs. in Phytopathology*, 4 (1914), No. 1, p. 53).—The author tested 28 different organic and inorganic chemicals to determine their affect on gum formation in citrus trees, the chemicals being inserted into the trunk of young budded trees. Thirteen of the number, including acids, alkalis, and salts of the heavy metals, induced the formation of gum in the living tissue bordering that killed by the chemical. The most copious production of gum was induced by copper sulphate and other salts of heavy metals. A microscopic examination showed that the gum originated in the live unlignified xylem tissue, usually in that adjacent to the dead tissue. In the case of gum production by the salts of the heavy metals, gum formation was induced in succulent terminal branches which showed no tissue killed by the chemicals.

Fungus gummosis of citrus in California, H. S. FAWCETT (*Abs. in Phytopathology*, 4 (1914), No. 1, p. 54).—The author states that at least four different and distinct gum diseases of citrus trees occur in California—psorosis, mal di gomma, and two forms of lemon gummosis. The latter two have been described (E. S. R., 30, p. 51). A number of other fungi, such as *Alternaria citri*, *Penicillium roseum*, *Coryneum beyerinckii*, and *Fusarium* sp., are capable of inducing gum formation when inserted into cuts. The disease, it is said, may be controlled by avoiding the conditions favorable for infection, by making all new plantings with trees budded high on sour stocks, and by trimming out and painting the trunks with concentrated Bordeaux mixture.

Citrus root nematode, N. A. COBB (*U. S. Dept. Agr., Jour. Agr. Research*, 2 (1914), No. 3, pp. 217–230, figs. 13).—An account is given of a study of the

life history of the citrus root parasite *Tylenchulus semipenetrans*, previously described (E. S. R., 30, p. 648.)

This nematode was first noted in California (E. S. R., 28, p. 850). The author, from material received from many of the citrus-producing countries, has found that this organism is widely spread and that it seems to be confined to plants belonging to the citrus family. It is believed that *T. semipenetrans* is an injurious parasite that kills the feeding roots of citrus trees, the extent of the damage varying in different regions and under different conditions. In the progress of the life history studies it was discovered that hot water was fatal to the nematode and that citrus roots would survive temperatures required to kill it. This fact, it is thought, would indicate that a hot water treatment may prove more or less efficient in controlling the spread of the pest.

The poor nitrifying power of soils a possible cause of die-back (exanthema) in lemons, C. B. LIPMAN (*Science, n. ser., 39 (1914), No. 1011, pp. 728-730*).—A preliminary account is given of observations and experiments made on several citrus soils, in which were trees affected with die-back.

The author is led to believe from his investigations that a poor nitrifying power on the part of the soil, with the ammonifying power remaining normal, may be the cause of the peculiar manifestations which are characteristic of the disease. Samples of these soils were examined, and in every case found to have a very slight nitrifying power or none at all. When dried blood or sulphate of ammonia was added to them there was only a slight increase or none of nitrates, while the ammonification proceeded very rapidly. The author believes, and his hypothesis is confirmed by results given by Florida investigators (E. S. R., 23, p. 447) relative to the increased amount of die-back where organic manures were used in citrus groves, that not only die-back is to be accounted for in this way, but that the equally destructive and much more widely spread disease, mottled leaf, is capable of being explained in a similar manner.

Pellicularia koleroga on coffee in Porto Rico, G. L. FAWCETT (*U. S. Dept. Agr., Jour. Agr. Research, 2 (1914), No. 3, pp. 231-233, figs. 3*).—As the result of a study of the leaf blight of coffee in Porto Rico, the author has concluded that it is due to the fungus *P. koleroga*, originally described from India, but which, it has been claimed by mycologists, does not occur in Porto Rico. In connection with this investigation a study was made of a disease known as candelillo in Venezuela. This disease has been formerly identified as being caused by *P. koleroga*, but the author believes it is not due to that fungus.

A destructive nematode introduced into the United States, L. P. BYARS (*Abs. in Phytopathology, 4 (1914), No. 1, pp. 45, 46*).—The author reports observing in hyacinths, in the bulb garden of the U. S. Department of Agriculture at Bellingham, Wash., the nematode *Tylenchus dipsaci*. This nematode not only attacks the bulbs but also the aerial portion of its host, abandoning the leaves toward the end of the season and returning to the bulb. The infection is said to be readily carried by the bulbs, and on account of the destructive nature of the parasite it is considered important to eradicate any bulbs that may be found infected and to make rigid inspection of all imported hyacinth bulbs.

Sphærospis canker of *Quercus prinus*, W. H. RANKIN (*Abs. in Phytopathology, 4 (1914), No. 1, pp. 44, 45*).—This disease of chestnut oaks is said to have been very prevalent at Youkers, N. Y., in July, 1912. The foliage was destroyed, and on the older limbs numerous cankers were found. Isolations were made of the above fungus, and inoculations produced cankers in 47 days. The organism agrees morphologically with the description of *S. malorum*, and

it is believed that this disease is the same as that described by Miss Ingram (E. S. R., 27, p. 654).

A little-known disease of chestnut and oak trees, F. D. HEALD (*Abs. in Phytopathology*, 4 (1914), No. 1, p. 49).—The author describes a disease of chestnut and oak trees due to *Strumella coryneoidea*.

Two forms of the disease are recognized, first, the canker type, in which the progress of the fungus is slow, with a pronounced callus formation at the advancing edge of the lesion; and second, the diffuse type, in which the fungus spreads more rapidly, killing the tissues so quickly that callus formation is impossible. Between these two forms there are said to be intermediate types. The trouble has been observed in widely separated localities in Pennsylvania and it is believed to be of general distribution in forests of the State.

The relation of temperature to the expulsion of ascospores of *Endothia parasitica*, R. C. WALTON (*Abs. in Phytopathology*, 4 (1914), No. 1, p. 52).—Field and laboratory tests are reported upon to determine the effect of temperature on the expulsion of ascospores of the chestnut blight fungus.

From November 26, 1912, to March 20, 1913, with maximum temperatures of from 35 to 60° F. there was no expulsion of ascospores. In the laboratory, when tested at temperatures from 36 to 100°, there was no expulsion of spores at the lowest temperature, but at higher temperatures there was a gradual increase in the amount until the optimum was reached, beyond which expulsion gradually lessened.

Wind dissemination of ascospores of the chestnut blight fungus, F. D. HEALD, M. W. GARDNER, and R. A. STUDHALTER (*Abs. in Phytopathology*, 4 (1914), No. 1, p. 51).—In a previous account (E. S. R., 29, p. 753) the results of ascospore dissemination under artificial conditions were described. In the present paper experiments under natural conditions are reported upon which indicate that viable spores were caught in agar plates 365 ft. to the leeward of infected trees. Prolonged exposures were made of sterile water in dishes located 380 ft. from the nearest chestnut tree, and when plated out colonies of the fungus developed in abundance.

Insects as carriers of the chestnut blight fungus, R. A. STUDHALTER (*Abs. in Phytopathology*, 4 (1914), No. 1, p. 52).—An investigation was made of 75 insects as possible carriers of spores of *Endothia parasitica*. Eight specimens of *Leptostylus maculata* gave positive results, indicating that this beetle is an important agent in the dissemination of spores of the blight fungus.

Control of the *Ribes* generation of the white pine blister rust, C. VON TUBEUF (*Naturw. Ztschr. Forst u. Landw.*, 12 (1914), No. 3, pp. 137-139).—Discussing a previous contribution by himself (E. S. R., 31, p. 50), also one by Ewert (E. S. R., 31, p. 346), the author states that tender shoots of young pines are infected by sporidia from *Cronartium ribicolum* originating on *Ribes*, and that infection from pine to pine does not occur.

ECONOMIC ZOOLOGY—ENTOMOLOGY.

The common mole.—Runway studies; hours of activity, T. H. SCHEFFER (*Trans. Kans. Acad. Sci.*, 26 (1912), pp. 160-163, fig. 1).—This is supplementary to the observations previously noted (E. S. R., 23, p. 752).

The infection of rats with *Bacterium pseudopestis murium* and goiter, B. GALLI-VALERIO (*Centbl. Bakt. [etc.]*, 1. Abt., Orig., 70 (1913), No. 5-6, pp. 278-281, figs. 4).—This second note confirms and completes the preceding one (E. S. R., 29, p. 58) on the rôle of this organism in the development of goiter in rats.

A system of notation applied to entomological accessions, E. S. TUCKER (*Trans. Kans. Acad. Sci.*, 26 (1912), pp. 142-145).—"An explanation of the entire plan for use of symbols may be summarized by steps composing the following course of procedure: All insects contained in an accession are first sorted into superordinal groups as a basis of classification. Each group is then designated by a Roman numeral according to the assignment given. The second step consists in separating the species in each group and indicating each species by a capital letter. In the third step the separate or collective stages of each species are determined, and designated by a small letter, as per assignment. Finally each specimen or pair with respect to one stage, or colony with respect to collective stages, is numbered in consecutive order as desired for special designation. Arabic figures are used for numbering."

[Report of the] Second International Congress of Entomology, Oxford, August, 1912 (*2. Internat. Cong. Ent., Oxford, 1912, vols. 1 (1914), pp. 183, pls. 3; 2 (1913), pp. 489, pls. 32, figs. 28*).—The first volume of this report, by K. Jordan, H. Eltringham et al., consists of the proceedings of the congress; the second volume, edited by K. Jordan and H. Eltringham, of the transactions.

Among the more important papers presented are The Silk of Spiders and Its Uses, by J. H. Comstock (pp. 1-10); The Founding of Colonies by Queen Ants, by W. C. Crawley and H. Donisthorpe (pp. 11-77); Observations on the Central American Acacia Ants, by W. M. Wheeler (pp. 109-139); Progress in Our Knowledge of the Odonata from 1895 to 1912, by P. P. Calvert (pp. 140-157); On the Sense of Vision in Insects, by A. Seitz (pp. 198-204); Observations and Notes on the Geographical Distribution of Some Bloodsucking Insects, by P. Speiser (pp. 205-207); Recent Work in Economic Entomology Carried Out in Western Australia, by N. J. Moore (pp. 221-226); Physiological Investigations of Insect Pests, by J. Dewitz (pp. 234-244); Some Entomological Problems in the West Indies, by H. A. Ballou (pp. 306-317); On Viviparity in Polytenidæ, by K. Jordan (pp. 342-350); Pellets Ejected by Insect-Eating Birds after a Meal of Butterflies, by C. F. M. Swynnerton (pp. 351-354); Notes on the Aphids of the Cultivated Peas (*Pisum sativum* and *Lathyrus latifolius*) and the Allied Species of Macrosiphum, by F. V. Theobald (pp. 380-393); A Synopsis of the Thysanopterous Family *Æcolothripidæ*, by R. S. Bagnall (pp. 394-397); The Differentiation of Zoogeographical Elements of Continental Regions, by H. J. Kolbe (pp. 433-476); and The Simulium-Pellagra Problem in Illinois, U. S. A., by S. A. Forbes (pp. 477-485).

Sixth annual report of the state entomologist of Indiana, C. H. BALDWIN (*Ann. Rpt. State Ent. Ind.*, 6 (1912-13), pp. 224, figs. 162).—This report consists largely of a popular account of insect pests and means for their control. It also includes papers on Some Scale Insects not Heretofore Reported from Indiana, by H. Morrison and H. F. Dietz (pp. 74-78); Some of the More Important Insects Affecting Grains and Grain Products, by H. F. Dietz (pp. 79-105); and Directions for Collecting and Preserving Insects, by H. Morrison (pp. 106-203).

Report of the entomologist's inspection trip to Santo Domingo (*Rpt. Bd. Comrs. Agr. P. R.*, 2 (1912-13), pp. 25-28).—This is a report of a trip made by W. V. Tower during April, 1913, to study insect pests and fungus diseases of sugar cane in Santo Domingo.

"La Changa", *Scapteriscus didactylus*, S. S. CROSSMAN (*Rpt. Bd. Comrs. Agr. P. R.*, 2 (1912-13), pp. 32-35).—A brief outline is given of proposed work with *S. didactylus*. The flea beetles *Epitrix parvula* and *E. cucumeris* are said to be important enemies of the tobacco plant in Porto Rico.

Insects of tobacco, J. JOHNSON (*Wisconsin Sta. Bul.* 237 (1914), pp. 3-34, figs. 10).—This is a popular account of the insect enemies of tobacco and the methods of control.

Insect enemies of fruit trees, P. LESNE (*Jour. Agr. Prat., n. ser.*, 26 (1913), No. 45, pp. 596-600, pl. 1).—This is a brief account of the more important insect enemies of fruit trees in France.

[Work with cranberry insects in 1913], H. J. FRANKLIN (*Ann. Rpt. Cape Cod Cranberry Growers' Assoc.*, 26 (1913), pp. 32-42).—The spanworm referred to in the author's last report (*E. S. R.*, 28, p. 854) as the true cranberry spanworm has been found to differ from that so named by Smith (*E. S. R.*, 15, p. 381). This new spanworm is said to have caused a great deal of damage on a bog at Yarmouth. In studies of its life history, 33 moths emerged between June 6 and June 15 from 42 pupæ collected on August 15, 1912, no parasites being reared therefrom. Barn swallows and tree swallows are said to be important enemies of the adult moths. The dissection of moths has shown at least 295 eggs to be deposited by the most productive and 187 by the least productive.

The experimental work with insects was confined to the flowed bog fire-worm (blackhead cranberry worm) and to the cranberry fruit worm. Studies of the fruit worm have shown the braconid *Phanerotoma tibialis* to outnumber all of its other parasites. All parasites obtained from the berries collected at the center of the state bog, all but one of those from the edge of this bog, and about four-fifths of the parasites from the berries collected from the dry bog were of this species. The berries from the dry bog produced nearly three times as many parasites in proportion to the fruit worm moths which emerged as did the berries from the flowed bog. "The time of the greatest emergence of the parasites from the berries from all three locations mentioned was from June 30 to July 9, inclusive. As slightly more parasites than moths emerged from the worms of the berries from the dry bog, it seems highly probable that more than 50 per cent of the fruit worms on that bog last year were killed by these parasites. This shows something of the importance of the natural enemies of this insect which we have been in the habit of considering as being comparatively free from parasites."

P. tibialis was found to deposit its eggs in the egg of the fruit worm. Whether or not the egg of the parasite hatches before that of the fruit worm has not been determined, but the fruit worm when it emerges from the egg carries the small parasite with it. The parasite larva becomes full grown sometime during the winter or spring, and emerging from the fruit worm forms a white cocoon about itself within the cocoon of the fruit worm.

The second most important parasite reared is a small ichneumon which lays its egg in the fruit worm after it has hatched and is working in the berry.

A monograph of the jumping plant lice or Psyllidæ of the New World, D. L. CRAWFORD (*U. S. Nat. Mus. Bul.* 85 (1914), pp. IX+186, pls. 30).—The study here presented has resulted in a complete rearrangement of the genera of Psyllidæ, a family of considerable economic importance. It is stated that while only the American genera were treated in this monograph, yet most of the genera of the world have been considered in connection with the new system of classification here presented. The American genera have been arranged in 6 subfamilies, namely, *Liviinæ*, *Pauropsyllinæ*, *Carsidarinae*, *Ceriacreminæ*, *Triozinæ*, and *Psyllinæ*. Eight genera and 62 of the species recognized are described as new.

A bibliography of 8 pages is appended.

[Papers on American Hemiptera published by O. M. Reuter], O. HEIDEMANN (*Proc. Ent. Soc. Wash.*, 16 (1914), No. 2, pp. 77, 78).—A bibliography of 32 titles is presented.

The scale insects of British Guiana, G. E. BODKIN (*Jour. Bd. Agr. Brit. Guiana*, 7 (1914), No. 3, pp. 106-124).—A preliminary list with an account of their host plants, natural enemies, and controlling agencies.

Arsenate of lead as an insecticide against the tobacco hornworms in the dark-tobacco district, A. C. MORGAN and D. C. PARMAN (*U. S. Dept. Agr., Farmers' Bul.* 595 (1914), pp. 8, figs. 2).—The subject matter of this publication, which deals especially with the advantages of the use of arsenate of lead and gives directions for its use, has been previously noted from another source (*E. S. R.*, 29, p. 356).

