Encyclopædia Britannica.

VOL. I.—(A–ANA).

Total number of Articles, 966.

PRINCIPAL CONTENTS.

ABBEY AND ABBOT. Rev. EDMUND VENABLES, Precentor and Canon of Lincoln.
ABELARD. G. CROOM ROBERTSON, M.A., Professor of Logic, University College, London.
ABERDEEN. ALEX. CRUICKSHANK, M.A.
ABRAHAM. Rev SAMUEL DAVIDSON, D.D., Author of "Introduction to the Old and New Testaments," &c.
ABYSSINIA. DAVID KAY, Fellow of the Royal Geographical Society.
ACADEMY. FRANCIS STORR, M.A., Author of "Tables of Irregular Greek Verbs."
ACCENT. JOHN M. ROSS, LL.D., late Editor of the "Globe Encyclopædia."
ACCLIMATISATION. ALFRED R. WALLACE, Author of "Theory of Natural Selection"
ACHILLES. A. STUART MURRAY, British Museum, London..
ACHIN. Col. HENRY YULE, C.B., F.R.G.S., Author of "The Book of Marco Polo."
ACOUSTICS. DAVID THOMSON, M.A., late Professor of Natural Philosophy, University of Aberdeen.
ACTS OF THE APOSTLES. Principal DONALDSON, LL.D., Author of "Early Christian Literature and Doctrine."
ACTINOZOA. T. H. HUXLEY, LL.D., F.R.S., Professor in the Royal School of Mines, London.
ADAM. Rev. SAMUEL DAVIDSON, D.D.
ADDISON. WILLIAM SPALDING, LL.D., late Professor of Rhetoric and Belles Lettres, University of Edinburgh.
ADMIRAL AND ADMIRALTY. F. W. ROWSELL, C.B., Superintendent of Naval Contracts, H.M. Admiralty.
ADULTERATION. Dr HENRY LETHEBY, Ph.D., formerly Medical Officer of Health to the City of London.
AERONAUTICS. JAMES GLAISHER, F.R.S., Superintendent of the Meteorological Section, Greenwich Observatory.
ÆSCHYLUS. J. STUART BLACKIE, late Professor of Greek, University of Edinburgh.
ÆSIR. Miss E. C. OTTÉ, Translator of Humboldt's "Cosmos."
ÆSTHETICS. JAMES SULLY, LL.D., Author of "Sensation and Intuition."
AFGHANISTAN. Col. YULE, C.B.
AFRICA. KEITH JOHNSTON, Fellow of the Royal Geographical Society.
AGASSIZ. W. C. WILLIAMSON, LL.D., F.R.S., Professor of Natural History, Owens College, Manchester.
AGRARIAN LAWS. GEORGE FERGUSON, LL.D., formerly Professor of Humanity, University of Aberdeen.
AGRICULTURE. JOHN WILSON, Member of Council, Highland and Agricultural Society, and W. T. THORNTON, Author of "A Plea for Peasant Proprietors."
ALCHEMY. JULES ANDRIEU.
ALEXANDER THE GREAT. Rev. Sir GEORGE W. COX, Baronet, Author of "A History of Greece," &c.
ALEXANDER VI. RICHARD GARNETT, British Museum, Author of "Idylls and Epigrams from Greek Anthology."
ALFORD, DEAN. CHARLES KENT, Author of "Charles Dickens as a Reader."
ALGÆ. Dr J. HUTTON BALFOUR, F.R.S., late Professor of Botany in the University of Edinburgh.
ALGEBRA. PHILIP KELLAND, F.R.S., late Professor of Mathematics, University of Edinburgh.
ALGERIA. DAVID KAY, F.R.G.S.
ALPHABET. JOHN PEILE, M.A., Fellow and Tutor of Christ's College, Cambridge.
ALPS. JOHN BALL, F.R.S., late President of the Alpine Club.
ALTAR. Rev. G. H. FORBES.
ALUM. JAMES DEWAR, F.R.S., Jacksonian Professor of Natural Experimental Philosophy, Cambridge.
AMAZON. A. STUART MURRAY, British Museum.
AMBASSADOR. HENRY REEVE, C.B., D.C.L., Registrar of H.M. Privy Council.
AMBULANCE. THOMAS LONGMORE, C.B., Professor of Army Surgery, Netley.
AMERICA (NORTH AND SOUTH). CHARLES MACLAREN, late Fel. of the Geolog. Soc., and of the Royal Society, Edin.
AMERICAN LITERATURE. JOHN NICHOL, LL.D., Professor of English Language, University of Glasgow.
AMMON. SAMUEL BIRCH, LL.D., D.C.L., Keeper of Department of Oriental Antiquities, British Museum.
AMMUNITION. Capt. C. ORDE BROWNE, R.A., Royal Laboratory, Woolwich.
AMOS. Rev. Canon T. K. CHEYNE, Oriel Professor of Exegesis, University of Oxford.
AMPHIBIA. Prof. T. H. HUXLEY.
AMPHITHEATRE. Rev. G. H. FORBES.
ANALOGY AND ANALYSIS. Prof. CROOM ROBERTSON.
ANÆSTHESIA. Dr. JAMES O. AFFLECK, Examiner, Royal College of Physicians, Edinburgh.
ANATOMY. Sir WM. TURNER, M.B., F.R.S., Professor of Anatomy in the University of Edinburgh.

PREFATORY NOTICE.

THE ENCYCLOPÆDIA BRITANNICA has long deservedly held a foremost place amongst English Encyclopædias. It secured this position by its plan and method of treatment, the plan being more comprehensive, and the treatment a happier blending of popular and scientific exposition than had previously been attempted in any undertaking of the kind. The distinctive feature of the work was that it gave a connected view of the more important subjects under a single heading, instead of breaking them up into a number of shorter articles. This method of arrangement had a twofold advantage. The space afforded for extended exposition helped to secure the services of the more independent and productive minds who were engaged in advancing their own departments of scientific inquiry. As a natural result, the work, while surveying in outline the existing field of knowledge, was able at the same time to enlarge its boundaries by embodying, in special articles, the fruits of original observation and research. The Encyclopædia Britannica thus became, to some extent at least, an instrument as well as a register of scientific progress.

This characteristic feature of the work will be retained and made even more prominent in the New Edition, as the list of contributors already published sufficiently indicates. In some other respects, however, the plan will be modified, to meet the multiplied requirements of advancing knowledge. In the first place, the rapid progress of science during the last quarter of a century necessitates many changes, as well as a considerable increase in the number of headings devoted to its exposition. In dealing with vast wholes, such as Physics and Biology, it is always a difficult problem how best to distribute the parts under an alphabetical arrangement, and perhaps impossible to make such a distribution perfectly consistent and complete. The difficulty of distribution is increased by the complexity of divisions and multiplication of details, which the progress of science involves, and which constitute indeed the most authentic note of advancing knowledge. This sign of progress is reflected in extensive changes of terminology and nomenclature, vague general headings once appropriate and sufficient, such as *Animalcule*, being of necessity abandoned for more precise and significant equivalents.

But, since the publication of the last Edition, science, in each of its main divisions, may be said to have changed as much in substance as in form. The new conceptions introduced into the Biological Sciences have revolutionized their points of view, methods of procedure, and systems of classification. In the light of larger and more illuminating generalizations, sections of the subject, hitherto only partially explored, have acquired new prominence and value, and are cultivated with the keenest interest. It is enough to specify the researches into the ultimate structures, serial gradations, and progressive changes of organic forms, into the laws of their distribution in space and time, and into the causes by which these phenomena have been brought about. The results of persistent labor in these comparatively new fields of inquiry will largely determine the classifications of the future. Meanwhile the whole system of grouping, and many points of general doctrine, are in a transition state; and what is said and done in these directions must be regarded, to a certain extent at least, as tentative and provisional. In these circumstances, the really important thing is, that whatever may be said on such unsettled questions should be said with the authority of the fullest knowledge and insight, and every effort has been made to secure this advantage for the New Edition of the Encyclopædia.

The recent history of Physics is marked by changes both of conception and classification almost equally great. In advancing from the older dynamic to the newer potential and kinetic conceptions of power, this branch of science may be said to have entered on a fresh stage, in which, instead of regarding natural phenomena as the result of forces acting between one body and another, the energy of a material system is looked upon as determined by its configuration and motion, and the ideas of configuration, motion and force are generalized to the utmost extent warranted by their definitions. This altered point of view, combined with the far-reaching doctrines of the correlation of forces and the conservation of energy, has produced extensive changes in the nomenclature and classification of the various sections of physics; while the fuller investigations into the ultimate constitution of matter, and into the phenomena and laws of light, heat and electricity, have created virtually new sections, which must now find a place in any adequate survey of scientific progress. The application of the newer principles to the mechanical arts and industries has rapidly advanced during the same period, and will require extended illustration in many fresh directions. Mechanical invention has, indeed, so kept pace with the progress of science, that in almost every department of physics improved machines and processes have to be described, as well as fresh discoveries and altered points of view. In recent as in earlier times, invention and discovery have acted and reacted on each other to a marked extent, the instruments of finer measurement and analysis having directly contributed to the finding out of physical properties and laws. The spectroscope is a signal instance of the extent to which in our day scientific discovery is indebted to appropriate instruments of observation and analysis.

These extensive changes in Physics and Biology involve corresponding changes in the method of their exposition. Much in what was written about each a generation ago is now of comparatively little value. Not only therefore does the system of grouping in these sciences require alteration and enlargement; the articles themselves must, in the majority of instances, be written afresh rather than simply revised. The scientific department of the work will thus be to a great extent new. In attempting to distribute the headings for the New Edition, so as fairly to cover the ground occupied by modern science, I have been largely indebted to Professor Huxley and Professor Clerk Maxwell, whose valuable help in the matter I am glad to have an opportunity of acknowledging.

Passing from Natural and Physical Science to Literature, History and Philosophy, it may be noted that many sections of knowledge connected with these departments display fresh tendencies, and are working towards new results, which, if faithfully reflected, will require a new style of treatment. Speaking generally, it may be said that human nature and human life are the great objects of inquiry in these departments. Man, in his individual powers, complex relationships, associated activities and collective progress, is dealt with alike in Literature, History and Philosophy. In this wider aspect, the rudest and most fragmentary records of savage and barbarous races, the earliest stories and traditions of every lettered people, no less than their developed literatures, mythologies and religions, are found to have a meaning and value of their own. As yet the rich materials thus supplied for throwing light on the central problems of human life and history have only been very partially turned to account. It may be said, indeed, that their real significance is perceived and appreciated, almost for the first time in our own day. But under the influence of the modern spirit, they are now being dealt with in a strictly scientific manner. The available facts of human history, collected over the widest areas, are carefully co-ordinated and grouped together, in the hope of ultimately evolving the laws of progress, moral and material, which underlie them, and which, when evolved, will help to connect and interpret the whole onward movement of the race. Already the critical use of the comparative method has produced very striking results in this new and stimulating field of research. Illustrations of this are seen in the rise and rapid development of the comparatively modern science of Anthropology, and the successful cultivation of the assistant sciences, such as Archæology, Ethnography and Philology, which directly contribute materials for its use. The activity of geographical research in both hemispheres, and the large additions recently made to our knowledge of older and newer continents by the discoveries of eminent travelers and explorers, afford the anthropologist additional materials for his work. Many branches of mental philosophy, again, such as Ethics, Psychology and Æsthetics, while supplying important elements to the new science, are at the same time very largely interested in its results, and all may be regarded as subservient to the wider problems raised by the philosophy of history. In the New Edition of the

Encyclopædia full justice will, it is hoped, be done to the progress made in these various directions.

It may be well, perhaps, to state at the outset the position taken by the Encyclopædia Britannica in relation to the active controversies of the time—Scientific, Religious and Philosophical. This is the more necessary, as the prolific activity of modern science has naturally stimulated speculation, and given birth to a number of somewhat crude conjectures and hypotheses. The air is full of novel and extreme opinions, arising often from a hasty or one-sided interpretation of the newer aspects and results of modern inquiry. The higher problems of philosophy and religion, too, are being investigated afresh from opposite sides in a thoroughly earnest spirit, as well as with a directness and intellectual power, which is certainly one of the most striking signs of the times. This fresh outbreak of the inevitable contest between the old and the new is a fruitful source of exaggerated hopes and fears, and of excited denunciation and appeal. In this conflict a work like the Encyclopædia is not called upon to take any direct part. It has to do with knowledge rather than opinion, and to deal with all subjects from a critical and historical, rather than a dogmatic, point of view. It cannot be the organ of any sect or party in Science, Religion or Philosophy. Its main duty is to give an accurate account of the facts and an impartial summary of results in every department of inquiry and research. This duty will, I hope, be faithfully performed

T. S. BAYNES.

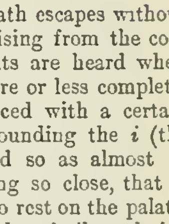
ENCYCLOPÆDIA BRITANNICA.

A

A, THE first symbol of every Indo-European alphabet, denotes also the primary vowel sound. This coincidence is probably only accidental. The alphabets of Europe, and perhaps of India also, were of Semitic origin, and in all the Semitic alphabets except one, this same symbol (in modified forms) holds the first place; but it represents a peculiar breathing, not the vowel *a*,—the vowels in the Semitic languages occupying a subordinate place, and having originally no special symbols. When the Greeks, with whom the vowel sounds were much more important, borrowed the alphabet of Phœnicia, they required symbols to express those vowels, and used for this purpose the signs of breathings which were strange to them, and therefore needed not to be preserved; thus the Phœnician equivalent of the Hebrew *aleph* became *alpha;* it denoted, however, no more a guttural breathing, but the purest vowel sound. Still, it would be too much to assume that the Greeks of that day were so skilled in phonetics that they assigned the first symbol of their borrowed alphabet to the *a*-sound, *because* they knew that sound to be the most essential vowel.

This primary vowel-sound (the sound of *a* in *father*) is produced by keeping the passage through which the air is vocalised between the glottis and the lips in the most open position possible. In sounding all other vowels, the air-channel is narrowed by the action either of the tongue or the lips. But here neither the back of the tongue is raised (as it is in sounding o and other vowels), so that a free space is left between the tongue and the uvula, nor is the front of the tongue raised (as in sounding *e*), so that the space is clear between the tongue and the palate. Again, no other vowel is pronounced with a wider opening of the lips; whereas the aperture is sensibly reduced at each side when we sound o, and still more when we sound *u* (that is, *yoo*). The whole channel, therefore, from the glottis, where the breath first issues forth to be modified in the oral cavity, to the lips, where it finally escapes, is thoroughly open. Hence arises the great importance of the sound, by reason of its thoroughly non-consonantal character. All vowels may be defined as open positions of the speech-organs, in which the breath escapes without any stoppage, friction, or sibilation arising from the contact of those organs, whereas consonants are heard when the organs open after such contact more or less complete. Now, all vowels except *a* are pronounced with a certain contraction of the organs; thus, in sounding the *i* (the English *e*-sound), the tongue is raised so as almost to touch the palate, the passage left being so close, that if the tongue were suffered for a second to rest on the palate, there would be heard not *i* but *y;* and a similar relation exists between *u* and *w*. This is commonly expressed by calling *y* and *w* semi-vowels. We might more exactly call *i* and *u* consonantal-vowels; and as an historic fact, *i* does constantly pass into *y*, and *u* into *w*, and *vice versa*. But no consonant has this relation to the *a*-sound; it has absolutely no affinity to any consonant; it is, as we have called it, the one primary essential vowel.

The importance of this sound may be shown by historical as well as by physiological evidence. We find by tracing the process of phonetic change in different languages, that when one vowel passes into another, it is the pure *a*-sound which thus assumes other forms, whereas other vowels do not pass into the *a*-sound, though sometimes the new sound may have this symbol. Roughly speaking, we might express the general character of vowel change by drawing two lines from a common point, at which *a* is placed. One of these lines marks the progress of an original *a* (*ah*-sound) through *e* (*a*-sound), till it sinks finally to *i* (*e*-sound); the other marks a similar degradation, through o to *u* (*oo*-sound). This figure omits many minor modifications, and is subject to some exceptions in particular languages. But it represents fairly in the main the general process of vowel-change. Now, we do not assert that there ever was a time when *a* was the only existing vowel, but we do maintain that in numberless cases an original *a* has passed into other sounds, whereas the reverse process is excessively



rare. Consequently, the farther we trace back the history of language, the more instances of this vowel do we find; the more nearly, if not entirely, does it become the one starting point from which all vowel-sound is derived.

It is principally to the effort required to keep this sound pure that we must attribute the great corruption of it in all languages, and in none more than our own. Indeed, in English, the short *a*-sound is never heard pure; it is heard in Scotland, *e.g.*, in *man*, which is quite different from the same word on English lips. We have it, however, long in *father*, &c., though it is not common. It has passed into a great many other sounds, all of which are denoted in a most confusing way by the original symbol, and some by other symbols as well. Thus *a* denotes—(1.) The English vowel-sound in *man*, perhaps the most common of all the substitutes, dating from the 17th century. (2.) It appears in *want;* for this sound o is also employed, as in *on*. (3.) A more open sound is heard in *all* (also denoted by *au* in *auk*, and *aw* in *awl*). (4.) Very commonly it represents the continental *e*, as in *ale* (here also we have the symbol *ai* in *ail*). (5.) It is found in *dare* and many similar words, where the sound is really the *e* of *den*, prolonged in the utterance; here also *ai* is sometimes an equivalent, as in *air*. Then (6) there is a sound which is not that of *a* either in *man* or in *father*, but something between the two. It is heard in such words as *ask*, *pass*, *grant*, &c. All these may be, and often are, pronounced with the sound either of *man* or of *father;* still, we do often hear in them a clearly distinguishable intermediate sound, which ought to have a special symbol. Lastly (7), there is the dull sound heard in final unaccentuated syllables, *e.g.*, in the word *final* itself. It is that to which all unaccentuated syllables tend; but it is also often heard even in monosyllables, where it is represented by every other vowel-symbol in the language, *e.g.*, in *her*, *sir*, *son*, *sun*. This Protean sound is commonly called the neutral vowel; it occurs in all languages, but perhaps in none so frequently as in English. This great variety of sounds, which are all denoted among us by one symbol, clearly shows the insufficiency of our written alphabet.

As in English, so in Sanskrit, the short *ah*-sound was lost, and was replaced regularly by the neutral sound. This was regarded by the grammarians as inherent in every consonant, and therefore was only written at the beginning of a word; in fact, it is the smallest amount of vowel-sound requisite to float a consonant. Long *a*, however, kept its sound pure, and does so still in the vernaculars of India. In Latin the sound was probably pure, both short and long, and it has been preserved so in the Romance languages down to the present day. In Greek there was considerable variation, proved in one case at least by a variation of symbol; in Ionic α commonly passed into η, a symbol which probably denoted the modern Italian open *e;* but possibly the close *e*, that is, the English *a* in *ale*. On the other hand, it is probable that the Doric α approximated to an *o*, being sounded as *a* in our word *want;* and it is likely that this variation was the πλατειασμός which the grammarians attribute to the Dorians. This is commonly supposed to have been the retention of α where the Ionic had η; but that was not peculiar to the Dorians, being common to all the Greeks except the Ionians. In the north of Europe we find a similar tendency to give to *a* an *o*-sound; thus in Norse, *aa* is sounded as an open o. By a further extension in the north of England, at least in such parts as have been specially exposed to Norwegian influence, *au* has the sound of o; *e.g.*, *law* is pronounced *lo*.

A is frequently used as a prefix in lieu of some fuller form in old English. Thus it stands for the preposition *on* (O.E. *an*) in *away*, *again*, *afoot*, *asleep;* for *off* in *adown* (O.E. *of-dune*); and seems to be intensive in *athirst* (O.E. *of-thirst*). Sometimes, especially with verbs, it represents the old English *â*, which in old High German appears as *ur* or *er*, and in modern German as *er*, which signifies the completion of an action, as in *erwachen*, to which *awake* corresponds. Frequently no special force seems to be added by the prefix, as in *abide*, *arise*, &c. Sometimes *a* appears as the representative of the prefix commonly used in past participles, which has the form *ge* in German, and *ge* and *y* in old English, *e.g.*, in *ago* or *agone;* compare *aware* (O.E. *gewaere*), *among* (O.E. *gemang*), &c. *A* also stood for the preposition *an* (*on*) in such expressions (now obsolete) as *a-doing*, *a-making*, where *doing* and *making* are verbal nouns. Lastly, it represents the prepositions *on* or *of* in the phrases *now-a-days*, *Jack-a-lantern*, and others.

The place that A occupies in the alphabet accounts for its being much employed as a mark or symbol. It is used, for instance, to name the sixth note of the gamut in music; in some systems of notation it is a numeral (see ARITHMETIC); and in Logic it denotes a universal affirmative proposition (see LOGIC). In algebra, *a* and the first letters of the alphabet are employed to represent known quantities. A1 marks the best class of vessels in Lloyd's Register of British and Foreign Shipping. In the old poets, "A *per se*" is found, meaning the highest degree of excellence; as when Chaucer calls Creseide "the floure and *A per se* of Troye and Grece."

A was the first of the eight *literæ nundinales* at Rome, and on this analogy it stands as the first of the seven Dominical letters.

It is often used as an abbreviation, as in A.D. for *anno domini*, A.M. for *ante meridiem*, A.B. and A.M. for *artium baccalaureus* and *artium magister*. In commerce A stands for *accepted*. (J. P.)

AA, the name of about forty small European rivers. The word is derived from the old German *aha*, cognate to the Latin *aqua*, water. The following are the more important streams of this name:—a river of Holland, in North Brabant, which joins the Dommel at Bois-le-Duc; two rivers in the west of Russia, both falling into the Gulf of Livonia, near Riga, which is situated between them; a river in the north of France, falling into the sea at Gravelines, and navigable as far as St Omer; and a river of Switzerland, in the cantons of Lucerne and Aargau, which carries the waters of Lakes Baldeker and Hallwyler into the Aar.

AACHEN. See AIX-LA-CHAPELLE.

AALBORG, a city and seaport of Denmark, is situated on the Liimfiord, about 15 miles from its junction with the Cattegat. It is the capital of the district of the same name, one of the subdivisions of the province of Jütland. The city is a place of considerable commercial importance, and contains a cathedral and a school of navigation. Soap, tobacco, and leather are manufactured; there are several distilleries; and the herring fishery is extensively prosecuted. Grain and herring are largely exported, as are also to a smaller extent wool, cattle, skins, tallow, salt provisions, and spirits. The harbour, which is good and safe, though difficult of access, is entered by about 800 vessels annually, and there is direct steam communication with Copenhagen. The district is celebrated for its breed of horses. Population (1870), 11,953.

AALEN, a walled town of Würtemberg, pleasantly situated on the Kocher, at the foot of the Swabian Alps, about 50 miles E. of Stuttgart. Woollen and linen goods are manufactured, and there are ribbon looms and tanneries in the town, and large iron works in the neighbourhood. Aalen was a free imperial city from 1360 till 1802, when it was annexed to Würtemberg. Population (1871), 5552.

AAR, or AARE, the most considerable river in Switzerland, after the Rhine and Rhone. It rises in the glaciers of the Finster-aarhorn, Schreckhorn, and Grimsel, in the canton of Bern; and at the Handeck in the valley of Hasli forms a magnificent water-fall of above 150 feet in height. It then falls successively into the lakes Brienz and Thun, and, emerging from the latter, flows through the cantons of Bern, Soleure, and Aargau, emptying itself into the Rhine, opposite Waldshut, after a course of about 170 miles. Its principal tributary streams are the Kander, Saane, and Thiele on the left, and the Emmen, Surin, Aa, Reuss, and Limmat, on the right. On its banks are situated Unterseen, Thun, Bern, Soleure or Solothurn, Aarburg, and Aarau. The Aar is a beautiful silvery river, abounding in fish, and is navigable from the Rhine as far as the Lake of Thun. Several small rivers in Germany have the same name.

AARAU, the chief town of the canton of Aargau in Switzerland, is situated at the foot of the Jura mountains, on the right bank of the river Aar, 41 miles N.E. of Bern. It is well built, and contains a town-hall, barracks, several small museums, and a library rich in histories of Switzerland. There is a cannon foundry at Aarau, and among the principal manufactures are silk, cotton, and leather; also cutlery and mathematical instruments, which are held in great repute. The slopes of the neighbouring mountains are partially covered with vines, and the vicinity of the town is attractive. About ten miles distant along the right bank of the Aar are the famous baths of Schinznach. Population, 5449.

AARD-VARK (*earth-pig*), an animal very common in South Africa, measuring upwards of three feet in length, and having a general resemblance to a short-legged pig. It feeds on ants, and is of nocturnal habits, and very timid and harmless. Its flesh is used as food, and when suitably preserved is considered a delicacy. The animal is the only known species of its genus (*Orycteropus*), and belongs to the order *Edentata* of the mammalia. The same prefix *Aard* appears in the name of the AARD-WOLF (*Proteles Lalandii*), a rare animal found in Caffraria, which is said to partake of the characters of the dog and civet. See MAMMALIA.

AARGAU (French, ARGOVIA), one of the cantons of Switzerland, derives its name from the river which flows through it, Aar-gau being the province or district of the Aar. It is bounded on the north by the Rhine, which divides it from the duchy of Baden, on the east by Zurich and Zug, on the south by Lucerne, and on the west by Bern, Soleure or Solothurn, and Basel. It has an area of 502½ square miles. By the census of 1870, the number of inhabitants was 198,873, showing an increase during the preceding ten years of 4665. Aargau stands sixth among the Swiss cantons in density of population, having 395 inhabitants to the square mile. The statistics of 1870 show that of the inhabitants 107,703 were Protestants, 89,180 Catholics, and 1541 Jews. German is the language almost universally spoken.

Aargau is the least mountainous canton of Switzerland. It forms part of a great table-land to the north of the Alps and the east of the Jura, having a general elevation of from 1200 to 1500 feet. The hills do not rise to any greater height than 1800 feet above this table-land, or 3000 feet above the level of the sea. The surface of the country is beautifully diversified, undulating tracts and well-wooded hills alternating with fertile valleys watered by the Aar and its numerous tributaries, and by the rivulets which flow northward into the Rhine. Although moist and variable, the climate is milder than in most parts of Switzerland.

The minerals of Aargau are unimportant, but remarkable palæontological remains are found in its rocks. The soil to the left of the Aar is a stiff clay, but to the right it is light and productive. Agriculture is in an advanced state, and great attention is given to the rearing of cattle. There are many vineyards, and much fruit is grown. The canton is distinguished by its industry and its generally diffused prosperity. Many of the inhabitants are employed in the fishings on the Aar, and in the navigation of the river. In the villages and towns there are considerable manufactures of cotton goods, silk, and linen. The chief exports are cattle, hides, cheese, timber, raw cotton, yarn, cotton cloths, silk, machinery, and wooden wares; and the imports include wheat, wine, salt, leather, and iron. The most important towns are Aarau, Baden, Zofingen, and Laufenburg, and there are mineral springs at Baden, Schinznach, Leerau, and Niederweil. The Swiss Junction Railway crosses the Rhine near Waldshut, and runs south through the canton to Turgi, whence one line proceeds S.E. to Zurich, and another S.W. to Aarau and Olben.

Until 1798, Aargau formed part of the canton of Bern, but when the Helvetic Republic was proclaimed, it was erected into a separate canton. In 1803 it received a considerable accession of territory, in virtue of the arrangement under which the French evacuated Switzerland. According to the law whereby the cantons are represented in the National Council by one member for every 20,000 inhabitants, Aargau returns ten representatives to that assembly. The internal government is vested in a legislative council elected by the body of the people, while a smaller council of seven members is chosen by the larger body for the general administration of affairs. The resources of Aargau are stated to amount to about a million sterling; its revenue in 1867 was nearly £82,000, and the expenditure slightly greater. There is a public debt of about £40,000. The canton is divided into eleven districts, and these again are subdivided into forty-eight circles. There is a court of law for each district, and a superior court for the whole canton, to which cases involving sums above 160 francs can be appealed. Education is compulsory; but in the Roman Catholic districts the law is not strictly enforced. By improved schools and other appliances great progress has been made in education within the last thirty or forty years.

AARHUUS, a city and seaport of Denmark, situated on the Cattegat, in lat. 56° 9′ N., long. 10° 12′ E. It is the chief town of a fertile district of the same name, one of the subdivisions of Jutland. The cathedral of Aarhuus is a Gothic structure, and the largest church in Denmark. The town also contains a lyceum, museum, and library. Aarhuus is a place of extensive trade. It has a good and safe harbour, has regular steam communication with Copenhagen, and is connected by rail with Viborg and the interior of the country. Agricultural produce, spirits, leather, and gloves are exported, and there are sugar refineries, and manufactures of wool, cotton, and tobacco. Population (1870), 15,020.

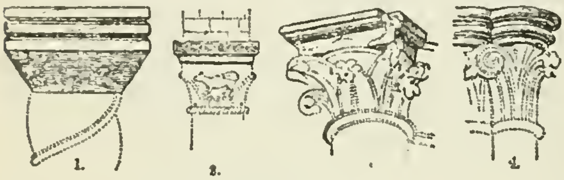
AARON, the first high-priest of the Jews, eldest son of Amram and Jochebed, of the tribe of Levi, and brother of Moses and Miriam. When Moses was commissioned to conduct the Israelites from Egypt to Canaan, Aaron was appointed to assist him, principally, it would appear, on account of his possessing, in a high degree, persuasive readiness of speech. On the occasion of Moses' absence in Mount Sinai (to which he had gone up to receive the tables of the law), the Israelites, regarding Aaron as their leader, clamorously demanded that he should provide them with a visible symbolic image of their God for worship. He weakly complied with the demand, and out of the ornaments of gold contributed for the purpose cast the figure of a calf, this form being doubtless chosen in recollection of the idols of Egypt. In obedience to instructions given by God to Moses, Aaron was appointed high-priest; his sons and descendants, priests; and his tribe was set apart as the sacerdotal caste. The office of high-priest was held by Aaron for nearly forty years, till the time of his death, which took place on Mount Hor, when he was 123 years old.

AARSSENS, Francis Van (1572-1641), one of the greatest diplomatists of the United Provinces. He represented the States-General at the Court of France for many years, and was also engaged in embassies to Venice, Germany, and England. His great diplomatic ability appears from the memoirs he wrote of his negotiations in 1624 with Richelieu, who ranked him among the three greatest politicians of his time. A deep stain rests on the memory of Aarssens from the share he had in the death of Barneveldt, who was put to death by the States-General, after the semblance of a trial, in 1619.

ABABDE, an African tribe occupying the country between the Red Sea and the Nile, to the S. of Kosseir, nearly as far as the latitude of Derr. Many of the race have settled on the eastern bank of the Nile, but the greater part still live like Bedouins. They are a distinct race from the Arabs, and are treacherous and faithless in their dealings. They have few horses; when at war with other tribes, they fight from camels, their breed of which is famed. They possess considerable property, and trade in senna, and in charcoal made from acacia wood, which they send as far as Cairo.

ABACA or Abaka, a name given to the *Musa textilis*, the plant that produces the fibre called Manilla Hemp, and also to the fibre itself.

ABACUS, an architectural term (from the Gr. ἄβαξ, a tray or flat board) applied to the upper part of the capital of a column, pier, &c. The early form of an abacus is



Forms of the Abacus.

simply a square flat stone, probably derived from the Tuscan order. In Saxon work it is frequently simply chamfered, but sometimes grooved, as in the crypt at Repton (fig. 1), and in the arcade of the refectory at Westminster. The abacus in Norman work is square where the columns are small; but on larger piers it is sometimes octagonal, as at Waltham Abbey. The square of the abacus is often sculptured, as at the White Tower and at Alton (fig. 2). In early English work the abacus is generally circular, and in larger work a continuation of circles (fig. 4), sometimes octagonal, and occasionally square. The mouldings are generally rounds, which overhang deep hollows. The abacus in early French work is generally square, as at Blois (fig. 3). The term is applied in its diminutive form (Abaciscus) to the chequers or squares of a tessellated pavement.

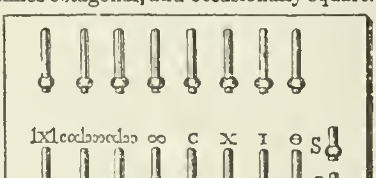


Fig. 5.—Roman Abacus.

Abacus also signifies an instrument employed by the ancients for arithmetical calculations; pebbles, bits of bone, or coins, being used as counters. The accompanying figure (5) of a Roman abacus is taken from an ancient monument. It contains seven long and seven shorter rods or bars, the former having four perforated beads running on them, and the latter one. The bar marked I indicates units, X tens, and so on up to millions. The beads on the shorter bars denote fives,—five units, five tens, &c. The rod Θ and corresponding short rod are for marking ounces; and the short quarter rods for fractions of an ounce.

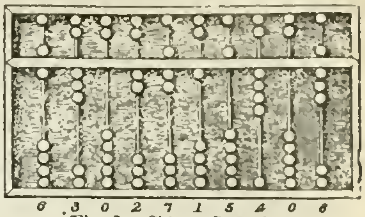

Fig. 6.—Chinese Swan-Pan.

The *Swan-Pan* of the Chinese (fig. 6) closely resembles the Roman abacus in its construction and use. Computations are made with it by means of balls of bone or ivory running on slender bamboo rods similar to the simpler board, fitted up with beads strung on wires, which is employed in teaching the rudiments of arithmetic in elementary schools.

ABÆ, a town of ancient Greece in the E. of Phocis, famous for a temple and oracle of Apollo. The temple was plundered and burned by the Persians (B.C. 480), and again by the Bœotians (B.C. 346), and was restored on a smaller scale by Hadrian. Remains of the temple and town may still be traced on a peaked hill near Exarkho. See Leake's *Northern Greece*.

ABAKANSK, a fortified town of Siberia, in the government of Yeniseisk, on the river Abakan, near its confluence with the Yenisei. Lat. 54° N.; long. 91° 14′ E. This is considered the mildest and most salubrious place in Siberia, and is remarkable for the tumuli in its neighbourhood, and for some statues of men from seven to nine feet high, covered with hieroglyphics. Population about 1000.

ABANA and Pharpar, "rivers of Damascus" (2 Kings v. 12), are now generally identified with the Barada and the Awaj respectively. The former flows through the city of Damascus; the Awaj, a smaller stream, passes eight miles to the south. Both run from west to east across the plain of Damascus, which owes to them much of its fertility, and lose themselves in marshes, or lakes, as they are called, on the borders of the great Arabian desert. Mr Macgregor, who gives an interesting description of these rivers in his *Rob Roy on the Jordan*, affirms that "as a work of hydraulic engineering, the system and construction of the canals by which the Abana and Pharpar are used for irrigation, may be still considered as the most complete and extensive in the world."

ABANCAY, a town of Peru, in the department of Cuzco, 65 miles W.S.W. of the town of that name. It lies on the river Abancay, which is here spanned by one of the finest bridges in Peru. Rich crops of sugar-cane are produced in the district, and the town has extensive sugar refineries. Hemp is also cultivated, and silver is found in the mountains. Population, 1200.

ABANDONMENT, in *Marine Assurance*, is the surrendering of the ship or goods insured to the insurers, in the case of a constructive total loss of the thing insured. There is an absolute total loss entitling the assured to recover the full amount of his insurance wherever the thing insured has ceased to exist to any useful purpose,—and in such a case abandonment is not required. Where the thing assured continues to exist in specie, yet is so damaged that there is no reasonable hope of repair, or it is not worth the expense of bringing it, or what remains of it, to its destination, the insured may treat the case as one of a total loss (in this case called constructive total loss), and demand the full sum insured. But, as the contract of insurance is one of indemnity, the insured must, in such a case, make an express cession of all his right to the recovery of the subject insured to the underwriter by abandonment. The insured must intimate his intention to abandon, within a reasonable thing after receiving correct information as to the loss; any unnecessary delay being held as an indication of his intention not to abandon. An abandonment when once accepted is irrevocable; but in no circumstances is the insured obliged to abandon. After abandonment, the captain and crew are still bound to do all in their power to save the property for the underwriter, without prejudice to the right of abandonment; for which they are entitled to wages and remuneration from the insurers, at least so far as what is saved will allow. See Arnould, Marshall, and Park, on the *Law of Insurance*, and the judgment of Lord Abinger in Roux *v.* Salvador, 3 Bing. N.C. 266, Tudor's *Leading Cases*, 139.

ABANDONMENT has also a legal signification in the law of railways. Under the Acts 13 and 14 Vict. c. 83, 14 and 15 Vict. c. 64, 30 and 31 Vict. c. 126, and 32 and 33 Vict. c. 114, the Board of Trade may, on the application of a railway company, made by the authority and with the consent of the holders of three-fifths of its shares or stock, and on certain conditions specified in the Acts, grant a warrant authorising the abandonment of the railway or a portion of it. After due publication of this warrant, the company is released from all liability to make, maintain, or work the railway, or portion of the railway, authorised to be abandoned, or to complete any contracts relating to it, subject to certain provisions and exceptions.

ABANDONING a young child under two years of age, so that its life shall be endangered, or its health permanently injured, or likely to be so, is in England a misdemeanour, punishable by penal servitude or imprisonment, 24 and 25 Vict. c. 100, § 273. In Scotland abandoning or exposing an infant is an offence at common law, although no evil consequences should happen to the child.

ABANO, a town of Northern Italy, 6 miles S.W. of Padua. There are thermal springs in the neighbourhood, which have been much resorted to by invalids for bathing, both in ancient and modern times. They were called by the Romans *Aponi Fons*, and also *Aquæ Patavinæ*. Population of Abano, 3000.

ABANO, PIETRO D', known also as *Petrus de Apono* or *Aponensis*, a distinguished physician and philosopher, was born at the Italian town from which he takes his name in 1250, or, according to others, in 1246. After visiting the east in order to acquire the Greek language, he went to study at Paris, where he became a doctor of medicine and philosophy. In Padua, to which he returned when his studies were completed, he speedily gained a great reputation as a physician, and availed himself of it to gratify his avarice by refusing to visit patients except for an exorbitant fee. Perhaps this as well as his meddling with astrology caused the charge to be brought against him of practising magic, the particular accusations being that he brought back into his purse, by the aid of the devil, all the money he paid away, and that he possessed the philosopher's stone. He was twice brought to trial by the Inquisition; on the first occasion he was acquitted, and he died (1316) before the second trial was completed. He was found guilty, however, and his body was ordered to be exhumed and burned; but a friend had secretly removed it, and the Inquisition had, therefore, to content itself with the public proclamation of its sentence and the burning of Abano in effigy. In his writings he expounds and advocates the medical and philosophical systems of Averrhoes and other Arabian writers. His best known works are the *Conciliator differentiarum quæ inter philosophos et medicos versantur* (Mantua, 1472, Venice. 1476), and *De venenis eorumque remediis* (1472), of which a French translation was published at Lyons in 1593.

ABARIS, the Hyperborean, a celebrated sage of antiquity, who visited Greece about 570 B.C., or, according to others, a century or two earlier. The particulars of his history are differently related by different authors, but all accounts are more or less mythical. He is said to have travelled over sea and land, riding on an arrow given him by Apollo, to have lived without food, to have delivered the whole earth from a plague, &c. Various works in prose and verse are attributed to Abaris by Suidas and others, but of these we have no certain information.

ABATEMENT, ABATE, from the French *abattre*, *abater*, to throw down, demolish. The original meaning of the word is preserved in various legal phrases. The abatement of a nuisance is the remedy allowed by law to a person injured by a public nuisance of destroying or removing it by his own act, provided he commit no breach of the peace in doing so. In the case of private nuisances abatement is also allowed, provided there be no breach of the peace, and no damage be occasioned beyond what the removal of the nuisance requires.

Abatement of freehold takes place where, after the death of the person last seised, a stranger enters upon lands before the entry of the heir or devisee, and keeps the latter out of possession. It differs from intrusion, which is a similar entry by a stranger on the death of a tenant for life, to the prejudice of the reversioner, or remainder man; and from disseisin, which is the forcible or fraudulent expulsion of a person seised of the freehold.

Abatement among legatees (*defalcatis*) is a proportionate deduction which their legacies suffer when the funds out of which they are payable are not sufficient to pay them in full.

Abatement in pleading is the defeating or quashing of a particular action by some matter of fact, such as a defect in form or personal incompetency of the parties suing, pleaded by the defendant. Such a plea is called a plea in abatement; and as it does not involve the merits of the cause, it leaves the right of action subsisting. Since 1852 it has been competent to obviate the effect of such pleas by amendment, so as to allow the real question in controversy between the parties to be tried in the same suit.

In litigation an action is said to abate or cease on the death of one of the parties.

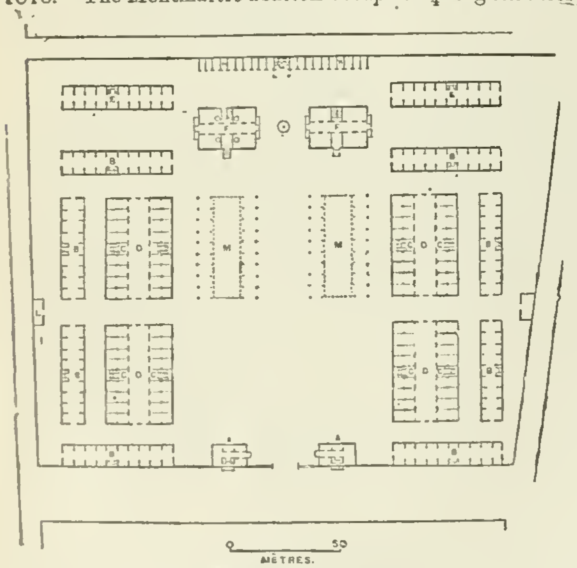
ABATEMENT, or REBATE, is a discount allowed for prompt payment; it also means a deduction sometimes made at the custom-house from the fixed duties on certain kinds of goods, on account of damage or loss sustained in warehouses. The rate and conditions of such deductions are regulated by Act 16 and 17 Vict. c. 107.

ABATI, or DELL'ABBATO, NICCOLO, a celebrated fresco-painter of Modena, born in 1512. His best works are at Modena and Bologna, and have been highly praised by Zanotti, Algarotti, and Lanzi. He accompanied Primaticcio to France, and assisted in decorating the palace at Fontainbleau (1552-1571). His pictures exhibit a combination of skill in drawing, grace, and natural colouring. Some of his easel pieces in oil are in different collections; one of the finest, now in the Dresden Gallery, represents the martyrdom of St Peter and St Paul. Abati died at Paris in 1571.

ABATTOIR, from *abattre*, primarily signifies a slaughter-house proper, or place where animals are killed as distinguished from *boucheries* and *étaux publics*, places where the dead meat is offered for sale. But the term is also employed to designate a complete meat market, of which the abattoir proper is merely part.

Perhaps the first indication of the existence of abattoirs may be found in the system which prevailed under the Emperors in ancient Rome. A corporation or guild of butchers undoubtedly existed there, which delegated to its officers the duty of slaughtering the beasts required to supply the city with meat. The establishments requisite for this purpose were at first scattered about the various streets, but were eventually confined to one quarter, and formed the public meat market. This market, in the time of Nero, was one of the most imposing structures in the city, and some idea of its magnificence has been transmitted to us by a delineation of it preserved on an ancient coin. As the policy and customs of the Romans made themselves felt in Gaul, the Roman system of abattoirs, if it may be so called, was introduced there in an imperfect form. A clique of families in Paris long exercised the special function of catering for the public wants in respect of meat. But as the city increased in magnitude and population, the necessity of keeping slaughter-houses as much as possible apart from dwelling-houses became apparent. As early as the time of Charles IX., the attention of the French authorities was directed to the subject, as is testified by a decree passed on the 25th of February 1567. But although the importance of the question was frequently recognised, no definite or decided step seems to have been taken to effect the contemplated reform until the time of Napoleon I. The evil had then reached a terribly aggravated form. Slaughter-houses abutted on many of the principal thoroughfares; the traffic was impeded by the constant arrival of foot-sore beasts, whose piteous cries pained the ear; and rivulets of blood were to be seen in the gutters of the public streets. The constant accumulation of putrid offal tainted the atmosphere, and the Seine was polluted by being used as a common receptacle for slaughter-house refuse. This condition of things could not be allowed to continue, and on the 9th of February 1810, a decree was passed authorising the construction of abattoirs in the outskirts of Paris, and appointing a Commission, to which was committed the consideration of the entire question.

The result of the appointment of this Commission was the construction of the five existing abattoirs, which were formally opened for business on the 15th of September 1818. The Montmartre abattoir occupies 8¾ English acres;



1. Ménilmontant Abattoir.

A. Residence of Officials.
B. Sheep and Cattle Sheds.
C. Slaughter-Houses.
D. Yards to do.
E. Stores.
F. Tallow-melting Houses.
G. Steam Engine.
H. Stable with Water Tanks, above.
I. Dung Pits.
L. Privies.
M. Layers for Cattle.

Ménilmontant, 10¼ acres; Grenelle, 7¾; Du Roule, 5¾; and Villejuif, 5½. The first two contain each 64 slaughter-houses and the same number of cattle-sheds; the third, 48; and each of the others 32. The dimensions of each of the slaughter-houses is about 29½ feet by 13. The general arrangement of the abattoirs will be understood from the preceding plan of that of Ménilmontant.

The component parts of a French abattoir are—1. *Echaudoirs*, which is the name given by the Paris butcher to the particular division allotted to him for the purpose of knocking down his beasts; 2. *Bouveries et Bergeries*, the places set apart for the animals waiting to be slaughtered, where the animals, instead of being killed at once, after a long and distressing journey, when their blood is heated and their flesh inflamed, are allowed to cool and rest till the body is restored to its normal healthy condition; 3. *Fondeurs*, or boiling-down establishments; and, 4. *Triperies*, which are buildings set apart for the cleaning of the tripe of bullocks, and the fat, heads, and tripe of sheep and calves. Besides these, a Paris abattoir contains *Logements des agens*, *Magasins*, *Réservoirs*, *Voiries*, *Lieux d'aisanee*, *Voûtes*, *Remises et écuries*, *Parcs aux Bœufs*, &c., and is provided with an abundant supply of water. All the abattoirs are under the control of the municipal authorities, and frequent inspections are made by persons regularly appointed for that purpose.

The abattoirs are situated within the barriers, each at a distance of about a mile and three-quarters from the heart of the city, in districts where human habitations are still comparatively few. There are two principal markets from which the abattoirs at Paris are supplied,—the one at Poissy, about 13 miles to the north-west, and the other at Sceaux, about 5 miles and a quarter to the south of the city. There are also two markets for cows and calves, namely, La Chapelle and Les Bernadins.

The Paris abattoirs were until recently the most perfect specimens of their class; and even now, although in some of their details they have been surpassed by the new Islington meat market, for their complete and compact arrangement they remain unrivalled.

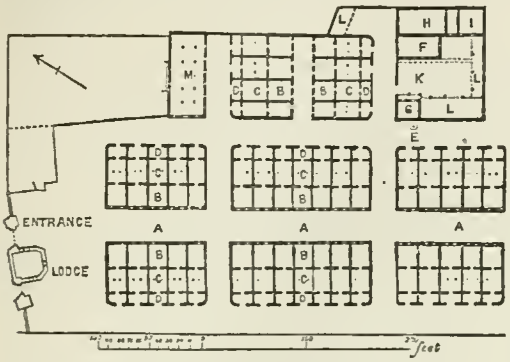
The example set by Paris in this matter has been followed in a more or less modified form by most of the principal Continental towns, and the system of abattoirs has become almost universal in France.

The condition of London in this important sanitary respect was for a long period little more endurable than that of Paris before the adoption of its reformed system. Smithfield market, situated in a very populous neighbourhood, continued till 1852 to be an abomination to the town and a standing reproach to its authorities. No fewer than 243,537 cattle and 1,455,249 sheep were sold there in 1852, to be afterwards slaughtered in the crowded courts and thoroughfares of the metropolis. But public opinion at length forced the Legislature to interfere, and the corporation was compelled to abandon Smithfield market and to provide a substitute for it elsewhere.

The site selected was in the suburb of Islington, and the designs for the work were prepared by Mr Bunning. The first stone was laid March 24, 1854, and the market was opened by Prince Albert, June 15, 1855. The Islington market is undoubtedly the most perfect of its kind. It occupies a space of some 20 acres on the high land near the Pentonville prison, and is open to both native and foreign cattle, excepting beasts from foreign countries under quarantine.

In connection with the Islington cattle market are a few slaughter-houses, half of which were originally public, and half rented to private individuals; but at present they are all practically private, and the majority of the cattle sold are driven away and killed at private slaughter-houses. In this respect the London system differs from that of Paris; and it may be said for the former that the meat is less liable to be spoiled by being carted to a distance, and is therefore probably delivered in better condition; but the latter secures that great desideratum, the practical extinction of isolated slaughter-houses.

The Edinburgh abattoir, erected in 1851 by the corporation, from designs prepared by Mr David Cousin, the city architect, is the best as regards both construction and management in the United Kingdom. It occupies an area of four acres and a quarter, surrounded by a screen-wall, from which, along the greater part of its length, the buildings are separated by a considerable open space. Opposite



2. Edinburgh Slaughter-Houses.

L. Sheds.
M. Blood House, now Albumen Factory.

the principal gateway is a double row of buildings, extending in a straight line to about 376 feet in length, with a central roadway (marked AA in the annexed plan), 25 feet wide. There are three separate blocks of building on each side of the roadway, the central one being 140 feet in length, and the others 100 feet each—cross-roads 18 feet wide separating the blocks. These ranges of building, as well as two smaller blocks that are placed transversely behind the eastern central block, are divided into compartments, numbering 42 in all, and all arranged on the same plan. Next the roadway is the slaughtering-booth (BB), 18 feet by 24, and 20 feet in height, and behind this is a shed (CC) 18 feet by 22, where the cattle are kept before being slaughtered. All the cattle are driven into these sheds by a back-entrance, through the small enclosed yards (DD). The large doors of the booths are hung by balance weights, and slide up and down, so as to present no obstruction either within the booth or outside. By a series of large ventilators along the roof, and by other contrivances, the slaughtering-booths are thoroughly ventilated. Great precautions have been used to keep rats out of the buildings. To effect this, the booths are laid with thick well-dressed pavement, resting on a stratum of concrete 12 inches thick, and the walls, to the height of 7 feet, are formed of solid ashlar; the roadways, too, are laid with concrete, and causewayed with dressed whinstone pavement; and the drainage consists entirely of glazed earthenware tubes.

The ground on which the abattoir is built was previously connected with a distillery, and contains a well 100 feet deep (E), which, with the extensive system of tunnels attached to it, provides the establishment with an abundant supply of pure water. By means of a steam-engine (F), introduced in 1872, the water is pumped up into a raised tank (G), whence it is distributed to the different booths and sheds, as well as for scouring the roadways and drains. The steam from the engine is utilised in heating water for the numerous cast-iron tanks required in the operations of cleansing and dressing the tripery (H) and pig slaughtering-house (I). By an ingenious arrangement of rotary brushes driven by the steam-engine,—the invention of Mr Rutherford, the superintendent,—the tripe is cleaned in a superior manner, and at greatly less cost than by the tedious and troublesome method of hand-cleaning.

By the Edinburgh Slaughter-Houses Act of 1850, the management is vested in the city authorities. Booths are let at a statutory rent of £8 each per annum, and, in addition to this, gate-dues are payable for every beast entering the establishment. The present rates for tenants of booths are $1\frac{1}{2}$d. for an ox or cow, $\frac{3}{4}$d. for a calf or pig, and $\frac{1}{4}$d. for a sheep. Common booths are provided for butchers who are not tenants, on payment of double gate-dues. The city claims the blood, gut, and manure. The tripe and feet are dressed for the trade without extra charge.

The blood was formerly collected in large casks, and disposed of for manufacturing purposes. This necessitated the storage of it for several days, causing in warm weather a very offensive effluvium. It even happened at times, when there was little demand for the commodity, that the blood had to be sent down the drains. All nuisance is now avoided, and the amount received annually for the blood has risen from between £200 and £450 to from £800 to £1200, by a contract into which Messrs Smith and Forrest of Manchester have entered with the city authorities, to take over the whole blood at a fixed price per beast. They have erected extensive premises and apparatus at their own cost, for extracting from the blood the albumen, for which there is great demand in calico-printing, and for converting the clot into manure.

In connection with the establishment is a boiling-house, where all meat unfit for human food is boiled down and destroyed. The number of carcases seized by the inspector, and sent to the boiling-house, during the $5\frac{1}{2}$ years ending with the close of 1872, amounted to 1449, giving a weight of upwards of 400,000 pounds.

Before the erection of these buildings, private slaughter-houses were scattered all over the city, often in the most populous districts, where, through want of drainage and imperfect ventilation, they contaminated the whole neighbourhood. Since the opening of the public abattoir, all private slaughtering, in the city or within a mile of it, is strictly prohibited.

Few of the provincial towns in Great Britain have as yet followed the example of London and Edinburgh. In some instances improvements on the old system have been adopted, but Great Britain is still not only far behind her foreign neighbours in respect of abattoirs, but has even been excelled by some of her own dependencies. In America abattoirs are numerous, and at Calcutta and other towns in British India, the meat markets present a very creditable appearance from their cleanliness and systematic arrangement. (C. N. B.)

ABAUZIT, FIRMIN, a learned Frenchman, was born of Protestant parents at Uzès, in Languedoc, in 1679. His father, who was of Arabian descent, died when he was but two years of age; and when, on the revocation of the Edict of Nantes in 1685, the authorities took steps to have him educated in the Roman Catholic faith, his mother contrived his escape. For two years his brother and he lived as fugitives in the mountains of the Cevennes, but they at last reached Geneva, where their mother afterwards joined them on escaping from the imprisonment in which she was held from the time of their flight. Abauzit's youth was spent in diligent study, and at an early age he acquired great proficiency in languages, physics, and theology. In 1698 he travelled into Holland, and there became acquainted with Bayle, Jurieu, and Basnage. Proceeding to England, he was introduced to Sir Isaac Newton, who found in him one of the earliest defenders of the great truths his discoveries disclosed to the world.

Sir Isaac corrected in the second edition of his *Principia* an error pointed out by Abauzit. The high estimate Newton entertained of his merits appears from the compliment he paid to Abauzit, when, sending him the *Commercium Epistolicum*, he said, "You are well worthy to judge between Leibnitz and me." The reputation of Abauzit induced William III. to request him to settle in England, but he did not accept the king's offer, preferring to return to Geneva. There from 1715 he rendered valuable assistance to a society that had been formed for translating the New Testament into French. He declined the offer of the chair of philosophy in the University in 1723, but accepted, in 1727, the sinecure office of librarian to the city of his adoption. Here he died at a good old age, in 1767. Abauzit was a man of great learning and of wonderful versatility. The varied knowledge he possessed was so well digested and arranged in his retentive mind as to be always within his reach for immediate use. Whatever chanced to be discussed, it used to be said of Abauzit, as of Professor Whewell of our own times, that he seemed to have made it a subject of particular study. Rousseau, who was jealously sparing of his praises, addressed to him, in his *Nouvelle Héloïse*, a fine panegyric; and when a stranger flatteringly told Voltaire he had come to see a great man, the philosopher asked him if he had seen Abauzit. Little remains of the labours of this intellectual giant, his heirs having, it is said, destroyed the papers that came into their possession, because their religious opinions differed from those of Abauzit. A few theological, archæological, and astronomical articles from his pen appeared in the *Journal Helvétique* and elsewhere, and he contributed several papers to Rousseau's *Dictionary of Music*. A work he wrote throwing doubt on the canonical authority of the Apocalypse was answered—conclusively, as Abauzit himself allowed—by Dr Leonard Twells. He edited, and made valuable additions to Spon's *History of Geneva*. A collection of his writings was published at Geneva in 1770, and another at London in 1773. Some of them were translated into English by Dr Harwood (1770, 1774). Information regarding Abauzit will be found in Senebier's *Histoire Littéraire de Genève*, Harwood's *Miscellanies*, and Orme's *Bibliotheca Biblica*, 1834.

ABB, a town of Yemen in Arabia, situated on a mountain in the midst of a very fertile country, 73 miles N.E. of Mocha. Lat. 13° 58′ N., long. 44° 15′ E. It contains about 800 houses, and is surrounded by a strong wall; the streets are well paved; and an aqueduct from a neighbouring mountain supplies it with water, which is received in a reservoir in front of the principal mosque. The population is about 5000.

ABBADIE, James, an eminent Protestant divine, was born at Nay in Bern about 1657. His parents were poor, but through the kindness of discerning friends, he received an excellent education. He prosecuted his studies with such success, that on completing his course at Sedan, though only seventeen years of age, he had conferred on him the degree of doctor in theology. After spending some years in Berlin as minister of a French Protestant church, he accompanied Marshal Schomberg, in 1688, to England, and became minister of the French church in the Savoy, London. His strong attachment to the cause of King William appears in his elaborate defence of the Revolution, as well as in his history of the conspiracy of 1696, the materials of which were furnished, it is said, by the secretaries of state. The king promoted him to the deanery of Killaloe in Ireland. He died in London in 1727. Abbadie was a man of great ability and an eloquent preacher, but is best known by his religious treatises, several of which were translated from the original French into other languages and had a wide circulation all over Europe. The most important these are *Traité de la Vérité de la Religion Chrétienne* its continuation, *Traité de la Divinité de Jésus-Christ* and *L'Art de se connaître Soi-même*.

ABBAS I., surnamed The Great, one of the most celebrated of the sovereigns of Persia, was the youngest son of Shah Mohammed Khodabendeh. After heading successful rebellion against his father, and causing one of his brothers (or, as some say, both) to be assassinated, he obtained possession of the throne at the early age of eighteen (1585). Determined to raise the fallen fortunes of his country, he first directed his efforts against the predatory Uzbeks, who occupied and harassed Khorasan. After a long and severe struggle, he defeated them in a great battle near Herat (1597), and drove them out of his dominions. In the wars he carried on with the Turks during nearly the whole of his reign, his successes were numerous, and he acquired or regained a large extent of territory. By the victory he gained at Bassorah (1605), he extended his empire beyond the Euphrates; Achmed I. was forced to cede Shirwan and Kurdistan in 1611; the united armies of the Turks and Tartars were completely defeated near Sultanieh in 1618, and Abbas made peace on very favourable terms; and on the Turks renewing the war, Baghdad fell into his hands after a year's siege (1623). In the same year he took the island of Ormuz from the Portuguese, by the assistance of the British. When he died in 1628, his dominions reached from the Tigris to the Indus. Abbas distinguished himself, not only by his successes in arms, and by the magnificence of his court, but also by his reforms in the administration of his kingdom. He encouraged commerce, and, by constructing highways and building bridges, did much to facilitate it. To foreigners, especially Christians, he showed a spirit of tolerance; two Englishmen, Sir Anthony and Sir Robert Shirley, were admitted to his confidence, and seem to have had much influence over him. His fame is tarnished, however, by numerous deeds of tyranny and cruelty. His own family, especially, suffered from his fits of jealousy; his eldest son was slain, and the eyes of his other children were put out, by his orders.

ABBAS MIRZA (*b.* 1785, *d.* 1833), Prince of Persia, third son of the Shah Feth Ali, was destined by his father to succeed him in the government, because of his mother's connection with the royal tribe of the Khadjars. He led various expeditions against the Russians, but generally without success (1803, 1813, 1826). By a treaty made between Russia and Persia in 1828, the right of Abbas to the succession was recognised. When the Russian deputies were murdered by the Persian populace in 1829, Abbas was sent to St Petersburg, where he received a hearty welcome from the Czar, and made himself a favourite by his courtesy and literary taste. He formed a design against Herat, but died shortly after the siege had been opened by his son, who succeeded Feth Ali as the Shah Mohammed Mirza. He was truthful—a rare quality in an Eastern—plain in dress and style of living, and fond of literature.

ABBASSIDES, the caliphs of Bagdad, the most famous dynasty of the sovereigns of the Mahometan or Saracen empire. They derived their name and descent from Abbas (*b.* 566, *d.* 652 A.D.), the uncle and adviser of Mahomet, and succeeded the dynasty of the Ommiads, the caliphs of Damascus. Early in the 8th century the family of Abbas had acquired great influence from their near relationship to the Prophet; and Ibrahim, the fourth in descent from Abbas, supported by the province of Khorasan, obtained several successes over the Ommiad armies, but was captured and put to death by the Caliph Merwan (747). Ibrahim's brother, Abul-Abbas, whom he had named his heir, assumed the title of caliph, and, by a decisive victory near the river Zab (750), effected the overthrow of the Ommiad dynasty. Merwan fled to Egypt, but was pursued and put to death, and the vanquished family was treated with a severity which gained for Abul-Abbas the surname of Al-Saffah, the Blood-shedder. From this time the house of Abbas was fully established in the government, but the Spanish provinces were lost to the empire by the erection of an independent caliphate of Cordova, under Abderrahman.

On the death of Abul-Abbas, Almansur succeeded to the throne, and founded Baghdad as the seat of empire. He and his son Mohdi waged war successfully against the Turkomans and Greeks of Asia Minor; but from this time the rule of the Abbassides is marked rather by the development of the liberal arts than by extension of territory. The strictness of the Mohammedan religion was relaxed, and the faithful yielded to the seductions of luxury. The caliphs Harun Al-Rashid (786-809) and Al-Mamun (813-833) attained a world-wide celebrity by their gorgeous palaces, their vast treasures, and their brilliant and numerous equipages, in all which their splendour contrasted strikingly with the poverty of European sovereigns. The former is known as one of the heroes of the *Arabian Nights;* the latter more worthily still as a liberal patron of literature and science. It is a mistake, however, to look in the rule of these caliphs for the lenity of modern civilisation. "No Christian government," says Hallam, "except perhaps that of Constantinople, exhibits such a series of tyrants as the caliphs of Baghdad, if deeds of blood, wrought through unbridled passion or jealous policy, may challenge the name of tyranny."

The territory of the Abbassides soon suffered dismemberment, and their power began to decay. Rival sovereignties (Ashlabites, Edrisites, &c.) arose in Africa, and an independent government was constituted in Khorasan (820), under the Taherites. In the West, again, the Greeks encroached upon the possessions of the Saracens in Asia Minor. Ruin, however, came from a less civilised race. The caliphs had continually been waging war with the Tartar hordes of Turkestan, and many captives taken in these wars were dispersed throughout the empire. Attracted by their bravery and fearing rebellion among his subjects, Motassem (833-842), the founder of Samarah, and successful opponent of the Grecian forces under Theophilus, formed body-guards of the Turkish prisoners, who became from that time the real governors of the Saracen empire. Motawakkel, son of Motassem, was assassinated by them in the palace (861); and succeeding caliphs became mere puppets in their hands. Radhi (934-941) was compelled by the disorganised condition of his kingdom to delegate to Mohammed ben Rayek (936 A.D.), under the title of *Emir-al-Omara,* commander of the commanders, the government of the army and the other functions of the caliphate. Province after province proclaimed itself independent; the caliph's rule became narrowed to Baghdad and its vicinity; and the house of Abbas lost its power in the East for ever, when Hulagu, prince of the Mongols, set Baghdad on fire, and slew Motassem, the reigning caliph (20th Feb. 1258). The Abbassides continued to hold a semblance of power in the merely nominal caliphate of Egypt, and feebly attempted to recover their ancient seat. The last of them, Motawakkel III., was taken by Sultan Selim I., the conqueror of Egypt, to Constantinople, and detained there for some time as a prisoner. He afterwards returned to Egypt, and died at Cairo a pensionary of the Ottoman government, in 1538.

ABBÉ is the French word corresponding to ABBOT, but, from the middle of the sixteenth century to the time of the French Revolution, the term had a wider application. The assumption by a numerous class of the name and style of abbé appears to have originated in the right conceded to the King of France, by a concordat between Pope Leo X. and Francis I., to appoint *abbés commendataires* to 225 abbeys, that is, to most of the abbeys in France. This kind of appointment, whereby the living was *commended* to some one till a proper election could take place, though ostensibly provisional, really put the nominee in full and permanent possession of the benefice. He received about one-third of the revenues of the abbey; but had no share in its government, the charge of the house being intrusted to a resident officer, the *prieur claustral.* The *abbés commendataires* were not necessarily priests; the papal bull required indeed that they should take orders within a stated time after their appointment; but there seems to have been no difficulty in procuring relief from that obligation. The expectation of obtaining these sinecures drew young men towards the Church in considerable numbers, and the class of abbés so formed—*abbés de cour* they were sometimes called, and sometimes (ironically) *abbés de sainte espérance,* abbés of St Hope—came to hold a recognised position, that perhaps proved as great an attraction as the hope of preferment. The connection many of them had with the Church was of the slenderest kind, consisting mainly in adopting the name of abbé, after a remarkably moderate course of theological study; practising celibacy; and wearing a distinctive dress—a short dark-violet coat with narrow collar. Being men of presumed learning and undoubted leisure, many of the class found admission to the houses of the French nobility as tutors or advisers. Nearly every great family had its abbé. As might be imagined from the objectless sort of life the class led, many of the abbés were of indifferent character; but there are not a few instances of abbés attaining eminence, both in political life and in the walks of literature and science. The Abbé Sieyès may be taken as a prominent example of the latter type.

ABBEOKUTA, or ABEOKUTA, a town of West Africa in the Yoruba Country, situated in N. lat. 7° 8′, and E. long. 3° 25′, on the Ogun River, about 50 miles north of Lagos, in a direct line, or 81 miles by water. It lies in a beautiful and fertile country, the surface of which is broken by masses of grey granite. Like most African towns, Abbeokuta is spread over an extensive area, being surrounded by mud walls, 18 miles in extent. The houses are also of mud, and the streets mostly narrow and filthy. There are numerous markets in which native products and articles of European manufacture are exposed for sale. Palm-oil and shea-butter are the chief articles of export, and it is expected that the cotton of the country will become a valuable article of commerce. The slave trade and human sacrifices have been abolished; but notwithstanding the efforts of English and American missionaries, the natives are still idle and degraded. The state called Egbaland, of which Abbeokuta is the capital, has an area of about 3000 square miles. Its progress has been much hindered by frequent wars with the king of Dahomey. Population of the town, about 150,000; of the state or adjacent territory, 50,000. (See Burton's *Abbeokuta and the Cameroon Mountains,* 2 vols.)

ABBESS, the female superior of an abbey or convent of nuns. The mode of election, position, rights, and authority of an abbess, correspond generally with those of an abbot. The office was elective, the choice being by the secret votes of the sisters from their own body. The abbess was solemnly admitted to her office by episcopal benediction, together with the conferring of a staff and pectoral, and held it for life, though liable to be deprived for misconduct. The Council of Trent fixes the qualifying age at forty, with eight years of profession. Abbesses had a right to demand absolute obedience of their nuns, over whom they exercised discipline, extending even to the power of expulsion, subject, however, to the bishop. As a female an abbess was incapable of performing the spiritual functions of the priesthood belonging to an abbot. She could not ordain, confer the veil, nor excommunicate. In the eighth century abbesses were censured for usurping priestly powers by presuming to give the veil to virgins, and to confer benediction and imposition of hands on men. In England they attended ecclesiastical councils, *e.g.* that of Becanfield in 694, where they signed before the presbyters.

By Celtic usage abbesses presided over joint-houses of monks and nuns. This custom accompanied Celtic monastic missions to France and Spain, and even to Rome itself. At a later period, A.D. 1115, Robert, the founder of Fontevraud, committed the government of the whole order, men as well as women, to a female superior.

Martene asserts that abbesses formerly confessed nuns, but that their undue inquisitiveness rendered it necessary to forbid the practice.

The dress of an English abbess of the 12th century consisted of a long white tunic with close sleeves, and a black overcoat as long as the tunic, with large and loose sleeves, the hood covering the head completely. The abbesses of the 14th and 15th centuries had adopted secular habits, and there was little to distinguish them from their lay sisters. (E. V.)

ABBEVILLE, a city of France, in the department of the Somme, is situated on the River Somme, 12 miles from its mouth in the English Channel, and 25 miles N.W. of Amiens. It lies in a pleasant and fertile valley, and is built partly on an island, and partly on both sides of the river. The streets are narrow, and the houses are mostly picturesque old structures, built of wood, with many quaint decaying gables and dark archways. The town is strongly fortified on Vauban's system. It has a tribunal and chamber of commerce. The most remarkable edifice is the Church of St Wolfran, which was erected in the time of Louis XII. Although the original design was not completed, enough was built to give a good idea of the splendid structure it was intended to erect. The façade is a magnificent specimen of the flamboyant Gothic style, and is adorned by rich tracery, while the western front is flanked by two Gothic towers. A cloth manufactory was established here by Van Robais, a Dutchman, under the patronage of the minister Colbert, as early as 1669; and since that time Abbeville has continued to be one of the most thriving manufacturing towns in France. Besides black cloths of the best quality, there are produced velvets, cottons, linens, serges, sackings, hosiery, packthread, jewellery, soap, and glass-wares. It has also establishments for spinning wool, print-works, bleaching-works, tanneries, a paper manufactory, &c.; and being situated in the centre of a populous district, it has a considerable trade with the surrounding country. Vessels of from 200 to 300 tons come up to the town at high-water. Abbeville is a station on the Northern Railway, and is also connected with Paris and Belgium by canals. Fossil remains of gigantic mammalia now extinct, as well as the rude flint weapons of pre-historic man, have been discovered in the geological deposits of the neighbourhood. A treaty was concluded here in 1259 between Henry III. of England and Louis IX. of France, by which the province of Guienne was ceded to the English. Population, 20,058.

ABBEY, a monastery, or conventual establishment, under the government of an ABBOT or an ABBESS. A *priory* only differed from an abbey in that the superior bore the name of *prior* instead of *abbot*. This was the case in all the English conventual cathedrals, *e.g.*, Canterbury, Ely, Norwich, &c., where the archbishop or bishop occupied the abbot's place, the superior of the monastery being termed prior. Other priories were originally offshoots from the larger abbeys, to the abbots of which they continued subordinate; but in later times the actual distinction between abbeys and priories was lost.

Reserving for the article MONASTICISM the history of the rise and progress of the monastic system, its objects, benefits, evils, its decline and fall, we propose in this article to confine ourselves to the structural plan and arrangement of conventual establishments, and a description of the various buildings of which these vast piles were composed.

The earliest Christian monastic communities with which we are acquainted consisted of groups of cells or huts collected about a common centre, which was usually the abode of some anchorite celebrated for superior holiness or singular asceticism, but without any attempt at orderly arrangement. The formation of such communities in the East does not date from the introduction of Christianity. The example had been already set by the Essenes in Judea and the Therapeutæ in Egypt, who may be considered the prototypes of the industrial and meditative communities of monks.

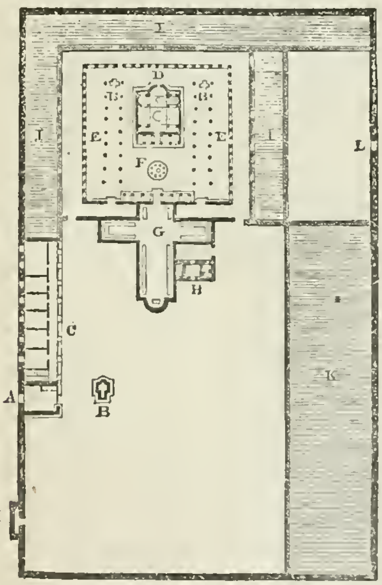
In the earliest age of Christian monasticism the ascetics were accustomed to live singly, independent of one another, at no great distance from some village, supporting themselves by the labour of their own hands, and distributing the surplus after the supply of their own scanty wants to the poor. Increasing religious fervour, aided by persecution, drove them further and further away from the abodes of men into mountain solitudes or lonely deserts. The deserts of Egypt swarmed with the cells or huts of these anchorites. Antony, who had retired to the Egyptian Thebaid during the persecution of Maximin, A.D. 312, was the most celebrated among them for his austerities, his sanctity, and his power as an exorcist. His fame collected round him a host of followers, emulous of his sanctity. The deeper he withdrew into the wilderness, the more numerous his disciples became. They refused to be separated from him, and built their cells round that of their spiritual father. Thus arose the first monastic community, consisting of anchorites living each in his own little dwelling, united together under one superior. Antony, as Neander remarks (*Church History*, vol. iii. p. 316, Clark's Trans.), "without any conscious design of his own, had become the founder of a new mode of living in common, Cœnobitism." By degrees order was introduced in the groups of huts. They were arranged in lines like the tents in an encampment, or the houses in a street. From this arrangement these lines of single cells came to be known as *Lauræ*, Λαῦραι, "streets" or "lanes."

The real founder of cœnobian monasteries in the modern sense was Pachomius, an Egyptian of the beginning of the 4th century. The first community established by him was at Tabennæ, an island of the Nile in Upper Egypt. Eight others were founded in his lifetime, numbering 3000 monks. Within 50 years from his death his societies could reckon 50,000 members. These cœnobia resembled villages, peopled by a hard-working religious community, all of one sex. The buildings were detached, small, and of the humblest character. Each cell or hut, according to Sozomen (H. E. iii. 14), contained three monks. They took their chief meal in a common refectory at 3 P.M., up to which hour they usually fasted. They ate in silence, with hoods so drawn over their faces that they could see nothing but what was on the table before them. The monks spent all the time, not devoted to religious services or study, in manual labour. Palladius, who visited the Egyptian monasteries about the close of the 4th century, found among the 300 members of the Cœnobium of Panopolis, under the Pachomian rule, 15 tailors, 7 smiths, 4 carpenters, 12 camel-drivers, and 15 tanners. Each separate community had its own *œconomus*, or steward, who was subject to a chief *œconomus* stationed at the head establishment. All the produce of the monks' labour was committed to him, and by him shipped to Alexandria. The money raised by the sale was expended in the purchase of stores for the support of the communities, and what was over was devoted to charity. Twice in the year the superiors of the several *cœnobia* met at the chief monastery, under the presidency of an Archimandrite ("the chief of the fold," from μάνδρα, a fold), and at the last meeting gave in reports of their administration for the year.

The *cœnobia* of Syria belonged to the Pachomian institution. We learn many details concerning those in the vicinity of Antioch from Chrysostom's writings. The monks lived in separate huts, κάλυβαι, forming a religious hamlet on the mountain side. They were subject to an abbot, and observed a common rule. (They had no refectory, but ate their common meal, of bread and water only, when the day's labour was over, reclining on strewn grass, sometimes out of doors.) Four times in the day they joined in prayers and psalms.

The necessity for defence from hostile attacks, economy of space, and convenience of access from one part of the community to another, by degrees dictated a more compact and orderly arrangement of the buildings of a monastic cœnobium. Large piles of building were erected, with strong outside walls, capable of resisting the assaults of an enemy, within which all the necessary edifices were ranged round one or more open courts, usually surrounded with cloisters. The usual Eastern arrangement is exemplified in the plan of the convent of Santa Laura, Mt. Athos (*Laura*, the designation of a monastery generally, being converted into a female saint).

Santa Laura, Mt. Athos.



A. Gateway.
B. Chapels.
C. Guest-house.
D. Church.
E. Cloister.
F. Fountain.
G. Refectory
H. Kitchen.
I. Cells.
K. Storehouses.
L. Postern Gate.
M. Tower.

Monastery of Santa Laura, Mount Athos (Lenoir).

This monastery, like the Oriental monasteries generally is surrounded by a strong and lofty blank stone wall, enclosing an area of between 3 and 4 acres. The longer side extends to a length of about 500 feet. There is only one main entrance, on the north side (A), defended by three separate iron doors. Near the entrance is a large tower (M), a constant feature in the monasteries of the Levant. There is a small postern gate at (L.) The *enceinte* comprises two large open courts, surrounded with buildings connected with cloister galleries of wood or stone. The outer court, which is much the larger, contains the granaries and storehouses (K), and the kitchen (H), and other offices connected with the refectory (G). Immediately adjacent to the gateway is a two-storeyed guest-house, opening from a cloister (C). The inner court is surrounded by a cloister (EE), from which open the monks' cells (II). In the centre of this court stands the catholicon or conventual church, a square building with an apse of the cruciform domical Byzantine type, approached by a domed narthex. In front of the church stands a marble fountain (F), covered by a dome supported on columns. Opening from the western side of the cloister, but actually standing in the outer court, is the refectory (G), a large cruciform building, about 100 feet each way, decorated within with frescoes of saints. At the upper end is a semicircular recess, recalling the Triclinium of the Lateran Palace at Rome, in which is placed the seat of the *Hegumenos* or abbot. This apartment is chiefly used as a hall of meeting, the Oriental monks usually taking their meals in their separate cells. St Laura is exceeded in magnitude by the Convent of Vatopede, also on Mount Athos. This enormous establishment covers at least 4 acres of ground, and contains so many separate buildings within its massive walls that it resembles a fortified town. It lodges above 300 monks, and the establishment of the Hegumenos is described as resembling the court of a petty sovereign prince. The immense refectory, of the same cruciform shape as that of St Laura, will accommodate 500 guests at its 24 marble tables.

The annexed plan of a Coptic monastery, from Lenoir shows us a church of three aisles, with cellular apses, and two ranges of cells on either side of an oblong gallery.

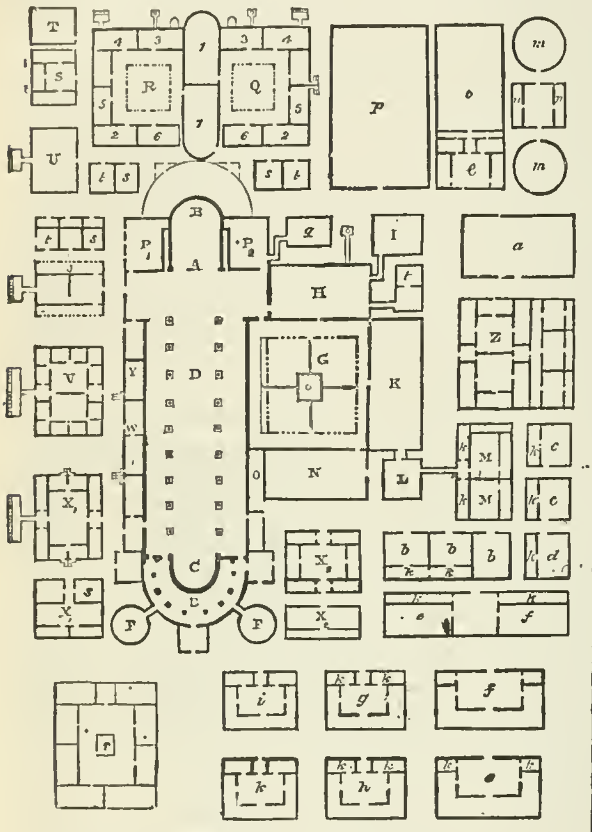
Monasticism in the West owes its extension and development to Benedict of Nursia (born A.D. 480). His rule was diffused with miraculous rapidity from the parent foundation on Monte Cassino through the whole of Western Europe, and every country witnessed the erection of monasteries far exceeding anything that had yet been seen in spaciousness and splendour. Few great towns in Italy were without their Benedictine convent, and they quickly rose in all the great centres of population in England, France, and Spain. The number of these monasteries founded between A.D. 520 and 700 is amazing. Before the Council of Constance, A.D. 1415, no fewer than 15,070 abbeys had been established of this order alone. The Benedictine rule, spreading with the vigour of a young and powerful life, absorbed into itself the older monastic foundations, whose discipline had too usually become disgracefully relaxed. In the words of Milman (*Latin Christianity*, vol. i. p. 425, note x.), "The Benedictine rule was universally received, even in the older monasteries of Gaul, Britain, Spain, and throughout the West, not as that of a rival order (all rivalry was of later date), but as a more full and perfect rule of the monastic life." Not only, therefore, were new monasteries founded, but those already existing were pulled down, and rebuilt to adapt them to the requirements of the new rule.

The buildings of a Benedictine abbey were uniformly arranged after one plan, modified where necessary (as at

Durham and Worcester, where the monasteries stand close to the steep bank of a river), to accommodate the arrangement to local circumstances.

We have no existing examples of the earlier monasteries of the Benedictine order. They have all yielded to the ravages of time and the violence of man. But we have fortunately preserved to us an elaborate plan of the great Swiss monastery of St Gall, erected about A.D. 820, which puts us in possession of the whole arrangements of a monastery of the first class towards the early part of the 9th century. This curious and interesting plan has been made the subject of a memoir both by Keller (Zurich, 1844) and by Professor Willis (*Arch. Journal*, 1848, vol. v. pp. 86–117). To the latter we are indebted for the substance of the following description, as well as for the above woodcut, reduced from his elucidated transcript of the original preserved in the archives of the convent.



Ground-plan of St Gall.

t, *t*, *t*. Baths.