It is stated that during the first 9 days of its life the tobacco hornworm eats about $7\frac{3}{4}$ sq. in. of the leaf surface, while during the last 10 to 11 days of its life it eats about $191\frac{1}{2}$ sq. in. This emphasizes the importance of applying arsenate of lead while the worms are small and easy to kill and before they have done much damage.

Studies of the nun moth, M. WOLFF (*Jahresber. Ver. Angew. Bot.*, 9 (1911), pp. 58-81; *Ztschr. Forst u. Jagdw.*, 45 (1913), Nos. 7, pp. 405-430, pls. 3; 8, pp. 503-522, pl. 1; 9, pp. 537-586).—A detailed report of biological studies conducted by the author.

The peach twig borer, an important enemy of stone fruits, M. A. YOTHERS (*Washington Sta. Popular Bul.* 61 (1914), pp. 4, figs. 5).—*Anarsia lineatella*, one of the most important enemies of the peach in this country, is said to be a common pest throughout Washington State wherever peaches are grown. During some seasons it causes considerable loss to the growers by destroying the fruit as well as the buds of the trees.

A brief account is given of its life history and of control measures. It is pointed out that it can be reached by a contact spray while in its cell beneath the bark, and that it can be killed by a stomach poison when it begins feeding upon the leaf buds in the spring. The author is of the opinion that where regular spraying with either lime-sulphur or crude oil emulsion for the San José scale is practiced each year as late as possible in the spring when the buds begin to swell the work of this pest will be reduced to a minimum and that further treatment will usually be unnecessary.

Late broods of the codling moth, B. S. PICKETT (*Illinois Sta. Circ.* 171 (1914), pp. 7, figs. 7).—This circular calls attention to the serious loss caused by late broods of the codling moth in 1913 and the need that strenuous efforts be made to combat this insect.

The author recommends as a supplement to spraying that attempts be made to trap and destroy the larvæ. This may be accomplished by furnishing suitable hiding places on the trunk, just above the ground and just below the main branches, where the larvæ will gather in large numbers to make their transformations and may be easily destroyed. Bands made of thick brown wrapping paper and of burlap, which are said to be the most readily available materials, are recommended for use as traps.

Notes on some forest Coleophora with descriptions of two new species, C. HEINRICH (*Proc. Ent. Soc. Wash.*, 16 (1914), No. 2, pp. 66-69).—*Coleophora leucochrysellæ* is reported to have been reared from *Castanea dentata* at Falls Church, Va., and Charter Oak, Pa.; *C. carpinella* n. sp. from *Carpinus* and *C. alniella* n. sp. from *Alnus*, both at Hyattsville, Md.; and *C. querciella* from *Quercus* at Falls Church, Va.

Antimosquito work in New Jersey, T. J. HEADLEE (*Jour. Econ. Ent.*, 7 (1914), No. 3, pp. 260-268).—The work in New Jersey, accounts of which have

been previously noted (E. S. R., 29, p. 559; 30, p. 361), is here described under the headings of salt marsh and inland or local mosquito work.

A remarkable outbreak of *Culex pipiens*, W. E. BRITTON (*Jour. Econ. Ent.*, 7 (1914), No. 3, pp. 257-260).—This article records the development of the rain barrel mosquito in edges of a stream at New Haven, and in ponds in the vicinity of Greenwich from which fish had been driven by mill waste, including dyestuffs, etc.

Diptera.—Family Cecidomyidæ, J. J. KIEFFER (*P. Wytsman's Genera Insectorum. Brussels, 1913, No. 152, pp. 346, pls. 15; rev. in Ent. News, 25 (1914), No. 4, pp. 185-188*).—This work lists some 2,500 species and 330 genera from all parts of the world. The review is by E. P. Felt.

The Hessian fly situation in Kansas, G. A. DEAN and J. W. MCCOLLOCH (*Kansas Sta. Circ. 37 (1914), pp. 4, figs. 3*).—A brief popular account based on studies reported in Bulletin 188, previously noted (E. S. R., 30, p. 157).

Ceratopogoninæ sucking the blood of caterpillars, F. KNAB (*Proc. Ent. Soc. Wash., 16 (1914), No. 2, pp. 63-66*).—Following a review of the literature relating to the subject the author presents a description of two new species, namely, *Forcipomyia erucicida* from Florida and *F. crudelis* from Mexico.

The sandfly and pellagra, III, S. J. HUNTER (*Jour. Econ. Ent.*, 7 (1914), No. 3, pp. 293, 294).—A brief summary of progress in continuation of the work previously noted (E. S. R., 29, p. 357).

Experiments with house fly baits and poisons, A. W. MORRILL (*Jour. Econ. Ent.*, 7 (1914), No. 3, pp. 268-274).—Among the more important conclusions drawn from the experiments conducted are the following:

"Vinegar in itself is an excellent bait for a fly trap, but when used with sugar or bread its attractiveness to flies is greatly increased. Equal parts of vinegar, sugar, and water appear to be approximately as attractive as equal parts of sugar and vinegar. An attractive combination poisonous to flies can be made with formalin and vinegar, but further tests are necessary to determine the best proportions. Formalin (40 per cent) differs greatly on different days in its attractiveness to flies. This variation is evidently not due directly to temperature conditions, and it suggests the possibility of the flies themselves differing from day to day in the degree of the sensitiveness of the sensory organs. . . . Beer, milk, and bread, in the order named, are excellent materials to use with formalin, increasing its attractiveness many times. . . . Commercial alcohol (95 per cent) and water at the rate of 1:20 appears from the experiments to be of about equal value with formalin and water mixed at the rate of 1:10, both as to attractive power and killing effects."

Further observations on the breeding habits and control of the house fly (*Musca domestica*), C. G. HEWITT (*Jour. Econ. Ent.*, 7 (1914), No. 3, pp. 281-293, figs. 2).—This preliminary report of investigations carried on during the summer of 1913 is presented primarily with a view to drawing the attention of other workers to the need of experimental work along similar lines.

Report of an expedition to Africa in search of the natural enemies of fruit flies (*Trypaneidæ*) with descriptions, observations, and biological notes, F. SILVESTRI (*Bd. Comrs. Agr. and Forestry Hawaii, Div. Ent. Bul. 3 (1914), pp. 176, pls. 25, fig. 1*).—The first part of this report (pp. 13-40) consists of the itinerary of the journey in which the Canary Islands, Senegal, French Guinea, Southern Nigeria, Kamerun, Gold Coast, Dahomey, Congo, Angola, South Africa, Australia, and Honolulu were visited. This is followed (pp. 41-96) by an account of the fruit flies observed during the expedition in Africa, which includes 10 species of *Ceratitis*, namely, *Ceratitis capitata*, *C. giffardi*, *C. silvestrii*, *C. stictica antistictica*, *C. punctata*, *C. anonæ*, *C. colæ*, *C. rubi-*

vora, *C. nigerrima*, and *C. tritea*; and 7 species of *Dacus*, namely, *Dacus oleæ*, *D. armatus*, *D. bipartitus*, *D. lounsburyi*, *D. vertebratus*, *D. brevistylus*, and *D. longistylus*. The hymenopterous parasites and predators of fruit flies next dealt with (pp. 96-128) include 15 species of Braconidæ, 2 of Proctotrupidæ, 6 of Chalcididæ, and 3 of Formicidæ, many of which are characterized for the first time.

The following are a part of the summary and conclusions drawn by the author: "Various species of *Ceratitis* and *Dacus* exist in West Africa; some of them, at least in the months in which they were observed, in such reduced numbers as to make it seem certain that they are effectually controlled by natural inimical factors. Certain braconid parasites of the genera *Opius*, *Diachasma*, *Hedylus*, and *Biosteres*, together with chalcids of the genera *Tetrastichus*, *Dirhinus*, and *Spalangia*, and proctotrupids of the genus *Galesus* seem to be the inimical factors most active in West Africa against fruit flies. . . . *C. capitata* was found in Nigeria and in Dahomey, but it was extremely rare, at least from November to February. It seems probable that its rarity is due to the action of the same parasites discovered by me for the other species of *Ceratitis* and *Dacus*, though it is quite possible that other inimical factors exist. Some species of hymenopterous parasites attack several different species of *Ceratitis* and of *Dacus*. Parasites of *C. giffardi* and *C. anonæ* were experimentally bred by me on *C. capitata* and developed to maturity. Living adults of *Opius perproximus*, *Dirhinus giffardi*, and *Galesus silvestrii* from West Africa, *O. humilis* and *Trichopria capensis* from South Africa, and *Diachasma tryoni* from Australia, were brought to Honolulu. Large numbers of the fruit fly parasites, *D. giffardi*, *G. silvestrii*, and *O. humilis* and a few specimens of *D. tryoni* were bred at Honolulu and distributed to other islands of the group. No statements can be made in regard to the results of these introductions until the permanent establishment of the species in question has been proved, but if *Opius*, *Diachasma*, *Dirhinus*, and *Galesus* become acclimatized a notable destruction of *C. capitata* may be hoped for."

Reports of the breeding and distribution of the parasites introduced by the author for the period from May 16 to September 30, by D. T. Fullaway (pp. 148-153), and that for the period from October 1 to December 31, by J. C. Bridwell (pp. 154-160), and a summary of the records are appended. A bibliography of 15 pages and a complete subject index are included.

The development of blow flies, STROH (*Berlin. Tierärztl. Wchnschr.*, 29 (1913), No. 42, pp. 753-757).—This article deals with *Calliphora vomitoria* and *C. erythrocephala*.

Four new species of Tachinidæ from North America, W. R. WALTON (*Proc. Ent. Soc. Wash.*, 16 (1914), No. 2, pp. 90-95, figs. 7).—*Polychætoneura elyii* n. g. and n. sp., reared from the red humped apple caterpillar, at East River, Conn.; *Dionea timberlakei*, species of which genus are said to be parasitic on beetles of the genus *Cassida* in Europe, from Cache County, Utah; *Linnæmyia fulvicauda*, reared from *Remigia repanda*, at Aibonito and Rio Piedras, P. R.; and *Compsilura oppugnator*, reared from *Cirphis latiuscula*, at Rio Piedras, P. R., are described as new to science.

Description of a new species of *Agromyza* from Porto Rico, J. R. MALLOCH (*Proc. Ent. Soc. Wash.*, 16 (1914), No. 2, pp. 89, 90, fig. 1).—*Agromyza inæqualis* reared from *Vigna repens* (?) at Rio Piedras, P. R., is described as new.

The apple flea weevil, P. A. GLENN (*Trans. Ill. Hort. Soc.*, n. ser., 47 (1913), pp. 66-78).—This report of work with *Orchestes pallicornis*, carried on largely from June 10 to 24, includes experiments with arsenical and contact sprays and sticky compounds as control measures.

The pest has been observed in Illinois since 1901 (E. S. R., 13, p. 1063), when it was found injuring apple foliage in various localities in the southern part of the State. In some localities the weevils have been abundant enough to be of considerable economic interest, the injury during the past two years having been quite serious, especially in orchards where the foliage is naturally scanty. The reduction of the leaf surface as a result of the work of the beetle has been variously estimated at from 1 to 50 per cent.

The weevil has been found to be single brooded. "It requires something less than four weeks from the time the egg is laid for the insects to reach maturity. Last year practically all the beetles of the new brood had reached maturity and emerged by June 10. This new brood of beetles is the one that does the injury. It feeds upon the undersides of the leaves for a month or six weeks, from about the middle of May to the first week in July, and then descends to the ground and there remains apparently without food for the remainder of the season and the following winter, to appear again the following spring.

"Since the egg is inserted in the tissues of the leaf and the larval and pupal stages are passed within the leaf where sprays will not reach them, remedial measures must be directed against the adult. The adults of the old brood are to be found on the trees after the first of April, the new brood after the middle of May. If possible, the old brood should be destroyed before April 15 or 20, in order to prevent the deposition of eggs for the new brood."

Arsenate of lead, arsenite of zinc, and ferrous arsenate were experimented with, the last two being less effective than arsenate of lead and both burning the foliage badly. The experiments show "that the beetle is susceptible to arsenical poisons, though perhaps less so than many other insects; that immediate excellent results followed the spraying with arsenate of lead in one case in which starch paste was used to secure an even spread of the spray and special pains were taken to cover thoroughly the undersides of the leaves, but that the spray thus applied did not seem to be effective after 36 hours had elapsed in destroying beetles then on the tree; and that flour paste, soap, lime-sulphur, and perhaps Bordeaux mixture added to the arsenical spray repel the beetles." On June 19 bands of tanglefoot fly paper, 2 in. in width, were placed about 2 ft. from the ground around the trunks of six trees. Five days later 408, 375, 426, 548, 387, and 395 beetles, respectively, were counted.

The most promising experiments were those made with contact sprays. Blackleaf 40 used at the rate of 0.25 oz. in a gallon of water in which 1 oz. of soap had been dissolved was found to be about equal in effectiveness to 5 per cent kerosene emulsion. A 6 per cent kerosene emulsion did not kill the beetles satisfactorily but an 8 per cent emulsion killed them almost instantly. "The contact sprays appear to be the most likely to prove effective, though it is very possible that by beginning early enough and spraying thoroughly enough with the poisons, satisfactory results may be accomplished. In either case the sticky bands will prove useful. If no single method succeeds, there is no doubt that by the combined use of all the methods suggested serious injury may be avoided."

The clover leaf weevil (*Hypera punctata*), T. H. PARKS (*Jour. Econ. Ent.*, 7 (1914), No. 3, p. 297).—This weevil, common in the Eastern States, has recently become abundant in a section of the Payette Valley in southwestern Idaho, where during April, 1914, a field of red clover was eaten to the ground and surrounding alfalfa seriously injured by the larvæ.

The boll weevil problem, B. L. MOSS ([*Birmingham, Ala.*], 1914, pp. VII+95, pls. 5, figs. 9).—A summarized account of the Mexican cotton boll weevil and its relation to cotton culture, remedial measures, etc.

Feeding habits of the boll weevil on plants other than cotton, B. R. COAD (*U. S. Dept. Agr., Jour. Agr. Research, 2 (1914), No. 3, pp. 235-245*).—This paper, which is based upon studies carried on at Victoria, Tex., during the summer of 1913, deals in large part with feeding experiments with *Hibiscus syriacus*, but also reports briefly upon feeding experiments with *Sphaeralcea lindheimeri*, *Callirrhoe involucrata*, and *C. pedata*.

The longevity of the weevils fed on the blooms of *H. syriacus* was found to be much greater than that of those fed on either cotton bolls or leaves and compared well with the longevity on cotton squares. The bloom (stamens and corolla) appears to be much preferred to all other parts. Hibiscus buds do not appear to prolong the life of the weevils.

"It is quite evident that it is possible for *Anthonomus grandis* and *A. grandis thurberiae* to breed in the buds of *H. syriacus*. And not only is this possible, but all indications point toward the conclusion that this breeding would be no rarity. . . . These data prove beyond doubt that the boll weevils fed from the time of emergence only on the buds and bloom of Hibiscus can develop sufficiently sexually to produce a number of normal fertile eggs and to deposit them normally.

"No boll weevils have been found breeding in plants other than cotton and *Thurberia* under field conditions, and only one case of feeding under such conditions has been observed. This was in the case of a single boll weevil found feeding on *H. syriacus* at Victoria, Tex., on June 16."

The food of ants, G. ARNOLD (*Proc. Rhodesia Sci. Assoc., 12 (1913), pt. 1, pp. 11-24*).—The chief sources of ant food are animal food, such as other insects and the carcasses of dead animals, and occasionally the excreta of other animals; the sap and sweet liquids of plants derived from the nectaries of the flowers, from wounds or from fruits, or from the sap in an altered form, as the honeydew, or from similar excretions of other insects which live on the juices of plants; the seeds of plants, bulbs, and the tender roots and cotyledons of seedlings or specialized plant structures, such as Muellerian bodies; and the hyphae of fungi.

The introduction of parasites of May beetles into Porto Rico, D. L. VAN DINE (*Rpt. Bd. Comrs. Agr. P. R., 2 (1912-13), pp. 36-48*).—This report relates to work with parasites of the larvæ of May beetles, carried on from January 1, 1912, to January 1, 1913, under the author's direction by C. E. Hood and G. N. Wolcott, particularly relating to work with species of *Tiphia* and *Elis* in Illinois. A brief statement of the work from January 1 to July 1, 1913, is appended.

Notes on the biology of *Diplazon lætatorius*, E. O. G. KELLY (*Jour. Econ. Ent., 7 (1914), No. 3, pp. 294-297*).—The author has found that the adult female ichneumonid (*D. lætatorius*) oviposits in the eggs of the syrphid *Baccha clavata*, following which the syrphid larva develops to maturity, feeding on *Aphis medicaginis* and pupates, from which stage the adult ichneumonids emerge, having required about 35 days for their development.

"Thus there are now four families of Hymenoptera in which certain forms have this method of parasitism; *D. lætatorius* representing the Ichneumonidæ; *Polygnotus hiemalis* and *P. minutus* representing the Proctotrypidæ; *Chelonus texanus* representing the Braconidæ; and *Tetrastichus asparagi*, *Ageniaspis fuscicollis*, and *Litomastix (Copidosoma) truncatellus* representing the Chalcididæ."

Concerning some Aphelininæ, L. O. HOWARD (*Proc. Ent. Soc. Wash., 16 (1914), No. 2, pp. 79-85, fig. 1*).—Among the species here described as new are *Mesidia gillettei*, reared from *Brachycolus tritici*, presumably at Fort Collins, Colo.; *Paraphelinus tomaspidis* n. sp., reared from the eggs of *Tomaspis varia*

in Trinidad; *Physcus fijiensis*, reared from an *Aspidiotus* at Sava, Fiji; *P. gracilis*, reared from a *Lepidosaphes* in West Australia; *P. stanfordi*, reared from *Leucaspis kelloggi*, at Stanford University; and *Azotus chionaspidis*, reared from *Chionaspis difficilis*, at Tokio, Japan.

The species of *Perilampidæ* of America north of Mexico, J. C. CRAWFORD (*Proc. Ent. Soc. Wash.*, 16 (1914), No. 2, pp. 69-76).—Among the twelve species here described several are of economic importance, including *Perilampus chrysopæ* n. sp., reared from cocoons of *Chrysopa* sp. at Batesburg, S. C.; and *Chrysolampus lycti* n. sp., a parasite of *Lyctus striatus*. Tables for the separation of the species of the genera *Perilampus* and *Chrysolampus* are given.

New parasitic Hymenoptera from British Guiana, J. C. CRAWFORD (*Proc. Ent. Soc. Wash.*, 16 (1914), No. 2, pp. 85-88).—A large series of (*Telenomus*) *Prophanurus minutissimus* is said to have been reared from the eggs of *Lycophotia infecta*. *P. alecto* reared from the eggs of the sugar cane borer; *P. thais* reared from the eggs of a large pentatomid; *Aphanurus bodkini* reared from the eggs of *Empicoris variolosus*; *Chalcis pandora* reared from the larva of a hesperid; and *Holcencyrtus calypso* and *Elachertus meridionalis* reared from the larvæ of *Calpodes ethlius* are described as new to science.

FOODS—HUMAN NUTRITION.

The biological significance of the fat content of fish (with special reference to their habitat), O. POLIMANTI (*Biochem. Ztschr.*, 56 (1913), No. 5-6, pp. 439-445; *abs. in Jour. Chem. Soc. [London]*, 104 (1913), No. 614, I, p. 1409).—It is pointed out that during the development of fish embryo the visible fat in the body diminishes, and that during this time the habitat gradually changes from that of an organism living on the surface to one living deeper in the water. Numerous analyses were made to determine whether or not nectonic fish, which move rapidly on the surface, usually contain a greater proportion of fat than benthonic or more slowly moving fish. The fat of the fish studied varied from 1.115 to 20.447 per cent of the dry matter, the fish living in deep water having the larger fat content.

A study of the influence of cold-storage temperatures upon the chemical composition and nutritive value of fish, C. S. SMITH (*Biochem. Bul.*, 3 (1913), No. 9, pp. 54-68).—From a chemical study of fresh fish (summer flounders or fluke and winter flounders), the author concludes that the proportion of water and ash in the flesh of flounders was not affected by a nine months' period of cold storage and that changes in the proportion of soluble, coagulable, and non-coagulable nitrogenous constituents were negligible, while there was practically no change in the content of ammonium nitrogen.

During this period there was apparently no increase in the acidity of the muscle lipins "for fish with a low content of lipins. . . . There was no production of reducing substance from any constituent of the flesh during any of the storage periods. There was no evidence whatever of any depreciation in the nutritive value, or any change in the sanitary character, of the fish at any time during nine months of cold storage."

A further study of the chemical composition and nutritive value of fish subjected to prolonged periods of cold storage, W. A. PERLZWEIG and W. J. GIES (*Biochem. Bul.*, 3 (1913), No. 9, pp. 69-71).—Continuing the work noted above, samples of fish stored up to two years were examined.

The gastric and intestinal membranes of the fish were found to be intact. The abdominal viscera in general were sound and had no odor when handled other than would be noted with fresh flounders.

"The constancy in the data for the yield of ammonium nitrogen, for the reaction of the aqueous extracts, and for acidity of the lipins, shows conclusively that there was no appreciable alteration of the flesh of the fish through bacterial influences. The uniformity in the data for 'soluble' and for 'non-coagulable' nitrogen (making due allowance for the gradual loss of water from most of the fish as the storage period lengthened) shows that there were no appreciable autolytic changes.

"Some of the fish that had been subjected to analysis, including three in storage for two years, were served with meals in conventional ways to a number of people, the authors among them. These portions were palatable and entirely acceptable. The taste was slightly different, perhaps somewhat more 'fishy,' though not unpleasantly so, but otherwise there was nothing to suggest a lack of freshness. . . .

"We do not suggest that our findings would apply in any degree to fish that were not strictly fresh and unspoiled before they were put in cold storage. It is obvious, also, that these results have no bearing on the condition of fish which have been removed from cold storage and kept a week or more in a shop, exposed, until sold, to public inspection during market hours, and iced or kept in a common refrigerator at night. It is equally obvious that these data have no material bearing on the cold storage of anything except fish.

"The results of our studies convince us that fresh fish, similar in general character to flounders, may be preserved frozen, by the best cold storage processes, for at least two years without undergoing any important chemical alteration, and without materially depreciating in nutritive value."

Sterilizing oysters, T. A. BEEL (*Ztschr. Fleisch u. Milchhyg.*, 24 (1913), No. 2, pp. 31-34).—A summary and discussion of data regarding the relation of oysters to typhoid fever.

Fish sausage, PUSCH (*Ztschr. Med. Beamte*, 26 (1913), No. 16, pp. 601-611; *abs. in Hyg. Rundschau*, 24 (1914), No. 6, p. 368).—The author believes that fish sausage is a valuable nutrient and states that, in his opinion, although micro-organisms may not all be destroyed by cooking for ten minutes any which remain would be harmless.

A commercial sausage binder, PETERS (*Ztschr. Untersuch. Nahr. u. Genussmitl.*, 27 (1914), No. 5, p. 397).—A commercial product called "schwarten" extract (hide extract) was found to contain no animal material but to consist essentially of agar-agar.

Relative nutritive value of pasteurized and raw milk, I. C. WELD (*Cream and Milk Plant Mo.*, 2 (1914), No. 7, pp. 1, 2).—A slightly greater rate of gain was observed in babies fed on pasteurized milk in comparison with raw milk.

This, according to the author, may perhaps be attributed "to the destruction of certain possible disturbing elements which, if present in milk not perfectly pasteurized, may tend to retard digestion or prevent the fullest possible assimilation of the milk.

"The actual difference in rate of increase in weight of the babies would seem to be convincing evidence that proper pasteurization does not impair the digestibility of milk or cause any possible injury to the nutritive properties of milk that can be detected even when used for infant feeding.

"The decidedly greater rate of increase in weight of the 110 babies when fed on pasteurized milk over the rate of increase of the same babies when fed on raw milk would seem to be corroborative and conclusive evidence that no possible injury to the nutritive properties of milk actually takes place as a result of modern scientific pasteurization and that even the best supplies of raw milk may at times be improved by such a process."

A study of the nutritive value of some proprietary infant foods, RUTH WHEELER and ALICE BEISTER (*Amer. Jour. Diseases Children*, 7 (1914), No. 3, pp. 169-183, figs. 30).—Laboratory animals (young and adult albino mice) were used in this experimental study of four proprietary infant foods. To adapt the material to use by mice each of these infant foods was modified by the addition of purified casein or of the salts of milk (Osborne and Mendel's protein-free milk) or of both. The authors' conclusions follow:

"Two of the four foods seemed to be complete foods . . . allowing maintenance of constant body weight, normal reproduction, and growth more rapid than normal. With [one] a third generation was produced. The other two foods studied . . . did not prove capable of serving as an exclusive ration. One modification of [one] food appeared to satisfy the nutritive requirements for maintenance and for repair in two instances, but not for growth."

Tin poisoning after eating canned asparagus, A. FRIEDMANN (*Ztschr. Hyg. u. Infektionskrankh.*, 75 (1913), No. 1, pp. 55-61; *abs. in Chem. Zentbl.*, 1914, I, No. 1, pp. 58, 59).—Bacteriological and serological examinations gave negative results, and the poisoning is explained by the tin content of the canned goods, one control sample containing 0.00874 gm. tin per box and the other 0.03428 gm. In the author's opinion the occasional occurrence of such tin poisoning is ascribable to the fact that some persons are especially sensitive to tin.

Analyses showing the composition of the different grades of commercial pack peas, J. C. DIGGS (*Jour. Indus. and Engin. Chem.*, 6 (1914), No. 4, pp. 310-313).—Great variations were noticeable in the composition of a pack of peas put up by a single firm under conditions as uniform as possible in factory work.

The variation in the proportion of peas to liquor in the different grades was considerable. "The composition of the liquor of the canned pea is largely determined by the blanching and processing, and as the more mature peas require a longer period, we may expect to find this grade with turbid liquors of high starch and proteid content. The young, immature dried peas contain 18 per cent more water than the oldest grade. The crude fiber decreases from 10.25 per cent to 7.15 per cent on the drained peas, water-free basis. The percentage of sugar seems to decrease with maturity. The reason is not apparent and should be a field for further study.

"The part played by selective absorption in determining the location of added constituents is one requiring further study. The change in ash is very slight. The composition of the ash seems to remain the same throughout the growth of the pea."

[Analysis of citrus fruit juices and of prickly pear products], H. J. VIBOND (*Union So. Africa Dept. Agr. Rpt. 1912-13*, pp. 308, 309).—The author states that determinations were made of the acidity and sugar content of 24 samples of citrus fruits, one sample in each case coming from trees budded on orange and another on lemon stocks.

The prickly-pear products included feeding stuffs, a so-called fertilizer, and prickly-pear vinegar sirups. "None of these showed much promise of usefulness. The sirups, for instance, were devoid of cane sugar, although one of them was labeled 'sugar, ready for granulating.'" The sugar actually present was grape sugar and levulose.

Has caffen-free coffee a diuretic effect, KAKIZAWA (*Arch. Hyg.*, 81 (1913), No. 1, pp. 43-47).—From experiments with mice as subjects, the author concludes that caffen-free coffee does not increase diuresis.

Studies of the temperature of beverages, A. FRIEDMANN (*Ztschr. Hyg. u. Infektionskrankh.*, 77 (1914), No. 1, pp. 114-124).—The author reviews the

literature of the temperature at which foods and beverages are taken into the body and reports the results of a large number of observations.

He states that, contrary to other observers, he has found that beverages are taken in restaurants as well as at home at a temperature of from 50 to 60° C. or higher. Adults, owing to the fact that they are accustomed to taking hot drinks, note temperature differences less acutely than children. According to his observation, children will seldom drink anything with a temperature over 50°, excepting in families where the adults use hot drinks. He believes that neither the climate nor the time of the year is responsible for any increase in the temperature at which beverages are taken.

Annual report of the food and drug commissioner to the governor of the State of Missouri, 1913, F. H. FRICKE (*Ann. Rpt. Food and Drug Comr. Missouri, 1913, pp. 68*).—A progress report is given of the examination of milk and miscellaneous food products, drug products, and other work under the state pure-food law. Out of a total number of 1,006 samples of food and drugs examined, 458 did not meet the requirements.

[Food inspection work] (*Quart. Rpt. Dairy and Food Comr. Va., 1913, Sept.-Nov., pp. 1-45, 54-68*).—Data are given regarding the examination of a large number of samples of miscellaneous foodstuffs and beverages and the inspection of bakeries and other places where food is prepared and sold.

Report of the Royal Commission on Uniform Standards for Foods and Drugs in the States of the Commonwealth of Australia; together with evidence and appendixes, J. A. THOMPSON (*Sydney: Govt., 1913, pp. LXXII+282*).—This report brings together in detail the evidence of traders and manufacturers affected by the pure-food law, which was taken and collected with a view to uniform legislation for the purpose of making regulations in the several States of the Commonwealth of Australia. In the form of appendixes this information is classified and summarized.

Report of the Royal Commission on Uniform Standards for Foods and Drugs in the States of the Commonwealth of Australia, J. W. GREEN (*Brit. Food Jour., 15 (1913), No. 178, pp. 182-186*).—An exhaustive digest of the report noted above.

Physical and chemical tests for the housewife, SADIE B. VANDERBILT (*Teachers Col. [N. Y.], Bul. 16, 4. ser. (1913), pp. 16*).—A number of tests are described which deal with gas and liquid fuels, water, food materials, food adulteration, soap, and soap powders.

Report of the committee on teachers' salaries and cost of living [National Education Association] (*Ann Arbor, Mich., 1913, pp. XX+328*).—This extended investigation has to do with the increased cost of living, the economic and social conditions of teachers in representative cities, and salary schedules, tenure, and pensions. The following quotation shows the attitude of the committee toward the general question:

"While the 15 per cent rise of prices between 1896 and 1903 may have seemed of minor importance to the earlier committee of the National Education Association on salaries, tenure, and pensions, the subsequent rise has been so large and rapid that, in the opinion of the present committee, it can not be left out of sight for an instant in any discussion or settlement of the question of teachers' salaries."

The nutrition of the people, M. RUBNER (*Trans. 15. Internat. Cong. Hyg. and Demogr. Washington, 1 (1913), pp. 385-407*).—This discussion of the food of the masses is approached, the author states, from a somewhat different standpoint from that of his earlier treatise on a similar subject (E. S. R., 20, p. 662). Nutritive requirements, changes in food conditions and in dietary habits, the merits of different types of diet, relation of food to housing and

other conditions, nutrition in childhood, the feeding of necessitous school children, and similar questions are considered. Suggestions are made for future work.

In closing the paper, which was one of the public addresses at the Fifteenth International Congress on Hygiene and Demography, the author states that "the nutrition of the great mass of the people is a question of the highest importance, deserving far more attention than it has hitherto received. All the great countries ought to have a central authority, a food commission, which should concern itself exclusively with the far-reaching questions of the well-being of the people. The material as it lies before us to-day is very incomplete, but suffices to indicate the main lines of useful work. The nutrition of the masses has so far been most studied with regard to political economy and according to methods and viewpoints which do not always withstand the tests of the physiology of nutrition. Only by means of the physiology of nutrition is it possible to carry on exact research.

"The nutrition of the masses is to us a problem which may be approached and improved from many different sides. It is necessary that not only the hygienists, in the narrower sense, take up the struggle for betterment, but that also the great army of men who are truly humanic in their hearts shall take their places beside us."

People and diet—some questions and solutions, M. RUBNER, trans. by E. BERTARELLI (*Popolo ed Alimentazione—Quesiti e Soluzioni. Turin, 1913, pp. 180*).—See a previous note (E. S. R., 20, p. 662), covering much the same ground.

Viewpoints in the study of growth, L. B. MENDEL (*Biochem. Bul., 3 (1914), No. 10, pp. 156–176*).—Theories of growth, the possibilities of growth, limitations, and other topics are considered in this digest of data on growth and growth phenomena.

Prenatal care, MRS. M. WEST (*U. S. Dept. Labor, Children's Bur. Pub., Care of Children Ser. 1, No. 4 (1913), 3. ed., pp. 41*).—Food and diet are among the subjects discussed in this summary of data.