The general appearance of the convent is that of a town of isolated houses with streets running between them. It is evidently planned in compliance with the Benedictine rule, which enjoined that, if possible, the monastery should contain within itself every necessary of life, as well as the buildings more intimately connected with the religious and social life of its inmates. It should comprise a mill, a bakehouse, stables and cow-houses, together with accommodation for carrying on all necessary mechanical arts within the walls, so as to obviate the necessity of the monks going outside its limits. The general distribution of the buildings may be thus described:—The church, with its cloister to the south, occupies the centre of a quadrangular area, about 430 feet square. The buildings, as in all great monasteries, are distributed into groups. The church forms the nucleus, as the centre of the religious life of the community. In closest connection with the church is the group of buildings appropriated to the monastic life and its daily requirements—the refectory for eating, the dormitory for sleeping, the common room for social intercourse, the chapter-house for religious and disciplinary conference. These essential elements of monastic life are ranged about a cloister court, surrounded by a covered arcade, affording communication sheltered from the elements, between the various buildings. The infirmary for sick monks, with the physician's house and physic garden, lies to the east. In the same group with the infirmary is the school for the novices. The outer school, with its head-master's house against the opposite wall of the church, stands outside the convent enclosure, in close proximity to the abbot's house, that he might have a constant eye over them. The buildings devoted to hospitality are divided into three groups,—one for the reception of distinguished guests, another for monks visiting the monastery, a third for poor travellers and pilgrims. The first and third are placed to the right and left of the common entrance of the monastery,—the hospitium for distinguished guests being placed on the north side of the church, not far from the abbot's house; that for the poor on the south side next to the farm buildings. The monks are lodged in a guest-house built against the north wall of the church. The group of buildings connected with the material wants of the establishment is placed to the south and west of the church, and is distinctly separated from the monastic buildings. The kitchen, buttery, and offices, are reached by a passage from the west end of the refectory, and are connected with the bakehouse and brewhouse, which are placed still further away. The whole of the southern and western sides is devoted to workshops, stables, and farm-buildings. The buildings, with some exceptions, seem to have been of one story only, and all but the church were probably erected of wood. The whole includes thirty-three separate blocks. The church (D) is cruciform, with a nave of nine bays, and a semicircular apse at either extremity. That to the west is surrounded by a semicircular colonnade, leaving an open "Paradise" (E) between it and the wall of the church. The whole area is divided by screens into various chapels. The high altar (A) stands immediately to the east of the transept, or ritual choir; the altar of St Paul (B) in the eastern, and that of St Peter (C) in the western apse. A cylindrical campanile stands detached from the church on either side of the western apse (FF).

The "cloister court" (G) on the south side of the nave of the church has on its east side the "pisalis" or "calefactory" (H), the common sitting-room of the brethren, warmed by flues beneath the floor. On this side in later monasteries we invariably find the chapter-house, the absence of which in this plan is somewhat surprising. It appears, however from the inscriptions on the plan itself, that the north walk of the cloisters served for the purposes of a chapter-house, and was fitted up with benches on the long sides. Above the calefactory is the "dormitory" opening into the south transept of the church, to enable the monks to attend the nocturnal services with readiness. A passage at the other end leads to the "necessarium" (I), a portion of the monastic buildings always planned with extreme care. The southern side is occupied by the "refectory" (K), from the west end of which by a vestibule the kitchen (L) is reached. This is separated from the main buildings of the monastery, and is connected by a long passage with a building containing the bakehouse and brewhouse (M), and the sleeping-rooms of the servants. The upper story of the refectory is the "vestiarium," where the ordinary clothes of the brethren were kept. On the western side of the cloister is another two story building (N). The cellar is below, and the larder and store-room above. Between this building and the church, opening by one door into the cloisters, and by another to the outer part of the monastery area, is the "parlour" for interviews with visitors from the external world (O). On the eastern side of the north transept is the "scriptorium" or writing-room (P_1), with the library above.

To the east of the church stands a group of buildings comprising two miniature conventual establishments, each complete in itself. Each has a covered cloister surrounded by the usual buildings, *i.e.*, refectory, dormitory, &c., and a church or chapel on one side, placed back to back. A detached building belonging to each contains a bath and a kitchen. One of these diminutive convents is appropriated to the "oblati" or novices (Q), the other to the sick monks as an "infirmary" (R).

The "residence of the physicians" (S) stands contiguous to the infirmary, and the physic garden (T) at the north-east corner of the monastery. Besides other rooms, it contains a drug store, and a chamber for those who are dangerously ill. The "house for blood-letting and purging" adjoins it on the west (U).

The "outer school," to the north of the convent area, contains a large school-room divided across the middle by a screen or partition, and surrounded by fourteen little rooms, termed the dwellings of the scholars. The head-master's house (W) is opposite, built against the side wall of the church. The two "hospitia" or "guest-houses" for the entertainment of strangers of different degrees (X_1 X_2) comprise a large common chamber or refectory in the centre, surrounded by sleeping apartments. Each is provided with its own brewhouse and bakehouse, and that for travellers of a superior order has a kitchen and store-room, with bed-rooms for their servants, and stables for their horses. There is also an "hospitium" for strange monks, abutting on the north wall of the church (Y).

Beyond the cloister, at the extreme verge of the convent area to the south, stands the "factory" (Z), containing workshops for shoemakers, saddlers (or shoemakers, *sellarii*), cutlers and grinders, trencher-makers, tanners, curriers, fullers, smiths, and goldsmiths, with their dwellings in the rear. On this side we also find the farm-buildings, the large granary and threshing-floor (*a*), mills (*c*), malthouse (*d*). Facing the west are the stables (*e*), ox-sheds (*f*), goat-stables (*g*), piggeries (*h*), sheep-folds (*i*), together with the servants' and labourers' quarters (*k*). At the south-east corner we find the hen and duck house, and poultry-yard (*m*), and the dwelling of the keeper (*n*). Hard by is the kitchen garden (*o*), the beds bearing the names of the vegetables growing in them, onions, garlic, celery, lettuces, poppy, carrots, cabbages, &c., eighteen in all. In the same way the physic garden presents the names of the medicinal herbs, and the cemetery (*p*) those of the trees, apple, pear, plum, quince, &c., planted there.

It is evident, from this most curious and valuable document, that by the 9th century monastic establishments had become wealthy, and had acquired considerable importance, and were occupying a leading place in education, agriculture, and the industrial arts. The influence such an institution would diffuse through a wide district would be no less beneficial than powerful.

The curious bird's eye view of Canterbury Cathedral and its annexed conventual buildings, taken about 1165, preserved in the Great Psalter in the library of Trinity College, Cambridge, as elucidated by Professor Willis with such admirable skill and accurate acquaintance with the existing remains,[1] exhibits the plan of a great Benedictine monastery in the 12th century, and enables us to compare it with that of the 9th, as seen at St Gall. We see in both the same general principles of arrangement, which indeed belong to all Benedictine monasteries, enabling us to determine with precision the disposition of the various buildings, when little more than fragments of the walls exist. From some local reasons, however, the cloister and monastic buildings are placed on the north, instead, as is far more commonly the case, on the south of the church. There is also a separate chapter-house, which is wanting at St Gall.

The buildings at Canterbury, as at St Gall, form separate groups. The church forms the nucleus. In immediate contact with this, on the north side, lie the cloister and the group of buildings devoted to the monastic life. Outside of these, to the west and east, are the "halls and chambers devoted to the exercise of hospitality, with which every monastery was provided, for the purpose of receiving as guests persons who visited it, whether clergy or laity, travellers, pilgrims, or paupers." To the north a large open court divides the monastic from the menial buildings, intentionally placed as remote as possible from the conventual buildings proper, the stables, granaries, barn, bakehouse, brewhouse, laundries, &c., inhabited by the lay servants of the establishment. At the greatest possible distance from the church, beyond the precinct of the convent, is the eleemosynary department. The *almonry* for the relief of the poor, with a great hall annexed, forms the pauper's hospitium.

The most important group of buildings is naturally that devoted to monastic life. This includes two cloisters, the great cloister surrounded by the buildings essentially connected with the daily life of the monks,—the church to the south, the refectory or frater-house here as always on the side opposite to the church, and furthest removed from it, that no sound or smell of eating might penetrate its sacred precincts, to the east the dormitory, raised on a vaulted undercroft, and the chapter-house adjacent, and the lodgings of the cellarer to the west. To this officer was committed the provision of the monks' daily food, as well as that of the guests. He was, therefore, appropriately lodged in the immediate vicinity of the refectory and kitchen, and close to the guest-hall. A passage under the dormitory leads eastwards to the smaller or infirmary cloister, appropriated to the sick and infirm monks. Eastward of this cloister extend the hall and chapel of the infirmary, resembling in form and arrangement the nave and chancel of an aisled church. Beneath the dormitory, looking out into the green court or herbarium, lies the "pisalis" or "calefactory," the common room of the monks. At its north-east corner access was given from the dormitory to the *necessarium*, a portentous edifice in the form of a Norman hall, 145 feet long by 25 broad, containing fifty-five seats. It was, in common with all such offices in ancient monasteries, constructed with the most careful regard to cleanliness and

[1] *The Architectural History of the Conventual Buildings of the Monastery of Christ Church in Canterbury.* By the Rev. Robert Willis. Printed for the Kent Archæological Society, 1869.

health, a stream of water running through it from end to end. A second smaller dormitory runs from east to west for the accommodation of the conventual officers, who were bound to sleep in the dormitory. Close to the refectory, but outside the cloisters, are the domestic offices connected with it; to the north, the kitchen, 47 feet square, surmounted by a lofty pyramidal roof, and the kitchen court; to the west, the butteries, pantries, &c. The infirmary had a small kitchen of its own. Opposite the refectory door in the cloister are two lavatories, an invariable adjunct to a monastic dining-hall, at which the monks washed before and after taking food.

The buildings devoted to hospitality were divided into three groups. The prior's group "entered at the south-east angle of the green court, placed near the most sacred part of the cathedral, as befitting the distinguished ecclesiastics or nobility who were assigned to him." The cellarer's buildings, were near the west end of the nave, in which ordinary visitors of the middle class were hospitably entertained. The inferior pilgrims and paupers were relegated to the north hall or almonry, just within the gate, as far as possible from the other two.

West-minster. Westminster Abbey is another example of a great Benedictine abbey, identical in its general arrangements, so far as they can be traced, with those described above. The cloister and monastic buildings lie to the south side of the church. Parallel to the nave, on the south side of the cloister, was the refectory, with its lavatory at the door. On the eastern side we find the remains of the dormitory, raised on a vaulted substructure, and communicating with the south transept. The chapter-house opens out of the same alley of the cloister. The small cloister lies to the south-east of the larger cloister, and still farther to the east we have the remains of the infirmary, with the *table hall*, the refectory of those who were able to leave their chambers. The abbot's house formed a small court-yard at the west entrance, close to the inner gateway. Considerable portions of this remain, including the abbot's parlour, celebrated as "the Jerusalem Chamber," his hall, now used for the Westminster King's scholars, and the kitchen and butteries beyond.

York St Mary's Abbey, York, of which the ground-plan is annexed, exhibits the usual Benedictine arrangements. The precincts are surrounded by a strong fortified wall on three sides, the river Ouse being sufficient protection on the fourth side. The entrance was by a strong gateway (U) to the north. Close to the entrance was a chapel, where is now the church of St Olaf (W), in which the new comers paid their devotions immediately on their arrival. Near the gate to the south was the guest's-hall or hospitium (T). The buildings are completely ruined, but enough remains to enable us to identify the grand cruciform church (A), the cloister-court with the chapter-house (B), the refectory (I), the kitchen-court with its offices (K, O, O), and the other principal apartments. The infirmary has perished completely.

Some Benedictine houses display exceptional arrangements, dependent upon local circumstances, *e.g.*, the dormitory of Worcester runs from east to west, from the west walk of the cloister, and that of Durham is built over the west, instead of as usual, over the east walk; but, as a general rule, the arrangements deduced from the examples described may be regarded as invariable.

The history of Monasticism is one of alternate periods of decay and revival. With growth in popular esteem came increase in material wealth, leading to luxury and worldliness. The first religious ardour cooled, the strictness of the rule was relaxed, until by the 10th century the decay of discipline was so complete in France that the monks are said to have been frequently unacquainted with the rule of St Benedict, and even ignorant that they were bound by any rule at all. (Robertson's *Church History*, ii. p. 538.) These alternations are reflected in the monastic buildings and the arrangements of the establishment.

The reformation of these prevalent abuses generally took the form of the establishment of new monastic orders, with new and more stringent rules, requiring a modification of the architectural arrangements. One of the earliest of these reformed orders was the *Cluniac*. This order took its name from the little village of Clugny, 12 miles N.W. of Macon, near which, about A.D. 909, a reformed Benedictine abbey was founded by William, Duke of Auvergne, under Berno, abbot of Beaume. He was succeeded by Odo, who is often regarded as the founder of the order. The fame of Clugny spread far and wide. Its rigid rule was adopted by a vast number of the old Benedictine abbeys, who placed themselves in affiliation to the mother society, while new foundations sprang up in large numbers, all owing allegiance to the "archabbot," established at Clugny. By the end of the 12th century the number of monasteries affiliated to Clugny in the various countries of Western Europe amounted to 2000. The monastic establishment of Clugny was one of the most extensive and magnificent in France. We may form some idea of its enormous dimensions from the fact recorded, that when, A.D. 1245, Pope Innocent IV., accompanied by twelve cardinals, a patriarch, three archbishops, the two generals of the Carthusians and Cistercians, the king (St Louis), and three of his sons, the queen mother, Baldwin, Count of Flanders and Emperor of Constantinople, the Duke of Burgundy, and six lords, visited the abbey, the whole party, with their attendants, were lodged within the monastery without disarranging the monks, 400 in number. Nearly the whole of the abbey buildings, including the magnificent church, were swept away at the close of the last century. When the annexed ground-plan was taken, shortly before its destruction, nearly all the monastery, with the exception of the church, had been rebuilt. The church, the ground-plan of which bears a remarkable resemblance to that of Lincoln Cathedral, was of vast dimensions. It was 656 feet by 130 feet wide. The nave was 102 feet, and the aisles 60 feet high. The nave (G) had double

vaulted aisles on either side. Like Lincoln, it had an eastern as well as a western transept, each furnished with apsidal chapels to the east. The western transept was 213 feet long, and the eastern 123 feet. The choir terminated in a semicircular apse (F), surrounded by five chapels, also semicircular. The western entrance was approached by an ante-church, or *narthex* (B), itself an aisled church of no mean dimensions, flanked by two towers, rising from a stately flight of steps bearing a large stone cross. To the south of the church lay the cloister-court (H), of immense size, placed much further to the west than is usually the case. On the south side of the cloister stood the refectory (P), an immense building, 100 feet long and 60 feet wide, accommodating six longitudinal and three transverse rows of tables. It was adorned with the portraits of the chief benefactors of the abbey, and with Scriptural subjects. The end wall displayed the Last Judgment. We are unhappily unable to identify any other of the principal buildings (N). The abbot's residence (K), still partly standing, adjoined the entrance-gate. The guest-house (L) was close by. The bakehouse (M), also remaining, is a detached building of immense size. The first English house of the Cluniac order was that of Lewes, founded by the Earl of Warren, *cir.* A.D. 1077. Of this only a few fragments of the domestic buildings exist. The best preserved Cluniac houses in England are Castle Acre, Norfolk, and Wenlock, in Shropshire. Ground-plans of both are given in Britton's *Architectural Antiquities*. They show several departures from the Benedictine arrangement. In each the prior's house is remarkably perfect. All Cluniac houses in England were French colonies, governed by priors of that nation. They did not secure their independence nor become "abbeys" till the reign of Henry VI. The Cluniac revival, with all its brilliancy, was but short lived. The celebrity of this, as of other orders, worked its moral ruin. With their growth in wealth and dignity the Cluniac foundations became as worldly in life and as relaxed in discipline as their predecessors, and a fresh reform was needed. The next great monastic revival, the Cistercian, arising in the last years of the 11th century, had a wider diffusion, and a longer and more honourable existence. Owing its real origin, as a distinct foundation of reformed Benedictines, in the year 1098, to a countryman of our own, Stephen Harding (a native of Dorsetshire, educated in the monastery of Sherborne), and deriving its name from Citeaux (*Cistercium*), a desolate and almost inaccessible forest solitude, on the borders of Champagne and Burgundy, the rapid growth and wide celebrity of the order is undoubtedly to be attributed to the enthusiastic piety of St Bernard, abbot of the first of the monastic colonies, subsequently sent forth in such quick succession by the first Cistercian houses, the far-famed abbey of Clairvaux (de Clara Valle), A.D. 1116.

The rigid self-abnegation, which was the ruling principle of this reformed congregation of the Benedictine order, extended itself to the churches and other buildings erected by them. The characteristic of the Cistercian abbeys was the extremest simplicity and a studied plainness. Only one tower—a central one—was permitted, and that was to be very low. Unnecessary pinnacles and turrets were prohibited. The triforium was omitted. The windows were to be plain and undivided, and it was forbidden to decorate them with stained glass. All needless ornament was proscribed. The crosses must be of wood; the candlesticks of iron. The renunciation of the world was to be evidenced in all that met the eye. The same spirit manifested itself in the choice of the sites of their monasteries. The more dismal the more savage, the more hopeless a spot appeared, the more did it please their rigid mood. But they came not merely as ascetics, but as improvers. The Cistercian monasteries are, as a rule, found placed in deep well-watered valleys. They always stand on the border of a stream; not rarely, as at Fountains, the buildings extend over it. These valleys, now so rich and productive, wore a very different aspect when the brethren first chose them as the place of their retirement. Wide swamps, deep morasses, tangled thickets, wild impassable forests, were their prevailing features. The "Bright Valley," *Clara Vallis* of St Bernard, was known as the "Valley of Wormwood," infamous as a den of robbers. "It was a savage dreary solitude, so utterly barren that at first Bernard and his companions were reduced to live on beech leaves."—(Milman's *Lat. Christ.* vol. iii. p. 335.)

Cistercian.

All Cistercian monasteries, unless the circumstances of the locality forbade it, were arranged according to one plan. The general arrangement and distribution of the various buildings, which went to make up one of these vast establishments, may be gathered from that of St Bernard's own Abbey of Clairvaux, which is here given.

It will be observed that the abbey precincts are surrounded by a strong wall, furnished at intervals with watch-

Clairvaux. towers and other defensive works. The wall is nearly encircled by a stream of water, artificially diverted from the small rivulets which flow through the precincts, furnishing the establishment with an abundant supply in every part, for the irrigation of the gardens and orchards, the sanitary requirements of the brotherhood, and for the use of the offices and workshops. The precincts are divided across the centre by a wall, running from N. to S., into an outer and inner ward,—the former containing the menial, the latter the monastic buildings. The precincts are entered by a gateway (P), at the extreme western extremity, giving admission to the lower ward. Here the barns, granaries, stables, shambles, workshops, and workmen's lodgings were placed, without any regard to symmetry, convenience being the only consideration. Advancing eastwards, we have before us the wall separating the outer and inner ward, and the gatehouse (D) affording communication between the two. On passing through the gateway, the outer court of the inner ward was entered, with the western *façade* of the monastic church in front. Immediately on the right of entrance was the abbot's house (G), in close proximity to the guest-house (F). On the other side of the court were the stables, for the accommodation of the horses of the guests and their attendants (H). The church occupied a central position. To the south were the great cloister (A), surrounded by the chief monastic buildings, and further to the east the smaller cloister, opening out of which were the infirmary, novices' lodgings, and quarters for the aged monks. Still further to the east, divided from the monastic buildings by a wall, were the vegetable gardens and orchards, and tank for fish. The

large fish-ponds, an indispensable adjunct to any ecclesiastical foundation, on the formation of which the monks lavished extreme care and pains, and which often remain as almost the only visible traces of these vast establishments, were placed outside the abbey walls.

The Plan No. 2 furnishes the ichnography of the distinctly monastic buildings on a larger scale. The usually unvarying arrangement of the Cistercian houses allows us to accept this as a type of the monasteries of this order. The church (A) is the chief feature. It consists of a vast nave of eleven bays, entered by a narthex, with a transept and short apsidal choir. (It may be remarked that the eastern limb in all unaltered Cistercian churches is remarkably short, and usually square.) To the east of each limb of

the transept are two square chapels, divided according to Cistercian rule by solid walls. Nine radiating chapels, similarly divided, surround the apse. The stalls of the monks, forming the ritual choir, occupy the four eastern bays of the nave. There was a second range of stalls in the extreme western bays of the nave for the *fratres conversi*, or lay brothers. To the south of the church, so as to secure as much sun as possible, the cloister was invariably placed, except when local reasons forbade it. Round the cloister (B) were ranged the buildings connected with the monks' daily life. The chapter-house (C) always opened out of the east walk of the cloister in a line with the south transept. In Cistercian houses this was quadrangular, and was divided by pillars and arches into two or three aisles. Between it and the transept we find the sacristy (X), and a small book room (Y), *armariolum*, where the brothers deposited the volumes borrowed from the library. On the other side of the chapter-house, to the south, is a passage (D) communicating with the courts and buildings beyond. This was sometimes known as the *parlour*, *colloquii locus*, the monks having the privilege of conversation here. Here also, when discipline became relaxed, traders, who had the liberty of admission, were allowed to display their goods. Beyond this we often find the *calefactorium* or *day-room*—an apartment warmed by flues beneath the pavement, where the brethren, half-frozen during the night offices, betook themselves after the conclusion of lauds, to gain a little warmth, grease their sandals, and get themselves ready for the work of the day. In the plan before us this apartment (E) opens from the south cloister walk, adjoining the refectory. The place usually assigned to it is occupied by the vaulted substructure of the *dormitory* (Z). The *dormitory*, as a rule, was placed on the east side of the cloister, running over the *calefactory* and *chapter-house*, and joined the south transept, where a flight of steps admitted the brethren into the church for nocturnal services. Opening out of the dormitory was always the *necessarium*, planned with the greatest regard to health and cleanliness, a water-course invariably running from end to end. The refectory opens out of the south cloister at (G). The position of the refectory is usually a marked point of difference between Benedictine and Cistercian abbeys. In the former, as at Canterbury, the refectory ran east and west parallel to the nave of the church, on the side of the cloister furthest removed from it. In the Cistercian monasteries, to keep the noise and sound of dinner still further away from the sacred building, the refectory was built north and south, at right angles to the axis of the church. It was often divided, sometimes into two, sometimes, as here, into three aisles. Outside the refectory door, in the cloister, was the *lavatory*, where the monks washed their hands at dinner time. The buildings belonging to the material life of the monks lay near the refectory, as far as possible from the church, to the S.W. With a distinct entrance from the outer court was the kitchen court (F), with its buttery, scullery, and larder, and the important adjunct of a stream of running water. Further to the west, projecting beyond the line of the west front of the church, were vast vaulted apartments (SS), serving as cellars and storehouses, above which was the dormitory of the *conversi*. Detached from these, and separated entirely from the monastic buildings, were various workshops, which convenience required to be banished to the outer precincts, a saw-mill and oil-mill (UU) turned by water, and a currier's shop (V), where the sandals and leathern girdles of the monks were made and repaired.

Returning to the cloister, a vaulted passage admitted to the small cloister (I), opening from the north side of which were eight small cells, assigned to the scribes employed in copying works for the library, which was placed in the upper story, accessible by a turret staircase. To the south of the small cloister a long hall will be noticed. This was a *lecture-hall*, or rather a hall for the religious disputations customary among the Cistercians. From this cloister opened the *infirmary* (K), with its hall, chapel, cells, blood-letting house, and other dependencies. At the eastern verge of the vast group of buildings we find the *novices' lodgings* (L), with a third cloister near the novices' quarters and the original guest-house (M). Detached from the great mass of the monastic edifices was the original abbot's house (N), with its dining-hall (P). Closely adjoining to this, so that the eye of the father of the whole establishment should be constantly over those who stood the most in need of his watchful care,—those who were training for the monastic life, and those who had worn themselves out in its duties,—was a fourth cloister (O), with annexed buildings, devoted to the aged and infirm members of the establishment. The cemetery, the last resting-place of the brethren, lay to the north side of the nave of the church (H).

It will be seen that the arrangement of a Cistercian monastery was in accordance with a clearly-defined system, and admirably adapted to its purpose.

The base court nearest to the outer wall contained the buildings belonging to the functions of the body as agriculturalists and employers of labour. Advancing into the inner court, the buildings devoted to hospitality are found close to the entrance; while those connected with the supply of the material wants of the brethren,—the kitchen, cellars, &c.,—form a court of themselves outside the cloister, and quite detached from the church. The church refectory, dormitory, and other buildings belonging to the professional life of the brethren, surround the great cloister. The small cloister beyond, with its scribes' cells, library, hall for disputations, &c., is the centre of the literary life of the community. The requirements of sickness and old age are carefully provided for in the infirmary cloister, and that for the aged and infirm members of the establishment. The same group contains the quarters of the novices.

This stereotyped arrangement is further illustrated by the accompanying bird's eye view of the mother establish- Citeaux.

ment of Citeaux. A cross (A), planted on the high road directs travellers to the gate of the monastery, reached by an avenue of trees. On one side of the gate-house (B) is a long building (C), probably the almonry, with a dormitory above for the lower class of guests. On the other side is a chapel (D). As soon as the porter heard a stranger knock at the gate, he rose, saying, *Deo gratias*, the opportunity for the exercise of hospitality being regarded as a cause for thankfulness. On opening the door he welcomed the new arrival with a blessing—*Benedicite*. He fell on his knees before him, and then went to inform the abbot. However important the abbot's occupations might be, he at once hastened to receive him whom heaven had sent. He also threw himself at his guest's feet, and conducted him to the chapel (D) purposely built close to the gate. After a short prayer, the abbot committed the guest to the care of the brother hospitaller, whose duty it was to provide for his wants, and conduct the beast on which he might be riding to the stable (F), built adjacent to the inner gate-house (E). This inner gate conducted into the base court (T), round which were placed the barns, stables, cow-sheds, &c. On the eastern side stood the dormitory of the lay brothers, *fratres conversi* (G), detached from the cloister, with cellars and storehouses below. At (H), also outside the monastic buildings proper, was the abbot's house, and annexed to it the guest-house. For these buildings there was a separate door of entrance into the church (S). The large cloister, with its surrounding arcades, is seen at V. On the south end projects the refectory (K), with its kitchen at (I), accessible from the base court. The long gabled building on the east side of the cloister contained on the ground floor the chapter-house and calefactory, with the monks' dormitory above (M), communicating with the south transept of the church. At (L) was the staircase to the dormitory. The small cloister is at (W), where were the *carols* or cells of the scribes, with the library (P) over, reached by a turret staircase. At (R) we see a portion of the infirmary. The whole precinct is surrounded by a strong buttressed wall (XXX), pierced with arches, through which streams of water are introduced. It will be noticed that the choir of the church is short, and has a square end instead of the usual apse. The tower, in accordance with the Cistercian rule, is very low. The windows throughout accord with the studied simplicity of the order.

The English Cistercian houses, of which there are such extensive and beautiful remains at Fountains, Rievaulx, Kirkstall, Tintern, Netley, &c., were mainly arranged after the same plan, with slight local variations. As an example, we give the ground-plan of Kirkstall Abbey, which is one of the best preserved and least altered. The church here is of the Cistercian type, with a short chancel of two squares, and transepts with three eastward chapels to each, divided by solid walls (2 2 2). The whole is of the most studied plainness. The windows are unornamented, and the nave has no triforium. The cloister to the south (4) occupies the whole length of the nave. On the east side stands the two-aisled chapter house (5), between which and the south transept is a small sacristy (3), and on the other side two small apartments, one of which was probably the parlour (6). Beyond this stretches southward the calefactory or day-room of the monks (14). Above this whole range of building runs the monks' dormitory, opening by stairs into the south transept of the church. At the other end were the necessaries. On the south side of the cloister we have the remains of the old refectory (11), running, as in Benedictine houses, from east to west, and the new refectory (12), which, with the increase of the inmates of the house, superseded it, stretching, as is usual in Cistercian houses, from north to south. Adjacent to this apartment are the remains of the kitchen, pantry, and buttery. The arches of the lavatory are to be seen near the refectory entrance. The western side of the cloister is, as usual, occupied by vaulted cellars, supporting on the upper story the dormitory of the lay brothers (8). Extending from the south-east angle of the main group of buildings are the walls and foundations of a secondary group of considerable extent. These have been identified either with the hospitium or with the abbot's house, but they occupy the position in which the infirmary is more usually found. The hall was a very spacious apartment, measuring 83 feet in length by 48 feet 9 inches in breadth

and was divided by two rows of columns. The fish-ponds lay between the monastery and the river to the south. The abbey mill was situated about 80 yards to the north-west. The mill-pool may be distinctly traced, together with the gowt or mill stream.

Fountains Abbey, first founded A.D. 1132, deserves special notice, as one of the largest and best preserved Cistercian houses in England. But the earlier buildings received considerable additions and alterations in the later period of the order, causing deviations from the strict Cistercian type. The church stands a short distance to the north of the river Skell, the buildings of the abbey stretching down to and even across the stream. We have the cloister (H) to the south, with the three-aisled chapter house (I) and calefactory (L) opening from its eastern walk, and the refectory (S), with the kitchen (Q) and buttery (T) attached, at right angles to its southern walk. Parallel with the western walk is an immense vaulted substructure (U), incorrectly styled the cloisters, serving as cellars and store-rooms, and supporting the dormitory of the *conversi* above. This building extended across the river. At its

S.W. corner were the necessaries (V), also built, as usual, above the swiftly flowing stream. The monks' dormitory was in its usual position above the chapter-house, to the south of the transept. As peculiarities of arrangement may be noticed the position of the kitchen (Q), between the refectory and calefactory, and of the infirmary (W) (unless there is some error in its designation) above the river to

the west, adjoining the guest-houses (XX). We may also call attention to the greatly lengthened choir, commenced by Abbot John of York, 1203–1211, and carried on by his successor, terminating, like Durham Cathedral, in an eastern transept, the work of Abbot John of Kent, 1220–1247, and to the tower (D), added not long before the dissolution by Abbot Huby, 1494–1526, in a very unusual position at the northern end of the north transept. The abbot's house, the largest and most remarkable example of this class of buildings in the kingdom, stands south to the east of the church and cloister, from which it is divided by the kitchen court (K), surrounded by the ordinary domestic offices. A considerable portion of this house was erected on arches over the Skell. The size and character of this house, probably, at the time of its erection, the most spacious house of a subject in the kingdom, not a castle, bespeaks the wide departure of the Cistercian order from the stern simplicity of the original foundation. The hall (2) was one of the most spacious and magnificent apartments in mediæval times, measuring 170 feet by 70 feet. Like the hall in the castle at Winchester, and Westminster Hall, as originally built, it was divided by 18 pillars and arches, with 3 aisles. Among other apartments, for the designation of which we must refer to the ground-plan, was a domestic oratory or chapel, 46½ feet by 23 feet, and a kitchen (7), 50 feet by 38 feet. The whole arrangements and character of the building bespeak the rich and powerful feudal lord, not the humble father of a body of hard-working brethren, bound by vows to a life of poverty and self-denying toil. In the words of Dean Milman, "the superior, once a man bowed to the earth with humility, care-worn, pale, emaciated, with a coarse habit bound with a cord, with naked feet, had become an abbot on his curvetting palfrey, in rich attire, with his silver cross before him, travelling to take his place amid the lordliest of the realm."—(*Lat. Christ.*, vol. iii. p. 330.)

The buildings of the *Austin Canons* or *Black Canons* (so called from the colour of their habit) present few distinctive peculiarities. Black or Austin Canons. This order had its first seat in England at Colchester, where a house for Austin Canons was founded about A.D. 1105, and it very soon spread widely. As an order of regular clergy, holding a middle position between monks and secular canons, almost resembling a community of parish priests living under rule, they adopted naves of great length to accommodate large congregations. The choir is usually long, and is sometimes, as at Llanthony and Christ Church (Twynham), shut off from the aisles, or, as at Bolton, Kirkham, &c., is destitute of aisles altogether. The nave in the northern houses, not unfrequently, had only a north aisle, as at Bolton, Brinkburn, and Lanercost. The arrangement of the monastic buildings followed the ordinary type. The prior's lodge was almost invariably attached to the S.W. angle of the nave. The annexed plan of the Abbey of St Augustine's at Bristol, now the cathedral church of

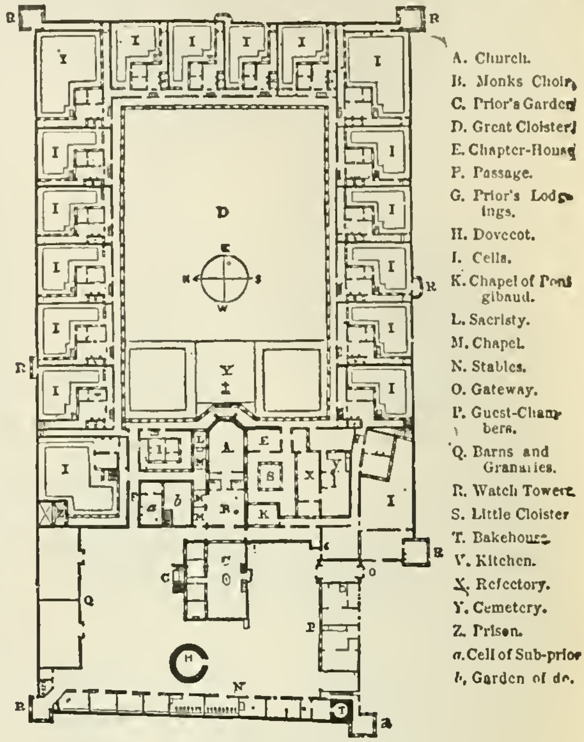
that city, shows the arrangement of the buildings, which departs very little from the ordinary Benedictine type. The Austin Canons' house at Thornton, in Lincolnshire, is remarkable for the size and magnificence of its gate-house, the upper floors of which formed the guest-house of the establishment, and for possessing an octagonal chapter-house of Decorated date.

The *Premonstratensian* regular canons, or White Canons, had as many as 35 houses in England, of which the most perfect remaining are those of Easby, Yorkshire, and Bayham, Sussex. The head house of the order in England was Welbeck. This order was a reformed branch of the Austin canons, founded, A.D. 1119, by Norbert (born at Xanten, on the Lower Rhine, c. 1080) at Prémontré, a secluded marshy valley in the forest of Coucy, in the diocese of Laon. The order spread widely. Even in the founder's lifetime it possessed houses in Syria and Palestine. It long maintained its rigid austerity, till in the course of years wealth impaired its discipline, and its members sank into indolence and luxury. The Premonstratensians were brought to England shortly after A.D. 1140, and were first settled at Newhouse, in Lincolnshire, near the Humber. The ground-plan of Easby Abbey, owing to its situation on the edge of the steeply-sloping banks of a river, is singularly irregular. The cloister is duly placed on the south side of the church, and the chief buildings occupy their usual positions round it. But the cloister garth, as at Chichester, is not rectangular, and all the surrounding buildings are thus made to sprawl in a very awkward fashion. The church follows the plan adopted by the Austin canons in their northern abbeys, and has only one aisle to the nave—that to the north; while the choir is long, narrow, and aisleless. Each transept has an aisle to the east, forming three chapels.

The church at Bayham was destitute of aisle either to nave or choir. The latter terminated in a three-sided apse. This church is remarkable for its exceeding narrowness in proportion to its length. Extending in longitudinal dimensions 257 feet, it is not more than 25 feet broad. To adopt the words of Mr Beresford Hope—"Stern Premonstratensian canons wanted no congregations, and cared for no processions; therefore they built their church like a long room."

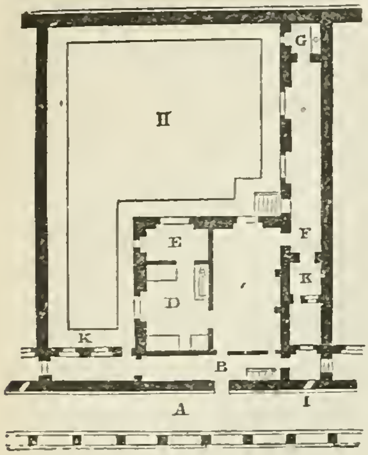
The *Carthusian* order, on its establishment by St Bruno, about A.D. 1084, developed a greatly modified form and arrangement of a monastic institution. The principle of this order, which combined the cœnobitic with the solitary life, demanded the erection of buildings on a novel plan. This plan, which was first adopted by St Bruno and his twelve companions at the original institution at Chartreux, near Grenoble, was maintained in all the Carthusian establishments throughout Europe, even after the ascetic severity of the order had been to some extent relaxed, and the primitive simplicity of their buildings had been exchanged for the magnificence of decoration which characterises such foundations as the *Certosas* of Pavia and Florence. According to the rule of St Bruno, all the members of a Carthusian brotherhood lived in the most absolute solitude and silence. Each occupied a small detached cottage, standing by itself in a small garden surrounded by high walls and connected by a common corridor or cloister. In these cottages or cells a Carthusian monk passed his time in the strictest asceticism, only leaving his solitary dwelling to attend the services of the Church, except on certain days when the brotherhood assembled in the refectory.

The peculiarity of the arrangements of a Carthusian monastery, or *charter-house*, as it was called in England, from a corruption of the French *chartreux*, is exhibited in the plan of that of Clermont, from Viollet le Duc. The whole establishment is surrounded with a wall, furnished at intervals with watch towers (R). The enclosure is divided into two courts, of which the eastern court, surrounded by a cloister, from which the cottages of the monks (I) open, is much the larger. The two courts are



Carthusian Monastery of Clermont.

divided by the main buildings of the monastery, including the church, the sanctuary (A), divided from (B), the monks' choir, by a screen with two altars, the smaller cloister to the south (S) surrounded by the chapter-house (E), the refectory (X)—these buildings occupying their normal position—and the chapel of Pontgibaud (K). The kitchen with its offices (V) lies behind the refectory, accessible from the outer court without entering the cloister. To the north of the church, beyond the sacristy (L), and the side chapels (M), we find the cell of the sub-prior (*a*), with its garden. The lodgings of the prior (G) occupy the centre of the outer court, immediately in front of the west door of the church, and face the gateway of the convent (O). A small raised court with a fountain (C) is before it. This outer court also contains the guest-chambers (P), the stables, and lodgings of the lay brothers (N), the barns and granaries (Q), the dovecot (H), and the bakehouse (T). At (Z) is the prison. (In this outer court, in all the earlier foundations, as at Witham, there was a smaller church in addition to the larger church of the monks.) The outer and inner court are connected by a long passage (F), wide enough to admit a cart laden with wood to supply the cells of the brethren with fuel. The number of cells surrounding the great cloister is 18. They are all arranged on a uniform plan. Each little dwelling contains three rooms: a sitting-room (C), warmed with a stove in winter; a sleeping-room (D), furnished with a bed, a table, a bench, and a bookcase; and a closet (E). Between the cell and the cloister gallery (A) is a passage or corridor (B), cutting off the inmate of the cell from all sound or movement which might interrupt his meditations. The superior had free access to this corridor, and through open niches was able to inspect the garden without being seen. At (I) is the hatch or turn-table, in which the daily allowance of food was deposited by a brother appointed for that purpose, affording no view either inwards or outwards. (H) is the garden,



Carthusian Cell, Clermont.

cultivated by the occupant of the cell. At (K) is the wood-house. (F) is a covered walk, with the necessary at the end. These arrangements are found with scarcely any variation in all the charter-houses of Western Europe. The Yorkshire Charter-house of Mount Grace, founded by Thomas Holland the young Duke of Surrey, nephew of Richard II., and Marshal of England, during the revival of the popularity of the order, about A.D. 1397, is the most perfect and best preserved English example. It is characterised by all the simplicity of the order. The church is a modest building, long, narrow, and aisleless. Within the wall of enclosure are two courts. The smaller of the two, the south, presents the usual arrangement of church, refectory, &c., opening out of a cloister. The buildings are plain and solid. The northern court contains the cells, 14 in number. It is surrounded by a double stone wall, the two walls being about 30 feet or 40 feet apart. Between these, each in its own garden, stand the cells; low-built two-storied cottages, of two or three rooms on the ground-floor, lighted with a larger and a smaller window to the side, and provided with a doorway to the court, and one at the back, opposite to one in the outer wall, through which the monk may have conveyed the sweepings of his cell and the refuse of his garden to the "eremus" beyond. By the side of the door to the court is a little hatch, through which the daily pittance of food was supplied, so contrived by turning at an angle in the wall that no one could either look in or look out. A very perfect example of this hatch—an arrangement belonging to all Carthusian houses—exists at Miraflores, near Burgos, which remains nearly as it was completed in 1480.

There were only nine Carthusian houses in England. The earliest was that at Witham in Somersetshire, founded by Henry II., by whom the order was first brought into England. The wealthiest and most magnificent was that of Shene or Richmond in Surrey, founded by Henry V. about A.D. 1414. The dimensions of the buildings at Shene are stated to have been remarkably large. The great court measured 300 feet by 250 feet; the cloisters were a square of 500 feet; the hall was 110 feet in length by 60 feet in breadth. The most celebrated historically is the Charter-house of London, founded by Sir Walter Manny A.D. 1371, the name of which is preserved by the famous public school established on the site by Thomas Sutton A.D. 1611.

An article on monastic arrangements would be incomplete without some account of the convents of the Mendicant or Preaching Friars, including the Black Friars or Dominicans, the Grey or Franciscans, the White or Carmelites, the Eremite or Austin Friars. These orders arose at the beginning of the 13th century, when the Benedictines, together with their various reformed branches, had terminated their active mission, and Christian Europe was ready for a new religious revival. Planting themselves, as a rule, in large towns, and by preference in the poorest and most densely populated districts, the Preaching Friars were obliged to adapt their buildings to the requirements of the site. Regularity of arrangement, therefore, was not possible, even if they had studied it. Their churches, built for the reception of large congregations of hearers rather than worshippers, form a class by themselves, totally unlike those of the elder orders in ground-plan and character. They were usually long parallelograms unbroken by transepts. The nave very usually consisted of two equal bodies, one containing the stalls of the brotherhood, the other left entirely free for the congregation. The constructional choir is often wanting, the whole church forming one uninterrupted structure, with a continuous range of windows. The east end was usually square, but the Friars Church at Winchelsea had a polygonal apse. We not unfrequently find a single transept, sometimes of great size, rivalling or exceeding the nave. This arrangement is frequent in Ireland, where the numerous small friaries afford admirable exemplifications of these peculiarities of ground-plan. The friars' churches were at first destitute of towers; but in the 14th and 15th centuries, tall, slender towers were commonly inserted between the nave and the choir. The Grey Friars at Lynn, where the tower is hexagonal, is a good example. The arrangement of the monastic buildings is equally peculiar and characteristic. We miss entirely the regularity of the buildings of the earlier orders. At the Jacobins at Paris, a cloister lay to the north of the long narrow church of two parallel aisles, while the refectory—a room of immense length, quite detached from the cloister—stretched across the area before the west front of the church. At Toulouse the nave also has two parallel aisles, but the choir is apsidal, with radiating chapels. The refectory stretches northwards at right angles to the cloister, which lies to the north of the church, having the chapter-house and sacristy on the east. As examples of English friaries the Dominican house at Norwich, and those of the Dominicans and Franciscans at Gloucester, may be mentioned. The Norwich. Gloucester church of the Black Friars of Norwich departs from the original type in the nave (now St Andrew's Hall), in having regular aisles. In this it resembles the earlier examples of the Grey Friars at Reading. The choir is long and aisleless; an hexagonal tower between the two, like that existing at Lynn, has perished. The cloister and monastic buildings remain tolerably perfect to the north. The Dominican convent at Gloucester still exhibits the cloister-court, on the north side of which is the desecrated church. The refectory is on the west side, and on the south the dormitory of the 13th century. This is a remarkably good example. There were 18 cells or cubicles on each side, divided by partitions, the bases of which remain. On the east side was the prior's house, a building of later date. At the Grey or Franciscan Friars. the church followed the ordinary type in having two equal bodies, each gabled, with a continuous range of windows. There was a slender tower between the nave and choir. Of the convents of the Carmelite or White Friars we have a good example in the Abbey of Hulme, near Alnwick, the first of the order in England, founded A.D. 1240. The church is a narrow oblong, destitute of aisles, 123 feet long by only 26 feet wide. The cloisters are to the south, with the chapter-house, &c., to the east, with the dormitory over. The prior's lodge is placed to the west of the cloister. The guest-houses adjoin the entrance gateway, to which a chapel was annexed on the south side of the conventual area. The nave of the church of the Austin Friars or Eremites in London is still standing. It is of Decorated date, and has wide centre and side aisles, divided by a very light and graceful arcade. Some fragments of the south walk of the cloister of the Grey Friars exist among the buildings of Christ's Hospital or the Blue-Coat School. Of the Black Friars all has perished but the name. Taken as a whole, the remains of the establishments of the friars afford little warrant for the bitter invective of the Benedictine of St Alban's, Matthew Paris:—"The friars who have been founded hardly 40 years have built residences as the palaces of kings These are they who, enlarging day by day their sumptuous edifices, encircling them with lofty walls, lay up in them their incalculable treasures, imprudently transgressing the bounds of poverty, and violating the very fundamental rules of their profession." Allowance must here be made for jealousy of a rival order just rising in popularity.

Every large monastery had depending upon it one or more smaller establishments known as *cells*. These cells were monastic colonies, sent forth by the parent house, and planted on some outlying estate. As an example, we may refer to the small religious house of St Mary Magdalene's, a cell of the great Benedictine house of St Mary's, York, in the valley of the Witham, to the south-east of the city of Lincoln. This consists of one long narrow range of building, of which the eastern part formed the chapel, and the western contained the apartments of the handful of monks of which it was the home. To the east may be traced the site of the abbey mill, with its dam and mill-lead. These cells, when belonging to a Cluniac house, were called *Obedientiæ*.

The plan given by Viollet le Duc of the Priory of *St Jean des Bons Hommes*, a Cluniac cell, situated between the town of Avallon and the village of Savigny, shows that these diminutive establishments comprised every essential feature of a monastery,—chapel, cloister, chapter-room, refectory, dormitory, all grouped according to the recognised arrangement.

These Cluniac *obedientiæ* differed from the ordinary Benedictine cells in being also places of punishment, to which monks who had been guilty of any grave infringement of the rules were relegated as to a kind of penitentiary. Here they were placed under the authority of a prior, and were condemned to severe manual labour, fulfilling the duties usually executed by the lay brothers, who acted as farm-servants.

The outlying farming establishments belonging to the monastic foundations were known as *villæ* or *granges*. They gave employment to a body of *conversi* and labourers under the management of a monk, who bore the title of *Brother Hospitaller*—the granges, like their parent institutions, affording shelter and hospitality to belated travellers.

V.)

ABBIATE GRASSO, a town in the north of Italy, near the Ticino, 14 miles W.S.W. of Milan. It has silk manufactures, and contains about 5000 inhabitants.

ABBON OF FLEURY, OR ABBO FLORIACENSIS, a learned Frenchman, born near Orleans in 945. He distinguished himself in the schools of Paris and Rheims, and was a proficient in science, as known in his time. After spending two years in England, assisting Archbishop Oswald of York in restoring the monastic system, he returned to France, and was made Abbot of Fleury (970). He was twice sent to Rome by Robert the Wise (986, 996), and on each occasion succeeded in warding off a threatened papal interdict. He was killed in 1004, in endeavouring to quell a monkish revolt. He wrote an epitome of the *Lives of the Roman Pontiffs*, besides controversial treatises, letters, &c.

ABBOT, the head and chief governor of a community of monks, called also in the East *Archimandrita*, from *mandra*, "a fold," or *Hegumenos*. The name *abbot* is derived from the Hebrew אב, *Ab*, or *father*, through the Syriac *Abba*. It had its origin in the monasteries of Syria, whence it spread through the East, and soon became accepted generally in all languages as the designation of the head of a monastery. At first it was employed as a respectful title for any monk, as we learn from St Jerome (in Epist. ad Gal. iv. 6, in Matt. xxiii. 9), but it was soon restricted to the Superior.

The name abbot, though general in the West, was not universal. Among the Dominicians, Carmelites, Augustines, &c., the superior was called *Præpositus*, "Provost," and *Prior;* among the Franciscans, *Custos*, "Guardian;" and by the monks of Camaldoli, *Major*.

Monks, as a rule, were laymen, nor at the outset was the abbot any exception. All orders of clergy, therefore, even the "doorkeeper," took precedence of him. For the reception of the sacraments, and for other religious offices, the abbot and his monks were commanded to attend the nearest church.—(*Novellæ*, 133, c. ii.) This rule naturally proved inconvenient when a monastery was situated in a desert, or at a distance from a city, and necessity compelled the ordination of abbots. This innovation was not introduced without a struggle, ecclesiastical dignity being regarded as inconsistent with the higher spiritual life, but, before the close of the 5th century, at least in the East, abbots seem almost universally to have become deacons, if not presbyters. The change spread more slowly in the West, where the office of abbot was commonly filled by laymen till the end of the 7th century, and partially so up to the 11th. Ecclesiastical Councils were, however, attended by abbots. Thus, at that held at Constantinople, A.D. 448, for the condemnation of Eutyches, 23 archimandrites or abbots sign, with 30 bishops, and, *cir.* A.D. 690, Archbishop Theodore promulgated a canon, inhibiting bishops from compelling abbots to attend councils. Examples are not uncommon in Spain and in England in Saxon times. Abbots were permitted by the Second Council of Nicæa, A.D. 787, to ordain their monks to the inferior orders. This rule was adopted in the West, and the strong prejudice against clerical monks having gradually broken down, eventually monks, almost without exception, belonged to some grade of the ministry.

Originally no abbot was permitted to rule over more than one monastic community, though, in some exceptional cases, Gregory the Great allowed the rule to be broken. As time went on, violations of the rule became increasingly frequent, as is proved by repeated enactments against it. The cases of Wilfrid of York, *cir.* A.D. 675, who held the abbacy of the monasteries he had founded at Hexham and Ripon, and of Aldhelm, who, at the same date, stood in the same double relation to those of Malmesbury, Frome, and Bradford, are only apparent transgressions of the rule. We find more decided instances of plurality in Hugh of the royal Carlovingian house, *cir.* 720, who was at the same time Bishop of Rouen, Paris, Bayeux, and Abbot of Fontenelle and Jumièges; and Sidonius, Bishop of Constance, who, being already Abbot of Reichenau, took the abbacy of St Gall also. Hatto of Mentz, *cir.* 912, annexed to his see no less than 12 abbacies.

In Egypt, the first home of monasticism, we find *abbots in chief* or *archimandrites* exercising jurisdiction over a large number of communities, each of which had its own abbot. Thus, Cassian speaks of an abbot in the Thebaid who had 500 monks under him, a number exceeded in other cases. In later times also, general jurisdiction was exercised over the houses of their order by the abbots of Monte Cassino, St Dalmatius, Clugny, &c. The abbot of Cassino was styled *Abbas Abbatum.* The chiefs of other orders had the titles of *Abbas Generalis*, or *Magister*, or *Minister Generalis.*

Abbots were originally subject to episcopal jurisdiction, and continued generally so, in fact, in the West till the 11th century. The *Codex of Justinian* (lib. i. tit. iii. de Ep. leg. xl.), expressly subordinates the abbot to episcopal oversight. The first case recorded of the partial exemption of an abbot from episcopal control is that of Faustus, Abbot of Lerins, at the Council of Arles, A.D. 456; but the oppressive conduct, and exorbitant claims and exactions of bishops, to which this repugnance to episcopal control is to be traced, far more than to the arrogance of abbots, rendered it increasingly frequent, and, in the 6th century, the practice of exempting religious houses partly or altogether from episcopal control, and making them responsible to the Pope alone, received an impulse from Gregory the Great. These exceptions, though introduced with a good object, had grown into a wide-spread and crying evil by the 12th century, virtually creating an *imperium in imperio*, and entirely depriving the bishop of all authority over the chief centres of power and influence in his diocese. In the 12th century the abbots of Fulda claimed precedence of the Archbishop of Cologne. Abbots more and more aped episcopal state, and in defiance of the express prohibition of early councils, and the protests of St Bernard and others, adopted the episcopal insignia of mitre, ring, gloves, and sandals. A mitre is said to have been granted to the Abbot of Bobbio by Pope Theodorus I., A.D. 643, and to the Abbot of St Savianus by Sylvester II., A.D. 1000. Ducange asserts that pontifical insignia were first assigned to abbots by John XVIII., A.D. 1004–1009; but the first undoubted grant is said to be that to the Abbot of St Maximinian at Treves, by Gregory VII. (Hildebrand), A.D. 1073–1085. The mitred abbots in England were those of Abingdon, St Alban's, Bardney, Battle, Bury St Edmund's, St Augustine's Canterbury, Colchester, Croyland, Evesham, Glastonbury, Gloucester, St Benet's Hulme, Hyde, Malmesbury, Peterborough, Ramsey, Reading, Selby, Shrewsbury, Tavistock, Thorney, Westminster, Winchcombe, St Mary's York. Of these the precedence was originally yielded to the Abbot of Glastonbury, until in A.D. 1154 Adrian IV. (Nicholas Breakspear) granted it to the Abbot of St Alban's, in which monastery he had been brought up. Next after the Abbot of St Alban's ranked the Abbot of Westminster.

To distinguish abbots from bishops, it was ordained that their mitre should be made of less costly materials, and should not be ornamented with gold, a rule which was soon entirely disregarded, and that the crook of their pastoral staff should turn inwards instead of outwards, indicating that their jurisdiction was limited to their own house. The adoption of episcopal insignia by abbots was followed by an encroachment on episcopal functions, which had to be specially but ineffectually guarded against by the Lateran Council, A.D. 1123. In the East, abbots, if in priests' orders, with the consent of the bishop, were, as we have seen, permitted by the Second Nicene Council, A.D. 787, to confer the tonsure and admit to the order of reader; but they gradually advanced higher claims, until we find them authorised by Bellarmine to be associated with a single bishop in episcopal consecrations, and permitted by Innocent IV., A.D. 1489, to confer both the subdiaconate and diaconate. Of course, they always and everywhere had the power of admitting their own monks, and vesting them with the religious habit. In the first instance, when a vacancy occurred, the bishop of the diocese chose the abbot out of the monks of the convent, but the right of election was transferred by jurisdiction to the monks themselves, reserving to the bishop the confirmation of the election and the benediction of the new abbot. In abbeys exempt from episcopal jurisdiction, the confirmation and benediction had to be conferred by the Pope in person, the house being taxed with the expenses of the new abbot's journey to Rome. By the rule of St Benedict, the consent of the laity was in some undefined way required; but this seems never to have been practically enforced. It was necessary that an abbot should be at least 25 years of age, of legitimate birth, a monk of the house, unless it furnished no suitable candidate, when a liberty was allowed of electing from another convent, well instructed himself, and able to instruct others, one also who had learned how to command by having practised obedience. In some exceptional cases an abbot was allowed to name his own successor. Cassian speaks of an abbot in Egypt doing this; and in later times we have another example in the case of St Bruno. Popes and sovereigns gradually encroached on the rights of the monks, until in Italy the Pope had usurped the nomination of all abbots, and the king in France, with the exception of Clugny, Prémontré, and other houses, chiefs of their order. The election was for life, unless the abbot was canonically deprived by the chiefs of his order, or, when he was directly subject to them, by the Pope or the bishop.

The ceremony of the formal admission of a Benedictine abbot in mediæval times is thus prescribed by the consuetudinary of Abingdon. The newly elected abbot was to put off his shoes at the door of the church, and proceed barefoot to meet the members of the house advancing in a procession. After proceeding up the nave, he was to kneel and pray at the topmost step of the entrance of the choir, into which he was to be introduced by the bishop or his commissary, and placed in his stall. The monks, then kneeling, gave him the kiss of peace on the hand, and rising, on the mouth, the abbot holding his staff of office. He then put on his shoes in the vestry, and a chapter was held, and the bishop or his commissary preached a suitable sermon.

The power of the abbot was paternal but absolute, limited, however, by the canons of the church, and, until the general establishment of exemptions, by episcopal control. As a rule, however, implicit obedience was enforced; to act without his orders was culpable; while it was a sacred duty to execute his orders, however unreasonable, until they were withdrawn. Examples among the Egyptian monks of this blind submission to the commands of the superiors, exalted into a virtue by those who regarded the entire crushing of the individual will as the highest excellence, are detailed by Cassian and others,—*e.g.*, a monk watering a dry stick, day after day, for months, or endeavouring to remove a huge rock immensely exceeding his powers. St Jerome, indeed, lays down, as the principle of the compact between the abbot and his monks, that they should obey their superiors in all things, and perform whatever they commanded.—(Ep. 2 ad Eustoch. de custod virgin.) So despotic did the tyranny become in the West, that in the time of Charlemagne it was necessary to restrain abbots by legal enactments from mutilating their monks, and putting out their eyes; while the rule of St Columba ordained 100 lashes as the punishment for very slight offences. An abbot also had the power of excommunicating refractory nuns, which he might use if desired by their abbess.

The abbot was treated with the utmost submission and reverence by the brethren of his house. When he appeared either in church or chapter all present rose and bowed. His letters were received kneeling, like those of the Pope and the king. If he gave a command, the monk receiving it was also to kneel. No monk might sit in his presence, or leave it without his permission. The highest place was naturally assigned to him, both in church and at table. In the East he was commanded to eat with the other monks. In the West the rule of St Benedict appointed him a separate table, at which he might entertain guests and strangers. This permission opening the door to luxurious living, the Council of Aix, A.D. 817, decreed that the abbot should dine in the refectory, and be content with the ordinary fare of the monks, unless he had to entertain a guest. These ordinances proved, however, generally ineffectual to secure strictness of diet, and contemporaneous literature abounds with satirical remarks and complaints concerning the inordinate extravagance of the tables of the abbots. When the abbot condescended to dine in the refectory, his chaplains waited upon him with the dishes, a servant, if necessary, assisting them. At St Alban's the abbot took the lord's seat, in the centre of the high table, and was served on silver plate, and sumptuously entertained noblemen, ambassadors, and strangers of quality. When abbots dined in their own private hall, the rule of St Benedict charged them to invite their monks to their table, provided there was room, on which occasions the guests were to abstain from quarrels, slanderous talk, and idle gossipping. The complaint, however, was sometimes made (as by Matt. Paris of Wulsig, the third abbot of St Alban's), that they invited ladies of rank to dine with them instead of their monks. The ordinary attire of the abbot was according to rule to be the same as that of the monks. But by the 10th century the rule was commonly set aside, and we find frequent complaints of abbots dressing in silk, and adopting great sumptuousness of attire. Nay, they sometimes laid aside the monastic habit altogether, and assumed a secular dress.[1] This was a necessary consequence of their following the chase, which was quite usual, and indeed at that time only natural. With the increase of wealth and power, abbots had lost much of their special religious character, and become great lords, chiefly distinguished from lay lords by celibacy. Thus we hear of abbots going out to sport, with their men carrying bows and arrows; keeping horses, dogs, and huntsmen; and special mention is made of an abbot of Leicester, *cir.* 1360, who was the most skilled of all the nobility in hare-hunting. In magnificence of equipage and retinue the abbots vied with the first nobles of the realm. They rode on mules with gilded bridles, rich saddles and housings, carrying hawks on their wrist, attended by an immense train of attendants. The bells of the churches were rung as they passed. They associated on equal terms with laymen of the highest distinction, and shared all their pleasures and pursuits. This rank and power was, however, often used most beneficially. For instance, we read of Whiting, the last Abbot of Glastonbury, judicially murdered by Henry VIII., that his house was a kind of well-ordered court, where as many as 300 sons of noblemen and gentlemen, who had been sent to him for virtuous education, had been brought up, besides others of a meaner rank, whom he fitted for the universities. His table, attendance, and officers were an honour to the nation. He would entertain as many as 500 persons of rank at one time, besides relieving the poor of the vicinity twice a-week. He had his country houses and fisheries, and when he travelled to attend Parliament his retinue amounted to upwards of 100 persons. The abbots of Clugny and Vendome were, by virtue of their office, cardinals of the Romish Church.

In process of time the title abbot was improperly transferred to clerics who had no connection with the monastic system, as to the principal of a body of parochial clergy; and under the Carlovingians to the chief chaplain of the king, *Abbas Curiæ*, or military chaplain of the emperor, *Abbas Castrensis*. It even came to be adopted by purely secular officials. Thus the chief magistrate of the republic at Genoa was called *Abbas Populi*. Ducange, in his Glossary, also gives us *Abbas Campanilis, Clocherii, Palatii, Scholaris*, &c.

Lay abbots, so called, had their origin in the system of *commendation*, in the 8th century. By this, to meet any great necessity of the state, such as an inroad of the Saracens, the revenues of monasteries were temporarily commended, *i.e.*, handed over to some layman, a noble, or even the king himself, who for the time became titular abbot. Enough was reserved to maintain the monastic brotherhood, and when the occasion passed away the revenues were to be restored to their rightful owners. The estates, however, had a habit of lingering in lay hands, so that in the 9th and 10th centuries most of the sovereigns and nobles among the Franks and Burgundians were titular abbots of some great monastery, the revenues of which they applied to their own purposes. These lay-abbots were styled *Abbacomites* or *Abbates Milites*. Hugh Capet, before his elevation to the throne, as an *Abbacomes* held the abbeys of St Denis and St Germain *in commendam*. Bishop Hatto, of Mentz, A.D. 891–912, is said to have held 12 abbeys *in commendam* at once. In England, as we see from the Acts of the Council of Cloveshoo, in the 8th century, monasteries were often invaded and occupied by laymen. This occurred sometimes from the monastery having voluntarily placed itself under the protection of a powerful layman, who, from its protector, became its oppressor. Sometimes there were two lines of abbots, one of laymen enjoying the lion's share of the revenues, another of clerics fulfilling the proper duties of an abbot on a small fraction of the income. The gross abuse of lay commendation which had sprung up during the corruption of the monastic system passed away with its reformation in the 10th century, either voluntarily or by compulsion. The like abuse prevailed in the East at a later period. John, Patriarch of Antioch, at the beginning of the 12th century, informs us that in his time most monasteries had been handed over to laymen, *beneficiarii*, for life, or for part of their lives, by the emperors.

In conventual cathedrals, where the bishop occupied the place of the abbot, the functions usually devolving on the superior of the monastery were performed by a *prior*. In other convents the prior was the second officer next to the abbot, representing him in his absence, and fulfilling his duties. The superiors of the cells, or small monastic establishments dependent on the larger monasteries, were also called priors. They were appointed by the abbots, and held office at their pleasure.

[1] Walworth, the fourth abbot of St Alban's, *circa* 930, is charged by Matthew Paris with adopting the attire of a sportsman.

ABBOT, Charles, speaker of the House of Commons from 1802 to 1817, afterwards created Lord Colchester. See Colchester.

ABBOT, George, Archbishop of Canterbury, was born October 19, 1562, at Guildford in Surrey, where his father was a cloth-worker. He studied at Balliol College, Oxford, and was chosen Master of University College in 1597. He was three times appointed to the office of Vice-Chancellor of the University. When in 1604 the version of the Bible now in use was ordered to be prepared, Dr Abbot's name stood second on the list of the eight Oxford divines to whom was intrusted the translation of the New Testament, excepting the Epistles. In 1608 he went to Scotland with the Earl of Dunbar to arrange for a union between the Churches of England and Scotland, and his conduct in that negotiation laid the foundation of his preferment, by attracting to him the notice and favour of the king. Without having held any parochial charge, he was appointed Bishop of Lichfield and Coventry in 1609, was translated to the see of London a month afterwards, and in less than a year was made Archbishop of Canterbury. This rapid preferment was due as much perhaps to his flattering his royal master as to his legitimate merits. After his elevation he showed on several occasions firmness and courage in resisting the king. In the scandalous divorce suit of the Lady Frances Howard against the Earl of Essex, the archbishop persistently opposed the dissolution of the marriage, though the influence of the king and court was strongly and successfully exerted in the opposite direction. In 1618, when a declaration was published by the king, and ordered to be read in all the churches, permitting sports and pastimes on the Sabbath, Abbot had the courage to forbid its being read at Croydon, where he happened to be at the time. As may be inferred from the incident just mentioned, Abbot was of the Protestant or Puritan party in the Church. He was naturally, therefore, a promoter of the match between the Elector Palatine and the Princess Elizabeth, and a firm opponent of the projected marriage of the Prince of Wales with the Infanta of Spain. This policy brought upon him the hatred of Laud and the court. The king, indeed, never forsook him; but Buckingham was his avowed enemy, and he was regarded with dislike by the Prince of Wales, afterwards Charles I. In 1622 a sad misfortune befell the archbishop while hunting in Lord Zouch's park at Bramzill. A bolt from his cross-brow aimed at a deer happened to strike one of the keepers, who died within an hour, and Abbot was so greatly distressed by the event that he fell into a state of settled melancholy. His enemies maintained that the fatal issue of this accident disqualified him for his office, and argued that, though the homicide was involuntary, the sport of hunting which had led to it was one in which no clerical person could lawfully indulge. The king had to refer the matter to a commission of ten, though he said that "an angel might have miscarried after this sort." A decision was given in the archbishop's favour; but to prevent disputes, it was recommended that the king should formally absolve him, and confer his office upon him anew. After this the archbishop seldom appeared at the council, chiefly on account of his infirmities. He attended the king constantly, however, in his last illness, and performed the ceremony of the coronation of Charles I. A pretext was soon found by his enemies for depriving him of all his functions as primate, which were put in commission by the king. This high-handed procedure was the result of Abbot's refusal to license a sermon preached by Dr Sibthorp, in which the king's prerogative was stretched beyond constitutional limits. The archbishop had his powers restored to him shortly afterwards, however, when the king found it absolutely necessary to summon a Parliament. His presence being unwelcome at court, he lived from that time in retirement, leaving Laud and his party in undisputed ascendency. He died at Croydon on the 5th August 1633, and was buried at Guildford, his native place, where he had endowed an hospital with lands to the value of £300 a year. Abbot wrote a large number of works; but, with the exception of his *Exposition on the Prophet Jonah* (1600), which was reprinted in 1845, they are now little known. His *Geography, or a Brief Description of the Whole World*, passed through numerous editions.

ABBOT, George, known as "The Puritan," has been oddly and persistently mistaken for others. He has been described as a clergyman, which he never was, and as son of Sir Morris Abbot, and his writings accordingly entered in the bibliographical authorities as by the nephew of the Archbishop of Canterbury. One of the sons of Sir Morris Abbot was, indeed, named George, and he was a man of mark, but the more famous George Abbot was of a different family altogether. He was son or grandson (it is not clear which) of Sir Thomas Abbot, knight of Easington, East Yorkshire, having been born there in 1603–4, his mother (or grandmother) being of the ancient house of Pickering. He married a daughter of Colonel Purefoy of Caldecote, Warwickshire, and as his monument, which may still be seen in the church there, tells, he bravely held it against Prince Rupert and Maurice during the civil war. He was a member of the Long Parliament for Tamworth. As a layman, and nevertheless a theologian and scholar of rare ripeness and critical ability, he holds an almost unique place in the literature of the period. His *Whole Booke of Job Paraphrased, or made easy for any to understand* (1640, 4to), is in striking contrast, in its concinnity and terseness, with the prolixity of too many of the Puritan expositors and commentators. His *Vindiciæ Sabbathi* (1641, 8vo) had a profound and lasting influence in the long Sabbatic controversy. His *Brief Notes upon the Whole Book of Psalms* (1651, 4to), as its date shows, was posthumous. He died February 2, 1648. (MS. collections at Abbeyville for history of all of the name of Abbot, by J. T. Abbot, Esq., F.S.A., Darlington; Dugdale's *Antiquities of Warwickshire*, 1656, p. 791; Wood's *Athenæ* (Bliss), s. v.; Cox's *Literature of the Sabbath;* Dr James Gilfillan on *The Sabbath; Lowndes, Bodleian, B. Museum Catal.* s. v.) (A. B. G.)

ABBOT, Robert. Noted as this Puritan divine was in his own time, and representative in various ways, he has hitherto been confounded with others, as Robert Abbot, Bishop of Salisbury, and his personality distributed over a Robert Abbot of Cranbrook; another of Southwick, Hants; a third of St Austin's, London; while these successive places were only the successive livings of the one Robert Abbot. He is also described as of the Archbishop's or Guildford Abbots, whereas he was in no way related, albeit he acknowledges very gratefully, in the first of his epistles-dedicatory of *A Hand of Fellowship to Helpe Keepe out Sinne and Antichrist* (1623, 4to), that it was from the archbishop he had "received all" his "worldly maintenance," as well as "best earthly countenance" and "fatherly incouragements." The worldly maintenance was the presentation to the vicarage of Cranbrook in Kent, of which the archbishop was patron. This was in 1616. He had received his education at Cambridge, where he proceeded M.A., and was afterwards incorporated at Oxford. In 1639, in the epistle to the reader of his most noticeable book historically, his *Triall of our Church-Forsakers* he tells us, "I have lived now, by God's gratious dispensation, above fifty years, and in the place of my allotment two and twenty full." The former date carries us back to 1588–89, or perhaps 1587–88—the

"Armada" year—as his birth-time; the latter to 1616-17 (*ut supra*). In his *Bee Thankfull London and her Sisters* (1626), he describes himself as formerly "assistant to a reverend divine . . . . now with God," and the name on the margin is "Master Haiward of Wool Church." This was doubtless previous to his going to Cranbrook. Very remarkable and effective was Abbot's ministry at Cranbrook, where the father of Phineas and Giles Fletcher was the first "Reformation" pastor, and which, relatively small as it is, is transfigured by being the birth-place of the poet of the "Locustæ" and "The Purple Island." His parishioners were as his own "sons and daughters" to him, and by day and night he thought and felt, wept and prayed, for them and with them. He is a noble specimen of the rural clergyman of his age. Puritan though he was in his deepest convictions, he was a thorough Churchman as toward Nonconformists, *e.g.*, the Brownists, with whom he waged stern warfare. He remained until 1643 at Cranbrook, and then chose the very inferior living of Southwick, Hants, as between the one and the other, the Parliament deciding against pluralities of ecclesiastical offices. Succeeding the "extruded" Udall of St Austine's, Abbot continued there until a good old age. In 1657, in the *Warning-piece*, he is described as still "pastor of Austine's in London." He disappears silently between 1657-8 and 1662. Robert Abbot's books are distinguished from many of the Puritans by their terseness and variety. (Brook's *Puritans*, iii. 182, 3; Walker's *Sufferings;* Wood's *Athenæ* (Bliss); *Catalogus Impressorum Librorum in Bibliotheca Bodleiana*, s.v.; Palmer's *Nonconf. Mem.*, ii. 218.) (A. B. G.)

ABBOTSFORD, the celebrated residence of Sir Walter Scott, situated on the south bank of the river Tweed, about three miles above Melrose. The nucleus of the property was a small farm of 100 acres, with the "inharmonious designation" of Clarty Hole, acquired by Scott on the lapse of his lease (1811) of the neighbouring house of Ashestiel. It was gradually increased by various acquisitions, the last and principal being that of Toftfield (afterwards named Huntlyburn), purchased in 1817. The present new house was then commenced, and was completed in 1824. The general ground-plan is a parallelogram, with irregular outlines—one side overlooking the Tweed, and the other facing a courtyard; and the general style of the building is the Scottish baronial. Scott had only enjoyed his new residence one year when (1825) he met with that reverse of fortune (connected with the failure of Ballantyne and Constable), which involved the estate in debt. In 1830, the library[1] and museum were presented as a free gift by the creditors; and after Scott's death, which took place at Abbotsford in September 1832, a committee of friends subscribed a further sum of about £8000 towards the same object. The property was wholly disencumbered in 1847, by Mr Cadell, the publisher, accepting the remaining claims of the family over Sir Walter Scott's writings in requital of his obligation to obliterate the heritable bond on the property. The result of this transaction was, that not only was the estate redeemed by the fruit of Scott's brain, but a handsome residue fell to the publisher. Scott's only son Walter (Lieutenant-Colonel 15th Hussars) did not live to enjoy the property, having died on his way from India in 1847. Its subsequent possessors have been Scott's son-in-law, J. G. Lockhart, and the latter's son-in-law, J. R. Hope Scott, Q.C., whose daughter (Scott's great-granddaughter) is the present proprietor. Mr Lockhart died at Abbotsford in 1854.—See *Life of Scott*, by J. G. Lockhart; *Abbotsford and Newstead Abbey*, by Washington Irving; *Abbotsford Notanda* in *Gentleman's Mag.*, April and May 1869; *The Lands of Scott*, by James F. Hunnewell, cr. 8vo, 1871; *Scott Loan Exhibition Catalogue*, 4to, 1871.

[1] The Catalogue of the Library at Abbotsford forms vol. lxi. of the Bannatyne Club publications.

ABBOTSFORD CLUB, one of the principal printing clubs, was founded in 1834 by Mr W. B. D. D. Turnbull, and named in honour of Sir Walter Scott. Taking a wider range than its predecessors, the Bannatyne and Maitland Clubs, it did not confine its printing (as remarked by Mr Lockhart) to works connected with Scotland, but admitted all materials that threw light on the ancient history of literature of any country, anywhere described or discussed by the Author of Waverley. The club, now dissolved, consisted of fifty members; and the publications extend to 31 vols. quarto, issued during the years 1835-1864.

ABBREVIATION, a letter or group of letters, taken from a word or words, and employed to represent them for the sake of brevity. Abbreviations, both of single words and of phrases, having a meaning more or less fixed and recognised, are common in ancient writings and inscriptions, and very many are in use at the present time. A distinction is to be observed between abbreviations and the contractions that are frequently to be met with in old manuscripts, and even in early printed books, whereby letters are dropped out here and there, or particular collocations of letters represented by somewhat arbitrary symbols. The commonest form of abbreviation is the substitution for a word of its initial letter; but, with a view to prevent ambiguity, one or more of the other letters are frequently added. Letters are often doubled to indicate a plural or a superlative.

I. Classical Abbreviations.—The following list contains a selection from the abbreviations that occur in the writings and inscriptions of the Romans:—

A.

A. Absolvo, Ædilis, Æs, Ager, Ago, Aio, Amicus, Annus, Antiquo, Auctor, Auditor, Augustus, Aulus, Aurum, Aut.

A. A. Æs alienum, Ante audita, Apud agrum, Aurum argentum.

AA. Augusti. AAA. Augusti tres.

A. A. A. F. F. Auro argento ære flando feriundo.[1]

A. A. V. Alter ambove.

A. C. Acta causa, Alius civis.

A. D. Ante diem; *e.g.*, A. D. V. Ante diem quintum.

A. D. A. Ad dandos agros.

ÆD. Ædes, Ædilis, Ædilitas.

ÆM. *and* AIM. Æmilius, Æmilia.

ÆR. Ærarium. ÆR. P. Ære publico.

A. F. Actum fide, Auli filius.

AG. Ager, Ago, Agrippa.

A. G. Animo grato, Aulus Gellius.

A. L. Æ. *and* A. L. E. Arbitrium litis æstimandæ.

A. M. *and* A. MILL. Ad milliarium.

AN. Aniensis, Annus, Ante.

ANN. Annales, Anni, Annona.

ANT. Ante, Antonius.

A. O. Alii omnes, Amico optimo.

AP. Appius, Apud.

A. P. Ad pedes, Ædilitia potestate.

A. P. F. Auro (*or* argento) publico feriundo.

A. P. M. Amico posuit monumentum, Annorum plus minus.

A. P. R. C. Anno post Romam conditam.

ARG. Argentum.

AR. V. V. D. D. Aram votam volens dedicavit, Arma votiva dono dedit.

A T. A tergo. *Also* A TE. *and* A TER.

A. T. M. D. O. Aio te mihi dare opertere.

AV. Augur, Augustus, Aurelius.

A. V. Annos vixit.

A. V. C. Ab urbe condita.

AVG. Augur, Augustus.

AVGG. Augusti (*generally of two*). AVGGG. Augusti tres.

AVT. PR. R. Auctoritas provinciæ Romanorum.

B.

B. Balbius, Balbus, Beatus, Bene, Beneficiarius, Beneficium, Bonus, Brutus, Bustum.

B. *for* V. Berna, Bivus, Bixit.

B. A. Bixit annos, Bonis auguriis, Bonus amabilis.

[1] Describing the function of the *triumviri monetales*.

BB. *or* B.B. Bene bene, *i.e.*, optime, Optimus.

B.D. Bonæ deæ, Bonum datum.

B.DD. Bonis deabus.

B.D.S.M. Bene de se merenti.

B.F. Bona femina, Bona fides, Bona fortuna, Bonum factum.

B.F. Bona femina, Bona filia.

B.H. Bona hereditaria, Bonorum heres.

B.I. Bonum judicium. B.I.I. Boni judicis judicium.

B.M. Beatæ memoriæ, Bene merenti.

B.N. Bona nostra, Bonum nomen.

BN.H.I. Bona hic invenies.

B.P. Bona paterna, Bonorum potestas, Bonum publicum.

B.Q. Bene quiescat, Bona quæsita.

B.RP.N. Bono reipublicæ natus.

BRT. Britannicus.

B.T. Bonorum tutor, Brevi tempore.

B.V. Bene vale, Bene vixit, Bonus vir.

B.V.V. Balnea vina Venus.

BX. Bixit, *for* vixit.

C.

C. Cæsar, Caius, Caput, Causa, Censor, Civis, Cohors, Colonia, Comitialis (dies), Condemno, Consul, Cum, Curo, Custos.

Ɔ. Caia, Centuria, Cum, *the prefix* Con.

C.B. Civis bonus, Commune bonum, Conjugi benemerenti, Cui bono.

C.C. Calumniæ causa, Causa cognita, Conjugi carissimæ, Consilium cepit, Curiæ consulto.

C.C.C. Calumniæ cavendæ causâ.

C.C.F. Cæsar (*or* Caius) curavit faciendum, Caius Caii filius.

CC.VV. Clarissimi viri.

C.D. Cæsaris decreto, Caius Decius. Comitialibus diebus.

CES. Censor, Censores. CESS. Censores.

C.F. Causa fiduciæ, Conjugi fecit, Curavit faciendum.

C.H. Custos heredum, Custos hortorum.

C.I. Caius Julius, Consul jussit, Curavit judex.

CL. Clarissimus, Claudius, Clodius, Colonia.

CL.V. Clarissimus vir, Clypeum vovit.

C.M. Caius Marius, Causa mortis.

CN. Cnæus.

COH Coheres, Cohors.

COL. Collega, Collegium, Colonia, Columna.

COLL. Collega, Coloni, Coloniæ.

COM. Comes, Comitium, Comparatum.

CON. Conjux, Consensus, Consiliarius, Consul, Consularis.

COR. Cornelia (tribus), Cornelius, Corona, Corpus.

COS. Consiliarius, Consul, Consulares. COSS. Consules.

C.P. Carissimus *or* Clarissimus puer, Civis publicus, Curavit ponendum.

C.R. Caius Rufus, Civis Romanus, Curavit reficiendum.

CS. Cæsar, Communis, Consul.

C.V. Clarissimus *or* consularis vir.

CVR. Cura, Curator, Curavit, Curia.

O.T.B.Q. Ossa tua bene quiescant.

P.

P. Pars, Passus, Pater, Patronus, Pax, Perpetuus, Pes, Pius, Plebs, Pondo, Populus, Post, Posuit, Præses, Prætor, Primus, Pro, Provincia, Publicus, Publius, Puer.

P.C. Pactum conventum, Patres conscripti, Pecunia constituta, Ponendum curavit, Post consulatum, Potestate censoria.

P.F. Pia fidelis, Pius felix, Promissa fides, Publii filius.
P.M. Piæ memoriæ, Plus minus, Pontifex maximus.
P.P. Pater patratus, Pater patriæ, Pecunia publica, Præpositus, Primipilus, Proprætor.
PR. Præses, Prætor, Pridie, Princeps.
P.R. Permissu reipublicæ, Populus Romanus.
P.R.C. Post Romam conditam.
PR.PR. Præfectus prætorii, Proprætor.
P. S. Pecunia sua, Plebiscitum, Proprio sumptu, Publicæ saluti.
P.V. Pia victrix, Præfectus urbi, Præstantissimus vir.

Q.

Q. Quæstor, Quando, Quantus, Que, Qui, Quinquennalis, Quintus, Quirites.
Q.D.R Qua de re.
Q.I.S.S. Quæ infra scripta sunt; *so* Q. S. S. S. Quæ supra, &c.
QQ. Quæcunque, Quinquennalis, Quoque.
Q.R. Quæstor reipublicæ

R.

R. Recte, Res, Respublica, Retro, Rex, Ripa, Roma, Romanus, Rufus, Rursus.
R.C. Romana civitas, Romanus civis.
RESP. *and* RP. Respublica.
RET. P. *and* RP. Retro pedes.

S.

S Sacrum, Scriptus, Semis, Senatus, Sepultus, Servius, Servus, Sextus, Sibi, Sine, Situs, Solus, Solvit, Sub, Suus.
SAC. Sacerdos, Sacrificium, Sacrum.
S.C. Senatus consultum.
S.D. Sacrum diis, Salutem dicit, Senatus decreto, Sententiam dedit.
S.D.M. Sacrum diis Manibus, Sine dolo malo.
SER. Servius, Servus.
S.E.T.L. Sit ei terra levis.
SN. Senatus, Sententia, Sine.
S.P. Sacerdos perpetua, Sine pecunia, Sua pecunia.
S.P.Q.R. Senatus populusque Romanus.
S.S. Sanctissimus senatus, Supra scriptum.
S.V.B.E.E.Q.V. Si vales bene est, ego quidem valeo.

T.

T. Terminus, Testamentum, Titus. Tribunus, Tu, Turma, Tutor.
TB., TI., *and* TIB. Tiberius.
TB., TR., *and* TRB. Tribunus.
T.F. Testamentum fecit, Titi filius, Titulum fecit, Titus Flavius.
TM. Terminus, Testamentum, Thermæ.
T.P. Terminum posuit, Tribunicia potestate, Tribunus plebis.
TVL. Tullius, Tullus.