Change of diet in certain skin diseases, Y. GERSHUN (*Practiceski Vrach, 12 (1913), No. 21, pp. 314–316; abs. in Chem. Abs., 8 (1914), No. 5, p. 955*).—Infants that are breast fed frequently have skin diseases. This is due to the presence of certain poisons in the mother's diet. Psoriasis vulgaris and eczema were often cured by putting the patient on a strictly vegetarian diet.

Studies of beri-beri, X, XI, C. FUNK (*Hoppe-Seyler's Ztschr. Physiol. Chem., 89 (1914) No. 5, pp. 373–380*).—Experimental data are reported in refutation of the theory of the toxic origin of beri-beri.

In experiments with pigeons beri-beri occurred at the same time when like amounts of either cooked or uncooked polished rice were fed exclusively. The disease also occurred when a ration of casein, fat, starch, sugar, and salts was fed. Commercial casein contains a trace of vitamin. When this was destroyed by cooking or by extraction with alcohol, beri-beri occurred more quickly than otherwise. An alcoholic extract made from pigeons suffering with beri-beri had a curative effect in the case of others and did not produce any toxic symptoms. Pigeons contracted beri-beri without using up entirely their stored vitamin.

See also previous notes (E. S. R., 29, p. 664; 30, p. 865).

Increased amounts of carbohydrates hastened the incidence of beri-beri, as did also the addition of starch and sugar to a standard diet. This shows that vitamins play an important rôle in the metabolism of carbohydrates and that they have a greater effect in the metabolism of starch than in that of other food constituents.

Zeism or pellagra? P. A. NIGHTINGALE (*Brit. Med. Jour.*, No. 2771 (1914), pp. 300-302).—The author describes in detail the pathological conditions noted with prisoners when Indian corn meal, from which the bulk of the bran had been removed in grinding, was used as a staple article of diet in place of ground "rapoko" (African millet) (*Eleusina coracana*), from which the husk had not been removed before grinding.

In spite of many symptoms in common, he does not believe that zeism is the same as pellagra. He states that "sufferers from zeism invariably steadily improved under rapoko meal, until in periods varying from 3 weeks to 7 months they showed no further signs or symptoms of it. . . . Relapses were not seasonal, but occurred only in apparently cured cases that returned too soon to the mealie meal diet. . . . The disease was in no way infectious or contagious." He states further that the prison cooks "never contracted the disease, and that any case suffering only mildly recovered rapidly when working in the kitchen, doubtless on account of the extra titbits that were to be procured there." The similarity of zeism to scurvy or beri-beri is also noted.

Analysis of maize samples in connection with the feeding of mine natives, H. J. VIPOND (*Union So. Africa Dept. Agr. Rpt. 1912-13*, pp. 307, 308).—Ash constituents were determined as well as water and protein in 27 samples of corn. The results according to the author, "although they do not reveal any new feature, . . . show what variations may be expected. The figures for protein are of agricultural interest, as they show the marked superiority of the flint over the dent varieties. The poverty of maize grain in lime is also very strikingly shown."

An experimental study of the relation of food to infection, I, E. THOMAS (*Biochem. Ztschr.*, 57 (1913), No. 5-6, pp. 456-472).—Experiments with laboratory animals (pigs) are reported and discussed.

An experimental study of the relation of food to infection, II, O. HORNE-MANN (*Biochem. Ztschr.*, 57 (1913), No. 5-6, pp. 473-491).—Experiments are reported in continuation of the work noted above. The general conclusion is reached that in comparison with carbohydrates a diet rich in protein had a marked effect in lowering tuberculosis infection.

Infection and diet, E. THOMAS (*Umschau*, 18 (1914), No. 10, pp. 195, 196).—A discussion of the experimental data reported in the above papers.

Experiments on the influence of diet on the resistance to disease made with laboratory animals (pigs) showed that resistance was greatest on a diet containing a relatively large amount of protein. The animals fed the carbohydrate diet were badly affected, one of the animals fed a fat diet being a little and the other decidedly affected, and those fed a mixed diet rather generally affected. The general conclusion reached is that protein affected resistance to tuberculosis favorably and carbohydrate unfavorably.

The influence of underfeeding and of subsequent abundant feeding on the basal metabolism of the dog, S. MORGULIS (*Biochem. Bul.*, 3 (1914), No. 10, pp. 264-268).—Under the experimental conditions the carbon dioxide production and oxygen consumption per hour returned to the normal values, as did the rate of respiration and pulsation and body temperature. "There had been no adaptation on the part of the organism to the greater inflow of energy. Its metabolic activity had been temporarily raised while the exhausted organs and tissues had been rapidly repaired, but as soon as the storing away of reserves predominated over the constructive processes, the basal metabolism went back to its original level, the level which was characteristic for this particular organism."

Protein storage in the liver, N. TICHMENEFF (*Biochem. Ztschr.*, 59 (1914), No. 3-4, pp. 326-332).—Whether or not one can conclude that there is a storage

of protein in the liver, from his experiments with laboratory animals (mice) and other data the author regards it as certain that the protein content of the liver is much more dependent upon the amount supplied in the diet than is the case with other organs. If it should prove that the protein stored in the liver on a very abundant diet is as quickly used up in subsequent fasting, the stored material can be regarded as a sort of labile protein. The possibility of its being regarded as a reserve protein is also suggested. Further work is promised.

The glycogen content of the liver after feeding protein and protein cleavage products, A. TSCHANNEN (*Biochem. Ztschr.*, 59 (1914), No. 3-4, pp. 202-225).—According to the author, the continued supply of protein cleavage products makes entirely different demands on the liver from feeding with native proteids or with a mixed diet. The experiments were made with laboratory animals.

The cleavage of fatty acids in the animal body, M. KOPPEL (*Über den Abbau der Fettsäuren im Tierkörper. Inaug. Diss., Univ. Strassburg, 1913; abs. in Zentbl. Biochem. u. Biophys.*, 16 (1914), No. 11-12, p. 366).—The author has studied the cleavage of saturated aliphatic acids of the acetic acid series with a view to determining the first step in the oxidation of fatty acids.

The cleavage of fatty acids in the animal body, L. HERMANN'S (*Biochem. Ztschr.*, 59 (1914), No. 3-4, pp. 333-336).—This theoretical discussion of fat cleavage is based upon the author's work and that of others.

Evidence of fat absorption by the mucosa of the mammalian stomach, C. W. GREENE and W. F. SKAER (*Amer. Jour. Physiol.*, 32 (1913), No. 7, pp. 358-368).—A series of experiments was made with laboratory animals (puppies and kittens), in which the amount of fat in the superficial gastric epithelium and in the gastric glands at different times was studied with relation to feeding and fasting. The main conclusion drawn, according to the authors, is that "there is a definite cycle of variation in quantity of fat in the gastric mucosa and in the different gastric glands in relation to the time following a meal rich in fats."

Chemical and morphological investigations on the importance of cholesterol in the organism.—IV, The cholesterol content of the blood of different animals and the influence of cholesterol intake, especially with the food, L. WACKER and W. HUECK (*Arch. Expt. Path. u. Pharmakol.*, 74 (1913), No. 6, pp. 416-441; *abs. in Jour. Chem. Soc. [London]*, 106 (1914), No. 615, I, p. 102).—The relationship of free to combined cholesterol varies and is affected by nutrition, muscular work, breathing, and other factors.

By feeding free cholesterol, the amount in the blood serum was increased and that in the ester form still more increased. The same results were noted when it was administered subcutaneously. The corpuscles, however, were but little affected. In growing animals cholesterol accelerates growth, leading especially to the deposition of fat. Its continued administration leads to disorders of the alimentary canal and to arterial sclerosis.

The experiments were made with laboratory animals.

Chemical and morphological investigations on the importance of cholesterol in the organism.—VI, The influence of muscular work on the cholesterol content of the blood and suprarenal bodies, E. PICARD (*Arch. Expt. Path. u. Pharmakol.*, 74 (1913), No. 6, pp. 450-460; *abs. in Jour. Chem. Soc. [London]*, 106 (1914), No. 615, I, p. 102).—With rapid muscular work the amount of cholesterol in the cortex was found to increase, while that in the blood fell slightly.

Muscular work—metabolic study with special reference to the efficiency of the human body as a machine, F. G. BENEDICT and E. P. CATHCART (*Carnegie Inst. Washington Pub. No. 187* (1913), pp. VII+176, pl. 1, figs. 10).—The

investigations reported were carried out with a special form of respiration apparatus (E. S. R., 21, p. 665), and with a bicycle ergometer described in a previous publication of the U. S. Department of Agriculture (E. S. R., 21, p. 68), and a second instrument which was a replica of it. Two essentially fundamental questions were considered, namely, the character of the material burned in the body before, during, and after muscular work, and the relationship between the amount of productive effective muscular work and the total heat output.

The subjects of the experiments were all young men in perfect health. Four of them were accustomed to bicycle riding, while the fifth, with whom most of the experiments were made, was a well trained professional bicyclist. The experiments were all carried out in the postabsorptive state, that is, at least twelve hours after the last food had been taken. The investigation as a whole covered several months and involved several hundred experiments.

The results showed that during severe muscular work there is a distinct alteration in the character of the materials burned in the body. The evidence indicated a selective combustion of carbohydrate material, though the experiments do not point to an exclusive combustion of carbohydrate during muscular work.

The greater part of the experiments was devoted to a study of the relationship between the total heat output and the effective external muscular work, thereby giving information in regard to the mechanical efficiency of man. The report also takes into account other important questions relative to the muscular work of man, such as the effect of muscular work on the pulse rate, the body temperature, the mechanics of respiration, and the drafts upon the body material, the maximum working capacity of man, and particularly the after-effects of work. A certain amount of evidence was provided by the experiments for a comparison of results obtained with trained and untrained individuals.

Under certain conditions, it is pointed out, particularly when the subject is riding with a moderately severe load and immediately begins riding with a very severe load, it is possible to superimpose a load upon the human body so that 40 per cent of the increment in the total heat output may be in the form of effective external muscular work transmitted to the machine, such as the bicycle ergometer. The experiments gave no indication of the possibility of "overloading" the human machine so far as mechanical efficiency was concerned. Obviously the power of human endurance is limited, but an interesting point brought out is the fact that the professional bicyclist performed all of the experiments without food and that on at least one day he did an amount of work equal to a "century" run over ordinary roads. This experiment gave the data for computations with respect to the probable amount of available glycogen in the human body.

An extensive review of the earlier literature with an analysis of the results obtained by former investigators accompanies the report.

The temperature of expired air and air in the lungs, A. LOEWY and H. GERHARTZ (*Pflüger's Arch. Physiol.*, 155 (1913), No. 3-5, pp. 231-244, figs. 3).—An extended series of observations is reported and discussed.

ANIMAL PRODUCTION.

Introduction to heredity, R. B. GOLDSCHMIDT (*Einführung in die Vererbungs-wissenschaft. Leipzig and Berlin, 1913, 2. ed. rev. and enl., pp. XII+546, figs. 189*).—This volume treats of the theories of inheritance, variation, mutation, hybrids, and other related subjects.

A monograph of albinism in man, K. PEARSON, E. NETTLESHIP, and C. H. USHER (*Drapers' Co. Research Mem., Biometric Ser.*, 8 (1913), pp. VII+265-524, pls. 33, figs. 3; 9 (1913), pp. VI+136+XXIII, pls. 59; rev. in *Nature* [London], 92 (1914), No. 2313, pp. 717, 718).—In this review attention is paid to the need of more clearly classifying the various kinds and degrees of albinism. The original article "gives a full account of the clinical and microscopic characters of various kinds of albinism in the widest sense of the word, both in man and animals; discusses their occurrence and geographical distribution; and includes, in part IV, nearly 700 fully described pedigrees, some of them extending to 100 or more individuals."

Studies of Guam range plants, J. B. THOMPSON (*Guam Sta. Rpt. 1913*, pp. 15-17).—This is an account of the principal grasses, sedges, and miscellaneous plants of Guam that are useful for pasture and feeding purposes.

Analyses of feeding stuffs, P. H. WESSELS ET AL. (*Rhode Island Sta. Insp. Bul.*, 1914, May, pp. 2-16).—Analyses are reported of the following feeding stuffs: Meat and bone scrap, cotton-seed meal and feed, linseed meal, gluten feed, malt sprouts, brewers' grains, wheat middlings, bran, hominy chop, corn meal, and various mixed and proprietary feeds.

[Feeding stuffs], W. D. SAUNDERS (*Quart. Rpt. Dairy and Food Comr. Va.*, 1913, Sept.-Nov., pp. 48-54).—Analyses are reported of dried beet pulp, rye middlings, oats, linseed meal, cracked corn, cotton-seed meal, wheat middlings, shipstuff, bran, shorts, gluten feed, and various mixed and proprietary feeds.

Chemical analyses of licensed feeding stuffs, 1914, F. W. WOLL and W. H. STROWD (*Wisconsin Sta. Circ. 47* (1914), pp. 3-89).—Analyses are reported of the following feeding stuffs: Linseed meal, cotton-seed meal, gluten feed, hominy feed, distillers' grains, wheat bran, middlings, red dog flour, germ middlings, rye, barley, and buckwheat feeds, rice meal, rice bran, dried brewers' grains, malt sprouts, alfalfa meal, molasses feeds, and various mixed and proprietary feeds.

There is included the text of the Wisconsin feeding stuffs law, definitions, etc.

Commercial feeding stuffs and fertilizers licensed for sale in Wisconsin, 1914, W. H. STROWD (*Wisconsin Sta. Circ. 46* (1914), pp. 3-21).—This circular gives a list of commercial feeding stuffs and fertilizers licensed for sale in Wisconsin, 1914, together with definitions of the important feeding stuffs and general instructions to manufacturers and dealers.

Analyses of feeding stuffs (*Jahresber. Landw. Kammer Stettin, Prov. Pommern*, 1912, pp. 37-42).—Analyses are reported of cotton-seed meal, peanut cake, sesame cake, palm kernel cake, cacao meal, rape-seed meal, linseed meal, sunflower-seed cake, soy-bean meal, germ-oil meal, rye bran, wheat bran, barley bran, oat meal, rice meal, molasses feeds, and fish meal.

Feeding principles, W. VÖLTZ (*Ztschr. Spiritusindus.*, 37 (1914), No. 10, pp. 147, 148, 151).—In this article the author describes the methods of steaming and ensiling potatoes and potato refuse as well as beets, green corn, and lucern. The composition and digestibility of these materials as determined by several investigators are given. A method of preserving beet leaves, potatoes, etc., by the use of a lactic acid starter is also described, in which the material is placed in trenches, inoculated with *Bacillus delbrücki* and the trench covered with boards and soil.

Animal production, M. HOFFMANN and VON OLLECH (*Jahresber. Landw.*, 27 (1912), pp. 272-465).—Recent German publications of investigations on this subject are classified and reviewed.

[Animal husbandry] (*Rpt. Dept. Agr. N. S. Wales*, 1913, pp. 9, 47-53).—This embodies statistics on live stock importations to New Zealand and a report of the sheep and wool industry, including the establishment of stud flocks, the

breeding work being done with longwools and Dorset Horns, and crossbreeding experiments which have been previously noted (E. S. R., 30, p. 372).

Animal feeding, dairy cattle, milk, butter, beef cattle (*Scranton, Pa., pp. IX+[624]+XI-XXIV, figs. 290*).—This volume, which is a part of the International Library of Technology, treats of animal feeding, breeding, and management, and contains chapters on dairy and beef cattle production.

Studies on the work of protein in the intestinal canal, F. A. KRAMM (*Studien über den Abbau der Proteine im Darmkanal. Inaug. Diss., Univ. Leipsic, 1912, pp. 14*).—The author reviews the work of Abderhalden on the work of the protein substances and peptones in the intestinal canal and gives the results of experiments showing the rapid transformation of these substances up to the amino acid stage.

Studies on the passage of drinking water through the stomach, R. OTTO (*Studien über den Transport getrunkenen Wassers durch den Magen. Inaug. Diss., Univ. Leipsic, 1912, pp. 59, pls. 6*).—This reports extended studies made of the passage of water through the stomach of the horse and dog.

[**Experiments in animal production**] (*Nebraska Sta. Rpt., 1913, pp. XI-XIII*).—This is a summarized account of recent experiments in animal production.