V.

V. Urbs, Usus, Uxor, Vale, Verba, Vestalis, Vester, Vir, Vivus, Vixit, Volo, Votum.
V.A Veterano assignatus, Vixit annos.
V.C. Vale conjux, Vir clarissimus, Vir consularis.
V.E. Verum etiam, Vir egregius, Visum est.
V.F. Usus fructus, Verba fecit, Vivus fecit.
V.P. Urbis præfectus, Vir perfectissimus, Vivus posuit.
V.R. Urbs Roma, Uti rogas, Votum reddidit.

II. Mediæval Abbreviations.—Of the different kinds of abbreviations in use in the middle ages, the following are examples:—

A.M. Ave Maria.
B.P. Beatus Paulus, Beatus Petrus.
CC. Carissimus (*also plur.* Carissimi), Clarissimus, Circum.
D. Deus, Dominicus, Dux.
D.N.PP. Dominus noster Papa.
FF. Felicissimus, Fratres, Pandectæ (*prob. for Gr.* Π).
I.C. *or* I.X. Jesus Christus.
I.D.N. In Dei nomine.
KK. Karissimus (*or* -mi).
MM. Magistri, Martyres, Matrimonium, Meritissimus.
O.S.B. Ordinis Sancti Benedicti.
PP. Papa, Patres, Piissimus.
R.F. Rex Francorum.
R.P.D. Reverendissimus Pater Dominus.
S.C.M. Sacra Cæsarea Majestas.
S.M.E. Sancta Mater Ecclesia.
S.M.M. Sancta Mater Maria.
S.R.I. Sanctum Romanum Imperium.
S.V. Sanctitas Vestra, Sancta Virgo.
V Venerabilis, Venerandus.
V.R.P. Vestra Reverendissima Paternitas.

III. Abbreviations now in use.—The import of these will often be readily understood from the connection in which they occur. There is no occasion to explain here the common abbreviations used for Christian names, books of Scripture, months of the year, points of the compass, grammatical and mathematical terms, or familiar titles, like "Mr," &c.

The ordinary abbreviations, now or recently in use, may be conveniently classified under the following headings:—

1. Abbreviated Titles and Designations.

A.A. Associate of Arts.
A.B. Able-bodied seaman.
A.M. (*Artium Magister*), Master of Arts.
A.R.A. Associate of the Royal Academy.
A.R.S.A. Associate of the Royal Scottish Academy.
B.A. Bachelor of Arts.
B.C.L. Bachelor of Civil Law.
B.D. Bachelor of Divinity.
B.LL. Bachelor of Laws.
B.Sc. Bachelor of Science.
C. Chairman.
C.A. Chartered Accountant.
C.B. Companion of the Bath.
C.E. Civil Engineer.
C.M. (*Chirurgiæ Magister*), Master in Surgery.
C.M.G. Companion of St Michael and St George.
C.S.I. Companion of the Star of India.
D.C.L. Doctor of Civil Law.
D.D. Doctor of Divinity
D.Lit. Doctor of Literature.
D.M. Doctor of Medicine [Oxford].
D.Sc. Doctor of Science.
Ebor. (*Eboracensis*), of York.[1]
F.C.S. Fellow of the Chemical Society.
F.D. (*Fidei Defensor*), Defender of the Faith.
F.F.P.S. Fellow of the Faculty of Physicians & Surgeons [Glasgow.]
F.G.S. Fellow of the Geological Society.
F.K.Q.C.P.I. Fellow of King and Queen's College of Physicians in Ireland.
F.L.S. Fellow of the Linnæan Society.
F.M. Field Marshal.
F.P.S. Fellow of the Philological Society.
F.R.A.S. Fellow of the Royal Astronomical Society.
F.R.C.P. Fellow of the Royal College of Physicians.
F.R.C.P.E. Fellow of the Royal College of Physicians of Edinburgh.
F.R.C.S. Fellow of the Royal College of Surgeons.
F.R.G.S. Fellow of the Royal Geographical Society.
F.R.S. Fellow of the Royal Society.
F.R.S.E. Fellow of the Royal Society of Edinburgh.
F.R.S.L. Fellow of the Royal Society of Literature.
F.S.A. Fellow of the Society of Antiquaries.
F.S.S. Fellow of the Statistical Society.
F.Z.S. Fellow of the Zoological Society.
G.C.B. Knight Grand Cross of the Bath.
G.C.H. Knight Grand Cross of Hanover.
G.C.M.G. Knight Grand Cross of St Michael and St George.
G.C.S.I. Knight Grand Commander of the Star of India.
H.R.H. His (*or* Her) Royal Highness.
J.P. Justice of the Peace.
J.U.D. (*Juris utriusque Doctor*), Doctor of Civil and Canon Law.
K.C.S.I. Knight Commander of the Star of India.
K.C.B. Knight Commander of the Bath.
K.G. Knight of the Garter.
K.P. Knight of St Patrick.
K.T. Knight of the Thistle.
L.A.H. Licentiate of the Apothecaries' Hall.
L.C.J. Lord Chief Justice.
LL.B. (*Legum Baccalaureus*), Bachelor of Laws.
LL.D. (*Legum Doctor*), Doctor of Laws.
LL.M. (*Legum Magister*), Master of Laws.
L.R.C.P. Licentiate of the Royal College of Physicians.
L.R.C.S. Licentiate of the Royal College of Surgeons.
L.S.A. Licentiate of the Apothecaries' Society.
M.A. Master of Arts.
M.B. (*Medicinæ Baccalaureus*), Bachelor of Medicine.
M.C. Member of Congress.
M.D. (*Medicinæ Doctor*), Doctor of Medicine.
M.P. Member of Parliament.
M.R.C.P. Member of the Royal College of Physicians.
M.R.I.A. Member of the Royal Irish Academy.
Mus. B. Bachelor of Music.

[1] An archbishop or bishop, in writing his signature, substitutes for his surname the name of his see; thus the prelates of Canterbury, York, Oxford, London, &c., subscribe themselves A. C. Cantuar., W. Ebor., J. F. Oxon., J. London. &c.

Mus. D. Doctor of Music.
N.P. Notary Public.
P.C. Privy Councillor.
Ph.D. (*Philosophiæ Doctor*), Doctor of Philosophy.
P.P. Parish Priest.
P.R.A. President of the Royal Academy.
Q.C. Queen's Counsel.
R. (*Rex, Regina*), King, Queen.
R.A. Royal Academician. Royal Artillery.
R.A.M. Royal Academy of Music.
R.E. Royal Engineers.
Reg. Prof. Regius Professor.
R.M. Royal Marines.
R.N. Royal Navy.
S. *or* St. Saint.
S.S.C. Solicitor before the Supreme Courts [of Scotland].
S.T.P. (*Sacrosanctæ Theologiæ Professor*), Professor of Sacred Theology.
V.C. Vice-Chancellor. Victoria Cross.
V.G. Vicar-General.
V.S. Veterinary Surgeon.
W.S. Writer to the Signet [in Scotland]. *Equivalent to Attorney.*

2. Abbreviations denoting Monies, Weights, and Measures :—[1]

ac.	acre.	L.,[2] £,[2] or *l.* (*libra*),	pound (money).
bar.	barrel.	lb. *or* ℔. (*libra*),	pound (weight).
bus.	bushel.	m. *or* mi.	mile; minute.
c.	cent.	♏.	minim.
c. (*or* cub.) ft. &c.	cubic foot, &c.	mo.	month.
cwt.	hundredweight.	na.	nail.
d.	(*denarius*), penny.	oz.	ounce.
deg.	degree.	pk.	peck.
dr.	drachm *or* dram.	po.	pole.
dwt.	pennyweight.	pt.	pint.
f.	franc.	q.	(*quadrans*), farthing.
fl.	florin.	qr.	quarter.
ft.	foot.	qt.	quart.
fur.	furlong.	ro.	rood.
gal.	gallon.	Rs.[2]	rupees.
gr.	grain.	s. *or* / (*solidus*),	shilling.
h. *or* hr.	hour.	s. *or* sec.	second.
hhd.	hogshead.	sc. *or* scr.	scruple.
in.	inch.	sq. ft. &c.	square foot, &c.
kilo.	kilometre.	st.	stone.
		yd.	yard.

3. Miscellaneous Abbreviations.

A. Accepted.
A.C. (*Ante Christum*), Before Christ.
acc., a/c., *or* acct. Account.
A.D. (*Anno Domini*), In the year of our Lord.
A.E.I.O.U. Austriæ est imperare orbi universo,[3] *or* Alles Erdreich Ist Oesterreich Unterthan.
Æt. *or* Ætat. (*Ætatis* [*anno*]), In the year of his age.
A.H. (*Anno Hegiræ*), In the year of the Hegira (the Mohammedan era).
A.M. (*Anno Mundi*), In the year of the world.
A.M. (*Ante meridiem*), Forenoon.
Anon. Anonymous.
A.U.C. (*Anno urbis conditæ*), In the year from the building of the city (*i.e.*, Rome.)
B.C. Before Christ.
C. *or* Cap. (*Caput*), Chapter.
C. Centigrade (*or* Celsius's) Thermometer.
cent.[4] (*Centum*), A hundred, *frequently* £100.
Cf. (*Confer*), Compare.
Ch. *or* Chap. Chapter.
Co. Company. County.
Cr. Creditor.
curt. Current, the present month.
D.G. (*Dei gratia*), By the grace of God.
Do. Ditto, the same.
D.O.M. (*Deo Optimo Maximo*), To God the Best and Greatest.
Dr. Debtor.
D.V. (*Deo volente*), God willing.

[1] Characters, not properly abbreviations, are used in the same way; *e.g.*, ° ′ ″ for "degrees, minutes, seconds," (circular measure); ℥, ʒ, ℈ for "ounces, drachms, scruples." ℥ is probably to be traced to the written form of the *z* in "*oz.*"

[2] These forms (as well as $, the symbol for the American dollar) are placed before their amounts.

[3] *It is given to Austria to rule the whole earth.* The device of Austria, first adopted by Frederick III.

[4] "Per cent." is often signified by °/₀, a form traceable to "100."

e.g. (*Exempli gratia*), For example.
etc. *or* &c. (*Et cætera*), And the rest; and so forth.
Ex. Example.
F. *or* Fahr. Fahrenheit's Thermometer.
Fec. (*Fecit*), He made (*or* did) it.
fl. Flourished.
Fo. *or* Fol. Folio.
f.o.b. Free on board.
G.P.O. General Post Office.
H.M.S. Her Majesty's Ship.
Ib. *or* Ibid. (*Ibidem*), In the same place.
Id. (*Idem*), The same.
i.e. (*Id est*), That is.
I.H.S. (*Jesus Hominum Salvator*), Jesus the Saviour of men.
Inf. (*Infra*), Below.
inst. Instant, the present month.
I.O.U. I owe you.
i.q. (*Idem quod*), The same as.
κ.τ.λ. (*καὶ τὰ λοιπά*), *Et cætera*, and the rest.
L. *or* Lib. (*Liber*), Book.
Lat. Latitude.
l.c. (*Loco citato*), In the place cited.
Lon. *or* Long. Longitude.
L.S. (*Locus sigilli*), The place of the seal.
Mem. (*Memento*), Remember, Memorandum.
MS. Manuscript. MSS. Manuscripts.
N.B. (*Nota bene*), Mark well; take notice.
N.B. North Britain (*i.e.*, Scotland).
N.D. No date.
nem. con. (*Nemine contradicente*), No one contradicting.
No. (*Numero*), Number.
N.S. New Style.
N.T. New Testament.
ob. (*Obiit*), Died.
Obs. Obsolete.
O.H.M.S. On Her Majesty's Service.
O.S. Old Style.
O.T. Old Testament.
P. Page. Pp. Pages.
℔. (*Per*), For; *e.g.*, ℔ lb., For one pound.
Pinx. (*Pinxit*), He painted it.
P.M. (*Post meridiem*), Afternoon.
P.O. Post Office. P.O.O. Post Office Order.
P.P.C. (*Pour prendre congé*), To take leave.
P.R. Prize-ring.
prox. (*Proximo* [*mense*]), Next month.
P.S. Postscript.
Pt. Part.
p.t. *or* pro. tem. (*Pro tempore*), For the time.
P.T.O. Please turn over.
Q., Qu., *or* Qy. Query; Question.
q.d. (*Quasi dicat*), As if he should say; as much as to say.
Q.E.D. (*Quod erat demonstrandum*), which was to be demonstrated.
Q.E.F. (*Quod erat faciendum*), which was to be done.
q.s. *or* quant. suff. (*Quantum sufficit*), As much as is sufficient.
q.v. (*Quod vide*), Which see.
R. *or* ℞. (*Recipe*), Take.
√ (= *r.* for *radix*), the sign of the square root.
R.I.P. (*Requiescat in pace!*), May he rest in peace!
sc. (*Scilicet*), Namely; that is to say.
Sc. *or* Sculp. (*Sculpsit*), He engraved it.
S.D.U.K. Society for the Diffusion of Useful Knowledge.
seq. *or* sq., seqq. *or* sqq. (*Sequens, sequentia*), The following.
s.p. (*Sine prole*), Without offspring.
S.P.G. Society for the Propagation of the Gospel.
Sup. (*Supra*), Above.
s.v. (*Sub voce*), Under the word (*or* heading).
T.C.D. Trinity College, Dublin.
ult. (*Ultimo* [*mense*]), Last month.
U.S. United States.
v. (*Versus*), Against.
v. *or* vid. (*Vide*), See.
viz. (*Videlicet*), Namely.
V. R. (*Victoria Regina*), Victoria the Queen.
Xmas. Christmas [*This X is a Greek letter, corresponding to* Ch].

(See Grævius's *Thesaurus Antiquitatum*, 1694, *sqq.*; Nicolai's *Tractatus de Siglis Veterum*; Mommsen's *Corpus Inscriptionum Latinarum*, 1863, *sqq.*; Natalis de Wailly's *Paléographie*, Paris, 1838; Alph. Chassant's *Paléographie*, 1854, and *Dictionnaire des Abréviations*, 3d ed., 1866. A manual of the abbreviations in current use is a desideratum.)

ABBREVIATORS, a body of writers in the Papal Chancery, whose business is to sketch out and prepare in due form the Pope's bulls, briefs, and consistorial decrees.

They are first mentioned in a bull of Benedict XII, early in the 14th century. Their number is fixed at seventy-two, of whom twelve, distinguished as *de parco majori*, hold prelatic rank; twenty-two, *de parco minori*, are clergymen of lower rank; and the remainder, *examinatores*, may be laymen.

ABDALLATIF, or ABD-UL-LATIF, a celebrated physician and traveller, and one of the most voluminous writers of the East, was born at Baghdad in 1162. An interesting memoir of Abdallatif, written by himself, has been preserved with additions by Ibn-Abu-Osaiba, a contemporary. From that work we learn that the higher education of the youth of Baghdad consisted principally in a minute and careful study of the rules and principles of grammar, and in their committing to memory the whole of the Koran, a treatise or two on philology and jurisprudence, and the choicest Arabian poetry. After attaining to great proficiency in that kind of learning, Abdallatif applied himself to natural philosophy and medicine. To enjoy the society of the learned, he went first to Mosul (1189), and afterwards to Damascus, the great resort of the eminent men of that age. The chemical fooleries that engrossed the attention of some of these had no attraction for him, but he entered with eagerness into speculative discussions. With letters of recommendation from Saladin's vizier, he visited Egypt, where the wish he had long cherished to converse with Maimonides, "the Eagle of the Doctors," was gratified. He afterwards formed one of the circle of learned men whom Saladin gathered around him at Jerusalem, and shared in the great sultan's favours. He taught medicine and philosophy at Cairo and at Damascus for a number of years, and afterwards, for a shorter period, at Aleppo. His love of travel led him in his old age to visit different parts of Armenia and Asia Minor, and he was setting out on a pilgrimage to Mecca when he died at Baghdad in 1231. Abdallatif was undoubtedly a man of great knowledge and of an inquisitive and penetrating mind, but is said to have been somewhat vain of his attainments. Of the numerous works—most of them on medicine—which Osaiba ascribes to him, one only, the *Account of Egypt*, appears to be known in Europe. The manuscript of this work, which was discovered by Pococke the Orientalist, is preserved in the Bodleian Library. It was translated into Latin by Professor White of Oxford in 1800, and into French, with very valuable notes, by De Sacy in 1810. It consists of two parts: the first gives a general view of Egypt; the second treats of the Nile, and contains a vivid description of a famine caused, during the author's residence in Egypt, by the river failing to overflow its banks. The work gives an authentic detailed account of the state of Egypt during the middle ages.

ABD-EL-KADER, celebrated for his brave resistance to the advance of the French in Algeria, was born near Mascara, in the early part of the year 1807. His father was a man of great influence among his countrymen from his high rank and learning, and Abd-el-Kader himself at an early age acquired a wide reputation for wisdom and piety, as well as for skill in horsemanship and other manly exercises. In 1831 he was chosen Emir of Mascara, and leader of the combined tribes in their attempt to check the growing power of the French in Africa. His efforts were at first successful, and in 1834 he concluded a treaty with the French general, which was very favourable to his cause. This treaty was broken in the succeeding year; but as the war that followed was mainly in favour of the Arabs, peace was renewed in 1837. War again broke out in 1839, and for more than a year was carried on in a very desultory manner. In 1841, however, Marshal Bugeaud assumed the chief command of the French force, which numbered nearly 100,000 men. The war was now carried on with great vigour, and Abd-el-Kader, after a most determined resistance, surrendered himself to the Duc d'Aumale, on the 22d December 1847. The promise, that he would be allowed to retire to Alexandria or St Jean d'Acre, upon the faith of which Abd-el-Kader had given himself up, was broken by the French government. He was taken to France, and was imprisoned first in the castle of Pau, and afterwards in that of Amboise. In 1852 Louis Napoleon gave him his liberty on condition of his not returning to Algeria. Since then he resided successively at Broussa, Constantinople, and Damascus. He is reported to have died at Mecca in October 1873. See ALGERIA.

ABDERA (1.), in *Ancient Geography*, a maritime town of Thrace, eastward from the mouth of the river Nestus. Mythology assigns the founding of the town to Hercules; but Herodotus states that it was first colonised by Timesias of Clazomenæ, whom the Thracians in a short time expelled. Rather more than a century later (B.C. 541), the people of Seos recolonised Abdera. The town soon became one of considerable importance, and in B.C. 408, when it was reduced by Thrasybulus the Athenian, it is described as in a very flourishing condition. Its prosperity was greatly impaired by its disastrous war with the Triballi (*circa* B.C. 376), and very little is heard of it thereafter. The Abderitæ, or Abderitani, were proverbial for their want of wit and judgment; yet their city gave birth to several eminent persons, as Protagoras, Democritus, and Anaxarchus the philosophers, Hecatæus the historian, Nicænetus the poet, and others.

ABDERA (2.), a town in *Hispania Bætica*, founded by the Carthaginians, on the south coast, between *Malaca* and *Prom. Charidemi*. It is probably represented by the modern Adra.

ABDICATION, the act whereby a person in office renounces and gives up the same before the expiry of the time for which it is held. The word is seldom used except in the sense of surrendering the supreme power in a state. Despotic sovereigns are at liberty to divest themselves of their powers at any time, but it is otherwise with a limited monarchy. The throne of Great Britain cannot be lawfully abdicated unless with the consent of the two Houses of Parliament. When James II., after throwing the Great Seal into the Thames, fled to France in 1688, he did not formally resign the crown, and the question was discussed in Parliament whether he had forfeited the throne or had abdicated. The latter designation was agreed on, for in a full assembly of the Lords and Commons, met in convention, it was resolved, in spite of James's protest, "that King James II. having endeavoured to subvert the constitution of the kingdom, by breaking the original contract between king and people, and, by the advice of Jesuits and other wicked persons, having violated the fundamental laws, and having withdrawn himself out of this kingdom, has abdicated the government, and that the throne is thereby vacant." The Scotch Parliament pronounced a decree of forfeiture and deposition. Among the most memorable abdications of antiquity may be mentioned that of Sulla the dictator, B.C. 79, and that of the Emperor Diocletian, A.D. 305. The following is a list of the more important abdications of later times:—

	A.D.
Benedict IX., Pope,	1048
Stephen II. of Hungary,	1131
Albert (the Bear) of Brandenburg,	1169
Ladislaus III., Duke of Poland,	1207
John Balliol of Scotland,	1296
John Cantacuzene, Emperor of the East,	1355
John XXIII., Pope,	1415
Eric VII. of Denmark and XIII. of Sweden,	1439
Amurath II., Ottoman Emperor,	1444 and 1445
Charles V., Emperor,	1556
Christina of Sweden,	1654
John Casimir of Poland,	1668
James II. of England,	1688
Frederick Augustus of Poland	1706

		A.D.
Philip V. of Spain,		1724
Victor Amadeus II. of Sardinia,		1730
Achmet III., Ottoman Emperor,		1730
Charles of Naples (on accession to throne of Spain),		1759
Stanislaus II. of Poland,		1795
Charles Emanuel IV. of Sardinia,	June 4,	1802
Charles IV. of Spain,	Mar. 19,	1808
Joseph Bonaparte of Naples,	June 6,	1808
Gustavus IV. of Sweden,	Mar. 29,	1809
Louis Bonaparte of Holland,	July 2,	1810
Napoleon of France,	April 4, 1814, and June 22,	1815
Victor Emanuel of Sardinia,	Mar. 13,	1821
Charles X. of France,	Aug. 2,	1830
Pedro of Brazil,[1]	April 7,	1831
Don Miguel of Portugal,	May 26,	1834
William I. of Holland,	Oct. 7,	1840
Louis Philippe of France,	Feb. 24,	1848
Louis Charles of Bavaria,	Mar. 21,	1848
Ferdinand of Austria,	Dec. 2,	1848
Charles Albert of Sardinia,	Mar. 23,	1849
Leopold II. of Tuscany,	July 21,	1859
Isabella II. of Spain,	June 25,	1870
Amadeus I. of Spain,	Feb. 11,	1873

ABDOMEN, in *Anatomy*, the lower part of the trunk of the body, situated between the thorax and the pelvis. See Anatomy.

ABDOMINALES, or Abdominal Fishes, a sub-division of the Malacopterygious Order, whose ventral fins are placed behind the pectorals, under the abdomen. The typical abdominals are carp, salmon, herring, silures, and pike.

ABDUCTION, a law term denoting the forcible or fraudulent removal of a person, limited by custom to the case where a woman is the victim. In the case of men or children, it has been usual to substitute the term Kidnapping (*q.v.*) The old severe laws against abduction, generally contemplating its object as the possession of an heiress and her fortune, have been repealed by 24 and 25 Vict. c. 100, s. 53, which makes it felony for any one from motives of lucre to take away or detain against her will, with intent to marry or carnally know her, &c., any woman of any age who has any interest in any real or personal estate, or is an heiress presumptive, or co-heiress, or presumptive next of kin to any one having such an interest; or for any one to cause such a woman to be married or carnally known by any other person; or for any one with such intent to allure, take away, or detain any such woman under the age of twenty-one, out of the possession and against the will of her parents or guardians. By s. 54, forcible taking away or detention against her will of any woman of any age with like intent is felony. Even without such intent, abduction of any unmarried girl under the age of sixteen is a misdemeanour. In Scotland, where there is no statutory adjustment, abduction is similarly dealt with by practice.

ABDUL MEDJID, Sultan of Turkey, the thirty-first sovereign of the house of Othman, was born April 23, 1823, and succeeded his father Mahmoud II. on the 2d of July 1839. Mahmoud appears to have been unable to effect the reforms he desired in the mode of educating his children, so that his son received no better education than that given, according to use and wont, to Turkish princes in the harem. When Abdul Medjid succeeded to the throne, the affairs of Turkey were in an extremely critical state. At the very time his father died, the news was on its way to Constantinople that the Turkish army had been signally defeated at Nisib by that of the rebel Egyptian viceroy, Mehemet Ali; and the Turkish fleet was at the same time on its way to Egypt, to be surrendered perfidiously by its commander to the same enemy. But through the intervention of the great European powers, Mehemet Ali was obliged to come to terms, and the Ottoman empire was saved. In compliance with his father's express instructions, Abdul Medjid set at once about carrying out the extensive reforms to which Mahmoud had so energetically devoted himself. In November 1839 was proclaimed an edict, known as the Hatti-sherif of Gulhané, consolidating and enforcing these reforms, which was supplemented, at the close of the Crimean war, by a similar statute, issued in February 1856. By these enactments it was provided that all classes of the sultan's subjects should have security for their lives and property; that taxes should be fairly imposed and justice impartially administered; and that all should have full religious liberty and equal civil rights. The scheme was regarded as so revolutionary by the aristocracy and the educated classes (the Ulema) that it met with keen opposition, and was in consequence but partially put in force, especially in the remoter parts of the empire; and more than one conspiracy was formed against the sultan's life on account of it. Of the other measures of reform promoted by Abdul Medjid the more important were—the reorganisation of the army (1843–4), the institution of a council of public instruction (1846), the abolition of an odious and unfairly imposed capitation tax, the repression of slave trading, and various provisions for the better administration of the public service and for the advancement of commerce. The public history of his times—the disturbances and insurrections in different parts of his dominions throughout his reign, and the great war successfully carried on against Russia by Turkey, and by England, France, and Sardinia, in the interest of Turkey (1853–56)—can be merely alluded to in this personal notice. When Kossuth and others sought refuge in Turkey, after the failure of the Hungarian rising in 1849, the sultan was called on by Austria and Russia to surrender them, but boldly and determinedly refused. It is to his credit, too, that he would not allow the conspirators against his own life to be put to death. He bore the character of being a kind and honourable man. Against this, however, must be set down his excessive extravagance, especially towards the end of his life. He died on the 25th of June 1861, and was succeeded, not by one of his sons, but by his brother, Abdul Aziz, the present sultan, as the oldest survivor of the family of Othman.

A BECKET, Thomas, Archbishop of Canterbury and Chancellor of England in the 12th century, was born in London on the 21st of December 1118. His father, Gilbert Becket, and his mother Roesa or Matilda, were both, there can be little doubt, of Norman extraction, if indeed they themselves were not immigrants from Normandy to England. Gilbert Becket, a merchant, and at one time Sheriff of London, a man of generous impulses and somewhat lavish hospitality, provided for his only child Thomas all the attainable advantages of influential society and a good education. At ten years of age Thomas was placed under the tuition of the canons regular of Merton on the Wandle in Surrey. From Merton he proceeded to study in the London schools, then in high repute. At Pevensey Castle, the seat of his father's friend Richer de l'Aigle, one of the great barons of England, he subsequently became a proficient in all the feats and graces of chivalry. From Pevensey he betook himself to the study of theology in the University of Paris. He never became a scholar, much less a theologian, like Wolsey, or even like some of the learned ecclesiastics of his own day; but his intellect was vigorous and original, and his manners captivating to his associates and popular with the multitude. His father's failure in business recalled him to London, and for three years he acted as a clerk in a lawyer's office. But a man so variously accomplished could not fail to stumble on preferment sooner or later. Accordingly, about 1142, Archdeacon Baldwin, a learned civilian, a friend of the elder Becket, introduced him to Theobald, Archbishop of

[1] Pedro had succeeded to the throne of Portugal in 1826, but abdicated it at once in favour of his daughter.

Canterbury, who at once appointed him to an office in the Archiepiscopal Court. His talents speedily raised him to the archdeaconry of the see. À Becket's tact in assisting to thwart an attempt to interest the Pope in favour of the coronation of Stephen's son Eustace, paved the way to the archdeacon's elevation to the Chancellorship of England under Henry II., a dignity to which he was raised in 1155. As he had served Theobald the archbishop, so he served Henry the king faithfully and well. It was his nature to be loyal. Enthusiastic partisanship is, in fact, the key to much that is otherwise inexplicable in his subsequent conduct towards Henry. When at a later period À Becket was raised to the primacy of England, a dignity not of his own seeking, he must needs quarrel with Henry in the interest of the Pope and "for the honour of God." As Chancellor of England he appeared in the war of Toulouse at the head of the chivalry of England, and "who can recount," says his attendant and panegyrist Grim, "the carnage, the desolation he made at the head of a strong body of soldiers? He attacked castles, and razed towns and cities to the ground; he burned down houses and farms, and never showed the slightest touch of pity to any one who rose in insurrection against his master." In single combat he vanquished and made prisoner the valiant Knight Engelram de Trie. Nor did À Becket the chancellor seek to quell Henry's secular foes alone. He was the able mouthpiece of the Crown in its contention with the Bishop of Chichester, who had alleged that the permission of the Pope was necessary to the conferring or taking away of ecclesiastical benefices; and he rigorously exacted *scutage*, a military tax in lieu of personal service in the field, from the clergy, who accused him of "plunging a sword into the bosom of his mother the church." His pomp and munificence as chancellor were beyond precedent. In 1159 he undertook, at Henry's request, an embassy to the French Court for the purpose of affiancing the king's eldest son to the daughter of the king of France. His progress through the country was like a triumphal procession. "How wonderful must be the king of England himself whose chancellor travels in such state!" was on every one's lips. In 1162 he was elected Archbishop of Canterbury, Gilbert Foliot, Bishop of Herford, alone dissenting, and remarking sarcastically, at the termination of the ceremony, that "the king had worked a miracle in having that day turned a layman into an archbishop and a soldier into a saint." Hitherto À Becket had only been in deacon's orders, and had made no profession of sanctity of life. At the same time, there is nothing to show that his character was stained by the gross licentiousness of the times. Now, however, he devoted himself body and soul to the service of the church. The fastidious courtier was at once transformed into the squalid penitent, who wore hair-cloth next his skin, fed on roots, drank nauseous water, and daily washed the feet of thirteen beggars. Henry, who had expected to see the archbishop completely sunk in the chancellor, was amazed to receive the following laconic message from À Becket:—"I desire that you will provide yourself with another chancellor, as I find myself hardly sufficient for the duties of one office, much less of two." From that moment there was strife between À Becket and Henry, À Becket straining every nerve to extend the authority of the Pope, and Henry doing his utmost to subject the church to his own will. Throughout the bitter struggle for supremacy which ensued between À Becket and the king, À Becket was backed by the sympathy of the Saxon populace, Henry by the support of the Norman barons and by the greater dignitaries of the church. At the outset À Becket was worsted. He was constrained to take an oath, "with good faith and without fraud or reserve, to observe the Constitutions of Clarendon," which subjected clerks guilty of crime to the ordinary civil tribunals, put ecclesiastical dignities at the royal disposal, prevented all appeals to Rome, and made Henry the virtual "head of the church." For his guilty compliance with these anti-papal constitutions he received the special pardon and absolution of his holiness, and proceeded to anathematise them with the energy of a genuine remorse. The king resolved on his ruin. He was summoned before a great council at Northampton, and in defiance of justice was called on to account for the sum of 44,000 marks declared to have been misappropriated by him during his chancellorship. "For what happened before my consecration," said À Becket, "I ought not to answer, nor will I. Know, moreover, that ye are my children in God; neither law nor reason allows you to judge your father. I refer my quarrel to the decision of the Pope. To him I appeal, and shall now, under the protection of the Catholic Church and the Apostolic See, depart." He effected his escape to France, and took refuge in the Cistercian monastery of Pontigny, whence he repeatedly anathematised his enemies in England, and hesitated not to speak of Henry as a "malicious tyrant." Pope Alexander III., though at heart a warm supporter of Becket, was guarded in his conduct towards Henry, who had shown a disposition to support the anti-pope Pascal III., and it was not till the Archbishop of York, in defiance of a papal bull, had usurped the functions of the exiled primate by officiating at the coronation of Henry's son, that Alexander became really formidable. À Becket was now resolute for martyrdom or victory. Henry began to tremble, and an interview between him and Becket was arranged to take place at Fereitville in 1170. It was agreed that À Becket should return to his see, and that the king should discharge his debts and defray the expenses of his journey. À Becket proceeded to the coast, but the king, who had promised to meet him, broke his engagement in every particular. À Becket, in retaliation, excommunicated the Archbishop of York and the Bishops of London and Salisbury for officiating at the coronation of the king's son. The terrified prelates took refuge in Normandy with Henry, who, on hearing their tale, accompanied by an account of À Becket's splendid reception at Canterbury, exclaimed in ungovernable fury, "Of the cowards who eat my bread, is there not one who will free me from this turbulent priest?" Four knights, Fitzurse, Tracy, Morville, and Brito, resolved to avenge their sovereign, who it appears was ignorant of their intention. They arrived in Canterbury, and finding the archbishop, threatened him with death if he would not absolve the excommunicated bishops. "In vain," replied À Becket, "you threaten me. If all the swords in England were brandishing over my head, your terrors could not move me. Foot to foot you will find me fighting the battle of the Lord." He was barbarously murdered in the great cathedral, at the foot of the altar of St Benedict, on the 29th December 1170. Two years thereafter he was canonised by the Pope; and down to the Reformation innumerable pilgrimages were made to the shrine of St Thomas of Canterbury by devotees from every corner of Christendom. So numerous were the miracles wrought at his tomb, that Gervase of Canterbury tells us two large volumes kept in the cathedral were filled with accounts of them. Every fiftieth year a jubilee was celebrated in his honour, which lasted fifteen days; plenary indulgences were then granted to all who visited his tomb; and as many as 100,000 pilgrims were registered at a time in Canterbury. The worship of St Thomas superseded the adoration of God, and even that of the Virgin. In one year there was offered at God's altar nothing; at that of the Virgin £4, 1s. 8d.; while St Thomas received for his share £954, 6s. 3d.—an enormous sum, if the purchasing power of money in those times be considered. Henry VIII., with a just if somewhat ludicrous appreciation of the issue which À Becket had raised with his royal predecessor Henry II., not only pillaged the rich shrine dedicated to St Thomas, but caused the saint himself to be cited to appear in court, and to be tried and condemned as a traitor, at the same time ordering his name to be struck out of the calendar, and his bones to be burned and the ashes thrown in the air. À Becket's character and aims have been the subject of the keenest ecclesiastical and historic controversy down to the present time, but it is impossible to doubt the fundamental sincerity of the one or the disinterestedness of the other, however inconsistent his actions may sometimes appear. If the fruit of the Spirit be "love, joy, peace, long-suffering, gentleness, goodness, faith, meekness, and temperance," À Becket was assuredly not a saint, for he indulged to the last in the bitterest invectives against his foes; but that he fought with admirable courage and devotion the "battle of the Lord," according to the warlike ideas of an age with which he was in intense sympathy, is beyond dispute. He was the leading Ultramontane of his day, hesitating not to reprove the Pope himself for lukewarmness in the cause of the "church's liberty." He was the last of the great ecclesiastics of the type of Lanfranc and Anselm, who struggled for supremacy with the civil power in England on almost equal terms. In his day the secular stream was running very strong, and he might as chancellor have floated down the current pleasantly enough, governing England in Henry's name. He nevertheless perished in a chivalrous effort to stem the torrent. The tendency of his principles was to supersede a civil by a spiritual despotism; "but, in point of fact," says Hook, in his valuable Life, "he was a high-principled, high-spirited demagogue, who taught the people to struggle for their liberties," a struggle soon to commence, and of which he was by no means an impotent if an unconscious precursor.—See Dr Giles's *Vita et Epistolæ S. Thomæ Cantuariensis;* Canon Morris's *Life of St Thomas Becket;* Canon Robertson's *Life of Becket;* Canon Stanley's *Historical Memorials of Canterbury;* J. G. Nichol's *Pilgrimages of Walsingham and Canterbury;* Hook's *Lives of the Archbishops of Canterbury;* and Lord Campbell's *Lives of the Chancellors of England.*

A'BECKETT, Gilbert Abbott, a successful cultivator of light literature, was born in London in 1811, and educated at Westminster School. He wrote burlesque dramas with success from his boyhood, took an active share in the establishment of different comic periodicals, particularly *Figaro in London* and *Punch*, and was a constant contributor to the columns of the latter from its commencement till the time of his death. His principal publications, all overflowing with kindly humour, and rich in quaint fancies, are his parodies of living dramatists (himself included), reprinted from *Punch* (1844); *The Small Debts Act, with Annotations and Explanations* (1845); *The Quizziology of the British Drama* and *The Comic Blackstone* (1846); *A Comic History of England* (1847); and *A Comic History of Rome* (1852). He contributed occasionally, too, to the *Times* and other metropolitan papers. A'Beckett was called to the bar in 1841, and from 1849 discharged with great efficiency the duties of a metropolitan police magistrate. He died at Boulogne on the 30th of August 1856.

ABEL (הֶבֶל, *breath, vanity, transitoriness*), the second son of Adam, slain by Cain his elder brother (Gen. iv 1–16). The narrative in Genesis, which tells us that "the Lord had respect unto Abel and to his offering, but unto Cain and to his offering he had not respect," is supplemented by the statement of the New Testament, that "by faith Abel offered unto God a more excellent sacrifice than Cain," (Heb. xi. 4), and that Cain slew Abel "because his own works were evil and his brother's righteous" (1 John iii. 12). In patristic theology the striking contrast between the brothers was mystically explained and typically applied in various ways. Augustine, for example, regards Abel as the representative of the regenerate or spiritual man, and Cain as the representative of the natural or corrupt man. Augustine in his treatise *De Hæresibus*, c. 86, mentions a sect of *Abelitae* or Abelians, who seem to have lived in North Africa, and chiefly in the neighbourhood of Hippo-Regius. According to their tradition, Abel, though married, lived in continence, and they followed his practice in this respect, so as to avoid the guilt of bringing sinful creatures into the world.

ABEL, Karl Friedrich (1726–1787), a celebrated German musician. His adagio compositions have been highly praised, but he attained greater distinction as a performer than as a composer, his instrument being the *Viola di gamba*, which from his time has given place to the violoncello. He studied under Sebastian Bach, played for ten years (1748–58) in the band formed at Dresden by the Elector of Saxony, under Hasse, and then, proceeding to England, became (1759) chamber-musician to the queen of George III. His life was shortened by habits of intemperance.

ABEL, Niels Henrik, one of the ablest and acutest mathematicians of modern times, was born at Findöe in Norway in 1802, and died near Arendal in 1829. Considering the shortness of his life, the extent and thoroughness of his mathematical investigations and analyses are marvellous. His great powers of generalisation were displayed in a remarkable degree in his development of the theory of elliptic functions. Legendre's eulogy of Abel, "Quelle tête celle du jeune Norvegien!" is the more forcible, that the French mathematician had occupied himself with those functions for most of his lifetime. Abel's works, edited by M. Holmboe, the professor under whom he studied at Christiania, were published by the Swedish government in 1839.

ABEL, Thomas, a Roman Catholic divine during the reign of Henry VIII., was an Englishman, but when or where born does not appear. He was educated at Oxford, where he passed B.A. on 4th July 1513, M.A. on 27th June 1516, and proceeded D.D. On 23d June 1530 he was presented by Queen Catherine to the rectory of Bradwell in Essex, on the sea-coast. He had been introduced to the court through the report of his learning in classical and living languages, and accomplishments in music; and he was appointed domestic chaplain to Queen Catherine. It speaks well both for the chaplain and his royal mistress, that to the last he defended the outraged queen against "bluff King Hal." The *Defence*, "*Invicta Veritas*," was printed at Luneberge in 1532. This pungent little book was replied to, but never answered, and remains *the* defence on Queen Catherine's part. Abel was ensnared, as greater men were, in the prophetic delusions and ravings of Elizabeth Barton, called the "Holy Maid of Kent." As belonging to the Church of Rome, he inevitably opposed Henry VIII.'s assumption of supremacy in the church. Ultimately he was tried and condemned for "misprision of treason," and perished in the usual cruel and ignoble way. The execution, as described, took place at Smithfield on July 30, 1540. If we may not concede the venerable and holy name of martyr to Abel—and John Foxe is passionate in his refusal of it—yet we must hold that he at least fell a victim to his unsparing defence of his queen and friend, the "misprision of treason" having been a foregone conclusion. In stat. 25, Henry VIII., c. 12, he is described as having "caused to be printed and set forth in this realme diverse books against the divorce and separation." Neither the *Tractatus* nor the "diverse books" are known.—Dodd, *Church History*, Brussels, 1737, folio, vol. i. p. 208; Bourchier, *Hist. Eccl.*

ABELARD, Peter, born at Pallet (Palais), not far from Nantes, in 1079, was the eldest son of a noble Breton house. The name *Abælardus* (also written *Abailardus*, *Abaielardus*, and in many other ways) is said to be a corruption of *Habelardus*, substituted by himself for a nickname *Bajolardus* given to him when a student. As a boy, he showed an extraordinary quickness of apprehension, and, choosing a learned life instead of the active career natural to a youth of his birth, early became an adept in the art of dialectic, under which name philosophy, meaning at that time chiefly the logic of Aristotle transmitted through Latin channels, was the great subject of liberal study in the episcopal schools. Roscellin, the famous canon of Compiègne, is mentioned by himself as his teacher; but whether he heard this champion of extreme Nominalism in early youth, when he wandered about from school to school for instruction and exercise, or some years later, after he had already begun to teach for himself, remains uncertain. His wanderings finally brought him to Paris, still under the age of twenty. There, in the great cathedral school of Notre-Dame, he sat for a while under the teaching of William of Champeaux, the disciple of St Anselm and most advanced of Realists, but, presently stepping forward, he overcame the master in discussion, and thus began a long duel that issued in the downfall of the philosophic theory of Realism, till then dominant in the early Middle Age. First, in the teeth of opposition from the metropolitan teacher, he proceeded to set up a school of his own at Melun, whence, for more direct competition, he removed to Corbeil, nearer Paris. The success of his teaching was signal, though for a time he had to quit the field, the strain proving too great for his physical strength. On his return, after 1108, he found William lecturing no longer at Notre-Dame, but in a monastic retreat outside the city, and there battle was again joined between them. Forcing upon the Realist a material change of doctrine, he was once more victorious, and thenceforth he stood supreme. His discomfited rival still had power to keep him from lecturing in Paris, but soon failed in this last effort also. From Melun, where he had resumed teaching, Abelard passed to the capital, and set up his school on the heights of St Geneviève, looking over Notre-Dame. When he had increased his distinction still further by winning reputation in the theological school of Anselm of Laon, no other conquest remained for him. He stepped into the chair at Notre-Dame, being also nominated canon, about the year 1115.

Few teachers ever held such sway as Abelard now did for a time. Distinguished in figure and manners, he was seen surrounded by crowds—it is said thousands—of students, drawn from all countries by the fame of his teaching, in which acuteness of thought was relieved by simplicity and grace of exposition. Enriched by the offerings of his pupils, and feasted with universal admiration, he came, as he says, to think himself the only philosopher standing in the world. But a change in his fortunes was at hand. In his devotion to science, he had hitherto lived a very regular life, varied only by the excitement of conflict: now, at the height of his fame, other passions began to stir within him. There lived at that time, within the precincts of Notre-Dame, under the care of her uncle, the canon Fulbert, a young girl named Heloise, of noble extraction and born about 1101. Fair, but still more remarkable for her knowledge, which extended beyond Latin, it is said, to Greek and Hebrew, she awoke a feeling of love in the breast of Abelard; and with intent to win her, he sought and gained a footing in Fulbert's house as a regular inmate. Becoming also tutor to the maiden, he used the unlimited power which he thus obtained over her for the purpose of seduction, though not without cherishing a real affection which she returned in unparalleled devotion. Their relation interfering with his public work, and being, moreover, ostentatiously sung by himself, soon became known to all the world except the too-confiding Fulbert; and, when at last it could not escape even his vision, they were separated only to meet in secret. Thereupon Heloise found herself pregnant, and was carried off by her lover to Brittany, where she gave birth to a son. To appease her furious uncle, Abelard now proposed a marriage, under the condition that it should be kept secret, in order not to mar his prospects of advancement in the church; but of marriage, whether public or secret, Heloise would hear nothing. She appealed to him not to sacrifice for her the independence of his life, nor did she finally yield to the arrangement without the darkest forebodings, only too soon to be realised. The secret of the marriage was not kept by Fulbert; and when Heloise, true to her singular purpose, boldly then denied it, life was made so unsupportable to her that she sought refuge in the convent of Argenteuil. Immediately Fulbert, believing that her husband, who aided in the flight, designed to be rid of her, conceived a dire revenge. He and some others broke into Abelard's chamber by night, and, taking him defenceless, perpetrated on him the most brutal mutilation. Thus cast down from his pinnacle of greatness into an abyss of shame and misery, there was left to the brilliant master only the life of a monk. Heloise, not yet twenty, consummated her work of self-sacrifice at the call of his jealous love, and took the veil.

It was in the Abbey of St Denis that Abelard, now aged forty, sought to bury himself with his woes out of sight. Finding, however, in the cloister neither calm nor solitude, and having gradually turned again to study, he yielded after a year to urgent entreaties from without and within, and went forth to reopen his school at the Priory of Maisoncelle (1120). His lectures, now framed in a devotional spirit, were heard again by crowds of students, and all his old influence seemed to have returned; but old enmities were revived also, against which he was no longer able as before to make head. No sooner had he put in writing his theological lectures (apparently the *Introductio ad Theologiam* that has come down to us), than his adversaries fell foul of his rationalistic interpretation of the Trinitarian dogma. Charging him with the heresy of Sabellius in a provincial synod held at Soissons in 1121, they procured by irregular practices a condemnation of his teaching, whereby he was made to throw his book into the flames, and then was shut up in the convent of St Médard. After the other, it was the bitterest possible experience that could befall him, nor, in the state of mental desolation into which it plunged him, could he find any comfort from being soon again set free. The life in his own monastery proving no more congenial than formerly, he fled from it in secret, and only waited for permission to live away from St Denis before he chose the one lot that suited his present mood. In a desert place near Nogent-sur-Seine, he built himself a cabin of stubble and reeds, and turned hermit. But there fortune came back to him with a new surprise. His retreat becoming known, students flocked from Paris, and covered the wilderness around him with their tents and huts. When he began to teach again, he found consolation, and in gratitude he consecrated the new oratory they built for him by the name of the Paraclete

Upon the return of new dangers, or at least of fears, Abelard left the Paraclete to make trial of another refuge, accepting an invitation to preside over the Abbey of St Gildas-de-Rhuys, on the far-off shore of Lower Brittany. It proved a wretched exchange. The region was inhospitable, the domain a prey to lawless exaction, the house itself savage and disorderly. Yet for nearly ten years he continued to struggle with fate before he fled from his charge, yielding in the end only under peril of violent death. The misery of those years was not, however, unrelieved; for he had been able, on the breaking-up of Heloise's convent at Argenteuil, to establish her as head of a new religious house at the deserted Paraclete, and in the capacity of spiritual director he often was called to revisit the spot thus made doubly dear to him. All this time Heloise had lived amid universal esteem for her knowledge and character, uttering no word under the doom that had fallen upon her youth; but now, at last, the occasion came for expressing all the pent-up emotions of her soul. Living on for some time in Brittany after his flight from St Gildas, Abelard wrote, among other things, his famous *Historia Calamitatum*, and thus moved her to pen her first *Letter*, which remains an unsurpassed utterance of human passion and womanly devotion; the first being followed by the two other *Letters*, in which she finally accepted the part of resignation which, now as a brother to a sister, Abelard commended to her. He not long after was seen once more upon the field of his early triumphs, lecturing on Mount St Geneviève in 1136 (when he was heard by John of Salisbury), but it was only for a brief space: no new triumph, but a last great trial, awaited him in the few years to come of his chequered life. As far back as the Paraclete days, he had counted as chief among his foes Bernard of Clairvaux, in whom was incarnated the principle of fervent and unhesitating faith, from which rational inquiry like his was sheer revolt, and now this uncompromising spirit was moving, at the instance of others, to crush the growing evil in the person of the boldest offender. After preliminary negotiations, in which Bernard was roused by Abelard's steadfastness to put forth all his strength, a council met at Sens, before which Abelard, formally arraigned upon a number of heretical charges, was prepared to plead his cause. When, however, Bernard, not without foregone terror in the prospect of meeting the redoubtable dialectician, had opened the case, suddenly Abelard appealed to Rome. The stroke availed him nothing; for Bernard, who had power, notwithstanding, to get a condemnation passed at the council, did not rest a moment till a second condemnation was procured at Rome in the following year. Meanwhile, on his way thither to urge his plea in person, Abelard had broken down at the Abbey of Cluni, and there, an utterly fallen man, with spirit of the humblest, and only not bereft of his intellectual force, he lingered but a few months before the approach of death. Removed by friendly hands, for the relief of his sufferings, to the Priory of St Marcel, he died on the 21st of April 1142. First buried at St Marcel, his remains soon after were carried off in secrecy to the Paraclete, and given over to the loving care of Heloise, who in time came herself to rest beside them. The bones of the pair were shifted more than once afterwards, but they were marvellously preserved even through the vicissitudes of the French Revolution, and now they lie united in the well-known tomb at Père-Lachaise.

Great as was the influence exerted by Abelard on the minds of his contemporaries and the course of mediæval thought, he has been little known in modern times but for his connection with Heloise. Indeed, it was not till the present century, when Cousin in 1836 issued the collection entitled *Ouvrages inédits d'Abélard*, that his philosophical performance could be judged at first hand: of his strictly philosophical works only one, the ethical treatise *Scito te ipsum*, having been published earlier, namely, in 1721. Cousin's collection, besides giving extracts from the theological work *Sic et Non* (an assemblage of opposite opinions on doctrinal points, culled from the Fathers as a basis for discussion), includes the *Dialectica*, commentaries on logical works of Aristotle, Porphyry, and Boëthius, and a fragment, *De Generibus et Speciebus*. The last-named work, and also the psychological treatise *De Intellectibus*, published apart by Cousin (in *Fragmens Philosophiques*, vol. ii.), are now considered upon internal evidence not to be by Abelard himself, but only to have sprung out of his school. A genuine work, the *Glossulæ super Porphyrium*, from which M. de Rémusat, in his classical monograph *Abélard* (1845), has given extracts, remains in manuscript.

The general importance of Abelard lies in his having fixed more decisively than any one before him the scholastic manner of philosophising, with its object of giving a formally rational expression to the received ecclesiastical doctrine. However his own particular interpretations may have been condemned, they were conceived in essentially the same spirit as the general scheme of thought afterwards elaborated in the 13th century with approval from the heads of the church. Through him was prepared in the Middle Age the ascendency of the philosophical authority of Aristotle, which became firmly established in the half-century after his death, when first the completed *Organon*, and gradually all the other works of the Greek thinker, came to be known in the schools: before his time it was rather upon the authority of Plato that the prevailing Realism sought to lean. As regards the central question of Universals, without having sufficient knowledge of Aristotle's views, Abelard yet, in taking middle ground between the extravagant Realism of his master, William of Champeaux, or of St Anselm, and the not less extravagant Nominalism (as we have it reported) of his other master, Roscellin, touched at more than one point the Aristotelian position. Along with Aristotle, also with Nominalists generally, he ascribed full reality only to the particular concretes; while, in opposition to the "*insana sententia*" of Roscellin, he declared the Universal to be no mere word (*vox*), but to consist, or (perhaps we may say) emerge, in the fact of predication (*sermo*). Lying in the middle between Realism and (extreme) Nominalism, this doctrine has often been spoken of as Conceptualism, but ignorantly so. Abelard, preeminently a logician, did not concern himself with the psychological question which the Conceptualist aims at deciding as to the mental subsistence of the Universal. Outside of his dialectic, it was in ethics that Abelard showed greatest activity of philosophical thought; laying very particular stress upon the subjective intention as determining, if not the moral character, at least the moral value, of human action. His thought in this direction, wherein he anticipated something of modern speculation, is the more remarkable because his scholastic successors accomplished least in the field of morals, hardly venturing to bring the principles and rules of conduct under pure philosophical discussion, even after the great ethical inquries of Aristotle became fully known to them. (G. C. R.)

ABENCERRAGES, a family or faction that is said to have held a prominent position in the Moorish kingdom of Granada in the 15th century. The name appears to have been derived from the Yussuf ben-Serragh, the head of the tribe in the time of Mahommed VII., who did that sovereign good service in his struggles to retain the crown of which he was three times deprived. Nothing is known of the family with certainty; but the name is familiar from the interesting romance of Gines Perez de Hita, *Guerras civiles de Granada*, which celebrates the feuds of the Abencerrages and the rival family of the Zegris, and the cruel treatment to which the former were subjected. Florian's *Gonsalvo of Cordova*, and Chateaubriand's *Last of the Abencerrages*, are imitations of Perez de Hita's work. The hall of the Abencerrages in the Alhambra takes its name from being the reputed scene of the massacre of the family.

ABENEZRA, or IBN EZRA, is the name ordinarily given to ABRAHAM BEN MEIR BEN EZRA (called also *Abenare* or *Evenare*), one of the most eminent of the Jewish literati of the Middle Ages. He was born at Toledo about 1090; left Spain for Rome about 1140: resided afterwards at Mantua (1145), at Lucca (1154), at Rhodes (1155 and 1166), and in England (1159); and died probably in 1168. He was distinguished as a philosopher, astronomer, physician, and poet, but especially as a grammarian and commentator. The works by which he is best known form a series of *Commentaries* on the books of the Old Testament, which have nearly all been printed in the great Rabbinic Bibles of Bomberg (1525–6), Buxtorf (1618–9), and Frankfurter (1724–7). Abenezra's commentaries are acknowledged to be of very great value; he was the first who raised biblical exegesis to the rank of a science, interpreting the text according to its literal sense, and illustrating it from cognate languages. His style is elegant, but is so concise as to be sometimes obscure; and he occasionally indulges in epigram. In addition to the commentaries, he wrote several treatises on astronomy or astrology, and a number of grammatical works.

ABENSBERG, a small town of Bavaria, 18 miles S.W. of Regensburg, containing 1300 inhabitants. Here Napoleon gained an important victory over the Austrians on the 20th of April 1809. The town is the *Abusina* of the Romans, and ancient ruins exist in its neighbourhood.

ABERAVON, a parliamentary and municipal borough of Wales, in the county of Glamorgan, beautifully situated on the Avon, near its mouth, 8 miles east of Swansea. The town and adjacent villages have increased rapidly in recent years, from the extension of the mines of coal and iron in the vicinity, and the establishment of extensive works for the smelting of tin, copper, and zinc. The harbour, Port Talbot, has been much improved, and has good docks; and there is regular steam communication with Bristol. Ores for the smelting furnaces are imported from Cornwall, and copper, tin, and coal are exported. Aberavon unites with Swansea, Kenfigg, Loughor, and Neath, in returning a member to Parliament. In 1871 the population of the parish was 3396, of the parliamentary borough, 11,906.

ABERCONWAY. See CONWAY.

ABERCROMBIE, JOHN, an eminent physician of Edinburgh, was the son of the Rev. George Abercrombie of Aberdeen, in which city he was born in 1781. After attending the Grammar School and Marischal College, Aberdeen, he commenced his medical studies at Edinburgh in 1800, and obtained his degree of M.D. there in 1803. Soon afterwards he went to London, and for about a year gave diligent attention to the medical practice and lectures in St George's Hospital. In 1804 he returned to Edinburgh, became a Fellow of the College of Surgeons, and commenced as general practitioner in that city; where, in dispensary and private practice, he laid the foundation of that character for sagacity as an observer of disease, and judgment in its treatment, that eventually elevated him to the head of his profession. In 1823, he became a Licentiate of the College of Physicians; in 1824, a Fellow of that body; and from the death of Dr Gregory in 1822 he was considered the first physician in Scotland. Abercrombie early began the laudable practice of preserving accurate notes of the cases that fell under his care; and at a period when pathological anatomy was far too little regarded by practitioners in this country, he had the merit of sedulously pursuing it, and collecting a mass of most important information regarding the changes produced by disease on different organs; so that, before the year 1824, he had more extended experience, and more correct views in this interesting field, than most of his contemporaries engaged in extensive practice. From 1816 he occasionally enriched the pages of the *Edinburgh Medical and Surgical Journal* with essays, that display originality and industry, particularly those "on the diseases of the spinal cord and brain," and "on diseases of the intestinal canal, of the pancreas, and spleen." The first of these formed the basis of his great and very original work, *Pathological and Practical Researches on Diseases of the Brain and Spinal Cord*, which appeared at Edinburgh in 1828. In the same year he published also another very valuable work, his *Researches on the Diseases of the Intestinal Canal, Liver, and other Viscera of the Abdomen.* Though his professional practice was very extensive and lucrative, he found time for other speculations and occupations. In 1830 he published his *Inquiries concerning the Intellectual Powers of Man and the Investigation of Truth*, a work which, though less original and profound than his medical speculations, contains a popular view of an interesting subject, expressed in simple language. It was followed in 1833 by a sequel, *The Philosophy of the Moral Feelings*, the object of which, as stated in the preface, was "to divest the subject of all improbable speculations," and to show "the important relation which subsists between the science of mind and the doctrines of revealed religion." Both works have been very extensively read, reaching the 18th and 14th editions respectively in 1869. Soon after the publication of *Moral Feelings*, the University of Oxford conferred on the author the honorary degree of Doctor of Medicine, and in 1835 he was elected Lord Rector of Marischal College, Aberdeen. Dr Abercrombie was much beloved by his numerous friends for the suavity and kindness of his manners, and was universally esteemed for his benevolence and unaffected piety. He died on the 14th of November 1844 of a very uncommon disease, the bursting (from softening of the muscular substance) of the coronary vessels of the heart.

ABERCROMBY, DAVID, M.D. This Scottish physician was sufficiently noteworthy half a century after his (probable) decease to have his *Nova Medicinæ Praxis* reprinted at Paris in 1740; while during his lifetime his *Tuta ac efficax luis venereæ sæpe absque mercurio ac semper absque salivatione mercuriali curando methodus* (1684, 8vo) was translated into German and published at Dresden in 1702 (8vo). In 1685 were published *De Pulsus Variatione* (London; Paris, 1688, 12mo), and *Ars explorandi medicas facultates plantarum ex solo sap.* (London). His *Opuscula* were collected in 1687. These professional writings gave him a place and memorial in Haller's *Bibliotheca Medicinæ Pract.* (4 vols. 8vo, 1779, tom. iii. p. 619); but he claims passing remembrance rather as a metaphysician by his remarkable controversial books in theology and philosophy. Formerly a Roman Catholic and Jesuit, he abjured Popery, and published *Protestancy proved Safer than Popery* (London, 1686). But by far the most noticeable of his productions is *A Discourse of Wit* (London, 1685). This treatise somehow has fallen out of sight—much as old coined gold gets hidden away—so that bibliographers do not seem to have met with it, and assign it at hap-hazard to Patrick Abercromby, M.D. Notwithstanding, the most cursory examination of it proves that in this *Discourse of Wit* are contained some of the most characteristic and most definitely-put metaphysical opinions of the Scottish philosophy of common sense. Of this early metaphysician nothing biographically has come down save that he was a Scotchman ("Scotus")—born at Seaton. He was living early in the 18th century. (Haller, as *supra;* Lawrence Charteris's M.S., *s. v.*) So recently as 1833 was printed *A Short Account of Scots Divines* by him, edited by James Maidment, Edinburgh. (A. B. G.)

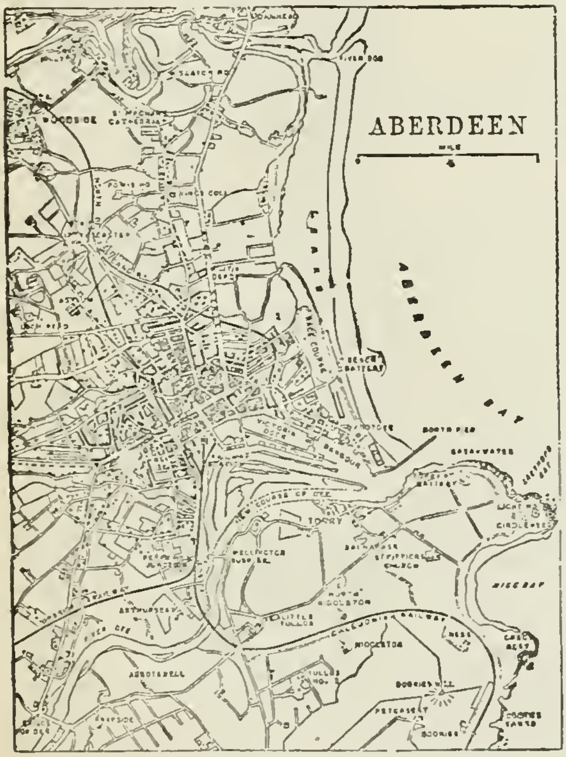
ABERCROMBY, JAMES, LORD DUNFERMLINE, third son of the celebrated Sir Ralph Abercromby, was born on the 7th Nov. 1776. Educated for the profession of the law, he was called to the bar at Lincoln's Inn in 1801, but he was prevented from engaging to any considerable extent in general practice by accepting appointments, first as commissioner in bankruptcy, and subsequently, as steward of the estates of the Duke of Devonshire. He commenced his political career in 1807, when he was elected member of Parliament for the borough of Midhurst. His sympathies with the small and struggling Opposition had already been declared, and he at once attached himself to the Whig party, with which he consistently acted throughout life. In 1812 he was returned for Calne, which he continued to represent until his elevation to the Scotch bench in 1830. During this lengthened period he rendered conspicuous and valuable services to his party and the country. In Scotch affairs he took, as was natural, a deep interest; and, by introducing, on two separate occasions, a motion for the redress of a special glaring abuse, he undoubtedly gave a strong impulse to the growing desire for a general reform. In 1824, and again in 1826, he presented a petition from the inhabitants of Edinburgh, and followed it up by a motion "for leave to bring in a Bill for the more effectual representation of the city of Edinburgh in the Commons House of Parliament." The motion was twice rejected, but by such narrow majorities as showed that the monopoly of the self-elected Council of thirty-three was doomed. In 1827, on the accession of the Whigs to power under Mr Canning, Abercromby received the appointment of Judge-Advocate-General and Privy Counsellor. In 1830 he was raised to the judicial bench as Chief Baron of the Exchequer in Scotland. The office was abolished in 1832; and almost contemporaneously, Edinburgh, newly enfranchised, was called to return two members to the first reformed Parliament. As the election marked the commencement of a new political era, the honour to be conferred possessed a peculiar value, and the choice of the citizens fell most appropriately on Francis Jeffrey and James Abercromby, two of the foremost of those to whom they were indebted for their hard-won privileges. In 1834 Mr Abercromby obtained a seat in the cabinet of Lord Grey as Master of the Mint. On the assembling of the new Parliament in 1835, the election of a speaker gave occasion for the first trial of strength between the Reform party and the followers of Sir Robert Peel. After a memorable division, in which more members voted than had ever before been known, Abercromby was elected by 316 votes, to 310 recorded for Manners-Sutton. The choice was amply justified, not only by the urbanity, impartiality, and firmness with which Abercromby discharged the public duties of the chair, but also by the important reforms he introduced in regard to the conduct of private business. In 1839 he resigned the office, and received the customary honour of a peerage, with the title of Lord Dunfermline. The evening of his life was passed in retirement at Colinton, near Edinburgh, where he died on the 17th April 1858. The courage and sagacity which marked his entire conduct as a Liberal were never more conspicuous than when, towards the close of his life, he availed himself of an opportunity of practically asserting his cherished doctrine of absolute religious equality. The important part he took in originating and supporting the United Industrial School in Edinburgh for ragged children, irrespective of their religious belief, deserves to be gratefully acknowledged and remembered, even by those who took the opposite side in the controversy which arose with regard to it.

ABERCROMBY, PATRICK, M.D., was the third son of Alexander Abercromby of Fetterneir in Aberdeenshire, and brother of Francis Abercromby, who was created by James II. Lord Glasford. He was born at Forfar in 1656. As throughout Scotland, he could have had there the benefits of a good parish school; but it would seem from after events that his family was Roman Catholic, and hence, in all probability, his education was private. This, and not the unproved charge of perversion from Protestantism in subserviency to James II., explains his Roman Catholicism and adhesion to the fortunes of that king. But, intending to become a doctor of medicine, he entered the University of St Andrews, where he took his degree of M.D. in 1685. From a statement in one of his preface-epistles to his *magnum opus*, the *Martial Achievements of the Scots Nation*, he must have spent most of his youthful years abroad. It has been stated that he attended the University of Paris. The *Discourse of Wit* (1685), assigned to him, belongs to Dr David Abercromby, a contemporary. On his return to Scotland, he is found practising as a physician in Edinburgh, where, besides his professional duties, he gave himself with characteristic zeal to the study of antiquities, a study to which he owes it that his name still lives, for he finds no place in either Haller or Hutchison's *Medical Biographies.* He was out-and-out a Scot of the old patriotic type, and, living as he did during the agitations for the union of England and Scotland, he took part in the war of pamphlets inaugurated and sustained by prominent men on both sides of the Border. He crossed swords with no less redoubtable a foe than Daniel Defoe in his *Advantages of the Act of Security, compared with those of the intended Union* (Edinburgh, 1707), and *A Vindication of the Same against Mr De Foe* (*ibid.*) The logic and reason were with Defoe, but there was a *sentiment* in the advocates of independence which was not sufficiently allowed for in the clamour of debate; and, besides, the disadvantages of union were near, hard, and actual, the advantages remote, and contingent on many things and persons. Union wore the look to men like Abercromby and Lord Belhaven of absorption, if not extinction. Abercromby was appointed physician to James II., but the Revolution deprived him of the post. Crawford (in his *Peerage*, 1716) ascribes the title of Lord Glasford to an intended recognition of ancestral loyalty; its bestowment in 1685 corresponding with the younger brother's graduation as M.D., may perhaps explain his appointment. A minor literary work of Abercromby's was a translation of M. Beague's partizan History (so called) of the War carried on by the Popish Government of Cardinal Beaton, aided by the French, against the English under the Protector Somerset, which appeared in 1707. The work with which Abercromby's name is permanently associated is his already noticed *Martial Achievements of the Scots Nation*, issued in two noble folios, vol. i. 1711, vol. ii. 1716. In the title-page and preface to vol. i. he disclaims the ambition of being an historian, but in vol. ii., in title-page and preface alike, he is no longer a simple biographer, but an historian. That Dr Abercromby did not use the word "*genuine* history" in his title-page without warrant is clear on every page of his large work. Granted that, read in the light of after researches, much of the first volume must necessarily be relegated to the region of the mythical, none the less was the historian a laborious and accomplished reader and investigator of all available authorities, as well manuscript as printed; while the roll of names of those who aided him includes every man of note in Scotland at the time, from Sir Thomas Craig and Sir George Mackenzie to Mr Alexander Nisbet and Mr Thomas Ruddiman. The *Martial Achievements* has not been reprinted, though practically the first example of Scottish typography in any way noticeable, vol. ii. having been printed under the scholarly supervision of Thomas Ruddiman. The date of his death is uncertain. It has been variously assigned to 1715, 1716, 1720, and 1726, and it is usually added that he left a widow in great poverty. That he was living in 1716 is certain, as Crawford speaks of him (in his *Peerage*, 1716) as "my worthy friend." Probably he died about 1716. *Memoirs of the Abercrombys*, commonly given to him, does not appear to have been published. (Chambers's *Eminent Scotsmen, s. v.*; Anderson's *Scottish Nation, s. v.*; Chalmers's *Biog. Dict., s. v.*; Chalmers's *Life of Ruddiman;* Haller's *Bibliotheca Medicinæ Pract.*, 4 vols. 4to, 1779; Hutchinson's *Biog. Medical*, 2 vols. 8vo, 1799; Lee's *Defoe*, 3 vols. 8vo.) (A. B. G.)

ABERCROMBY, SIR RALPH, K.B., Lieutenant-General in the British army, was the eldest son of George Abercromby of Tullibody, Clackmannanshire, and was born in October 1734. After passing some time at an excellent school at Alloa, he went to Rugby, and in 1752–53 he attended classes in Edinburgh University. In 1754 he was sent to Leipsic to study civil law, with a view to his proceding to the Scotch bar, of which it is worthy of notice that both his grandfather and his father lived to be the oldest members. On returning from the Continent he expressed a strong preference for the military profession, and a cornet's commission was accordingly obtained for him (March 1756) in the 3d Dragoon Guards. He rose through the intermediate gradations to the rank of lieutenant-colonel of the regiment (1773), and in 1781 he became colonel of the 103d infantry. When that regiment was disbanded in 1783 he retired upon half-pay. That up to this time he had scarcely been engaged in active service, was owing mainly to his disapproval of the policy of the Government, and especially to his sympathies with the American colonists in their struggles for independence; and his retirement is no doubt to be ascribed to similar feelings. But on France declaring war against England in 1793, he hastened to resume his professional duties; and, being esteemed one of the ablest and most intrepid officers in the whole British forces, he was appointed to the command of a brigade under the Duke of York, for service in Holland. He commanded the advanced guard in the action on the heights of Cateau, and was wounded at Nimeguen. The duty fell to him of protecting the British army in its disastrous retreat out of Holland, in the winter of 1794–5. In 1795 he received the honour of knighthood, the Order of the Bath being conferred on him in acknowledgment of his services. The same year he was appointed to succeed Sir Charles Grey, as commander-in-chief of the British forces in the West Indies. In 1796, Grenada was suddenly attacked and taken by a detachment of the army under his orders. He afterwards obtained possession of the settlements of Demerara and Essequibo, in South America, and of the islands of St Lucia, St Vincent, and Trinidad. He returned in 1797 to Europe, and, in reward for his important services, was appointed to the command of the regiment of Scots Greys, intrusted with the governments of the Isle of Wight, Fort George, and Fort Augustus, and raised to the rank of lieutenant-general. He held, in 1797–8, the chief command of the forces in Ireland. There he laboured to maintain the discipline of the army, to suppress the rising rebellion, and to protect the people from military oppression, with a care worthy alike of a great general and an enlightened and beneficent statesman. When he was appointed to the command in Ireland, an invasion of that country by the French was confidently anticipated by the English Government. He used his utmost efforts to restore the discipline of an army that was utterly disorganised; and, as a first step, he anxiously endeavoured to protect the people, by re-establishing the supremacy of the civil power, and not allowing the military to be called out, except when it was indispensably necessary for the enforcement of the law and the maintenance of order. Finding that he received no adequate support from the head of the Irish Government, and that all his efforts were opposed and thwarted by those who presided in the councils of Ireland, he resigned the command. His departure from Ireland was deeply lamented by the reflecting portion of the people, and was speedily followed by those disastrous results which he had anticipated, and which he so ardently desired and had so wisely endeavoured to prevent. After holding for a short period the office of Commander-in-Chief in Scotland, Sir Ralph, when the enterprise against Holland was resolved upon in 1799, was again called to command under the Duke of York. The difficulties of the ground, the inclemency of the season, unavoidable delays, the disorderly movements of the Russians, and the timid duplicity of the Dutch, defeated the objects of that expedition. But it was confessed by the Dutch, the French, and the British alike, that even victory the most decisive could not have more conspicuously proved the talents of this distinguished officer. His country applauded the choice, when, in 1801, he was sent with an army to dispossess the French of Egypt. His experience in Holland and the West Indies particularly fitted him for this new command, as was proved by his carrying his army in health, in spirits, and with the requisite supplies, in spite of very great difficulties, to the destined scene of action. The debarkation of the troops at Aboukir, in the face of an opposing force, is justly ranked among the most daring and brilliant exploits of the English army. A battle in the neighbourhood of Alexandria (March 21, 1801) was the sequel of this successful landing, and it was Sir R. Abercromby's fate to fall in the moment of victory. He was struck by a spent ball, which could not be extracted, and died seven days after the battle. The Duke of York paid a just tribute to the great soldier's memory in the general order issued on the occasion of his death:—"His steady observance of discipline, his ever-watchful attention to the health and wants of his troops, the persevering and unconquerable spirit which marked his military career, the splendour of his actions in the field, and the heroism of his death, are worthy the imitation of all who desire, like him, a life of heroism and a death of glory." By a vote of the House of Commons, a monument was erected in honour of Sir Ralph Abercromby in St Paul's Cathedral. His widow was created a peeress, and a pension of £2000 a year was settled on her and her two successors in the title. It may be mentioned that Abercromby was returned, after a keen contest, as member of Parliament for his native county of Clackmannanshire in 1773; but a parliamentary life had no attractions for him, and he did not seek re-election. A memoir of the later years of his life (1793–1801), by his son, Lord Dunfermline, was published in 1861.

ABERDARE, a town of Wales, in the county of Glamorgan, on the right bank of the river Cynon, four miles S.W. of Merthyr-Tydvil. The district around is rich in valuable mineral products, and coal and iron mining are very extensively carried on in the neighbourhood. Important tin-works, too, have been recently opened. Part of the coal is used at the iron-works, and large quantities are sent to Cardiff for exportation. Aberdare is connected with the coast by canal and railway. Owing to the great development of the coal and iron trade, it has rapidly increased from a mere village to a large and flourishing town. Handsome churches, banks, and hotels have been erected, a good supply of water has been introduced, and a public park has been opened. Two markets are held weekly. The whole parish falls within the parliamentary borough of Merthyr-Tydvil. The rapid growth of its population is seen by the following figures: in 1841 the number of inhabitants was 6471; in 1851, 14,999; in 1861, 32,299; and in 1871, 37,774.

ABERDEEN, a royal burgh and city, the chief part of a parliamentary burgh, the capital of the county of Aberdeen, the chief seaport in the north of Scotland, and the fourth Scottish town in population, industry, and wealth. It lies in lat. 57° 9′ N. and long. 2° 6′ W., on the German Ocean, near the mouth of the river Dee, and is 542 miles north of London, and 111 miles north of Edinburgh, by the shortest railway routes.



Aberdeen, probably the Devana on the Diva of Ptolemy, was an important place in the 12th century. William the Lion had a residence in the city, to which he gave a charter in 1179, confirming the corporate rights granted by David I. The city received many subsequent royal charters. It was burned by Edward III. in 1336, but it was soon rebuilt and extended, and called New Aberdeen. The houses were of timber and thatched, and many such existed till 1741. The burgh records are the oldest of any Scottish burgh. They begin in 1398, and are complete to the present time, with only a short break. Extracts from them, extending from 1398 to 1570, have been published by the Spalding Club. For many centuries the city was subject to attacks by the barons of the surrounding districts, and its avenues and six ports had to be guarded. The ports had all been removed by 1770. Several monasteries existed in Aberdeen before the Reformation. Most of the Scottish sovereigns visited the city and received gifts from the authorities. In 1497 a blockhouse was built at the harbour mouth as a protection against the English. During the religious struggle in the 17th century between the Royalists and Covenanters the city was plundered by both parties. In 1715 Earl Marischal proclaimed the Pretender at Aberdeen. In 1745 the Duke of Cumberland resided a short time in the city. In the middle of the 18th century boys were kidnapped in Aberdeen, and sent as slaves to America. In 1817 the city became insolvent, with a debt of £225,710, contracted by public improvements, but the debt was soon paid off. The motto on the city arms is Bon-Accord. It formed the watchword of the Aberdonians while aiding King Robert the Bruce in his battles with the English.

Of eminent men connected with Aberdeen, New and Old, may be mentioned—John Barbour, Hector Boece or Boethius, Bishop Elphinstone, the Earls Marischal; George Jamesone, the famous portrait painter; Edward Raban, the first printer in Aberdeen, 1622; Rev. Andrew Cant, the Covenanter; David Anderson (Davie do a' thing), a mechanic; James Gregory, inventor of the reflecting telescope; Dr Thomas Reid, the metaphysician; Dr George Campbell, Principal of Marischal College, author of several important works, and best known by his *Philosophy of Rhetoric;* Dr James Beattie; Lord Byron; Sir James Mackintosh; Robert Hall; Dr R. Hamilton, who wrote on the National Debt.

Till 1800 the city stood on a few eminences, and had steep, narrow, and crooked streets, but, since the Improvement Act of that year, the whole aspect of the place has been altered by the formation of two new spacious and nearly level streets (Union Street and King Street, meeting in Castle Street), and by the subsequent laying out of many others, besides squares, terraces, &c., on nearly flat ground. The city is above eight miles in circuit, and is built on sand, gravel, and boulder clay. The highest parts are from 90 to 170 feet above the sea. The chief thoroughfare is Union Street, nearly a mile long and 70 feet broad. It runs W.S.W. from Castle Street, and crosses the Denburn, now the railway valley, by a noble granite arch 132 feet in span and 50 feet high, which cost, with a hidden arch on each side, £13,000.

Aberdeen is now a capacious, elegant, and well-built town, and from the material employed, consisting chiefly of light grey native granite, is called the "granite city." It contains many fine public buildings. The principal of these is Marischal College or University Buildings, which stands on the site of a pre-Reformation Franciscan Convent, and was rebuilt, 1836–1841, at a cost of about £30,000. It forms three sides of a court, which is 117 by 105 feet, and has a back wing, and a tower 100 feet high. The accommodation consists of twenty-five large class-rooms and laboratories, a hall, library, museums, &c.

The University of Aberdeen was formed by the union and incorporation, in 1860, by Act of Parliament, of the University and King's College of Aberdeen, founded in Old Aberdeen, in 1494, by William Elphinstone, Bishop of Aberdeen, under the authority of a Papal bull obtained by James IV., and of the Marischal College and University of Aberdeen, founded in New Aberdeen, in 1593, by George Keith, Earl Marischal, by a charter ratified by Act of Parliament. The officials consist of a chancellor, with rector and principal; there are 21 professors and 8 assistants. Arts and divinity are taught in King's College, and medicine, natural history, and law in Marischal College. The arts session lasts from the end of October to the beginning of April. The arts curriculum of four years, with graduation, costs £36, 11s. There are 214 arts bursaries, 29 divinity, and 1 medical, of the aggregate annual value of £3646, £650, and £26, respectively. About 60 arts bursaries, mostly from £10 to £35 in value, are given yearly by competition, or by presentation and examination. Two-thirds of the arts students are bursars. Seventeen annual scholarships and prizes of the yearly value of £758 are given at the end of the arts curriculum. The average yearly number of arts students, in the thirteen years since the union of the arts classes of the two colleges in 1860, has been 342, while in the separate colleges together for the nine years before the union, it was 431. In winter session 1872–73 there were 623 matriculated students in all the faculties. In 1872, 32 graduated in arts, 68 in medicine, 5 in divinity, and 1 in law. The library has above 80,000 volumes. The General Council in 1873 had 2075 registered members. who, with those of Glasgow University, return one member to Parliament.

The Free Church Divinity College was built in 1850, at the cost of £2025, in the Tudor-Gothic style It has a large hall, a library of 12,000 volumes, and 15 bursaries of the yearly value of from £10 to £25.

At the east end of Union Street, and partly in Castle Street, on the north side, are the new County and Municipal buildings, an imposing Franco-Scottish Gothic pile, 225 feet long, 109 feet broad, and 64 feet high, of four stories, built 1867–1873 at the cost of £80,000, including £25,000 for the site. Its chief feature is a tower 200 feet high. It contains a great hall, 74 feet long, 35 feet broad, and 50 feet high, with an open timber ceiling: a Justiciary Court-House, 50 feet long, 37 feet broad, and 31 feet high; a Town Hall, 41 feet long, 25 feet broad, and 15 feet high, and a main entrance corridor 60 feet long, 16 feet broad, and 24 feet high. A little to the west is the Town and County Bank, a highly ornamented building inside and outside, in the Italian style, costing about £24,000.

A very complete closed public market of two floors was built in 1842, at a cost of £28,000, by a company incorporated by Act of Parliament. The upper floor or great hall is 315 feet long, 106 feet broad, and 45 feet high, with galleries all round. The lower floor is not so high. The floors contain numerous small shops for the sale of meat, fowls, fish, &c., besides stalls and seats for the sale of vegetables, butter, eggs, &c. The galleries contain small shops for the sale of drapery, hardware, fancy goods, and books. On the upper floor is a fountain of polished Peterhead granite, costing £200, with a basin 7½ feet diameter, cut out of one block of stone. Connected with this undertaking was the laying out of Market Street from Union Street to the quay. At the foot of this street is being built in the Italian style the new post and telegraph office, at a cost of £16,000, including £4000, the cost of the site. It is to form a block of about 100 feet square and 40 feet high.

Aberdeen has about 60 places of worship, with nearly 48,000 sittings. There are 10 Established churches; 20 Free, 6 Episcopalian, 6 United Presbyterian, 5 Congregational, 2 Baptist, 2 Methodist, 2 Evangelical Union, 1 Unitarian, 1 of Roman Catholic, 1 of Friends, and 1 of Original Seceders. There are also several mission chapels. In 1843 all the Established ministers seceded, with 10,000 lay members. The Established and Free Church denominations have each about 11,000 members in communion. The Established West and East churches, in the centre of the city, within St Nicholas churchyard, form a continuous building 220 feet long, including an intervening aisle, over which is a tower and spire 140 feet high. The West was built in 1775 in the Italian style, and the East in 1834 in the Gothic, each costing about £5000. They occupy the site of the original cruciform church of St Nicholas, erected in the 13th, 14th, and 15th centuries. One of the nine bells in the tower bears the date of 1352, and is 4 feet diameter at the mouth, 3½ feet high, and very thick. The Union Street front of the churchyard is occupied by a very elegant granite façade, built in 1830, at the cost of £1460. It is 147½ feet long, with a central arched gateway and entablature 32½ feet high, with two attached Ionic columns on each side. Each of the two wings has six Ionic columns (of single granite blocks, 15 feet 2 inches long), with basement and entablature, the whole being 23½ feet high. The following are the style, cost, and date of erection of the other principal Aberdeen churches—St Andrew's, Episcopal, Gothic, £6000, 1817; North Church, Established, Greek, £10,000, 1831; three churches in a cruciform group, Free, simple Lancet Gothic, with a fine brick spire 174 feet high, £5000, 1844; Roman Catholic, Gothic, £12,000, 1859; Free West, Gothic, £12,856, 1869, with a spire 175 feet high.