Six lots of cattle were fed upon corn and the following supplements: Lot 1, prairie hay and cold pressed cotton-seed cake; lot 2, corn silage and cotton-seed cake; lot 3, corn silage and prairie hay; lot 4, a heavy ration of corn silage and alfalfa hay; lot 5, a light ration of corn silage and alfalfa hay; and lot 6, alfalfa hay. The respective daily gains per head were 1.92, 2.01, 1.75, 2.24, 2.04, and 2.29 lbs., and the costs per pound of gain 9.53, 9.21, 9.08, 7.76, 8.33, and 7.21 cts., respectively. These results do not correspond with those of earlier experiments and it is purposed to duplicate the work before final results are published.

Four lots of hogs were fed as follows: Lot 1, soaked whole wheat; lot 2, soaked whole wheat and tankage; lot 3, soaked ground wheat; and lot 4, soaked ground wheat and tankage. Wheat was valued at 75 cts. per bushel and tankage at \$2.50 per hundredweight. The lots of pigs made a total gain of 705, 825, 1,000, and 1,108 lbs., respectively, costing 8.40, 6.6, 5.84, and 6.06 cts. per pound of gain.

Economical cattle feeding in the corn belt, J. S. COTTON and W. F. WARD (*U. S. Dept. Agr., Farmers' Bul. 588 (1914), pp. 19, figs. 6*).—The authors discuss the cost of producing and of feeding cattle, the care of manure and maintenance of soil fertility, methods of cattle feeding adapted to high-priced and moderate-priced land, use of hogs following cattle, shrinkage, etc.

Cost of beef production under semi-range conditions, G. E. MORTON ET AL. (*Colorado Sta. Bul. 189 (1913), pp. 3-8*).—The object of the experiment here reported was to secure information concerning the cost of producing fat 2-year-old cattle under modified range conditions, the cattle to be run on native grass within fences in summer and to be winter fed.

It is estimated that about 20 acres of range is required per head with ordinary weather conditions. Fifteen head of range-bred 3-year-old cows of Hereford and Shorthorn blood were used in the experiment. These calved in May to July. The 15 calves were brought in on October 20 and winter fed until June 3. The average gain in weight per head was 339 lbs., or 1.63 lbs. daily gain. The amount of feed consumed per head was 2,200 lbs. alfalfa hay and 788 lbs. barley, valued at \$13.38, and the cost per pound of gain 3.85 cts. It is stated that these results encourage the liberal winter feeding of range calves.

The yearlings were summer ranged under adverse conditions, and made only 26 lbs. average gain per head. Again they were winter fed, going in September

18 at 658 lbs. per head and coming out April 6 at 1,031 lbs., or an average daily gain of 1.78 lbs. at a cost of gain of 6.85 cts. per pound. The estimated profit per head, over cost of feed and shrink, for the entire 2 years' feeding was \$13.47 per head. These figures do not include the cost of labor in winter feeding.

Owing to the adverse conditions under which the experiment was conducted, only general conclusions are drawn from these results. The main profit came in the winter feeding of calves, which bears out the results of earlier work (E. S. R., 23, p. 276). Also "the fattening of the steers as yearlings was a profitable operation, and with reasonable growth on range there is every encouragement for the production of beef in valleys of the State where alfalfa and barley can be grown and there is outside range for the cattle."

A table is included giving information gathered from a selected lot of men running range cattle in different sections of the State and showing estimates of the normal cost of ranging cattle.

Feeding beef cattle, C. A. WILLSON and S. A. ROBERT (*Tennessee Sta. Bul. 104 (1914), pp. 77-107, figs. 4*).—Three groups of 2-year-old steers, group 1 consisting of 8 lots comprising 82 head; group 2, 6 lots of 56 head; and group 3, 5 lots of 45 head were fed during a 90-day period corn silage, cotton-seed hulls, and cotton-seed meal in various combinations, the cotton-seed meal being fed in low (3 to 5 lbs.), medium (5 to 7 lbs.), and high (7 to 9 lbs.) daily amounts, respectively. The average daily gains were 1.52, 1.75, and 1.72 lbs. per head, respectively; the average cost per pound of gain 8.53, 8.52, and 12.1 cts.

The general results from the work on cotton-seed meal for steer feeding indicate first, that the best and cheapest gains can be made when the amount of cotton-seed meal fed increases from 5 to 7 lbs. per head throughout the feeding period; second, that the feeder is not warranted in the use of cotton-seed meal to the extent of from 7 to 9 lbs. per head per day, except in very short feeding periods of from 30 to 50 days; and third, that medium meal rations are as efficient from the standpoint of gains as high meal rations, increasing from 7 to 9 lbs. and are much more efficient from the standpoint of economy. In comparing corn silage and cotton-seed hulls as roughage it was found that when small amounts of cotton-seed meal are fed, such as 3, 4, and 5 lbs., silage gives better results than cotton-seed hulls, but that where large amounts are fed the cotton-seed hulls give the better results.

On another series of tests, 117 steers fed silage and cotton-seed meal made an average daily gain of 1.72 lbs. per head, 82 on cotton-seed hulls and cotton-seed meal 1.6 lbs., and 32 on a combination of silage, hulls, and cotton-seed meal 1.91 lbs. The average cost per pound of gain was 8.20, 11.3, and 7.6 cts., respectively. These results indicate that much better gains may be made through the use of silage with cotton-seed meal than through the exclusive use of cotton-seed hulls for the roughage portion of the ration. When silage is fed, however, greater gains may be made by the addition of a small amount of some dry feed, such as hulls. The largest and most economical gain was made where a small amount of hulls was fed in conjunction with the silage. The average returns per ton of silage fed are estimated to be \$7.65, those of cotton-seed hulls \$13.78. From this it is concluded that it requires a much wider margin to feed steers with hulls than with silage.

A study made of the influence of breed on gains showed a gain of 25.6 lbs. in favor of the steers with one or more beef-bred crosses. Not only did the better-bred steers make more gains, but the gains were put on in the more valuable beef cuts, and thus made the beef-bred steers sell at a wider margin and greater profits. Steers classed as very good made an average gain for 90 days of 158.8 lbs.; those classed as good, 143.6 lbs.; medium, 122 lbs.; and poor, 124.9 lbs.

Corn silage and mill products for steers, J. W. WILSON (*South Dakota Sta. Bul. 148 (1914), pp. 332-343, figs. 5*).—This bulletin is a continuation of work previously noted (E. S. R., 27, p. 872).

Three lots of yearling steers of 4 head each were fed during a 146-day feeding period, each lot receiving all the silage the steers would eat and 12 lbs. of a by-product, this being for lot 1 oil meal, lot 2 cotton-seed meal, and lot 3 dried distillers' grains. The average daily gains per head were 2.45, 1.95, and 2.17 lbs., respectively; and during the first ninety days 2.69, 2.08, and 2.49 lbs. The estimated cost per pound of gain was 5.86, 6.64, and 5.5 cts.

In 2 other lots grain was substituted for one-half by weight of the silage fed in the former lots, lot 4 receiving oats and lot 5 corn. The former lot made average daily gains of 2.18 lbs. per head, the latter 2.09, and during the first 90 days 2.3 and 2.01 lbs., respectively, costing 6.88 and 8.22 cts. per pound of gain. The average amount of feed required to produce a pound of gain for the 146-day feeding period was as follows: Lot 1, 19.7 lbs. of silage and 1.2 lbs. of oil meal; lot 2, 21.2 lbs. of silage and 1.5 lbs. of cotton-seed meal; lot 3, 20.3 lbs. of silage and 1.3 lbs. of dried distilled grains; lot 4, 10.9 lbs. of silage and 4.7 lbs. of oats; and lot 5, 11.6 lbs. of silage and 5.9 lbs. of shelled corn.

A chemical analysis, by G. E. Youngberg, of the feeds used is appended.

Results of pasture fattening, CLAUSEN (*Deut. Landw. Presse, 41 (1914), No. 16, pp. 195, 196*).—Oxen from 1 to 4 years old were pastured on various types of pasture. The average daily gains on 100-year-old heavy moorland pasture without manure were 1.45 kg. per hectare, on an 8-year-old light moorland pasture fertilized with stable manure and Thomas meal 1.09 kg., and on a 14-year-old moorland pasture fertilized with offal and Thomas meal, 1.22 kg.

[Color inheritance in Shorthorns], J. WILSON (*Live Stock Jour. [London], 79 (1914), No. 2085, p. 287*).—The author presents evidence to show that whereas ordinarily when a red Shorthorn and a white breed are crossed there is no possibility of anything but a roan being produced, there is a class of white cattle having red or black points which do not breed like ordinary Shorthorn whites. These are similar to the wild white cattle and are dominant in color to ordinary cattle, breeding like blacks or reds.

How to handle sheep for profit, F. KLEINHEINZ (*[Chicago], 1913, pp. 25, figs. 12*).—This pamphlet gives practical suggestions for the feeding, care, and management of sheep. There is included an article on Scotch sheep feeding by J. Clay.

Swine, sheep, horses, mules, ponies, asses (*Scranton, Pa., pp. VI+[640]+VII-XVII, pl. 1, figs. 327*).—This volume, which is a part of the International Library of Technology, treats of swine, sheep, horse, pony, ass, and mule breeding and management.

Pasture and grain crops for hogs in the Pacific Northwest, B. HUNTER (*U. S. Dept. Agr., Farmers' Bul. 599 (1914), pp. 27, figs. 9*).—This is a reprint of an earlier publication previously noted (E. S. R., 30, p. 771).

Alfalfa pasture for pigs, L. FOSTER and H. H. SIMPSON (*New Mexico Sta. Bul. 90 (1914), pp. 31, figs. 7*).—Four lots of 8 pigs each were pastured on alfalfa during a 65-day feeding period, lots 2, 3, and 4 receiving in addition 1 lb. grain, 2 lbs. grain, and 8 lbs. skim milk, respectively, per 82 lbs. live weight. The grain consisted principally of wheat. The average daily gain per head was 0.254, 0.66, 0.73, and 0.6 lb., respectively, and the profits per acre of pasture \$16.48, \$22.39, \$16.85, and \$19.58.

Three lots of 8 or 9 pigs each, of the Tamworth, Duroc, and Yorkshire breeds, were pastured on alfalfa during a 153-day feeding period and fed supplementary rations as follows: Lot 1, $\frac{3}{4}$ to 1 lb. corn, lot 2, $\frac{1}{4}$ to $\frac{3}{4}$ lb. corn, and lot

3, 5 to 6 lbs. skim milk per 85 lbs. live weight. The respective average daily gains per head were 0.49, 0.38, and 0.41 lb.; the cost per pound of gain 4.75, 4.05, and 3.81 cts.; and the returns per acre of alfalfa pasture, \$17.56, \$16.33, and \$18.44. The low returns per acre of pasture are attributed to the small number of pigs kept on the area, which would have carried one-half more pigs. Tamworth pigs made an average of 75½ lbs. gain per head, Durocs 71¾, and Yorkshires 47. The latter made their best gain on the light grain ration. It is concluded that the greatest profit can be made by running pigs on alfalfa pasture and feeding from ½ to 1 lb. of grain per 100 lbs. live weight per day.

Two lots of pigs, one of 13 Tamworths and the other of 21 Durocs, were pastured on alfalfa during a 126-day period, receiving supplementary feeds of skim milk, bran, and shorts. The Tamworth pigs gained 7.3 lbs. per head more than the Durocs and made their gains at a cost of 0.3 ct. less per pound, thus indicating that they are a little better suited to grazing on alfalfa pasture and to utilizing a bulky ration.

Three lots of 12 pigs each, comprising Duroc, Tamworths, Duroc-Tamworths, and Yorkshire-Tamworths were pastured on alfalfa during a 59-day period, receiving supplementary feeds as follows: Lot 1, 4 to 6 lbs. per head per day of skim milk; lot 2, ¾ to 1 lb. per head per day of ground wheat; and lot 3, 2¼ to 3½ lbs. ground wheat and skim milk, about 1:6. The average daily gains per head were 0.43, 0.57, and 0.51 lb., respectively; the returns per acre of alfalfa, \$14.03, \$19.11, and \$17.15. The breeds ranked in gains as follows: Duroc-Tamworth, Tamworth, Duroc, and Yorkshire-Tamworth. Wheat was found to be a satisfactory and economical supplementary feed for alfalfa pasture, and skim milk a fair supplement, but not worth over 17 cts. per hundredweight where the ground wheat is worth \$1.32 per hundredweight. It is estimated that 8.15 lbs. skim milk are equivalent to 1 lb. ground wheat for supplementary alfalfa pasture.

Three lots of 9 pigs each were pastured on alfalfa during a 120-day period, receiving supplementary feeds as follows: Lot 1, 4 to 6½ lbs. per head per day of skim milk; lot 2, 2 to 3½ lbs. per head per day of skim milk, together with ¼ to ¾ lb. ground milo maize; and lot 3, 2 to 3½ lbs. skim milk and ¼ to ¾ lb. shorts per head per day. The respective average daily gains per head were 0.25, 0.28, and 0.29 lb.; the cost per pound of gain 4.11, 3.5, and 3.64 cts.; and the returns per acre of alfalfa \$24.35, \$28.82, and \$27.88.

The general results indicate that for six months' pasturing, supplemented with a medium ration of concentrated feed, a gain of 782 lbs. per acre may be credited to alfalfa pasture.

Swine husbandry (*Ohio Sta. Bul.* 274 (1914), pp. 306, 307).—Two 3-acre plats of 45 bu. per acre corn were "hogged down" with sixty 76-lb. pigs, all the pigs having access to only one plat at a time. In addition to the standing corn, the pigs received 0.3 lb. of tankage daily per pig and some shelled corn at the beginning and close of the experiment. The pigs made an average gain of 1.51 lbs. daily per pig during the 42 days required to hog-down the 6 acres, and at 6 cts. per pound live weight showed a return of \$34.31 per acre for the standing corn.

Second biennial report of the state board of horse commissioners, W. E. CARROLL (*Utah Sta. Circ.* 17 (1914), pp. 59-74).—This circular reports the distribution of the breeds of licensed stallions and jacks in Utah. The Percheron breed leads with 31.7 per cent.

British horse breeding, G. T. BURROWS (*Breeder's Gaz.*, 65 (1914), No. 11, p. 592).—At the annual meeting of the Clydesdale Horse Society of the United Kingdom of Great Britain and Ireland it was reported that 837 certificates for

export animals had been issued, as follows: Canada, 629; United States, 37; South Africa, 51; Sweden, 15; Germany, 1; Russia, 55; South America, 20; New Zealand, 19; and Australia, 10.

It is stated that a keen demand has existed for weighty young geldings of the Shire breed. The demand for the Suffolk from America, Canada, South Africa, and Australasia has been greater than ever. Hackneys have stood still, while there has been some trade in polo ponies and hunters.

Experiments with poultry, R. M. SHERWOOD and W. J. BUSS (*Ohio Sta. Bul.* 262 (1913), pp. 515-542, figs. 8).—In order to secure data relative to the cost of egg production and to the variation in rate and economy of production that may be expected when different lots of fowls are treated alike, four lots of about 50 White Leghorn pullets were fed the same ration for one year and the amount of feed consumed recorded. The average grain and mash consumed per pullet ranged between 67.95 and 70.75 lbs.; the average cost of feed per pullet per year 94.6 and 98.5 cts.; the average gain in weight per pullet 0.177 and 0.376 lb.; the average number of eggs per pullet 117.1 and 125.5; and the cost per dozen of eggs produced 9.17 and 10.09 cts. In another experiment, 5 lots of pullets ranged in average egg production between 104.8 and 141.6 per pullet at an average cost per dozen between 7.62 and 10.77 cts.

Four lots of caponized Barred Plymouth Rocks were fed as follows: Lots 1 and 3 corn, wheat, oats, ground corn, bran, and beef scrap; lots 2 and 4 corn, ground corn, and beef scrap. There was a wide variation in the amount of feed consumed and in the gains made, and hence in the cost of feed per pound of gain, this being respectively 10.95, 9.67, 14.02, and 10.71 cts. The greater cost of lots 1 and 3 was attributed to the variety of feeds in the rations fed these lots. The lots which received corn, ground corn, and beef scrap had a yellower skin than that of the other lots.

A study of the fertility of eggs of 230 fowls shows that the number of fertile eggs began to decrease from 8 to 12 days after mating. In experiments in individual mating the shortest time after mating in which fertile eggs were produced was about 42 hours. The length of time after mating through which fertile eggs were produced varied with different individuals from a little less than a week up to nearly 18 days.

Plans of the poultry buildings at the station are included.

Twelve months' poultry-laying competition, 1912-13, at Harper Adams Agricultural College, Newport, Salop, F. W. RHODES (*Field Expts. Harper Adams Agr. Col., and Staffordshire, Rpt. 1913, pp. 49, pls. 2, figs. 6*).—One hundred pens of six birds each, comprising seventeen breeds of poultry, were represented in this competition, pens of White Wyandottes winning first, third, fourth, fifth, and sixth position; White Leghorns, seventh, eighth, and ninth; and Buff Plymouth Rocks, second. The greatest number of eggs laid by any pen during the entire year was 1,389, and the greatest number by any one hen, 275.

The grain feed used consisted of a mixture made up of dari, buckwheat, hemp, millet, ground peas, ground beans, and corn meal 5 (by measure) : 5 : 1 : 1 : 2½ : 2½ : 5. With this mixture was fed an equal quantity of cracked wheat, cracked wheat and whole oats. A warm mash consisting of biscuit meal, bran, fish or meat meal, middlings, and ground oats 6 : 6 : 3 : 3 : 2, scalded and soaked, was also fed. Vegetables were given in the form of swedes, carrots, and raw chopped onions during the winter, and lettuce, alfalfa, and cabbage during the summer. Green bone, bone meal, and oyster shell were fed as required.

It is estimated that the total weight of eggs laid during the entire year was 9,576 lbs. and the total weight of feed consumed 51,728 lbs., or approximately 5.4 lbs. of dry feed per pound of eggs.

Of the total number of eggs laid, 91,115, 76.46 per cent graded as large, weighing over 2 oz., 23.43 per cent as medium, weighing from 1½ to 2 oz., and 0.11 per cent as small, weighing under 1½ oz.

Of the 554 hens examined as to weight it was found that the light and medium birds proved themselves more prolific than the heavier types.

The real money in eggs, H. A. ROBERTS (*Country Gent.*, 79 (1914), No. 7, pp. 316, 317).—A financial account of a 2,000-hen plant, having a total investment of \$10,000. Pure-bred and high-grade White Leghorns are used. The average yearly egg production claimed is 144 eggs, the feed cost per hen per year \$1.54, and all other expenses \$1.06, making a total of \$2.60, or 21⅓ cts. per dozen of eggs. The average net price received was 36 cts. per dozen, thus making a profit of \$1.72. The manure was valued at 25 cts. per hen, making the total yearly profit per hen \$1.97.

The availability of the nitrogen of cotton-seed meal and of beef scrap for chicks, B. L. HARTWELL and R. A. LICHTENTHAELER (*Rhode Island Sta. Bul.* 156 (1914), pp. 219-282, pls. 2, fig. 1).—This bulletin contains the results of eight experiments which conclude the study previously noted (*E. S. R.*, 25, p. 676) of the value of different protein concentrates in the growth of chicks. A comparison was made of the two protein concentrates, beef scrap and cotton-seed meal, both being fed on an equal nitrogen basis.

A pepsin-pancreatin extract made from one of the lots of cotton-seed meal had no harmful effect upon rabbits and hens to which it was fed. The basal ration in these experiments was so deficient in protein that a considerable amount of this ingredient could be added in the concentrates without supplying enough for the maximum growth of the chicks. Hence under these conditions the amount of protein was the main factor in growth, and since the non-protein constituents of the feeds were usually in such liberal amounts the protein was probably mainly efficient as a source of nitrogen rather than as a source of energy.

It was demonstrated that for the growth of young chicks it is more important within reasonable limits for the amount of protein to be sufficient than that it be associated with a definite proportion of carbohydrates and fat, or in other words that there be a definite nutritive ratio. Analyses of the cooked portions of chicks showed that between the ages of about 4 to 15 weeks the chicks retained about 18 per cent of the nitrogen consumed during that period in the medium protein rations, in which case there was no unnecessary waste of nitrogen. In the majority of cases there was a larger gain in live weight per gram of nitrogen fed in case of the beef scrap than the cotton-seed meal lots, but this is not deemed significant under the conditions.

It is concluded that if "the constituents of bone are supplied, there appears to be no reason why cotton-seed meal may not be used to furnish a considerable portion of the protein required by chicks, especially if a moderate consumption of food is satisfactory to the feeder. If the most rapid growth is desired, regardless of the amount of feed consumed, beef scrap will be found more satisfactory since the chicks consumed more of the beef-scrap ration when allowed to have all they would eat and made a more rapid growth in consequence. When limited to the same amount of nitrogen, however, the gains were not very different whether cotton-seed meal or beef scrap formed a prominent part of the rations."

Rich-colored yolks, C. L. OPPERMAN (*Country Gent.*, 79 (1914), No. 9, pp. 432, 433, fig. 1).—Three lots of 40 white Leghorn hens each were fed as follows: Lot 1, yellow corn, bran, gluten meal, beef scrap, 9:6:4:2; lot 2, wheat, bran, wheat meal, beef scrap, 9:6:4:2; and lot 3, wheat, yellow corn, bran, wheat meal, gluten meal, beef scrap, 4½:4½:6:2:2:2. In this test all eggs from pen

1 showed a yolk with a deep yellow color, those from pen 3 had a yolk of good yellow color, and those from pen 2 were noticeably pale in color of yolk.

In a second test in which white corn was substituted for the yellow in pen 1, pens 1 and 2 produced eggs with very pale yolks in all cases but one, and pen 3 a good yellow in all cases. The results of this experiment tend to show that the color of the corn influences the coloring of the yolks and that wheat exerts no influence.

Vitality and activity of sperm cells and artificial insemination of the chicken, L. F. PAYNE (*Oklahoma Sta. Circ. 30 (1914), pp. 3-8, figs. 2*).—The objects of the work reported in this circular were first to study the vitality of the sperm cells of fowls under both laboratory and natural conditions, and secondly to test the possibility of artificial insemination of poultry.

Under artificial conditions the cells did not appear active after 28 hours when kept at body temperature. Cells kept at 34° F. lived from 2 to 3 times as long as those at body temperature. The number of cells per cubic millimeter from five cock birds of approximately the same age ranged between 2,000,000 and 5,000,000.

Virgin pullets were bred and killed at certain periods after breeding and a microscopic examination for sperm cells made of scrapings from the oviduct. It was found that sperm cells pass very quickly from the cloaca to the infundibulum or full length of the oviduct. After the fourteenth day cells in the oviduct appeared to have greatly degenerated. From the fourteenth to the fifty-sixth day the movement in cells was the same and had all the appearance of life, although fertile eggs were not laid more than 16 days after the males were removed. Hens laying infertile eggs were treated artificially with seminal fluid with a resulting fair percentage of fertile eggs.

Standard-bred poultry (*Scranton, Pa., vols. 1, pp. VIII+[385]+IX-XXII, pls. 28, figs. 79; 2, pp. VII+[281]+IX-XVIII, pls. 43, figs. 15*).—These two volumes, which are a part of the International Library of Technology, treat the various breeds of poultry.

Poultry farming (*Scranton, Pa., vols. 1, pp. VIII+[617]+IX-XXXIV, figs. 337; 2, pp. VII+[548]+IX-XXIX, pls. 2, figs. 247*).—These volumes, which are a part of the International Library of Technology, treat of the various phases of poultry breeding and management.

DAIRY FARMING—DAIRYING.

Dutch methods of breeding dairy stock, W. WRIGHT (*Jour. Agr. [New Zeal.], 8 (1914), No. 3, pp. 277-293, figs. 8*).—The author states that there are at present three breeds of native cattle to be distinguished in the Netherlands, the black and white Holland, the red and white Meuse-Rhine-Yssel, and the black white-head Groningen breeds. The body characteristics and measurements of the three breeds are described.

While each group comprises various tribes, families, and types, the typical characteristics of the breeds are constant and permanent. With regard to their relative aptitudes for the accumulation of flesh these groups rank as 40: 50: 55, respectively; as to milking powers, as 60: 50: 45.

It is stated that the fundamental principle of the reorganized Netherland herdbook is the improvement of each of the three native breeds by straight breeding. Animals which do not possess the coat proclaimed typical of one of these breeds are excluded from the herdbook. A rigid system of inspection and of registry is practiced in connection with the herdbook recording. The animals are judged by a prescribed score card especially adapted to each breed.

Care of the dairy bull, C. L. HILL (*Hoard's Dairyman*, 47 (1914), No. 17, pp. 623, 628, figs. 2).—The author presents evidence tending to show that bulls at their maturity are better sires than when young. The records of fourteen of the most successful sires of the Guernsey breed that were kept until mature are given, showing that in the majority of cases their two highest record daughters were sired when the bull was from 4 to 10 years of age.

German dairying, K. FRIEDEL and A. KELLER (*Deutsche Milchwirtschaft. Halle, Germany, 1914, pp. XX+237, pl. 1, figs. 264*).—This book treats of the production of sanitary milk in Germany. Special attention is given to stable construction and to dairy and creamery equipment. The book is copiously illustrated, showing approved modern methods of sanitary milk production and delivery.

Bacteriological and chemical report upon the samples of milk obtained at the milking machine trials, Bishop Auckland, April, 1913, J. GOLDING, R. S. WILLIAMS, and J. MACKINTOSH (*Jour. Roy. Agr. Soc. England*, 74 (1913), pp. 247-256).—In these trials it was observed that the best machines were those in which the teat cups did not depend solely upon suction for their support, those in which the tubes leading from the cups to the can were short and in which rubber and joints were avoided, and those in which cleansing was facilitated. On the whole, the bacteriological content was larger in machine-drawn milk than in hand drawn.

Observations on the bacteriological and chemical examination of the milk supply of Bombay, L. L. JOSHI (*Calcutta, 1913, pp. 20*).—This paper, given at the All-India Sanitary Conference, Lucknow, 1913, discusses the condition of the milk supply in Bombay and gives suggestions for its improvement. An interesting observation made is that "out of 614 samples of milk examined, not a single sample showed genuine tubercle bacilli, from which it may be concluded that tuberculosis is rarely, if at all, conveyed by milk in India."

Bacteriological standards for milk (*Pub. Health Rpts. [U. S.], 29 (1914), No. 20, pp. 1218-1221*).—A list of cities of the United States is given showing the bacteriological standards adopted by these municipalities.

Studies on homogenized milk, A. BURR and H. WEISE (*Molk. Ztg. [Hildesheim]*, 28 (1914), Nos. 20, pp. 367, 368; 21, pp. 381, 382).—A difference of from 0.01 to 10 per cent of the fat was found to exist in milk homogenized by the Gerber method over that by the Röse-Gottlieb process. From 3.8 to 7.3 per cent of the total fat content in the milk was retained in raw milk after centrifuging, while from 72.7 to 87.5 per cent was retained in homogenized milk.

Experiments in butter making from whole and mixed milks, E. MATHEWS (*Jour. Roy. Agr. Soc. England*, 74 (1913), pp. 276-280).—It was demonstrated in connection with milk and butter tests at the Bristol Show, 1913, that no advantage in point of weight of butter is obtained in mixing milks showing a large percentage of fat with those of poorer quality. However, the butter made from the mixed milks of different breeds was better both in appearance and in quality than that made from the unmixed milks of these breeds.

Comparing results obtained in churning from differently treated creams, on the average the butter yield ranked as follows: (1) Cream ripened with starters, (2) cream ripened naturally, (3) scalded cream, and (4) sweet cream.

In cheese-making experiments with the different breeds of dairy cattle it was indicated that cheeses made from milks rich in fat are superior in quality.

On the question of the fat building out of protein in the ripening of cheese, K. KONDO (*Biochem. Ztschr.*, 59 (1914), No. 1-2, pp. 113-165, fig. 1).—A study was made of the diminution of fats in cheese during the ripening process.

The greatest loss was found to occur after 10 days' storage and to continue thereafter. This decrease did not depend so much upon the duration of the storage period as upon the physical character of the cheese and the temperature of the room. After 15 days' storage the fat diminution varied from 1.04 to 5.37 per cent, and after 40 days from 6.28 to 11.76 per cent. The fat loss depended largely upon the extent of the mold formation, for as this proceeded and covered the surface the amount of fat removed from the cheese was increased. Mold formation ordinarily began after 10 days' storage and increased thereafter.

The fat loss was practically as great when the cheese was thinly coated with paraffin as without. However, if the cheeses are dipped repeatedly in the paraffin bath from the beginning of the experiment the fungus makes very little growth during the storage and the decrease in fat is much less. The formation of mold could not be completely restrained by the paraffin method.

The ripening process and the loss of fat were found to be two wholly independent processes, for the ripening of cheese was as effective in the absence of oxygen-containing air as in ordinary air, but in the former no loss of fats occurred. The characteristic feature of ripening cheese is the cleavage of the casein into the albumoses and peptones, and finally into the amino acids, such as leucin, tyrosin, etc. The extent of this cleavage depends upon the quantity of precipitable and unprecipitable nitrogen present. In the ripening process the presence of the aerobes was found to be indispensable, while that of the anaerobes is yet an unsettled question.

In conclusion, it is stated that in the ripening process of cheese under no circumstances is there an increase of fats, much less a building up of fats out of the proteins. The amount of fat is determined by the growth of a vegetable mold on the surface of the cheese during the ripening process, and it remains wholly unchanged if ripened in an oxygen-free room.

Bacteria concerned in the production of the characteristic flavor in cheese of the Cheddar type, ALICE C. EVANS, E. G. HASTINGS, and E. B. HART (*U. S. Dept. Agr., Jour. Agr. Research* 2 (1914), No. 3, pp. 167-192).—This work was in cooperation with the Wisconsin Station. The authors summarize the results as follows:

"The organisms constantly found in Cheddar cheese in such numbers as to indicate they must function in the ripening process are included in four groups: First, the *Bacterium lactis acidi*; second, the *B. casei*; third, *Streptococcus*; fourth, *Micrococcus*. On the basis of the fermentation powers each of the four groups may be divided into a number of varieties. The distribution of the varieties of the four groups in Cheddar cheese prepared from raw milk has been studied, as has also been done with cheese prepared from pasteurized milk.

"The flora of raw-milk cheese is varied and consists of all the varieties into which the four groups were divided. The flora of pasteurized-milk cheese, with the exception of the *B. casei* group, is dependent upon the flora of the starter. The *B. casei* group is apparently responsible for the pungent taste that develops late in the ripening period of both raw-milk and pasteurized-milk cheeses. It is probable that growth of this group continues during the major part of the ripening period.

"The action of two or more organisms growing together is not the sum of their individual actions when growing alone. When growing together, they may attack substances that neither can attack alone, or they may produce a larger quantity of acid than the sum of the quantities that either can produce alone. When added to pasteurized milk, the organisms of the *B. casei* group produce a sour taste in the cheese during the early part of the ripening period. No Cheddar flavor is obtained in pasteurized-milk cheese when the organisms of the *B. lactis acidi* group alone are used as starters. The varieties that are

able to ferment the more complex substances are likely to produce a bitter taste.

"Starters composed of both *B. lactis acidi*, b, and Streptococcus, b, when added to pasteurized milk, improve the quality of the cheese. It does not seem unreasonable to hope that starters may be obtained that will give the characteristic Cheddar flavor to the cheese prepared from pasteurized milk."

A bibliography of cited literature is appended.

Relation of the action of certain bacteria to the ripening of cheese of the Cheddar type, E. B. HART, E. G. HASTINGS, E. M. FLINT, and ALICE C. EVANS (*U. S. Dept. Agr., Jour. Agr. Research*, 2 (1914), No. 3, pp. 193-216).—This work was in cooperation with the Wisconsin Station. The authors summarize the results as follows:

"Representatives of the coccus groups of organisms isolated from Cheddar cheese when grown in milk produced large quantities of the volatile acids, particularly acetic acid. These acids were produced from citric acid or lactose or protein, as the medium was practically free from fat. These organisms did not produce formic acid. As they are present at times in very large numbers in cheese, they, no doubt, produce much of the volatile fatty acids which arise during the ripening process. One of the strains of Streptococcus, b, was found to produce comparatively large quantities of alcohols and esters—bodies which contribute in a large degree to the flavor of cheese.