In 1873 there were in Aberdeen about 110 schools, with from 10,000 to 11,000 pupils in attendance. About 2500 students attend the University, Mechanics' Institution, and private schools for special branches.

Five miles south-west of Aberdeen, on the south side of the Dee, in Kincardineshire, is St Mary's Roman Catholic College of Blairs, with a president and three professors.

The Aberdeen Grammar School, dating from about 1263, is a preparatory school for the university. It has a rector and four regular masters, who teach classics, English, arithmetic, and mathematics, for the annual fee of £4, 10s. for each pupil. Writing, drawing, &c., are also taught. Nearly 200 pupils attend, who enter about the age of twelve. Like the Edinburgh High School, it has no elementary department. There are 30 bursaries. A new granite building for the school was erected, 1861–1863, in the Scotch baronial style, at the cost of £16,000, including site. It is 215 feet long and 60 feet high, and has three towers.

The Mechanics' Institution, founded 1824, and reorganised 1834, has a hall, class-rooms, and a library of 14,000 volumes, in a building erected in 1846, at a cost of £3500. During the year 1872–73, there were at the School of Science and Art 385 pupils; and at other evening classes, 538.

Aberdeen has two native banks, besides branch banks, and a National Security Savings Bank; three insurance companies, four shipping companies, three railway companies, and a good many miscellaneous companies. There are ten licensed pawnbroking establishments, with about 440,000 pledges in the year for £96,000, and with a capital of £27,000. There are seven incorporated trades, originating between 1398 and 1527, and having charitable funds for decayed members, widows, and orphans. They have a hall, built in 1847 for £8300, in the Tudor Gothic style. The hall, 60 feet long, 29 wide, and 42 high, contains curious old chairs, and curious inscriptions on the shields of the crafts.

Among the charitable institutions is Gordon's Hospital, founded in 1729 by a miser, Robert Gordon, a Dantzic merchant, of the Straloch family, and farther endowed by Alexander Simpson of Collyhill in 1816. It is managed by the Town Council and four of the Established ministers of Aberdeen, incorporated by royal charters of 1772 and 1792. The central part of the house was built in 1739, and the wings in 1830–1834, the whole costing £17,300, and being within a garden of above four acres. It now (1873) maintains and educates (in English, writing, arithmetic, physics, mathematics, drawing, music, French, &c.) 180 boys of the age 9 to 15, the sons and grandsons of decayed burgesses of guild and trade of the city; and next those of decayed inhabitants (not paupers). Expenditure for year to 31st October 1872, £4353 for 164 boys. It has a head-master. three regular, and several visiting masters. The Boys' and Girls' Hospital, lately built for £10,000, maintains and educates 50 boys and 50 girls.

The Female Orphan Asylum, founded by Mrs Elmslie, in 1840, and managed by trustees, maintains and educates, chiefly as domestic servants, 46 girls between the ages of 4 and 16, at the yearly cost for each of about £23, 13s. Those admitted must be legitimate orphan daughters of respectable parents, who have lived three years immediately before death in Aberdeen or in the adjoining parishes of Old Machar and Nigg. The Hospital for Orphan and Female Destitute Children, endowed by John Carnegie and the trustees of the Murtle Fund, maintains and educates 50 girls, chiefly for domestic service. The Asylum for the Blind, established in 1843, on a foundation by Miss Cruickshank, maintains and educates about 10 blind children, and gives industrial employment to blind adults. There is a boys' and girls' school for 150 boys and 150 girls on Dr Bell's foundation. The Industrial Schools, begun by Sheriff Watson in 1841, and the Reformatory Schools, begun in 1857, having some 600 pupils on the roll, have greatly diminished juvenile crime in the district. The Murtle or John Gordon's Charitable Fund, founded in 1815, has an annual revenue from land of about £2400, applicable to all kinds of charity, in sums from £5 to £300. The Midbeltie Fund, founded by a bequest of £20,000, in 1848, by James Allan of Midbeltie, gives yearly pensions ranging from £5 to £15 to respectable decayed widows in the parishes of St Nicholas and Old Machar.

The two parishes in which Aberdeen is situated, viz., St Nicholas and Old Machar, have each a large poor-house. The poor of both parishes cost about £20,000 a year.

The Royal Infirmary, instituted in 1740, was rebuilt 1833–1840, in the Grecian style, at the cost of £17,000. It is a well-situated, large, commodious, and imposing building. It has three stories, the front being 166 feet long and 50 feet high, with a dome. A detached fever-house was built in 1872 for about £2500. The managers were incorporated by royal charter in 1773, and much increased in number in 1852. The institution is supported by land rents, feu-duties, legacies, donations, subscriptions, church collections, &c. Each bed has on an average 1200 cubic feet of space. There are on the average 130 resident patients, costing each on the average a shilling daily, and the number of patients treated may be stated at 1700 annually, besides outdoor patients receiving advice and medicine. The recent annual expenditure has been about £4300. There is a staff of a dozen medical officers.

The Royal Lunatic Asylum, opened in 1800, consists of two separate houses, valued in 1870 at £40,000, in an enclosure of 40 acres. It is under the same management as the Infirmary. The recent daily average of patients has been about 420, at an annual cost of £13,000. The annual rate for each pauper is £25, 10s. The General Dispensary, Vaccine, and Lying-in Institution, founded in 1823, has had as many as 6781 cases in one year. The Hospital for Incurables has a daily average of 26 patients, and the Ophthalmic and Auric Institution has had 671 cases in a year.

The Music Hall, built in 1821 and 1859 at the cost of £16,500, has a front 90 feet long, with a portico of 6 Ionic pillars 30 feet high; large, highly-decorated lobbies and rooms; and a hall 150 feet long, 68 broad, and 50 high, with a flat ceiling, and galleries. The hall holds 2000 persons seated, and has a fine organ and an orchestra for 300. Here H.R.H. Prince Albert opened the British Association, as president, 14th September 1859. A new Theatre and Opera House was built in 1872, in the mixed Gothic style, for £8400, with the stage 52½ feet by 29, and the auditorium for 1700 to 1800 persons. The front wall is of bluish granite and red and yellow freestone, with some polished Peterhead granite pillars, the rest being built of concrete.

In Castle Street, the City Place and Old Market Stance, is the Market Cross, a beautiful, open-arched, hexagonal structure of freestone, 21 feet diameter, and 18 feet high. It has Ionic columns and pilasters, and an entablature of twelve panels. On ten of the panels are medallions, cut in stone, in high relief, of the Scottish sovereigns from James I. to James VII. From the centre rises a composite column 12½ feet high, with a Corinthian capital, on which is the royal unicorn rampant. This cross was planned and erected about 1682 by John Montgomery, a native architect, for £100 sterling. On the north side of the same street, adjoining the municipal buildings, is the North of Scotland Bank, a Grecian building in granite, with a portico of Corinthian columns, having most elaborately carved capitals. On an eminence east of Castle Street are the military barracks for 600 men, built in 1796 for £16,000.

The principal statues in the city are those of the last Duke of Gordon—died 1836—in grey granite, 10 feet high; Queen Victoria, in white Sicilian marble, 8½ feet high; Prince Albert, bronze, natural-size, sitting posture; and a curious rough stone figure, of unknown date, supposed to be Sir William Wallace.

The Dee to the south of the city is crossed by three bridges, the old bridge of Dee, an iron suspension bridge, and the Caledonian Railway bridge. The first, till 1832 the only access to the city from the south, consists of seven semicircular ribbed arches, is about 30 feet high, and was built early in the 16th century by Bishops Elphinstone and Dunbar. It was nearly all rebuilt 1718–1723, and from being 14½ feet wide, it was in 1842 made 26 feet wide. From Castle Street, King Street leads in the direction of the new bridge of Don (a little east of the old "Brig o' Balgownie"), of five granite arches, each 75 feet span, built for nearly £13,000 in 1827–1832.

A defective harbour, and a shallow sand and gravel bar at its entrance, long retarded the trade of Aberdeen, but, under various Acts since 1773, they have been greatly deepened. The north pier, built partly by Smeaton, 1775–1781, and partly by Telford, 1810–1815, extends 2000 feet into the German Ocean. It is 30 feet broad, and, with the parapet, rises 15 feet above high water. It consists of large granite blocks. It has increased the depth of water on the bar from a few feet to 22 or 24 feet at spring tides, and to 17 or 18 feet at neap. The wet dock, of 29 acres, and with 6000 feet of quay, was completed in 1848, and called Victoria Dock, in honour of Her Majesty's visit to the city in that year. These and other improvements of the harbour and its entrance cost £325,000 down to 1848. By the Harbour Act of 1868, the Dee near the harbour has been diverted to the south, at the cost of £80,000, and 90 acres of new ground (in addition to 25 acres formerly made up) for harbour works are being made up on the city or north side of the river; £80,000 has been laid out in forming in the sea, at the south side of the river, a new breakwater of concrete, 1050 feet long, against south and south-east storms. The navigation channel is being widened and deepened, and the old pier or breakwater on the north side of the river mouth is to be lengthened at least 500 feet seaward. A body of 31 commissioners manage the harbour affairs.

Aberdeen Bay affords safe anchorage with off-shore winds, but not with those from the N.E., E., and S.E. On the Girdleness, the south point of the bay, a lighthouse was built in 1833, in lat. 57° 8′ N., and long. 2° 3′ W., with two fixed lights, one vertically below the other, and respectively 115 and 185 feet above mean tide. There are also fixed leading lights to direct ships entering the harbour at night. In fogs, a steam whistle near the lighthouse is sounded ten seconds every minute. Near the harbour mouth are three batteries mounting nineteen guns.

The water supplied to the city contains only 3½ grains solid matter in a gallon, with a hardness of about 2 degrees. It is brought by gravitation, in a close brick culvert, from the Dee, 21 miles W.S.W. of the city, to a reservoir, which supplies nine-tenths of the city. The other tenth, or higher part of the city, is supplied by a separate reservoir, to which part of the water from the culvert is forced up by a hydraulic engine. Nearly 40 gallons water per head of the population are consumed daily for all purposes. The new water works cost £160,000, and were opened by Her Majesty, 16th October 1866.

The gas is made of cannel coal, and is sent through 71 miles of main pipes, which extend 5 miles from the works.

The manufactures, arts, and trade of Aberdeen and vicinity are large and flourishing. Woollens were made as early as 1703, and knitting of stockings was a great industry in the 18th century. There are two large firms in the woollen trade, with 1550 hands, at £1000 weekly wages, and making above 1560 tons wool in the year into yarns, carpets, hand-knit hosiery, cloths, and tweeds. The linen trade, much carried on since 1749, is now confined to one firm, with 2600 hands, at £1200 wages weekly, who spin, weave, and bleach 50 tons flax and 60 tons tow weekly, and produce yarns, floorcloths, sheetings, dowlas, ducks, towels, sail-canvas, &c. The cotton manufacture, introduced in 1779, employs only one firm, with 550 hands, at £220 weekly wages, who spin 5000 bales of cotton a-year into mule yarn. The wincey trade, begun in 1839, employs 400 hands, at £200 weekly wages, who make 2,100,000 yards cloth, 27 to 36 inches broad, in the year. Paper, first made here in 1696, is now manufactured by three firms in the vicinity. The largest has 2000 hands, at £1250 weekly wages, and makes weekly 75 to 80 tons of writing paper, and 6¼ millions of envelopes, besides much cardboard and stamped paper; another firm makes weekly 77 tons coarse and card paper; and a third, 20 tons printing and other paper. The comb works of Messrs Stewart & Co., begun in 1827, are the largest in the world, employing 900 hands, at £500 weekly wages, who yearly convert 1100 tons horns, hoofs, india-rubber, and tortoise-shells into 11 millions of combs, besides spoons, cups, scoops, paper-knives, &c. Seven iron foundries and many engineering works employ 1000 men, at £925 weekly wages, and convert 6000 tons of iron a-year into marine and land steam engines and boilers, corn mills, wood-preparing machinery, machinery to grind and prepare artificial manures, besides sugar mills and frames and coffee machinery for the colonies.

The Sandilands Chemical Works, begun in 1848, cover five acres, and employ over 100 men and boys, at £90 to £100 weekly wages. Here are prepared naphtha, benzole, creosote oil, pitch, asphalt, sulphate of ammonia, sulphuric acid, and artificial manures. Paraffin wax and ozokerite are refined. An Artesian well within the works, 421 feet deep, gives a constant supply of good water, always at 51° Fahr. Of several provision-curing works, the largest employs 300 hands, chiefly females, in preserving meats, soups, sauces, jams, jellies, pickles, &c., and has in connection with it, near the city, above 230 acres of fruit, vegetable, and farm ground, and a large piggery. The products of the breweries and distilleries are mostly consumed at home. A large agricultural implement work employs 70 or 80 men and boys. Nearly 200 acres of ground, within three miles of the city, are laid out in rearing shrub and forest-tree seedlings. In 1872 about 145 acres of strawberries were reared within three miles of Aberdeen, and 80 tons of this fruit are said to have been exported.

Very durable grey granite has been quarried near Aberdeen for 300 years, and blocked and dressed paving, kerb, and building granite stones have long been exported from the district. In 1764, Aberdeen granite pavement was first used in London. About the year 1795, large granite blocks were sent for the Portsmouth docks. The chief stones of the New Thames Embankment, London, are from Kemnay granite quarries, 16 miles north-west of the city. Aberdeen is almost entirely built of granite, and large quantities of the stone are exported to build bridges, wharfs, docks, lighthouses, &c., elsewhere. Aberdeen is famed for its polishing-works of granite, especially grey and red. They employ about 1500 hands in polishing vases, tables, chimney-pieces, fountains, monuments, columns, &c., for British and foreign demand. Mr Alexander Macdonald, in 1818, was the first to begin the granite polishing trade, and the works of the same firm, the only ones of the kind till about 1850, are still the largest in the kingdom.

In 1820, 15 vessels from Aberdeen were engaged in the northern whale and seal fishing; in 1860, one vessel, but none since. The white fishing at Aberdeen employs some 40 boats, each with a crew of 5 men. Of the 900 tons wet fish estimated to be brought to market yearly, above a third are sent fresh by rail to England. The salmon caught in the Dee, Don, and sea are nearly all sent to London fresh in ice. The herring fishing has been prosecuted since 1836, and from 200 to 350 boats are engaged in it.

Aberdeen has been famed for shipbuilding, especially for its fast clippers. Since 1855 nearly a score of vessels have been built of above 1000 tons each. The largest vessel (a sailing one) ever built here was one in 1855, of 2400 tons. In 1872 there were built 11 iron vessels of 9450 tons, and 6 wooden of 2980 tons, consuming 5900 tons iron, and costing £252,700, including £70,700 for engines and other machinery. 1400 hands were employed in shipbuilding in that year, at the weekly wages of about £1230.

In 1872, there belonged to the port of Aberdeen 236 vessels, of 101,188 tons, twenty-four of the vessels, of 7483 tons, being steamers. They trade with most British and Irish ports, the Baltic and Mediterranean ports, and many more distant regions. In 1872, 434,108 tons shipping arrived at the port, and the custom duties were £112,414. The export trade, exclusive of coasting, is insignificant. The shore or harbour dues were £126 in 1765, and £1300 in 1800. In the year ending 30th September 1872, they were £25,520; while the ordinary harbour revenue was £37,765, expenditure £28,598, and debt £324,614. The introduction of steamers in 1821 greatly promoted industry and traffic, and especially the cattle trade of Aberdeenshire with London. These benefits have been much increased by the extension of railways. Commodious steamers ply regularly between Aberdeen and London, Hull, Newcastle, Leith, Wick, Kirkwall, and Lerwick.

The joint railway station for the Caledonian, Great North of Scotland, and Deeside lines, was opened 1867, and is a very handsome erection, costing about £26,000. It is 500 feet long, and 102 feet broad, with the side walls 32 feet high. The arched roof of curved lattice-iron ribs, covered with slate, zinc, and glass, is all in one span, rising 72 feet high, and is very light and airy.

The Medico-Chirurgical Society of Aberdeen was founded in 1789. The hall was built in 1820 at a cost of £4000, and is adorned with an Ionic portico of four granite columns, 27 feet high. It has 42 members, and a library of 5000 volumes. The legal practitioners of Aberdeen have been styled advocates since 1633, and received royal charters in 1774, 1779, and 1862. They form a society, called the Society of Advocates, of 127 members in 1873, with a hall built in 1871 for £5075, a library of nearly 6000 volumes, and a fund to support decayed and indigent members, and their nearest relatives. The revenue in 1872 was £2880.'

Aberdeen has one daily and three weekly newspapers. *The Aberdeen Journal*, established in 1748, is the oldest newspaper north of the Forth.

The places of out-door recreation and amusement are chiefly the following:—The Links, a grassy, benty, and sandy tract, 2 miles long and ¼ to ⅓ mile broad, along the shore between the mouths of the Dee and the Don. It is mostly only a few feet above the sea, but the Broad Hill rises to 94 feet. Cattle shows, reviews, &c., are held on the Links. To the north-west of the town, a Public Recreation Park of 13 acres was laid out in 1872, at the cost of £3000, with walks, grass, trees, shrubs, and flowers.

Daily observations from 1857 to 1872 show the mean temperature of Aberdeen for the year to be 45°·8 Fahr., for the three summer months 56° Fahr., and for the three winter months 37°·3. The average yearly rainfall is 30·57 inches. Aberdeen is the healthiest of the large Scottish towns. East winds prevail in spring.

Since 1867 £50,000 has been spent in constructing main sewers throughout the city. A few acres of farm land have been irrigated by part of the sewage.

The city is governed by a corporation, the magistrates and town council, consisting of twenty-five councillors, including a provost, six bailies, a dean of guild, a treasurer, &c. The corporation revenue in the year 1871–72 was £11,498. The police, water, and gas are managed by the council. The municipal and police burgh has an area of nearly three square miles, with 12,514 municipal electors, and with assessable property valued at £230,000 in 1873. The Parliamentary burgh has an area of nine square miles, including Old Aberdeen and Woodside, with 14,253 Parliamentary electors, and real property to the value of £309,328 in 1873. It returns one member to Parliament. The population of Aberdeen in 1396 was about 3000; in 1643, 8750; in 1708, 5556; in 1801, 26,992; in 1841, 63,262; and in 1871, 88,125; with 6718 inhabited houses, 292 uninhabited, and 77 building.

Aberdeen, Old, is a small, quiet, ancient town, a burgh of barony and regality, a mile north of Aberdeen, and as far south-west of the mouth of the Don. It mostly forms one long street, 45 to 80 feet above the sea. The Don, to the north of the town, runs through a narrow, wooded, rocky ravine, and is spanned by a single Gothic arch, the "Brig o' Balgownie" of Lord Byron. The bridge rests on gneiss, and is 67 feet wide and 34½ feet high above the surface of the river, which at ebb tide is here 19 feet deep. The bridge is the oldest in the north of Scotland, and is said to have been built about 1305. The funds belonging to the bridge amount to £24,000.

The town was formerly the see of a bishop, and had a large cathedral dedicated to St Machar. In 1137 David I. translated to Old Aberdeen the bishopric, founded at Mortlach in Banffshire in 1004 by Malcolm II. in memory of his signal victory there over the Danes. In 1153 Malcolm IV. gave the bishop a new charter.

The cathedral of St Machar, begun about 1357, occupied nearly 170 years in building, and did not remain entire fifty years. What is still left is the oldest part, viz., the nave and side aisles, 126 feet long and 62½ feet broad, now used as the parish church. It is chiefly built of *outlayer* granite stones, and while the plainest Scottish cathedral, is the only one of granite in the kingdom. On the flat pannelled ceiling of the nave are 48 heraldic shields of the princes, nobles, and bishops who aided in its erection. It has been lately repaired, and some painted windows inserted, at the cost of £4280.

The chief structure in Old Aberdeen is the stately fabric of King's College near the middle of the town. It forms a quadrangle, with interior court 108 feet square, two sides of which have been rebuilt, and a projecting wing for a library added since 1860. The oldest parts, the Crown Tower and Chapel, date from about 1500. The former is 30 feet square and 60 feet high, and is surmounted by a structure about 40 feet high, consisting of a six-sided lantern and a royal crown, both sculptured, and resting on the intersections of two arched ornamented slips rising from the four corners of the top of the tower. The chapel, 120 feet long, 28 feet broad, and 37 feet high, still retains in the choir the original oak canopied stalls, miserere seat, and lofty open screen. These fittings are 300 years old, in the French flamboyant style, and are unsurpassed, in tasteful design and delicate execution, by the oak carving of any other old church in Europe. This carved woodwork owes its preservation to the Principal of Reformation times, who armed his people, and protected it from the fury of the barons of the Mearns after they had robbed the cathedral of its bells and lead. The chapel is still used for public worship during the University session.

Connected with Old Aberdeen is a brewery in the town, and a brick and coarse pottery work in the vicinity. There are also a Free church, two secondary schools, and two primary schools. Old Aberdeen has its own municipal officers, consisting of a provost, 4 bailies, and 13 councillors. The town is drained, lighted, supplied with water, and is within the Parliamentary boundary of New Aberdeen. There are several charitable institutions. Population in 1871, 1857; inhabited houses, 233. (A. C.)

ABERDEENSHIRE, a maritime county in the north-east of Scotland, between 56° 52′ and 57° 42′ N. lat. and between 1° 49′ and 3° 48′ long. W. of Greenwich. It is bounded on the north and east by the German Ocean; on the south by the counties of Kincardine, Forfar, and Perth; and on the west by those of Inverness and Banff. Its greatest length is 102 miles, and breadth 50 miles. Its circuit with sinuosities is about 300 miles, 60 being sea-coast. It is the fifth of Scotch counties in size, and is one-sixteenth of the extent of Scotland. Its area is 1970 square miles, or 1,260,625 acres, of which, in 1872, 36·6 per cent., or 585,299 acres, were cultivated, 93,339 in woods (mostly Scotch fir and larch), and 6400 in lakes. It contains 85 civil parishes and parts of 6 others, or 101 parishes, including civil and *quoad sacra*. The county is generally hilly, and mountainous in the south-west, whence, near the centre of Scotland, the Grampians send out various branches, mostly to the north-east, through the county. The run of the rivers and the general slope of the county is to the north-east and east. It is popularly divided into five districts:—First, *Mar*, mostly between the Dee and Don, and forming nearly the south half of the county. It is mountainous, especially Braemar, its west and Highland part, which contains the greatest mass of elevated land in the British Isles. Here the Dee rises amid the grandeur and wildness of lofty mountains, much visited by tourists, and composed chiefly of granite and gneiss, forming many high precipices, and showing patches of snow throughout every summer. Here rises Ben Muichdhui, the second highest mountain in Scotland and in the British Isles, 4296 feet; Braeriach, 4225; Cairntoul, 4245; Cairngorm (famed for "Cairngorm stones," a peculiar kind of rock crystal), 4090; Ben-a-Buird, 3860; Ben Avon, 3826; and Byron's "dark Lochnagar," 3786. The soil on the Dee is sandy, and on the Don loamy. The city of Aberdeen is in Mar. Second, *Formartin*, between the lower Don and Ythan, with a sandy coast, succeeded by a clayey, fertile, tilled tract, and then by low hills, moors, mosses, and tilled land. Third, *Buchan*, north of the Ythan, and next in size to

Mar, with parts of the coast bold and rocky, and with the interior bare, low, flat, undulating, and in parts peaty. On the coast, six miles south of Peterhead, are the Bullers of Buchan,—a basin in which the sea, entering by a natural arch, boils up violently in stormy weather. Buchan Ness is the eastmost point of Scotland. Fourth, *Garioch*, a beautiful, undulating, loamy, fertile valley, formerly called the granary of Aberdeen, with the prominent hill Benachie, 1676 feet, on the south. Fifth, *Strathbogie*, mostly consisting of hills (The Buck, 2211 feet; Noath, 1830 feet), moors, and mosses. The county as a whole, except the low grounds of Buchan, and the Highlands of Braemar, consists mainly of nearly level or undulating tracts, often naked and infertile, but interspersed with many rich and highly cultivated spots.

The chief rivers are the Dee, 96 miles long; Don, 78; Ythan, 37, with mussel beds at its mouth; Ugie, 20; and Deveron, 58, partly on the boundary of Banffshire. The pearl mussel occurs in the Ythan and Don. A valuable pearl in the Scottish crown is said to be from the Ythan. Loch Muick, the largest of the few lakes in the county, 1310 feet above the sea, is only $2\frac{1}{2}$ miles long and $\frac{1}{4}$ to $\frac{1}{2}$ mile broad. The rivers have plenty of salmon and trout. There are noted chalybeate springs at Peterhead, Fraserburgh, and Pananich near Ballater.

The climate of Aberdeenshire, except in the mountainous districts, is comparatively mild, from the sea being on two sides. The mean annual temperature at Braemar is 43°·6 Fahr., and at Aberdeen 45°·8. The mean yearly rainfall varies from about 30 to 37 inches. The summer climate of the Upper Dee and Don valleys is the driest and most bracing in the British Isles, and grain is cultivated up to 1600 feet above the sea, or 400 to 500 feet higher than elsewhere in North Britain. All the crops cultivated in Scotland ripen, and the people often live to a great age.

The rocks are mostly granite, gneiss, with small tracts of syenite, mica slate, quartz rock, clay slate, grauwacke, primary limestone, old red sandstone, serpentine, and trap. Lias, greensand, and chalk flints occur. The rocks are much covered with boulder clay, gravel, sand, and alluvium. Brick clay occurs near the coast. The surface of the granite under the boulder clay often presents glacial smoothings, grooves, and roundings. Cairngorm stone, beryl, and amethyst are found in the granite of Braemar.

The tops of the highest mountains have an arctic flora. At Her Majesty's Lodge, Loch Muick, 1350 feet above the sea, grow larches, vegetables, currants, laurels, roses, &c. Some ash trees, 4 or 5 feet in girth, are growing at 1300 feet above the sea. The mole occurs at 1800 feet above the sea, and the squirrel at 1400. Trees, especially Scotch fir and larch, grow well in the county, and Braemar abounds in natural timber, said to surpass any in the north of Europe. Stumps of Scotch fir and oak found in peat in the county are often far larger than any now growing. Grouse, partridges, and hares abound in the county, and rabbits are often too numerous. Red deer abound in Braemar, the deer forest being there valued at £5000 a year, and estimated at 500,000 acres, or one-fourth the area of deer forests in Scotland.

Poor, gravelly, clayey, and peaty soils prevail much more in Aberdeenshire than good rich loams, but tile draining, bones, and guano, and the best modes of modern tillage, have greatly increased the produce. Farm-houses and steadings have greatly improved, and the best agricultural implements and machines are in general use. About two-thirds of the population depend entirely on agriculture, and oatmeal in various forms, with milk, is the chief food of farm-servants. Farms are generally small, compared with those in the south-east counties. The fields are separated by dry-stone dykes, and also by wooden and wire fences. Leases of 19 or 21 years prevail, and the five, six, or seven shift rotation is in general use. In 1872 there were 11,642 occupiers of land, with an average of 50 acres each, and paying about £536,000 in rent. Of the 585,299 acres of the county in crop in 1872, 191,880 acres were in oats, 18,930 in barley and bere, 1633 in rye, 1357 in wheat, 95,091 in turnips (being one-fifth of the turnips grown in Scotland), 8414 in potatoes, 232,178 in grasses and clover. In 1872 the county had 23,117 horses, 157,960 cattle (being above one-seventh of all the cattle in Scotland), 123,308 sheep, and 13,579 pigs. The county is unsurpassed in breeding, and unrivalled in feeding cattle, and this is more attended to than the cultivation of grain-crops. About 40,000 fat cattle are reared, and above £1,000,000 value of cattle and dead meat is sent from the county to London yearly. The capital invested in agriculture within the county is estimated at about £5,133,000.

The great mineral wealth in Aberdeenshire is its long-famed durable granite, which is largely quarried for building, paving, causewaying, and polishing. An acre of land on being reclaimed has yielded £40 to £50 worth of causewaying stones. Gneiss is also quarried, as also primary limestone, old red sandstone, conglomerate millstone, grauwacke, clay slate, syenite, and hornblende rock. Iron ore, manganese, and plumbago occur in the county.

A large fishing population in villages along the coast engage in the white and herring fishery. Haddocks are salted and rock-dried (speldings), or smoked (finnans). The rivers and coasts yield many salmon. Peterhead was long the chief British port for the north whale and seal fishery, but Dundee now vies with it in this industry.

The manufactures and arts of the county are mainly prosecuted in or near the town of Aberdeen, but throughout the rural districts there are much milling of corn, brick and tile making, stone-quarrying, smith-work, brewing and distilling, cart and farm implement making, casting and drying of peat, timber felling, especially on Deeside and Donside, for pit-props, railway sleepers, lath, barrel staves, &c. The chief imports into the county are, coals, lime, timber, iron, slates, raw materials of textile manufactures, wheat, cattle-feeding stuffs, bones, guano, sugar, alcoholic liquors, fruits, &c. The chief exports are granite (rough, dressed, and polished), flax, woollen, and cotton goods, paper, combs, preserved provisions, oats, barley, live and dead cattle, &c. In the county there are about 520 fairs in the year for cattle, horses, sheep, hiring servants, &c.

Aberdeenshire communicates with the south by the Caledonian Railway, and five macadamised roads across the east Grampians, the highest rising 2200 feet above the sea. About 188 miles of railway (the Great North of Scotland, Formartin and Buchan, and Deeside lines), and 2359 miles of public roads, ramify through the county. Tolls over the county were abolished in 1865, and the roads are kept up by assessment. The railway lines in the county have cost on the average about £13,500 a mile. Several macadamised roads and the Great North of Scotland Railway form the main exits from the county to the north-west.

The chief antiquities in Aberdeenshire are Picts' houses or weems; stone foundations of circular dwellings; monoliths, some being sculptured; the so-called Druid circles; stone cists; stone and earthen enclosures; the vitrified forts of Dunnideer and Noath; cairns; crannoges; earthen mounds, as the Bass; flint arrow-heads; clay funeral urns; stone celts and hammers. Remains of Roman camps occur at Peterculter, Kintore, and Auchterless, respectively $107\frac{1}{2}$, 100, and 115 acres. Roman arms have been found. Ruins of ancient edifices occur. On the top of a conical hill called Dunnideer, in the Garioch district, are the remains of a castle, supposed to be 700 years old, and surrounded by a vitrified wall, which must be still older. The foundations of two buildings still remain, the one in Braemar, and the other in the Loch of Cannor (the latter with the remains of a wooden bridge between it and the land), which are supposed to have belonged to Malcolm Canmore, King of Scotland. The most extensive ruins are the grand ones of Kildrummy Castle, evidently once a princely seat, and still covering nearly an acre of ground. It belonged to David Earl of Huntingdon in 1150, and was the seat of the Earls of Marr attainted in 1716. The Abbey of Deer, now in ruins, was begun by Cumyn Earl of Buchan about 1219.

In Roman times, Aberdeenshire formed part of Vespasiana in Caledonia, and was occupied by the Taixali, a warlike tribe. The local names are mostly Gaelic. St Columba and his pupil Drostan visited Buchan in the 6th century. In 1052 Macbeth fell near the Peel Bog in Lumphanan, and a cairn which marks the spot is still shown. In 1309 Bruce defeated Comyn, Earl of Buchan, near Inverurie, and annihilated a powerful Norman family. In 1411 the Earl of Marr defeated Donald of the Isles in the battle of Harlaw, near Inverurie, when Sir Robert Davidson, Provost of Aberdeen, was killed. In 1562 occurred the battle of Corrichie on the Hill of Fare, when the Earl of Murray defeated the Marquis of Huntly. In 1715 the Earl of Marr proclaimed the Pretender in Braemar. In 1746 the Duke of Cumberland with his army marched through Aberdeenshire to Culloden. In 1817 a base line of verification, 5 miles 100 feet long, was measured in connection with the Trigonometrical Survey of the British Isles, on the Belhelvie Links 5 to 10 miles north of Aberdeen.

Among eminent men connected with Aberdeenshire are, Robert Gordon of Straloch, who in 1648 published the first atlas of Scotland from actual survey; the Earls Marischal, whose chief seat was Inverugie Castle; Field-Marshal Keith, born at Inverugie Castle, 1696; Dr Thomas Reid, the metaphysician, minister of New Machar 1737 to 1752; Lord Pitsligo, attainted 1745; Sir Archibald Grant of Monymusk, who introduced turnips into the county 1756, and was the first to plant wood on a great scale; Peter Garden, Auchterless, said to have died at the age of 132, about 1780; Rev. John Skinner, author of some popular Scottish songs; Morrison the hygeist; the Earl of Aberdeen, Prime Minister during the Crimean war.

The native Scotch population of Aberdeenshire are long-headed, shrewd, careful, canny, active, persistent, but reserved and blunt, and without demonstrative enthusiasm. They have a physiognomy distinct from the rest of the Scottish people, and have a quick, sharp, rather angry accent. The local Scotch dialect is broad, and rich in diminutives, and is noted for the use of *e* for *o* or *u*, *f* for *wh*, *d* for *th*, &c. In 1830 Gaelic was the fireside language almost every family in Braemar, but now it is little used.

Aberdeenshire has a Lord-Lieutenant and 3 Vice and 60 Deputy-Lieutenants. The Supreme Court of Justiciary sits in Aberdeen twice a-year to try cases from the counties of Aberdeen, Banff, and Kincardine. The counties of Aberdeen and Kincardine are under a Sheriff and two Sheriffs-Substitute. The Sheriff Courts are held in Aberdeen and Peterhead. Sheriff Small-Debt and Circuit Courts are held at seven places in the county. There are Burgh or Bailie Courts in Aberdeen and the other royal burghs in the county. Justice of the Peace and Police Courts are held in Aberdeen, &c. The Sheriff Courts take cognisance of Commissary business. During 1871, 994 persons were confined in the Aberdeenshire prisons. In the year 1870–71, 74 parishes in the county were assessed £53,703 for 7702 poor on the roll and 1847 casual poor.

Aberdeenshire contains 105 Established churches, 99 Free, 31 Episcopal, 15 United Presbyterian, 9 Roman Catholic, and 31 of other denominations. This includes detached parts of the two adjacent counties.

By the census of 1871, 84·83 per cent. of the children in the county, of the ages 5 to 13, were receiving education. Those formerly called the parochial schoolmasters of Aberdeenshire participate in the Dick and Milne Bequests, which contributed more salary to the schoolmasters in some cases than did the heritors. Most of the schoolmasters are Masters of Arts, and many are preachers. Of 114 parochial schools in the county before the operation of the new Education Act, 89 received the Milne Bequest of £20 a year, and 91 the Dick Bequest, averaging £30 a year, and a schoolmaster with both bequests would have a yearly income of £145 to £150, and in a few cases £250. The higher branches of education have been more taught in the schools of the shires of Aberdeen and Banff than in the other Scotch counties, and pupils have been long in the habit of going direct from the schools of these two counties to the University.

The value of property, or real rental of the lands and heritages in the county (including the burghs, except that of Aberdeen), for the year 1872–73, was £769,191. The railway and the water works in the city and county were for the same year valued at £11,133. For general county purposes for the year ending 15th May 1872, there was assessed £14,803 to maintain police, prisons, militia, county and municipal buildings, &c., and £19,320 to maintain 2359 miles of public county roads.

The chief seats on the proprietary estates are—Balmoral Castle, the Queen; Mar Lodge and Skene House, Earl of Fife; Aboyne Castle, Marquis of Huntly; Dunecht House, Earl of Crawford and Balcarres; Keith Hall, Earl of Kintore; Slains Castle, Earl of Errol; Haddo House, Earl of Aberdeen; Castle Forbes, Lord Forbes; Philorth House, Lord Saltoun; Huntly Lodge, the Duke of Richmond. Other noted seats are—Drum, Irvine; Invercauld, Farquharson; Newe Castle, Forbes; Castle Fraser, Fraser; Cluny Castle, Gordon; Meldrum House, Urquhart; Craigston Castle, Urquhart; Pitfour, Ferguson; Ellon Castle, Gordon; Fyvie Castle, Gordon. Ten baronets and knights have residences in the county. Of the proprietors many live permanently on their estates. Their prevailing names are Gordon, Forbes, Grant, Fraser, Duff, and Farquharson.

Aberdeenshire has one city, Aberdeen, a royal parliamentary burgh; three other royal parliamentary burghs, Inverurie, Kintore, and Peterhead; and seven burghs of barony, Old Aberdeen, Charleston of Aboyne, Fraserburgh, Huntly, Old Meldrum, Rosehearty, and Turriff.

The county sends two members to Parliament—one for East Aberdeenshire, with 4341 electors, and the other for West Aberdeenshire, with 3942 electors. The county has also four parliamentary burghs, which, with their respective populations in 1871, are—Aberdeen, 88,125; Peterhead, 8535; Inverurie, 2856; and Kintore, 659. The first sends one member to Parliament, and the other three unite with Elgin, Cullen, and Banff, in sending another.

By the census 1801 the county had 121,065 inhabitants, and by that of 1871, 244,603, with 53,576 families, 111 females to 100 males, 34,589 inhabited houses, 1052 uninhabited houses, and 256 building. In 1871 there were in eight towns (Aberdeen, Peterhead, Fraserburgh, Huntly, Inverurie, Old Meldrum, Turriff, and New Pitsligo), 111,978 inhabitants; in 32 villages, 19,561; and in rural districts, 113,064.

(*New Statistical Account of Scotland*, vol. xii.; the charters of the burgh; extracts from the Council Register down to 1625, and selections from the letters, guildry, and treasurer's accounts, forming 3 volumes of the Spalding Club; *Collections for a History of the Shires of A. and Banff*, edited by Joseph Robertson, Esq., 4to, Spalding Club;

(A. C.)

ABERDEEN, George Hamilton Gordon, Fourth Earl of, was born at Edinburgh on the 28th January 1784. He was educated at Harrow School, and at St John's College, Cambridge, where he graduated in 1804. He succeeded his grandfather in the earldom in 1801, and in the same year he made an extended tour through Europe, visiting France, Italy, and Greece. On his return he founded the Athenian Club, the membership of which was confined to those who had travelled in Greece. This explains Lord Byron's reference in the *English Bards and Scotch Reviewers* to "the travelled Thane, Athenian Aberdeen." Soon after his return he contributed a very able article to the *Edinburgh Review* (vol. vi.), on Gell's *Topography of Troy*. Another literary result of his tour was the publication in 1822 of *An Inquiry into the Principles of Beauty in Grecian Architecture*, the substance of which had appeared some years before in the form of an introduction to a translation of Vitruvius' *Civil Architecture*. In 1806, having been elected one of the representative peers for Scotland, he took his seat in the House of Lords on the Tory side. He was already on terms of intimacy with the leading members of the then predominant party, and in particular with Pitt, through the influence of his relative, the celebrated Duchess of Gordon. In 1813 he was intrusted with a delicate and difficult special mission to Vienna, the object being to induce the Emperor of Austria to join the alliance against his son-in-law Napoleon. His diplomacy was completely successful; the desired alliance was secured by the treaty of Töplitz, which the Earl signed as representative of Great Britain in September 1813. On his return at the conclusion of the war, he was raised to a British peerage, with the title of Viscount Gordon. Lord Aberdeen was a member of the Cabinet formed by the Duke of Wellington in 1828, for a short time as Chancellor of the Duchy of Lancaster, and then as Foreign Secretary. He was Colonial Secretary in the Tory Cabinet of 1834–5, and again received the seals of the Foreign Office under Sir Robert Peel's administration of 1841. The policy of non-intervention, to which he stedfastly adhered in his conduct of foreign affairs, was at once his strength and his weakness. According to the popular idea, he failed to see the limitations and exceptions to a line of policy which nearly all admitted to be as a general rule both wise and just. On the whole, his administration was perhaps more esteemed abroad than at home. It has been questioned whether any English minister ever was on terms of greater intimacy with foreign courts, but there is no substantial warrant for the charge of want of patriotism which was sometimes brought against him. On the two chief questions of home politics which were finally settled during his tenure of office, he was in advance of most of his party. While the other members of the Government yielded Catholic Emancipation and the repeal of the Corn Laws as unavoidable concessions, Lord Aberdeen spoke and voted for both measures from conviction of their justice. On the 13th June 1843, he moved the second reading of his bill "to remove doubts respecting the admission of ministers to benefices in Scotland," and it was passed into law in that session, though a similar measure had been rejected in 1840. As the first proposal did not prevent, so the passing of the Act had no effect in healing, the breach in the Established Church of Scotland which occurred in 1843. On the defeat of Lord Derby's government in 1852, the state of parties was such as to necessitate a coalition government, of which Lord Aberdeen, in consequence of the moderation of his views, was the natural chief. He had been regarded as the leader of the Peel party from the time of Sir Robert's death, but his views on the two great questions of home policy above mentioned rendered him more acceptable to the Liberals, and a more suitable leader of a coalition government than any other member of that party could have been. His administration will chiefly be remembered in connection with the Crimean war, which, it is now generally believed, might have been altogether prevented by a more vigorous policy. The incompetence of various departments at home, and the gross mismanagement of the commissariat in the terrible winter of 1854, caused a growing dissatisfaction with the government, which at length found emphatic expression in the House of Commons, when a motion submitted by Mr Roebuck, calling for inquiry, was carried by an overwhelming majority. Lord Aberdeen regarded the vote as one of no-confidence, and at once resigned. From this period Lord Aberdeen took little part in public business. In recognition of his services he received, soon after his resignation, the decoration of the Order of the Garter. He died December 13, 1860. Lord Aberdeen was twice married,—first in 1805, to a daughter of the first Marquis of Abercorn, who died in 1812, and then to the widow of Viscount Hamilton. He was succeeded in the title and estates by Lord Haddo, his son by the second marriage.

ABERDOUR, a village in the county of Fife, in Scotland, pleasantly situated on the north shore of the Firth of Forth, and much resorted to for sea-bathing. It is 10 miles N.W. of Edinburgh, with which there is a frequent communication by steamer.

ABERFELDY, a village in Perthshire, celebrated in Scottish song for its "birks" and for the neighbouring falls of Moness. It is the terminus of a branch of the Highland Railway.

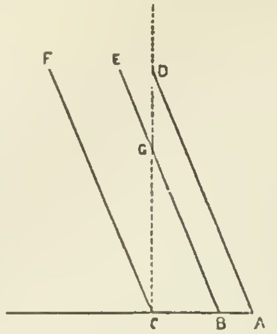
ABERGAVENNY, a market town in Monmouthshire, 14 miles west of Monmouth, situated at the junction of a small stream called the Gavenny, with the river Usk. It is supposed to have been the *Gobannium* of the Romans, so named from *Gobannio*, the Gavenny. The town was formerly walled, and has the remains of a castle built soon after the Conquest, and also of a Benedictine monastery. The river Usk is here spanned by a noble stone bridge of fifteen arches. Two markets are held weekly, and elegant market buildings have recently been erected. There is a free grammar school, with a fellowship and exhibitions at Jesus College, Oxford. No extensive manufacture is carried on except that of shoes; the town owes its prosperity mainly to the large coal and iron works in the neighbourhood. Abergavenny is a polling place for the county. Population of parish (1871), 6318.

ABERNETHY, a town in Perthshire, situated in the parish of the same name, on the right bank of the Tay, 7 miles below Perth. The earliest of the Culdee houses was founded there, and it is said to have been the capital of the Pictish kings. It was long the chief seat of the Episcopacy in the country, till, in the 9th century, the bishopric was transferred to St Andrews. There still remains at Abernethy a curious circular tower, 74 feet high and 48 feet in circumference, consisting of sixty-four courses of hewn stone. A number of similar towers, though not so well built, are to be met with in Ireland, but there is only one other in Scotland, viz., that at Brechin. Petrie argues, in his *Round Towers of Ireland*, that these structures have been used as belfries, and also as keeps.

ABERNETHY, John,—a Protestant dissenting divine of Ireland, was born at Coleraine, county Londonderry, Ulster, where his father was minister (Nonconformist), on the 19th October 1680. In his thirteenth year he entered a student at the University of Glasgow. On concluding his course at Glasgow he went to Edinburgh University, where his many brilliant gifts and quick and ready wit—thought-born, not verbal merely—struck the most eminent of his contemporaries and even his professors. Returning home, he received licence to preach from his Presbytery before he was twenty-one. In 1701 he was urgently invited to accept the ministerial charge of an important congregation in Antrim; and after an interval of two years, he was ordained there on 8th August 1703. His admiring biographer tells of an amount and kind of work done there, such as only a man of fecund brain, of large heart, of healthful frame, and of resolute will, could have achieved. In 1717 he was invited to the congregation of Usher's Quay, Dublin, as colleague with Rev. Mr Arbuckle, and contemporaneously, to what was called the Old Congregation of Belfast. The Synod assigned him to Dublin. He refused to accede, and remained at Antrim. This refusal was regarded then as ecclesiastical high-treason; and a controversy of the most intense and disproportionate character followed. The controversy and quarrel bears the name of the two camps in the conflict, the "Subscribers" and the "Non-subscribers." Out-and-out evangelical as John Abernethy was, there can be no question that he and his associates sowed the seeds of that after-struggle in which, under the leadership of Dr Henry Cooke, the Arian and Socinian elements of the Irish Presbyterian Church were thrown out. Much of what he contended for, and which the "Subscribers" opposed bitterly, has been silently granted in the lapse of time. In 1726 the "Non-subscribers," spite of an almost wofully pathetic pleading against separation by Abernethy, were cut off, with due ban and solemnity, from the Irish Presbyterian Church. In 1730, spite of being a "Non-subscriber," he was called by his early friends of Wood Street, Dublin, whither he removed. In 1731 came on the greatest controversy in which Abernethy engaged, viz., in relation to the Test Act nominally, but practically on the entire question of tests and disabilities. His stand was "against all laws that, upon account of mere differences of religious opinions and forms of worship, excluded men of integrity and ability from serving their country." He was nearly a century in advance of his century. He had to reason with those who denied that a Roman Catholic or Dissenter could be a "man of integrity and ability." His *Tracts*—afterwards collected—did fresh service, generations later. And so John Abernethy through life was ever foremost where unpopular truth and right were to be maintained; nor did he, for sake of an ignoble expediency, spare to smite the highest-seated wrongdoers any more than the hoariest errors (as he believed). He died in 1740, having been twice married. (Kippis' *Biog. Brit.*, s. v.; Dr Duchal's *Life*, prefixed to *Sermons; Diary* in MS., 6 vols. 4to; *History of Irish Presbyterian Church*). (A. B. G.)

ABERNETHY, John, grandson of the preceding, an eminent surgeon, was born in London on the 3d of April 1764. His father was a London merchant. Educated at Wolverhampton Grammar School, he was apprenticed in 1779 to Sir Charles Blicke, a surgeon in extensive practice in the metropolis. He attended Sir William Blizzard's anatomical lectures at the London Hospital, and was early employed to assist Sir William as "demonstrator;" he also attended Pott's surgical lectures at St Bartholomew's Hospital, as well as the lectures of the celebrated John Hunter. On Pott's resignation of the office of surgeon of St Bartholomew's, Sir Charles Blicke, who was assistant-surgeon, succeeded him, and Abernethy was elected assistant-surgeon in 1787. In this capacity he began to give lectures in Bartholomew Close, which were so well attended that the governors of the hospital built a regular theatre (1790-91), and Abernethy thus became the founder of the distinguished School of St Bartholomew's. He held the office of assistant-surgeon of the hospital for the long period of twenty-eight years, till, in 1815, he was elected principal surgeon. He had before that time been appointed surgeon of Christ's Hospital (1813), and Professor of Anatomy and Surgery to the Royal College of Surgeons (1814). Abernethy had great fame both as a practitioner and as a lecturer, his reputation in both respects resting on the efforts he made to promote the practical improvement of surgery. His *Surgical Observations on the Constitutional Origin and Treatment of Local Diseases* (1809)—known as "My Book," from the great frequency with which he referred his patients to it, and to page 72 of it in particular, under that name—was one of the earliest popular works on medical science. The views he expounds in it are based on physiological considerations, and are the more important that the connection of surgery with physiology had scarcely been recognised before the time he wrote. The leading principles on which he insists in "My Book" are chiefly these two:—1*st*, That topical diseases are often mere symptoms of constitutional maladies, and then can only be removed by general remedies; and 2*d*, That the disordered state of the constitution very often originates in, or is closely allied to deranged states of the stomach and bowels, and can only be remedied by means that beneficially affect the functions of those organs. His profession owed him much for his able advocacy of the extension in this way of the province of surgery. He had great success as a teacher from the thorough knowledge he had of his science, and the persuasiveness with which he enunciated his views. It has been said, however, that the influence he exerted on those who attended his lectures was not beneficial in this respect, that his opinions were delivered so dogmatically, and all who differed from him were disparaged and denounced so contemptuously, as to repress instead of stimulating inquiry. It ought to be mentioned, that he was the first to suggest and to perform the daring operation of securing by ligature the carotid and the external iliac arteries. The celebrity Abernethy attained in his practice was due not only to his great professional skill, but also in part to the singularity of his manners. He used great plainness of speech in his intercourse with his patients, treating them often brusquely, and sometimes even rudely. In the circle of his family and friends he was courteous and affectionate; and in all his dealings he was strictly just and honourable. He resigned his surgery at St Bartholomew's Hospital in 1827, and his professorship at the College of Surgeons two years later, on account of failing health, and died at his residence at Enfield on the 20th of April 1831. A collected edition of his works in five volumes was published in 1830. A biography, *Memoirs of John Abernethy*, by George Macilwain, F.R.C.S., appeared in 1853, and though anything but satisfactory, passed through several editions.

ABERRATION, or (more correctly) the Aberration of Light, is a remarkable phenomenon, by which stars appear to deviate a little, in the course of a year, from their true places in the heavens. It results from the eye of the observer being carried onwards by the motion of the earth on its orbit, during the time that light takes to travel from the star to the earth. The effect of this combination of motions may be best explained by a familiar illustration. Suppose a rain-drop falling vertically is received in a tube that has a lateral motion. In order that the drop may fall freely down the axis of the tube, the latter must be inclined at such an angle as to move from the position AD to BE, and again to CF, in the times the drop moves from D to G, and from G to C. The drop in this case, since it moves down the axis all the way, must strike the bottom of the tube at C *in the direction* FC. The light proceeding from a star is not seen in its true direction, but strikes the eye obliquely, for a precisely similar reason. If lines be taken to represent the motions, so that the eye is carried from A to C during the time that light moves from D to C, the light will appear to the eye at C to come, not from D, but from F. The angle DCF, contained by the true and apparent directions of the star, is the *aberration*. It is greatest when the two motions are at right angles to each other, *i.e.*, when the star's longitude is 90° in advance of, or behind, the heliocentric longitude of the earth, or (which amounts to the same thing) 90° behind, or in advance of, the geocentric longitude of the sun. (See ASTRONOMY.) Now, in the right-angled triangle ACD, tan ADC (*i.e.*, DCF) $= \frac{AC}{DC}$; whence it appears that the tangent of the angle of aberration (or, since the angle is very small, the aberration itself) is equal to the ratio, $\frac{\text{velocity of earth in orbit}}{\text{velocity of light}}$. The rate of the earth's motion being to the velocity of light in the proportion of 1 to 10,000 nearly, the maximum aberration is small, amounting to about 20·4 seconds of arc,—a quantity, however, which is very appreciable in astronomical observations.



Aberration always takes place in the direction of the earth's motion; that is, it causes the stars to appear nearer than they really are to the point towards which the earth is at the moment moving. That point is necessarily on the ecliptic, and 90° in advance of the earth in longitude. The effect is to make a star at the pole of the ecliptic appear to move in a plane parallel to the ecliptic, so as to form a small ellipse, similar to the earth's orbit, but having its major axis parallel to the minor axis of that orbit, and *vice versâ*. As we proceed from the pole, the apparent orbits the stars describe become more and more elliptical, till in the plane of the ecliptic the apparent motion is in a straight line. The length of this line, as well as of the major axes of the different ellipses, amounts, in angular measure, to about 40″·8. The stars thus appear to oscillate, in the course of the year, 20″·4 on each side of their true position, in a direction parallel to the plane of the ecliptic, and the quantity 20″·4 is therefore called the *constant of aberration*.

For the discovery of the aberration of light, one of the finest in modern astronomy, we are indebted to the distinguished astronomer Dr Bradley. He was led to it, in 1727, by the result of observations he made with the view of determining the annual parallax of some of the stars; that is, the angle subtended at these stars by the diameter of the earth's orbit. He observed certain changes in the positions of the stars that he could not account for. The deviations were not in the direction of the apparent motion that parallax would give rise to; and he had no better success in attempting to explain the phenomenon by the nutation of the earth's axis, radiation, errors of observation, &c. At last the true solution of the difficulty occurred to him, suggested, it is said, by the movements of a vane on the top of a boat's mast. Roemer had discovered, a quarter of a century before, that light has a velocity which admits of measurement; and Bradley perceived that the earth's motion, having a perceptible relation to that of light, must affect the direction of the visual rays, and with this the apparent positions of the stars. He calculated the aberration from the known relative velocities of the earth and of light, and the results agreed entirely with his observations.

The observed effects of aberration are of importance as supplying an independent method of measuring the velocity of light, but more particularly as presenting one of the few direct proofs that can be given of the earth's motion round the sun. It is indeed the most satisfactory proof of this that astronomy furnishes, the phenomenon being quite inexplicable on any other hypothesis.

ABERYSTWITH, a municipal and parliamentary borough, market town, and seaport of Wales, in the county of Cardigan, is situated at the western end of the Vale of Rheidol, near the confluence of the rivers Ystwith and Rheidol, and about the centre of Cardigan Bay. It is the terminal station of the Cambrian Railway, and a line to the south affords direct communication with South Wales, Bristol, &c. The borough unites with Cardigan, Lampeter, &c., in electing a member of Parliament. Coal, timber, and lime are imported, and the exports are lead, oak bark, flannel, and corn. The harbour has of late been much improved; and the pier, completed in 1865, forms an excellent promenade. There are many elegant buildings, and it has been proposed to establish here a University College of Wales. On a promontory to the S.W. of the town are the ruins of its ancient castle, erected in 1277, by Edward I., on the site of a fortress of great strength, built by Gilbert de Strongbow, and destroyed by Owen Gwynedd. From its picturesque situation and healthy climate, and the suitableness of the beach for bathing, Aberystwith has risen into great repute as a watering-place, and attracts many visitors. Much of the finest scenery in Wales, such as the Devil's Bridge, &c., lies within easy reach. Population (1871), 6898.

ABETTOR, a law term implying one who instigates, encourages, or assists another to perform some criminal action. See ACCESSORY.

ABEYANCE, a law term denoting the expectancy of an estate. Thus, if lands be leased to one person for life, with reversion to another for years, the remainder for years is in abeyance till the death of the lessee.

ABGAR, the name or title of a line of kings of Edessa in Mesopotamia. One of them is known from a correspondence he is said to have had with Jesus Christ. The letter of Abgar, entreating Jesus to visit him and heal him of a disease, and offering Him an asylum from the wrath of the Jews, and the answer of Jesus promising to send a disciple to heal Abgar after His ascension, are given by Eusebius, who believed the documents to be genuine. The same belief has been held by a few moderns, but there can be no doubt whatever that the letter of Jesus at least is apocryphal. It has also been alleged that Abgar possessed a picture of Jesus, which the credulous may see either at Rome or at Genoa. Some make him the possessor of the handkerchief a woman gave Jesus, as He bore the cross, to wipe the sweat from His face with, on which, it is fabled, His features remained miraculously imprinted.

ABIAD, BAHR-EL-, a name given to the western branch of the Nile, above Khartoum. It is better known as the White Nile. See NILE.

ABIES. See Fir.

ABILA, a city of ancient Syria, the capital of the tetrarchy of Abilene, a territory whose limits and extent it is impossible now to define. The site of Abila is indicated by some ruins and inscriptions on the banks of the river Barada, between Baalbec and Damascus, about twelve miles from the latter city. Though the names Abel and Abila differ in derivation and in meaning, their similarity has given rise to the tradition that this was the scene of Abel's death.

ABILDGAARD, Nikolaj, called "the Father of Danish Painting," was born in 1744. He formed his style on that of Claude and of Nicolas Poussin, and was a cold theorist, inspired not by nature but by art. As a technical painter he attained remarkable success, his tone being very harmonious and even, but the effect, to a foreigner's eye, is rarely interesting. His works are scarcely known out of Copenhagen, where he won an immense fame in his own generation, and where he died in 1809. He was the founder of the Danish school of painting, and the master of Thorwaldsen and Eckersberg.

ABIMELECH (אֲבִימֶלֶךְ, *father of the king*, or rather perhaps *king-father*), occurs first in the Bible as the name of certain kings of the Philistines at Gerar (Gen. xx. 2, xxi. 22, xxvi. 1). From the fact that the name is applied in the inscription of the thirty-fourth psalm to Achish, it has been inferred with considerable probability that it was used as the official designation of the Philistinian kings. The name was also borne by a son of Gideon, judge of Israel, by his Shechemite concubine (Judges viii. 31). On the death of Gideon, who had refused the title of king both for himself and his children, Abimelech set himself to obtain the sovereignty through the influence of his mother's relatives. In pursuance of his plan he slew seventy of his brethren "upon one stone" at Ophrah, Jotham, the youngest of them, alone contriving to escape. This is one of the earliest recorded instances of a practice exceedingly common on the accession of Oriental despots. Abimelech was eventually made king, although his election was opposed by Jotham, who boldly appeared on Mount Gerizim and told the assembled Shechemites the fable of the trees desiring a king. At the end of the third year of his reign the Shechemites revolted, and under the leadership of Gaal made an unsuccessful attempt to throw off the authority of Abimelech. In Judges ix. there is an account of this insurrection, which is specially interesting owing to the full details it gives of the nature of the military operations. After totally destroying Shechem, Abimelech proceeded against Thebez, which had also revolted. Here, while storming the citadel, he was struck on the head by the fragment of a millstone thrown from the wall by a woman. To avoid the disgrace of perishing by a woman's hand, he requested his armour-bearer to run him through the body. Though the immediate cause of his death was thus a sword-thrust, his memory was not saved from the ignominy he dreaded (2 Sam. xi. 21). It has been usual to regard Abimelech's reign as the first attempt to establish a monarchy in Israel. The facts, however, seem rather to support the theory of Ewald (*Gesch.* ii. 444), that Shechem had asserted its independence of Israel, when it chose Abimelech as its king.

ABINGDON, a parliamentary and municipal borough and market town of England, in Berkshire, on a branch of the Thames, 7 miles south of Oxford, and 51 miles W.N.W. of London. It is a place of great antiquity, and was an important town in the time of the Heptarchy. Its name is derived from an ancient abbey. The streets, which are well paved, converge to a spacious area, in which the market is held. In the centre of this area stands the market-house, supported on lofty pillars, with a large hall above, appropriated to the summer assizes for the county, and the transaction of other public business. The town contains two churches, which are said to have been erected by the abbots of Abingdon, one dedicated to St Nicholas and the other to St Helena; several charitable institutions, and a free grammar school, with scholarships at Pembroke College, Oxford. In 1864 a memorial of Prince Albert was erected at Abingdon, a richly ornamented structure, surmounted by a statue of the Prince. Abingdon was incorporated by Queen Mary. It sends one member to Parliament, and is governed by a mayor, four aldermen, and twelve councillors. In the beginning of the century it manufactured much sail-cloth and sacking; but its chief trade now is in corn and malt, carpets, and coarse linen. It is a station on a branch of the Great Western Railway. Population (1871), 6571.

ABIOGENESIS, as a name for the production of living by not-living matter, has of late been superseding the less accurate phrase "Spontaneous Generation." Professor Huxley, who made use of the word in his presidential address to the British Association in 1870, distinguished Abiogenesis from "Xenogenesis" or "Heterogenesis," which occurs, or is supposed to occur, not when dead matter produces living matter, but when a living parent gives rise to offspring which passes through a totally different series of states from those exhibited by the parent, and does not return into the parent's cycle of changes. When a "living parent gives rise to offspring which passes through the same cycle of changes as itself," there occurs "Homogenesis." "Biogenesis" includes both of these. Other names for Abiogenesis are *Generatio Æquivoca*, *Generatio Primaria*, Archigenesis (Urzeugung), Archebiosis, &c. The question of Abiogenesis—whether under certain conditions living matter is produced by not-living matter—as it is one of the most fundamental, is perhaps also the oldest in Biology; but within recent years—partly because the means of accurate experimentation have been increased and the microscope improved, and partly because the question has been recognised in its important bearings on evolution, the correlation of forces, and the theory of infectious diseases—naturalists have been led to bestow more attention upon it than at any previous period. While, therefore, the doctrine of Abiogenesis cannot be said to be either finally established or refuted, it is at least reasonable to believe that we are gradually advancing to a solution. Among the older observers of phenomena bearing on the question may be named Aristotle, who, with the ancients generally, favoured Abiogenesis; Redi, the founder of the opposite view; Vallisnieri; Buffon; Needham; and Spallanzani; among later observers, Schwann and Schulze, Schrœder and Dusch, Pasteur, Pouchet, Haeckel, Huxley, Bastian, and many others. The experiments and observations made by these naturalists, and their results—the ingenious expedients employed to prevent inaccuracy—the interesting and often marvellous transformations which microscopists declare they have witnessed—will be discussed in the article Histology; here it will be enough to note the general nature of the reasonings with which the opponents and defenders of Abiogenesis support their views. The opponents maintain that all trustworthy observations have hitherto shown living matter to have sprung from pre-existing living matter; and that the further we search and examine, the smaller becomes the number of those organisms which we cannot demonstrate to have arisen from living parents. They hold that seeming instances of spontaneous generation are usually to be explained by the germ-theory—the presence of invisible germs in the air; and they call to their aid such high authorities as Pasteur and Tyndall. The defenders of Abiogenesis, on the other hand, while interpreting the results of past observation and experiment in their own favour, are yet less disposed to rest on these, rather preferring to argue from those wide analogies of evolution and correlation which seem to support their doctrine. Thus Haeckel expressly embraces Abiogenesis as a necessary and integral part of the theory of universal evolution; and Huxley, in the same spirit, though from the opposite camp, confesses that if it were given him to look beyond the abyss of geologically recorded time to the still more remote period when the earth was passing through physical and chemical conditions, he should expect to be a witness of the evolution of living protoplasm from not-living matter. (*Critiques and Addresses*, p. 239.) From this point of view, of course, any microscopic observations that have been made seem very limited and comparatively unimportant. The Abiogenists, indeed, are not without arguments to oppose the results of past observation that seem unfavourable to their views; they argue that, as yet, all the forms observed and shown to be produced by Biogenesis are forms possessing a certain degree of organisation, which in their case makes Abiogenesis unlikely, from the first; whereas it has not been shown that the simplest structures—the *Monera*—do not arise by Abiogenesis. But it is not so much on grounds of fact and experiment the defenders of the Abiogenesis theory are convinced of its truth, as because it seems to gain confirmation from reasonings of much wider scope; because Abiogenesis aids the theory of evolution by tracing the organic into the inorganic; because it fosters the increasing unpopularity of the hypothesis of a special "vital force;" and because, if this theory of the "perpetual origination of low forms of life, now, as in all past epochs," were established, it would agree well with the principle of uniformity, and by disclosing the existence of unknown worlds of material for development, would relieve natural selection with its assisting causes from what many consider the too Herculean labour of evolving all species from one or a very few primary forms. The fullest discussion of the subject of Abiogenesis, from the Abiogenist's point of view, is to be found in Dr Bastian's *Beginnings of Life*. Professor Huxley's address, already referred to, contains an interesting historical survey, as well as a masterly summary of facts and arguments in favour of Biogenesis. For many interesting experiments, see *Nature*, 1870–73.

ABIPONES, a tribe of South American Indians, inhabiting the territory lying between Santa Fé and St Iago. They originally occupied the Chaco district of Paraguay, but were driven thence by the hostility of the Spaniards. According to M. Dobrizhoffer, who, towards the end of last century, lived among them for a period of seven years, they have many singular customs and characteristics. They seldom marry before the age of thirty, are chaste and otherwise virtuous in their lives, though they practise infanticide, and are without the idea of God. "With the Abipones," says Darwin, "when a man chooses a wife, he bargains with the parents about the price. But it frequently happens that the girl rescinds what has been agreed upon between the parents and bridegroom, obstinately rejecting the very mention of marriage. She often runs away and hides herself, and thus eludes the bridegroom." The Abiponian women suckle those infants that are spared for the space of two years,—an onerous habit, which is believed to have led to infanticide as a means of escape. The men are brave in war, and pre-eminently expert in swimming and horsemanship. Numerically the tribe is insignificant. M. Dobrizhoffer's account of the Abiponians was translated into English by Sara Coleridge, at the suggestion of Mr Southey, in 1822.

ABJURATION. See ALLEGIANCE, OATH OF.

ABKHASIA, or ABASIA, a tract of Asiatic Russia, on the border of the Black Sea, comprehending between lat. 42° 30′ and 44° 45′ N. and between long. 37° 3′ and 40° 36′ E. The high mountains of the Caucasus on the N and N.E. divide it from Circassia; on the S.E. it is bounded by Mingrelia; and on the S.W. by the Black Sea. Though the country is generally mountainous, there are some deep well-watered valleys, and the climate is mild. The soil is fertile, producing grain, grapes, and other fruits. Some of the inhabitants devote themselves to agriculture, some to the rearing of cattle and horses, and not a few support themselves by piracy and robbery. Honey is largely produced, and is exported to Turkey; and excellent arms are made. Both in ancient and in modern times there has been considerable traffic in slaves. This country was early known to the ancients, and was subdued by the Emperor Justinian, who introduced civilisation and Christianity. Afterwards the Persians, then the Georgians, and more recently the Turks, ruled over the land. Under the Turks Christianity gradually disappeared, and Mohammedanism was introduced in its stead. By the treaties of Akerman and Adrianople, Russia obtained possession of the fortresses of this territory; but till the insurrection of 1866, the chiefs had almost unlimited power. The principal town is Sukumkaleh. The population of Abkhasia is variously stated at from 50,000 to 250,000. See Palgrave's *Essays on Eastern Questions*, 1872.

ABLUTION, a ceremonial purification, practised in nearly every age and nation. It consisted in washing the body in whole or part, so as to cleanse it symbolically from defilement, and to prepare it for religious observances. Among the Jews we find no trace of the ceremony in patriarchal times, but it was repeatedly enjoined and strictly enforced under the Mosaic economy. It denoted either—(1.) Cleansing from the taint of an inferior and less pure condition, and initiation into a higher and purer state, as in the case of Aaron and his sons on their being set apart to the priesthood; or (2.) Cleansing from the soil of common life, in preparation for special acts of worship, as in the case of the priests who were commanded, upon pain of death, to wash their hands and feet before approaching the altar; or (3.) Cleansing from the pollution occasioned by particular acts and circumstances, as in the case of the eleven species of uncleanness mentioned in the Mosaic law; or (4.) The absolving or purifying one's self from the guilt of some particular criminal act, as in the case of Pilate at the trial of the Saviour. The sanitary reasons which, in a warm climate and with a dry sandy soil, rendered frequent ablution an imperative necessity, must not be allowed to empty the act of its symbolic meaning. In the Hebrew different words are used for the washing of the hands before meals, which was done for the sake of cleanliness and comfort, and for the washing or plunging enjoined by the ceremonial law. At the same time it is impossible to doubt that the considerations which made the law so suitable in a physical point of view were present to the mind of the Lawgiver when the rite was enjoined. Traces of the practice are to be found in the history of nearly every nation. The customs of the Mohammedans, in this as in other matters, are closely analogous to those of the Jews. With them ablution must in every case precede the exercise of prayer, and their law provides that in the desert, where water is not to be found, the Arabs may perform the rite with sand. Various forms of ablution practised by different nations are mentioned in the sixth book of the Æneid, and we are told that Æneas washed his ensanguined hands after the battle before touching his Penates. Symbolic ablution finds a place under the New Testament dispensation in the rite of baptism, which is observed, though with some variety of form and circumstances, throughout the whole Christian Church. By Roman Catholics and Ritualists, the term ablution is applied to the cleansing of the chalice and the fingers of the celebrating priest after the administration of the Lord's Supper.

ABNER (אַבְנֵר, *father of light*), first cousin of Saul (1 Sam. xiv. 50) and commander-in-chief of his army. The chief references to him during the lifetime of Saul are found in 1 Sam. xvii. 55, and xxvi. 5. It was only after that monarch's death, however, that Abner was brought into a position of the first political importance. David, who had some time before been designated to the throne, was accepted as king by Judah alone, and was crowned at Hebron. The other tribes were actuated by a feeling hostile to Judah, and, as soon as they had thrown off the Philistinian yoke, were induced by Abner to recognise Ishbosheth, the surviving son of Saul, as their king. One engagement between the rival factions under Joab and Abner respectively (2 Sam. ii. 12) is noteworthy, inasmuch as it was preceded by an encounter between twelve chosen men from each side, in which the whole twenty-four seem to have perished. In the general engagement which followed, Abner was defeated and put to flight. He was closely pursued by Asahel, brother of Joab, who is said to have been "light of foot as a wild roe." As Asahel would not desist from the pursuit, though warned, Abner was compelled to slay him in self-defence. This originated a deadly feud between the leaders of the opposite parties, for Joab, as next of kin to Asahel, was by the law aud custom of the country the avenger of his blood. For some time afterwards the war was carried on, the advantage being invariably on the side of David. At length Ishbosheth lost the main prop of his tottering cause by remonstrating with Abner for marrying Rizpah, one of Saul's concubines, an alliance which, according to Oriental notions, implied pretensions to the throne. Abner was indignant at the rebuke, and immediately transferred his allegiance to David, who not only welcomed him, but promised to give him the command of the combined armies on the re-union of the kingdoms. Almost immediately after, however, Abner was slain by Joab and his brother Abishai at the gate of Hebron. The ostensible motive for the assassination was a desire to avenge Asahel, and this would be a sufficient justification for the deed according to the moral standard of the time. There can be little doubt, however, that Joab was actuated in great part by jealousy of a new and formidable rival, who seemed not unlikely to usurp his place in the king's favour. The conduct of David after the event was such as to show that he had no complicity in the act, though he could not venture to punish its perpetrators. The dirge which he repeated over the grave of Abner (2 Sam. iii. 33–4) has been thus translated:—

> Should Abner die as a villain dies?—
> Thy hands—not bound.
> Thy feet—not brought into fetters:
> As one falls before the sons of wickedness, fellest thou.

ABO, a city and seaport, and chief town of the district of the same name in the Russian province of Finland, is situated in N. lat. 60° 26′, E. long. 22° 19′, on the Aura-joki, about 3 miles from where it falls into the Gulf of Bothnia. It was a place of importance when Finland formed part of the kingdom of Sweden, and the inhabitants of the city and district are mostly of Swedish descent. By the treaty of peace concluded here between Russia and Sweden on 17th August 1743, a great part of Finland was ceded to the former. Abo continued to be the capital of Finland till 1819. In November 1827, nearly the whole city was burnt down, the university and its valuable library being entirely destroyed. Before this calamity Abo contained 1100 houses, and 13,000 inhabitants; and its university had 40 professors, more than 500 students, and a library of upwards of 30,000 volumes, together with a botanical garden, an observatory, and a chemical laboratory. The university has since been removed to Helsingfors. Abo is the seat of an archbishop, and of the supreme court of justice for South Finland; and it has a cathedral, a town-hall, and a custom-house. Sail-cloth, linen, leather, and tobacco are manufactured; shipbuilding is carried on, and there are extensive saw-mills. There is also a large trade in timber, pitch, and tar. Vessels drawing 9 or 10 feet come up to the town, but ships of greater draught are laden and discharged at the mouth of the river, which forms an excellent harbour and is protected. Population in 1867, 18,109.

ABOLITIONIST. See SLAVERY.

ABOMASUM, *caillette*, the fourth or rennet stomach of Ruminantia. From the *omasum* the food is finally deposited in the abomasum, a cavity considerably larger than either the second or third stomach, although less than the first. The base of the abomasum is turned to the *omasum*. It is of an irregular conical form. It is that part of the digestive apparatus which is analogous to the single stomach of other Mammalia, as the food there undergoes the process of chymification, after being macerated and ground down in the three first stomachs.

ABOMEY, the capital of Dahomey, in West Africa, is situated in N. lat. 7°, E. long. 2° 4′, about 60 miles N. of Whydah, the port of the kingdom. It is a clay-built town, surrounded by a moat and mud walls, and occupies a large area, part of which is cultivated. The houses stand apart; there are no regular streets; and the place is very dirty. It has four larger market-places, and trade is carried on in palm-oil, ivory, and gold, Mohammedan traders from the interior resorting to its markets. The town contains the principal palace of the king of Dahomey. It is the scene of frequent human sacrifices, a "custom" being held annually, at which many criminals and captives are slain; while on the death of a king a "grand custom" is held, at which sometimes as many as 2000 victims have perished. The slave-trade is also prosecuted, and the efforts of the British Government to induce the king to abolish it and the "customs" have proved unsuccessful. Population, about 30,000. See DAHOMEY.

ABORIGINES, originally a proper name given to an Italian people who inhabited the ancient Latium, or country now called *Campagna di Roma*. Various derivations of this name have been suggested; but there can be scarcely any doubt that the usual derivation (*ab origine*) is correct, and that the word simply indicated a settled tribe, whose origin and earlier history were unknown. It is thus the equivalent of the Greek *autochthones*. It is therefore, strictly speaking, not a proper name at all, although, from being applied to one tribe (or group of tribes), it came to be regarded as such. Who the Aborigines were, or whence they came, is uncertain; but various traditions that are recorded seem to indicate that they were an Oscan or Opican tribe that descended from the Apennines into Latium, and united with some Pelasgic tribe to form the Latins. The stories about Æneas's landing in Italy represent the Aborigines as at first opposing and then coalescing with the Trojans, and state that the united people then assumed the name of *Latins*, from their king *Latinus*. These traditions clearly point to the fact that the Latins were a mixed race, a circumstance which is proved by the structure of their language, in which we find numerous words closely connected with the Greek, and also numerous words that are of an entirely different origin. These non-Greek words are mostly related to the dialects of the

Opican tribes. In modern times the term *Aborigines* has been extended in signification, and is used to indicate the inhabitants found in a country at its first discovery, in contradistinction to colonies or new races, the time of whose introduction into the country is known.

ABORTION, in *Midwifery* (from *aborior*, I perish), the premature separation and expulsion of the contents of the pregnant uterus. When occurring before the eighth lunar month of gestation, *abortion* is the term ordinarily employed, but subsequent to this period it is designated *premature labour*. The present notice includes both these terms. As an accident of pregnancy, abortion is far from uncommon, although its relative frequency, as compared with that of completed gestation, has been very differently estimated by accoucheurs. It is more liable to occur in the earlier than in the later months of pregnancy, and it would also appear to occur more readily at the periods corresponding to those of the menstrual discharge. Abortion may be induced by numerous causes, both of a local and general nature. Malformations of the pelvis, accidental injuries, and the diseases and displacements to which the uterus is liable, on the one hand; and, on the other, various morbid conditions of the ovum or placenta leading to the death of the fœtus, are among the direct local causes of abortion. The general causes embrace certain states of the system which are apt to exercise a more or less direct influence upon the progress of utero-gestation. A deteriorated condition of health, whether hereditary or as the result of habits of life, certainly predisposes to the occurrence of abortion. Syphilis is known to be a frequent cause of the death of the fœtus. Many diseases arising in the course of pregnancy act as direct exciting causes of abortion, more particularly the eruptive fevers and acute inflammatory affections. Prolonged irritation in other organs may, by reflex action, excite the uterus to expel its contents. Strong impressions made upon the nervous system, as by sudden shocks and mental emotions, occasionally have a similar effect. Further, certain medicinal substances, particularly ergot of rye, borax, savin, tansy, and cantharides, are commonly believed to be capable of exciting uterine action, but the effects, as regards at least early pregnancy, are very uncertain, while the strong purgative medicines sometimes employed with the view of procuring abortion have no effect whatever upon the uterus, and can only act remotely and indirectly, if they act at all, by irritating the alimentary canal. In cases of poisoning with carbonic acid, abortion has been observed to take place, and the experiments of Dr Brown Sequard show that anything interfering with the normal oxygenation of the blood may cause the uterus to contract and expel its contents. Many cases of abortion occur without apparent cause, but in such instances the probability is that some morbid condition of the interior of the uterus exists, and the same may be said of many of those cases where the disposition to abort has become habitual. The tendency, however, to the recurrence of abortion in persons who have previously miscarried is well known, and should ever be borne in mind with the view of avoiding any cause likely to lead to a repetition of the accident. Abortion resembles ordinary labour in its general phenomena, excepting that in the former hemorrhage often to a large extent forms one of the leading symptoms. The treatment of abortion embraces the means to be used by rest, astringents, and sedatives, to prevent the occurrence when it merely threatens; or when, on the contrary, it is inevitable, to accomplish as speedily as possible the complete removal of the entire contents of the uterus. The artificial induction of premature labour is occasionally resorted to by accoucheurs under certain conditions involving the safety of the mother or the fœtus. For *Criminal Abortion*, see MEDICAL JURISPRUDENCE.

ABOUKIR, a small village on the coast of Egypt, 13 miles N.E. of Alexandria, containing a castle which was used as a state prison by Mehemet Ali. Near the village, and connected with the shore by a chain of rocks, is a small island remarkable for remains of ancient buildings. Stretching to the eastward as far as the Rosetta mouth of the Nile is the spacious bay of Aboukir, where Nelson fought "the Battle of the Nile," defeating and almost destroying the French fleet that had conveyed Napoleon to Egypt. It was near Aboukir that the expedition to Egypt, under Sir Ralph Abercromby, in 1801, effected a landing in the face of an opposing force.

ABRABANEL, ISAAC (called also *Abravanel, Abarbanel, Barbanella*, and *Ravanella*), a celebrated Jewish statesman, philosopher, theologian, and commentator, was born at Lisbon in 1437. He belonged to an ancient family that claimed descent from the royal house of David, and his parents gave him an education becoming so renowned a lineage. He held a high place in the favour of King Alphonso V., who intrusted him with the management of important state affairs. On the death of Alphonso in 1481, his counsellors and favourites were harshly treated by his successor John; and Abrabanel was, in consequence, compelled to flee to Spain, where he held for eight years (1484–1492), the post of a minister of state under Ferdinand and Isabella. When the Jews were banished from Spain in 1492, no exception was made in Abrabanel's favour. He afterwards resided at Naples, Corfu, and Monopoli, and in 1503 removed to Venice, where he held office as a minister of state till his death in 1508. Abrabanel was one of the most learned of the rabbis. His writings are chiefly exegetical and polemical; he displays in them an intense antipathy to Christianity, though he lived on terms of friendship with Christians. He wrote commentaries on the greater part of the Old Testament, in a clear but somewhat diffuse style, anticipating much that has been advanced as new by modern theologians.

ABRACADABRA, a meaningless word once supposed to have a magical efficacy as an antidote against agues and other fevers. Ridiculously minute directions for the proper use of the charm are given in the *Præcepta de Medicina* of Serenus Sammonicus. The paper on which the word was written had to be folded in the form of a cross, suspended from the neck by a strip of linen so as to rest on the pit of the stomach, worn in this way for nine days, and then, before sunrise, cast behind the wearer into a stream running to the east. The letters of this word were usually arranged to form a triangle in one or other of the following ways :—

ABRACADABRA	ABRACADABRA
ABRACADABR	BRACADABR
ABRACADAB	RACADAB
ABRACADA	ACADA
ABRACAD	CAD
ABRACA	A
ABRAC	
ABRA

ABRAHAM or ABRAM, father of the Israelite race, was the first-born son of Terah, a Shemite, who left Ur of the Chaldees, in the north-east of Mesopotamia, along with Abram, Sarai, and Lot, and turned westwards in the direction of Canaan. Abram had married his half-sister Sarai, who was ten years younger than himself; and though such relationship was afterwards forbidden by the law, it was common in ancient times, both among other peoples, and among the Hebrews themselves at least before Moses. The cause of Terah's removing from his native country is not given. Having come to Haran, he abode there till his death, at the age of 205. According to Genesis xii., Abram left Haran when he was 75 years of age, that is, before the death of his father, in consequence of a divine command, to which was annexed a gracious promise, "And I will make of thee a great nation, and I will bless thee, and make thy name great; and thou shalt be a blessing. And I will bless them that bless thee, and curse him that curseth thee; and in thee shall all families of the earth be blessed" (xii. 2, 3). Another tradition makes him leave Haran only after Terah's decease (Acts vii. 4). The later account is that Abram's departure was the result of religious considerations, because he had already become emancipated from surrounding idolatry. Perhaps the desire of a nomadic life, the love of migration natural to an Oriental, had more to do with his pilgrimage than a spiritual impulse from within; but it is likely that his culture advanced in the course of his sojournings, and that he gradually attained to purer conceptions of duty and life. Traditions subsequent to the Jehovistic represent him as driven forth by the idolatrous Chaldeans (Judith v. 6, &c.) on account of his monotheistic doctrines, and then dwelling in Damascus as its king (Josephus's *Antiquities*, i. 7). The true cause of departure may be suggested by Nicolaus of Damascus saying that he came out of Chaldea with an army. The leader of a horde, worsted in some encounter or insurrection, he emigrated at the head of his adherents in quest of better fortunes. The word *redeemed*, in Isaiah xxix. 22, out of which Ewald conjectures so much, as if Abram had been rescued from great bodily dangers and battles, does not help the portrait, because it means no more than the patriarch's migration from heathen Mesopotamia into the Holy Land. Journeying south-west to Canaan with his wife and nephew, he arrived at Sichem, at *the oak of the seer* or *prophet*, where Jehovah appeared to him, assuring him for the first time that his seed should possess the land he had come to. He travelled thence southward, pitching his tent east of Bethel. Still proceeding in the same direction, he arrived at the Negeb, or most southern district of Palestine, whence a famine forced him down to Egypt. His plea that Sarai was his sister did not save her from Pharaoh; for she was taken into the royal harem, but restored to her husband in consequence of divine chastisments inflicted upon the lawless possessor of her person, leading to the discovery of her true relationship. The king was glad to send the patriarch away under the escort and protection of his men. A similar thing is said to have subsequently happened to Sarai at Gerar with the Philistine king Abimelech (Genesis xx.), as also to Rebekah, Isaac's wife (xxvi.) The three narratives describe one and the same event in different shapes. But the more original (the junior Elohistic)[1] is that of the 20th chapter, so that Gerar was the scene, and Abimelech the offender; while the later Jehovistic narrative (xii.) deviates still more from verisimilitude. Though this occurrence, however, belongs to the southern borders of Palestine, we need not doubt the fact of Abram's sojourn in Egypt, especially as he had an Egyptian slave (Genesis xvi.) How long the patriarch remained there is not related; nor are the influences which the religion, science, and learning of that civilised land had upon him alluded to. That they acted beneficially upon his mind, enlightening and enlarging it, can scarcely be doubted. His religious conceptions were transformed. The manifold wisdom of Egypt impressed him. Intercourse with men far advanced in civilisation taught him much. Later tradition speaks of his communicating to the Egyptians the sciences of arithmetic and astronemy (Josephus i. 7); but this is founded upon the notion entertained at the time of the civilised Chaldeans of Babylon, whereas Ur of the Chaldees was a district remote from the subsequent centre of recondite knowledge. Abram received more than he imparted, for the Egyptians were doubtless his superiors in science. He found the rite of circumcision in use. There, too, he acquired great substance—flocks and herds, male and female slaves. After returning to Canaan, to his former locality, Abram and Lot separated, because of disputes between their herdsmen, there not being sufficient room for all their cattle in common. After this separation the possession of Canaan was again assured to Abram and to his seed, who should be exceedingly numerous. This is the third theocratic promise he received. He is also commanded by Jehovah to walk through it in its length and breadth as a token of inheritance,—a later Jehovistic tradition that must be judged according to its inherent verisimilitude. Abram settled again at the oak of Mamre near Hebron. This was his headquarters. After Lot had been taken prisoner in the expedition of the kings of Shinar, Ellasar, Elam, and Goyim, against the old inhabitants of Basan, Ammonitis, Moabitis, Edomitis, and others besides, Abram gave chase to the enemy, accompanied by his 318 slaves and friendly neighbours, rescuing his nephew at Hobah, near Damascus. On his return, the royal priest Melchizedek of Salem came forth to meet him with refreshments, blessed the patriarch, and received from him the tithe of the spoils. The king acted generously towards the victor, and was still more generously treated in return.

Jehovah again promised to Abram a numerous offspring, with the possession of Canaan. He also concluded a covenant with him in a solemn form, and revealed the fortunes of his posterity in Egypt, with their deliverance from bondage. In consequence of the barrenness of Sarai, she gave her handmaid Hagar to Abram, who, becoming pregnant by him, was haughtily treated by her mistress, and fled towards Egypt. But an angel met her in the desert and sent her back, telling of a numerous race that should spring from her. Having returned, she gave birth to Ishmael, in the 86th year of Abram's age.

Again did Jehovah appear to the patriarch, promising as before a multitudinous seed, and changing his name in conformity with such promise. He assured him and his posterity of the possession of Canaan, and concluded a covenant with him for all time. At the institution of circumcision on this occasion, Sarai's name was also changed, because she was to be the maternal progenitor of the covenant people through Isaac her son. Abram, and all the males belonging to him, were then circumcised. He had become acquainted with the rite in Egypt, and transferred it to his household, making it a badge of distinction between the worshippers of the true God and the idolatrous Canaanites—the symbol of the flesh's subjection to the spirit. Its introduction into the worship of the colony at Mamre indicated a decided advance in Abram's religious conceptions. He had got beyond the cruel practice of human sacrifice. The gross worship of the Canaanites was left behind; and the small remnant of it which he retained comported with a faith approaching monotheism. Amid prevailing idolatry this institution was a protection to his family and servants—a magic circle drawn around them. But, though powerful and respected wherever his name was known, he confined the rite to his own domestics, without attempting to force it on the inhabitants of the land where he sojourned. The punishment of death

[1] Three documents at least are traceable in the Pentateuch; the Elohistic, the junior Elohistic, and the Jehovistic. These were put together by a redactor. Nearly the whole of the fifth book was added by the Deuteronomist.

for neglecting it, because the uncircumcised person was thought to be a breaker of the covenant and a despiser of its Author, seems a harsh measure on the part of Abram; yet it can hardly be counted an arbitrary transference of the later Levitical severities to the progenitor of the race, since it is in the Elohist.

Accompanied by two angels, Jehovah appeared again to Abram at the oak of Mamre, accepted his proposed hospitality, and promised him a son by Sarai within a year. Though she laughed incredulously, the promise was definitely repeated. When the angels left, Jehovah communicated to Abram the divine purpose of destroying the dwellers in Siddim because of their wickedness, but acceded to the patriarch's intercession, that the cities of the plain should be spared if ten righteous men could be found in them. The two angels, who had gone before, arrived at Sodom in the evening, and were entertained by Lot, but threatened with shameful treatment by the depraved inhabitants. Seeing that the vengeance of Heaven was deserved, they proceeded to execute it, saving Lot with his wife and two daughters, and sparing Zoar as a place of refuge for them. Jehovah rained down fire and brimstone from heaven, turning all the Jordan district to desolation, so that when Abram looked next morning from the spot where Jehovah and himself had parted, he saw a thick smoke ascend from the ruins.

Abram then journeyed from Hebron to the Negeb, settled between Kadesh and Shur in Gerar, where Sarai is said to have been treated as a prior account makes her to have been in Egypt. At the patriarch's prayer the plague inflicted on the king and his wives was removed. This is a duplicate of the other story. Whatever historical truth the present narrative has belongs to an earlier period of Abram's life. His second removal to Gerar originated in the former journeying through it into Egypt. He must have remained in the neighbourhood of Hebron, his first settlement, where Isaac was born according to the Elohistic account. After the birth of the legitimate heir, succeeding events were the expulsion of Hagar and Ishmael from the paternal home, and the making of a covenant between Abimelech and Abram at Beersheba. Here Abram "called on the name of the Lord," and is said to have planted a noted tamarisk in commemoration of the event.

Abram was now commanded by God to offer up Isaac in the land of Moriah. Proceeding to obey, he was prevented by an angel just as he was about to slay his son, and sacrificed a ram that presented itself at the time. In reward of his obedience he received the promise of a numerous seed and abundant prosperity. Thence he returned to Beersheba.

Sarai died and was buried in the cave of Machpelah near Hebron, which Abram purchased, with the adjoining field, from Ephron the Hittite. The measures taken by the patriarch for the marriage of Isaac are circumstantially described. His steward Eliezer was sent to the country and kindred of Abram to find a suitable bride, which he did in Haran, whither he was divinely conducted. Rebekah appeared as the intended one; she parted from Bethuel and her family with their full approbation, was brought to Isaac, and became a maternal ancestor of the chosen people.

It is curious that, after Sarah's death, Abram should have contracted a second marriage with Keturah, and begotten six sons. The Chronicles, however, make her his concubine (1 Chron. i. 32), so that these children may have been born earlier. Probably the narrative intends to account for the diffusion of Abram's posterity in Arabia. Keturah's sons were sent away with gifts from their home into Arabia, and all the father's substance was given to Isaac. The patriarch died at the age of 175 years, and was buried by Isaac and Ishmael beside Sarai in Machpelah. The book of Genesis gives two lists of Arab tribes, descended partly from Abram and Keturah, partly from him and Hagar or Ishmael. These dwelt in Arabia Deserta and Petræa, as also in the northern half of Arabia Felix.

1. We cannot adopt the opinion of Von Bohlen and Dozy that Abram is a mythical person. He must be regarded as a historical character, though the accounts of his life have mythical elements intermingled with much that is traditional or legendary. The difficulty of separating the historic from the merely traditional, hinders the presentation of a natural portrait. Later legends have invested him with extraordinary excellence. They have made him a worshipper of Jehovah, a prophet, the friend of God, favoured with visible manifestations of His presence, and receiving repeated promises of the most far-reaching character. He is the typical ancestor of the chosen race, living under the constant guidance of God, prospering in worldly goods, delivered from imminent perils. A superhuman halo surrounds him. It is the Jehovist in particular who invests him with the marvellous and improbable, connecting him with altars and sacrifices—a cultus posterior to both his time and mental development—making him the subject of theophanies, talking familiarly to Jehovah himself, and feeding angels with flesh. The Elohist's descriptions are simpler. His patriarchs are usually colourless men, upright and plain. They have neither characteristic features nor distinct outline. Abram stands out an honest, peaceable, generous, high-minded patriarch; a prince, rich, powerful, and honoured, fitted for rule, and exercising it with prudence. We need not expect a full history of the man from writers long posterior, the representatives of popular traditions. Only fragments of the life are given, designed to show his greatness. Legend assigned ideal lineaments to the progenitor whom a remote antiquity shrouded with its hoary mantle, and thus he became a model worthy of imitation.

2. The biblical sources of his biography are three at least; and sometimes all appear in a single chapter, as in Gen. xxii., which describes the severest trial of faith. The oldest or Elohim-document is seen in verses 20–24, which link on to chap. xxi. 2–5, from the same. The rest of the chapter belongs to the junior Elohist, except verses 14–18, added by the Jehovist to connect Abram's sacrifice with Jerusalem. These different documents, out of which the general narrative was finally put together by a redactor, create diversities and contradictions. Thus the Elohist makes Abram laugh at the announcement of a son by Sarai (xvii. 17); the Jehovist, jealous for the patriarch's honour, assigns the laughter to the woman as a sign of incredulity (xviii. 12).

3. The account of the change of names given to Abram and Sarai when circumcision was instituted, cannot be regarded as historical. The Elohist says that *Abram* became *Abraham*, the latter meaning *father of much people.* But the Hebrew tongue has no word *rahâm*, and no root with the three letters רהם. Hence the Jews found the etymology a puzzle.[1] The old reading was undoubtedly *Abram* and *Sarai*, though the later Jews expressly forbade *Abram* either in speaking or writing. The difference is one of mere orthography. The forms רהם and רום are cognate ones, as are שרי and שרה. The etymologising propensity of the Elohist is well known. The names signify *father of height* and *princess* respectively.

4. The religion of Abram was not pure Jehovism. According to Exodus vi. 3, the name Jehovah was unknown before Moses. Pure Jehovism was a growth not reached

[1] See Beer's *Leben Abraham's*, pp. 150, 151.

before the prophets. It was a late development, the creed of the most spiritual teachers, not of the people generally. Abram was a distinguished Oriental sheikh, who laid aside the grossness of idolatry, and rose by degrees, through contact with many peoples and his own reflection, to the conception of a Being higher than the visible world, the God of the light and the sun. He was a civilised nomad, having wider and more spiritual aspirations than the peoples with whom he lived. As a worshipper of God, his faith was magnified by later ages throwing back their more advanced ideas into his time, because he was the founder of a favoured race, the type of Israel as they were or should be.

5. The leading idea forming the essence of the story respecting Abram's sacrifice of Isaac, presents some difficulty of explanation. The chapter did not proceed from the earliest writer, but from one acquainted with the institution of animal sacrifices. That the patriarch was familiar with human sacrifices among the peoples round about is beyond a doubt. Was he tempted from within to comply, on one occasion, with the prevailing custom; or did the disaffected Canaanites call upon him to give such proof of devotion to his God? Perhaps there was a struggle in his mind between the better ideas which led to the habitual renunciation of the barbarous rite, and scruples of the universal impropriety attaching to it. The persuasion that it could never be allowed may have been shaken at times. The general purport of the narrative is to place in a strong light the faith of one prepared to make the most costly sacrifice in obedience to the divine command, as well as God's aversion to human offerings.

6. It is impossible to get chronological exactness in Abram's biography, because it is composed of different traditions incorporated with one another, the product of different times, and all passing through the hands of a later redactor for whom the true succession of events was not of primary importance. The writers themselves did not know the accurate chronology, having to do with legends as well as facts impregnated with the legendary, which the redactor afterwards altered or adapted. The Elohist is much more chronological than the other writers. It is even impossible to tell the time when Abram lived. According to Lepsius, he entered Palestine 1700–1730 B.C.; according to Bunsen, 2886; while Schenkel gives 2130–2140 B.C. In Beer's *Leben Abraham's* his birth is given 1948 A.M., *i.e.*, 2040 B.C.

7. The Midrashim contain a good deal about Abram which is either founded on biblical accounts or spun out of the fancy. Nimrod was king of Babylon at the time. The patriarch's early announcement of the doctrine of one God, his zeal in destroying idols, including those worshipped by his father, his miraculous escape from Nimrod's wrath, his persuading Terah to leave the king's service and go with him to Canaan, are minutely told. During his life he had no fewer than ten temptations. Satan tried to ruin him, after the fiend had appeared at the great feast given when Isaac was weaned, in the form of a poor bent old man, who had been neglected. We can only refer to one specimen of rabbinic dialogue-making. God appeared to Abram by night, saying to him, "Take thy son"—(Abram interrupting), "Which? I have two of them." The voice of God—"Him who is esteemed by you as your only son." Abram—"Each of them is the only son of his mother." God's voice—"Him whom thou lovest." Abram—"I love both." God's voice—"Him whom thou especially lovest." Abram—"I cherish my children with like love." God's voice—"Now, then, take Isaac." Abram—"And what shall I begin with in him?" God's voice—"Go to the land where at my call mountains will rise up out of valleys . . . . . to Moriah, and offer thy son Isaac as a holocaust." Abram—"Is it a sacrifice I shall offer, Lord? Where is the priest to prepare it?" "Be thou invested with that dignity as Shem was formerly." Abram—"But that land counts several mountains, which shall I ascend?" "The top of the mountain where thou shalt see my glory veiled in the clouds," &c. (Beer, pp. 59, 60.)

The Arabic legends about Ibrahim are mostly taken from the Jewish fountain, very few being independent and pre-Islamite. Mohammed collected all that were current, and presented them in forms best suited to his purpose. His sources were the biblical accounts and later Jewish legends. Those about the patriarch building the Kaaba along with Ishmael, his giving this son the house and all the country in which it was, his going as a pilgrim to Mecca every year, seeing Ishmael, and then returning to his own land, Syria, his foot-print on the black stone of the temple, and similar stories, are of genuine Arabic origin. The rest are Jewish, with certain alterations. The collected narratives of the Arabic historians are given by Tabari, constituting a confused mass of legends drawn from the Old Testament, the Koran, and the Rabbins. (See Ewald's *Geschichte des Volkes Israel*, vol. i. pp. 440–484, third edition; Bertheau's *Zur Geschichte der Israeliten*, p. 206, *et seq.*; Tuch's *Kommentar ueber die Genesis*, 1838; Knobel's *Die Genesis*, 1852; Dozy's *Die Israeliten zu Mekka*, p. 16, *et seq.*; B. Beer's *Leben Abraham's nach Auffassung der jüdischen Sage*, 1859; *Chronique d'Abou Djafar Mohammed Tabari*, par L. Dubeux, tome premier, chapters 47–60; Chwolson's *Ssabier und der Ssabismus*, vol. ii.) (S. D.)

ABRAHAM-A-SANCTA-CLARA, was born at Krähenheimstetten, a village in Suabia, on the 4th of June 1642. His family name was Ulrich Megerle. In 1662 he joined the order of Barefooted Augustinians, and assumed the name by which alone he is now known. In this order he rose step by step until he became prior provincialis and definitor of his province. Having early gained a great reputation for pulpit eloquence, he was appointed court preacher at Vienna in 1669. There the people flocked in crowds to hear him, attracted by the force and homeliness of his language, the grotesqueness of his humour, and the impartial severity with which he lashed the follies of all classes of society. The vices of courtiers and court-life in particular were exposed with an admirable intrepidity. In general he spoke as a man of the people in the language of the people, the predominating quality of his style, which was altogether unique, being an overflowing and often coarse wit. There are, however, many passages in his sermons in which he rises to loftier thought, and uses more refined and dignified language. He died at Vienna on the 1st December 1709. In his published writings Abraham-a-Sancta-Clara displayed much the same qualities as in the pulpit. Perhaps the most favourable specimen of his style is furnished in *Judas der Erzschelm*. His works have been several times reproduced in whole or part, though with many spurious interpolations, within the last thirty years, and have been very extensively read by both Protestants and Catholics. A selection was issued at Heilbronn in 1845, and a complete edition in 21 vols. appeared at Passau and Lindau, in 1835–54.

ABRANTES, a town of Portugal, Estremadura province, on the Tagus, about 70 miles N.E. of Lisbon, delightfully situated on the brow of a hill, of which the slopes are covered with olive trees, gardens, and vineyards. It has considerable trade with Lisbon, particularly in fruit, corn, and oil. The town is strongly fortified, and is an important military position. At the convention of Cintra it was surrendered to the British. Junot derived from it his title of Duke of Abrantes. Population about 6000.

ABRANTES, Duke and Duchess of. See Junot.

ABRAXAS, or Abrasax, a word engraved on certain antique stones, which were called on that account *Abraxas stones*, and were used as amulets or charms. The Basilidians, a Gnostic sect, attached importance to the word, if, indeed, they did not bring it into use. The letters of ἀβραξάς, in the Greek notation, make up the number 365, and the Basilidians gave the name to the 365 orders of spirits, which, as they conceived, emanated in succession from the Supreme Being. These orders were supposed to occupy as many heavens, each fashioned like, but inferior to that above it; and the lowest of the heavens was thought to be the abode of the spirits who formed the earth and its inhabitants, and to whom was committed the administration of its affairs. The Abraxas stones, which are frequently to be met with in the cabinets of the curious, are of very little value. In addition to the word *Abraxas* and other mystical characters, they have often engraved on them cabalistic figures. The commonest of these have the head of a fowl, and the arms and bust of a man, and terminate in the body and tail of a serpent.

ABRUZZO, originally one of the four provinces of the continental part of the kingdom of the two Sicilies, afterward subdivided into Abruzzo Ulteriore I., Abruzzo Ulteriore II., and Abruzzo Citeriore, which were so named from their position relative to Naples, and now form three of the provinces of the kingdom of Italy. The district, which was the most northerly part of the kingdom of the two Sicilies, is bounded by the Adriatic on the E., and by the provinces of Ascoli Piceno on the N., Umbria and Rome on the W., and Terra di Lavoro, Molise, and Capitanata on the S. The Abruzzi provinces have an area of nearly 4900 English square miles, and extend from N. lat. 41°40′ to 42°55′. Though presenting to the Adriatic a coast of about 80 miles in length, they have not a single good port. This territory is mostly rugged, mountainous, and covered with extensive forests, but contains also many fertile and well-watered valleys. The Apennines traverse its whole extent, running generally from N.W. to S.E., and here attaining their greatest elevation. Near Aquila is Monte Corno, the loftiest peak of that chain, called *Il gran Sasso d'Italia*, or the great rock of Italy, which rises to the height of 9813 feet. Monte Majella and Monte Velino attain the height of 9500 and 8792 feet respectively. From the main range of the Apennines a number of smaller branches run off towards the west. The country is watered by numerous small rivers, most of which fall into the Adriatic. They are often suddenly swollen by the rains, especially in the spring, and thus cause considerable damage to the lands through which they pass. The principal rivers are the Tronto, Trentino, Pescara, and Sangro. In Abruzzo Ulteriore II. is lake Celano or Lago di Fucino, the *Lacus Fucinus* of the Romans, now reduced to about one-third of its former extent. The climate varies with the elevation, but, generally speaking, is temperate and healthy. Agriculture is but little understood or attended to, although in many of the lower parts of the country the land is fertile. The rivers are not embanked, nor is irrigation practised; so that the best of the land is frequently flooded during the rainy season, and parched in the heat of summer. The principal productions are corn, hemp, flax, almonds, olives, figs, grapes, and chestnuts. In the neighbourhood of Aquila saffron is extensively cultivated, although not to such an extent as formerly. The rearing and tending of sheep is the chief occupation of the inhabitants of the highlands; and the wool, which is of a superior quality, is an important article of commerce, while the skins are sent in large quantities to the Levant. Bears, wolves, and wild boars inhabit the mountain fastnesses; and in the extensive oak forests numerous herds of swine are fed, the hams of which are in high repute. The manufactures are very inconsiderable, being chiefly woollen, linen, and silk stuffs, and earthen and wood wares. Abruzzo was of great importance to the kingdom of Naples, being its chief defence to the north, and presenting almost insurmountable difficulties to the advance of an enemy. The country is now free of the daring brigands by whom it was long infested. The inhabitants are a stout, well-built, brave, and industrious race. Their houses are generally miserable huts; their food principally maize, and their drink bad wine. The railway from Ancona to Brindisi passes through Abruzzo Ulteriore I. and Abruzzo Citeriore, skirting the coast; and a line has been projected from Pescara, by Popoli, the Lago di Fucino, and the valley of the Liris, to join the railway from Rome to Naples, and thus open up the interior of the country. The line is open for traffic between Pescara and Popoli.

Abruzzo Ulteriore I. is the most northerly of the three provinces, and has an area of 1283 square miles, with a population in 1871 of 245,684. The western part of the province is very mountainous, the highest crest of the Apennines dividing it from Abruzzo Ulteriore II. The valleys possess a rich soil, well watered by rivulets and brooks in the winter and spring, but these are generally dried up in the summer months. The streams run mostly into the Pescara, which bounds the province towards Abruzzo Citeriore, or into the Tronto, which is the northern boundary. The city of Teramo is the capital of the province.

Abruzzo Ulteriore II. is an inland district, nearly covered with mountains of various heights, one of which is the *Gran Sasso*. There are no plains; but among the mountains are some beautiful and fruitful valleys, watered by the various streams that run through them. None of the rivers are navigable. The province has an area of 2510 square miles, and in 1871 contained 332,782 inhabitants. Its chief town is Aquila.

Abruzzo Citeriore lies to the south and east of the other two provinces. It is the least hilly of the three, but the Apennines extend through the south-west part. They, however, gradually decline in height, and stretch away into plains of sand and pebbles. The rivers all run to the Adriatic, and are very low during the summer months. The soil is not very productive, and agriculture is in a very backward state; the inhabitants prefer the chase and fishing. The province contains 1104 square miles, with a population of 340,299 in 1871. Its chief town is Chieti.

ABSALOM (אַבְשָׁלוֹם, *father of peace*), the third son of David, king of Israel. He was deemed the handsomest man in the kingdom. His sister Tamar having been violated by Amnon, David's eldest son, Absalom caused his servants to murder Amnon at a feast, to which he had invited all the king's sons. After this deed he fled to the kingdom of his maternal grandfather, where he remained three years; and it was not till two years after his return that he was fully reinstated in his father's favour. Absalom seems to have been by this time the eldest surviving son of David, but he was not the destined heir of his father's throne. The suspicion of this excited the impulsive Absalom to rebellion. For a time the tide of public opinion ran so strong in his favour, that David found it expedient to retire beyond the Jordan. But, instead of adopting the prompt measures which his sagacious counsellor Ahithophel advised, Absalom loitered at Jerusalem till a large force was raised against him, and when he took the field his army was completely routed. The battle was fought in the forest of Ephraim; and Absalom, caught in the boughs of a tree by the superb hair in which he gloried, was run through the body by Joab. The king's grief for his worthless son vented itself in the touching lamentation —"O my son Absalom, my son, my son Absalom! would God I had died for thee, O Absalom, my son, my son!"

ABSALON, Archbishop of Lund, in Denmark, was born in 1128, near Soroe in Zealand, his family name being Axel. In 1148 he went to study at Paris, where a college for Danes had been established. He afterwards travelled extensively in different countries; and returning to Denmark in 1157, was the year after chosen Bishop of Roeskilde or Rothschild. Eloquent, learned, endowed with uncommon physical strength, and possessing the confidence of the king, Waldemar I., known as the Great, Absalon held a position of great influence both in the church and state. In that age warlike pursuits were not deemed inconsistent with the clerical office, and Absalon was a renowned warrior by sea and land, as well as a zealous ecclesiastic, his avowed principle being that "both swords, the spiritual and the temporal, were entrusted to the clergy." To his exertions as statesman and soldier Waldemar was largely indebted for the independence and consolidation of his kingdom. In 1177 he was chosen by the chapter Archbishop of Lund and Primate of the church, but he declared himself unwilling to accept the appointment; and when an attempt was made to install him by force, he resisted, and appealed to Rome. The Pope decided that the choice of the chapter must be respected, and commanded Absalon to accept the Primacy on pain of excommunication. He was consecrated accordingly by the papal legate Galandius in 1178. He set the Cistercian monks of Soroe the task of preparing a history of the country, the most valuable result being the *Danish Chronicle* of Saxo Grammaticus, who was secretary to Absalon and his companion in an expedition against the Wendish pirates. A tower or castle which the archbishop caused to be built as a defence against these pirates, was the commencement of the present capital, Copenhagen, which from this circumstance is sometimes known in history as Axelstadt. The archbishop died in 1201, in the monastery at Soroe, and was buried in the parish church, where his grave may still be seen.

ABSCESS, in *Surgery* (from *abscedo*, to separate), a collection of pus among the tissues of the body, the result of inflammation. Abscesses are divided into acute and chronic. See SURGERY.

ABSINTHE, a liqueur or aromatised spirit, prepared by pounding the leaves and flowering tops of various species of wormwood, chiefly *Artemisia Absinthium*, along with angelica root (*Archangelica officinalis*), sweet flag root (*Acorus Calamus*), the leaves of dittany of Crete (*Origanum Dictamnus*), star-anise fruit (*Illicium anisatum*), and other aromatics, and macerating these in alcohol. After soaking for about eight days the compound is distilled, yielding an emerald-coloured liquor, to which a proportion of an essential-oil, usually that of anise, is added. The liqueur thus prepared constitutes the genuine *Extrait d'Absinthe* of the French; but much of an inferior quality is made with other herbs and essential oils, while the adulterations practised in the manufacture of absinthe are very numerous and deleterious. In the adulterated liqueur the green colour is usually produced by turmeric and indigo, but the presence of even cupric sulphate (blue vitriol) as a colouring ingredient has been frequently detected. In commerce two varieties of absinthe are recognised—common and Swiss absinthe—the latter of which is prepared with highly concentrated spirit; and when really of Swiss manufacture, is of most trustworthy quality as regards the herbs used in its preparation. The chief seat of the manufacture is in the canton of Neufchâtel in Switzerland, although absinthe distilleries are scattered generally throughout Switzerland and France. The liqueur is chiefly consumed in France, but there is also a considerable export trade to the United States of America. In addition to the quantity distilled for home consumption in France, the amount imported from Switzerland in recent years has not been less than 2,000,000 gallons yearly. The introduction of this beverage into general use in France is curious. During the Algerian war (1844–47) the soldiers were advised to mix absinthe with their wine as a febrifuge. On their return they brought with them the habit of drinking it, which is now so widely disseminated in French society, and with such disastrous consequences, that the custom is justly esteemed a grave national evil. A French physician, M. Legrand, who has studied the physiological effects of absinthe drinking, distinguishes two trains of results according as the victim indulges in violent excesses of drinking or only in continuous steady tippling. In the case of excessive drinkers there is first the feeling of exaltation peculiar to a state of intoxication. The increasing dose necessary to produce this state quickly deranges the digestive organs, and destroys the appetite. An unappeasable thirst takes possession of the victim, with giddiness, tingling in the ears, and hallucinations of sight and hearing, followed by a constant mental oppression and anxiety, loss of brain power, and, eventually, idiocy. The symptoms in the case of the tippler commence with muscular quiverings and decrease of physical strength; the hair begins to drop off, the face assumes a melancholy aspect, and he becomes emaciated, wrinkled, and sallow. Lesion of the brain follows, horrible dreams and delusions haunt the victim, and gradually paralysis overtakes him and lands him in his grave. It has been denied by a French authority, M. Moreau, that these symptoms are due to wormwood or any of the essential oils contained in absinthe, and he maintains that the strong spirit and such adulterations as salts of copper are sufficient to account for the effects of the liqueur. There is, however, no doubt that proportionately the consumption of absinthe is much more deleterious to the human frame than the drinking of brandy or other strong spirits. The use of absinthe has been prohibited in both the army and navy of France.

ABSOLUTE (from the Latin *absolvere*), having the general meaning of *loosened from*, or *unrestricted*, in which sense it is popularly used to qualify such words as "monarchy" or "power," has been variously employed in philosophy. Logicians use it to mark certain classes of names. Thus a term has been called absolute in opposition to *attributive*, when it signifies something that has or is viewed as having independent existence; most commonly, however, the opposition conveyed is to *relative*. A relative name being taken as one which, over and above the object which it denotes, implies in its signification the existence of another object, also deriving a denomination from the same fact, which is the ground of the first name (Mill), as, *e.g.*, father and son, the non-relative or absolute name is one that has its meaning for and in itself, as man. This distinction is a convenient one, although, as has been observed, it can hardly in perfect strictness be maintained. The so-called absolute name, if used with a meaning, does always stand in some relation, however variable or indefinite, and the meaning varies with the relation. Thus man, which is a word of very different meanings, as, *e.g.*, not woman, not boy, not master, not brute, and so forth, may be said to have them according to the different relations in which it admits of being viewed, or, as it has been otherwise expressed, according to the different notions whose "universe" it composes, along with its different correlatives. From this point of view there is always one relation in which a real thing must stand, namely, the relation to its contradictory (as not man) within the universe of being; the correlatives, under less general notions, being then generally expressed positively as contraries (woman, boy, master, brute, and so forth, for man). If there is thus no name or notion that can strictly be called absolute, all knowledge may be said to be relative, or of the relative. But the knowledge of an absolute has also been held impossible, on the ground that knowing is itself a relation between a subject and an object; what is known only in relation to a mind cannot be known as absolute. This doctrine, now commonly spoken of under the name of the Relativity of Knowledge, may, indeed, be brought under the former view, in which subject-object marks the relation of highest philosophical significance within the whole universe of things. Keeping, however, the two views apart, we may say with double force that of the absolute there is no knowledge,—(1), because, to be known, a thing must be consciously discriminated from other things; and (2), because it can be known only in relation with a knowing mind. Notwithstanding, there have been thinkers from the earliest times, who, in different ways, and more or less explicitly, allow of no such restriction upon knowledge, or at least consciousness, but, on the contrary, starting from a notion, by the latter among them called the absolute, which includes within it the opposition of subject and object, pass therefrom to the explanation of all the phenomena of nature and of mind. In earlier days the Eleatics, Plato, and Plotinus, in modern times Spinoza, Leibnitz, Fichte, Schelling, Hegel, and Cousin, all have joined, under whatever different forms, in maintaining this view. Kant, while denying the absolute or unconditioned as an object of knowledge, leaves it conceivable, as an idea regulative of the mind's intellectual experience. It is against any such absolute, whether as real or conceivable, that Hamilton and Mansel have taken ground, the former in his famous review of Cousin's philosophy, reprinted in his *Discussions*, the latter in his Bampton Lectures on *The Limits of Religious Thought*, basing their arguments indifferently on the positions as to the Relativity of Knowledge indicated above. For absolute in its more strictly metaphysical use, see METAPHYSICS. (G. C. R.)

ABSOLUTION, a term used in civil and ecclesiastical law, denotes the act of setting free or acquitting. In a criminal process it signifies the acquittal of an accused person on the ground that the evidence has either disproved or failed to prove the charge brought against him. It is now little used except in Scotch law, in the forms *assoilzie* and *absolvitor*. The ecclesiastical usage of the word is essentially different from the civil. It refers to sin actually committed, and denotes the setting of a person free from its guilt, or from its penal consequences, or from both. It is invariably connected with penitence, and some form of confession, the Scripture authority, to which the Roman Catholics, the Greek Church, and Protestants equally appeal, being found in John xx. 23, James v. 16, &c. In the primitive church the injunction of James was literally obeyed, and confession was made before the whole congregation, whose presence and concurrence were reckoned necessary to the validity of the absolution pronounced by the presbyter. In the 4th century the bishops began to exercise the power of absolution in their own right, without recognising the congregations. In consequence of this the practice of private confession (*confessio auricularis*) was established, and became more and more common, until it was rendered imperative once a year by a decree of the fourth Lateran Council (1215). A distinction, indeed, was made for a time between *peccata venialia*, which might be confessed to a layman, and *peccata mortalia*, which could only be confessed to a priest; but this was ultimately abolished, and the Roman Canon Law now stands, *Nec venialia nec mortalia possumus confiteri sacramentaliter, nisi sacerdoti.* A change in the form of absolution was almost a logical sequence of the change in the nature of the confession. At first the priest acted ministerially as an intercessory, using the *formula absolutionis precativa* or *deprecativa*, which consisted of the words: *Dominus absolvat te—Misereatur tui omnipotens Deus et dimittat tibi omnia peccata tua.* This is still the only form in the Greek Church, and it finds a place in the Roman Catholic service, though it is no longer used in the act of absolution. The Romish form was altered in the 13th century, and the Council of Trent decreed the use of the *formula absolutionis indicativa*, where the priest acts judicially, as himself possessed of the power of binding and loosing, and says, *Ego absolvo te.* Where a form of absolution is used in Protestant Churches, it is simply declarative, the state being only indicated, and in no sense or degree assumed to be caused by the declaration.

ABSORPTION, in the animal economy, the function possessed by the absorbent system of vessels of taking up nutritive and other fluids. See PHYSIOLOGY.

ABSTEMII, a name formerly given to such persons as could not partake of the cup of the eucharist on account of their natural aversion to wine. Calvinists allowed these to communicate in the species of bread only, touching the cup with their lip; which was by the Lutherans deemed a profanation. Among several Protestant sects, both in Great Britain and America, *abstemii* on a somewhat different principle have recently appeared. These are total abstainers, who maintain that the use of stimulants is essentially sinful, and allege that the wine used by Christ and his disciples at the supper was unfermented. They accordingly communicate in the unfermented "juice of the grape." The difference of opinion on this point has led to a good deal of controversy in many congregations, the solution generally arrived at being to allow both wine and the pure juice of the grape to be served at the communion table.

ABSTRACTION, in *Psychology* and *Logic*, is a word used in several distinguishable but closely allied senses. First, in a comprehensive sense, it is often applied to that process by which we fix the attention upon one part of what is present to the mind, to the exclusion of another part; abstraction thus conceived being merely the negative of ATTENTION (*q. v.*) In this sense we are able in thought to *abstract* one object from another, or an attribute from an object, or an attribute perceived by one sense from those perceived by other senses. Even in cases when thoughts or images have become inseparably associated, we possess something of this power of abstracting or turning the attention upon one rather than another. Secondly, the word is used, with a more special signification, to describe that concentration of attention upon the resemblances of a number of objects, which constitutes classification. And thirdly, not to mention other less important changes of meaning, the whole process of generalisation, by which the mind forms the notions expressed by common terms, is frequently, through a curious transposition of names, spoken of as abstraction. Especially when understood in its less comprehensive connection, the process of abstraction possesses a peculiar interest. To the psychologist it is interesting, because there is nothing he is more desirous to understand than the mode of formation and true nature of what are called general notions. And fortunately, with regard to the abstractive process by which these are formed, at least in its initial stages, there is little disagreement; since every one describes it as a process of comparison, by which the mind is enabled to consider the objects confusedly presented to it in intuition, to recognise and attend exclusively to their points of agreement, and so to classify them in accordance with their perceived resemblances. Further, this process is admitted without much dispute to belong to the discursive or elaborative action of the intellect; although, perhaps—should the view of some modern psychologists be correct, that all intelligence proceeds by the establishment of relations of *likeness* and *unlikeness*—abstraction will be better conceived as thus related to intelligence in general and typical of all its processes, than as the action merely of a special and somewhat indefinite faculty. No such harmony, however, exists regarding the nature of the *product* of abstraction; for that is the subject-matter of Nominalism and Realism, which has produced more controversy, and stimulated to more subtlety of thought, than any other subject ever debated in philosophy. The concept or abstract idea has been represented in a multitude of ways: sometimes as an idea possessing an objective existence independent of particulars, even more real and permanent than theirs; sometimes as an idea composed of all the circumstances in which the particulars agree, and of no others; again, as the idea of an individual, retaining its individualising qualities, but with the accompanying knowledge that these are not the properties of the class; and yet again, as the idea of a miscellaneous assemblage of individuals belonging to a class. It is still impossible to say that the many-sided controversy is at an end. The only conclusion generally admitted seems to be, that there exists between the concept and the particular objects of intuition some very intimate relation of thought, so that it is necessary, for all purposes of reasoning, that the general and particular go hand in hand, that the idea of the class—if such exists—be capable of being applied, in every completed act of thought, to the objects comprised within the class.

To the student of ontology, also, abstraction is of special interest, since, according to many distinguished thinkers, the recognition of abstraction as a powerful and universal mental process is to explain all ontology away, and give the ontologist his eternal quietus. The thorough-going nominalist professes to discover in the mind an inveterate tendency to abstraction, and a proneness to ascribe separate existence to abstractions, amply sufficient to account for all those forms of independent reality which metaphysics defend, and to exhibit them all in their true colours as fictitious assumptions. In reply, the ontologist, strengthened by the instinct of self-preservation, commonly contends that the analogy between general notions and metaphysical principles does not hold good, and that the latter are always more than simple abstractions or mere names. Only after abstraction is understood can the question be settled.

In like manner to logic, whether regarded as the science of the formal laws of thought, or, more widely, as the science of scientific methods, a true understanding of abstraction is of the greatest importance. It is important in pure logic, because, as we have seen, every act of judgment and reasoning postulates a concept or concepts, and so presupposes abstraction. Abstraction, determining the possibility alike of reason and speech, creates those notions that bear common names; it is indispensable to the formation of classes, great or small; and just according as it ascends, increasing the extension and diminishing the intension of classes, the horizon visible to reason and to logic gradually recedes and widens. And to logic as the science of the sciences a true doctrine of abstraction is not less necessary; because the process of extending knowledge is, in all its developments, essentially the same as the first rudimentary effort to form a concept and think of particulars as members of a class; a "natural law" at least in its subjective aspect, is invariably an abstraction made by comparing phenomena—an abstraction under which phenomena are classed in order to the extension of knowledge, just as under a concept are grouped the particulars presented in intuition. As proof of this identity it is found that the same differences exist regarding the objective or subjective nature of the "natural law" as regarding that of the concept. Some affirm that the law is brought ready-made by the mind and superinduced on the facts; others, that it is never in any sense more than a mere mental conception, got by observing the facts; while there are yet others who maintain it to be such a subjective conception, but one corresponding at the same time to an external relation which is real though unknowable.

ABSURDUM, Reductio ad, a mode of demonstrating the truth of a proposition, by showing that its contradictory leads to an absurdity. It is much employed by Euclid.

ABU, a celebrated mountain of Western India, between 5000 and 6000 feet in height, situated in 24° 40′ N. lat., and 72° 48′ E. long., within the Rájputáná State of Sirohí. It is celebrated as the site of the most ancient Jain temples in India, and attracts pilgrims from all parts of the country. The Jains are the modern Indian representatives of the Buddhists, and profess the ancient theistic doctrines of that sect, modified by saint worship and incarnations. The elevations and platforms of the mountain are covered with elaborately sculptured shrines, temples, and tombs. On the top of the hill is a small round platform containing a cavern, with a block of granite, bearing the impression of the feet of Dátá-Bhrigu, an incarnation of Vishnu. This is the chief great place of pilgrimage for the Jains, Shrawaks, and Banians. The two principal temples are situated at Deulwárá, about the middle of the mountain, and five miles south-west of Guru Sikrá, the highest summit. They are built of white marble, and are pre-eminent alike for their beauty and as typical specimens of Jain architecture in India. The following description is condensed from Mr Fergusson's *History of Architecture*, vol. ii. pp. 623 to 625:—The more modern of the two was built by two brothers, rich merchants, between the years 1197 and 1247, and for delicacy of carving and minute beauty of detail stands almost unrivalled, even in this land of patient and lavish labour. The other was built by another merchant prince, Bimalá Sháh, apparently about 1032 A.D., and although simpler and bolder in style, is as elaborate as good taste would allow in a purely architectural object. It is one of the oldest as well as one of the most complete examples of Jain architecture known. The principal object within the temple is a cell lighted only from the door, containing a cross-legged seated figure of the god Paresnáth. The portico is composed of forty-eight pillars, the whole enclosed in an oblong court-yard about 140 feet by 90 feet, surrounded by a double colonnade of smaller pillars, forming porticos to a range of fifty-five cells, which enclose it on all sides, exactly as they do in a Buddhist monastery (*vihára*). In this temple, however, each cell, instead of being the residence of a monk, is occupied by an image of Paresnáth, and over the door, or on the jambs of each, are sculptured scenes from the life of the deity. The whole interior is magnificently ornamented. The Emperor Akbar, by a farmán dated in the month of Rabi-ul-ául, in the 37th year of his reign, corresponding with 1593, made a grant of the hill and temples of Abu, as well as of the other hills and places of Jain pilgrimage in the empire, to Harbijai Sur, a celebrated preceptor of the Setámbarí sect of the Jain religion. He also prohibited the slaughter of animals at these places. The farmán of this enlightened monarch declared that "it is the rule of the worshippers of God to preserve all religions."

ABU-BEKR (*father of the virgin*), was originally called Abd-el-Caaba (*servant of the temple*), and received the name by which he is known historically in consequence of the marriage of his virgin daughter Ayesha to Mohammed. He was born at Mecca in the year 573 A.D., a Koreishite of the tribe of Benn-Taim. Possessed of immense wealth, which he had himself acquired in commerce, and held in high esteem as a judge, an interpreter of dreams, and a depositary of the traditions of his race, his early accession to Islamism was a fact of great importance. On his conversion he assumed the name of Abd-Alla (*servant of God*). His own belief in Mohammed and his doctrines was so thorough as to procure for him the title El Siddik (*the faithful*), and his success in gaining converts was correspondingly great. In his personal relationship to the prophet he showed the deepest veneration and most unswerving devotion. When Mohammed fled from Mecca, Abu-Bekr was his sole companion, and shared both his hardships and his triumphs, remaining constantly with him until the day of his death. During his last illness the prophet indicated Abu-Bekr as his successor, by desiring him to offer up prayer for the people. The choice was ratified by the chiefs of the army, and ultimately confirmed, though Ali, Mohammed's son-in-law, disputed it, asserting his own title to the dignity. After a time Ali submitted, but the difference of opinion as to his claims gave rise to a controversy which still divides the followers of the prophet into the rival factions of Sunnites and Shiites. Abu-Bekr had scarcely assumed his new position under the title Khalifet-Resul-Allah (*successor of the prophet of God*), when he was called to suppress the revolt of the tribes Hedjaz and Nedjd, of which the former rejected Islamism, and the latter refused to pay tribute. He encountered formidable opposition from different quarters, but in every case he was successful, the severest struggle being that with the impostor Mosailima, who was finally defeated by Khaled at the battle of Akraba. Abu-Bekr's zeal for the spread of the new faith was as conspicuous as that of its founder had been. When the internal disorders had been repressed and Arabia completely subdued, he directed his generals to foreign conquest. The Irak of Persia was overcome by Khaled in a single campaign, and there was also a successful expedition into Syria. After the hard-won victory over Mosailima, Omar, fearing that the sayings of the prophet would be entirely forgotten when those who had listened to them had all been removed by death, induced Abu-Bekr to see to their preservation in a written form. The record, when completed, was deposited with Hafsu, daughter of Omar, and one of the wives of Mohammed. It was held in great reverence by all Moslems, though it did not possess canonical authority, and furnished most of the materials out of which the Koran, as it now exists, was prepared. When the authoritative version was completed, all copies of Hafsu's record were destroyed, in order to prevent possible disputes and divisions. Abu-Bekr died on the 23d of August 634, having reigned as Khalif fully two years. Shortly before his death, which one tradition ascribes to poison, another to natural causes, he indicated Omar as his successor, after the manner Mohammed had observed in his own case.

ABULFARAGIUS, Gregor Abulfaraj (called also Barhebræus, from his Jewish parentage), was born at Malatia, in Armenia, in 1226. His father Aaron was a physician, and Abulfaragius, after studying under him, also practised medicine with great success. His command of the Arabic, Syriac, and Greek languages, and his knowledge of philosophy and theology, gained for him a very high reputation. In 1244 he removed to Antioch, and shortly after to Tripoli, where he was consecrated Bishop of Guba, when only twenty years of age. He was subsequently transferred to the see of Aleppo, and was elected in 1266 *Maphrian* or Primate of the eastern section of the Jacobite Christians. This dignity he held till his death, which occurred at Maragha, in Azerbijan, in 1286. Abulfaragius wrote a large number of works on various subjects, but his fame as an author rests chiefly on his *History of the World*, from the creation to his own day. It was written first in Syriac, and then, after a considerable interval, an abridged version in Arabic was published by the author at the request of friends. The latter is divided into ten sections, each of which contained the account of a separate dynasty. The historic value of the work lies entirely in the portions that treat of eastern nations, especially in those relating to the Saracens, the Tartar Mongols, and the conquests of Genghis Khan. The other sections are full of mistakes, arising partly no doubt from the author's comparative ignorance of classical languages. A Latin translation of the Arabic abridgement was published by Dr Pococke at Oxford in 1663. A portion of the original text, with Latin translation, edited, by no means carefully or accurately, by Bruns and F. W. Kirsch, appeared at Leipsic in 1788.

ABULFAZL, vizier and historiographer of the great Mongol emperor, Akbar, was born about the middle of the 16th century, the precise date being uncertain. His career as a minister of state, brilliant though it was, would probably have been by this time forgotten but for the record he himself has left of it in his celebrated history. The *Akbar Nameh*, or *Book of Akbar*, as Abulfazl's chief literary work is called, consists of two parts,—the first being a complete history of Akbar's reign, and the second, entitled *Ayin-i-Akbari*, or *Institutes of Akbar*, being an account of the religious and political constitution and administration of the empire. The style is singularly elegant, and the contents of the second part possess a unique and lasting interest. An excellent translation of that part by Mr Francis Gladwin was published in Calcutta, 1783–6. It was reprinted in London very inaccurately, and copies of the original edition are now exceedingly rare and correspondingly valuable. Abulfazl died by the hand of an assassin, while returning from a mission to the Deccan in 1602. Some writers say that the murderer was instigated by the heir-apparent, who had become jealous of the minister's influence.

ABULFEDA, Ismael ben-Ali, Emad-eddin, the celebrated Arabian historian and geographer, born at Damascus in the year 672 of the Hegira (1273 A.D.), was directly descended from Ayub, the father of the emperor Saladin. In his boyhood he devoted himself to the study of the Koran and the sciences, but from his twelfth year he was almost constantly engaged in military expeditions, chiefly against the crusaders. In 1285 he was present at the assault of a stronghold of the Knights of St John, and he took part in the sieges of Tripoli, Acre, and Roum. In 1298 the princedom of Hamah and other honours, originally conferred by Saladin upon Omar, passed by inheritance to Abulfeda; but the succession was violently disputed by his two brothers, and the Court availed itself of the opportunity to supersede all the three, and to abolish the principality. The sultan Melik-el-Nassir ultimately (1310) restored the dignity to Abulfeda, with additional honours, as an acknowledgment of his military services against the Tartars and Bibars, the sultan's rival. He received an independent sovereignty, with the right of coining money, &c., and had the title Melik Mowayyad (*victorious prince*) conferred upon him. For twenty years, till his death in October 1331, he reigned in tranquillity and splendour, devoting himself to the duties of government and to the composition of the works to which he is chiefly indebted for his fame. He was a munificent patron of men of letters, who repaired in large numbers to his court. Abulfeda's chief historical work is *An Abridgement of the History of the Human Race*, in the form of annals, extending from the creation of the world to the year 1328. A great part of it is compiled from the works of previous writers, and it is difficult to determine accurately what is the author's and what is not. Up to the time of the birth of Mohammed, the narrative is very succinct; it becomes more full and valuable the nearer the historian approaches his own day. It is the only source of information on many facts connected with the Saracen empire, and altogether is by far the most important Arabian history we now possess. Various translations of parts of it exist, the earliest being a Latin rendering of the section relating to the Arabian conquests in Sicily, by Dobelius, Arabic professor at Palermo, in 1610. This is preserved in Muratori's *Rerum Italicarum Scriptores*, vol. i. The history from the time of Mohammed was published with a Latin translation by Reiske, under the title *Annales Moslemici* (5 vols., Copenhagen, 1789–94), and a similar edition of the earlier part was published by Fleischer at Leipsic in 1831, under the title *Abulfedæ Historia Ante-Islamitica*. His *Geography* is chiefly valuable in the historical and descriptive parts relating to the Moslem empire. From his necessarily imperfect acquaintance with astronomy, his notation of latitude and longitude, though fuller than that of any geographer who preceded him, can in no case be depended on, and many of the places whose position he gives with the utmost apparent precision cannot be now identified. A complete edition was published by MM. Reinaud and De Slane at Paris in 1840; and Reinaud published a French translation, with notes and illustrations, in 1848. MSS. of both Abulfeda's great works are preserved in the Bodleian Library and in the National Library of France.

ABULGHAZI-BAHADUR (1605–1663), a khan of Khiva, of the race of Genghis-Khan, who, after abdicating in favour of his son, employed his leisure in writing a history of the Mongols and Tartars. He produced a valuable work, which has been translated into German, French, and Russian.

ABUNA, the title given to the archbishop or metropolitan of Abyssinia.

ABUSHEHR. See BUSHIRE.

ABU-SIMBEL, or IPSAMBUL, the ancient *Aboccis* or *Abuncis*, a place in Nubia, on the left bank of the Nile, about 50 miles S.W. of Derr, remarkable for its ancient Egyptian temples and colossal figures hewn out of the solid rock. For a description of these see NUBIA.

ABU-TEMAN, one of the most highly esteemed of Arabian poets, was born at Djacem in the year 190 of the Hegira (806 A.D.) In the little that is told of his life it is difficult to distinguish between truth and fable. He seems to have lived in Egypt in his youth, and to have been engaged in servile employment, but his rare poetic talent speedily raised him to a distinguished position at the court of the caliphs of Bagdad. Arabian historians assert that a single poem frequently gained for him many thousand pieces of gold, and the rate at which his contemporaries estimated his genius may be understood from the saying, that "no one could ever die whose name had been praised in the verses of Abu-Teman." Besides writing original poetry, he made three collections of select pieces from the poetry of the East, of the most important of which, called *Hamasa*, Sir William Jones speaks highly. Professor Carlyle quoted this collection largely in his *Specimens of Arabic Poetry* (1796). An edition of the text, with Latin translation, was published by Freytag at Bonn (1828–51), and a meritorious translation in German verse by Rückert appeared in 1846. Abu-Teman died 845 A.D.

ABYDOS (1.), in *Ancient Geography*, a city of Mysia in Asia Minor, situated on the Hellespont, which is here scarcely a mile broad. It probably was originally a Thracian town, but was afterwards colonised by Milesians. Nearly opposite, on the European side of the Hellespont, stood Sestos; and it was here that Xerxes crossed the strait on his celebrated bridge of boats when he invaded Greece. Abydos was celebrated for the vigorous resistance it made when besieged by Philip II. of Macedon; and is famed in story for the loves of Hero and Leander. The old castle of the Dardanelles, built by the Turks, lies a little southward of Sestos and Abydos.

ABYDOS (2.), in *Ancient Geography*, a town of Upper Egypt, a little to the west of the Nile, between Ptolemais and Diospolis Parva, famous for the palace of Memnon and the temple of Osiris. Remains of these two edifices are still in existence. In the temple of Osiris Mr Bankes discovered in 1818, the tablet of Abydos, containing a double series of twenty-six shields of the predecessors of Rameses the Great. This tablet is now deposited in the British Museum.

ABYSSINIA

ABYSSINIA is an extensive country of Eastern Africa, the limits of which are not well defined, and authorities are by no means agreed respecting them. It may, however, be regarded as lying between 7° 30′ and 15° 40′ N. lat., and 35° and 40° 30′ E. long., having, N. and N.W., Nubia; E., the territory of the Danakils; S., the country of the Gallas; and W., the regions of the Upper Nile.[1] It has an area of about 200,000 square miles, and a population of from 3,000,000 to 4,000,000.

The name Abyssinia, or more properly Habessinia, is derived from the Arabic word *Habesch*, which signifies mixture or confusion, and was applied to this country by the Arabs on account of the mixed character of the people. This was subsequently Latinised by the Portuguese into *Abassia* and *Abassinos*, and hence the present name. The Abyssinians call themselves *Itiopyawan*, and their country *Itiopia*, or *Manghesta Itiopia*, the kingdom of Ethiopia.

The country of Abyssinia rises rather abruptly from the low arid district on the borders of the Red Sea in lofty ranges of mountains, and slopes away more gradually to the westward, where the tributaries of the Nile have formed numerous deep valleys. It consists for the most part of extensive and elevated table-lands, with mountain ranges extending in different directions, and intersected by numerous valleys. The table-lands are generally from 6000 to 9000 feet above the level of the sea, but in the south there are

[1] It is usual to include in Abyssinia the flat country which lies between it and the Red Sea, and to regard the latter as forming its boundary on the east. This, however, is not strictly correct. Abyssinia proper comprises only the mountainous portion of this territory, the low lying portion being inhabited by distinct and hostile tribes, and claimed by the Viceroy of Egypt as part of his dominions. The low country is very unhealthy, the soil dry and arid, and with few exceptions uncultivated, whereas the highlands are generally salubrious, well watered, and in many parts very fertile. This arid track of country is only a few miles broad at Massowah, in the north, but widens out to 200 or 300 miles at Tajurrah, in the south. It is, in a great measure, owing to Abyssinia being thus cut off from intercourse with the civilised world by this inhospitable region, which has for three centuries been in the hands of enemies, that it is at present so far sunk in ignorance and barbarism.

some of considerable extent, which attain a height of more than 10,000 feet. The mountains in various parts of the country rise to 12,000 and 13,000 feet above the sea, and some of the peaks of Samen are said to reach to 15,000 feet, and to be always covered with snow. The average height of the range which divides the streams flowing to the east from those that flow westward is about 8000 feet, rising to 10,000 or 11,000 in the south, and sinking in the north. The whole country presents the appearance of having been broken up and tossed about in a remarkable manner, the mountains assuming wild and fantastic forms, with sides frequently abrupt and precipitous, and only accessible by very difficult passes. The Samen range of mountains are the highest in Abyssinia, and together with the Lamalmon and Lasta mountains form a long but not continuous chain, running from north to south.

Sketch Chart of Abyssinia.

The principal rivers of Abyssinia are tributaries of the Nile. The western portion of the country may be divided into three regions, drained respectively by the Mareb, the Atbara, and the Abai. The most northern of these rivers is the Mareb, which rises in the mountains of Taranta, flows first south, then west, and afterwards turns to the north, where it is at length, after a course of upwards of 500 miles, lost in the sand, but in the rainy season it falls into the Atbara. The Atbara, or Takazza, rises in the mountains of Lasta, and flowing first north, then west, and again turning to the north, at length falls into the Nile, after a course of about 800 miles. The Abai, Bahr-el-Azrek or Blue River, the eastern branch of the Nile, and considered by Bruce to be the main stream of that river, rises from two mountains near Geesh, in lat. 10° 59′ 25″ N., long. 36° 55′ 30″ E., about 10,000 feet above the level of the sea. It flows first north to the Lake of Dembea or Tzana, then takes a long semicircular sweep round the province of Godjam, and afterwards flows northward to about the 15th degree of N. lat., where it unites with the Bahr-el-Abiad, which has now been ascertained to be the true Nile. The Hawash, the principal river of eastern Abyssinia, rises about lat. 9° 30′ N., long. 38° E., and, flowing in a north-easterly direction towards the Red Sea, is lost in Lake Aussa, lat. 11° 25′ N., long. 41° 40′ E. The principal lake of Abyssinia is the Dembea, which lies between 11° 30′ and 12° 30′ N. lat., and 37° and 37° 35′ E. long., being about 60 miles in length by 40 in width, and containing a number of small islands. It is fed by numerous small streams. The lake of Ashangi, in lat. 12° 35′ N., long. 39° 40′ E., is about 4 miles long by 3 broad, and upwards of 8000 feet above the sea.

The fundamental rocks of Tigré, and probably of all Abyssinia, are metamorphic. They compose the mass of the table-land, and while they occupy no inconsiderable portion of its surface, they are exposed, in Tigré at least, in every deep valley. The metamorphics vary greatly in mineral character, "every intermediate grade being found between the most coarsely crystalline granite and a slaty rock so little altered that the lines of the original bedding are still apparent. Perhaps the most prevalent form of rock is a rather finely crystalline gneiss. Hornblende-schist and mica-schist are met with, but neither of the minerals from which they are named appears to be so abundant as in some metamorphic tracts. On the other hand, a compact felspathic rock, approaching felsite in composition, is prevalent in places, as in the Suru defile, between Komayli and Senafé." There are a few exceptions, but as a general rule it may be asserted that in the neighbourhood of the route followed by the British army, so much of the country as is more than 8000 feet above the sea consists of bedded traps, and this is probably the case in general over Abyssinia. "Between the traps and the metamorphics a series of sandstones and limestones intervene, one group of the former underlying the latter. The limestone alone is fossiliferous, and is of Jurassic age." "On the route to Magdala volcanic rocks were first met with at Senafé, where several hills consist of trachyte, passing into claystone and basalt. Trap hills, chiefly of trachyte, are dotted over the country to the southward as far as Fokada, a distance of nearly 30 miles. Here a great range of bedded traps commences, and extends for about 25 miles to the south, passing to the west of Adigerat." At Meshek, two marches south of Antalo, "the route entered high ranges entirely composed of trap, and thence no other rocks were seen as far as Magdala." "The trappean rocks belong to two distinct and unconformable groups. The lower of these is much inclined, while the higher rests on its upturned and denuded edges." Denudation has evidently been going on to a great extent in this country. One of its most striking features are the deep ravines which have been worked out by the action of the streams, sometimes to the depth of 3000 or 4000 feet. "How much of the Abyssinian highlands has been removed by these great torrents, and spread as an alluvial deposit over the basin of the Nile?" "Probably over the whole of northern Abyssinia there existed at least 4000 feet of bedded traps, of which now only a few vestiges remain."—*W. T. Blanford.*

Abyssinia is said to enjoy "probably as salubrious a climate as any country on the face of the globe."—*Parkyns.* The heat is by no means oppressive, a fine light air counteracting the power of the sun; and during the rainy season, the sky being cloudy, the weather is always agreeable and cool, while the rain itself is not very severe. In certain of the low valleys, however, malarious influences prevail before and after the rainy season, and bring on dangerous fevers. On the higher parts the cold is sometimes intense, particularly at night. The natural division of the seasons is into a cold, a hot, and a rainy season. The cold season may be said to extend from October to February, the hot from the beginning of March to the middle of June, and the wet or monsoon period from this time to the end of September. The rainy season is of importance, not only in equalising the temperature, increasing the fertility, and keeping up the water supply of the country, but, as Sir S. Baker has shown, it plays a most important part in the annual overflow of the Nile.

On the summits and slopes of the highest mountains the vegetation is of a thoroughly temperate and even English character; the plateaux have a flora of the same character; while on the lower slopes of the hills and in the ravines occur many trees and shrubs of warmer climes. "The general appearance of the plateaux and plains is that of a comparatively bare country, with trees and bushes thinly scattered over it, and clumps and groves only occurring round villages and churches. But the glens and ravines in the plateau sides, each with its little bright spring, are often thickly wooded, and offer a delicious contrast to the open country."—*Markham.* This refers more particularly to the northern portion of the country, that drained by the Mareb; the central and southern parts are much more fertile and productive. Here the fertility is so great that in some parts three crops are raised annually. Agriculture receives considerable attention, and large quantities of maize, wheat, barley, peas, beans, &c., are grown. Very extensively cultivated is *teff* (*Poa abyssinica*), a herbaceous plant with grains not larger than the head of a pin, of which is made the bread in general use throughout the country. The low grounds produce also a kind of corn called *tocussa*, of which a black bread is made, which constitutes the food of the lower classes. Coffee grows wild on the western mountains, and the vine and sugar-cane are cultivated in favourable localities. Cotton is also grown to a considerable extent. Among the fruit-trees are the date, orange, lemon, pomegranate, and banana. Myrrh, balsam, and various kinds of valuable medicinal plants are common.

Most of the domestic animals of Europe are found here. The cattle are in general small, and the oxen belong to the humped race. The famous Galla oxen have horns sometimes four feet long. The sheep belong to the short and fat-tailed race, and are covered with wool. Goats are very common, and have sometimes horns two feet in length. The horses are strong and active. Of wild animals the spotted hyæna is among the most numerous, as well as the fiercest and most destructive, not only roaming in immense numbers over the country, but frequently entering the towns, and even the houses of the inhabitants. The elephant and rhinoceros are numerous in the low grounds. The Abyssinian rhinoceros has two horns; its skin, which has no folds, is used for shields, and for lining drinking vessels, being regarded as an antidote to poison. Crocodiles and hippopotami are plentiful in the rivers; lions, panthers, and leopards are seen occasionally, and buffaloes frequently. Among other animals may be mentioned as common various species of antelopes, wild swine, monkeys, hares, squirrels, several species of hyrax, jackals, &c.

The birds of Abyssinia are very numerous, and many of them remarkable for the beauty of their plumage. Great numbers of eagles, vultures, hawks, and other birds of prey are met with; and partridges, snipes, pigeons, parrots, thrushes, and swallows are very plentiful. Among insects the most numerous and useful is the bee, honey everywhere constituting an important part of the food of the inhabitants, and several of the provinces paying a large proportion of their tribute in this article. Of an opposite class is the locust, the ravages of which here, as in other parts of Northern Africa, are terrible. Serpents are not numerous, but several species are poisonous.

The inhabitants of Abyssinia form a number of different tribes, and evidently belong to several distinct races. The majority are of the Caucasian race, and are in general well-formed and handsome, with straight and regular features, lively eyes, hair long and straight or somewhat curled, and colour dark olive, approaching to black. Rüppell regards them as identical in features with the Bedouin Arabs. The tribes inhabiting Tigré, Amhara, Agow, &c., belong to this race. The Galla race, who came originally from the south, have now overrun the greater part of the country, constituting a large portion of the soldiery, and, indeed, there are few of the chiefs who have not an intermixture of Galla blood in their veins. They are fierce and turbulent in character, and addicted to cruelty. Many of them are still idolaters, but most of them have now adopted the Mohammedan faith, and not a few of them the Christianity of the Abyssinians. They are generally large and well-built, of a brown complexion, with regular features, small deeply-sunk but very bright eyes, and long black hair. A race of Jews, known by the name of Falashas, inhabit the district of Samen. They affirm that their forefathers came into the country in the days of Rehoboam, but it seems more probable that they arrived about the time of the destruction of Jerusalem. From the 10th century they enjoyed their own constitutional rights, and were subject to their own kings, who, they pretend, were descended from King David, until the year 1800, when the royal race became extinct, and they then became subject to Tigré.

The prevailing religion of Abyssinia is a very corrupted form of Christianity. This is professed by the majority of the people, as well as by the reigning princes of the different states. There are also scattered over the country many Mohammedans, and some Falashas or Jews. Christianity was introduced into this country about the year 330, but since that time it has been so corrupted by errors of various kinds as to have become little more than a dead formality mixed up with much superstition and Judaism. Feasts and fast-days are very frequent, and baptism and the Lord's supper are dispensed after the manner of the Greek Church. The children are circumcised, and the Mosaic commandments with respect to food and purification are observed. The eating of animals which do not chew the cud and which have not cloven hoofs is prohibited. The ecclesiastical body is very numerous, consisting of priests of various kinds, with monks and nuns, and is looked upon with great awe and reverence. If a priest be married previous to his ordination, he is allowed to remain so; but no one can marry after having entered the priesthood. The primate or chief bishop is called *Abuna* (*i.e.*, our father), and is nominated by the patriarch of Cairo, whom they acknowledge as their spiritual father. The churches are rude edifices, chiefly of a circular form, with thatched roofs, the interior being divided into three compartments,—an outer one for the laity, one within for the priests, and in the centre the Holy of Holies, exactly after the manner of a Jewish temple. The worship consists merely in reading passages of Scripture and dispensing the Lord's supper, without any preaching. Like the Greek Church, they have no images of any kind in their places of worship, but paintings of the saints are very common—their faces always in full, whatever may be the position of their bodies. They have innumerable saints, but above all is the Virgin, whom they regard as queen of heaven and earth, and the great intercessor for the sins of mankind. Their reverence for a saint is often greater than for the Almighty, and a man who would not hesitate to invoke the name of his Maker in witness to a falsehood may decline so to use the name of St Michael or St George. Legends of saints and works of religious controversy form almost their entire literature. "At present," says Bishop Gobat, "the Christians of Abyssinia are divided into three parties, so inimical to each other that they curse one another, and will no longer partake of the sacrament together. It is one single point of theology that disunites them—the unceasing dispute concerning the unction of Jesus Christ."

In manners the Abyssinians are rude and barbarous

Engaged as they are in continual wars, and accustomed to bloodshed, human life is little regarded among them. Murders and executions are frequent, and yet cruelty is said not to be a marked feature of their character; and in war they seldom kill their prisoners. When one is convicted of murder, he is handed over to the relatives of the deceased, who may either put him to death or accept a ransom. When the murdered person has no relatives, the priests take upon themselves the office of avengers. The Abyssinians are irritable, but easily appeased; and are a gay people, fond of festive indulgences. On every festive occasion, as a saint's day, birth, marriage, &c., it is customary for a rich man to collect his friends and neighbours, and kill a cow and one or two sheep. The principal parts of the cow are eaten raw while yet warm and quivering, the remainder being cut into small pieces, and cooked with the favourite sauce of butter and red pepper paste. The raw meat in this way is considered to be very superior in taste and much tenderer than when cold. "I can readily believe," says Mr Parkyns," that raw meat would be preferred to cooked meat by a man who from childhood had been accustomed to it." The statement by Bruce respecting the cutting of steaks from a live cow has frequently been called in question, but there can be no doubt that Bruce actually saw what he narrates, though it would appear to have been a very exceptional case Mr Parkyns was told by a soldier, "that such a practice was not uncommon among the Gallas, and even occasionally occurred among themselves, when, as in the case Bruce relates, a cow had been stolen or taken in foray." The principal drinks are *mése*, a kind of mead, and *bousa*, a sort of beer made from fermented cakes. Their dress consists of a large folding mantle and close-fitting drawers; and their houses are very rude structures of a conical form, covered with thatch. Marriage is a very slight connection among them, dissolvable at any time by either of the parties; and polygamy is by no means uncommon. Hence there is little family affection, and what exists is only among children of the same father and mother. Children of the same father, but of different mothers, are said to be "always enemies to each other."—*Gobat.*

Abyssinia is one of the most ancient monarchies in the world, and has been governed from time immemorial by an emperor. For many years, however, until the accession of the late Emperor Theodore, he had been a mere puppet in the hands of one or other of his chiefs. Each chief is entire master of all sources of revenue within his territory, and has practically full power of life and death. His subjection consists in an obligation to send from time to time presents to his superior, and to follow him to war with as large a force as he can muster. For several generations the emperor had been little better than a prisoner in his palace at Gondar, his sole revenue consisting of a small stipend and the tolls of the weekly markets of that city, the real power being in the hands of the ras or vizier of the empire, who was always the most powerful chief for the time. If at any time a chief "has found himself strong enough to march upon the capital, he has done so, placed upon the throne another puppet emperor, and been by him appointed ras or vizier, till a rival stronger than himself could turn him out and take his place."—*Dr Beke.*

The three principal provinces of Abyssinia are Tigré in the north, Amhara (in which Gondar the capital is situated) in the centre, and Shoa in the south. The governors of these have all at different times assumed the title of Ras. Three other provinces of some importance are Lasta and Waag, whose capital is Sokota; Godjam, to the south of Lake Dembea; and Kivara, to the west of that lake, the birth-place of the Emperor Theodore The two provinces of Tigré and Shoa have generally been in a state of rebellion from or acknowledged independence of the central power at Gondar. The geographical position of Tigré enhances its political importance, as it lies between Gondar and the sea at Massowah, and thus holds as it were the gate of the capital. The province of Shoa is almost separated from that of Amhara by the Wolla Gallas, a Mohammedan tribe, and for a long time the former had been virtually independent, and governed by a hereditary line of princes, to one of whom the Indian government sent a special embassy under Major Harris in 1841.

The principal towns are Gondar in Amhara, the former capital of the kingdom, and containing about 7000 inhabitants, and Debra Tabor in Amhara, formerly a small village, but which rose to be a place of considerable size in consequence of the Emperor Theodore having fixed upon it as his residence, and near it was Gaffat, where the European workmen resided. It was burned by the emperor when he set out on his fatal march to Magdala. Adowa is the capital of Tigré, and the second city in the empire, having about 6000 inhabitants. Antalo is also one of the principal towns of Tigré, and the capital of Enderta. Near Antalo is Chelicut. Sokota, the capital of Lasta Waag, is a town of considerable size. The capital of Shoa is Ankobar, and near it is Angolala, also a place of considerable size. The capital of Agamé is Adigerat.

The language of the religion and literature of the country is the Geez, which belongs to the Ethiopic class of languages, and is the ancient language of Tigré; of this the modern Tigré is a dialect. The Amharic, the language of Amhara, is that of the court, the army, and the merchants, and is that too which travellers who penetrate beyond Tigré have ordinarily occasion to use. But the Agow in its various dialects is the language of the people in some provinces almost exclusively, and in others, where it has been superseded by the language of the dominant race, it still exists among the lowest classes. This last is believed to be the original language of the people; and from the affinity of the Geez, Amharic, and cognate dialects, to the Arabic, it seems probable that they were introduced by conquerors or settlers from the opposite shores of the Red Sea. The Gallas, who have overrun a great part of Abyssinia, have introduced their own language into various parts of the country, but in many cases they have adopted the language of the people among whom they have come. The literature of Abyssinia is very poor, and contains nothing of much value. During the late war the libraries in connection with the religious communities were found to contain only modern works of little interest. On the capture of Magdala, a large number of MSS. were found there, which had been brought by Theodore from Gondar and other parts. Of these 359 were brought home for examination, and are now deposited in the British Museum The oldest among them belong to the 15th and 16th centuries, but the great bulk of them are of the 17th and 18th, and some are of the present century. They are mostly copies of the Holy Scriptures, canonical and apocryphal, including the Book of Enoch, prayer and hymn books, missals, lives of saints, and translations of various of the Greek fathers.

The trade and manufactures of Abyssinia are insignificant, the people being chiefly engaged in agriculture and pastoral pursuits. Cotton cloths, the universal dress of the country, are made in large quantities. The preparation of leather and parchment is also carried on to some extent, and manufactures of iron and brass. "The Abyssinians are, I think," says Mr Markham, "capable of civilisation. Their agriculture is good, their manufactures are not to be despised; but the combined effects of isolation, Galla inroads, and internal anarchy, have thrown them back for centuries." The foreign trade of Abyssinia is carried on entirely through Massowah. Its principal imports are lead, tin, copper, silk, gunpowder, glass wares, Persian carpets, and coloured cloths. The chief exports are gold, ivory, slaves, coffee, butter, honey, and wax.

Abyssinia, or at least the northern portion of it, was included in the ancient kingdom of Ethiopia. The connection between Egypt and Ethiopia was in early times very intimate, and occasionally the two countries were under the same ruler, so that the arts and civilisation of the one naturally found their way into the other. In early times, too, the Hebrews had commercial intercourse with the Ethiopians; and according to the Abyssinians, the Queen of Sheba, who visited Solomon, was a monarch of their country, and from her son Menilek the kings of Abyssinia are descended. During the captivity many of the Jews settled here, and brought with them a knowledge of the Jewish religion. Under the Ptolemies, the arts as well as the enterprise of the Greeks entered Ethiopia, and led to the establishment of Greek colonies. A Greek inscription at Adulis, no longer extant, but copied by Cosmos, and preserved in his *Topographia Christiana*, records that Ptolemy Euergetes, the third of the Greek dynasty in Egypt, invaded the countries on both sides of the Red Sea, and, having reduced most of the provinces of Tigré to subjection, returned to the port of Adulis, and there offered sacrifices to Jupiter, Mars, and Neptune. Another inscription, not so ancient, found at Axum, and copied by Salt and others, states that Aeizanas, king of the Axomites, the Homerites, &c., conquered the nation of the Bogos, and returned thanks to his father, the god Mars, for his victory. The ancient kingdom of Auxume flourished in the first or second century of our era, and was at one time nearly coextensive with the modern Abyssinia. The capital Auxume and the seaport Adulis were then the chief centres of the trade with the interior of Africa in gold dust, ivory, leather, aromatics, &c. At Axum, the site of the ancient capital, many vestiges of its former greatness still exist; and the ruins of Adulis, which was once a seaport on the Bay of Annesley, are now about 4 miles from the shore. Christianity was introduced into the country by Frumentius, who was consecrated first bishop of Abyssinia by St Athanasius of Alexandria about A.D. 330. Subsequently the monastic system was introduced, and between 470 and 480 a great company of monks appear to have entered and established themselves in the country. Since that time Monachism has been a power among the people, and not without its influence on the course of events. In 522 the king of the Homerites, on the opposite coast of the Red Sea, having persecuted the Christians, the Emperor Justinian requested the king of Abyssinia, Caleb or Elesbaan, to avenge their cause. He accordingly collected an army, crossed over into Arabia, and conquered Yemen, which remained subject to Abyssinia for 67 years. This was the most flourishing period in the annals of the country. The Ethiopians possessed the richest part of Arabia, carried on a large trade, which extended as far as India and Ceylon, and were in constant communication with the Greek empire. Their expulsion from Arabia, followed by the conquest of Egypt by the Mohammedans in the middle of the 7th century, changed this state of affairs, and the continued advances of the followers of the Prophet at length cut them off from almost every means of communication with the civilised world; so that, as Gibbon says, "encompassed by the enemies of their religion, the Ethiopians slept for near a thousand years, forgetful of the world by whom they were forgotten." About A.D. 960, a Jewish princess, Judith, conceived the bloody design of murdering all the members of the royal family, and of establishing herself in their stead. During the execution of this project, the infant king was carried off by some faithful adherents, and conveyed to Shoa, where his authority was acknowledged, while Judith reigned for 40 years over the rest of the kingdom, and transmitted the crown to her descendants. In 1268 the kingdom was restored to the royal house in the person of Icon Imlac.

Towards the close of the 15th century the Portuguese missions into Abyssinia commenced. A belief had long prevailed in Europe of the existence of a Christian kingdom in the far east, whose monarch was known as Prester John, and various expeditions had been sent in quest of it. Among others who had engaged in this search was Pedro de Covilham, who arrived in Abyssinia in 1490, and, believing that he had at length reached the far-famed kingdom, presented to the Negus, or emperor of the country, a letter from his master the king of Portugal, addressed to Prester John. Covilham remained in the country, but in 1507 an Armenian named Matthew was sent by the Negus to the king of Portugal to request his aid against the Turks. In 1520 a Portuguese fleet, with Matthew on board, entered the Red Sea in compliance with this request, and an embassy from the fleet visited the country of the Negus, and remained there for about six years. One of this embassy was Father Alvarez, from whom we have the earliest and not the least interesting account of the country. Between 1528 and 1540 armies of Mohammedans, under the renowned general Mohammed Gragn, entered Abyssinia from the low country, and overran the kingdom, obliging the emperor to take refuge in the mountain fastnesses. In this extremity recourse was again had to the Portuguese, and Bermudez, who had remained in the country after the departure of the embassy, was ordained successor to the Abuna, and sent on this mission. In consequence a Portuguese fleet, under the command of Stephen de Gama, was sent from India and arrived at Massowah. A force of 450 musqueteers, under the command of Christopher de Gama, younger brother of the admiral, marched into the interior, and being joined by native troops were at first successful against the Turks, but were subsequently defeated, and their commander taken prisoner and put to death. Soon afterwards, however, Mohammed Gragn was shot in an engagement, and his forces totally routed. After this, quarrels arose between the Negus and the Catholic primate Bermudez, who wished the former publicly to profess himself a convert to Rome. This the Negus refused to do, and at length Bermudez was obliged to make his way out of the country. The Jesuits who had accompanied or followed Bermudez into Abyssinia, and fixed their head-quarters at Fremona, were oppressed and neglected, but not actually expelled. In the beginning of the following century Father Paez arrived at Fremona, a man of great tact and judgment, who soon rose into high favour at court, and gained over the emperor to his faith. He directed the erection of churches, palaces, and bridges in different parts of the country, and carried out many useful works. His successor Mendez was a man of much less conciliatory manners, and the feelings of the people became more strongly excited against the intruders, till at length, on the death of the Negus, and the accession of his son Facilidas in 1633, they were all sent out of the country, after having had a footing there for nearly a century and a half. The French physician Poncet, who went there in 1698, was the only European that afterwards visited the country before Bruce in 1769.

It was about the middle of the 16th century that the Galla tribes first entered Abyssinia from the south; and notwithstanding frequent efforts to dislodge them, they gradually extended and strengthened their positions till they had overrun the greater part of the country. The power of the emperor was thus weakened, independent chiefs set themselves up in different parts, until at length he became little better than a puppet in the hands of the most powerful of his chiefs. In 1805 the country was visited by Lord Valentia and Mr Salt, and again by Salt in 1810. In

1829 Messrs Gobat and Kugler were sent out as missionaries by the Church Missionary Society, and were well received by the Ras of Tigré. Mr Kugler died soon after his arrival, and his place was subsequently supplied by Mr Isenberg, who was followed by Messrs Blumhardt and Krapf. In 1830 Mr Gobat proceeded to Gondar, where he also met with a favourable reception. In 1833 he returned to Europe, and published a journal of his residence here. In the following year he went back to Tigré, but in 1836 he was compelled to leave from ill health. In 1838 other missionaries were obliged to leave the country, owing to the opposition of the native priests. Messrs Isenberg and Krapf went south, and established themselves at Shoa. The former soon after returned to England, and Mr Krapf remained in Shoa till March 1842. Dr Rüppel, the German naturalist, visited the country in 1831, and remained nearly two years. MM. Combes and Tamisier arrived at Massowah in 1835, and visited districts which had not been traversed by Europeans since the time of the Portuguese. In 1839 the French Government sent out a scientific commission under M. Lefebvre. Its labours extended over five years, and have thrown great light on the condition and productions of the country. In 1841 a political mission was sent by the Governor-General of India to Shoa, under the direction of Major Harris, who subsequently published an account of his travels. One who has done much to extend our geographical knowledge of this country is Dr Beke, who was there from 1840 to 1843. Mr Mansfield Parkyns was there from 1843 to 1846, and has written the most interesting book on the country since the time of Bruce. Bishop Gobat having conceived the idea of sending lay missionaries into the country, who would engage in secular occupations as well as carry on missionary work, Dr Krapf and Mr Flad arrived in 1855 as pioneers of that mission. Six came out at first, and they were subsequently joined by others. Their work, however, was more valuable to Theodore than their preaching, so that he employed them as workmen to himself, and established them at Gaffat, near his capital. Mr Stern arrived in Abyssinia in 1860, but returned to Europe, and came back in 1863, accompanied by Mr and Mrs Rosenthal.