"A dilute solution of acetic acid and alcohol formed esters by mere contact, without bacterial action. In cheese, however, the dilution is probably too great for this manner of ester formation. Lactic acid was generally not formed by the coccus groups. The representatives of the *Bacterium casei* group examined gave results different from those obtained from the coccus forms. They produced no formic acid, but did form some propionic and much acetic acid. These organisms produced a large quantity of lactic acid, both active and racemic, and decomposed the citric acid of the media. Cheese made from chloroformed fresh milk did not yield any volatile fatty acids, showing that inherent milk enzymes are not capable of producing these bodies in any appreciable quantity. Representatives of both the coccus and *B. casei* groups were able to produce ammonia from milk. Whey and fresh curds contained active lactic acid. Cheese one day old contained a mixture of active and racemic lactic acids.

"The cause of the disappearance of active lactic acid and the appearance of racemic acid may be due to enzymic action, combined with the action of those bacteria which can produce both kinds of acid. Some representatives of the *B. casei* group produced levo lactic acid and others dextro lactic acid from milk. A mixture of these two varieties produced racemic lactic acid. A mixture of *B. lactis acidi* and a levo-producing member of the *B. casei* group gave racemic and active lactic acid. The active acid was probably the result of the longer continued activity of *B. casei*. Racemic lactic acid found in curing cheese may therefore be produced in a small degree by enzym action, but more probably by the combined action of *B. lactis acidi* and the organisms of the *B. casei* group."

A bibliography of cited literature is appended.

The action of *Bacillus bulgaricus* in suppressing gassy fermentations in cheese making, C. F. DOANE (*Centbl. Bakt. [etc.]*, 2. Abt., 40 (1914), No. 9-10, p. 163).—"It was found that pure cultures of *B. bulgaricus* could be used with perfect results in suppressing the undesirable fermentations, principally gas, which have worried Swiss cheese makers in the past. There seems to be a difference in the efficiency of different strains of *B. bulgaricus* for this purpose without respect to their activity in forming acid. One per cent of a whey

starter made from one culture was sufficient, while it required 3 per cent of another. The *B. bulgaricus* starters could not be seen to have any effect on the formation of the eyes or interfere with the flavor or texture. It is believed that the proper use of *B. bulgaricus* starters will go far toward making a more uniform cheese during the summer months and will make it possible to produce good Swiss cheese during the entire year."

The normal bacteria of Swiss cheese, E. E. ELDRIDGE and L. A. ROGERS (*Centbl. Bakt. [etc.]*, 2. Abt., 40 (1914), No. 9-10, pp. 164, 165).—The authors made numerous investigations of the bacteria of the cheese of the Emmental type, and a detailed study of their fermentative abilities. Three morphological groups were separated, the long rod, the short rod, and the coccus.

It is stated that "at the beginning of the ripening the bacterial flora consisted almost entirely of the short rods. The long rods appeared in the early stages of the ripening and increased steadily. The short rods decreased and in each of the three cheeses made up about 50 per cent of the bacteria at 7 or 8 weeks, a period corresponding in a general way with the end of the eye formation. Glycerin-fermenting cocci appeared in small numbers in each of the cheeses at an age of 5 or 6 weeks. At the end of 20 weeks the bacterial flora was composed almost exclusively of the long rods."

It is concluded that "the essential bacteria of Emmental cheese are evidently not ubiquitous."

VETERINARY MEDICINE.

Some minute animal parasites or unseen foes in the animal world, H. B. FANTHAM and ANNIE PORTER (*London, 1914, pp. XI+319, pl. 1, figs. 56; rev. in Science, n. ser., 40 (1914), No. 1020, pp. 105-107*).—This is a popular account of the protozoa responsible for diseases of man and animals. The review is by G. N. Calkins.

New remedies: Their composition, action, and use, C. BACHEM (*Neuere Arzneimittel ihre Zusammensetzung, Wirkung und Anwendung. Berlin and Leipsic, 1913, pp. 144*).—This is a compilation of new but chiefly nonofficial remedies, most of which are prepared on the European Continent.

The staining of yeasts by Gram's method, A. T. HENRICI (*Jour. Med. Research, 30 (1914), No. 3, pp. 409-415, pl. 1*).—"It has been shown that yeast cells retain Gram's stain more firmly than the common Gram-positive bacteria. It has been further shown that, unlike the bacteria, the cytoplasm of the yeast cell is not homogeneous with regard to its ability to retain the stain, certain granules appearing in the decolorizing cell which hold the dye longer than others. It is suggested that the ability of these granules to resist decolorization is in direct proportion to their ability to resist autolysis."

The complement fixation test (Gay's modification of the Besredka method) in the differentiation of acid-fast bacilli, W. H. HARRIS and J. A. LANFORD (*Jour. Infect. Diseases, 13 (1913), No. 2, pp. 301-308, table 1*).—It was noted from this work that rabbits injected with whole bacilli or with extracts of the acid-fast group produced antistances of a high titer. The whole bacilli, however, produced antibodies of lower potency than those obtained with the Besredka antigen. The Besredka antigen showed the strongest production of antibodies when it was intravenously given at 3-day intervals for four injections. The animals were bled eight days following the last injection. "Regardless of the various methods used to produce these sensibilizers, no clear-cut specificity for complement fixation has been found for the acid-fast bacilli made use of in these experiments."

Alterations produced in complement-containing sera by introduction of lecithin, J. CRUICKSHANK and T. J. MACKIE (*Jour. Path. and Bact., 18 (1913)*),

No. 1, pp. 99-113; abs. in *Jour. Amer. Med. Assoc.*, 61 (1913), No. 13, pp. 1074, 1075).—Lecithin is deemed capable of rendering active a component or complement normally present in an inactive or latent state in sera. In the case of guinea pig serum the property of the complement resembles the ordinary middle piece, but differs from it in so far that it is not precipitated by carbon dioxid.

Preparation of nontoxic serum and immune blood preparations (*German Patent 257,977, April 26, 1911; abs. in Chem. Ztg.*, 37 (1913), No. 41, *Repert.*, p. 188).—In passive immunization the presence of heterologous proteins is detrimental to animal life and especially when the injections of sera, etc., are repeated. According to this patent specification the toxic action can be eliminated if the immune sera or blood are acidified. It is claimed that by doing this the hemoglobin of the immune blood is transformed into methemoglobin. By autoprecipitation at temperatures varying between 70 to 100° C. the toxic solution can be rendered nontoxic. The autoprecipitation is conducted fractionally, and thereby sera, etc., are submitted at various intervals to certain temperatures for a specific length of time. The procedure is as follows:

From 0.1 to 0.5 cc. of lactic acid is added to immune blood and heated in the water bath at 37°, and after a short time the temperature is raised to 40 to 45°. Between the temperatures of 37 and 54° one-half of the immune fluid is drawn off and the remainder of the blood is heated to 70 to 100°. After it has been held at this temperature for a quarter of an hour the blood is cooled and mixed with the blood or serum which has been drawn off at between 37 and 54°.

The local specific therapy of infections.—I, The biologic basis, S. FLEXNER (*Jour. Amer. Med. Assoc.*, 61 (1913), No. 7, pp. 447-452).—An account of the main facts in regard to the biological principles underlying specific therapy in infectious diseases. It constitutes the first Trimble lecture given before the Medico-Chirurgical Faculty of Baltimore, and the Harben lecture given before the Royal Institute of Public Health, London.

Bacteriology and control of acute infections in laboratory animals, N. S. FERRY (*Jour. Path. and Bact.*, 18 (1914), No. 4, pp. 445-455).—"From the results of the cultural tests and agglutination experiments as carried out on the micro-organisms included in this study, it is shown very clearly that the *Bacillus bronchisepticus* is a distinct species." The author has encountered but two organisms which may simulate *B. bronchisepticus* in its reactions toward litmus milk and potato, namely, *B. fæcalis alkaligenes* and an organism here described as a bacillus of Group IV.

Antistreptococcus serum, G. H. WEAVER (*Jour. Amer. Med. Assoc.*, 61 (1913), No. 9, pp. 661, 662).—"If active antistreptococcus serum is injected into normal guinea pigs in quantities of from 2 to 6 cc. and an interval allowed for its absorption, the blood of the animal comes to contain a considerable amount of demonstrable streptococco-opsonin, and the animal can withstand an amount of highly virulent living streptococci which would promptly kill a control animal. The immunity thus produced is, then, a passive one, since preformed antibodies are injected. It is of short duration, lasting about a week. In animals, antistreptococcus serum has little curative power over an established infection."

This finding was taken advantage of in treating the disease in man. Following the injection a prompt fall in temperature, an improvement in the general toxic condition, a reduction in the number of leucocytes, and a rise in the opsonic index were noted. In this condition there may also be an increased phagocytic activity of the leucocytes.

To secure the best results the serum must be given intravenously, but where the case is not an urgent one it is given intramuscularly or subcutaneously. It

was found that the protective value of serum is in direct proportion to the amount of opsonin present.

Report on foot-and-mouth disease in Ireland in the year 1912 (*Dept. Agr. and Tech. Instr. Ireland, Rpt. Foot-and-mouth Disease, 1912, pp. 74, pls. 29; Vet. Jour., 70 (1914), Nos. 463, pp. 6-23, figs. 6; 464, pp. 57-73, figs. 3*).—This is a detailed report upon the outbreaks of foot-and-mouth disease in Ireland in 1912 and measures taken for its eradication, a brief account of which from another source has been previously noted (E. S. R., 29, p. 677).

About a new serodiagnostic method, W. PFEILER and G. WEBER (*Berlin. Tierärztl. Wchnschr., 29 (1913), No. 25, pp. 449-452*).—It has been found that the conglutination method (E. S. R., 28, p. 478) is on a par with the complement fixation method for diagnosing glanders. In fact, in some cases of glandered horses which were not detected by the complement fixation method the condition was diagnosed by it. It also has the advantage that (1) it is more easily conducted, as it does not require a specially prepared amboceptor. (2) guinea pig serum is replaced by horse serum, which is more easily obtainable and must not be standardized, and (3) the test can be conducted without the use of an incubator. In this work it was found also that neither the presence of complement nor bovine serum containing conglutinins is necessary for the conglutination test.

Theoretically speaking, horse serum contains a substance capable of conglutinating glanders bacilli, and which is consequently similar to Bordet's substance which he terms "colloide de boeuf." It is believed that many of the agglutinins which are present under normal conditions are not agglutinins at all, and, in fact, it seems reasonable to believe that another substance is present whose function it is to combat infection. It was found to be absent in the sera of infected animals and its action is especially noted when the sera of normal animals are heated to 56° C.

The effect of quinin on rabbits inoculated with rabies, L. FROTHINGHAM and J. HALLIDAY (*Jour. Med. Research, 30 (1914), No. 3, pp. 275-280*).—In these experiments neither quinin bisulphate nor quinin and urea hydrochlorid, dissolved in water and administered subcutaneously, had any curative effect upon rabbits which showed symptoms of rabies after intracerebral, subdural, and intramuscular inoculation with street virus. The injections caused a local reaction with necrosis and, in the control rabbits, subsequent sloughing.

The quinin treatment of rabies, J. G. CUMMING (*Jour. Infect. Diseases, 15 (1914), No. 1, pp. 205-208*).—"Inasmuch as the quinin failed as a preventive measure against extremely small doses of virus in actual tests, can it not reasonably be assumed that this method of treatment is of no curative value in cases of hydrophobia manifesting symptoms in which the amount of virus would be many thousand times greater?"

The duration of passive immunity against tetanus toxin, E. H. RUEDIGER (*Philippine Jour. Sci., Sect. B, 8 (1913), No. 2, pp. 139-142; abs. in Berlin. Tierärztl. Wchnschr., 29 (1913), No. 39, p. 696*).—The subcutaneous injection of 1,500 units of (horse) tetanus antitoxin produces a passive immunity in horses in about 6 to 8 weeks. If normal horse serum is repeatedly injected into guinea pigs and the injection followed with antitoxin, the immunity produced in these animals is greater than in animals which have received no horse serum.

New observations upon the trombidiasis of goats and its transmission to man, B. GALLI-VALERIO (*Centbl. Bakt. [etc.], 1. Abt., Orig., 72 (1914), No. 6-7, pp. 488-490, figs. 2*).—In this paper (E. S. R., 31, p. 284) the author reports that the larvæ of *Microtrombidium pusillum*, which cause the trombidiasis of goats in Valtelline, also cause a cutaneous eruption in man which is accompanied by violent itching.

Investigations in regard to the tuberculosis problem, LYDIA RABINOWITSCH (*Deut. Med. Wchnschr.*, 39 (1913), No. 3, pp. 103-106; *abs. in Ztschr. Fleisch u. Milchhyg.*, 23 (1913), No. 20, p. 474).—On injecting the bile from seventeen tuberculous subjects into guinea pigs, that of twelve produced tuberculosis in these animals. With the antiformin and microscopical methods only one case yielded positive findings, consequently it is concluded that the gall bladder is a source of elimination for the tubercle bacillus and must be reckoned with when dealing with preventive measures for this disease. Six strains of organisms isolated were more closely examined, and four belonged to the human and two to the bovine type. The author considers these results as confirmatory of the findings of Schroeder and Cotton (*E. S. R.*, 19, p. 181) and Joest and Emshoff (*E. S. R.*, 29, p. 582).

The virulence of the tubercle bacilli in the so-called "rayed caseation," HAFEMANN and BINDER (*Ztschr. Fleisch u. Milchhyg.*, 23 (1913), No. 23, pp. 529-531).—A continuation of the work previously noted (*E. S. R.*, 30, p. 882). The tubercle bacilli obtained from the rayed foci were found to be very virulent.

A contribution to the occurrence of primary pudic and vaginal tuberculosis in the bovine, W. MEYER (*Ztschr. Fleisch u. Milchhyg.*, 22 (1912), No. 10, pp. 303-306, fig. 1; *abs. in Centbl. Bakt. [etc.]*, 1. Abt., Ref., 56 (1913), No. 7, p. 201).—A description of a case, the identity of which was established by vaccinating rabbits with some of the tuberculous material. This affection as of man is rarely observed in animals.

The diagnosis of tuberculosis with the anaphylactic test in vitro, A. TADINI (*Pathologica*, 4 (1912), No. 98, pp. 719-721; *abs. in Ztschr. Immunitätsf. u. Expt. Ther.*, II, Ref., 6 (1913), No. 15, p. 1112).—By injecting into a rabbit a mixture from a tuberculous subject consisting of tuberculin and serum which has been kept in the incubator for two hours, or a control injection of normal serum and tuberculin, no anaphylactic phenomena were ever noted. Likewise no effect was produced by injecting normal or tuberculosis serum alone into rabbits, except in two animals, one of which received tuberculosis serum and the other a normal serum, and which is explained as due to the toxicity of the serum. A passive conveyance of anaphylaxis from a tuberculous subject to an animal is not deemed possible.

The diagnosis of tuberculosis with the anaphylaxis reaction, F. VALENTI (*Pathologica*, 4 (1912), No. 91, pp. 488-490; *abs. in Ztschr. Immunitätsf. u. Expt. Ther.*, II, Ref., 6 (1913), No. 15, p. 1110).—The results were very satisfactory when conducted by a procedure different from that of Yamanouchi's. Further tests should be made with it, however, in order to determine its value as a diagnostic agent.

The thermoprecipitation reaction in tuberculosis, A. FAGIUOLI (*Pathologica*, 4 (1912), No. 89, pp. 410, 411; *abs. in Ztschr. Immunitätsf. u. Expt. Ther.*, II, Ref., 6 (1913), No. 15, p. 1112).—The sputum was mixed with physiological salt solution, boiled, and then filtered through asbestos, or the extract was mixed in the cold with concentrated acetic acid, neutralized, and filtered through a bisque filter and paper. The specific serum used was Vallée's. The layer test was characteristic but it was not specific for tuberculous subjects.

A reaction was obtained also with sputum from subjects affected with pneumonia and simple bronchitis.