Lij Kassa, who came subsequently to be known as the Emperor Theodore, was born in Kuara, a western province of Abyssinia, about the year 1818. His father was of noble family, and his uncle was governor of the provinces of Dembea, Kuara, and Chelga. He was educated in a convent, but, preferring a wandering life, he became leader of a band of malcontents. On the death of his uncle he was made governor of Kuara, but, not satisfied with this, he seized upon Dembea, and having defeated several generals sent against him, peace was restored on his receiving Tavavitch, daughter of Ras Ali, in marriage. This lady is said to have been his good genius and counsellor, and during her life his conduct was most exemplary. He next turned his arms against the Turks, but was defeated; and the mother of Ras Ali having insulted him in his fallen condition, he proclaimed his independence. The troops sent against him were successively defeated, and eventually the whole of the possessions of Ras Ali fell into his hands. He next defeated the chief of Godjam, and then turned his arms against the governor of Tigré, whom he totally defeated in February 1855. In March of the same year he took the title of Theodore III., and caused himself to be crowned king of Ethiopia by the Abuna. Theodore was now in the zenith of his career. He is described as being generous to excess, free from cupidity, merciful to his vanquished enemies, and strictly continent, but subject to violent bursts of anger, and possessed of unyielding pride and fanatical religious zeal. He was also a man of education and intelligence, superior to those among whom he lived, with natural talents for governing, and gaining the esteem of others. He had further a noble bearing and majestic walk, a frame capable of enduring any amount of fatigue, and is said to have been "the best shot, the best spearman, the best runner, and the best horseman in Abyssinia." Had he contented himself with what he now possessed, the sovereignty of Amhara and Tigré, he might have maintained his position; but he was led to exhaust his strength against the Gallas, which was probably one of the chief causes of his ruin. He obtained several victories over that people, ravaged their country, took possession of Magdala, which he afterwards made his principal stronghold, and enlisted many of the chiefs and their followers in his own ranks. He shortly afterwards reduced the kingdom of Shoa, and took Ankobar, the capital; but in the meantime his own people were groaning under his heavy exactions, rebellions were breaking out in various parts of his provinces, and his good queen was now dead. He lavished vast sums of money upon his army, which at one time amounted to 100,000 or 150,000 fighting men; and in order to meet this expenditure, he was forced to exact exorbitant tributes from his people. The British consul, Plowden, who was strongly attached to Theodore, having been ordered by his Government in 1860 to return to Massowah, was attacked on his way by a rebel named Garred, mortally wounded, and taken prisoner. Theodore attacked the rebels, and in the action the murderer of Mr Plowden was slain by his friend and companion Mr Bell, but the latter lost his life in preserving that of Theodore. The deaths of the two Englishmen were terribly avenged by the slaughter or mutilation of nearly 2000 rebels. Theodore soon after married his second wife Terunish, the proud daughter of the late governor of Tigré, who felt neither affection nor respect for the upstart who had dethroned her father, and the union was by no means a happy one. In 1862 he made a second expedition against the Gallas, which was stained with atrocious cruelties. Theodore had now given himself up to intoxication and lust. When the news of Mr Plowden's death reached England, Captain Cameron was appointed to succeed him as consul, and arrived at Massowah in February 1862. He proceeded to the camp of the king, to whom he presented a rifle, a pair of pistols, and a letter in the Queen's name. In October Captain Cameron was dismissed by Theodore, with a letter to the Queen of England, which reached the Foreign Office on the 12th of February 1863. For some reason or other this letter was put aside and no answer returned, and to this in no small degree is to be attributed the difficulties that subsequently arose with that country. After forwarding the letter, Captain Cameron, hearing that the Christians of Bogos had been attacked by the Shangallas and other tribes under Egyptian rule, proceeded to that district, and afterwards went to Kassala, the seat of the Egyptian administration in that quarter. Thence he went to Metemch, where he was taken ill, and in order to recruit his health he returned to Abyssinia, and reached Jenda in August 1863. In November despatches were received from England, but no answer to the emperor's letter, and this, together with the consul's visit to Kassala, greatly offended him, and in January 1864 Captain Cameron and his suite, with Messrs Stern and Rosenthal, were cast into prison. When the news of this reached England, the Government resolved, when too late, to send an answer to the emperor's letter, and selected Mr Hormuzd Rassam to be its bearer. He arrived at Massowah in July 1864, and immediately despatched a messenger requesting permission to present himself before the emperor. Neither to this nor a subsequent application was any answer returned till August 1865, when a curt note was received, stating that Consul Cameron had been released, and if Mr Rassam still desired to visit the king, he was to proceed by the route of Metemeh. They reached Metemeh on 21st November, and five weeks more were lost before they heard from the emperor, whose reply was now courteous, informing them that the governors of all the districts through which they had to march had received orders to furnish them with every necessary. They left Metemeh on the 28th December, and on 25th January following arrived at Theodore's camp in Damot. They were received with all honour, and were afterwards sent to Kuarata, on Lake Dembea, there to await the arrival of the captives. The latter reached this on 12th March, and everything appeared to proceed very favourably. A month later they started for the coast, but had not proceeded far when they were all brought back and put into confinement. Theodore then wrote a letter to the Queen, requesting European workmen and machinery to be sent to him, and despatched it by Mr Flad. The Europeans, although detained as prisoners, were not at first unkindly treated; but in the end of June they were sent to Magdala, where they were soon afterwards put in chains. They suffered hunger, cold, and misery, and were in constant fear of death, till the spring of 1868, when they were relieved by the British troops. In the meantime the power of Theodore in the country was rapidly waning. In order to support his vast standing army, the country was drained of its resources: the peasantry abandoned the fertile plains, and took refuge in the fastnesses, and large fertile tracts remained uncultivated. Rebellions broke out in various parts of the country, and desertions took place among his troops, till his army became little more than a shadow of what it once was. Shoa had already shaken off his yoke; Godjam was virtually independent; Walkeit and Samen were under a rebel chief; and Lasta Waag and the country about Lake Ashangi had submitted to Wagsham Gobaze, who had also overrun Tigré, and appointed Dejach Kassai his governor. The latter, however, in 1867 rebelled against his master, and assumed the supreme power of that province. This was the state of matters when the English troops made their appearance in the country. With a view if possible to effect the release of the prisoners by conciliatory measures, Mr Flad was sent back, with some artisans and machinery, and a letter from the Queen, stating that these would be handed over to his Majesty on the release of the prisoners and their return to Massowah. This, however, failed to influence the emperor, and the English Government at length saw that they must have recourse to arms. In July 1867, therefore, it was resolved to send an army into Abyssinia to enforce the release of the captives, and Sir Robert Napier was appointed commander-in-chief. A reconnoitring party was despatched beforehand, under Colonel Merewether, to select the landing-place and anchorage, and explore the passes leading into the interior. They also entered into friendly relations with the different chiefs in order to secure their co-operation. The landing-place selected was Mulkutto, on Annesley Bay, the point of the coast nearest to the site of the ancient Adulis, and we are told that "the pioneers of the English expedition followed to some extent in the footsteps of the adventurous soldiers of Ptolemy, and met with a few faint traces of this old world enterprise."—*C. R. Markham.* The force amounted to upwards of 16,000 men, besides 12,640 belonging to the transport service, and followers, making in all upwards of 32,000 men. The task to be accomplished was to march over 400 miles of a mountainous and little-known country, inhabited by savage tribes, to the camp or fortress of Theodore, and compel him to deliver up his captives. The commander-in-chief landed on 7th January 1868, and soon after the troops began to move forward through the pass of Senafé, and southward through the districts of Agamé, Tera, Endarta, Wojerat, Lasta, and Wadela. In the meantime Theodore had been reduced to great straits. His army was rapidly deserting him, and he could hardly obtain food for his followers. He resolved to quit his capital Debra Tabor, which he burned, and set out with the remains of his army for Magdala. During this march he displayed an amount of engineering skill in the construction of roads, of military talent, and fertility of resource, that excited the admiration and astonishment of his enemies. On the afternoon of the 10th of April a force of about 3000 men suddenly poured down upon the English in the plain of Arogié, a few miles from Magdala. They advanced again and again to the charge, but were each time driven back, and finally retired in good order. Early next morning Theodore sent Lieut. Prideaux, one of the captives, and Mr Flad, accompanied by a native chief, to the English camp to sue for peace. Answer was returned, that if he would deliver up all the Europeans in his hands, and submit to the Queen of England, he would receive honourable treatment. The captives were liberated and sent away, and along with a letter to the English general was a present of 1000 cows and 500 sheep, the acceptance of which would, according to Eastern custom, imply that peace was granted. Through some misunderstanding, word was sent to Theodore that the present would be accepted, and he felt that he was now safe; but in the evening he learned that it had not been received, and despair again seized him. Early next morning he attempted to escape with a few of his followers, but subsequently returned. The same day (13th April) Magdala was stormed and taken, and within they found the dead body of the emperor, who had fallen by his own hand. The inhabitants and troops were subsequently sent away, the fortifications destroyed, and the town burned. The queen Terunish having expressed her wish to go back to her own country, accompanied the British army, but died during the march, and her son Alam-ayahu, the only legitimate son of the emperor, was brought to England, as this was the desire of his father. The success of the expedition was in no small degree owing to the aid afforded by the several native chiefs through whose country it passed, and no one did more in this way than Prince Kassai of Tigré. In acknowledgment of this several pieces of ordnance, small arms, and ammunition, with much of the surplus stores, were handed over to him, and the English troops left the country in May 1868. Soon after this Prince Kassai declared his independence; and in a war which broke out between him and Wagsham Gobaze, the latter was defeated, and his territory taken possession of by the conqueror. In 1872 Kassai was crowned king of Abyssinia with great ceremony at Axum, under the title of King Johannes. In that year the governor of Massowah, Munzinger Bey, a Swiss, by command of the Viceroy of Egypt, marched an armed force against the Bogos country. The king solicited the aid of England, Germany, and Russia against the Egyptians, whose troops, however, were after a time withdrawn. Sir Bartle Frere, in the blue-book published respecting his mission to Zanzibar, is of the opinion that England, having regard to the passage to India by the Red Sea, should not have wholly abandoned Abyssinia. ACACIA, a genus of shrubs and trees belonging to the natural family Leguminosæ and the section Mimoseæ. The flowers are small, arranged in rounded or elongated clusters. The leaves are compound pinnate in general. In some instances, however, more especially in the Australian species, the leaf-stalks become flattened, and serve the purpose of leaves; the plants are hence called leafless Acacias, and as the leaf-stalks are often placed with their edges towards the sky and earth, they do not intercept light so fully as ordinary trees. There are about 420 species of Acacias widely scattered over the warmer regions of the globe. They abound in Australia and Africa. Various species, such as *Acacia vera*, *arabica*, *Ehrenbergii*, and *tortilis*, yield gum arabic; while *Acacia Verek*, *Seyal*, and *Adansonii* furnish a similar gum, called gum Senegal. These species are for the most part natives of Arabia, the north-eastern part of Africa, and the East Indies. The wattles of Australia are species of Acacia with astringent barks. *Acacia dealbata* is used for tanning. An astringent medicine, called catechu or cutch, is procured from several species, but more especially from *Acacia Catechu*, by boiling down the wood and evaporating the solution so as to get an extract. The bark of *Acacia arabica*, under the name of *Babul* or *Babool*, is used in Scinde for tanning. *Acacia formosa* supplies the valuable Cuba timber called sabicu. *Acacia Seyal* is the plant which is supposed to be the shittah tree of the Bible, which supplied shittim-wood. The pods of *Acacia nilotica*, under the name of neb-neb, are used by tanners. The seeds of *Acacia Niopo* are roasted and used as snuff in South America. The seeds of all the varieties of Acacia in South Australia to the west called Nundo, are used as food after being roasted. *Acacia melanoxylon*, black wood of Australia, sometimes called light wood, attains a great size; its wood is used for furniture, and receives a high polish. *Acacia homalophylla*, myall wood, yields a fragrant timber, used for ornamental purposes. A kind of Acacia is called in Australia Bricklow. In common language the term Acacia is often applied to species of the genus Robinia, which belongs also to the Leguminous family, but is placed in a different section. *Robinia Pseudo-acacia*, or false Acacia, is cultivated in the milder parts of Britain, and forms a large tree, with beautiful pink pea-like blossoms. The tree is sometimes called the Locust tree.

Leaf of *Acacia heterophylla*.

ACADEMY

ACADEMY, ἀκαδήμεια,[1] a suburb of Athens to the north, forming part of the Ceramicus, about a mile beyond the gate named Dypilum. It was said to have belonged to the hero Academus, but the derivation of the word is unknown. It was surrounded with a wall by Hipparchus, and adorned with walks, groves, and fountains by Cimon, the son of Miltiades, who at his death bequeathed it as a public pleasure-ground to his fellow-citizens. The Academy was the resort of Plato, who possessed a small estate in the neighbourhood. Here he taught for nearly fifty years, till his death in 348 B.C.; and from these "groves of the Academy where Plato taught the truth,"[2] his school, as distinguished from the Peripatetics, received the name of the Academics.

The same name (Academia) was in after times given by Cicero to his villa or country-house near Puteoli. There was composed his famous dialogue, *The Academic Questions.*

Of the academic school of philosophy, in so far as it diverged from the doctrines of its great master (see PLATO), we must treat very briefly, referring the reader for particulars to the founders of the various schools, whose names we shall have occasion to mention.

The Academy lasted from the days of Plato to those of Cicero. As to the number of successive schools, the critics are not agreed. Cicero himself and Varro recognised only two, the old and the new; Sextus Empiricus adds a third, the middle; others a fourth, that of Philo and Charmidas; and some even a fifth, the Academy of Antiochus.

Of the old Academy, the principal leaders were Speusippus, Plato's sister's son, and his immediate successor; Xenocrates of Chalcedon, who with Speusippus accompanied Plato in his journey to Sicily; Polemo, a dissolute young Athenian, who came to laugh at Xenocrates, and remained to listen (Horace, *Sat.*, ii. 3, 253); Crates, and Crantor, the latter of whom wrote a treatise, περὶ πένθους, praised by Cicero. Speusippus, like the Pythagoreans, with whom Aristotle compares him, denied that the Platonic Good could be the first principle of things, for (he said) the Good is not like the germ which gives birth to plants and animals, but is only to be found in already existing things. He therefore derived the universe from a primeval indeterminate unit, distinct from the Good; from this unit he deduced three principles—one for numbers, one for magnitude, and one for the soul. The Deity he conceived as that living force which rules all and resides everywhere. Xenocrates, though like Speusippus infected with Pythagoreanism, was the most faithful of Plato's successors. He distinguished three essences: the sensible, the intelligible, and a third, compounded of the other two. The sphere of the first is all below the heavens, of the second all beyond the heavens, of the third heaven itself. To each of these three spheres one of our faculties corresponds. To the sensible, sense; to the intelligible, intellect or reason; to the mixed sphere, opinion (δόξα). So far he closely follows the psychology and cosmogeny of his master; but Cicero notes as the characteristic of both Speusippus and Xenocrates, the abandonment of the Socratic principle of hesitancy.

Of the remaining three, the same writer (who is our principal authority for the history of the Academic school) tells us that they preserved the Platonic doctrine, but emphasised the moral part. On the old Academy he pronounces the following eulogium (*De Fin.* v. 3): "Their writings and method contain all liberal learning, all history, all polite discourse; and besides, they embrace such a variety of arts, that no one can undertake any noble career without their aid. . . . In a word, the Academy is, as it were, the workshop of every artist." Modern criticism has not endorsed this high estimate. They preserved, it is true, and

[1] The bye-form ἑκαδημία, which occurs in Diogenes Laertius, is probably a rationalistic attempt to interpret the word, such as we commonly meet with in the writings of Plato.

[2] Horace, *Ep.* ii. 2, 45.

elaborated many details of the Platonic teaching, which we could ill have spared; but of Plato's originality and speculative power, of his poetry and enthusiasm, they inherited nothing; "nor amid all the learning which has been profusely lavished upon investigating their tenets, is there a single deduction calculated to elucidate distinctly the character of their progress or regression."[1] There is a saying of Polemo's, which will illustrate their virtual abandonment of philosophy proper: "We should exercise ourselves in business, not in dialectical speculation."

Arcesilaus, the successor of Crates, the disciple of Theophrastus and Polemo, was the founder of the second or middle Academy. He professed himself the strict follower of Plato, and seems to have been sincerely of opinion that his was nothing but a legitimate development of the true Platonic system. He followed the Socratic method of teaching in dialogues; and, like Socrates, left no writings,—at least the ancients were not acquainted with any. But we have no evidence that he maintained the ideal theory of Plato, and from the general tendency of his teaching it is probable that he overlooked it. He affirmed that neither our senses nor our mind can attain to any certainty; in all we must suspend our judgment; probability is the guide of life. Cicero tells us that he was more occupied in disputing the opinions of others than in advancing any of his own. Arcesilaus is, in fact, the founder of that academic scepticism which was developed and systematised by Carneades, the founder of the third or new Academy. He was the chief opponent of the Stoics and their doctrine of certitude. This is attested by a well-known saying of his: "If there had been no Chrysippus, there would have been no Carneades." To the Stoical theory of perception, the φαντασία καταληπτική, by which they expressed a conviction of certainty arising from impressions so strong as to amount to science, he opposed the doctrine of ἀκαταληψία, which denied any necessary correspondence between perceptions and the objects perceived. But while denying the possibility of any knowledge of things in themselves, he saved himself from absolute scepticism by the doctrine of probability or verisimilitude, which may serve as a practical guide in life. Thus he announced as his criterion of truth an imagination or impression (φαντασία) at once credible, irrefragable, and attested by comparison with other impressions. The wise man might be permitted to hold an opinion, though he allowed that that opinion might be false. In ethics, however, he appeared as the pure sceptic. On his visit to Rome as an ambassador from Athens, he alternately maintained and denied in his public disputations the existence of justice, to the great scandal of Cato and all honest citizens.

On the fourth and fifth Academies, we need not dwell long. Philo and Antiochus both taught Cicero, and without doubt communicated to him that mild scepticism, that eclecticism compounded of almost equal sympathy with Plato and Zeno, which is the characteristic of his philosophical writings. The Academy exactly corresponded to the moral and political wants of Rome. With no genius for speculation, the better Romans of that day were content to embrace a system which, though resting on no philosophical basis, and compounded of heterogeneous dogmas, offered notwithstanding a secure retreat from religious scepticism and political troubles. "My words," says Cicero, speaking as a true Academician, "do not proclaim the truth, like a Pythian priestess; but I conjecture what is probable, like a plain man; and where, I ask, am I to search for anything more than verisimilitude?" And again: "The characteristic of the Academy is never to interpose one's judgment, to approve what seems most probable, to compare together different opinions, to see what may be advanced on either side, and to leave one's listeners free to judge without pretending to dogmatise."

[1] Archer Butler. *Lect. on Anc. Phil.* ii. 318.

Academy, in its modern acceptation, signifies a society or corporate body of learned men, established for the advancement of science, literature, or the arts.

The first institution of this sort we read of in history was that founded at Alexandria by Ptolemy Soter, which he named the Museum, μουσεῖον. After completing his conquest of Egypt, he turned his attention to the cultivation of letters and science, and gathered about him a large body of literary men, whom he employed in collecting books and treasures of art. This was the origin of the library of Alexandria, the most famous of the ancient world. Passing by the academies which were founded by the Moors at Grenada, Corduba, and as far east as Samarcand, the next instance of an academy is that founded by Charlemagne at the instigation of the celebrated Alcuin, for promoting the study of grammar, orthography, rhetoric, poetry, history, and mathematics. In order to equalise all ranks, each member took the pseudonym of some ancient author or celebrated person of antiquity. For instance, Charlemagne himself was David, Alcuin became Flaccus Albinus. Though none of the labours of this academy have come down to us, it undoubtedly exerted considerable influence in modelling the language and reducing it to rules.

In the following century Alfred founded an academy at Oxford. This was rather a grammar school than a society of learned men, and from it the University of Oxford originated.

But the academy which may be more justly considered as the mother of modern European academies is that of *Floral Games*, founded at Toulouse in the year 1325, by Clemens Isaurus. Its object was to distribute prizes and rewards to the troubadours. The prizes consisted of flowers of gold and silver. It was first recognised by the state in 1694, and confirmed by letters-patent from the king, and its numbers limited to thirty-six. It has, except during a few years of the republic, continued to the present day, and distributes annually the following prizes:—An amaranth of gold for the best ode, a silver violet for a poem of sixty to one hundred Alexandrine lines, a silver eglantine for the best prose composition, a silver marigold for an elegy, and a silver lily presented in the last century by M. de Malpeyre for a hymn to the Virgin.

It was the Renaissance which was *par excellence* the era of academies, and as the Italians may be said to have discovered anew the buried world of literature, so it was in Italy that the first and by far the most numerous academies arose. The earliest of these was the *Platonic* Academy, founded at Florence by Cosmo de Medici for the study of the works of Plato, though subsequently they added the explanation of Dante and other Italian authors.

Marsilius Ficinus, its principal ornament, in his *Theologica Platonica*, developed a system, chiefly borrowed from the later Platonists of the Alexandrian school, which, as it seemed to coincide with some of the leading doctrines of Christianity, was allowed by the church. His Latin translation of Plato is at once literal, perspicuous, and correct; and as he had access to MSS. of Plato now lost, it has in several places enabled us to recover the original reading. After the expulsion of the Medici from Florence, the Platonic Academy was dissolved.

In giving some account of the principal academies of Europe, which is all that this article professes to do, we shall, as far as possible, arrange them under different heads, according to—1*st*, The object which they were designed to promote; 2*d*, The countries to which they belong. This classification, though, perhaps, the best available, is necessarily imperfect, inasmuch as several of those we shall mention were at once literary and scientific, and many associations for similar objects were known by some other name. Thus, with the doubtful exception of the Royal Academy of Arts, England has no academies in the proper sense of the word. For those institutions in England which answer to Italian academies, we must refer the reader to the article SOCIETY.

I. SCIENTIFIC ACADEMIES.—*Italy.*—The first society for the prosecution of physical science was that established at Naples, 1560, under the presidency of Baptista Porta. It was called *Academia Secretorum Naturæ* or *de Secreti.* It arose from a meeting of some scientific friends, who assembled at Porta's house, and called themselves the *Otiosi.* No member was admitted who had not made some useful discovery in medicine or natural philosophy The name suggested to an ignorant public the prosecution of magic and the black arts. Porta went to Rome to justify himself before Paul III. He was acquitted by the Pope, but the academy was dissolved, and he was ordered to abstain for the future from the practice of all illicit arts.

At Rome he was admitted to the *Lincei*, an academy founded by Federigo Cesi, the Marcese di Monticelli. The device of the Lincei was a lynx with its eyes turned towards heaven tearing a Cerberus with its claws, intimating that they were prepared to do battle with error and falsehood. Their motto was the verse of Lucretius describing rain dropping from a cloud—"Redit agmine dulci." Besides Porta, Galileo and Colonna were enrolled among its members. The society devoted itself exclusively to physical science. Porta, under its auspices, published his great work, *Magiæ Naturalis libri xx.*, 1589, in fol.; his *Phytognomonica*, or, the occult virtue of plants; his *De Humana Physiognomia*, from which Lavater largely borrowed; also various works on optics and pneumatics, in which he approached the true theory of vision. He is even said by some to have anticipated Galileo in the invention of the telescope.

But the principal monument still remaining of the zeal and industry of Cesi and his academy is the *Phytobasanos*, a compendium of the natural history of Mexico, written by a Spaniard, Hernendez. During fifty years the MS. had been neglected, when Cesi discovered it, and employed Terentio, Fabro, and Colonna, all Lynceans, to edit it and enrich it with notes and emendations. Cesi's own great work, *Theatrum Naturæ*, was never published. The MS. still exists in the Albani Library at Rome. After Cesi's death, 1630, the academy languished for some years under the patronage of Urban VIII. An academy of the same name was inaugurated at Rome 1784, and still flourishes. It numbers among its members some of our English philosophers. But the fame of the *Lincei* was far outstripped by that of the *Accademia del Cimento*, established in Florence 1657, under the patronage of the Grand Duke Ferdinand II., at the instigation of his brother Leopold, acting under the advice of Viviani, one of the greatest geometers of Europe. The object of this academy was (as the name implies) to make *experiments* and relate them, abjuring all preconceived notions. Unfortunately for science, it flourished for only ten years. Leopold in 1667 was made a cardinal, and the society languished without its head. It has, however, left a record of its labours in a volume containing an account of the experiments, published by the secretary in 1667. It is in the form of a beautifully printed folio, with numerous full print pages of illustrations. It contains, among others, those on the supposed incompressibility of water, on the pressure of the air, and on the universal gravity of bodies. Torricelli, the inventor of the barometer, was one of its members.

Passing by numerous other Italian Academies of Science, we come to those of modern times.

The Royal Academy of Sciences at Turin originated in 1757 as a private society; in 1759 it published a volume of *Miscellanea Philosophico-Mathematica Societatis privatæ Taurinensis;* shortly after it was constituted a Royal Society by Charles Emanuel III., and in 1783 Victor Amadeus III. made it a Royal Academy of Sciences. It consists of 40 members, residents of Turin, 20 non-resident, and 20 foreign members. It publishes each year a quarto volume of proceedings, and has crowned and awarded prizes to many learned works.

France.—The *Old Academy of Sciences* originated in much the same way as the French Academy. A private society of scientific men had for some thirty years been accustomed to meet first at the house of Montmort, the maître des requêtes, afterwards at that of Thevenot, a great traveller and man of universal genius, in order to converse on their studies, and communicate their discoveries. To this society belonged, among others, Descartes, Gassendi, Blaise Pascal, and his father. Hobbes, the philosopher of Malmesbury, was presented to it during his visit to Paris in 1640. Colbert, just as Richelieu in the case of the French Academy, conceived the idea of giving an official status to this body of learned men. Seven eminent mathematicians, among whom were Huyghens and De Bessy, the author of a famous treatise on magic squares, were chosen to form the nucleus of the new society. A certain number of chemists, physicians, and anatomists were subsequently added. Pensions were granted by Louis XIV. to each of the members, and a fund for instruments and experimentations placed at their disposal They commenced their session the 22d December 1666 in the Royal Library. They met twice a week—the mathematicians on the Wednesdays, the physicists (as the naturalists and physiologists were then called) on the Saturdays. Duhamel was appointed secretary by the king. This post he owed more to his polished Latinity than to his scientific attainments, all the proceedings of the society being recorded in Latin. A treasurer was also nominated, who, notwithstanding his pretentious title, was nothing more than conservator of the scientific instruments, &c. At first the academy was rather a laboratory and observatory than an academy proper Experiments were undertaken in common and results discussed. Several foreign *savants*, in particular the Danish astronomer Rœmer, joined the society, attracted by the liberality of the Grand Monarque; and the German physician and geometer Tschirnhausen and Sir Isaac Newton were made foreign associates. The death of Colbert, who was succeeded by Louvois, exercised a disastrous effect on the fortunes of the academy. The labours of the academicians were diverted from the pursuit of pure science to such works as the construction of fountains and cascades at Versailles, and the mathematicians were employed to calculate the odds of the games of lansquenet and bassett. In 1699 the academy was reconstituted by M. de Pontchartrain, under whose department as secretary of state the academies came. By its new constitution it consisted of ten honorary members, men of high rank, who interested themselves in science, fifteen pensionaries, who were the working members, viz., three geometricians, and the same number of astronomers, mechanicians, anatomists, and chemists. Each section of three had two associates attached to it, and besides, each pensionary had the power of naming a pupil. There were eight foreign and four free associates. The officers were, a president and a vice-president, named by the king from among the honorary members, and a secretary and treasurer chosen from the pensionaries, who held their offices for life. Fontenelle, a man of wit, and rather a populariser of sciences than an original investigator, succeeded Duhamel secretary. The constitution, as is evident, was purely aristocratical, and unlike that of the French Academy, in which the principle of equality among the members was never violated. Science was not yet strong enough to dispense with the patronage of the great. The two leading spirits of the academy at this period were Clairaut and Réaumur. Clairaut was the first to explain capillary attraction, and predicted within a few days of the correct time the return of Halley's comet. His theory on the figure of the earth was only superseded by Laplace's *Mécanique Céleste.* Réaumur was principally distinguished by his practical discoveries, and a thermometer in common use at the present day bears his name.

To trace the subsequent fortunes of this academy would far exceed our limits, being equivalent to writing the history of the rise and progress of science in France. It has reckoned among its members Laplace, Buffon, Lagrange, D'Alembert, Lavoisier, and Jussieu, the father of modern botany. Those of our readers who wish for further information we would refer to M. Alfred Maury's excellent history.

On 21st December 1792, the old Academy of Sciences met for the last time. Many of the members fell by the guillotine, many were imprisoned, more reduced to indigence. The aristocracy of talent was almost as much detested and persecuted by the Revolution as that of rank.

In 1795 the Convention decided on founding an Institute, which was to replace all the academies. The first class of the Institute corresponded closely to the old academy. See INSTITUTE.

In 1816 the Academy was reconstituted as a branch of the Institute. The new academy has reckoned among its members, besides many other brilliant names, Carnot the engineer, the physicians Fresnel, Ampère, Arago, Biot, the chemists Gay-Lussac and Thénard, the zoologists G. Cuvier and the two Geoffroy Saint-Hilaires.

The French had also considerable academies in most of their large towns. Montpellier, for example, had a Royal Academy of Sciences, founded in 1706 by Louis XIV., on nearly the same footing as that at Paris, of which, indeed, it was in some measure the counterpart. It was reconstituted in 1847, and organised under three sections—medicine, science, and letters. It has continued to publish annual reports of considerable value. Toulouse also had an academy under the denomination of Lanternists; and there were analogous institutions at Nîmes, Arles, Lyons, Dijon, Bordeaux, and other places. Of these several, we believe, are still in existence, if not in activity.

Before passing on to German academies, we may here notice a private scientific and philosophical society, the precursor of the French Academy of Sciences. It does not appear to have had any distinguishing name; but the promoter of it was Eusebius Renaudot, Counsellor and Physician in Ordinary to the King of France, and Doctor Regent of the Faculty of Physic at Paris, by whom a full account of its conferences was published, translated into English by G. Havers, 1664. In the preface it is said to be "a production of an assembly of the choicest wits of France." We will quote a few of the subjects of these discussions in order to show the character of the society:—"Why the loadstone draws iron;" "Whether the soul's immortality is demonstrable by natural reason;" "Of the little hairy girl lately seen in this city." On subjects of popular superstition their views were far in advance of the time. Of judicial astrology it is said, "Why should we seek in heaven the causes of accidents which befall us if we can find them on earth?" Of the philosopher's stone—"This most extravagant conceit, that it is the panacea, joined to the other absurdities of that chimerical art, makes us believe that it is good for nothing but to serve for imaginary consolation to the miserable."

Germany.—The *Collegium Curiosum* was a scientific society, founded by J. C. Sturm, professor of mathematics and natural philosophy in the University of Altorff, in Franconia, in 1672, on the plan of the Accademia del Cimento. It originally consisted of 20 members, and continued to flourish long after the death of its founder. The early labours of the society were devoted to the repetition (under varied conditions) of the most notable experiments of the day, or to the discussion of the results. Two volumes of proceedings were published by Sturm in 1676 and 1685 respectively. The *Programma Invitatorium* is dated June 3, 1672; and Sturm therein urges that, as the day of disputatious philosophy had given way to that of experimental philosophy, and as, moreover, scientific societies had been founded at Florence, London, and Rome, it would therefore seem desirable to found one in Germany, for the attainment of which end he requests the co-operation of the learned.

The work of 1676, entitled *Collegium Experimentale sive Curiosum,* commences with an account of the diving-bell, "a new invention;" next follow chapters on the camera obscura, the Torricellian experiment, the air-pump, microscope, telescope, &c. The two works have been pronounced by a competent authority[1] to constitute a nearer approach to a text-book of the physics of the period than any preceding work.

The *Royal Academy of Sciences at Berlin* was founded in 1700 by Frederic I. after Leibnitz' comprehensive plan, but was not opened till 1711. Leibnitz was the first president. Under Maupertuis, who succeeded him, it did good service. Its present constitution dates from January 24, 1812. It is divided into four sections—physical, mathematical, philosophical, and historical. Each section is under a paid secretary elected for life, each secretary presides in turn for a quarter of a year. The members are—1*st,* Regular members who are paid; these hold general meetings every Thursday, and sectional meetings every Monday. 2*d,* Foreign members, not to exceed 24 in number. 3*d,* Honorary members and correspondents. Since 1811 it has published yearly, *Mémoires de l'Académie Royale des Sciences et Belles Lettres à Berlin.* For its scientific and philosophical attainments the names of W. and A. v. Humboldt, Ideles, Savigny, Schleiermacher, Bopp, and Ranke, will sufficiently vouch.

The *Academy of Sciences at Mannheim* was established by Charles Theodore, Elector Palatine, in the year 1755. The plan of this institution was furnished by Schæpflin, according to which it was divided into two classes, the historical and physical. In 1780 a sub-division of the latter took place into the physical, properly so-called, and the meteorological. The meteorological observations are published separately, under the title of *Ephemerides Societatis Meteorologicæ Palatinæ.* The historical and physical memoirs are published under the title of *Acta Academiæ Theodoro-Palatinæ.*

The *Electoral Bavarian Academy of Sciences at Munich* was established in 1759, and publishes its memoirs under the title of *Abhandlungen der Baierischen Akademie.* Soon after the Elector of Bavaria was raised to the rank of king, the Bavarian government, by his orders, directed its attention to a new organisation of the Academy of Sciences of Munich. The design of the king was, to render its labours more extensive than those of any similar institution in Europe, by giving to it, under the direction of the ministry, the immediate superintendence over all the establishments for public instruction in the kingdom of Bavaria. The Privy-Councillor Jacobi, a man of most excellent character, and of considerable scientific attainments, was appointed president.

[1] Mr G. F. Rodwell, in the *Chemical News,* June 21, 1867.

The *Electoral Academy at Erfurt* was established by the Elector of Mentz, in the year 1754. It consists of a protector. president, director, assessors, adjuncts, and associates. Its object is to promote the useful sciences. The memoirs were originally published in Latin, but afterwards in German. The Hessian Academy of Sciences at Giessen publish their transactions under the title of *Acta Philosophico-Medica Academiæ Scientiarum Principalis Hessiacæ.* In the Netherlands there are scientific academies at Flushing and Brussels, both of which have published their transactions.

Russia.—The *Imperial Academy of Sciences at St Petersburg* was projected by the Czar Peter the Great. Having in the course of his travels observed the advantage of public societies for the encouragement and promotion of literature, he formed the design of founding an academy of sciences at St Petersburg. By the advice of Wolff and Leibnitz, whom he consulted on this occasion, the society was accordingly regulated, and several learned foreigners were invited to become members. Peter himself drew the plan, and signed it on the 10th of February 1724; but he was prevented, by the suddenness of his death, from carrying it into execution. His decease, however, did not prevent its completion; for on the 21st of December 1725, Catharine I. established it according to Peter's plan, and on the 27th of the same month the society assembled for the first time. On the 1st of August 1726, Catharine honoured the meeting with her presence, when Professor Bulfinger, a German naturalist of great eminence, pronounced an oration upon the advances made in the theory of magnetic variations, and also on the progress of research in so far as regarded the discovery of the longitude. A short time afterwards the empress settled a fund of £4982 per annum for the support of the academy; and 15 members, all eminent for their learning and talents, were admitted and pensioned, under the title of professors in the various branches of science and literature. The most distinguished of these professors were Nicholas and Daniel Bernouilli, the two De Lisles, Bulfinger, and Wolff.

During the short reign of Peter II. the salaries of the members were discontinued, and the academy utterly neglected by the Court; but it was again patronised by the Empress Anne, who even added a seminary for the education of youth under the superintendence of the professors. Both institutions flourished for some time under the direction of Baron Korf; but upon his death, towards the end of Anne's reign, an ignorant person being appointed president, many of the most able members quitted Russia. At the accession of Elizabeth, however, new life and vigour were infused into the academy. The original plan was enlarged and improved; some of the most learned foreigners were again drawn to St Petersburg; and, what was considered as a good omen for the literature of Russia, two natives, Lomonosof and Rumovsky, men of genius and abilities, who had prosecuted their studies in foreign universities, were enrolled among its members. Lastly, the annual income was increased to £10,659, and sundry other advantages were conferred upon the institution.

The Empress Catharine II., with her usual zeal for promoting the diffusion of knowledge, took this useful society under her immediate protection. She altered the court of directors greatly to the advantage of the whole body, corrected many of its abuses, and infused a new vigour and spirit into their researches. By Catharine's particular recommendation the most ingenious professors visited the various provinces of her vast dominions; and as the funds of the academy were not sufficient to defray the whole expense of these expeditions, the empress supplied the deficiency by a grant of £2000, which was renewed as occasion required.

The purpose and object of these travels will appear from the instructions given by the academy to the several persons who engaged in them. They were ordered to institute inquiries respecting the different sorts of earths and waters; the best methods of cultivating barren and desert spots; the local disorders incident to men and animals, together with the most efficacious means of relieving them; the breeding of cattle, particularly of sheep; the rearing of bees and silk-worms; the different places and objects for fishing and hunting; minerals of all kinds; the arts and trades; and the formation of a *Flora Russica*, or collection of indigenous plants. They were particularly instructed to rectify the longitude and latitude of the principal towns; to make astronomical, geographical, and meteorological observations; to trace the courses of rivers; to construct the most exact charts; and to be very distinct and accurate in remarking and describing the manners and customs of the different races of people, their dresses, languages, antiquities, traditions, history, religion; in a word, to gain every information which might tend to illustrate the real state of the whole Russian empire. More ample instructions cannot well be conceived; and they appear to have been very zealously and faithfully executed. The consequence was that, at that time, no country could boast, within the space of so few years, such a number of excellent publications on its internal state, its natural productions, its topography, geography, and history, and on the manners, customs, and languages of the different tribes who inhabit it, as issued from the press of this academy. In its researches in Asiatic languages, and general knowledge of Oriental customs and religions, it proved itself the worthy rival of our own Royal Asiatic Society

The first transactions of this society were published in 1728, and entitled *Commentarii Academiæ Scientiarum Imperialis Petropolitanæ ad annum* 1726, with a dedication to Peter II. The publication was continued under this form until the year 1747, when the transactions were called *Novi Commentarii Academiæ*, &c.; and in 1777, the academy again changed the title into *Acta Academiæ Scientiarum Imperialis Petropolitanæ*, and likewise made some alteration in the arrangements and plan of the work. The papers, which had been hitherto published in the Latin language only, were now written indifferently either in that language or in French, and a preface added, entitled *Partie Historique*, which contains an account of its proceedings, meetings, the admission of new members, and other remarkable occurrences. Of the *Commentaries*, 14 volumes were published: the first of the *New Commentaries* made its appearance in 1750, and the twentieth in 1776. Under the new title of *Acta Academiæ*, a number of volumes have been given to the public; and two are printed every year. These transactions abound with ingenious and elaborate disquisitions upon various parts of science and natural history; and it may not be an exaggeration to assert, that no society in Europe has more distinguished itself for the excellence of its publications, particularly in the more abstruse parts of pure and mixed mathematics.

The academy is still composed, as at first, of 15 professors, besides the president and director. Each of these professors has a house and an annual stipend of from £200 to £600. Besides the professors, there are four adjuncts, with pensions, who are present at the sittings of the society, and succeed to the first vacancies. The direction of the academy is generally entrusted to a person of distinction.

The buildings and apparatus of this academy are on a vast scale. There is a fine library, consisting of 36,000 curious books and manuscripts; together with an extensive museum, in which the various branches of natural history, &c., are distributed in different apartments. The latter is extremely rich in native productions, having been considerably augmented by the collections made by Pallas, Gmelin, Guldenstaedt, and other professors, during their expeditions through the various parts of the Russian empire. The stuffed animals and birds occupy one apartment. The chamber of rarities, the cabinet of coins, &c., contain innumerable articles of the highest curiosity and value. The motto of the society is exceedingly modest; it consists of only one word, *Paulatim.*

Sweden.—The *Academy of Sciences at Stockholm*, or the *Royal Swedish Academy*, owes its institution to six persons of distinguished learning, among whom was the celebrated Linnæus. They originally met on the 2d of June 1739, when they formed a private society, in which some dissertations were read; and in the end of the same year their first publication made its appearance. As the meetings continued and the members increased, the society attracted the notice of the king; and, accordingly, on the 31st of March 1741, it was incorporated under the name of the Royal Swedish Academy. Not receiving any pension from the crown, it is merely under the protection of the king, being directed, like our Royal Society, by its own members. It has now, however, a large fund, which has chiefly arisen from legacies and other donations; but a professor of experimental philosophy, and two secretaries, are still the only persons who receive any salaries. Each of the members resident at Stockholm becomes president by rotation, and continues in office during three months. There are two kinds of members, native and foreign; the election of the former take places in April, that of the latter in July; and no money is paid at the time of admission. The dissertations read at each meeting are collected and published four times in the year: they are written in the Swedish language, and printed in octavo, and the annual publications make a volume. The first 40 volumes, which were completed in 1779, are called the *Old Transactions.*

Denmark.—The *Royal Academy of Sciences at Copenhagen* owes its institution to the zeal of six individuals, whom Christian VI., in 1742, ordered to arrange his cabinet of medals. These persons were John Gram, Joachim Frederic Ramus, Christian Louis Scheid, Mark Woldickey, Eric Pontopidan, and Bernard Moelman, who, occasionally meeting for this purpose, extended their designs; associated with them others who were eminent in several branches of science; and forming a kind of literary society, employed themselves in searching into, and explaining the history and antiquities of their country. The Count of Holstein, the first president, warmly patronised this society, and recommended it so strongly to Christian VI. that, in 1743, his Danish majesty took it under his protection, called it the Royal Academy of Sciences, endowed it with a fund, and ordered the members to join to their former pursuits natural history, physics, and mathematics. In consequence of the royal favour the members engaged with fresh zeal in their pursuits; and the academy has published 15 volumes in the Danish language, some of which have been translated into Latin.

England.—In 1616 a scheme for founding a Royal Academy was started by Edmund Bolton, an eminent scholar and antiquary. Bolton, in his petition to King James, which was supported by George Villiers, Marquis of Buckingham, proposed that the title of the academy should be "King James, his Academe or College of honour." In the list of members occurs the name of Sir Kenelm Digby, one of the original members of the Royal Society. The death of the king proved fatal to the undertaking. In 1635 a second attempt was made to found an academy, under the patronage of Charles I., with the title of "Minerva's Musæum," for the instruction of young noblemen in the liberal arts and sciences, but the project was soon dropped. About 1645 some of the more ardent followers of Bacon used to meet, some in London, some at Oxford, for the discussion of subjects connected with experimental science. This was the origin of the Royal Society, which received its charter in 1662. See ROYAL SOCIETY.

Ireland.—The *Royal Irish Academy* arose out of a society established at Dublin about the year 1782, and consisting of a number of gentlemen, most of whom belonged to the university. They held weekly meetings, and read essays in turn on various subjects. The members of this society afterwards formed a more extensive plan, and, admitting only such names as might add dignity to their new institution, became the founders of the *Royal Irish Academy.* They professed to unite the advancement of science with the history of mankind and polite literature. The first volume of their transactions (for 1787) appeared in 1788, and seven volumes were afterwards published. A society was formed in Dublin, similar to the Royal Society in London, as early as the year 1683; but the distracted state of the country proved unpropitious to the cultivation of philosophy and literature.

Holland.—The *Royal Academy of Sciences at Amsterdam*, erected by a royal ordinance 1852, succeeded the Royal Institute of the Low Countries, founded by Louis Napoleon, King of Holland, 1808. In 1855 it had published 192 volumes of proceedings, and received an annual subsidy of 14,000 florins from the state.

Spain.—The *Academy of Sciences at Madrid*, founded 1774, after the model of the French Academy.

Portugal.—The *Academy of Sciences at Lisbon* is divided into three classes—natural history, mathematics, and national literature. It consists of 24 ordinary and 36 extraordinary members. Since 1779 it has published *Memorias de Letteratura Portugueza; Memorias Economicas; Collecçao de Livros ineditos di Historia Portugueza.*

II. ACADEMIES OF BELLES LETTRES.—*Italy.*—Italy in the 16th century was remarkable for the number of its literary academies. Tiraboschi, in his *History of Italian Literature*, has given a list of 171; and Jarkius, in his *Specimen Historiæ Academiarum Conditarum*, enumerates nearly 700. Many of these, with a sort of Socratic irony, gave themselves names expressive of ignorance or simply ludicrous. Such were the *Lunatici* of Naples, the *Estravaganti*, the *Fulminales*, the *Trapessati*, the *Drowsy*, the *Sleepers*, the *Anxious*, the *Confused*, the *Unstable*, the *Fantastic*, the *Transformed*, the *Ætherial.* "The first academies of Italy chiefly directed their attention to classical literature; they compared manuscripts; they suggested new readings, or new interpretations; they deciphered inscriptions or coins; they sat in judgment on a Latin ode, or debated the propriety of a phrase. Their own poetry had, perhaps, never been neglected; but it was not till the writings of Bembo furnished a new code of criticism in the Italian language, that they began to study it with the same minuteness as modern Latin." "They were encouragers of a numismatic and lapidary erudition, elegant in itself, and throwing for ever little specks of light on the still ocean of the past, but not very favourable to comprehensive observation, and tending to bestow on an unprofitable pedantry the honours of real learning."[1] The Italian nobility, excluded as they mostly were from politics, and living in cities, found in literature a consolation and a career. Such academies were oligarchical in their constitution; they encouraged culture, but tended to hamper genius and extinguish originality. Of their academies, by far the most celebrated was the *Accademia della Crusca* or *Furfuratorum;* that is, of Bran, or of the Sifted. The title was borrowed from a previous society at Perugia, the *Accademia degli Scossi*, of the Well-shaken. Its device

[1] Hallam's *Int. to Lit. of Europe*, vol. i. 651, and vol. ii. 502.

was a sieve; its motto, "Il più bel fior ne coglie, it collects the finest flour of it; its principal object the purification of the language. Its great work was the *Vocabulario della Crusca*, the first edition of which was published 1613. It was composed avowedly on Tuscan principles, and regarded the 14th century as the Augustan period of the language. Beni assailed it in his *Anti-Crusca*, and this exclusive Tuscan spirit has disappeared in subsequent editions. The Accademia della Crusca is now incorporated with two older societies—the Accademia degli Apatici (the Impartials) and the Accademia Fiorentina.

Among the numerous other literary academies of Italy we may mention the Academy of Naples, founded about 1440 by Alfonso, the king; the *Academy of Florence*, founded 1540, to illustrate and perfect the Tuscan tongue, especially by a close study of Petrarch; the *Intronati* of Siena, 1525; the *Infiammati* of Padua, 1534; the *Rozzi* of Siena, suppressed by Cosmo, 1568.

The *Academy of Humourists*, *Umoristi*, had its origin at Rome in the marriage of Lorenzo Marcini, a Roman gentleman, at which several persons of rank were guests. It was carnival time, and so to give the ladies some diversion, they betook themselves to the reciting of verses, sonnets, speeches, first *extempore*, and afterwards premeditately, which gave them the denomination of *Belli Humori*. After some experience, and coming more and more into the taste of these exercises, they resolved to form an academy of belles lettres, and changed the title of *Belli Humori* for that of *Humoristi*.

In 1690 the *Academy* or *Society of Arcadians* was established at Rome, for the purpose of reviving the study of poetry. The founder Crescimbeni is the author of a well-known history of Italian poetry. It numbered among its members many princes, cardinals, and other ecclesiastics; and, to avoid disputes about pre-eminence, all appeared masked after the manner of Arcadian shepherds. Within ten years from its first establishment the number of *academicians* amounted to 600.

The *Royal Academy of Savoy* dates from 1719, and was made a royal academy by Charles Felix in 1848. Its emblem is a gold orange tree full of flowers and fruit; its motto "Flores fructusque perennes," being the same as those of the famous *Florimentane* Academy, founded at Annecy by St Francis de Sales. It has published valuable memoirs on the history and antiquities of Savoy.

Germany.—Of the German literary academies, the most celebrated was *Die Fruchtbringende Gesellschaft*, the Fruitful Society, established at Weimar 1617. Five princes enrolled their names among the original members. The object was to purify the mother tongue. The German academies copied those of Italy in their quaint titles and petty ceremonials, and exercised little permanent influence on the language or literature of the country.

France.—The *French Academy* was established by order of the king in the year 1635, but in its original form it came into existence some four or five years earlier. About the year 1629 certain literary friends in Paris agreed to meet weekly at the house of one of their number. These meetings were quite informal, but the conversation turned mostly on literary topics; and when, as was often the case, one of the number had composed some work, he read it to the rest, and they gave their opinions upon it. The place of meeting was the house of M. Conrard, which was chosen as being the most central. The fame of these meetings, though the members were bound over to secrecy, reached at length the ears of Cardinal Richelieu, who conceived so high an opinion of them, that he at once promised them his protection, and offered to incorporate them by letters patent. Nearly all the members would have preferred the charms of privacy, but, considering the risk they would run in incurring the cardinal's displeasure, and that by the letter of the law all meetings of any sort or kind were prohibited, they expressed their gratitude for the high honour the cardinal thought fit to confer on them. They proceeded at once to organise their body, settle their laws and constitution, appoint officers, and choose their name. Their officers consisted of a director and a chancellor, both chosen by lot, and a permanent secretary, chosen by votes. They elected besides a publisher, not a member of the body. The director presided at the meetings, being considered as *primus inter pares*, and performing much the same part as the speaker in the English House of Commons. The chancellor kept the seals, and sealed all the official documents of the academy. The office of the secretary explains itself. The cardinal was *ex officio* protector. The meetings were weekly as before.

The letters patent were at once granted by the king, but it was only after violent opposition and long delay that the president, who was jealous of the cardinal's authority, consented to grant the verification required by the old constitution of France.

The object for which the academy was founded, as set forth in its statutes, was the purification of the French language. "The principal function of the academy shall be to labour with all care and diligence to give certain rules to our language, and to render it pure, eloquent, and capable of treating the arts and sciences" (Art. 24). They proposed "to cleanse the language from the impurities it has contracted in the mouths of the common people, from the jargon of the lawyers, from the misusages of ignorant courtiers, and the abuses of the pulpit."—*Letter of Academy to Cardinal Richelieu.*

Their numbers were fixed at forty. The original members who formed the nucleus of the body were eight, and it was not till 1639 that the full number was completed. Their first undertaking consisted of essays written by all the members in rotation. To judge by the titles and specimens which have come down to us, these possessed no special originality or merit, but resembled the ἐπιδείξεις of the Greek rhetoricians. They next, at the instance of Cardinal Richelieu, undertook a criticism of Corneille's *Cid*, the most popular work of the day. It was a rule of the academy that no work could be criticised except at the author's request. It was only the fear of incurring the cardinal's displeasure which wrung from Corneille an unwilling consent. The critique of the academy was rewritten several times before it met with the cardinal's approbation. After six months of elaboration, it was published under the title, *Sentiments de l'Académie Françoise sur le Cid.* This judgment did not satisfy Corneille, as a saying attributed to him on the occasion shows. "*Horatius*," he said, referring to his last play, "was condemned by the Duumviri, but he was absolved by the people." But the crowning labour of the academy, commenced in 1639, was a dictionary of the French language. By the twenty-sixth article of their statutes, they were pledged to compose a dictionary, a grammar, a treatise on rhetoric, and one on poetry. M. Chapelain, one of the original members and leading spirits of the academy, pointed out that the dictionary would naturally be the first of these works to be undertaken, and drew up a plan of the work, which was to a great extent carried out. A catalogue was to be made of all the most approved authors, prose and verse: these were to be distributed among the members, and all words and phrases of which they approved to be marked by them in order to be incorporated in the dictionary. For this they resolved themselves into two committees, which sat on other than the regular days. M. de Vaugelas[1]

[1] A *bon mot* of his is worth recording. When returning thanks for

was appointed editor in chief. To remunerate him for his labours, he received from the cardinal a pension of 2000 francs. The first edition of this dictionary appeared in 1694, the last *Complément* in 1854.

Instead of following the history of the French Academy,—which, like its two younger sisters, the Academy of Sciences and the Academy of Inscriptions, was suppressed in 1793, and reconstituted in 1795, as a class of the Institute,—a history which it would be impossible to treat adequately in the limit of an article, we will attempt briefly to estimate its influence on French literature and language, and point out its principal merits and defects. To begin with its merits, it may justly boast that there is hardly a single name of the first rank among French *littérateurs* that it has not enrolled among its members. Molière, it is true, was rejected as a player; but we can hardly blame the academy for a social prejudice which it shared with the age; and it is well known that it has, as far as was in its power, made the *amende honorable.* In the *Salle des Séances* is placed the bust of the greatest of modern comedians, with the inscription, "Rien ne manque à sa gloire ; il manquait à la notre." Descartes was excluded from the fact of his residing in Holland. Scarron was confined by paralysis to his own house. Pascal is the only remaining exception, and Pascal was better known to his contemporaries as a mathematician than a writer. His *Lettres Provinciales* were published anonymously; and just when his fame was rising he retired to Port-Royal, where he lived the life of a recluse. On the other hand, it cannot be denied that the *fauteuils* have often been occupied by men of no mark in literature. Nor is the academy wholly exonerated by M. Livet's ingenious defence, that there are but eight marshals in the French army, and yet the number has never appeared too restricted ; for its most ardent admirers will not assert that it has, as a rule, chosen the forty most distinguished living authors. Court intrigue, rank, and *finesse* have too often prevailed over real merit and honesty Though his facts are incorrect, there is much truth in Courier's caustic satire :—"Dans une compagnie de gens faisant profession d'esprit ou de savoir, nul ne veut près de soi un plus habile que soi, mais bien un plus noble, un plus riche : un duc et pair honore l'Académie Française, qui ne veut point de Boileau,[1] refuse la Bruyère, fait attendre Voltaire, mais reçoit tout d'abord Chapelain et Conrart."

We have next to consider the influence of the French Academy on the language and literature, a subject on which the most opposite opinions have been advanced. On the one hand, it has been asserted that it has corrected the judgment, purified the taste, and formed the language of French writers, and that to it we owe the most striking characteristics of French literature, its purity, delicacy, and flexibility. Thus Mr Matthew Arnold, in his well-known *Essay on the Literary Influence of Academies*, has pronounced a glowing panegyric on the French Academy as a high court of letters, and rallying point for educated opinion, as asserting the authority of a master in matters of tone and taste. To it he attributes in a great measure that thoroughness, that openness of mind, that absence of vulgarity which he finds everywhere in French literature ; and to the want of a similar institution in England he traces that eccentricity, that provincial spirit, that coarseness, which, as he thinks, is barely compensated by English genius. Thus, too, M. Renan, one of its most distinguished living members, says that it is owing to the academy "qu'on peut tout dire sans appareil scholastique avec la langue des gens du monde." "Ah ne dites," he exclaims, "qu'ils n'ont rien fait, ces obscures beaux esprits dont la vie se passe à instruire le procès des mots, à peser les syllables. Ils ont fait un chef-d'œuvre—la langue française." On the other hand, its inherent defects have been so well summed up by M. Lanfrey, that we cannot do better than quote from his recent *History of Napoleon.* "This institution," he says, speaking of the French Academy, "had never shown itself the enemy of despotism. Founded by the monarchy and for the monarchy, eminently favourable to the spirit of intrigue and favouritism, incapable of any sustained or combined labour, a stranger to those great works pursued in common which legitimise and glorify the existence of scientific bodies, occupied exclusively with learned trifles, fatal to emulation, which it pretends to stimulate, by the compromises and calculations to which it subjects it, directed in everything by petty considerations, and wasting all its energy in childish tournaments, in which the flatteries that it showers on others are only the foretaste of the compliments it expects in return for itself, the French Academy seems to have received from its founders the special mission to transform genius into *bel esprit*, and it would be hard to produce a man of talent whom it has not demoralised. Drawn in spite of itself towards politics, it alternately pursues and avoids them ; but it is specially attracted by the gossip of politics, and whenever it has so far emancipated itself as to go into opposition, it does so as the champion of ancient prejudices. If we examine its influence on the national genius, we shall see that it has given it a flexibility, a brilliancy, a polish, which it never possessed before ; but it has done so at the expense of its masculine qualities, its originality, its spontaneity, its vigour, its natural grace. It has disciplined it, but it has emasculated, impoverished, and rigidified it. It sees in taste, not a sense of the beautiful, but a certain type of correctness, an elegant form of mediocrity. It has substituted pomp for grandeur, school routine for individual inspiration, elaborateness for simplicity, *fadeur* and the monotony of literary orthodoxy for variety, the source and spring of intellectual life; and in the works produced under its auspices we discover the rhetorician and the writer, never the man. By all its traditions the academy was made to be the natural ornament of a monarchical society. Richelieu conceived and created it as a sort of superior centralisation applied to intellect, as a high literary court to maintain intellectual unity, and protest against innovation. Bonaparte, aware of all this, had thought of re-establishing its ancient privileges; but it had in his eyes one fatal defect—*esprit.* Kings of France could condone a witticism even against themselves, a *parvenu* could not."

In conclusion, we would briefly state our own opinion. The influence of the French Academy has been conservative rather than creative. While it has raised the general standard of writing, it has tended to hamper and crush originality. It has done much by its example for style, but its attempts to impose its laws on language have, from the nature of the case, failed. For, however perfectly a dictionary or a grammar may represent the existing language of a nation, an original genius is certain to arise—a Victor Hugo, or an Alfred de Musset, who will set at defiance all dictionaries and academic rules.

Spain.—The *Royal Spanish Academy at Madrid* held its first meeting in July 1713, in the palace of its founder, the Duke d'Escalona. It consisted at first of 8 academicians, including the duke ; to which number 14 others were afterwards added, the founder being chosen president or director. In 1714 the king granted them the royal confirmation and protection. Their device is a crucible in

his pension, the cardinal remarked, "Well, Monsieur, you will not forget the word *pension* in your dictionary." "No, Monseigneur," replied Vaugelas, "and still less the word *gratitude.*"

[1] Boileau was elected to the French Academy 1684, La Bruyère in 1693.

the middle of the fire, with this motto, *Limpia, fixa, y da esplendor*—"It purifies, fixes, and gives brightness." The number of its members was limited to 24; the Duke d'Escalona was chosen director for life, but his successors were elected yearly, and the secretary for life. Their object, as marked out by the royal declaration, was to cultivate and improve the national language. They were to begin with choosing carefully such words and phrases as have been used by the best Spanish writers; noting the low, barbarous, or obsolete ones; and composing a dictionary wherein these might be distinguished from the former.

Sweden.—The *Royal Swedish Academy* was founded in the year 1786, for the purpose of purifying and perfecting the Swedish language. A medal is struck by its direction every year in honour of some illustrious Swede This academy does not publish its transactions.

Belgium.—Belgium has always been famous for its literary societies. The little town of Diest boasts that it possessed a society of poets in 1302, and the Catherinists of Alost date from 1107. Whether or not there is any foundation for these claims, it is certain that numerous *Chambers of Rhetoric* (so academies were then called) existed in the first years of the rule of the house of Burgundy.

The present *Royal Academy of Belgium* was founded by the Count of Coblenzl at Brussels, 1769. Count Stahrenberg obtained for it in 1772 letters patent from Maria Theresa, who also granted pensions to all the members, and a fund for printing their works. All academicians were *ipso facto* ennobled. It was reorganised, and a class of fine arts added in 1845 through the agency of M. Van de Weyer, the learned Belgian ambassador at London. It has devoted itself principally to national history and antiquities.

III. Academies of Archæology and History.—*Italy.*—Under this class the *Academy of Herculaneum* properly ranks. It was established at Naples about 1755, at which period a museum was formed of the antiquities found at Herculaneum, Pompeii, and other places, by the Marquis Tanucci, who was then minister of state. Its object was to explain the paintings, &c., which were discovered at those places; and for this purpose the members met every fortnight, and at each meeting three paintings were submitted to three academicians, who made their report on them at their next sitting. The first volume of their labours appeared in 1775, and they have been continued under the title of *Antichità di Ercolano.* They contain engravings of the principal paintings, statues, bronzes, marble figures, medals, utensils, &c., with explanations. In the year 1807, an Academy of History and Antiquities, on a new plan, was established at Naples by Joseph Bonaparte. The number of members was limited to forty; twenty of whom were to be appointed by the king, and these twenty were to present to him, for his choice, three names for each of those wanted to complete the full number. Eight thousand ducats were to be annually allotted for the current expenses, and two thousand for prizes to the authors of four works which should be deemed by the academy most deserving of such a reward. A grand meeting was to be held every year, when the prizes were to be distributed, and analyses of the works read. The first meeting took place on the 25th of April 1807; but the subsequent changes in the political state of Naples prevented the full and permanent establishment of this institution. In the same year an academy was established at Florence for the illustration of Tuscan antiquities, which published some volumes of memoirs.

France.—The old *Academy of Inscriptions and Belles Lettres* was an off-shoot from the French Academy, which then at least contained the *élite* of French learning. Louis XIV. was of all French kings the one most occupied with his own aggrandisement. Literature, and even science, he only encouraged so far as they redounded to his own glory. Nor were literary men inclined to assert their independence. Boileau well represented the spirit of the age when, in dedicating his tragedy of *Berenice* to Colbert, he wrote—"The least things become important if in any degree they can serve the glory and pleasure of the king." Thus it was that the Academy of Inscriptions arose. At the suggestion of Colbert, a company (a committee we should now call it) had been appointed by the king, chosen from the French Academy, charged with the office of furnishing inscriptions, devices, and legends for medals. It consisted of four academicians: Chapelain, then considered the poet laureate of France, one of the authors of the critique on the *Cid* (see above); l'abbé de Bourzeis; François Carpentier, an antiquary of high repute among his contemporaries; and l'abbé de Capagnes, who owed his appointment more to the fulsome flattery of his odes than his really learned translations of Cicero and Sallust. This company used to meet in Colbert's library in the winter, at his country-house at Sceaux in the summer, generally on Wednesdays, to serve the convenience of the minister, who was constantly present. Their meetings were principally occupied with discussing the inscriptions, statues, and pictures intended for the decoration of Versailles; but M. Colbert, a really learned man and an enthusiastic collector of manuscripts, was often pleased to converse with them on matters of art, history, and antiquities. Their first published work was a collection of engravings, accompanied by descriptions, designed for some of the tapestries at Versailles. Louvois, who succeeded Colbert as a superintendent of buildings, revived the company, which had begun to relax its labours. Félibien, the learned architect. and the two great poets Racine and Boileau, were added to their number. A series of medals was commenced, entitled *Médailles de la Grande Histoire*, or, in other words, the history of le Grand Monarque.

But it was to M. de Portchartrain, comptroller-general of finance and secretary of state, that the academy owed its institution. He added to the company Renaudot and Tourreil, both men of vast learning, the latter tutor to his son, and put at its head his nephew, l'abbé Bignon, librarian to the king. By a new regulation, dated the 16th July 1701, the *Royal Academy of Inscriptions and Medals* was instituted, being composed of ten honorary members, ten pensioners, ten associates, and ten pupils. On its constitution we need not dwell, as it was an almost exact copy of that of the Academy of Science. Among the regulations we find the following, which indicates clearly the transition from a staff of learned officials to a learned body:—"The academy shall concern itself with all that can contribute to the perfection of inscriptions and legends, of designs for such monuments and decorations as may be submitted to its judgment; also with the description of all artistic works, present and future, and the historical explanation of the subject of such works: and as the knowledge of Greek and Latin antiquities, and of these two languages, is the best guarantee for success in labours of this class, the academicians shall apply themselves to all that this division of learning includes, as one of the most worthy objects of their pursuit."

Among the first honorary members we find the indefatigable Mabillon (excluded from the pensioners by reason of his orders), Père La Chaise, the king's confessor, and Cardinal Rohan; among the associates Fontenelle, and Rollin, whose *Ancient History* was submitted to the academy for revision. In 1711 they completed *L'Histoire Métallique du Roi*, of which Saint-Simon was asked to write the preface. In 1716 the regent changed its title to that of the *Academy of Inscriptions and Belles Lettres*, a title which better suited its new character.

In the great battle between the Ancients and the Moderns which divided the learned world in the first half of the 18th century, the Academy of Inscriptions naturally espoused the cause of the Ancients, as the Academy of Sciences did that of the Moderns. During the earlier years of the French Revolution the academy continued its labours uninterruptedly; and on the 22d of January 1793, the day after the death of Louis XVI., we find in the *Proceedings* that M. Bréquigny read a paper on the projects of marriage between Queen Elizabeth and the Dukes of Anjou and Alençon. In the same year were published the 45th and 46th vols. of the *Mémoires de l'Académie*. On the 2d of August of the same year the last *séance* of the old academy was held. More fortunate than its sister Academy of Sciences, it lost only three of its members by the guillotine. One of these was the astronomer Sylvain Bailly. Three others sat as members of the Convention; but for the honour of the academy, we must add that all three were distinguished by their moderation.

In the first draught of the new Institute, October 25, 1795, no class corresponded exactly to the old Academy of Inscriptions; but most of the members who survived found themselves re-elected either in the 2d class of moral and political science, under which history and geography were included as sections, or more generally under the 3d class of literature and fine arts, which embraced ancient languages, antiquities, and monuments.

In 1816 the academy received again its old name. The *Proceedings* of the Society embrace a vast field, and are of very various merits. Perhaps the subjects on which it has shown most originality are comparative mythology, the history of science among the ancients, and the geography and antiquities of France. The old academy has reckoned among its members De Sacy the Orientalist, Dansse de Villoison the philologist, Du Perron the traveller, Sainte-Croix and Du Theil the antiquarians, and Le Beau, who has been named the last of the Romans. The new academy has already inscribed on its lists the well-known names of Champollion, A. Rémusat, Raynouard, Burnouf, and Augustin Thierry.

Celtic Academy.—In consequence of the attention of several literary men in Paris having been directed to Celtic antiquities, a *Celtic Academy* was established in that city in the year 1800. Its objects were, first, the elucidation of the history, customs, antiquities, manners, and monuments of the Celts, particularly in France; secondly, the etymology of all the European languages, by the aid of the Celto-British, Welsh, and Erse; and, thirdly, researches relating to Druidism. The attention of the members was also particularly called to the history and settlements of the Galatæ in Asia. Lenoir, the keeper of the museum of French monuments, was appointed president. The academy still exists as *La Société Royale des Antiquaires de France.*

IV. Academies of Medicine and Surgery.—*Germany.*—The Academy of *Naturæ Curiosi*, called also the *Leopoldine Academy*, was founded in 1602, by J. L. Bausch, a physician of Leipsic, who, imitating the example of the English, published a general invitation to medical men to communicate all extraordinary cases that occurred in the course of their practice. The works of the *Naturæ Curiosi* were at first published separately; but this being attended with considerable inconvenience, a new arrangement was formed, in 1770, for publishing a volume of observations annually. From some cause, however, the first volume did not make its appearance until 1784, when it came forth under the title of *Ephemerides*. In 1687, the Emperor Leopold took the society under his protection, and established it at Vienna; hence the title of *Leopoldine* which it in consequence assumed. But though it thus acquired a name, it had no fixed place of meeting, and no regular assemblies; instead of which there was a kind of bureau or office, first established at Breslau, and afterwards removed to Nuremberg, where communications from correspondents were received, and persons properly qualified admitted as members. By its constitution the Leopoldine Academy consists of a president, two adjuncts or secretaries, and colleagues or members, without any limitation as to numbers. At their admission the last come under a two fold obligation—first, to choose some subject for discussion out of the animal, vegetable, or mineral kingdom, provided it has not been previously treated of by any colleague of the academy; and, secondly, to apply themselves to furnish materials for the annual *Ephemerides*. Each member also bears about with him the symbol of the academy, consisting of a gold ring, whereon is represented a book open, with an eye on one side, and on the other the academical motto of *Nunquam otiosus*.

The *Academy of Surgery* at Vienna was instituted by the present emperor, under the direction of the celebrated Brambella In it there were at first only two professors; and to their charge the instruction of a hundred and thirty young men was committed, thirty of whom had formerly been surgeons in the army. But latterly the number both of teachers and pupils was considerably increased. Gabrielli was appointed to teach pathology and practice; Boecking, anatomy, physiology, and physics; Streit, medical and pharmaceutical surgery; Hunczowsky, surgical operations, midwifery, and *chirurgia forensis;* and Plenk, chemistry and botany. To these was also added Beindel, as prosecutor and extraordinary professor of surgery and anatomy. Besides this, the emperor provided a large and splendid edifice in Vienna, which affords accommodation both for the teachers, the students, pregnant women, patients for clinical lectures, and servants. For the use of this academy the emperor also purchased a medical library, which is open every day; a complete set of chirurgical instruments; an apparatus for experiments in natural philosophy; a collection of natural history; a number of anatomical and pathological preparations; a collection of preparations in wax, brought from Florence; and a variety of other useful articles. Adjoining the building there is also a good botanical garden. With a view to encourage emulation among the students of this institution, three prize medals, each of the value of 40 florins, are annually bestowed on those who return the best answers to questions proposed the year before. These prizes, however, are not entirely founded by the emperor, but are in part owing to the liberality of Breudellius, formerly protochirurgus at Vienna.

France.—Royal Academy of Medicine.—Medicine is a science which has always engaged the attention of the kings of France. Charlemagne established a school of medicine in the Louvre, and various societies have been founded, and privileges granted to the faculty by his successors. The *Royal Academy of Medicine* succeeded to the old Royal Society of Medicine and the Academy of Surgery. It was erected by a royal ordinance, dated December 20, 1820. It was divided into three sections—medicine, surgery, and pharmacy. In its constitution it closely resembled the Academy of Sciences (*vid. sup.*) Its function was to preserve or propagate vaccine matter, and answer inquiries addressed to it by the Government on the subject of epidemics, sanitary reform, and public health generally. It has maintained an enormous correspondence in all quarters of the globe, and published extensive minutes.

V. Academies of the Fine Arts.—*Russia.*—The academy at St Petersburg was established by the Empress Elizabeth, at the suggestion of Count Shuvaloff, and annexed to the Academy of Sciences. The fund for its support was £4000 per annum, and the foundation admitted forty scholars. Catharine II. formed it into a separate institution, augmented the annual revenue to £12,000, and increased the number of scholars to three hundred; she also constructed, for the use and accommodation of the members, a large circular building, which fronts the Neva. The scholars are admitted at the age of six, and continue until they have attained that of eighteen. They are clothed, fed, and lodged at the expense of the crown, and are all instructed in reading and writing, arithmetic, the French and German languages, and drawing At the age of fourteen they are at liberty to choose any of the following arts, divided into four classes, viz., first, painting in all its branches of history portraits, war-pieces, and landscapes, architecture, mosaic, enamelling, &c.; secondly, engraving on copperplates, seal-cutting, &c.; thirdly, carving on wood, ivory, and amber; fourthly, watch-making, turning, instrument making, casting statues in bronze and other metals, imitating gems and medals in paste and other compositions, gilding, and varnishing. Prizes are annually distributed to those who excel in any particular art; and, from those who have obtained four prizes, twelve are selected, who are sent abroad at the charge of the crown. A certain sum is paid to defray their travelling expenses; and when they are settled in any town, they receive an annual salary of £60, which is continued during four years. There is a small assortment of paintings for the use of the scholars; and those who have made great progress are permitted to copy the pictures in the imperial collection. For the purpose of design, there are models in plaster, all done at Rome, of the best antique statues in Italy, and of the same size with the originals, which the artists of the academy were employed to cast in bronze.

France.—The *Academy of Painting and Sculpture at Paris* was founded by Louis XIV. in 1648, under the title of Académie Royale des Beaux Arts, to which was afterwards united the Academy of Architecture, erected 1671. The academy is composed of painters, sculptors, architects, engravers, and musical composers. From among the members of the society, who are painters, is chosen the director of the French Académie des Beaux Arts at Berne, also instituted by Louis XIV. in 1677. The director's province is to superintend the studies of the painters, sculptors, &c., who, having been chosen by competition, are sent to Italy at the expense of the Government, to complete their studies in that country. Most of the celebrated French painters have begun their career in this way.

The *Royal Academy of Music* is the name which, by a strange perversion of language, is given in France to the grand opera. In 1571 the poet Baïf established in his house an academy or school of music, at which ballets and masquerades were given. In 1645 Mazarin brought from Italy a troupe of actors, and established them in the Rue du Petit Bourbon, where they executed Jules Strozzi's "Achille in Sciro," the first opera performed in France. After Molière's death in 1673, his theatre in the Palais Royal was given to Sulli, and there were performed all Gluck's great operas; there Vestris danced, and there was produced Jean Jacques Rousseau's "Devin du Village."

Italy.—In 1778 an Academy of Painting and Sculpture was established at Turin. The meetings were held in the palace of the king, who distributed prizes among the most successful members. In Milan an Academy of Architecture was established so early as the year 1380, by Galeas Visconti. About the middle of the last century an Academy of the Arts was established there, after the example of those at Paris and Rome. The pupils were furnished with originals and models, and prizes were distributed annually. The prize for painting was a gold medal, and no prize was bestowed till all the competing pieces had been subjected to the examination and criticism of competent judges. Before the effects of the French Revolution reached Italy this was one of the best establishments of the kind in that kingdom. In the hall of the academy were some admirable pieces of Correggio, as well as several ancient paintings and statues of great merit,—particularly a small bust of Vitellius, and a statue of Agrippina, of most exquisite beauty, though it wants the head and arms. The Academy of the Arts, which had been long established at Florence, fell into decay, but was restored in the end of last century. In it there are halls for nude and plaster figures, for the use of the sculptor and the painter. The hall for plaster figures had models of all the finest statues in Italy, arranged in two lines; but the treasures of this and the other institutions for the fine arts were greatly diminished during the occupancy of Italy by the French. In the saloon of the Academy of the Arts at Modena there are many casts of antique statues; but after being plundered by the French it dwindled into a petty school for drawings from living models; it contains the skull of Correggio. There is also an Academy of the Fine Arts in Mantua, and another at Venice.

Spain.—In Madrid an Academy for Painting, Sculpture, and Architecture, was founded by Philip V. The minister for foreign affairs is president. Prizes are distributed every three years. In Cadiz a few students are supplied by Government with the means of drawing and modelling from figures; and such as are not able to purchase the requisite instruments are provided with them.

Sweden.—An Academy of the Fine Arts was founded at Stockholm in the year 1733 by Count Tessin. In its hall are the ancient figures of plaster presented by Louis XIV. to Charles XI. The works of the students are publicly exhibited, and prizes are distributed annually. Such of them as display distinguished ability obtain pensions from Government, to enable them to reside in Italy for some years, for the purposes of investigation and improvement. In this academy there are nine professors, and generally about four hundred students. In the year 1705 an Academy of Painting, Sculpture, and Architecture was established at Vienna, with the view of encouraging and promoting the fine arts.

England.—The *Royal Academy of Arts in London* was instituted for the encouragement of designing, painting, sculpture, &c., in the year 1768, with Sir J. Reynolds for its president. This academy is under the immediate patronage of the queen, and under the direction of forty artists of the first rank in their several professions. It furnishes, in winter, living models of different characters to draw after; and in summer, models of the same kind to paint after. Nine of the ablest academicians are annually elected out of the forty, whose business it is to attend by rotation, to set the figures, to examine the performance of the students, and to give them necessary instructions. There are likewise professors of painting, sculpture, architecture, anatomy, and chemistry, who annually read public lectures on the subjects of their several departments; besides a president, a council, and other officers. The admission to this academy is free to all students properly qualified to reap advantage from the studies cultivated in it; and there is an annual exhibition at Burlington House of paintings, sculptures, and designs, open to all artists of distinguished merit.

The *Academy of Ancient Music* was established in London in 1710, by several persons of distinction, and other amateurs, in conjunction with the most eminent masters of the time, with the view of promoting the study and practice of vocal and instrumental harmony. This institution, which had the advantage of a library, consisting of the most celebrated compositions, both foreign and domestic, in manuscript and in print, and which was aided by the performances of the gentlemen of the chapel royal, and the choir of St Paul's, with the boys belonging to each, continued to flourish for many years. In 1731 a charge of plagiarism brought against Bononcini, a member of the academy, for claiming a madrigal of Lotti of Venice as his own, threatened the existence of the institution. Dr Greene, who had introduced the madrigal into the academy, took part with Bononcini, and withdrew from the society, taking with him the boys of St Paul's. In 1734 Mr Gates, another member of the society, and master of the children of the royal chapel, also retired in disgust; so that the institution was thus deprived of the assistance which the boys afforded it in singing the soprano parts. From this time the academy became a seminary for the instruction of youth in the principles of music and the laws of harmony. Dr Pepusch, who was one of its founders, was active in accomplishing this measure; and by the expedient of educating boys for their purpose, and admitting auditor members, the subsistence of the academy was continued. The *Royal Academy of Music* was formed by the principal nobility and gentry of the kingdom, for the performance of operas, composed by Handel, and conducted by him at the theatre in the Haymarket. The subscription amounted to £50,000, and the king, besides subscribing £1000, allowed the society to assume the title of *Royal Academy*. It consisted of a governor, deputy-governor, and twenty directors. A contest between Handel and Senesino, one of the performers, in which the directors took the part of the latter, occasioned the dissolution of the academy, after it had subsisted with reputation for more than nine years. The present *Royal Academy of Music* dates from 1822, and was incorporated in 1830 under the patronage of the queen. It instructs pupils of both sexes in music, charging 33 guineas per annum; but many receive instruction free. It also gives public concerts. In this institution the leading instrumentalists and vocalists of England have received their education. (See *Musical Directory* published by Rudall, Carte, and Co.)

ACADEMY is a term also applied to those royal collegiate seminaries in which young men are educated for the navy and army. In our country there are three colleges of this description—the Royal Naval College at Portsmouth, the Royal Military Academy at Woolwich, and the Royal Military College, Sandhurst.

(F. S.

ACADIE, or ACADIA, the name borne by Nova Scotia while it remained a French settlement.

ACALEPHÆ (from ἀκαλήφη, a nettle), a name given to the animals commonly known as *jelly-fish*, *sea-blubber*, *Medusæ*, *sea-nettles*, &c.

ACANTHOCEPHALA (from ἄκανθα, a thorn, and κεφαλή, the head), a group of parasitic worms, having the heads armed with spines or hooks.

ACANTHOPTERYGII (from ἄκανθα, a thorn, and πτέρυξ, a wing), an order of fishes, having bony skeletons with prickly spinous processes in the dorsal fins.

ACANTHUS, a genus of plants belonging to the natural order Acanthaceæ. The species are natives of the southern parts of Europe. The most common species is the *Acanthus mollis* or *Brankursine*. It has large, deeply-cut, hairy, shining leaves, which are supposed to have suggested the decoration of the Corinthian column. Another species, *Acanthus spinosus*, is so called from its spiny leaves.

ACAPULCO, a town and port in Mexico, on a bay of the Pacific Ocean, about 190 miles S.S.W. of Mexico, in N. lat. 16° 50′, W. long. 99° 46′. The harbour, which is the best on the Pacific coast, is almost completely landlocked. It is easy of access, and the anchorage is so secure that heavily-laden ships can lie close to the rocks which surround it. The town lies N.W. of the harbour, and is defended by the castle of San Diego, which stands on an eminence. During a part of the dry season the air is infected with the putrid effluvia of a morass eastward of the town. This, together with the heat of the climate, aggravated by the reflection of the sun's rays from the granite rocks that environ the town, renders it very unhealthy, especially to Europeans, though a passage cut through the rocks, to let in the sea breeze, has tended to improve its salubrity. Acapulco was in former times the great depôt of the trade of Spain with the East Indies. A galleon sailed from this port to Manilla in the Philippine Islands, and another returned once a year laden with the treasures and luxuries of the East. On the arrival of this galleon a great fair was held, to which merchants resorted from all parts of Mexico. The trade between Acapulco and Manilla was annihilated when Mexico became independent, and, from this cause, and also on account of the frequent earthquakes by which the town has been visited, it had sunk to comparative insignificance, when the discovery of gold in California gave its trade a fresh impetus. It is now the most important seaport in Mexico, and is regularly touched at by the Pacific mail steamers. Besides having a large transit trade, it exports wool, skins, cocoa, cochineal, and indigo; and the imports include cottons, silks, and hardware. Population about 5000.

ACARNANIA, a province of ancient Greece, now called Carnia. It was bounded on the N. by the Ambracian gulf, on the N.E. by Amphilochia, on the W. and S.W. by the Ionian Sea, and on the E. by Ætolia. It was a hilly country, with numerous lakes and tracts of rich pasture, and its hills are to the present day crowned with thick wood. It was celebrated for its excellent breed of horses. The Acarnanians, according to Mr Grote, though admitted as Greeks to the Pan-Hellenic games, were more akin in character and manners to their barbarian neighbours of Epirus. Up to the time of the Peloponnesian war, they are mentioned only as a race of rude shepherds, divided into numerous petty tribes, and engaged in continual strife and rapine. They were, however, favourably distinguished from their Ætolian neighbours by the fidelity and steadfastness of their character. They were good soldiers, and excelled as slingers. At the date above mentioned they begin, as the allies of the Athenians, to make a more prominent figure in the history of Greece. The chief town was Stratos, and subsequently Leucas.

ACARUS (from ἄκαρι, a mite), a genus of Arachnides, represented by the cheese mite and other forms.

ACCELERATION is a term employed to denote generally the rate at which the velocity of a body, whose motion is not uniform, either increases or decreases. As the velocity is continually changing, and cannot therefore be estimated as in uniform motion, by the space actually passed over in a certain time, its value at any instant has to be measured by the space the body would describe in the unit of time, supposing that at and from the instant in question the motion became and continued uniform. If the motion is such that the velocity, thus measured, increases or decreases by equal amounts in equal intervals of time, it is said to be *uniformly* accelerated or retarded. In that case, if f denote the amount of increase or decrease of velocity corresponding to the unit of time, the whole of such increase or decrease in t units of time will evidently be ft, and therefore if u be the initial and v the final velocity for that interval, $v=u\pm ft$,—the upper sign applying to accelerated, the lower to retarded, motion. To find the distance or space, s, gone over in t units of time, let t be divided into n equal intervals. The velocities at the end of the successive intervals will be $u\pm f\frac{t}{n}$, $u\pm f\frac{2t}{n}$, $u\pm f\frac{3t}{n}$, &c. Let it now be supposed that during each of these small intervals the body has moved uniformly with its velocity at the end of the interval, then (since a body moving uniformly for x seconds with a velocity of y feet per second will move through xy feet) the spaces described in the successive intervals would be the product of the velocities given above by $\frac{t}{n}$, and the whole space in the time t would be the sum of these spaces; *i.e.*,

$$s=u\frac{t}{n}(1+1\ \ldots.\ \text{repeated } n \text{ times})\pm f\cdot\frac{t^2}{n^2}(1+2+3\ldots..+n)$$

$$=ut\pm f\cdot\frac{t^2}{n^2}\cdot\frac{n(n+1)}{2}=ut\pm\frac{1}{2}ft^2\left(1+\frac{1}{n}\right).$$

It is evident, however, that as the increase or decrease of velocity takes place continuously, this sum will be too large; but the greater n is taken, or (which is the same thing) the smaller the intervals are during which the velocity is supposed to be uniform, the nearer will the result be to the truth. Hence making n as large as possible, or $\frac{1}{n}$ as small as possible, *i.e.*, $=0$, we obtain as the correct expression $s=ut\pm\frac{1}{2}ft^2$. In the case of motion from rest, $u=0$, and the above formulæ become $v=ft$, $s=\frac{1}{2}ft^2$.

We have a familiar instance of uniformly accelerated and uniformly retarded motion in the case of bodies falling and rising vertically near the earth's surface, where, if the resistance of the air be neglected, the velocity of the body is increased or diminished, in consequence of the earth's attraction, by a uniform amount in each second of time. To this amount is given the name of the acceleration of gravity (usually denoted by the letter g), the value of which, in our latitudes and at the surface of the sea, is very nearly $32\frac{1}{6}$ feet per second. Hence the space a body falls from rest in any number of seconds is readily found by multiplying $16\frac{1}{12}$ feet by the square of the number of seconds. For a fuller account of accelerating force,—expressed in the notation of the Differential Calculus by $f=\pm\frac{dv}{dt}$ or $f=\pm\frac{d^2s}{dt^2}$,—the reader is referred to the article DYNAMICS.

ACCENT, in reading or speaking, is the stress or pressure of the voice upon a *syllable* of a word. The derivation of the term (Lat. *accentus, quasi adcantus*) clearly shows that it was employed by the classical grammarians to express the production of a musical effect. Its origin is therefore to be sought in the natural desire of man to gratify the ear by modulated sound, and probably no language exists in which it does not play a more or less important part. "Only a machine," says Professor Blackie (*Place and Power of Accent in Language*, in the *Transactions of the Royal Society of Edinburgh*, 1871), "could produce a continuous series of sounds in undistinguished monotonous repetitions like the *tŭm, tŭm, tŭm*, of a drum; a rational being using words for a rational purpose to manifest his thoughts and feelings, necessarily accents both words and sentences in some way or other." That the accentuation of some languages is more distinct, various, and effective than that of others is beyond question, but there are none, so far as we know, in which its power is not felt. The statement sometimes made, that the French have no accent in their words, can only mean that their accent is less emphatic or less variously so than that of certain other nations. If it means more, it is not merely an error, but an absurdity. From this conception of the subject, it is obvious that accent must be fundamentally the same thing in all languages, and must aim more or less successfully at the same results, however diverse the rules by which it is governed. But there are, nevertheless, important differences between the conditions under which accent operated in the classical, and those in which it operates in modern tongues. It did not wholly determine the rhythm, nor in the least affect the metre of classical verse; it did not fix the quantity or length of classical syllables. It was a musical element superadded to the measured structure of prose and verse.

Passing over the consideration of the accentual system of the Hebrews with the single remark, that it exhibits, though with more elaborate and complicated expression, most of the characteristics both of Greek and English accent, we find that the Greeks employed three grammatical accents, viz., the *acute accent* (´), which shows when the tone of the voice is to be raised; the *grave accent* (`), when it is to be depressed; and the *circumflex accent* (ˆ), composed of both the acute and the grave, and pointing out a kind of undulation of the voice. The Latins have made the same use as the Greeks of these three accents, and various modern nations, French, English, &c., have also adopted them. As to the Greek accents, now seen both in manuscripts and printed books, there has been great dispute about their antiquity and use. But the following things seem to be undoubtedly taught by the ancient grammarians and rhetoricians:—(1.) That by *accent* (προσωδία, τόνος) the Greeks understood the elevation or falling of the voice on a particular syllable of a word, either absolutely, or in relation to its position in a sentence, accompanied with an *intension* or *remission* of the vocal utterance on that syllable (ἐπίτασις, ἄνεσις), occasioning a marked predominance of that syllable over the other syllables of the word. The predominance thus given, however, had no effect whatever on the quantity—long or short—of the accented syllable. The accented syllable in Greek as in English, might be long or it might be short; elevation and emphasis of utterance being one thing, and prolongation of the vocal sound quite another thing, as any one acquainted with the first elements of music will at once perceive. The difficulty which many modern scholars have experienced in conceiving how a syllable could be accented and not lengthened, has arisen partly from a complete want of distinct ideas on the nature of the elements of which human speech is composed, and partly also from a vicious practice which has long prevailed in the English schools, of reading Greek, not according to the laws of its own accentuation, but according to the accent of Latin handed down to us through the Roman Catholic Church. For the rules of Latin accentuation are, as Quintilian and Cicero and the grammarians expressly mention, very different from the Greek; and the long syllable of a word has the accent in Latin in a hundred cases, where the musical habit of the Greek ear placed it upon the short. There is, besides, a vast number of words in Greek accented on the last syllable (like *voluntee'r*, *ambusca'de*, in English), of which not a single instance occurs in the Latin language. Partly, however, from ignorance, partly from carelessness, and partly perhaps from stupidity, our scholars transferred the pronunciation of the more popular learned language to that which was less known; and with the help of time and constant usage, so habituated themselves to identify the accented with the long syllable, according to the analogy of the Latin, that they began seriously to doubt the possibility of pronouncing otherwise. English scholars have long ceased to recognise its existence, and persist in reading Greek as if the accentual marks meant nothing at all. Even those who allow (like Mr W. G. Clark and Professor Munro) that ancient Greek accent denoted an elevation of voice or tone, are still of opinion that it is impossible to reproduce it in modern times. "Here and there," says the former (*Cambridge Journal of Philology*, vol. i. 1868), "a person may be found with such an exquisite ear, and such plastic organs of speech, as to be able to reproduce the ancient distinction between the length and tone of syllables accented and unaccented, and many not so gifted may fancy that they reproduce it when they do nothing of the kind. For the mass of boys and men, pupils as well as teachers, the distinction is practically impossible." But, in spite of such pessimist views, it may, on the whole, be safely asserted that since the appearance of a more philosophical spirit in philology, under the guidance of Hermann, Boeckh, and other master-minds among the Germans, the best grammarians have come to recognise the importance of this element of ancient Hellenic enunciation, while not a few carry out their principles into a consistent practice. The only circumstance, indeed, that prevents our English scholars from practically recognising the element of accent in classical teaching, is the apprehension that this would interfere seriously with the practical inculcation of quantity; an apprehension in which they are certainly justified by the practice of the modern Greeks, who have given such a predominance to accent, as altogether to subordinate, and in many cases completely overwhelm quantity; and who also, in public token of this departure from the classical habit of pronunciation, regularly compose their verses with a reference to the spoken accent only, leaving the quantity —as in modern language generally— altogether to the discretion of the poet. But, as experiment will teach any one that there is no necessity whatever in the nature of the human voice for this confusion of two essentially different elements, it is not unlikely that English scholars will soon follow the example of the Germans, and read Greek prose at least systematically according to the laws of classical speech, as handed down to us by the grammarians of Alexandria and Byzantium. In the recitation of classical verse, of course, as it was not constructed on accentual principles, the skilful reader will naturally allow the musical accent, or the emphasis of the rhythm to overbear, to a great extent, or altogether to overwhelm, the accent of the individual word; though with regard to the recitation of verse, it will always remain a problem how far the ancients themselves did not achieve an "*accentuum cum quantitate apta conciliatio*," such as that which Hermann (*De emendanda ratione, &c.*) describes as the perfection of a polished classical enunciation. A historic survey of the course of learned opinion on the subject of accent, from the age of Erasmus down to the present day, forms an interesting and important part of Professor Blackie's essay quoted above. See Pennington's work on Greek Pronunciation, Cambridge, 1844; the German work on Greek Accent by Göttling (English), London, 1831; and Blackie's essay on the *Place and Power of Accent*, in the *Transactions of the Royal Society of Edinburgh*, 1870–71.

If there is any perplexity regarding the nature or influence of classical accent, there is none about English. It does not conflict or combine with the modulations of quantity. It is the sole determining element in our metrical system. Almost the very earliest of our authors, the Venerable Bede, notices this. In defining rhythm he says—"It is a modulated composition of words, not according to the laws of metre, but adapted in the number of its syllables to the judgment of the ear, *as are the verses of our vulgar poets*" (*Bede*, *Op.* vol. i. p. 57, ed. 1553). We have, of course, long vowels and short, like the Greeks and the Romans, but we do not regulate our verse by them; and our mode of accentuation is sufficiently despotic to occasionally almost change their character, so that a long vowel shall seem short, and *vice versa*. In reality this is not so. The long vowel remains long, but then its length gives it no privilege of place in a verse. It may modify the enunciation, it may increase the roll of sound, but a short vowel could take its place without a violation of metre. Take the word *far*, for example; there the vowel *a* is long, yet in the line

"O Moon, far-spooming Ocean bows to thee,

it is not necessary that the *a* in *far* should be long; a short vowel would do as well for metrical purposes, and would even bring out more distinctly the accentuation of the syllable *spoom*.

Originally English accent was upon the root, and not upon inflectional syllables. Göttling finds the same principle operating in Greek, but in that language it certainly never exercised the universal sway it does in the earlier forms of English. In the following passage from *Beowulf*, the oldest monument of English literature, belonging, in its first form, to a period even anterior to the invasion of Britain by the Angles and Saxons, we shall put the accented or emphatic syllables in italics:—

Strǽt waes *stán*-fah . .	The street was of variegated stone
stig wísode	the path directed
*gum*um aet-*gaed*ere . .	the men together;
gúđ-byrne scán	the war-corselet shone
heard, *hond*-locen . . .	hard, hand-locked;
hring-íren scír	the ring-iron bright
song in *sear*wum . . .	sang in their trappings,
þá híe tó *sele* furđum .	when they to the hall forward
in hyra *gryre-geat*wum .	in their terrible armour
*gang*an cwomon . . .	came to go.

It will be observed that in these verses the accent (not to be confounded with the mark which is used in Anglo-Saxon to show that the vowel over which it is placed is long) is invariably on a monosyllable, or on the root part of a word of more than one syllable. The passage is also a good illustration of what has previously been stated, that the metre or rhythm in English is determined not by the vowel-quantity of a syllable, but by the stress of the voice on particular syllables, whether the vowels are long or short. In the older forms of English verse the accent is somewhat irregular; or, to put it more accurately, the number of syllables intervening between the recurrent accents is not definitely fixed. Sometimes two or more intervene, sometimes none at all. Take, for example, the opening lines of Langland's poem, entitled the *Vision of Piers the Plowman*:—

"In a *somer seson*
Whan soft was the *son*ne,
I *shope* me in *shroudes*,
As I a *shepe* were,
In *ha*bit as an *he*remite
Un*ho*ly of workes,
Went *wide* in this *world*
*Won*ders to here.
Ac on a *May morn*ynge
On *Mal*uerne hulles,

Me by*fel* a *ferly*,
Of *fairy*, me thoughte;
I was *wery* for*wand*red,
And *went* me to reste
Under a *brode banke*
By a *bornes* side.
And as I *lay* and *len*ed,
And *lok*ed in the waters,
I *slom*bred in a *slepyng*,
It *sweyu*ed so merye."

But no matter how irregular the time elapsing between the recurrence of the accents, they are always on the root-syllables.

The Norman Conquest, however, introduced a different system, which gradually modified the rigid uniformity of the native English accentuation. The change is visible as early as the end of the 12th century. By the middle of the 14th, that is to say, in the age of Chaucer, it is in full operation. Its origin is thus explained by Mr Marsh, in his *Origin and History of the English Language* (Lond., 1862):—"The vocabulary of the French language is derived, to a great extent, from Latin words deprived of their terminal inflections. The French adjectives *mortal* and *fatal* are formed from the Latin *mortalis* and *fatalis*, by dropping the inflected syllable; the French nouns *nation* and *condition* from the Latin accusatives *nationem*, *conditionem*, by rejecting the *em* final. In most cases, the last syllable retained in the French derivatives was prosodically long in the Latin original; and either because it was also accented, or because the slight accent which is perceivable in the French articulation represents temporal length, the stress of the voice was laid on the *final* syllable of all these words. When we borrowed such words from the French we took them with their native accentuation; and as accent is much stronger in English than in French, the *final* syllable was doubtless more forcibly enunciated in the former than in the latter language." The new mode of accentuation soon began to affect even words of pure English origin—*e.g.*, in *Robert of Gloucester* we find fals*hede* instead of *fals*hede, tid*inge* instead of *tid*inge, trewe*hede* instead of *trewe*hede, glad*dore* instead of *glad*dore, wis*liche* instead of *wis*liche, begynn*yng* instead of begynnyng, end*yng* instead of *end*yng. In the *Proverbs of Hendyng* we have no*thyng* for *noth*ing, habb*en* for *hab*ben, fo*mon* for *fo*mon; in *Robert of Brunne*, haly*dom* for *haly*dom, cloth*yng* for *cloth*ing, gret*and* for *gret*and. Chaucer furnishes numerous instances of the same foreign influence revolutionising the native accent; fre*dom* for *fre*dom, hethen*esse* for *hethe*nesse, worthin*esse* for *worth*inesse, low*ly* for *low*ly, wynn*ynge* for *wynn*ynge, wedd*ynge* for *wedd*ynge, com*ynge* for *com*ynge; and it is traceable even in Spenser. On the other hand, a contrary tendency must not be overlooked. We see an effort, probably unconscious, to compel words of French origin to submit to the rule of English accentuation. It is noticeable in the century before Chaucer: in Chaucer himself it begins to work strongly; mor*tal* becomes *mor*tal; tem*pest*, *tem*pest; sub*stance*, *sub*stance; amy*able*, *am*yable; mor*sel*, *mor*sel; ser*vise*, *ser*vise; duch*esse*, *duch*esse; co*syn*, *co*syn, &c.; while a multitude of words oscillate between the rival modes of accentuation, now following the French and now the English. Before and during the Elizabethan period, the latter began to prove the stronger, and for the last 300 years it may be said to have, for the most part, Anglicised the accent and the nature of the foreign additions to our vocabulary. Nevertheless, many French words still retain their own accent. Morris (*Historical Outlines of English Accidence*, p. 75) thus classifies these:—

"(1.) Nouns in *-ade*, *-ier* (*-eer*), *-é*, *-ee*, or *-oon*, *-ine*, (*-in*), as *cascade'*, *crusade'*, &c.; *cavalier'*, *chandelier'*, &c.; *gazetteer'*, *pioneer'*, &c. (in conformity with these we say *harpooneer'*, *mountaineer'*,); *legatee'*, *payee'*, &c.; *balloon'*, *cartoon'*, &c.; *chagrin'*, *violin'*, &c.; *routine'*, *marine'*, &c.

"Also the following words:—*cadet'*, *brunette'*, *gazette'*, *cravat'*, *canal'*, *control'*, *gazelle'*, *amateur'*, *fatigue'*, *antique'*, *police'*, &c.

"(2.) Adjectives (*a*) from Lat. adj. in *us*, as *august'*, *benign'*, *robust'*, &c.; (*b*) in *-ose*, as *morose'*, *verbose'*, &c.; (*c*) *-esque*, as *burlesque'*, *grotesque'*, &c.

"(3.) Some verbs, as *baptize'*, *cajole'*, *caress'*, *carouse'*, *chastise'*, *escape'*, *esteem'*, &c."

To these may be added the Greek and Latin words which have been introduced into English for scientific and other learned purposes, and which, not having been altered in form, retain their original accentuation—as *auro'ra*, *coro'na*, *colos'sus*, *ide'a*, *hypoth'esis*, *cæsu'ra*, *diœ'resis*, *diagno'sis*, *dilu'vium*, *diplo'ma*, *efflu'vium*, *elys'ium*, &c.; besides the still larger number that have suffered a slight modification of form, but no change of accent, as *dialec'tic*, *diagnos'tic*, *effores'cent*, *ellip'tic*, *emer'sion*, *emol'lient*, &c. The Italian contributions to our tongue retain their original accent when the form is untouched, as *mulat'to*, *sona'ta*, *volca'no*, but lose it when the form is shortened, as *ban'dit* (It. *bandi'to*).

A change in the position of the accent serves a variety of purposes in English. It distinguishes (1.) a *noun* from a *verb*, as ac'cent, accent'; aug'ment, augment'; tor'ment, torment'; com'ment, comment'; con'sort, consort'; con'test, contest'; con'trast, contrast'; di'gest, digest'; dis'count, discount'; in'sult, insult', &c.; (2.) an *adjective* from a *verb*, as ab'sent, absent'; fre'quent, frequent'; pre'sent, present'; com'pound, compound', &c.; (3.) an *adjective* from a *noun*, as ex'pert, expert'; com'pact, compact'. It also denotes a difference of meaning, *e.g.*, con'jure, conjure': in'cense, incense'; au'gust, august'; su'pine, supine'.

Accent has exercised a powerful influence in changing the *forms* of words. The unaccented syllables in the course of time frequently dropped off. This process was necessarily more rapid and thorough in English than in many other languages which were not subjected to equal strain. The Norman Conquest made havoc of the English tongue for a time. It was expelled from the court, the schools, the church, and the tribunals of justice; it ceased to be spoken by priests, lawyers, and nobles; its only guardians were churls, ignorant, illiterate, indifferent to grammar, and careless of diction. Who can wonder if, in circumstances like these, it suffered disastrous eclipse? The latter part of the Anglo-Saxon *Chronicle* furnishes melancholy evidence of the chaos into which it had fallen, yet out of this chaos it rose again into newness of life, reforming and re-accenting its half-ruined vocabulary, and drawing from the very agent of its destruction the elements of a richer and more plastic expression. For it cannot be doubted that the irregularities now existing in English accent, though perplexing to a foreigner, copiously vary the modulation, and so increase the flexibility and power of the language. The older forms of English, those in use before the Conquest, and down to the period of Chaucer, are stiff, monotonous, and unmusical. A hard strength is in the verse, but no liquid sweetness or nimble grace. Now, it is possible, in spite of our deficiency in vowel endings, to produce the noblest melody in accent words known to the modern world. Almost every kind of metre, swift or slow, airy or majestic, has been successfully attempted since the age of the *Canterbury Tales*. When we compare the drone of Caedmon with the aerial melody of the *Skylark*, the *Cloud*, and the *Arethusa* of Shelley, we see what an infinite progress has been made by the development of accent in the rhythm of our native tongue.

Marsh (Lond. 1862); *Historische Grammatik der Englische Sprache*, von. C. Friedrich Koch (1863–69); *The English Language*, by R. G. Latham (1855); *Philological Essays*, by the Rev. Richard Garnett (Lond. 1859); *On Early English Pronunciation, with especial reference to Shakspere and Chaucer*, by A. J. Ellis (Lond. 1867–71); *Historical Outlines of English Accidence*, by Dr R. Morris (Lond. 1872). (J. M. R.)

ACCEPTANCE is the act by which a person binds himself to comply with the request contained in a bill of exchange addressed to him by the drawer. In all cases it is understood to be a promise to pay the bill *in money*, the law not recognising an acceptance in which the promise is to pay in some other way, as, for example, partly in money and partly by another bill. Acceptance may be absolute, conditional, or partial. *Absolute* acceptance is an engagement to pay the bill strictly according to its tenor, and is made by the drawee subscribing his name, with or without the word "accepted," at the bottom of the bill, or across the face of it. *Conditional* acceptance is a promise to pay on a contingency occurring, as, for example, on the sale of certain goods consigned by the drawer to the acceptor. No contingency is allowed to be mentioned in the body of the bill, but a contingent acceptance is quite legal, and equally binding with an absolute acceptance upon the acceptor when the contingency has occurred. *Partial* acceptance is where the promise is to pay only part of the sum mentioned in the bill, or to pay at a different time or place from those specified. In all cases acceptance involves the signature of the acceptor either by himself or by some person duly authorised on his behalf. A bill can be accepted in the first instance only by the person or persons to whom it is addressed; but if he or they fail to do so, it may, after being protested for non-acceptance, be accepted by another "*supra* protest," for the sake of the honour of one or more of the parties concerned in it.

ACCESSION is applied, in a historical or constitutional sense, to the coming to the throne of a dynasty or line of sovereigns, as the accession of the House of Hanover. The corresponding term, when a single sovereign is spoken of, is "succession." In law, accession is a method of acquiring property, by which, in things that have a close connection with or dependence on one another, the property of the principal draws after it the property of the accessory, according to the principle, *accessio cedet principali*, or *accessorium sequitur principale.* Thus, the owner of a cow becomes likewise the owner of the calf, and a landowner becomes proprietor of what is added to his estate by alluvion. Accession produced by the art or industry of man has been called industrial accession, and may be by specification, as when wine is made out of grapes, or by confusion or commixture. Accession sometimes likewise signifies consent or acquiescence. Thus, in the bankrupt law of Scotland, when there is a settlement by a trust-deed, it is accepted on the part of each creditor by a deed of accession.

ACCESSORY, a person guilty of a felonious offence, not as principal, but by participation; as by advice, command, aid, or concealment. In treason, accessories are excluded, every individual concerned being considered as a principal. In crimes under the degree of felony, also, all persons concerned, if guilty at all, are regarded as principals. (See 24 and 25 Vict. c. 94. s. 8.) There are two kinds of accessories—*before* the fact, and *after* it. The first is he who commands or procures another to commit felony, and is not present himself; for if he be present, he is a principal. The second is he who receives, assists, or comforts any man that has done murder or felony, whereof he has knowledge. An accessory before the fact is liable to the same punishment as the principal; and there is now indeed no practical difference between such an accessory and a principal in regard either to indictment, trial, or punishment (24 and 25 Vict. c. 94). Accessories after the fact are in general punishable with imprisonment for a period not exceeding two years (*ib.* s. 4). The law of Scotland makes no distinction between the accessory to any crime (called *art and part*) and the principal. Except in the case of treason, accession after the fact is not noticed by the law of Scotland, unless as an element of evidence to prove previous accession.

ACCIAJUOLI, DONATO, was born at Florence in 1428. He was famous for his learning, especially in Greek and mathematics, and for his services to his native state. Having previously been intrusted with several important embassies, he became Gonfalonier of Florence in 1473. He died at Milan in 1478, when on his way to Paris to ask the aid of Louis XI. on behalf of the Florentines against Pope Sixtus IV. His body was taken back to Florence, and buried in the church of the Carthusians at the public expense, and his daughters were portioned by his fellow-citizens, the fortune he left being, owing to his probity and disinterestedness, very small. He wrote a Latin translation of some of Plutarch's *Lives* (Florence, 1478); Commentaries on Aristotle's *Ethics* and *Politics;* and the lives of Hannibal, Scipio, and Charlemagne. In the work on Aristotle he had the co-operation of his master Argyropylus.

ACCIDENT. An attribute of a thing or class of things, which neither belongs to, nor is in any way deducible from, the essence of that thing or class, is termed its *accident.* An accident may be either inseparable or separable: the former, when we can conceive it to be absent from that with which it is found, although it is always, as far as we know, present, *i.e.*, when it is not necessarily but is universally present; the latter, when it is neither necessarily nor universally present. It is often difficult to determine whether a particular attribute is essential or accidental to the object we are investigating, subsequent research frequently proving that what we have described as accidental ought to be classed as essential, and *vice versa.* Practically, and for the time being, an attribute, which neither directly nor indirectly forms part of the signification of the term used to designate the object, may be considered an accident; and many philosophers look upon this as the only intelligible ground for the distinction. Propositions expressing the relation between a thing or class and an accident, and also between a thing or class and its property (*i.e.*, something deducible from, but not strictly forming part of, its essence), are variously styled "accidental," "synthetical," "real," "ampliative," in contradistinction to "essential," "analytical," "verbal," and "explicative" propositions. The former give us information that we could not have discovered from an analysis of the subject notion—*e.g.*, "man is found in New Zealand;" the latter merely state what we already know, if we understand the meaning of the language employed, *e.g.*, "man is rational."

ACCIUS, a poet of the 16th century, to whom is attributed *A Paraphrase of Æsop's Fables*, of which Julius Scaliger speaks with great praise.

ACCIUS (or ATTIUS), LUCIUS, a Latin tragic poet, was the son of a freedman, born, according to St Jerome, in the year of Rome 583, though this appears somewhat uncertain. He made himself known before the death of Pacuvius by a dramatic piece, which he exhibited the same year that Pacuvius brought one on the stage, the latter being then eighty years of age, and Accius only thirty. We do not know the name of this piece of Accius's, but the titles of several of his tragedies are mentioned by various authors. He wrote on the most celebrated stories which had been represented on the Athenian stage; but he did not always take his subject from Grecian story; for he composed at least one dramatic piece wholly Roman, entitled *Brutus*, and referring to the expulsion of the Tarquins. Only fragments of his tragedies remain. He did not confine himself to dramatic writing, having left other productions, particularly his *Annals*, mentioned by Macrobius, Priscian, Festus, and Nonnius Marcellus. He has been censured for the harshness of his style, but in other respects he has been esteemed a great poet. He died at an advanced age; and Cicero, who evidently attaches considerable weight to his opinions, speaks of having conversed with him in his youth.

ACCLAMATION, the expression of the opinion. favourable or unfavourable, of any assembly by means of the voice. *Applause* denotes strictly a similar expression by clapping of hands, but this distinction in the usage of the words is by no means uniformly maintained. Among the Romans acclamation was varied both in form and purpose. At marriages it was usual for the spectators to shout *Io Hymen, Hymenæe*, or *Talassio;* a victorious army or general was greeted with *Io triumphe;* in the theatre acclamation was called for at the close of the play by the last actor, who said, *Plaudite;* in the senate opinions were expressed and votes passed by acclamation in such forms as *Omnes, omnes, Æquum est, Justum est*, &c; and the praises of the emperor were celebrated in certain pre-arranged sentences, which seem to have been chanted by the whole body of senators. The acclamations which authors and poets who recited their works in public received were at first spontaneous and genuine, but in time became very largely mercenary, it being customary for men of fortune who affected literary tastes to keep applauders in their service and lend them to their friends. When Nero performed in the theatre his praises were chanted, at a given signal, by five thousand soldiers, who were called *Augustals.* The whole was conducted by a music-master, *mesochorus* or *pausarius.* It was this case of Nero which, occurring to the recollection of the French poet Dorat, may be said to have originated the well-known Paris *claque.* Buying up a number of the tickets for a performance of one of his plays, he distributed them gratuitously to those who promised to express approbation. From that time the *claque*, or organised body of professional applauders, has been a recognised institution in connection with the theatres of Paris. In the early ages of the Christian church it was by no means uncommon for an audience to express their approbation of a favourite preacher during the course of his sermon. Chrysostom especially was very frequently interrupted both by applause and by acclamations. In ecclesiastical councils vote by acclamation is very common, the question being usually put in the form, *placet* or *non placet.* This differs from the acclamation with which in other assemblies a motion is said to be carried, when, no amendment being proposed, approval is expressed by shouting such words as *Aye* or *Agreed.*

ACCLIMATISATION is the process of adaptation by which animals and plants are gradually rendered capable of surviving and flourishing in countries remote from their original habitats, or under meteorological conditions different from those which they have usually to endure, and which are at first injurious to them.

The subject of acclimatisation is very little understood, and some writers have even denied that it can ever take place. It is often confounded with *domestication* or with *naturalisation;* but these are both very different phenomena. A *domesticated* animal or a cultivated plant need not necessarily be *acclimatised;* that is, it need not be capable of enduring the severity of the seasons without protection. The canary bird is *domesticated* but not *acclimatised*, and many of our most extensively cultivated plants are in the same category. A *naturalised* animal or plant, on the other hand, must be able to withstand all the vicissitudes of the seasons in its new home, and it may therefore be thought that it must have become acclimatised. But in many, perhaps most cases of *naturalisation*, there is no evidence of a gradual adaptation to new conditions which were at first injurious, and this is essential to the idea of *acclimatisation.* On the contrary, many species, in a new country and under somewhat different climatic conditions, seem to find a more congenial abode than in their native land, and at once flourish and increase in it to such an extent as often to exterminate the indigenous inhabitants. Thus Agassiz (in his work on Lake Superior) tells us that the road-side weeds of the north-eastern United States, to the number of 130 species, are all European, the native weeds having disappeared westwards; while in New Zealand there are, according to Mr T. Kirk (*Transactions of the New Zealand Institute*, vol. ii. p. 131), no less than 250 species of naturalised plants, more than 100 of which spread widely over the country, and often displace the native vegetation. Among animals, the European rat, goat, and pig, are naturalised in New Zealand, where they multiply to such an extent as to injure and probably exterminate many native productions. In neither of these cases is there any indication that *acclimatisation* was necessary or ever took place.

On the other hand, the fact that an animal or plant cannot be *naturalised* is no proof that it is not *acclimatised.* It has been shown by Mr Darwin that, in the case of most animals and plants in a state of nature, the competition of other organisms is a far more efficient agency in limiting their distribution than the mere influence of climate. We have a proof of this in the fact that so few, comparatively, of our perfectly hardy garden plants ever run wild; and even the most persevering attempts to naturalise them usually fail. Alphonse de Candolle (*Géographie Botanique*, p. 798) informs us that several botanists of Paris, Geneva, and especially of Montpellier, have sown the seeds of many hundreds of species of exotic hardy plants, in what appeared to be the most favourable situations, but that in hardly a single case has any one of them become naturalised. Attempts have also been made to naturalise continental insects in this country, in places where the proper food-plants abound and the conditions seem generally favourable, but in no case do they seem to have succeeded. Even a plant like the potato, so largely cultivated and so perfectly hardy, has not established itself in a wild state in any part of Europe.

Different Degrees of Climatal Adaptation in Animals and Plants.—Plants differ greatly from animals in the closeness of their adaptation to meteorological conditions. Not only will most tropical plants refuse to live in a temperate climate, but many species are seriously injured by removal a few degrees of latitude beyond their natural limits. This is probably due to the fact, established by the experiments of M. Becquerel, that plants possess no proper temperature, but are wholly dependent on that of the surrounding medium.

Animals, especially the higher forms, are much less sensitive to change of temperature, as shown by the extensive range from north to south of many species. Thus, the tiger ranges from the equator to northern Asia as far as the river Amour, and to the isothermal of 32° Fahr. The mountain sparrow (*Passer montana*) is abundant in Java and Singapore in a uniform equatorial climate, and also inhabits this country and a considerable portion of northern Europe. It is true that most terrestrial animals are restricted to countries not possessing a great range of temperature or very diversified climates, but there is reason to believe that this is due to quite a different set of causes, such as the presence of enemies or deficiency of appropriate food. When supplied with food and partially protected from enemies, they often show a wonderful capacity of enduring climates very different from that in which they originally flourished. Thus, the horse and the domestic fowl, both natives of very warm countries, flourish without special protection in almost every inhabited portion of the globe. The parrot tribe form one of the most pre-eminently tropical groups of birds, only a few species extending into the warmer temperate regions; yet even the most exclusively tropical genera are by no means delicate birds as regards climate. In the *Annals and Magazine of Natural History* for 1868 (p. 381) is a most interesting account, by Mr Charles Buxton, M.P., of the naturalisation of parrots at Northreps Hall, Norfolk. A considerable number of

African and Amazonian parrots, Bengal parroquets, four species of white and rose crested cockatoos, and two species of crimson lories, have been at large for many years. Several of these birds have bred, and they almost all live in the woods the whole year through, refusing to take shelter in a house constructed for their use. Even when the thermometer fell 6° below zero, all appeared in good spirits and vigorous health. Some of these birds have lived thus exposed for nearly twenty years, enduring our cold easterly winds, rain, hail, and snow, all through the winter,—a marvellous contrast to the equable equatorial temperature (hardly ever less than 70°) which many of them had been accustomed to for the first year or years of their existence.

Mr Jenner Weir records somewhat similar facts in the *Zoologist* for 1865 (p. 9411). He keeps many small birds in an open aviary in his garden at Blackheath, and among these are the Java rice bird (*Padda oryzivora*), two West African weaver birds (*Hyphantornis textor* and *Euplectes sanguinirostris*), and the blue bird of the southern United States (*Spiza cyanea*). These denizens of the tropics prove quite as hardy as our native birds, having lived during the severest winters without the slightest protection against the cold, even when their drinking water had to be repeatedly melted.

Hardly any group of Mammalia is more exclusively tropical than the Quadrumana, yet there is reason to believe that, if other conditions are favourable, some of them can withstand a considerable degree of cold. The *Semnopithecus schistaceus* was found by Captain Hutton at an elevation of 11,000 feet in the Himalayas, leaping actively among fir-trees whose branches were laden with snow-wreaths. In Abyssinia a troop of dog-faced baboons were observed by Mr Blandford at 9000 feet above the sea. We may therefore conclude that the restriction of the monkey tribe to warm latitudes is probably determined by other causes than temperature alone.

Similar indications are given by the fact of closely allied species inhabiting very extreme climates. The recently extinct Siberian mammoth and woolly rhinoceros were closely allied to species now inhabiting tropical regions exclusively. Wolves and foxes are found alike in the coldest and hottest parts of the earth, as are closely allied species of falcons, owls, sparrows, and numerous genera of waders and aquatic birds.

A consideration of these and many analogous facts might induce us to suppose that, among the higher animals at least, there is little constitutional adaptation to climate, and that in their case acclimatisation is not required. But there are numerous examples of domestic animals which show that such adaptation does exist in other cases. The yak of Thibet cannot long survive in the plains of India, or even on the hills below a certain altitude; and that this is due to climate, and not to the increased density of the atmosphere, is shown by the fact that the same animal appears to thrive well in Europe, and even breeds there readily. The Newfoundland dog will not live in India, and the Spanish breed of fowls in this country suffer more from frost than most others. When we get lower in the scale the adaptation is often more marked. Snakes, which are so abundant in warm countries, diminish rapidly as we go north, and wholly cease at lat. 62°. Most insects are also very susceptible to cold, and seem to be adapted to very narrow limits of temperature.

From the foregoing facts and observations we may conclude, firstly, that some plants and many animals are not constitutionally adapted to the climate of their native country only, but are capable of enduring and flourishing under a more or less extensive range of temperature and other climatic conditions; and, secondly, that most plants and some animals are, more or less closely, adapted to climates similar to those of their native habitats. In order to domesticate or naturalise the former class in countries not extremely differing from that from which the species was brought, it will not be necessary to *acclimatise*, in the strict sense of the word. In the case of the latter class, however, acclimatisation is a necessary preliminary to naturalisation, and in many cases to useful domestication, and we have therefore to inquire whether it is possible.

Acclimatisation by Individual Adaptation.—It is evident that acclimatisation may occur (if it occurs at all) in two ways, either by modifying the constitution of the individual submitted to the new conditions, or by the production of offspring which may be better adapted to those conditions than their parents. The alteration of the constitution of individuals in this direction is not easy to detect, and its possibility has been denied by many writers. Mr Darwin believes, however, that there are indications that it occasionally occurs in plants, where it can be best observed, owing to the circumstance that so many plants are propagated by cuttings or buds, which really continue the existence of the same individual almost indefinitely. He adduces the example of vines taken to the West Indies from Madeira, which have been found to succeed better than those taken directly from France. But in most cases habit, however prolonged, appears to have little effect on the constitution of the individual, and the fact has no doubt led to the opinion that acclimatisation is impossible. There is indeed little or no evidence to show that any animal to which a new climate is at first prejudicial can be so acclimatised by habit that, after subjection to it for a few or many seasons, it may live as healthily and with as little care as in its native country; yet we may, on general principles, believe that under proper conditions such acclimatisation would take place. In his *Principles of Biology* (chap. v.), Mr Herbert Spencer has shown that every organ and every function of living beings undergoes modification to a limited extent under the stimulus of any new conditions, and that the modification is almost always such as to produce an adaptation to those conditions. We may feel pretty sure, therefore, that if robust and healthy individuals are chosen for the experiment, and if the change they are subjected to is not too great, a real individual adaptation to the new conditions—that is, a more or less complete acclimatisation—will be brought about. If now animals thus modified are bred from, we know that their descendants will inherit the modification. They will thus start more favourably, and being subject to the influence of the same or a slightly more extreme climate during their whole lives, the acclimatisation will be carried a step further; and there seems no reason to doubt that, by this process alone, if cautiously and patiently carried out, most animals which breed freely in confinement could in time be acclimatised in almost any inhabited country. There is, however, a much more potent agent, which renders the process of adaptation almost a certainty.

Acclimatisation by Variation.—A mass of evidence exists showing that variations of every conceivable kind occur among the offspring of all plants and animals, and that, in particular, constitutional variations are by no means uncommon. Among cultivated plants, for example, hardier and more tender varieties often arise. The following cases are given by Mr Darwin:—Among the numerous fruit-trees raised in North America, some are well adapted to the climate of the Northern States and Canada, while others only succeed well in the Southern States. Adaptation of this kind is sometimes very close, so that, for example, few English varieties of wheat will thrive in Scotland. Seed-wheat from India produced a miserable crop when planted by the Rev. M. J. Berkeley on land which would have produced a good crop of English wheat. Conversely, French wheat taken to the West Indies produced only barren spikes, while native wheat by its side yielded an enormous harvest. Tobacco in Sweden, raised from home-grown seed, ripens its seeds a month earlier than plants grown from foreign seed. In Italy, as long as orange trees were propagated by grafts, they were tender; but after many of the trees were destroyed by the severe frosts of 1709 and 1763, plants were raised from seed, and these were found to be hardier and more productive than the former kinds. Where plants are raised from seed in large quantities, varieties always occur differing in constitution, as well as others differing in form or colour; but the former cannot be perceived by us unless marked out by their behaviour under exceptional conditions, as in the following cases. After the severe winter of 1860–61, it was observed that in a large bed of araucarias some plants stood quite unhurt among numbers killed around them. In Mr Darwin's garden two rows of scarlet runners were entirely killed by frost, except three plants, which had not even the tips of their leaves browned. A very excellent example is to be found in Chinese history, according to M. Huc, who, in his *L'Empire Chinois* (tom. ii. p. 359), gives the following extract from the *Memoirs of the Emperor Khang*:—"On the 1st day of the 6th moon I was walking in some fields where rice had been sown to be ready for the harvest in the 9th moon. I observed by chance a stalk of rice which was already in ear. It was higher than all the rest, and was ripe enough to be gathered. I ordered it to be brought to me. The grain was very fine and well grown, which gave me the idea to keep it for a trial, and see if the following year it would preserve its precocity. It did so. All the stalks which came from it showed ear before the usual time, and were ripe in the 6th moon. Each year has multiplied the produce of the preceding, and for thirty years it is this rice which has been served at my table. The grain is elongate, and of a reddish colour, but it has a sweet smell and very pleasant taste. It is called *Yu-mi*, Imperial rice, because it was first cultivated in my gardens. It is the only sort which can ripen north of the great wall, where the winter ends late and begins very early; but in the southern provinces, where the climate is milder and the land more fertile, two harvests a year may be easily obtained, and it is for me a sweet reflection to have procured this advantage for my people." M. Huc adds his testimony that this kind of rice flourishes in Mandtchuria, where no other will grow. We have here, therefore, a perfect example of acclimatisation by means of a spontaneous constitutional variation.

That this kind of adaptation may be carried on step by step to more and more extreme climates is illustrated by the following examples. Sweet-peas raised in Calcutta from seed imported from England rarely blossom, and never yield seed; plants from French seed flower better, but are still sterile; but those raised from Darjeeling seed (originally imported from England) both flower and seed profusely. The peach is believed to have been tender, and to have ripened its fruit with difficulty, when first introduced into Greece; so that (as Darwin observes) in travelling northward during two thousand years it must have become much hardier. Dr Hooker ascertained the average vertical range of flowering plants in the Himalayas to be 4000 feet, while in some cases it extended to 8000 feet. The same species can thus endure a great difference of temperature; but the important fact is, that the individuals have become acclimatised to the altitude at which they grow, so that seeds gathered near the upper limit of the range of a species will be more hardy than those gathered near the lower limit. This was proved by Dr Hooker to be the case with Himalayan conifers and rhododendrons, raised in this country from seed gathered at different altitudes.

Among animals exactly analogous facts occur. M. Roulin states that when geese were first introduced into Bogota they laid few eggs at long intervals, and few of the young survived. By degrees the fecundity improved, and in about twenty years became equal to what it is in Europe. The same author tells us that, according to Garcilaso, when fowls were first introduced into Peru they were not fertile, whereas now they are as much so as in Europe. Mr Darwin adduces the following examples. Merino sheep bred at the Cape of Good Hope have been found far better adapted for India than those imported from England; and while the Chinese variety of the Ailanthus silk-moth is quite hardy, the variety found in Bengal will only flourish in warm latitudes. Mr Darwin also calls attention to the circumstance that writers of agricultural works generally recommend that animals should be removed from one district to another as little as possible. This advice occurs even in classical and Chinese agricultural books as well as in those of our own day, and proves that the close adaptation of each variety or breed to the country in which it originated has always been recognised.

Constitutional Adaptation often accompanied by External Modification.—Although in some cases no perceptible alteration of form or structure occurs when constitutional adaptation to climate has taken place, in others it is very marked. Mr Darwin has collected a large number of cases in his *Animals and Plants under Domestication* (vol. ii. p. 277), of which the following are a few of the most remarkable. Dr Falconer observed that several trees, natives of cooler climates, assumed a pyramidal or fastigiate form when grown in the plains of India; cabbages rarely produce heads in hot climates; the quality of the wood, the medicinal products, the odour and colour of the flowers, all change in many cases when plants of one country are grown in another. One of the most curious observations is that of Mr Meehan, who "compared twenty-nine kinds of American trees belonging to various orders, with their nearest European allies, all grown in close proximity in the same garden, and under as nearly as possible the same conditions. In the American species Mr Meehan finds, with the rarest exceptions, that the leaves fall earlier in the season, and assume before falling a brighter tint; that they are less deeply toothed or serrated; that the buds are smaller; that the trees are more diffuse in growth, and have fewer branchlets; and, lastly, that the seeds are smaller;—all in comparison with the European species." Mr Darwin concludes that there is no way of accounting for these uniform differences in the two series of trees than by the long-continued action of the different climates of the two continents.

In animals equally remarkable changes occur. In Angora, not only goats, but shepherd-dogs and cats, have fine fleecy hair; the wool of sheep changes its character in the West Indies in three generations; M. Costa states that young oysters, taken from the coast of England, and placed in the Mediterranean, at once altered their manner of growth and formed prominent diverging rays, like those on the shells of the proper Mediterranean oyster.

In his *Contributions to the Theory of Natural Selection* (p. 167), Mr Wallace has recorded cases of simultaneous variation among insects, apparently due to climate or other strictly local causes. He finds that the butterflies of the family *Papilionidæ*, and some others, become similarly modified in different islands and groups of islands. Thus, the species inhabiting Sumatra, Java, and Borneo, are almost always much smaller than the closely allied species of Celebes and the Moluccas; the species or varieties of the small island of Amboyna are larger than the same species or closely allied forms inhabiting the surrounding islands; the species found in Celebes possess a peculiar form of wing, quite distinct from that of the same or closely allied species of adjacent islands; and, lastly, numerous species which have tailed wings in India and the western islands of the Archipelago, gradually lose the tail as we proceed eastward to New Guinea and the Pacific.

Many of these curious modifications may, it is true, be due to other causes than climate only, but they serve to show how powerfully and mysteriously local conditions affect the form and structure of both plants and animals; and they render it probable that changes of constitution are also continually produced, although we have, in the majority of cases, no means of detecting them. It is also impossible to determine how far the effects described are produced by spontaneous favourable variations or by the direct action of local conditions; but it is probable that in every case both causes are concerned, although in constantly varying proportions.

The Influence of Heredity.—Adaptation by variation would, however, be a slow and uncertain process, and might for considerable periods of time cease to act, did not heredity come into play. This is the tendency of every organism to produce its like, or more exactly, to produce a set of new forms varying slightly from it in many directions—a group of which the parent form is the centre. If now one of the most extreme of these variations is taken, it is found to become the centre of a new set of variations; and by continually taking the extreme in the same direction, an increasing variation in that direction can be effected, until checked by becoming so great that it interferes with the healthy action of the organism, or is in any other way prejudicial. It is also found that acquired constitutional peculiarities are equally hereditary; so that by a combination of those two modes of variation any desired adaptation may be effected with greater rapidity. The manner in which the form or constitution of an organism can be made to change continuously in *one* direction, by means of variations which are indefinite and in *all* directions, is often misunderstood. It may perhaps be illustrated by showing how a tree or grove of trees might, by natural causes, be caused to travel during successive generations in a definite course. The tree has branches radiating out from its stem to perhaps twenty feet on every side. Seeds are produced on the extremities of all these branches, drop to the ground, and produce seedlings, which, if untouched, would form a ring of young trees around the parent. But cattle crop off every seedling as soon as it rises above the ground, and none can ever arrive at maturity. If, however, one side is protected from the cattle, young trees will grow up on that side only. This protection may exist in the case of a grove of trees which we may suppose to occupy the whole space between two deep ravines, the cattle existing on the lower side of the wood only. In this case young trees would reach maturity on the upper side of the wood, while on the lower side the trees would successively die, fall, and rot away, no young ones taking their place. If this state of things continued unchanged for some centuries, the wood might march regularly up the side of the mountain till it occupied a position many miles away from where it once stood; and this would have taken place, not because more seed was produced on one side than the other (there might even be very much less), nor because soil or climate were better on the upper side (they might be worse), nor because any intelligent being chose which trees should be allowed to live and which should be destroyed;—but simply because, for a series of generations, the conditions permitted the existence of young trees on one side, and wholly prevented it on the other. Just in an analogous way animals or plants are caused to vary in definite directions, either by the influence of natural agencies, which render existence impossible for those that vary in any other direction, or by the action of the judicious breeder, who carefully selects favourable variations to be the parents of his future stock; and in either case the rejected variations may far outnumber those which are preserved.

Evidence has been adduced by Mr Darwin to show that the tendency to vary is itself hereditary; so that, so far from variations coming to an end, as some persons imagine, the more extensively variation has occurred in any species in the past, the more likely it is to occur in the future. There is also reason to believe that individuals which have varied largely from their parents in a special direction will have a greater tendency to produce offspring varying in that direction than in any other; so that the facilities for adaptation, that is, for the production and increase of favourable variations in certain definite directions, are far greater than the facilities for locomotion in one direction in the hypothetical illustration just given.

Selection and Survival of the Fittest as Agents in Naturalisation.—We may now take it as an established fact, that varieties of animals and plants occur, both in domesticity and in a state of nature, which are better or worse adapted to special climates. There is no positive evidence that the influence of new climatal conditions on the parents has any tendency to produce variations in the offspring better adapted to such conditions, although some of the facts mentioned in the preceding sections render it probable that such may be the case. Neither does it appear that this class of variations are very frequent. It is, however, certain that whenever any animal or plant is largely propagated constitutional variations will arise, and some of these will be better adapted than others to the climatal and other conditions of the locality. In a state of nature, every recurring severe winter or otherwise unfavourable season, weeds out those individuals of tender constitution or imperfect structure which may have got on very well during favourable years, and it is thus that the adaptation of the species to the climate in which it has to exist is kept up. Under domestication the same thing occurs by what Mr Darwin has termed "unconscious selection." Each cultivator seeks out the kinds of plants best suited to his soil and climate, and rejects those which are tender or otherwise unsuitable. The farmer breeds from such of his stock as he finds to thrive best with him, and gets rid of those which suffer from cold, damp, or disease. A more or less close adaptation to local conditions is thus brought about, and breeds or races are produced which are sometimes liable to deterioration on removal even to a short distance in the same country, as in numerous cases quoted by Mr Darwin (*Animals and Plants under Domestication*, vol. ii. p. 278).

The Method of Acclimatisation.—Taking into consideration the foregoing facts and illustrations, it may be considered as proved—1*st*, That habit has little (though it appears to have some) definite effect in adapting the constitution of animals to a new climate; but that it has a decided, though still slight, influence in plants when, by the process of propagation by buds, shoots, or grafts, the individual can be kept under its influence for long periods; 2*d*, That the offspring of both plants and animals vary in their constitutional adaptation to climate, and that this adaptation may be kept up and increased by means of heredity; and, 3*d*, That great and sudden changes of climate often check reproduction even when the health of the individuals does not appear to suffer. In order, therefore, to have the best chance of acclimatising any animal or plant in a climate very dissimilar from that of its native country, and in which it has been proved that the species in question cannot live and maintain itself without acclimatisation, we must adopt some such plan as the following:—

1. We must transport as large a number as possible of adult healthy individuals to some intermediate station, and increase them as much as possible for some years. Favourable variations of constitution will soon show themselves, and these should be carefully selected to breed from, the tender and unhealthy individuals being rigidly eliminated.

2. As soon as the stock has been kept a sufficient time to pass through all the ordinary extremes of climate, a number of the hardiest may be removed to the more remote station, and the same process gone through, giving protection if necessary while the stock is being increased, but as soon as a large number of healthy individuals are produced, subjecting them to all the vicissitudes of the climate.

It can hardly be doubted that in most cases this plan would succeed. It has been recommended by Mr Darwin, and at one of the early meetings of the Société Zoologique d'Acclimatisation, at Paris, M. Geoffroy St Hilaire insisted that it was the only method by which acclimatisation was possible. But in looking through the long series of volumes of Reports published by this Society, there is no sign that any systematic attempt at acclimatisation has even once been made. A number of foreign animals have been introduced, and more or less domesticated, and some useful exotics have been cultivated for the purpose of testing their applicability to French agriculture or horticulture; but neither in the case of animals nor of plants has there been any systematic effort to modify the constitution of the species, *by breeding largely and selecting the favourable variations that appeared.*

Take the case of the *Eucalyptus globulus* as an example. This is a Tasmanian gum-tree of very rapid growth and great beauty, which will thrive in the extreme south of France. In the *Bulletin* of the Society a large number of attempts to introduce this tree into general cultivation in other parts of France are recorded in detail, with the failure of almost all of them. But no precautions such as those above indicated appear to have been taken in any of these experiments; and we have no intimation that either the Society or any of its members are making systematic efforts to acclimatise the tree. The first step would be, to obtain seed from healthy trees growing in the coldest climate and at the greatest altitude in its native country, sowing these very largely, and in a variety of soils and situations, in a part of France where the climate is somewhat but not much more extreme. It is almost a certainty that a number of trees would be found to be quite hardy. As soon as these produced seed, it should be sown in the same district and farther north in a climate a little more severe. After an exceptionally cold season, seed should be collected from the trees that suffered least, and should be sown in various districts all over France. By such a process there can be hardly any doubt that the tree would be thoroughly acclimatised in any part of France, and in many other countries of central Europe; and more good would be effected by one well-directed effort of this kind than by hundreds of experiments with individual animals and plants, which only serve to show us which are the species that *do not require to be acclimatised.*

Acclimatisation of Man.—On this subject we have, unfortunately, very little direct or accurate information. The general laws of heredity and variation have been proved to apply to man as well as to animals and plants; and numerous facts in the distribution of races show that man must, in remote ages at least, have been capable of constitutional adaptation to climate. If the human race constitutes a single species, then the mere fact that man now inhabits every region, and is in each case constitutionally adapted to the climate, proves that acclimatisation has occurred. But we have the same phenomenon in single varieties of man, such as the American, which inhabits alike the frozen wastes of Hudson's Bay and Terra del Fuego, and the hottest regions of the tropics,—the low equatorial valleys and the lofty plateaux of the Andes. No doubt a sudden transference to an extreme climate is often prejudicial to man, as it is to most animals and plants; but there is every reason to believe that, if the migration occurs step by step, man can be acclimatised to almost any part of the earth's surface in comparatively few generations. Some eminent writers have denied this. Sir Ranald Martin, from a consideration of the effects of the climate of India on Europeans and their offspring, believes that there is no such thing as acclimatisation. Dr Hunt, in a report to the British Association in 1861, argues that "time is no agent," and —"if there is no sign of acclimatisation in one generation, there is no such process." But he entirely ignores the effect of favourable variations, as well as the direct influence of climate acting on the organisation from infancy.

Professor Waitz, in his *Introduction to Anthropology*, adduces many examples of the comparatively rapid constitutional adaptation of man to new climatic conditions. Negroes, for example, who have been for three or four generations acclimatised in North America on returning to Africa become subject to the same local diseases as other unacclimatised individuals. He well remarks, that the debility and sickening of Europeans in many tropical countries are wrongly ascribed to the climate, but are rather the consequences of indolence, sensual gratification, and an irregular mode of life. Thus the English, who cannot give up animal food and spirituous liquors, are less able to sustain the heat of the tropics than the more sober Spaniards and Portuguese. The excessive mortality of European troops in India, and the delicacy of the children of European parents, do not affect the real question of acclimatisation under proper conditions. They only show that acclimatisation is in most cases necessary, not that it cannot take place. The best examples of partial or complete acclimatisation are to be found where European races have permanently settled in the tropics, and have maintained themselves for several generations. There are, however, two sources of inaccuracy to be guarded against, and these are made the most of by the writers above referred to, and are supposed altogether to invalidate results which are otherwise opposed to their views. In the first place, we have the possibility of a mixture of native blood having occurred; in the second, there have almost always been a succession of immigrants from the parent country, who continually intermingle with the families of the early settlers. It is maintained that one or other of these mixtures is absolutely necessary to enable Europeans to continue long to flourish in the tropics.

There are, however, certain cases in which the sources of error above mentioned are reduced to a minimum, and cannot seriously affect the results; such as those of the Jews, the Dutch at the Cape of Good Hope and in the Moluccas, and the Spaniards in South America.

The Jews are a good example of acclimatisation, because they have been established for many centuries in climates very different from that of their native land; they keep themselves almost wholly free from intermixture with the people around them; and they are often so populous in a country that the intermixture with Jewish immigrants from other lands cannot seriously affect the local purity of the race. They have, for instance, attained a population of near two millions in such severe climates as Poland and Russia; and according to Mr Brace (*Races of the Old World*, p. 185), "their increase in Sweden is said to be greater than that of the Christian population; in the towns of Algeria they are the only race able to maintain its numbers: and in

Cochin China and Aden they succeed in rearing children and forming permanent communities."

In some of the hottest parts of South America Europeans are perfectly acclimatised, and where the race is kept pure it seems to be even improved. Some very valuable notes on this subject have been furnished to the present writer by the well-known botanist Dr Richard Spruce, who resided many years in South America, but who has hitherto been prevented by ill health from giving to the world the results of his researches. As a careful, judicious, and accurate observer, both of man and nature, he has few superiors. He says—

"The white inhabitants of Guayaquil (lat. 2° 13′ S.) are kept pure by careful selection. The slightest tincture of red or black blood bars entry into any of the old families who are descendants of Spaniards from the Provincias Vascongadas, or those bordering the Bay of Biscay, where the morals are perhaps the purest (as regards the intercourse of the sexes) of any in Europe, and where for a girl, even of the poorest class, to have a child before marriage is the rarest thing possible. The consequence of this careful breeding is, that the women of Guayaquil are considered (and justly) the finest along the whole Pacific coast. They are often tall, sometimes very handsome, decidedly healthy, although pale, and assuredly prolific enough. Their sons are big, stout men, but when they lead inactive lives are apt to become fat and sluggish. Those of them, however, who have farms in the savannahs, and are accustomed to take long rides in all weathers, and those whose trade obliges them to take frequent journeys in the mountainous interior, or even to Europe and North America, are often as active and as little burdened with superfluous flesh as a Scotch farmer.

"The oldest Christian town in Peru is Piura (lat. 5° S.), which was founded by Pizarro himself. The climate is very hot, especially in the three or four months following the southern solstice. In March 1843 the temperature only once fell as low as 83°, during the whole month, the usual lowest night temperature being 85°. Yet people of all colours find it very healthy, and the whites are very prolific. I resided in the town itself nine months, and in the neighbourhood seven months more. The population (in 1863–4) was about 10,000, of which not only a considerable proportion was white, but was mostly descended from the first emigrants after the conquest. Purity of descent was not, however, quite so strictly maintained as at Guayaquil. The military adventurers, who have often risen to high or even supreme rank in Peru, have not seldom been of mixed race, and fear or favour has often availed to procure them an alliance with the oldest and purest-blooded families."

These instances, so well stated by Dr Spruce, seem to demonstrate the complete acclimatisation of Spaniards in some of the hottest parts of South America. Although we have here nothing to do with mixed races, yet the want of fertility in these has been often taken to be a fact inherent in the mongrel race, and has been also sometimes held to prove that neither the European nor his half-bred offspring can maintain themselves in the tropics. The following observation is therefore of interest :—

"At Guayaquil for a lady of good family—married or unmarried—to be of loose morals is so uncommon, that when it does happen it is felt as a calamity by the whole community. But here, and perhaps in most other towns in South America, a poor girl of mixed race—especially if good-looking—rarely thinks of marrying one of her own class until she has—as the Brazilians say—'approveitada de sua mocidade' (made the most of her youth) in *receiving presents from gentlemen.* If she thus bring a good dowry to her husband, he does not care to inquire, or is not sensitive, about the mode in which it was acquired. The consequences of this indiscriminate sexual intercourse, especially if much prolonged, is to diminish, in some cases to paralyse, the fertility of the female. And as among people of mixed race it is almost universal, the population of these must fall off both in numbers and quality."

The following example of divergent acclimatisation of the same race to hot and cold zones is very interesting, and will conclude our extracts from Dr Spruce's valuable notes :—

"One of the most singular cases connected with this subject that have fallen under my own observation, is the difficulty, or apparent impossibility, of acclimatising the Red Indian in a certain zone of the Andes. Any person who has compared the physical characters of the native races of South America must be convinced that these have all originated in a common stirps. Many local differences exist, but none capable of invalidating this conclusion. The warmth yet shade-loving Indian of the Amazon; the Indian of the hot, dry, and treeless coasts of Peru and Guayaquil, who exposes his bare head to the sun with as much zest as an African negro; the Indian of the Andes, for whom no cold seems too great, who goes constantly bare-legged and often bare-headed, through whose rude straw hut the piercing wind of the paramos sweeps, and chills the white man to the very bones;—all these, in the colour and texture of the skin, the hair, and other important features, are plainly of one and the same race.

"Now there is a zone of the equatorial Andes, ranging between about 4000 and 6000 feet altitude, where the very best flavoured coffee is grown, where cane is less luxuriant but more saccharine than in the plains, and which is therefore very desirable to cultivate, but where the red man sickens and dies. Indians taken down from the sierra get ague and dysentery. Those of the plains find the temperature chilly, and are stricken down with influenza and pains in the limbs. I have seen the difficulty experienced in getting farms cultivated in this zone, on both sides of the Cordillera. The permanent residents are generally limited to the major domo and his family; and in the dry season labourers are hired, of any colour that can be obtained—some from the low country, others from the highlands—for three, four, or five months, who gather in and grind the cane, and plant for the harvest of the following year; but a staff of resident Indian labourers, such as exists in the farms of the sierra, cannot be kept up in the *Yungas*, as these half-warm valleys are called. White men, who take proper precautions, and are not chronically soaked with cane-spirit, stand the climate perfectly, but the creole whites are still too much *caballeros* to devote themselves to agricultural work.

"In what is now the republic of Ecuador, the only peopled portions are the central valley, between the two ridges of the Andes—height 7000 to 12,000 feet—and the hot plain at their western base; nor do the wooded slopes appear to have been inhabited, except by scattered savage hordes, even in the time of the Incas. The Indians of the highlands are the descendants of others who have inhabited that region exclusively for untold ages; and a similar affirmation may be made of the Indians of the plain. Now there is little doubt that the progenitors of both these sections came from a temperate region (in North America); so that here we have one moiety acclimatised to endure extreme heat, and the other extreme cold; and at this day exposure of either to the opposite extreme (or even, as we have seen, to the climate of an intermediate zone) is always pernicious and often fatal. But if this great difference has been brought about in the red man, might not the same have happened to the white man? Plainly it might, time being given; for one cannot doubt that the inherent adaptability is the same in both, or (if not) that the white man possesses it in a higher degree."

The observations of Dr Spruce are of themselves almost conclusive as to the possibility of Europeans becoming acclimatised in the tropics; and if it is objected that this evidence applies only to the dark-haired southern races, we are fortunately able to point to facts, almost equally well authenticated and conclusive, in the case of one of the typical Germanic races. At the Cape of Good Hope the Dutch have been settled and nearly isolated for about 200 years, and have kept themselves almost or quite free from native intermixture. They are described as being still perfectly fair in complexion, while physically they are the finest body of men in the colony, being very tall and strong. They marry young, and have large families. The population, according to a census taken in 1798, was under 22,000. In 1865 it was near 182,000, the majority being (according to the *Statesman's Year Book* for 1873) of "Dutch, German, or French origin, mostly descendants of original settlers." We have here a population which has doubled itself every twenty-two years; and the greater part of this rapid increase must certainly be due to the old European immigrants. In the Moluccas, where the Dutch have had settlements for nearly 250 years, some of the inhabitants trace their descent to early immigrants; and these, as well as most of the people of Dutch descent in the East, are quite as fair as their European ancestors, enjoy excellent health, and are very prolific. But the Dutch accommodate themselves admirably to a tropical climate, doing much of their work early in the morning, dressing very lightly, and living a quiet, temperate, and cheerful life. They also pay great attention to drainage and general cleanliness. In addition to these examples, it may be maintained that the rapid increase of English-speaking populations in the United States and in Australia, only a comparatively small portion of which can be due to direct immigration, is far from supporting the view of Dr Knox, that Europeans cannot permanently maintain themselves in those countries. Mr Brace expressly denies that the American physique has degenerated from the English type. He asserts that manufacturers and others find that "for labours requiring the utmost physical endurance and muscular power, such as iron-puddling and lumbering in the forests and on the streams, and pioneer work, foreigners are never so suitable as native Americans. The reports of the examining surgeons for volunteers—such as that of Dr W. H. Thomson to the Surgeon-General in 1862, who examined 9000 men—show a far higher average of physique in the Americans examined than in the English, Germans, or Irish. It is a fact well known to our life insurance companies, that the average length of life here is greater than that of the English tables."—*The Races of the Old World*, p. 375. Although the comparisons here instituted may not be quite fair or conclusive, they furnish good arguments against those who maintain that the Americans are physically deteriorating.

On the whole, we seem justified in concluding that, under favourable conditions, and with a proper adaptation of means to the end in view, man may become acclimatised with at least as much certainty and rapidity (counting by generations rather than by years) as any of the lower animals. (A. R. W.)

ACCOLADE (from *collum*, the neck), a ceremony anciently used in conferring knighthood; but whether it was an embrace (according to the use of the modern French word, *accolade*), or a slight blow on the neck or cheek, is not agreed. Both these customs appear to be of great antiquity. Gregory of Tours writes that the early kings of France, in conferring the gilt shoulder-belt, kissed the knights on the left cheek; and William the Conqueror is said to have made use of the blow in conferring the honour of knighthood on his son Henry. At first it was given with the naked fist, a veritable box on the ear, but for this was substituted a gentle stroke on the shoulder with the flat of the sword. A custom of a similar kind is still followed in bestowing the honour of knighthood.

ACCOLTI, BENEDICT, was born in 1415 at Arezzo, in Tuscany, of a noble family, several members of which were distinguished like himself for their attainments in law. He was for some time professor of jurisprudence in the University of Florence, and on the death of the celebrated Poggio in 1459 became chancellor of the Florentine republic. He died in 1466. In conjunction with his brother Leonard, he wrote in Latin a history of the first crusade, entitled *De Bello a Christianis contra Barbaros, pro Christi Sepulchro et Judæa recuperandis, libri tres*, which, though itself of little interest, furnished Tasso with the historic basis for his *Jerusalem Delivered.* This work appeared at Venice in 1432, and was translated into Italian in 1543, and into French in 1620. Another work of Accolti's—*De Præstantia Virorum sui Ævi*—was published at Parma in 1689.

ACCOLTI, BERNARD (1465–1535), son of the preceding, known in his own day as *l'Unico Aretino*, acquired great fame as a reciter of impromptu verse. He was listened to by large crowds, composed of the most learned men and the most distinguished prelates of the age. Among others, Cardinal Bembo has left on record a testimony to his extraordinary talent. His high reputation with his contemporaries seems scarcely justified by the poems he published, though they give evidence of brilliant fancy. It is probable that he succeeded better in his extemporary productions than in those which were the fruit of deliberation. His works, under the title *Virginia, Comedia, Capitoli e Strambotti di Messer Bernardo Accolti Aretino*, were published at Florence in 1513, and have been several times reprinted.

ACCOLTI, PIETRO, brother of the preceding, was born at Florence in 1455, and died there in 1549. He was abbreviator under Leo X., and in that capacity drew up in 1520 the famous bull against Luther. In 1527 he was made a cardinal by Clement VII., who had employed him as his secretary.

ACCOMMODATION, a term used in Biblical interpretation to denote the presentation of a truth not absolutely as it is in itself, but relatively or under some modification, with the view of suiting it either to some other truth or to the persons addressed. It is generally distinguished into *formal* and *material*,—the accommodation in the one case being confined to the *method* of teaching, and in the other being extended to the *matter* taught. To the former head may be referred teaching by symbols or parables, by progressive stages graduated according to the capacity of the learner, by the application of prophecy to secondary fulfilments, &c. To the latter head are to be referred the allegations of the anti-supranaturalistic school, that Christ and the writers of Scripture modified or perverted the truth itself in order to secure wider acceptance and speedier success, by speaking in accordance with contemporary ideas rather than with absolute and eternal truth.

ACCOMMODATION, in commerce, denotes generally temporary pecuniary aid given by one trader to another, or by a banker to his customers, but it is used more particularly to describe that class of bills of exchange which represents no actual exchange of real value between the parties.

ACCORAMBONI, VITTORIA, an Italian lady remarkable for her extraordinary beauty and her tragic history. Her contemporaries regarded her as the most captivating woman that had ever been seen in Italy. She was sought in marriage by Paolo Giordano Orsini, Duke of Bracciano, who, it was generally believed, had murdered his wife, Isabella de Medici, with his own hand; but her father gave her in preference to Francesco Peretti, nephew of Cardinal Montalto. Peretti was assassinated (1581), and a few days afterwards Vittoria fled from the house of the Cardinal, where she had resided, to that of the Duke of Bracciano. The opposition of Pope Gregory XIII., who even went so far as to confine Vittoria to Fort St Angelo for nearly a year, did not prevent her marriage with the duke. On the accession of Montalto to the papal throne as Sixtus V. (1585), the duke thought it prudent to take refuge with his wife in the territory of the Venetian republic. After a few months' residence at Salò, on the Lake of Garda, he died, bequeathing nearly the whole of his large fortune to his widow. This excited the anger of Ludovico Orsini, a relative, who caused Vittoria to be murdered in her residence at Padua (Dec. 22, 1585). The history of this beautiful and accomplished but unfortunate woman has been written by Adry (1800), and recently by Count Gnoli, and forms the basis of Webster's tragedy, *The White Devil*, and of Tieck's romance, *Vittoria Accoramboni.*

ACCORDION (from the French *accord*), a small musical instrument in the shape of a bellows, which produces sounds by the action of wind on metallic reeds of various sizes. It is played by being held in both hands and pulled backwards and forwards, the fingers being left free to touch the keys, which are ranged along each side. The instrument is akin to the concertina, but differs from it in having the chords *fixed* by a mechanical arrangement. It is manufactured chiefly in Paris.

ACCORSO (in Latin *Accursius*), FRANCIS, an eminent lawyer, born at Florence about 1182. After practising for some time in his native city, he was appointed professor at Bologna, where he had great success as a teacher. He undertook the great work of arranging into one body the almost innumerable comments and remarks upon the Code, the Institutes, and Digests, the confused dispersion of which among the works of different writers caused much obscurity and contradiction. When he was employed in this work, it is said that, hearing of a similar one proposed and begun by Odofred, another lawyer of Bologna, he feigned indisposition, interrupted his public lectures, and shut himself up, till he had, with the utmost expedition, accomplished his design. His work has the vague title of the *Great Gloss*, and, though written in barbarous Latin, has more method than that of any preceding writer on the subject. The best edition of it is that of Godefroi, published at Lyons in 1589, in 6 vols. folio. Accursius was greatly extolled by the lawyers of his own and the immediately succeeding age, and he was even called the *Idol of Jurisconsults*, but those of later times formed a much lower estimate of his merits. There can be no doubt that he has disentangled with much skill the sense of many laws; but it is equally undeniable that his ignorance of history and antiquities has often led him into absurdities, and been the cause of many defects in his explanations and commentaries. He died at Bologna in 1260. His eldest son Francis, who filled the chair of law at Bologna with great reputation, was invited to Oxford by King Edward I., and in 1275 or 1276 read lectures on law in that university. In 1280 he returned to Bologna, where he died in 1293.

ACCORSO (or ACCURSIUS), MARIANGELO, a learned and ingenious critic, was born at Aquila, in the kingdom of Naples, about 1490. He was a great favourite with Charles V., at whose court he resided for thirty-three years, and by whom he was employed on various foreign missions. To a perfect knowledge of Greek and Latin he added an intimate acquaintance with several modern languages. In discovering and collating ancient manuscripts, for which his travels abroad gave him special opportunities, he displayed uncommon diligence. His work entitled *Diatribæ in Ausonium, Solinum, et Ovidium*, printed at Rome, in folio, in 1524, is a singular monument of erudition and critical skill. He bestowed, it is said, unusual pains on Claudian, and made, from different manuscripts, above seven hundred corrections on the works of that poet. Unfortunately these criticisms were never published. He was the first editor of the *Letters of Cassiodorus*, with his *Treatise on the Soul;* and his edition of *Ammianus Marcellinus* (1533) contains five books more than any former one. The affected use of antiquated terms, introduced by some of the Latin writers of that age, is humorously ridiculed by him, in a dialogue published in 1531 (republished, with his name, in 1574), entitled *Osco, Volsco, Romanaque Eloquentia Interlocutoribus, Dialogus Ludis Romanis actus.* Accorso was accused of plagiarism in his notes on Ausonius; and the determined manner in which he repelled, by a most solemn oath, this charge of literary theft, presents us with a singular instance of anxiety and care to preserve a literary reputation unstained.

ACCOUNT, a Stock Exchange term: *e.g.*, "*To Buy or Sell for the Account*," &c. The word has different, though kindred, significations, all derived from the making up and settling of accounts on particular days, in which stricter sense the word "Settlement" is more specially used.

The financial importance of *the Account* may be gathered from the Clearing House returns. Confining ourselves to the six years, from the 30th of April 1867 to the 30th of April 1873, we have the following figures, furnished by the Clearing House to Sir John Lubbock, and communicated by him to the *Times*:—

April to April	On fourths of the Month.	On Stock Exchange Account Days.	On Consols Settling Days.
1867 to 1868	£147,113,000	£444,443,000	£132,293,000
1868 to 1869	161,861,000	550,622,000	142,270,000
1869 to 1870	168,523,000	594,763,000	148,822,000
1870 to 1871	186,517,000	635,946,000	169,141,000
1871 to 1872	229,629,000	942,446,000	233,843,000
1872 to 1873	265,965,000	1,032,474,000	243,561,000

During the year ending April 30, 1873, the *total* amount of bills, checks, &c., paid at the Clearing House showed an increase of £613,613,000 during the same period ending April 1872, and of £2,745,924,000 over 1868. The amounts passing through on the *4ths of the month* amounted to £265,965,000, showing an increase of £36,336,000 over 1872. The payments on *Stock Exchange Account Days* formed a sum of £1,032,474,600, being an increase of £90,028,000 over 1872. The payments on *Consols Account Days* for the same period amounted to £243,561,000, giving an increase of £9,718,000 over 1872.

In English and Indian Government Securities, the settlements are monthly, and for foreign, railway, and other securities, generally speaking, they are fortnightly. It follows therefore that in 1867–1868, an ordinary Stock Exchange Account Day involved payments, on Stock Exchange accounts only, averaging about £10,000,000 sterling, and in 1872–3 something like £25,000,000 sterling; and these sums again, enormous as they are, represent for the most part only the balance of much larger transactions. The London Account is, in fact, probably the greatest and most important periodical event in the financial world. The great European centres have their own Account Days and methods of settlement, but the amounts dealt in are very much less than on the London market. The leading cities in the United Kingdom have also their Stock Exchanges, but their practice follows more or less that of London, where the bulk of their business is transacted by means of post and telegraph.

The Account in Consols or other English Government Securities, or in the securities of the Government of India, or in Bank of England Stock, or other Stocks transferable at the Bank of England, extends over a month, the settlements being monthly, and in them the committee of the Stock Exchange does not take cognisance of any bargain for a future account if it shall have been effected more than eight days previously to the close of the existing account.

The Account in Securities to Bearer, and, with the above exceptions, in Registered Securities also, extends over a period of from twelve to nineteen days. This period is in each case terminated by the "settlement," which occurs twice in each month (generally about the middle and end), on days fixed by the committee for general purposes of the Stock Exchange in the preceding month.

This "settlement" occupies three continuous days, which are all termed Account days, but the third day is the true Account, Settling, or Pay Day.

Continuation or Carrying-over is the operation by which the settlement of a bargain transacted for money, or for a given account, may for a consideration (called either a "Contango" or a "Backwardation") be deferred for the period of another account. Such a continuation is equivalent to a sale "for the day," and a repurchase for the succeeding account, or to a purchase "for the day," and a re-sale for the succeeding account. The price at which such transactions are adjusted is the "Making-Up" price of the day.

Contango is a technical term which expresses the rate of interest charged for the loan of money upon the security of stock transferred for the period of an account or otherwise, or the rate of interest paid by the buyer to the seller to be allowed to defer paying for the stock purchased, until the next settlement day.

Backwardation, or, as it is more often called, *Back* (for brevity), in contradistinction to contango, is the amount charged for the loan of stock from one account to the other, and it is paid to the purchaser by the seller in order to allow the seller to defer the delivery of the stock.

A *Bull Account* is one in which either the purchases have predominated over the sales, or the disposition to purchase has been more marked than the disposition to sell.

A *Bear Account* is one in which either the sales have preponderated over the purchases, or in which the disposition to sell has been more strongly displayed than the disposition to buy.

Sometimes the Bull or the Bear disposition extends to the great majority of securities, as when there are general falls or general rises. Sometimes a Bull Account in one set of securities is contemporaneous with a Bear Account in another.—*Vide* Cracroft's *Stock Exchange Manual.*

ACCOUNTANT, earlier form ACCOMPTANT, in the most general sense, is a person skilled in accounts. It is applied to the person who has the charge of the accounts in a public office or in the counting-house of a large private business. It is also the designation of a distinct profession, which deals in any required way with mercantile accounts.

ACCOUNTANT-GENERAL, an officer in the English Court of Chancery, who receives all monies lodged in court, and by whom they are deposited in bank and disbursed.

ACCRA or ACRA, a town, or rather a collection of forts, in a territory of the same name, on the Gold Coast of Africa, about 75 miles east of Cape Coast Castle. Of the forts, Fort St James is a British settlement, Crèvecœur was established by the Dutch, and Christianborg by the Danes; but the two last have since been ceded to Britain—Christianborg in 1850, and Crèvecœur in 1871. Accra is considered to be one of the healthiest stations on the west coast of Africa, and has some trade in the productions of the interior,—ivory, gold dust, and palm-oil; while cotton goods, tobacco, rum, and beads are imported in exchange. It is the residence of a British civil commandant.

ACCRINGTON, an important manufacturing town of England, in Lancashire, lies on the banks of a stream called the Hindburn, in a deep valley, 19 miles N. from Manchester and 5 miles E. of Blackburn. It has increased rapidly in recent years, and is the centre of the Manchester cotton-printing trade. There are large cotton factories and print-works, besides bleach-fields, &c., employing many hands. Coal is extensively wrought in the neighbourhood. The town has a good appearance, and among the more handsome buildings are a fine church, in the Gothic style, erected in 1838, and the Peel Institution, an Italian structure, containing an assembly room, a lecture room, &c., The sanitary arrangements generally are good, and a reservoir capable of containing 140,000,000 gallons has been constructed for the water supply of the town. Accrington is a station on the Lancashire and Yorkshire Railway. The population of the two townships of Old and New Accrington was in 1861, 17,688; and in 1871, 21,788.

ACCUM, FREDERICK, chemist, born at Bückeburg in 1769, came to London in 1793, and was appointed teacher of chemistry and mineralogy at the Surrey Institution in 1801. While occupying this position he published several scientific manuals (*Chemistry*, 1803; *Mineralogy*, 1808; *Crystallography*, 1813), but his name will be chiefly remembered in connection with gas-lighting, the introduction of which was mainly due to him and to the enterprising printseller, Ackermann. His excellent *Practical Treatise on Gaslight* appeared in 1815; and he rendered another valuable service to society by his *Treatise on Adulterations of Food and Culinary Poisons* (1820), which attracted much notice at the time it appeared. Both works, as well as a number of his smaller publications, were translated into German. In consequence of charges affecting his honesty, Accum left London for Germany, and in 1822 was appointed professor in the Industrial Institute and Academy of Architecture at Berlin. He died there in 1838.

ACCUMULATOR, a term applied frequently to a powerful electrical machine, which generates or accumulates, by means of friction, electric currents of high tension,—manifested by sparks of considerable length. Accumulators have been employed in many places for exploding torpedoes and mines, for blasting, &c. An exceedingly powerful apparatus of this kind was employed by the Confederate authorities during the civil war in America for discharging submarine and river torpedoes. Whatever the nature of the materials employed in the construction of the accumulator, or the form which it may assume mechanically, it is simply a modification of, or an improvement upon, the ordinary cylindrical or the plate-glass frictional electrical machine,—the fundamental scientific principles being the same in nearly every case. The exciting body consists generally of a large disc or circular plate of vulcanite,—more frequently termed by electricians "ebonite," in consequence of its resemblance, in point of hardness and of polish, to polished ebony,—the vulcanite disc taking the place of the ordinary circular plate of thick glass.

ACE, the received name for the single point on cards or dice—the unit. Mr Fox Talbot has a speculation (*English Etymologies*, p. 262) that the Latins invented, if not the game of dice, at least the name for the single point, which they called *unus.* The Greeks corrupted this into ὄνος, and at length the Germanic races, learning the game from the Greeks, translated the word into *ass*, which has now become *ace.* The fact, however, is, that the root of the word lies in the Latin *as*, the monetary unit, which is to be identified with the Greek εἷς; Doric, αἶς or ἆς.

ACEPHALA, a name sometimes given to a section of the molluscous animals, which are divided into *encephala* and *acephala*, according as they have or want a distinctly differentiated head. The Acephala, or *Lamellibranchiata*, as they are also called, are commonly known as bivalve shell-fish.

ACEPHALI (from ἀ privative, and κεφαλή, a head), a term applied to several sects as having no head or leader; and in particular to a sect that separated itself, in the end of the 5th century, from the rule of the patriarchs of Alexandria, and remained without king or bishop for more than 300 years (*Gibbon*, c. xlvii.)

ACEPHALI was also the name given to the levellers in the reign of Henry I., who are said to have been so poor as to have no tenements, in virtue of which they might acknowledge a superior lord.

ACEPHALI, or *Acephalous Persons*, fabulous monsters, described by some ancient naturalists and geographers as having no heads.

ACER. See MAPLE.

ACERBI, GIUSEPPE (JOSEPH), an Italian traveller, born at Castel-Goffredo, near Mantua, on the 3d May 1773, studied at Mantua, and devoted himself specially to natural science. In 1798 he undertook a journey through Denmark, Sweden, Finland, and Lapland; and in the following year he reached the North Cape, which no Italian had previously visited. He was accompanied in the latter part of the journey by the Swedish colonel Skiöldebrand, an excellent landscape-painter. On his return Acerbi stayed for some time in England, and published his *Travels through Sweden*, &c. (London, 1802), which was translated into German (Weimar, 1803), and, under the author's personal superintendence, into French (Paris, 1804). The French translation received numerous corrections, but even in this amended form the work contains many mistakes. Acerbi rendered a great service to Italian literature by starting the *Biblioteca Italiana* (1816), in which he opposed the pretensions of the Academy della Crusca. Being appointed Austrian consul-general to Egypt in 1826, he entrusted the management of the *Biblioteca* to Gironi, contributing to it afterwards a series of valuable articles on Egypt. While in the East he obtained for the museums of Vienna, Padua, Milan, and Pavia many objects of interest. He returned from Egypt in 1836, and took up his residence in his native place, where he occupied himself with his favourite study till his death in August 1846.