Tuberculous antigens and antibodies.—Inhibition reaction, A. CALMETTE and L. MASSOL (*Compt. Rend. Soc. Biol. [Paris]*, 75 (1913), No. 28, pp. 160, 161).—By introducing a stream of carbon dioxid into an inhibiting serum diluted 1:10 with distilled water, a precipitate is obtained which shows precipitating and inhibiting properties greater than those of the original serum. On the other hand the serum, after removal of the precipitate, while robbed of

most of its inhibiting properties, retains its agglutinins and sensibilisins, and these can be more easily detected.

The reciprocal affinity of tuberculins prepared from tubercle bacilli obtained from man, bird, fish, and Rabinowitsch's bacillus, E. CARAPPELLE (*Biochim. e Terapia Sper.*, 3 (1912), pp. 357-367; *abs. in Ztschr. Immunitätsf. u. Expt. Ther.*, II, Ref., 6 (1912), No. 11, pp. 874, 875).—It was the object of this work to determine whether the various tuberculins contain the same principle, and if so, whether this principle produces the same antibody. After determining the minimal fatal dose of each of the tuberculins for guinea pigs, animals were immunized with increasing doses. The sera of the animals were then tested for their content of opsonins, agglutinins, complement fixing substances, and meiostagmins.

The tuberculin prepared from the acid-fast strain of Rabinowitsch's bacillus had a different behavior toward the various biological reactions than any of the other preparations, i. e., Wright's positive and negative phase did not appear. The human, avian, and fish tuberculins produced amboceptors and agglutinins in the serum which behaved alike toward the opposite strains, and consequently it is concluded that all of the organisms produced the same antibody. Evidently a strong affinity exists between the various tuberculins. Meiostagmins were not noted in the blood of the various guinea pigs.

Guinea pigs infected with the organism of human tubercle bacilli, followed by treatment with small doses of tuberculin, died 25 days later than the controls. If tuberculin is given first, the conditions are reversed.

The production of passive hypersensitiveness to tuberculin, C. R. AUSTRIAN and H. FRIED (*Bul. Johns Hopkins Hosp.*, 24 (1913), No. 271, pp. 280-282).—The results confirm the established fact that free sensibilisin can not be demonstrated in the blood of most individuals affected with pulmonary tuberculosis. The anaphylactic nature of the tuberculin reaction was shown.

Proposal for an extension of the measures for combating mammary gland tuberculosis in bovines in Sweden, A. M. BERGMAN (*Ztschr. Fleisch u. Milchhyg.*, 23 (1913), No. 10, pp. 217-219).—After showing that tuberculosis of the udder is still on the increase in Sweden and Denmark, various recommendations are made with a view of detecting this condition at an early date. It is considered essential that dairy animals be examined at least four times a year by competent veterinarians.

[Periods of high temperature in cattle imported into Guam], J. B. THOMPSON (*Guam Sta. Rpt.* 1913, pp. 9-11, figs. 4).—The author presents temperature charts which show the periods of high temperature that have occurred in imported cattle. In some instances these fever periods have not been marked by excessively high temperature and have been of comparatively short duration. On the other hand, cases have been dealt with in which the temperatures have risen above 107° F., and the period prolonged for more than a week.

Experimental bovine mastitis produced with hemolytic streptococci of human origin, D. J. DAVIS and J. A. CAPPS (*Jour. Infect. Diseases*, 15 (1914), No. 1, pp. 135-140).—"Hemolytic streptococci of human origin may cause mastitis, lasting for several weeks in cows. This time roughly corresponds to the duration of milk-borne epidemics. The streptococci may gain entrance through an abraded or injured surface of the teat. It appears possible, therefore, for mastitis in cows to be produced by an infection from the milker whose hands are contaminated perhaps from a sore throat. Mastitis results promptly when the cocci are injected directly into the udder by means of a catheter. The mastitis may exist without physical evidence. A caked bag may not occur, though pus and streptococci in large numbers are being secreted in the milk.

Stringy, ropy, or gargety milk may or may not occur during the course of the mastitis.

"In order to detect such infections, it might be necessary to examine milk from each quarter for bacteria and for pus. This may explain the failure to detect the source of the streptococci in some of the epidemics of sore throat. No change was noted in the cultural or pathogenic properties of the streptococci after growing in the udder of a cow for four weeks. The presence of various contaminating bacteria tend to inhibit the growth of hemolytic streptococci in milk."

The formation of arsenate in dipping tanks, J. LEWIS (*Agr. Jour. Union So. Africa*, 7 (1914), No. 5, pp. 658-664).—In the first part of this paper the literature relating to the subject is briefly reviewed. In a large number of analyses made by the author of dips only four contained appreciable quantities of arsenate. The studies lead to the conclusion that in tanks in use the conflicting activities of the arsenate formers and the arsenite formers result in the liquid being kept sufficiently constant in composition for all practical purposes. The author's advice is to continue using a dip unless there is strong evidence that it has altered in composition.

The seventh annual report of the state veterinarian of Alabama, 1913, C. A. CARY (*Ann. Rpt. State Vet. Ala., 1913, pp. 50*).—This reports upon progress and results of cattle tick eradication, gives directions for testing dips in dipping vats for active arsenious acid, discusses hog cholera and its prevention, etc.

Erysipelas in hogs and its relation to swine plague, W. RIEBE (*Der Rotlauf der Schweine und seine Wechselbeziehungen zur Schweineseuche. Inaug. Diss., Univ. Giessen, 1911, pp. 56; abs. in Hyg. Rundschau, 23 (1913), No. 12, pp. 740-742*).—Aggressins may be produced in rabbits infected with agar cultures of the *Bacillus erysipelatis*. The swine plague aggressins act aggressively upon the erysipelas bacteria, and mice vaccinated by the simultaneous method after receiving swine plague aggressins die from acute erysipelas. Erysipelas exudates act aggressively on swine plague bacteria and a nonlethal erysipelas infection is made lethal by the administration of artificially prepared swine plague exudates.

For preparing sterile aggressins the erysipelas bacteria in the exudates are killed with vapors of formaldehyde. Heating to 44° C. will not suffice for preparing the aggressin because it requires four days to kill this organism at this temperature. With formaldehyde it requires only four hours. Artificially prepared erysipelas aggressins are toxic in large doses; erysipelas exudates are not. The pericardial fluid of pigeons which have died from erysipelas has not the aggressive properties.

By exposing erysipelas bacteria, isolated from the spleen and kidneys, on slides for fourteen days to sunlight the virulence for mice is lost. If kept from the light, however, and stored in a cool place, the bacteria are still virulent for mice after four weeks. The right half of the heart is more often infected than the left. The valvular infections (endocarditis verrucosa) were in the following order of frequency: (1) Bicuspid, (2) tricuspid, (3) aortic, and (4) the pulmonary valves. In the course of the tests a diplococcus causing endocarditis was noted which was pathogenic for mice. The verrucose material of the heart valves was usually pathogenic for mice, but viruses often occur which show a diminished virulence. In thrombosis of the valves avirulent forms of bacteria of granular consistency were noted in 7 out of 28 cases.

The organs of pigs which died from endocarditis showed virulent bacteria, and out of 28 cases the bacterium was noted in 14 cases by microscopical methods and animal inoculation tests. In the remainder the organism could

not be detected. At times the material obtained from the heart valves was not infectious, while that from the organs was. When the heart valve vegetations and organs were infectious, they killed pigeons much sooner than mice.

Hog cholera, H. P. HOSKINS (*Univ. Minn., Dept. Agr., Ext. Bul. 37 (1913), pp. 16, figs. 9; Amer. Vet. Rev., 43 (1913), No. 5, pp. 473-496, figs. 9*).—This is a popular description of hog cholera, with noteworthy illustrations. It deals with the distribution of hog cholera in the United States, the symptoms, pathology, diagnosis, prognosis, and treatment of the disease, and enumerates and describes diseases which are often mistaken for hog cholera. The methods utilized for preventing the spread of hog cholera, the serum treatment, the serum-virus method and its value, and the preparation of serum are all described.

Influence of the mode of penetration, cutaneous or buccal, of *Stephanurus dentatus* on the localization of this nematode in the body of swine and on its development, P. N. BERNARD and J. BAUCHE (*Ann. Inst. Pasteur, 28 (1914), No. 5, pp. 450-469, pl. 1, figs. 2*).—A more detailed report of investigations substantially noted from another source (*E. S. R., 29, p. 783*).

Fistula of the withers: Autotherapy, W. A. DUFFIN (*Amer. Vet. Rev., 43 (1913), No. 4, p. 406*).—A case in a mare treated for fistula of the withers, which was caused by rubbing of the collar, is described. See also a previous note by Duncan (*E. S. R., 29, p. 175*).

Bacillary white diarrhea of young chicks, L. F. RETTGER, W. F. KIRKPATRICK, and R. E. JONES (*Connecticut Storrs Sta. Bul. 77 (1914), pp. 263-309, pls. 2, figs. 15*).—This fourth report of investigations of bacillary white diarrhea (*E. S. R., 29, p. 288*), which deals with the carrier problem, the macroscopic agglutination test as an important aid in the diagnosis of ovarian infection in adult fowls, and milk feeding and its influence on growth and mortality, has been summarized as follows:

“Female chicks which are infected with *Bacterium pullorum* when small may develop into permanent bacillus carriers and be a constant source of danger to young and old stock. This carrier condition may be established in fully 25 per cent of an infected flock. Thus, the last link in our proposed cycle of infection has been experimentally proved.

“The macroscopic agglutination test devised by F. S. Jones [*E. S. R., 28, p. 887*] is an important aid in the recognition of bacillary white diarrhea infection in laying hens.

“Sour milk feeding has a most beneficial influence on the growth of chicks and in lessening mortality from all causes. As an important agent in the prevention and suppression of white diarrhea its value is somewhat doubtful, and further investigation is necessary before unqualified statements can be made. Milk which is soured by the *bulgaricus* bacillus of Metchnikoff possesses no distinct advantages over naturally soured milk; on the other hand, it has several disadvantages. Its method of preparation involves considerable time and care, and it is not relished by chicks to the same extent as naturally soured milk.”

An appendix discussing the importance of breeding from sound, uninfected stock, symptoms and post-mortem appearances of the disease, its detection by the examination of the ovaries, and the importance of bacteriological examinations, with a description of *B. pullorum*, is given.

Ovarian infection in the domestic fowl and direct transmission of disease to the offspring, L. F. RETTGER (*Jour. Expt. Med., 19 (1914), No. 6, pp. 552-561*).—The data here presented are based upon the investigation above noted. The author summarizes the study as follows:

“Ovarian infection and germinal transmission of disease have been conclusively demonstrated. . . . The disease . . . primarily affects young chicks

that are but a few weeks old. Chicks which survive frequently become permanent bacillus carriers, the ovary being the important seat of infection. The eggs from such carriers often harbor the organism of the disease in the yolk. Chicks that develop in infected eggs become in turn infected, and have the disease at the time of hatching. The disease is transmitted to normal chicks through the infected droppings; thus an epidemic is produced, and the cycle of infection is completed.

"There is no evidence to indicate that germinal transmission through the male takes place. In view of the frequent negative results bearing on this question it seems probable that it does not."

Studies on fowl cholera.—III, The inheritance in rabbits of immunity to infection with the bacterium of fowl cholera, P. B. HADLEY (*Rhode Island Sta. Bul.* 157 (1914), pp. 285-307).—This continuation of the work previously noted (E. S. R., 27, p. 583) has been summarized as follows:

"Female rabbits, immunized by inoculation with an avirulent culture of the fowl cholera bacterium are able to transmit to their offspring a high degree of resistance to virulent cultures. Some immune mothers are able to produce such immune offspring for at least more than 2 years and 3 months after the date of their immunization. Immunity is not transmitted by the immune male. The resistance in the offspring is not permanent, enduring for not more than 40 days. This inherited, passive resistance can be transformed into a durable, active resistance by inoculating the young animals, sometime within the first 40 days of life, with a virulent culture."

A bibliography of the cited literature is appended.

A note on the occurrence of spirochetosis of fowls in Southern Nigeria, J. W. S. MACFIE and J. E. L. JOHNSTON (*Ann. Trop. Med. and Par.*, 8 (1914), No. 1, pp. 41-48, pls. 2).—This records the occurrence of this disease in Southern Nigeria.

On certain spontaneous chicken tumors as manifestations of a single disease (*Jour. Expt. Med.*, 19 (1914), No. 6, pp. 570-580, pls. 6).—The first paper, by P. Rous (pp. 570-576), deals with spindle-celled sarcomata rifted with blood sinuses; and the second paper, by Linda B. Lange (pp. 577-580), with simple spindle-celled sarcomata.

RURAL ENGINEERING.

Flumes and fluming, E. S. BRUCE (*U. S. Dept. Agr. Bul.* 87 (1914), pp. 36, pls. 9, figs. 7).—This bulletin discusses the use of flumes in lumbering operations, and describes the most salient points of their construction.

The author considers the V-shaped type of flume to be the most generally used and generally satisfactory for the transportation of manufactured lumber or timber in its different forms. The right angle is said to be the most satisfactory form of V box construction for all purposes. Many different methods and styles of construction are used in building V-shaped flumes, the sections of which vary in length from 6 ft. up to 20 ft. More commonly the lining of boxes is constructed of two thicknesses of boards with the joints broken by varying the width of the boards. "For railroad crossties, cants, poles, cordwood, etc., the 30-in. flume is usually large enough, wherever there is a sufficient volume of water available to fill the flume two-thirds full, while for the handling of logs, piling, long timbers, or 'brailed' sawed lumber it is usually advisable to have the flume constructed with the sides of the V from 40 to 60 in. in height, according to the volume of water available and the size of the material to be handled."

In flume construction it is considered advisable usually to erect a small saw-mill to saw out the lumber needed for construction. An accurate and careful survey of the proposed line of flume construction is considered a prime necessity, particularly as regards grades and curves. In general, the lowest grade considered satisfactory for successful operation is about 1 per cent, and the most satisfactory results are obtained when the grade is from 2 to 10 per cent, with a maximum of 15 per cent. The degree of curvature should be kept as low as practicable with a usual maximum of 20°. Where the topographic conditions in a locality are such that abrupt curves in the flume are absolutely necessary, it is considered advisable to reduce the length of the boxes, and correspondingly shorten the distance apart of the bents, arms, and braces, and to increase or raise the height of the V on the outside of the curve. The most satisfactory distance between bents is said to vary from 12 to 16 ft., according to the capacity of the flume and the use to which it is to be put. "Flume construction should usually be strongly reinforced at those points from which it is contemplated to do extensive shipping or where such material is to be loaded into the flume over the side."

Other general information is given regarding feeders for maintaining the required amount of water, tunneling, small holding reservoirs at different points of flume, reservoir ponds at the head of flumes, branch flumes, switches, the use of telephones in flume operation, and cost of construction of flumes. Tabular data on the weight of water in a 16-ft. section of flume when filled to various depths, amount of water required to fill flumes, and velocity of water in flumes when filled to various depths at different grades, and estimates of the approximate amount of material required for the construction of typical flumes are given.

The use of coordinates in surveying and laying out tracts for irrigation, H. H. LOGAN (*Engin. News*, 71 (1914), No. 14, pp. 738-740, fig. 1).—This method is described and illustrated.

Soil porosity and the distance between drainage channels, L. SCHMEER (*Engin. and Contract.*, 41 (1914), No. 13, pp. 398, 399, figs. 2).—The author, by means of formulas and tabulations, deduces values of the transmission constant for soils, noted in previous work (*E. S. R.*, 30, p. 289), as modified by humus in the top layers of the soil.

The road drag and how it is used (*U. S. Dept. Agr., Farmers' Bul.* 597 (1914), pp. 15, figs. 8).—The purpose of this paper is to describe the best methods of constructing and using road drags and to supply information concerning the conditions for which such drags are adapted. The principal points discussed are summarized as follows:

The road drag is the simplest and least expensive contrivance yet devised for maintaining roads constructed of earth or earthy material. Its successful operation depends to a very great extent on the skill and intelligence of the operator. The time to use the drag is when the material composing the road surface is sufficiently moist to compact readily under traffic after it has been moved by the drag and when it does not contain sufficient moisture for the traffic following the drag to produce mud. Dragging can not usually be so arranged as to keep teams employed all the time, making it desirable to have it done by interested persons who are otherwise employed when not engaged in dragging.