ACERNUS, the Latinised name by which SEBASTIAN FABIAN KLONOWICZ, a celebrated Polish poet, is generally known, was born at Sulmierzyce in 1551, and died at Lublin in 1608. He was for some time burgomaster and president of the Jews' civil tribunal in the latter town, where he had taken up his residence after studying at Cracow. Though himself of an amiable disposition, his domestic life was very unhappy, the extravagance and misconduct of his wife driving him at last to the public hospital of Lublin, where he ended his days. He wrote both Latin and Polish poems, and the genius they displayed won for him the name of the *Sarmatian Ovid*. The titles of fourteen of his works are known; but a number of these were totally destroyed by the Jesuits and a section of the Polish nobility, and copies of the others are for the same reason exceedingly rare. The *Victoria Deorum ubi continetur Veri Herois Educatio*, a poem in forty-four cantos, cost the poet ten years' labour.

ACERRA, in *Antiquity*, a little box or pot, wherein were put the incense and perfumes to be burned on the altars of the gods, and before the dead. It appears to have been the same with what was otherwise called *thuribulum* and *pyxis*. The *censers* of the Jews were *acerræ;* and the Romanists still retain the use of *acerræ*, under the name of *incense pots*.

The name *acerra* was also applied to an altar erected among the Romans, near the bed of a person recently deceased, on which his friends offered incense daily till his burial. The real intention probably was to fumigate the apartment. The Chinese have still a somewhat similar custom.

ACERRA, a town of Italy, in the province of Terra di Lavoro, situated on the river Agno, 7 miles N.E. of Naples, with which it is connected by rail. It is the ancient *Acerrae*, the inhabitants of which were admitted to the privileges of Roman citizenship so early as 332 B.C., and which was plundered and burnt by Hannibal during the second Punic war. A few inscriptions are the only traces time has left of the ancient city. The town stands in a fertile district, but is rendered very unhealthy by the malaria rising from the artificial water-courses of the surrounding Campagna. It is the seat of a bishop, and has a cathedral and seminary. Flax is grown in the neighbourhood. Population, 11,717.

ACETIC ACID, one of the most important organic acids. It occurs naturally in the juice of many plants, and in certain animal secretions; but is generally obtained, on the large scale, from the oxidation of spoiled wines, or from the destructive distillation of wood. In the former process it is obtained in the form of a dilute aqueous solution, in which also the colouring matters of the wine, salts, &c., are dissolved; and this impure acetic acid is what we ordinarily term vinegar. The strongest vinegar sold in commerce contains 5 per cent. of real acetic acid. It is used as a mordant in calico-printing, as a local irritant in medicine, as a condiment, and in the preparation of various acetates, varnishes, &c. Pure acetic acid is got from the distillation of wood, by neutralising with lime, separating the tarry matters from the solution of acetate of lime, evaporating off the water, and treating the dry residue with sulphuric acid. On applying heat, pure acetic acid distills over as a clear liquid, which, after a short time, if the weather is cold, becomes a crystalline mass known by the name of Glacial Acetic Acid. For synthesis, properties, &c., see CHEMISTRY.

ACHAIA, in *Ancient Geography*, a name differently applied at different periods. In the earliest times the name was borne by a small district in the south of Thessaly, and was the first residence of the Achæans. At a later period *Achaia Propria* was a narrow tract of country in the north of the Peloponnesus, running 65 miles along the Gulf of Corinth, and bounded by the Ionian Sea on the W., by Elis and Arcadia on the S., and by Sicyonia on the E. On the south it is separated from Arcadia by lofty mountains, but the plains between the mountains and the sea are very fertile. Its chief town was Patræ. The name of Achaia was afterwards employed to denote collectively the states that joined the Achæan League. When Greece was subdued by the Romans, *Achaia* was the name given to the most southerly of the provinces into which they divided the country, and included the *Peloponnesus*, the greater part of Greece Proper, and the islands.

Achæans and the Achæan League.—The early inhabitants of Achaia were called *Achæans*. The name was given also in those times to some of the tribes occupying the eastern portions of the Peloponnesus, particularly *Argos* and *Sparta*. Afterwards the inhabitants of Achaia Propria appropriated the name. This republic was not considerable, in early times, as regards either the number of its troops, its wealth, or the extent of its territory, but was famed for its heroic virtues. The Crotonians and Sybarites, to re-establish order in their towns, adopted the laws and customs of the Achæans. After the famous battle of Leuctra, a difference arose betwixt the Lacedæmonians and Thebant, who held the virtue of this people in such veneration, that they terminated the dispute by their decision. The government of the Achæans was democratical. They preserved their liberty till the time of Philip and Alexander; but in the reign of these princes, and afterwards, they were either subjected to the Macedonians, who had made themselves masters of Greece, or oppressed by domestic tyrants. The Achæan commonwealth consisted of twelve inconsiderable towns in Peloponnesus. About 280 years before Christ the republic of the Achæans recovered its old institutions and unanimity. This was the renewal of the ancient confederation, which subsequently became so famous under the name of the ACHÆAN LEAGUE—having for its object, not as formerly a common worship, but a substantial political union. Though dating from the year B.C. 280, its importance may be referred to its connection with Aratus of Sicyon, about 30 years later, as it was further augmented by the splendid abilities of Philopœmen. Thus did this people, so celebrated in the heroic age, once more emerge from comparative obscurity, and become the greatest among the states of Greece in the last days of its national independence. The inhabitants of Patræ and of Dyme were the first assertors of ancient liberty. The tyrants were banished, and the towns again made one commonwealth. A public council was then held, in which affairs of importance were discussed and determined; and a register was provided for recording the transactions of the council. This assembly had two presidents, who were nominated alternately by the different towns. But instead of two presidents, they soon elected but one. Many neighbouring towns, which admired the constitution of this republic, founded on equality, liberty, the love of justice, and of the public good, were incorporated with the Achæans, and admitted to the full enjoyment of their laws and privileges. The Achæan League affords the most perfect example in antiquity of the federal form of government; and, allowing for difference of time and place, its resemblance to that of the United States government is very remarkable. (See Arts. AMPHICTYONY and FEDERAL GOVERNMENT; also Freeman's *Federal Government*, 2 vols. 8vo. 1863, and *Comparative Politics*, 8vo. 1873; Droysen, *Geschichte des Hellenismus*, 2 vols.; Helwing, *Geschichte des Achaïschen Bundes*.)

ACHAN, the son of Carmi, of the tribe of Judah, at the taking of Jericho concealed two hundred shekels of silver, a Babylonish garment, and a wedge of gold, contrary to the express command of God. This sin proved fatal to the Israelites, who were repulsed at the siege of Ai. In this emergency Joshua prostrated himself before the Lord, and begged that he would have mercy upon his people. Achan was discovered by casting lots, and he and his children were stoned to death. This expiation being made, Ai was taken by stratagem. (Josh. vii. viii.)

ACHARD, FRANZ CARL, a Prussian chemist, born at Berlin on the 28th April 1753, was the first to turn Marggraff's discovery of the presence of sugar in beet-root to commercial account. He erected a factory on an estate in Silesia, granted to him about 1800 by the king of Prussia, and produced there large quantities of sugar to meet the scarcity occasioned by the closing of the West Indian ports to continental traders. In 1812 a similar establishment was erected by Napoleon at Rambouillet, although the Institute of France in 1800, while honouring Achard for his researches, had declared his process to have little practical value. At the close of the war the manufacture of beet-root sugar was protected by duties on other sugars that were almost prohibitive, so that the real worth of Achard's discoveries could not be tested. Achard was a frequent contributor to the *Memoirs of the Academy of Berlin*, and published in 1780 *Chymisch-Physische Schriften*, containing descriptions and results of his very numerous and carefully conducted experiments on the adhesion of bodies. He died in 1821.

ACHARIUS, ERIK, a Swedish physician and botanist, born at Gefle in 1757. The son of a comptroller of customs, he studied first in his native town, and then in 1773 at the University of Upsal, where Linnæus was one of his teachers. In 1782 he took the degree of M.D. at the University of Lund, and practised thereafter in various districts of Sweden. But the direction of his studies had been determined by his contact with Linnæus, and he found his appropriate sphere when he was appointed Professor of Botany at the Wadstena Academy in 1801. Five years before he had been admitted a member of the Academy at Stockholm. He devoted himself to the study of the cryptogamic orders of plants, and especially of the family of lichens. All his publications were connected with this subject, the *Lichenographia Universalis* (Göttingen, 1801) being the most important. Acharius died of apoplexy in 1819. His name has been given by botanists to more than one species of plants.

ACHATES, the faithful friend and companion of Æneas, celebrated in Virgil's *Æneid* as *fidus Achates*.

ACHEEN. See ACHIN.

ACHELOUS, the largest river in Greece, rises in Mount Pindus, and dividing Ætolia from Acarnania, falls into the Ionian Sea. In the lower part of its course the river winds in an extraordinary manner through very fertile but marshy plains. Its water descends from the mountains, heavily charged with fine mud, which is deposited along its banks and in the sea at its mouth, where a number of small islands have gradually been formed. It was formerly called *Thoas*, from its impetuosity in its upper portion, and Homer gave it the name of *king of rivers*. It has a course of 130 miles. The epithet *Acheloius* is used for *aqueus* (Virgil), the ancients calling all water *Achelous*, according to Ephorus. The river is now called *Aspro Potamo*.

ACHENWALL, GOTTFRIED, a German writer, celebrated as having formulated and developed the science (*Wissenschaft der Staaten*), to which he was the first to apply the name *scientia statistica*, or *statistics*. Born at Elbing, in East Prussia, in October 1719, he studied at Jena, Halle, and Leipsic, and took a degree at the last-named university. He removed to Marburg in 1746, where for two years he read lectures on history, and on the law of nature and of nations. Here, too, he commenced those inquiries in statistics by which his name became known. In 1748, having been invited by Münchhausen, the Hanoverian minister, to occupy a chair at the university, he removed to Göttingen, where he resided till his death in 1772. His chief works were connected with statistics. The *Staatsverfassungen der europäischen Reiche* appeared first in 1752, and revised editions—corrected from information which he travelled through England, France, and other countries to collect—were published in 1762 and 1768. He was married in 1752 to a lady named Walther, who obtained some celebrity by a volume of poems published in 1750, and by other writings.

ACHERON, in *Classical Mythology*, the son of Ceres, who, for supplying the Titans with drink when they were in contest with Jupiter, was turned into a river of Hades, over which departed souls were ferried on their way to Elysium. The name eventually was used to designate the whole of the lower world.

ACHILL, or "Eagle" Island, off the west coast of Ireland, forms part of the county of Mayo. It is of triangular shape, and extends 15 miles from east to west, and 12 from north to south, its total area being 51,521 acres. The island is very mountainous; its extreme western point, Achill Head, is a bold and rugged promontory rising to a height of 2222 feet above the sea. Large bogs, incapable of cultivation, alternate with the hills of this desolate isle, of whose extensive surface not more than 500 acres have been reclaimed. The inhabitants earn a scanty subsistence by fishing and tillage; their dwellings are miserable hovels. There is a mission-station on the island, and remains of ancient churches are still extant.

ACHILLES (Ἀχιλλεύς). When first taken up by the legendary history of Greece, the ancestors of Achilles were settled in Phthia and in Ægina. That their original seat, however, was in the neighbourhood of Dodona and the Achelous is made out from a combination of the following facts: That in the *Iliad* (xvi. 233) Achilles prays to Zeus of Dodona; that this district was the first to bear the name of Hellas; that the followers of Achilles at Troy were the only persons named Hellenes in the time of Homer

(Thucyd. i .3 ; cf. *Iliad*, ii. 684, where the more usual name of Myrmidones also occurs); that in Ægina Zeus was styled "Hellanios;" and that the name of Selloi, applied to the priesthood at Dodona, is apparently identical with the name Hellenes. Whether from this local connection the derivation of the name of Achilles from the same root as Ἀχελῷος should be preferred to the other derivations, such as Ἀχι-λεύς = Ἐχέλαος, "ruler," or Ἀχ-ιλεύς, = "the bane of the Ilians," remains undecided. But this is gained, that we see in what manner the legend of Achilles had its root in the earlier Pelasgic religion, his adherence to which in the prayer just cited would otherwise appear very strange on the part of a hero who, through the influence of Homer and his successors, is completely identified with the Olympian system of gods. According to the genealogy, Æacus had two sons, Peleus and Telamon, of whom the former became the father of Achilles—the latter, of Ajax; but of this relationship between Achilles and Ajax there is no sign in the *Iliad*. Peleus ruled in Phthia ; and the gods remarking his piety, rewarded him with, among other presents, a wife in the person of the beautiful nereid Thetis. After her son was born, Thetis appears to have returned to her life in the sea. The boy was placed under his father's friend, the centaur Cheiron. When six years old he slew lions and boars, and could run down a stag. When nine, he was removed from his instruction to the island of Scyrus, where, dressed as a girl, he was to be brought up among the daughters of Lycomedes, his mother preferring for him a long inglorious life to a brief but splendid career. The same desire for his safety is apparent in other legends, which describe her as trying to make him invulnerable when a child by placing him in boiling water or in a fire, and then salving him with ambrosia; or again, in later story, by dipping him in the river Styx, from which he came out, all but the heel which she held, proof against wounds. When the aid of Achilles was found indispensable to the expedition against Troy, Odysseus set out for Scyrus as a pedlar, spread his wares, including a shield and spear, before the king's daughters, among whom was Achilles in disguise. Then he caused an alarm of danger to be sounded, upon which, while the girls fled, Achilles seized the arms, and thus revealed himself. Provided with a contingent of 50 ships, and accompanied by the aged Phœnix and Patroclus, he joined the expedition, which after occupying nine years in raids upon the towns in the neighbourhood of Troy and in Mysia, as detailed in the epic poem entitled the *Cypria*, culminated in the regular siege of Troy, as described in the *Iliad*, the grand object of which is the glorification of our hero. Estranged from his comrades, because his captive Briseïs had been taken from him, Achilles remained inexorable in his tent, while defeat attended the Greeks. At length, at their greatest need, he yielded so far as to allow Patroclus to take his chariot and to assume his armour. Patroclus fell, and the news of his death roused Achilles, who, now equipped with new armour fashioned by Hephæstus, drove back the Trojans, slew Hector, and after dragging his body thrice round the Trojan walls, restored it to Priam. With the funeral rites of Patroclus the *Iliad* concludes, and the story is taken up by the *Æthiopis*, a poem by Arctinus of Miletus, in which is described the combat of Achilles first with the amazon Penthesilea, and next with Memnon. When the latter fell, Achilles drove back the Trojans, and, impelled by fate, himself advanced to the Scæan gate, where an arrow from the bow of Paris struck his vulnerable heel, and he fell, bewailed through the whole camp. (A. S. M.)

ACHILLES TATIUS, a Greek writer, born at Alexandria. The precise time when he flourished is uncertain, but it cannot have been earlier than the 5th century, as in his principal work he evidently imitates Heliodorus. Suidas, who calls him Achilles Statius, says that he was converted from heathenism and became a Christian bishop, but this is doubtful, the more so that Suidas also attributes to him a work on the sphere (περὶ σφαίρας) which is referred to by Firmicus (330-50), and must, therefore, have been written by another person. The erotic romance of Achilles Tatius, entitled *The Loves of Clitophon and Leucippe*, is almost certainly the work of a heathen writer. The style of the work is ornate and rhetorical, while the story is often unnatural, and sometimes coarse, and the development of the plot irregular and frequently interrupted. Its popularity at the time it appeared is proved by the many manuscripts of it which still exist, and the value attached to it by modern scholars and critics is seen in the frequency with which it has been reprinted and translated. A Latin translation by Annibal Cruceeius was published, first in part at Leyden in 1544, and then complete at Basel in 1554. The Greek text was first printed by Commelin, at Heidelberg, in 1601. Other editions by Salmasius (Leyden, 1640), Mitscherlich (Biponti, 1792), and Jacobs (Leipsic, 1821), have been superseded by the editions of Hirschig (Paris, 1856), and Hercher (Leipsic, 1857). An English translation by A. H. (Anthony Hodges) appeared at Oxford in 1638.

ACHILLINI, Alexander (1463–1512), a native of Bologna, was celebrated as a lecturer both in medicine and in philosophy, and was styled the second Aristotle. He and Mundinus were the first at Bologna to avail themselves of the permission given by Frederick II. to dissect dead bodies. His philosophical works were printed in one volume folio, at Venice, in 1508, and reprinted with considerable additions in 1545, 1551, and 1568. He also wrote several medical works, chiefly on anatomy.

ÁCHÍN (pronounced *Atcheen*), a town and also a state of Northern Sumatra; the one state of that island which has been powerful at any time since the discovery of the Cape route to the East, and the only one that still remains independent of the Dutch, though that independence is now menaced.

De Barros names Áchín among the twenty-nine states that divided the sea-board of Sumatra when the Portuguese took Malacca. Northern Sumatra had been visited by several European travellers in the Middle Ages, such as Marco Polo, Friar Odorico, and Nicolo Conti. Some of these as well as Asiatic writers mention Lambri, a state which must have nearly occupied the position of Áchín. But the first voyager to visit Áchín, by that name, was Alvaro Tellez, a captain of Tristan d'Acunha's fleet, in 1506. It was then a mere dependency of the adjoining state of Pedir; and the latter, with Pasci, formed the only states on the coast whose chiefs claimed the title of Sultan. Yet before twenty years had passed Áchín had not only gained independence, but had swallowed up all other states of Northern Sumatra. It attained its climax of power in the time of Sultan Iskandar Muda (1607–1636), under whom the subject coast extended from Aru opposite Malacca round by the north to Padang on the west coast, a sea-board of not less than 1100 miles; and besides this, the king's supremacy was owned by the large island of Nyás, and by the continental Malay states of Johōr, Páháng, Quedah, and Perák.

The present limits of Áchín supremacy in Sumatra are reckoned to be, on the east coast the River Tamiang, in about 4° 25′ N. lat., which forms the frontier of territories tributary to Siák; and on the west coast a line in about 2° 48′ N., the frontier of Trumon, a small modern state lying between Áchín and the Dutch government of Padang. Even within these limits the actual power of Áchín is precarious, and the interior boundary can be laid down only from conjecture. This interior country is totally unexplored. It is believed to be inhabited by tribes kindred to the Battas, that remarkable race of anthropophagi who adjoin on the south. The whole area of Áchín territory, defined to the best of our ability, will contain about 16,400 English square miles. A rate of 20 per square mile, perhaps somewhat too large an average, gives a probable population of 328,000.

The production of rice and pepper forms the chief industry of the Áchín territory. From Pedir and other ports on the north coast large quantities of betel-nut are exported to continental India, to Burmah, and to Penang for China. Some pepper is got from Pedir, but the chief export is from a number of small ports and anchorages on the west coast, where vessels go from port to port making up a cargo. Áchín ponies are of good repute, and are exported. Minor articles of export are sulphur, iron, sappan-wood, gutta-percha, *dammer*, rattans, bamboos, benzoin, and camphor from the interior forests. The camphor is that from the *Dryabalanops camphora*, for which so high a price is paid in China, and the whole goes thither, the bulk of that whole being, however, extremely small. Very little silk is now produced, but in the 16th century the quantity seems to have been considerable. What is now wanted for the local textures, which are in some esteem, is imported from China.

The chief attraction to the considerable trade that existed at Áchín two centuries ago must have been gold. No place in the East, unless Japan, was so abundantly supplied with gold. We can form no estimate of the annual export, for it is impossible to accept Valentyn's statement that it sometimes reached 80 bahars (512,000 ounces!). Crawford (1820), who always reckoned low, calculated the whole export of Sumatra at 35,530 ounces, and that of Áchín at 10,450; whilst Anderson (1826), who tends to put figures too high, reckoned the whole Áchín export alone at 32,000 ounces. The chief imports to Áchín are opium (largely consumed), rice (the indigenous supply being inadequate), salt, iron ware, piece-goods, arms and ammunition, vessels of copper and pottery, China goods of sorts, and a certain kind of dried fish.

The great repute of Áchín at one time as a place of trade is shown by the fact, that to this port the first Dutch (1599) and first English (1602) commercial ventures to the Indies were directed. Lancaster, the English commodore, carried letters from Queen Elizabeth to the king of Áchín, and was well received by the prince then reigning, Aláuddín Sháh. Another exchange of letters took place between King James I. and Iskandar Muda in 1613. But native caprice and natural jealousy at the growing force of the European nations in those seas, the reckless rivalries of the latter and their fierce desire for monopoly, were alike destructive of sound trade; and the English factory, though several times set up, was never long maintained. The French made one great effort under Beaulieu (1621) to establish relations with Áchín, but nothing came of it.

Still the foreign trade of Áchín, though subject to spasmodic interruptions, was important. Dampier and others speak of the number of foreign merchants settled there,—English, Dutch, Danes, Portuguese, Chinese, Banyans from Guzerat, &c. Dampier says the roads were rarely without ten or fifteen sail of different nations, bringing vast quantities of rice, as well as silks, chintzes, muslins, and opium. Besides the Chinese merchants settled at Áchín, others used to come annually with the junks, ten or twelve in number, which arrived in June. A regular fair was then established, which lasted two months, and was known as the China camp,—a lively scene, and great resort of foreigners.

The Áchínese are not identical with the Malays proper either in aspect or language. They are said to be taller, handsomer, and darker, as if with a mixture of blood from India proper. Their language is little known; but though it has now absorbed much Malay, the original part of it is said to have characteristics connecting it both with the Batta and with the Indo-Chinese tongues. The Áchín literature, however, is entirely Malay; it embraces poetry, a good deal of theology, and several chronicles.

The name of the state is properly *Ácheh*. This the Portuguese made into *Achem;* whilst we, with the Dutch, learned to call it *Áchín*. The last appears to have been a Persian or Indian form, suggested by jingling analogy with Máchín (China).

The town itself lies very near the north-west extremity of Sumatra, known in charts as Áchín Head. Here a girdle of ten or twelve small islands affords protection to the anchorage. This fails in N.W. winds, but it is said that vessels may find safe riding at all seasons by shifting their berths. The town lies between two and three miles from the sea, chiefly on the left bank of a river of no great size. This forms a swampy delta, and discharges by three mouths. The central and chief mouth is about 100 yards wide, and has a depth of 20 to 30 feet within the bar. But the latter has barely 4 feet at low tide; at high tide it admits native craft of 20 or 30 tons, and larger craft in the rainy season. The town, like most Malay towns, consists of detached houses of timber and thatch, clustered in enclosed groups called *kampongs*, and buried in a forest of fruit-trees. The chief feature is the palace of the Sultan, which communicates with the river by a canal, and is enclosed, at least partially, by a wall of cut stone.

The valley or alluvial plain in which Áchín lies is low, and subject to partial inundation; but it is shut in at a short distance from the town, on the three landward sides, by hills. It is highly cultivated, and abounds in small villages and kampongs, with white mosques interspersed. The hills to the eastward are the spurs of a great volcanic mountain, upwards of 6000 feet in height, called by natives Yamuria, by mariners "the Golden Mountain."[1] Of the town population we find no modern estimate.

The real original territory of the Áchínese, called by them Great Áchín (in the sense of Áchín proper), consists of three districts immediately round the city, distinguished respectively as the 26, the 25, and the 22 múkims[2] (or hundreds, to use the nearest English term).

Each of these three districts has two heads, called *panglimas;* and these, according to some modern accounts, constitute the council of state, who are the chief administrators, and in whose hands it lies to depose the sovereign or to sanction his choice of a successor. Late notices speak of a chief minister, apparently distinct from these; and another important member of the government is the Shábandar, who is over all matters of customs, shipping, and commerce.

The court of Áchín, in the 17th century, maintained a good deal of pomp; and, according to Beaulieu, the king had always 900 elephants. These animals, though found throughout Sumatra, are now no longer tamed or kept.

Hostilities with the Portuguese began from the time of the first independent king of Áchín; and they had little remission till the power of Portugal fell with the loss of Malacca (1641). Not less than ten times before that event were armaments despatched from Áchín to reduce Malacca, and more than once its garrison was very hard pressed. One of these armadas, equipped by Iskandar Muda in 1615, gives an idea of the king's resources. It consisted of 500 sail, of which 250 were galleys, and

[1] Several other great volcanic cones exist in the Áchín territory, and two visible from seaward rise to a height of 11,000 feet or more in the unexplored interior.

[2] A múkim is said properly to embrace 44 households.

among these a hundred were greater than any then used in Europe. 60,000 men were embarked, with the king and his women.

On the death of Iskandar's successor in 1641, the widow was placed on the throne; and as a female reign favoured the oligarchical tendencies of the Malay chiefs, three more queens were allowed to reign successively. Though this series of female sovereigns lasted only fifty-eight years altogether, so dense is apt to be the ignorance of recent history, that long before the end of that period it had become an accepted belief among foreign residents at Áchín that there never had been any sovereigns in Áchín except females; and hence, by an easy inference, that the Queen of Sheba had been Queen of Áchín!

In 1699 the Arab or fanatical party suppressed female government, and put a chief of Arab blood on the throne. The remaining history of Áchín is one of rapid decay. Thirty sovereigns in all have reigned from the beginning of the 16th century to the present day.

After the restoration of Java to the Netherlands in 1816, a good deal of weight was attached by the neighbouring English colonies to the maintenance of our influence in Áchín; and in 1819 a treaty of friendship was concluded with the Calcutta Government, which excluded other European nationalities from fixed residence in Áchín. When the home Government, in 1824, made a treaty with the Netherlands, surrendering our remaining settlements in Sumatra in exchange for certain possessions on the continent of Asia, no reference was made in the articles to the Indian treaty of 1819; but an understanding was exchanged that it should be modified by us, whilst no proceedings hostile to Áchín should be attempted by the Dutch.

This reservation was formally abandoned by our Government in a convention signed at the Hague, November 2, 1871; and little more than a year elapsed before the government of Batavia declared war upon Áchín. Doubtless there was provocation, as there always will be between such neighbours; but the necessity for war has been greatly doubted, even in Holland. A Dutch force landed at Áchín in April 1873, and attacked the palace. It was defeated with considerable loss, including that of the general (Köhler). The approach of the south-west monsoon was considered to preclude the immediate renewal of the attempt; but hostilities were resumed, and Áchín fell in January 1874.

(De Barros; Faria y Souza; Valentyn, vol. v.; Beaulieu (in Thévenot's Collection); Dampier; Marsden; Crawfurd's *Hist. and Decl. of the Ind. Archip.; J. of Ind. Archip.;* Dulaurier in *J. Asiatique*, 3d s. vol. viii.; Anderson's *Acheen*, 1840; Veth, *Atchin*, &c. Leyden, 1873, &c.) (H. Y.)

ACHMET, or AHMED, the name of three emperors or sultans of Turkey, the first of the name reigning from 1603 to 1617, the second from 1691 to 1695. Achmet III. succeeded his brother Mustapha II., whom the Janissaries deposed in 1703. After the battle of Pultowa in 1709, Charles XII. of Sweden took refuge with him, and incited him to war with Peter the Great, Czar of Russia. Achmet recovered the Morea from the Venetians (1715); but his expedition into Hungary was less fortunate, his army being defeated at Peterwardein by Prince Eugene in 1716, and again near Belgrade the year after. The empire was distracted during his reign by political disturbances, which were occasioned, in part at least, by his misgovernment; and the discontent of his soldiers at last (1730) drove him from the throne. He died in prison in 1736.

ACHRAY, a small picturesque lake in Perthshire, near Loch Katrine, 20 miles W. of Stirling, which has obtained notoriety from Scott's allusion to it in the *Lady of the Lake.*

ACHROMATIC GLASSES are so named from being specially constructed with a view to prevent the confusion of colours and distortion of images that result from the use of lenses in optical instruments. When white light passes through a lens, the different-coloured rays that constitute it are refracted or bent aside at different angles, and so converge at different foci, producing a blurred and coloured image. To remedy this compound lenses have been devised, which present a well-defined image, unsurrounded by coloured bands of light. To instruments fitted with lenses of this kind has been given the name *achromatic*, from ἀ privative, and χρῶμα, colour. The celebrated optician, John Dollond, was the first to surmount this practical difficulty, about the year 1757, by the use of a combination of crown and flint glass. See OPTICS, MICROSCOPE, &c.

ACI REALE, a city and seaport of Sicily, in the Italian province of Catania, near the base of Mount Etna. It stands on solidified lava, which has here been deposited by different streams to a depth of 560 feet. The town, which has been almost entirely re-erected since the earthquake of 1693, is built of lava, contains many handsome edifices, and is defended by a fortress. Linen, silks, and cutlery are manufactured, and the trade in cotton, flax, grain, and wines is considerable. The place is celebrated for its cold sulphurous mineral waters. Near Aci Reale is the reputed scene of the mythical adventures of Acis and Galatea; and on this account several small towns in the neighbourhood also bear the name of Aci, such as Aci Castello, Aci Terra, &c. Aci Reale has a population of 24,151.

ACID, a general term in chemistry, applied to a group of compound substances, possessing certain very distinctive characteristics. All acids have one essential property, viz., that of combining chemically with an alkali or base, forming a new compound that has neither acid nor alkaline characters. The new bodies formed in this way are termed *salts.* Every acid is therefore capable of producing as many salts as there are basic substances to be neutralised; and this salt-forming power is the best definition of an acid substance.

The majority of acids possess the following *contingent* properties:—

1. When applied to the tongue, they excite that sensation which is called *sour* or *acid.*

2. They change the blue colours of vegetables to a red. The vegetable blues employed for this purpose are generally tincture of litmus and syrup of violets or of radishes, which have obtained the name of *re-agents* or *tests.* If these colours have been previously converted to a *green* by alkalies, the acids restore them.

All these secondary properties are variable; and if we attempted to base a definition on any one of them, many important acids would be excluded. Take the case of a body like silica, so widely diffused in nature. Is pure silicious sand or flint an acid or a neutral substance? When it is examined, it is found to be insoluble in water, to be devoid of taste, and to possess no action on vegetable colouring matters; yet this substance is a true acid, because when it is heated along with soda or lime, it forms the new body commonly called glass, which is chemically a salt of silicic acid. Many other acids resemble silica in properties, and would be mistaken for neutral bodies if the salt-forming power was overlooked.

Another method of regarding an acid, which is found of great importance in discussing chemical reactions, is to say an acid is a *salt* whose base is *water.* This definition is very apparent if we regard what takes place in separating the acid from a salt. In this decomposition the acid would appear to be left without having any substitute for the removed alkali. This is not however the case, as *water* is found to enter into union instead of the base. Thus every true acid must contain *hydrogen;* and if this is displaced by a metal, salts are formed directly. An acid is therefore a salt, whose metal is *hydrogen*. The full importance of the definition of an acid will be learned under the heading CHEMISTRY.

ACIDALIUS, VALENS, a very distinguished scholar and critic, born in 1567 at Wittstock, in Brandenburg. After studying at Rostock and Helmstaedt, and residing about three years in Italy, he took up his residence at Breslau, where he professed the Roman Catholic religion. His excessive application to study was supposed to have caused his untimely death, which occurred in 1595, when he had just completed his twenty-eighth year. He wrote notes on Tacitus and Curtius, a commentary on Plautus, and a number of poems, which are inserted in the *Deliciæ* of the German poets. Baillet gave him a place among his *Enfans Célèbres*, and tells that he wrote the commentary on Plautus and several of the Latin poems when he was only seventeen or eighteen years of age.

ACINACES, an ancient Persian sword, short and straight, and worn, contrary to the Roman fashion, on the right side, or sometimes in front of the body, as shown in the bas-reliefs found at Persepolis. Among the Persian nobility they were frequently made of gold, being worn as a badge of distinction. The acinaces was an object of religious worship with the Scythians and others (*Herod.* iv. 62).

ACIS, in *Mythology*, the son of Faunus and the nymph Symæthis, was a beautiful shepherd of Sicily, who being beloved by Galatea, Polyphemus the giant was so enraged that he crushed his rival with a rock, and his blood gushing forth from under the rock, was metamorphosed into the river bearing his name (Ovid, *Met.* xiii. 750; Sil. Ital. xiv. 221). This river, now *Fiume di Jaci*, or *Acque Grandi*, rises under a bed of lava on the eastern base of Etna, and passing Aci Reale, after a rapid course of one mile, falls into the sea. The waters of the stream, once celebrated for their purity, are now sulphureous.

ACKERMANN, JOHN CHRISTIAN GOTTLIEB, a learned physician and professor of medicine, born at Zeulenroda, in Upper Saxony, in 1756. At the early age of fifteen he became a student of medicine at Jena, where he soon attracted the favourable notice of Baldinger, who undertook the direction of his studies. When Baldinger was transferred to Göttingen in 1773, Ackermann went with him, and afterwards studied for two years at Halle. A few years' practice at Stendal (1778–99), where there were numerous factories, enabled him to add many valuable original observations to his translation of Ramazzini's *Treatise of the Diseases of Artificers* (1780–83). In 1786 he became professor of medicine at the university of Altorf, in Franconia, occupying first the chair of chemistry, and then, from 1794 till his death in 1801, that of pathology and therapeutics. Dr Ackermann's knowledge of the history of medicine may be estimated by his valuable contributions to Harless's edition of Fabricius' *Bibliotheca Græca*. He wrote numerous original works, besides translations.

ACŒMETÆ (ἀκοίμητος, sleepless), an order of monks instituted by Alexander, a Syrian, about the middle of the 5th century. Founding on the precept, *Pray without ceasing*, they celebrated divine service uninterruptedly night and day, for which purpose they divided themselves into three sections, that relieved each other in turn. The chief seat of the Acœmetæ was the cloister *Studium* at Constantinople, whence they were sometimes called *Studites*. Having adopted the monophysite heresy, they were put under the Papal ban about the year 536.

ACOLYTE (from ἀκόλουθος, an attendant), one of a minor order of clergy in the ancient church, ranking next to the sub-deacon. We learn from the canons of the fourth Council of Carthage that the archdeacon, at their ordination, put into their hands a candlestick with a taper and an empty pitcher, to imply that they were appointed to light the candles of the church and to furnish wine for the eucharist. Their dress was the cassock and surplice. The name and office still exist in the church.

ACONCAGUA, a province of Chile, South America, is about 100 miles long by 40 miles wide, and lies between 31° 30′ and 33° 20′ S. lat., and 70° and 71° 30′ W. long., between the provinces of Valparaiso and Santiago on the N. and Coquimbo on the S. A large part of the province is mountainous, but it contains several rich and fertile valleys, which yield wheat, maize, sugar-cane, fruits, and garden produce in abundance. In the agricultural districts there are raised from 50 to 60 fanegas of wheat for every quadra, equal to about 35 bushels per English acre. The province has also mineral resources, but not to such extent as Coquimbo or Atacama. Its chief town is San Felipe. The mountain Acóncagua, one of the loftiest peaks of the Andes, rises to the height of 23,910 feet above the sea on the frontier between this province and Mendoza, a department of the Argentine Republic. A river of the same name rises on the south side of the mountain, and after a course of 230 miles falls into the Pacific 12 miles N. of Valparaiso. Population (1870), 134,178.

ACONITE, ACONITUM, a genus of plants commonly known as Aconite, Monkshood, Friar's Cap, or Helmet flower, and embracing about 18 species, chiefly natives of the mountainous parts of the northern hemisphere. They are distinguished by having one of the five blue or yellow coloured sepals in the form of a helmet; hence the English name. Two of the petals placed under the hood of the calyx are supported on long stalks, and have a hollow spur at their apex. The genus belongs to the natural order Ranunculaceæ, or the Buttercup family. *Aconitum Napellus*, common monkshood, is a doubtful native of Britain. It is an energetic irritant and narcotic poison. It causes death by a depressing effect on the nervous system, by producing palsy of the muscles concerned in breathing, and by fainting. A tincture prepared by the action of spirit on the roots is used medicinally to allay pain, especially in cases of tic. Its roots have occasionally been mistaken for horse-radish. The Aconite has a short underground stem, from which dark-coloured tapering roots descend. The crown or upper portion of the root gives rise to new plants. When put to the lip, the juice of the Aconite root produces a feeling of numbness and tingling. The horse-radish root, which belongs to the natural order Cruciferæ, is much longer than that of the Aconite, and it is not tapering; its colour is yellowish, and the top of the root has the remains of the leaves on it. It has a pungent taste. Many species of Aconite are cultivated in gardens, some having blue and others yellow flowers. *Aconitum Lycoctonum*, Wolfsbane, is a yellow-flowered species common on the Alps of Switzerland. One species, *Aconitum heterophyllum*, found in the East Indies, and called Butees, has tonic properties in its roots. The roots of *Aconitum ferox* supply the famous Indian (Nipal) poison called Bikh, Bish, or Nabee. This species is considered by Hooker and Thomson as a variety of *Aconitum Napellus*. *Aconitum palmatum* yields another of the celebrated Bikh poisons. *Aconitum luridum*, of the Himalayas, also furnishes a poison.

ACONTIUS, the Latinised form of the name of GIACOMO ACONCIO, a philosopher, jurisconsult, engineer, and theologian, born at Trent on the 7th September 1492. He embraced the reformed religion; and after having taken refuge for a time in Switzerland and Strasburg, he came to England about 1558. He was very favourably received by

Queen Elizabeth, at whose court, it is said, though on doubtful authority, that he resided for a considerable period. With the sanction of Parliament, he carried on for several years extensive works for the embankment of the Thames, and so reclaimed a large quantity of waste land, part of which was bestowed upon him by way of recompense. His gratitude to Queen Elizabeth was expressed in the dedication to her of his celebrated *Collection of the Stratagems of Satan*, which has been often translated, and has passed through many editions. Various opinions have been given of this work, which advocated toleration to an extent that many considered indifference. The nature of its doctrine may perhaps be best gathered from the fact that it gained for the author the praise of Arminius, and the strong condemnation of the Calvinists. Acontius also wrote a treatise, *De Methodo*, which was published at Basel in 1558. He died in London about the year 1566.

ACORUS, a genus of monocotyledonous plants belonging to the natural order Aroideæ, and the sub-order Orontiaceæ. *Acorus Calamus*, sweet-sedge or sweet-flag, is a native of Britain. It has an agreeable odour, and has been used as a strengthening remedy, as well as to allay spasms. The starchy matter contained in its running stem or rhizome is associated with a fragrant oil, and it is used as hair-powder. Confectioners form a candy from the rhizomes of the plant, and it is also used by perfumers in preparing aromatic vinegar.

ACOSTA, Christoval d', a Portuguese naturalist, born at Mozambique in the early part of the 16th century. On a voyage to Asia he was taken captive by pirates, who exacted from him a very large ransom. After spending some years in India, chiefly at Goa, a Portuguese colony, he returned home, and settled as a surgeon at Burgos. Here he published his *Tratado de las drogas y medecinas de las Indias orientales* (1578). This work was translated into Latin, Italian, and French, became well known throughout Europe, and is still consulted as an authority. Acosta also wrote an account of his travels, a book in praise of women, and other works. He died in 1580.

ACOSTA, Joseph d', a celebrated Spanish author, was born at Medina del Campo about the year 1539. In 1571 he went to Peru as a provincial of the Jesuits; and, after remaining there for seventeen years, he returned to his native country, where he became in succession visitor for his order of Aragon and Andalusia, superior of Valladolid, and rector of the university of Salamanca, in which city he died in February 1600. About ten years before his death he published at Seville his valuable *Historia Natural y Moral de las Indias*, part of which had previously appeared in Latin, with the title *De Natura Novi Orbis, libri duo.* This work, which has been translated into all the principal languages of Europe, gives exceedingly valuable information regarding the condition of South America at the time. On the subject of climate Acosta was the first to propound the theory, afterwards advocated by Buffon, which attributed the different degrees of heat in the old and new continents to the agency of the winds. He also contradicted, from his own experience, the statement of Aristotle, that the middle zone of the earth was so scorched by the sun as to be destitute of moisture, and totally uninhabitable. Even after the discovery of America this Aristotelian dogma was an article of faith, and its denial was one ground of the charge of scepticism and atheism brought against Sir Walter Raleigh. Acosta, however, boldly declared that what he had seen was so different from what he had expected, that he could not but "laugh at Aristotle's meteors and his philosophy." In speaking of the conduct of his countrymen, and the means they employed for the propagation of their faith, Acosta is in no respect superior to the other prejudiced writers of his country and age. Though he acknowledges that the career of Spanish conquest was marked by the most savage cruelty and oppression, he yet represents this people as chosen by God to spread the gospel among the nations of America, and recounts a variety of miracles as a proof of the constant interposition of Heaven in favour of the merciless and rapacious invaders. Besides his History, Acosta wrote the following works:—1. *De Promulgatione Evangelii apud Barbaros*; 2. *De Christo Revelato*; 3. *De Temporibus Novissimis*, lib. vi.; 4. *Concionum tomi iii.*

ACOSTA, Uriel d', a Portuguese of noble family, was born at Oporto towards the close of the 16th century. His father being a Jewish convert to Christianity, he was brought up in the Roman Catholic faith, and strictly observed the rites of the church till the course of his inquiries led him, after much painful doubt, to abandon the religion of his youth for Judaism. Passing over to Amsterdam, he was received into the synagogue, having his name changed from Gabriel to Uriel. He soon discovered, however, that those who sat in Moses' seat were shameful perverters of the law; and his bold protests served only to exasperate the rabbis, who finally punished his contumacy with the greater excommunication. Persecution seemed only to stimulate his temerity, and he soon after published a defence, *Examen das tradiçoens Phariseas, &c.*, in which he not merely exposed the departures of the Jewish teachers from the law, but combated the doctrine of a future life, holding himself supported in this position by the silence of the Mosaic Books. For this he was imprisoned and fined, besides incurring public odium as a blasphemer and atheist. Nothing deterred, he pursued his speculations, which ended in his repudiating the divine authority of the law of Moses. Wearied, however, by his melancholy isolation, and longing for the benefits of society, he was driven, in the inconsistency of despairing scepticism, to seek a return to the Jewish communion. Having recanted his heresies, he was re-admitted after an excommunication of fifteen years, but was soon excommunicated a second time. After seven years of miserable exclusion, he once more sought admission, and, on passing through a humiliating penance, was again received. These notices of his singular and unhappy life are taken from his autobiography, *Exemplar Humanæ Vitæ*, published, with a "refutation," by Limborch, and republished in 1847. It has been said that he died by his own hand, but this is, to say the least, doubtful. His eventful history forms the subject of a tale and of a tragedy by Gutzkow.

ACOTYLEDONES, the name given to one of the Classes of the Natural System of Botany, embracing flowerless plants, such as ferns, lycopods, horse-tails, mosses, liverworts, lichens, sea-weeds, and mushrooms. The name is derived from the character of the embryo, which has no cotyledon. Flowering plants have usually one or two cotyledons, that is, seed-leaves or seed-lobes connected with their embryo; while in flowerless plants the body representing the embryo consists of a cell, called a spore, without any leaves. The plants have no flowers, and their organs of reproduction are inconspicuous, hence they are called by Linnæus cryptogamous. Some flowering plants, such as dodders, have no cotyledons; and some have the cotyledons divided into more than two, as in conifers. Some acotyledonous spores, when sprouting, produce a leaf-like expansion called a prothallus, on which the organs of reproduction, consisting of antheridia and archegonia, are produced. This is well seen in the case of ferns. In the interior of the antheridian cells, moving filamentous bodies, called spermatozoids, have been observed. These fertilise the archegonial cells, whence new plants are produced. In the article Botany these plants will be noticed under Class III. of the Natural System.

ACOUSTICS

1. Acoustics (from ἀκούω, to hear) is that branch of Natural Philosophy which treats of the nature of sound, and the laws of its production and propagation, in so far as these depend on physical principles. The description of the mechanism of the organ of voice and of the ear, and the difficult questions connected with the processes by which, when sound reaches the drum of the ear, it is transmitted to the brain, must be dealt with in separate articles of this work. It is to the physical part of the science of acoustics that the present article is restricted.

Part I.

General notions as to Vibrations, Waves, &c.

Sound is due to vibrations.

2. We may easily satisfy ourselves that, in every instance in which the sensation of sound is excited, the body, whence the sound proceeds, must have been thrown, by a blow or other means, into a state of agitation or tremor, implying the existence of a vibratory motion, or motion to and fro, of the particles of which it consists.

Thus, if a common glass-jar be struck so as to yield an audible sound, the existence of a motion of this kind may be felt by the finger lightly applied to the edge of the glass; and, on increasing the pressure so as to destroy this motion, the sound forthwith ceases. Small pieces of cork put in the jar will be found to dance about during the continuance of the sound; water or spirits of wine poured into the glass will, under the same circumstances, exhibit a ruffled surface. The experiment is usually performed, in a more striking manner, with a bell-jar and a number of small light wooden balls suspended by silk strings to a fixed frame above the jar, so as to be just in contact with the widest part of the glass. On drawing a violin bow across the edge, the pendulums are thrown off to a considerable distance, and falling back are again repelled, &c.

It is also in many cases possible to follow with the eye the motions of the particles of the sounding body, as, for instance, in the case of a violin string or any string fixed at both ends, when the string will appear, by a law of optics, to occupy at once all the positions which it successively assumes during its vibratory motion.

3. It is, moreover, essential, in order that the ear may be affected by a sounding body, that there be interposed between it and the ear one or more intermediate bodies (*media*), themselves capable of molecular vibration, which shall receive such motion from the source of sound, and transmit it to the external parts of the ear, and especially to the *membrana tympani* or *drum* of the ear. This statement is confirmed by the well-known effect of stopping the ear with soft cotton, or other substance possessing little elasticity.

The air around us forms the most important medium of communication of sound to our organs of hearing; in fact, were air devoid of this property, we should practically be without the sense of hearing. In illustration of the part thus assigned to the atmosphere in acoustics, an apparatus has been constructed, consisting of a glass receiver, in which is a bell and a hammer connected with clock-work, by which it can be made to strike the bell when required. The receiver is closed air-tight by a metal plate, through which passes, also air-tight, into the interior, a brass rod. By properly moving this rod with the hand, a detent is released, which checks the motion of the wheel-work, and the hammer strikes the bell continuously, till the detent is pushed into its original position. As long as the air in the receiver is of the usual atmospheric density, the sound is perfectly audible. But on rarefying the air by means of an air-pump (the clock-work apparatus having been separated from the plate of the pump by means of a padding of soft cotton), the sound grows gradually fainter, and at last becomes inaudible when the rarefaction of the air has reached a very low point. If, however, at this stage of the experiment, the metal rod be brought into contact with the bell, the sound will again be heard clearly, because now there is the necessary communication with the ear. On readmitting the air, the sound recovers its original intensity. This experiment was first performed by Hawksbee in 1705.

4. Inasmuch, then, as sound necessarily implies the existence in the sounding body, in the air, &c., and (we may add) in the ear itself, of vibratory motion of the particles of the various media concerned in the phenomenon, a general reference to the laws of such motion is essential to a right understanding of the principles of acoustics. Laws of vibratory motion

The most familiar instance of this kind of motion is afforded by the pendulum, a small heavy ball, for instance, attached to a fine string, which is fixed at its other end. There is but one position in which the ball will remain at rest, viz., when the string is vertical, there being then equilibrium between the two forces acting on the body, the tension of the string and the earth's attractive force or gravity. Thus, in the adjoining fig., if C is the point of suspension, and CA the vertical through that point of length l, equal to the string, A is the equilibrium position of the particle.

Let now the ball be removed from A to P, the string being kept tight, so that P describes the arc AP of a circle of radius equal to l, and let the ball be there dropped. The tension of the string not being now directly opposite in direction to gravity (g), motion will ensue, and the body will retrace the arc PA. In doing so, it will continually increase its velocity until it reaches the point A, where its velocity will be a maximum, and will consequently pass to the other side of A towards Q. But now gravity tends to draw it back towards A, and hence the motion becomes a retarded one; the velocity continually diminishes, and is ultimately destroyed at some point Q, which would be at a distance from A equal to that of P, but for the existence of friction, resistance of the air, &c., which make that distance less. From Q it will next move down with accelerated motion towards A, where it will have its greatest velocity in the direction from left to right, and whence it will pass onwards towards P, and so on. Thus the body will vibrate to and fro on either side of A, its *amplitude* of vibration or distance between its extreme positions gradually diminishing in consequence of the resistances before mentioned, and at last being sensibly reduced to nothing, the body then resuming its equilibrium-position A.

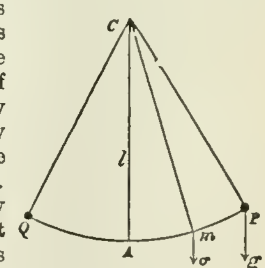

Fig. 1

If the amplitude of vibration is restricted within inconsiderable limits, it is easy to prove that the motion takes place just as if the string were removed, the ball deprived altogether of weight and urged by a force directed to the point A, and proportional to the distance from that point. For then, if m be any position of the ball, the chord mA may be regarded as coincident with the tangent to the circle at m, and therefore as being perpendicular to Cm. Hence g, acting parallel to CA, being resolved along Cm and mA, the former component is counteracted by the tension of the string, and there remains as the only effective acceleration, the tangential component along mA, which, by the triangle of forces, is equal to $g\cdot\frac{\mathrm{A}m}{\mathrm{C}m}$ or $\frac{g}{l}\cdot\mathrm{A}m$, and is therefore proportional to Am.

On this supposition of indefinitely small vibrations, the pendulum is isochronous; that is, the time occupied in passing from one extreme position to the other is the same, for a given length l of the pendulum, whatever the extent of vibration.

We conclude from this that, whatever may be the nature of the forces by which a particle is urged, if the resultant of those forces is directed towards a fixed point, and is proportional to the distance from that point, the particle will oscillate to and fro about that point in times which are independent of the amplitudes of the vibrations, provided these are very small.

5. The particle, whose vibratory motion we have been considering, is a solitary particle acted on by external forces. But, in acoustics, we have to do with the motion of particles forming a connected system or medium, in which the forces to be considered arise from the mutual actions of the particles. These forces are in equilibrium with each other when the particles occupy certain relative positions. But, if any new or disturbing force act for a short time on any one or more of the particles, so as to cause a mutual approach or a mutual recession, on the removal of the disturbing force, the disturbed particles will, if the body be *elastic*, forthwith move towards their respective positions of equilibrium. Hence arises a vibratory motion to and fro of each about a given point, analogous to that of a pendulum, the velocity at that point being always a maximum, alternately in opposite directions. Thus, for example, if to one extremity of a pipe containing air were applied a piston, of section equal to that of the pipe, by pushing in the piston slightly and then removing it, we should cause particles of air, forming a thin section at the extremity of the pipe, to vibrate in directions parallel to its axis.

In order that a medium may be capable of molecular vibrations, it must, as we have mentioned, possess *elasticity*, that is, a tendency always to return to its original condition when slightly disturbed out of it.

6. We now proceed to show how the disturbance whereby certain particles of an elastic medium are displaced from their equilibrium-positions, is successively transmitted to the remaining particles of the medium, so as to cause these also to vibrate to and fro.

Let us consider a line of such particles y, x, a, b, &c.

$$y \quad x\, a_1\, a\, a_2\, b \quad c \quad d \quad e \quad f \quad g \quad h \quad i \quad k \quad l \quad m \quad n \quad o \quad p$$

equidistant from each other, as above; and suppose one of them, say a, to be displaced, by any means, to a_1. As we have seen, this particle will swing from a_1 to a_2 and back again, occupying a certain time T, to complete its double vibration. But it is obvious that, the distance between a and the next particle b to the right being diminished by the displacement of the former to a_1, a tendency is generated in b to move towards a_1, the mutual forces being no longer in equilibrium, but having a resultant in the direction ba_1. The particle b will therefore also suffer displacement, and be compelled to swing to and fro about the point b. For similar reasons the particles c, d . . . will all likewise be thrown into vibration. Thus it is, then, that the disturbance propagates itself in the direction under consideration. There is evidently also, in the case supposed, a transmission from a to x, y, &c., *i.e.*, in the opposite direction.

Confining our attention to propagation in the direction abc . . ., we have next to remark that each particle in that line will be affected by the disturbance always later than the particle immediately preceding it, so as to be found in the same stage of vibration a certain interval of time after the preceding particle.

7. Two particles which are in the same stage of vibration, that is, are equally displaced from their equilibrium-positions, and are moving in the same direction and with equal velocities, are said to be in the same *phase*. Hence we may express the preceding statement more briefly thus. Two particles of a disturbed medium at different distances from the centre of disturbance, are in the same phase at different times, the one whose distance from that centre is the greater being later than the other.

8. Let us in the meantime assume that, the intervals ab, bc, cd . . . . being equal, the intervals of time which elapse between the like phases of b and a, of c and b . . . . are also equal to each other, and let us consider what at any given instant are the appearances presented by the different particles in the row.

T being the time of a *complete* vibration of each particle, let $\frac{\mathrm{T}}{p}$ be the interval of time requisite for any phase of a to pass on to b. If then at a certain instant a is displaced to its greatest extent to the right, b will be somewhat short of, but moving towards, its corresponding position, c still further short, and so on. Proceeding in this way, we shall come at length to a particle p, for which the distance $ap = p\,.\,ab$, which therefore lags in its vibrations behind a by a time $= p \times \frac{\mathrm{T}}{p} = \mathrm{T}$, and is consequently precisely in the same phase as a. And between these two particles a, p, we shall evidently have particles in all the possible phases of the vibratory motion. At h, which is at distance from $a = \frac{1}{2}ap$, the difference of phase, compared with a, will be $\frac{1}{2}$T, that is, h will, at the given instant, be displaced to the greatest extent on the opposite side of its equilibrium-position from that in which a is displaced; in other words, h is in the exactly opposite phase to a.

9. In the case we have just been considering, the vibrations of the particles have been supposed to take place in a direction coincident with that in which the disturbance passes from one particle to another. The vibrations are then termed *longitudinal*.

But it need scarcely be observed that the vibrations may take place in any direction whatever, and may even be curvilinear. If they take place in directions at right angles to the line of progress of the disturbance, they are said to be *transversal*.

10. Now the reasoning employed in the preceding case will evidently admit of general application, and will, in particular, hold for transversal vibrations. Hence if we mark (as is done in fig. 2) the positions a_1 b_1 c_1 . . ., occupied by the various particles, when swinging transversely, at the instant at which a has its maximum displacement *above* its equilibrium-position, and trace a continuous line running through the points so found, that line will by its ordinates indicate to the eye the state of motion at the given instant.

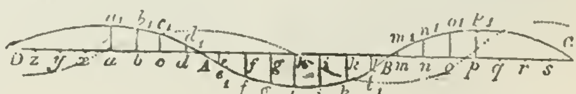

Fig. 2.

Thus a and p are in the *same* phase, as are also b and q, c and r, &c. a and h are in *opposite* phases, as are also b and i, c and k, &c.

Distances ap, bq, &c., separating particles in the same phase, and each of which, as we have seen, is passed over by the disturbance in the time T of a complete vibration, include within them *all* the possible phases of the motion.

Beyond this distance, the curve repeats itself exactly, that is, the phases recur in the same order as before.

Now the figure so traced offers an obvious resemblance to the undulating surface of a lake or other body of water, after it has been disturbed by wind, exhibiting a wave with its trough Ah_1B, and its crest Bp_1C. Hence have been introduced into Acoustics, as also into Optics, the terms *wave* and *undulation*. The distance ap, or bq . . . or A C, which separates two particles in same phase, or which includes both a wave-crest and a wave-trough, is termed the *length of the wave*, and is usually denoted by λ.

As the curve repeats itself at intervals each $=\lambda$, it follows that particles are in the same phase at any given moment, when the distances between them in the direction of transmission of the disturbance $=\lambda, 2\lambda, 3\lambda$ . . . and generally $=n\lambda$, where n is any whole number.

Particles such as a and h, b and i, &c., which are at distances $=\frac{1}{2}\lambda$, being in *opposite* phases, so will also be particles separated by distance, $\frac{1}{2}\lambda+\lambda=\frac{3}{2}\lambda$, or, in general, by $\frac{1}{2}\lambda+m\lambda=(2m+1)\frac{\lambda}{2}$, that is, by any *odd* multiple of $\frac{\lambda}{2}$.

Wave of velocities

11. A like construction to the one just adopted for the displacements of the particles at any given instant, may be also applied for exhibiting graphically their velocities at the same instant. Erect at the various points a, b, c, &c., perpendiculars to the line joining them, of lengths proportional to and in the direction of their velocities, and draw a line through the extreme points of these perpendiculars; this line will answer the purpose required. It is indicated by dots in the previous figure, and manifestly forms a wave of the same length as the wave of displacements, but the highest and lowest points of the one wave correspond to the points in which the other wave crosses the line of equilibrium.

Waves for longitudinal vibrations

12. In order to a graphic representation of the displacements and velocities of particles vibrating *longitudinally*, it is convenient to draw the lines which represent those quantities, not in the actual direction in which the motion takes place and which coincides with the line $a\,b\,c$ . . ., but at right angles to it, ordinates drawn upwards indicating displacements or velocities to the right (*i.e.*, in the direction of transmission of the disturbance), and ordinates drawn downwards indicating displacements or velocities in the opposite direction. When this is done, waves of displacement and velocity are figured identically with those for transversal vibrations, and are therefore subject to the same resulting laws.

13. But not only will the above waves enable us to see at a glance the circumstances of the vibratory motion at the instant of time for which it has been constructed, but also for any subsequent moment. Thus, if we desire to consider what is going on after an interval $\frac{T}{p}$, we have simply to conceive the whole wave (whether of displacement or velocity) to be moved to the right through a distance $=a\,b$. Then the state of motion in which a was before will have been transferred to b, that of b will have been transferred to c, and so on. At the end of another such interval, the state of the particles will in like manner be represented by the wave, if pushed onward through another equal space. In short, the whole circumstances may be pictured to the eye by two waves (of displacement and of velocity) advancing continuously in the line $a\,b\,c$ . . . with a velocity V which will take it over the distance ab in the time $\frac{T}{p}$, V being therefore $=\frac{ab}{\frac{T}{p}}=\frac{p.ab}{T}=\frac{AC}{T}$ or $V=\frac{\lambda}{T}$.

This is termed the velocity of propagation of the wave, and, as we see, is equal to the length of the wave divided by the time of a complete vibration of each particle.

If, as is usually more convenient, we express T in terms of the number n of complete vibrations performed in a given time, say in the unit of time, we shall have $\frac{1}{T}=n$, and hence

$$V=n\lambda.$$

14. There is one very important distinction between the two cases of longitudinal and of transversal vibrations which now claims our attention, viz., that whereas vibrations of the latter kind, when propagated from particle to particle in an elastic medium, do not alter the relative distances of the particles, or, in other words, cause no change of density throughout the medium; longitudinal vibrations, on the other hand, by bringing the particles nearer to or further from one another than they are when undisturbed, are necessarily accompanied by alternate condensations and rarefactions.

Thus, in fig. 2, we see that at the instant to which that fig. refers, the displacements of the particles immediately adjoining a are equal and in the same direction; hence at that moment the density of the medium at a is equal to that of the undisturbed medium. The same applies to the points h, p, &c., in which the displacements are at their maxima and the velocities of vibration $=0$.

At any point, such as c, between a and A, the displacements of the two adjoining particles on either side are both to the right, but that of the *preceding* particle is now the greater of the two, and hence the density of the medium throughout aA exceeds the undisturbed density. So at any point, such as f, between A and h, the same result holds good, because now the displacements are to the left, but are in excess on the right side of the point f. From a to h, therefore, the medium is condensed.

From h to B, as at k, the displacements of the two particles on either side are both to the *left*, that of the preceding particle being, however, the greater. The medium, therefore, is here in a state of rarefaction. And in like manner it may be shown that there is rarefaction from B to p; so that the medium is rarefied from h to p.

At A the condensation is a maximum, because the displacements on the two sides of that point are equal and both directed towards A. At B, on the other hand, it is the rarefaction which is a maximum, the displacements on the right and left of that point being again equal, but directed outwards from B.

It clearly follows from all this that, if we trace a curve of which any ordinate shall be proportional to the difference between the density of the corresponding point of the disturbed medium and the density of the undisturbed medium—ordinates drawn upwards indicating condensation, and ordinates drawn downwards rarefaction—that curve will cross the line of rest of the particles $a\,b\,c$ . . . in the same points as does the curve of velocities, and will therefore be of the same length λ, and will also rise above that line and dip below it at the same parts. But the connection between the *wave* of condensation and rarefaction and the wave of velocity, is still more intimate, when the extent to which the particles are displaced is very small, as is always the case in acoustics. For it may be shown that then the degree of condensation or rarefaction at any point of the medium is proportional to the velocity of vibration at that point. The same ordinates, therefore, will represent the degrees of condensation, which represent the velocities, or, in other words, the wave of condensation and rarefaction may be regarded as coincident with the velocity wave.

Part II.

Velocity of propagation of waves of longitudinal disturbance through any elastic medium.

15. Sir Isaac Newton was the first who attempted to determine, on theoretical grounds, the velocity of sound in air and other fluids. The formula obtained by him gives, however, a numerical value, as regards air, falling far short of the result derived from actual experiment; and it was not till long afterwards, when Laplace took up the question, that complete coincidence was arrived at between theory and observation. We are indebted to the late Professor Rankine, of Glasgow (*Phil. Trans.* 1870, p. 277)[1], for a very simple and elegant investigation of the question, which we will here reproduce in an abridged form.

Let us conceive the longitudinal disturbance to be propagated through a medium contained in a straight tube having a transverse section equal to unity, but of indefinite length.

Let two transverse planes A_1 A_2 (fig. 3) be conceived as moving along the interior of the tube in the same direction and with the same velocity V as the disturbance-wave itself.

Fig. 3.

Let u_1 u_2 be the velocities of displacement of the particles of the medium at A_1 A_2 respectively, at any given instant, estimated in the same direction as V; and ρ_1 ρ_2 the corresponding densities of the medium.

The disturbances under consideration, being such as preserve a permanent type throughout their propagation, it follows that the quantity of matter between A_1 and A_2 remains constant during the motion of these planes, or that as much must pass into the intervening space through one of them as issues from it through the other. Now at A_1 the velocity of the particles relatively to A_1 itself is $V - u_1$ *inwards*, and consequently there flows into the space A_1 A_2 through A_1 a mass $(V - u_1)\rho_1$ in the unit of time.

Forming a similar expression as regards A_2, putting m for the invariable mass through which the disturbance is propagated in the unit of time, and considering that if ρ denote the density of the undisturbed medium, m is evidently equal to $V\rho$, we have—

$$(V - u_1)\rho_1 = (V - u_2)\rho_2 = V\rho = m \quad . \quad . \quad (1.)$$

Now, $p_1 p_2$ being the pressures at A_1, A_2 respectively, and therefore $p_2 - p_1$ the force generating the acceleration $u_2 - u_1$, in unit of time, on the mass m of the medium, by the second law of motion,

$$p_2 - p_1 = m(u_2 - u_1) \quad . \quad . \quad . \quad (2.)$$

Eliminating u_1, u_2 from these equations, and putting for $\frac{1}{\rho_1}$, $\frac{1}{\rho_2}$, $\frac{1}{\rho}$ the symbols s_1, s_2, s (which therefore denote the volumes of the unit of mass of the disturbed medium at A_1, A_2, and of the undisturbed medium), we get:

$$m^2 = \frac{p_2 - p_1}{s_1 - s_2} \text{ and } V^2 = s^2\,\frac{p_2 - p_1}{s_1 - s_2}$$

Now, if (as is generally the case in sound) the changes of pressure and volume occurring during the disturbance of the medium are very small, we may assume that these changes are proportional one to the other. Hence, denoting the ratio which any increase of pressure bears to the diminution of the unit of volume of the substance, and which is termed the *elasticity* of the substance, by e, we shall obtain for the velocity of a wave of longitudinal displacements, supposed small, the equation:

$$\left.\begin{aligned} V &= \sqrt{es} \\ \text{or } V &= \sqrt{\frac{e}{\rho}} \end{aligned}\right\} \quad . \quad . \quad . \quad . \quad (I.)$$

16. In applying this formula to the determination of the velocity of sound in any particular medium, it is requisite, as was shown by Laplace, to take into account the thermic effects produced by the condensations and rarefactions which, as we have seen, take place in the substance. The heat generated during the sudden compression, not being conveyed away, raises the value of the elasticity above that which otherwise it would have, and which was assigned to it by Sir Isaac Newton.

Thus, in a *perfect* gas, it is demonstrable by the principles of Thermodynamics, that the elasticity e, which, in the undisturbed state of the medium, would be simply equal to the pressure p, is to be made equal to γp, where γ is a number exceeding unity and represents the ratio of the specific heat of the gas under constant pressure to its specific heat at constant volume.

Hence, as air and most other gases may be practically regarded as perfect gases, we have for them:

$$V = \sqrt{\gamma p s} = \sqrt{\frac{\gamma p}{\rho}} \quad . \quad . \quad . \quad (II.)$$

17. From this the following inference may be drawn:— The velocity of sound in a given gas is unaffected by change of pressure if unattended by change of temperature. For, by Boyle's law, the ratio $\frac{p}{\rho}$ is constant at a given temperature. The accuracy of this inference has been confirmed by recent experiments of Regnault. Velocity of sound in air is independent of the pressure.

18. To ascertain the influence of change of temperature on the velocity of sound in a gas, we remark that, by Gay Lussac's law, the pressure of a gas at different temperatures varies proportionally both to its density ρ and to $1 + \alpha t$, where t is the number of degrees of temperature above freezing point of water (32° Fahr.), and α is the expansion of unit of volume of the gas for every degree above 32°. Effect of change of temperature.

If, therefore, p, p_0, ρ, ρ_0 denote the pressures and densities corresponding to temperatures $32° + t°$ and $32°$, we have:

$$\frac{p}{p_0} = \frac{\rho}{\rho_0}\ (1 + \alpha t)$$

and hence, denoting the corresponding velocities of sound by V, V_0, we get:

$$\frac{V}{V_0} = \sqrt{(1 + \alpha t)}$$

whence, α being always a very small fraction, is obtained very nearly:

$$\frac{V}{V_0} = 1 + \frac{\alpha}{2}t \text{ and } V - V_0 = \frac{\alpha}{2}.t.V_0.$$

The velocity increases, therefore, by $\frac{\alpha}{2}V_0$ for every degree of rise of temperature above 32°.

19. The general expression for V given in (II.) may be put in a different form: if we introduce a height H of the gas, regarded as having the same density ρ throughout and exerting the pressure p, then $p = g\rho H$, where g is the acceleration of gravity, and there results: Another expression for V.

$$V = \sqrt{\gamma g H} \quad . \quad . \quad . \quad (III.)$$

Now $\sqrt{gH}$ or $\sqrt{2g.\frac{H}{2}}$ is the velocity U which would be acquired by a body falling *in vacuo* from a height $\frac{H}{2}$. Hence $V = U\sqrt{\gamma}$.

[1] See also Maxwell *Theory of Heat*, p. 203.

If γ were equal to 1, $V = U$, which is the result obtained by Newton, and would indicate that the velocity of sound in a gas equals the velocity of a body falling from a height equal to half of that of a homogeneous atmosphere of the gas.

20. In common dry air at 32° Fahr., g being 32·2 ft., and the mercurial barometer 30 ins. or 2·5 ft., the density of air is to that of mercury as 1 : 10,485·6; hence $H = 10,458·6 \times 2·5$ ft. $= 26,214$ ft.

Also $\gamma = 1·408$

Hence $V_0 = \sqrt{1,408 \times 32,2 \times 26,214} = 1090$ ft.

and, by § 18, the increase of velocity for each degree of rise of temperature $\left(a \text{ being } \frac{1}{491}\right)$ is $\frac{1090}{982}$ or $\frac{545}{491} = 1·110$ ft. $1\frac{1}{9}$ ft. very nearly.

21. If the value of γ were the same for different gases, it is obvious from formula $V = \sqrt{\gamma \frac{p}{\rho}}$ that, at a given temperature, the velocities of sound in those gases would be to each other inversely as the square roots of their densities. Regnault has found that this is so for common air, carbonic acid, nitrous oxide, hydrogen and ammoniacal gas (though less so as regards the two last).

22. The experimental determination of the velocity of sound in air has been carried out by ascertaining accurately the time intervening between the flash and report of a gun as observed at a given distance, and dividing the distance by the time. A discussion of the many experiments conducted on this principle in various countries and at various periods, by Van Der Kolk (*Lond. and Edin. Phil. Mag.*, July 1865), assigns to the velocity of sound in dry air at 32° Fahr., 1091 ft. 8 in. per second, with a probable error of ± 3·7 ft.; and still more recently (in 1871) Mr Stone, the Astronomer Royal at the Cape of Good Hope, has found 1090·6 as the result of careful experiments by himself there. The coincidence of these numbers with that we have already obtained theoretically sufficiently establishes the general accuracy of the theory.

23. Still it cannot be overlooked that the formula for V is founded on assumptions which, though approximately, are not strictly correct. Thus, the air is not a perfect gas, nor is the variation of elastic force, caused by the passage through it of a wave of disturbance always very small in comparison with the elastic force of the undisturbed air. Earnshaw (1858) first drew attention to these points, and came to the conclusion that the velocity of sound increases with its loudness, that is, with the violence of the disturbance. In confirmation of this statement, he appeals to a singular fact, viz., that, during experiments made by Captain Parry, in the North Polar Regions, for determining the velocity of sound, it was invariably found that the report of the discharge of cannon was heard, at a distance of $2\frac{1}{2}$ miles, perceptibly earlier than the sound of the word *fire*, which, of course, preceded the discharge.

As, in the course of propagation in unlimited air, there is a gradual decay in the intensity of sound, it would follow that the velocity must also gradually decrease as the sound proceeds onwards. This curious inference has been verified experimentally by Regnault, who found the velocity of sound to have decreased by 2·2 ft. per second in passing from a distance of 4000 to one of 7500 feet.

24. Among other interesting results, derived by the accurate methods adopted by Regnault, but which want of space forbids us to describe, may be mentioned the dependence of the velocity of sound on its pitch, lower notes being, *cæt. par.*, transmitted at a more rapid rate than higher ones. Thus, the fundamental note of a trumpet travels faster than its harmonics.

25. The velocity of sound in liquids and solids (the displacements being longitudinal), may be obtained by formula (I.), neglecting the thermic effects of the compressions and expansions as being comparatively inconsiderable, and may be put in other forms:

Thus, if we denote by ϵ the change in length of one foot of a column of the substance produced by its own weight w, then e being $= \frac{w}{\epsilon}$ or $\frac{g\rho}{\epsilon}$, we have $\frac{e}{\rho} = \frac{g}{\epsilon}$ and hence:

$$V = \sqrt{\frac{g}{\epsilon}} \quad . \quad . \quad . \quad . \quad \text{(IV.)}$$

or, replacing $\frac{1}{\epsilon}$ (which is the length in feet of a column that would be increased 1 foot by the weight of 1 cubic foot) by l,

$$V = \sqrt{gl} \qquad \text{(V.)}$$

which shows that the velocity is that due to a fall through $\frac{l}{2}$.

Or, again, in the case of a liquid, if η denote the change of volume, which would be produced by an increase of pressure equal to one atmosphere, or to that of a column H of the liquid, since ϵ is the change of volume due to weight of a column 1 of the liquid, and $\therefore \frac{\eta}{\epsilon} = \frac{H}{1}$ and $\frac{1}{\epsilon} = \frac{H}{\eta}$, we get

$$V = \sqrt{\frac{gH}{\eta}} \quad . \quad . \quad . \quad \text{(VI.)}$$

Ex. 1. For water, $\frac{1}{\eta} = 20,000$ very nearly; $H = 34$ ft and hence $V = 4680$ feet.

This number coincides very closely with the value obtained, whether by direct experiment, as by Colladon and Sturm on the Lake of Geneva in 1826, who found 4708, or by indirect means which assign to the velocity in the water of the River Seine at 59° Fahr. a velocity of 4714 ft. (Wertheim).

Ex. 2. For iron. Let the weight necessary to double the length of an iron bar be 4260 millions of lbs. on the square foot. Then a length l will be extended to $l + 1$ by a force of $\frac{4260 \text{ millions lbs.}}{l}$ on the sq. ft. This, therefore, by our definition of l, must be the weight of a cubic foot of the iron. Assuming the density of iron to be 7·8, and 62·32 lbs. as the weight of a cubic foot of water, we get $7·8 \times 62·32$ or 486 lbs. as the weight of an equal bulk of iron. Hence $\frac{4260 \text{ millions}}{l} = 486$ and $l = \frac{4260}{486}$ millions.

$$\text{which gives } V = \sqrt{gl} = \sqrt{\frac{32·2 \times 4260}{486} \text{ millions}}$$

$$= \sqrt{\frac{4260}{15}} \times 1000 = 1000\sqrt{284}$$

or $V = 17,000$ feet per second nearly.

As in the case of water and iron, so, in general, it may be stated that sound travels faster in liquids than in air, and still faster in solids, the ratio $\frac{e}{\rho}$ being least in gases and greatest in solids.

26. Biot, about 50 years ago, availed himself of the great difference in the velocity of the propagation of sound through metals and through air, to determine the ratio of the one velocity to the other. A bell placed near one extremity of a train of iron pipes forming a joint length of upwards of 3000 feet, being struck at the same instant as the same extremity of the pipe, a person placed at the other extremity heard first the sound of the blow on the pipe, conveyed through the iron, and then, after an interval

Experimental determination of V in solids.

of time, which was noted as accurately as possible, the sound of the bell transmitted through the air. The result was a velocity for the iron of 10·5 times that in air. Similar experiments on iron telegraph wire, made more recently near Paris by Wertheim and Brequet, have led to an almost identical number. Unfortunately, owing to the metal in those experiments not forming a continuous whole, and to other causes, the results obtained, which fall short of those otherwise found, cannot be accepted as correct.

Other means therefore, of an indirect character, to which we will refer hereafter, have been resorted to for determining the velocity of sound in solids. Thus Wertheim, from the pitch of the lowest notes produced by longitudinal friction of wires or rods, has been led to assign to that velocity values ranging, in different metals, from 16,822 feet for iron, to 4030 for lead, at temperature 68° Fahr., and which agree most remarkably with those calculated by means of the formula $V=\sqrt{\frac{e}{\rho}}$. He points out, however, that these values refer only to solids whose cross dimensions are small in comparison with their length, and that in order to obtain the velocity of sound in an unlimited solid mass, it is requisite to multiply the value as above found by $\sqrt{\frac{3}{2}}$ or $\frac{6}{5}$ nearly. For while, in a solid bar, the extensions and contractions due to any disturbance take place laterally as well as longitudinally; in an extended solid, they can only occur in the latter direction, thus increasing the value of e.

27. To complete the discussion of the velocity of the propagation of sound, we have still to consider the case of transversal vibrations, such as are executed by the points of a stretched wire or cord when drawn out of its position of rest by a blow, or by the friction of a violin-bow.

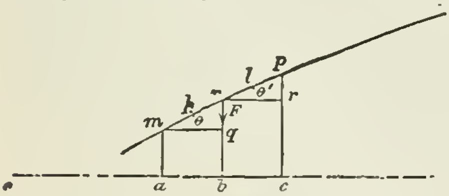

Fig. 4.

[Ve]locity of [pr]opaga[tio]n of [tra]nsversal [vib]rations.

Let ox (fig. 4) be the position of the string when undisturbed, mnp when displaced. We will suppose the amount of displacement to be very small, so that we may regard the distance between any two given points of it as remaining the same, and also that the tension P of the string is not changed in its amount, but only in its direction, which is that of the string.

Take any origin o in ox; and $ab=bc=\delta x$ (a very small quantity), then the perpendiculars am, bn, cp, are the displacements of abc. Let k, l be the middle points of mn, np; then kl (which $=mn$ or ab very nearly) may be regarded as a very small part of the string acted on by two forces each $=$ P, and acting at n in the directions np, nm. These give a component parallel to ac, which on our supposition is negligible, and another F along nb, such that

$$F=P(\sin\theta-\sin\theta')=P.\left(\frac{nq}{mn}-\frac{pr}{nq}\right)=P.\frac{nq-pr}{\delta x}.$$

Now if $c=$ a length of string of weight equal to P, and the string be supposed of uniform thickness and density, the weight of $kl=\frac{P}{c}.kl=\frac{P}{c}.\delta x$, and the mass m of $kl=\frac{P}{gc}.\delta x$.

Hence the acceleration f in direction nb is—

$$f=\frac{F}{m}=gc\frac{nq-pr}{\delta x^2}.$$

If we denote ma by y, oa by x, and the time by t, we shall readily see that this equation becomes ultimately,

$$\frac{d^2y}{dt^2}=gc\frac{d^2y}{dx^2}$$

which is satisfied by putting

$$y=\phi(x+\sqrt{gc}.t)+\psi(x-\sqrt{gc}.t)$$

where ϕ and ψ indicate any functions.

Now we know that if for a given value of t, x be increased by the length λ of the wave, the value of y remains unchanged; hence,

$$\phi(x+\sqrt{gc}.t)+\&c.=\phi(x+\lambda+\sqrt{gc}.t)\ \&c.$$

But this condition is equally satisfied for a given value of x, by increasing $\sqrt{gc}.t$. by λ, *i.e.*, increasing t by $\frac{\lambda}{\sqrt{gc}}$. This therefore must $=$ T (the time of a complete vibration of any point of the string). But $V=\frac{\lambda}{T}$. Hence,

$$V=\sqrt{gc}\quad.\quad.\quad.\quad.\quad.\quad(\text{VII.})$$

is the expression for the velocity of sound when due to very small transversal vibrations of a thin wire or chord, which velocity is consequently the same as would be acquired by a body falling through a height equal to one half of a length of the chord such as to have a weight equal to the tension.

The above may also be put in the form—

$$V=\sqrt{\frac{gP}{w}},$$

where P is the tension, and w the weight of the unit of length of the chord.

28. It appears then that while sound is propagated by longitudinal vibrations through a given substance with the same velocity under all circumstances, the rate of its transmission by transversal vibrations through the same substance depends on the tension and on the thickness. The former velocity bears to the latter the ratio of $\sqrt{l}:\sqrt{c}$, (where l is the length of the substance, which would be lengthened *one* foot by the weight of *one* foot, if we take the foot as our unit) or of $\sqrt{\frac{l}{c}}:1$, that is, of the square root of the length which would be extended *one* foot by the weight of c feet, or by the tension, to 1. This, for ordinary tensions, results in the velocity for longitudinal vibrations being very much in excess of that for transversal vibrations.

Comparison of V for transversal and for longitudinal vibration[s].

29. It is a well known fact that, in all but very exceptional cases, the loudness of any sound is less as the distance increases between the source of sound and the ear. The law according to which this decay takes place is the same as obtains in other natural phenomena, viz., that in an unlimited and uniform medium the loudness or intensity of the sound proceeding from a very small sounding body (strictly speaking, a point) varies inversely as the square of the distance. This follows from considering that the ear AC receives only the conical portion OAC of the whole volume of sound emanating from O, and that in order that an ear BD, placed at a greater distance from O, may admit the same quantity, its area must be to that of AC : as OB^2 : OA^2. But if A' = AC be situated at same distance as BD, the amount of sound received by it and by BD (and therefore by AC) will be as the area of A' or AC to that of BD. Hence, the intensities of the sound as

Law of decay of intensity of sounds with increased distance.

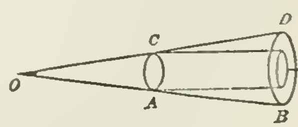

Fig. 5.

heard by the same ear at the distances OA and OB are to each other as OB^2 to OA^2.

Influence of diminished density of the air on intensity of sound.

30. In order to verify the above law when the atmosphere forms the intervening medium, it would be necessary to test it at a considerable elevation above the earth's surface, the ear and the source of sound being separated by air of constant density. As the density of the air diminishes, we should then find that the loudness of the sound at a given distance would decrease, as is the case in the air-pump experiment previously described. This arises from the decrease of the quantity of matter impinging on the ear, and the consequent diminution of its *vis-viva*. The decay of sound due to this cause is observable in the rarefied air of high mountainous regions. De Saussure, the celebrated Alpine traveller, mentions that the report of a pistol at a great elevation appeared no louder than would a small cracker at a lower level.

But it is to be remarked that, according to Poisson, when air-strata of different densities are interposed between the source of sound and the ear placed at a given distance, the intensity depends only on the density of the air at the source itself; whence it follows that sounds proceeding from the surface of the earth may be heard at equal distances as distinctly by a person in a floating balloon as by one situated on the surface itself; whereas any noise originating in the balloon would be heard at the surface as faintly as if the ear were placed in the rarefied air on a level with the balloon. This was exemplified during a balloon ascent by Glaisher and Coxwell, who, when at an elevation of 20,000 feet, heard with great distinctness the whistle of a locomotive passing beneath them.

Part III.

Reflexion and Refraction of Sound.

Laws of refraction.

31. When a wave of sound travelling through one medium meets a second medium of a different kind, the vibrations of its own particles are communicated to the particles of the new medium, so that a wave is excited in the latter, and is propagated through it with a velocity dependent on the density and elasticity of the second medium, and therefore differing in general from the previous velocity. The direction, too, in which the new wave travels is different from the previous one. This change of direction is termed *refraction*, and takes place according to the same laws as does the refraction of light, viz., (1.) The new direction or *refracted ray* lies always in the *plane of incidence*, or plane which contains the incident ray (*i.e.*, the direction of the wave in the first medium), and the normal to the surface separating the two media, at the point in which the incident ray meets it; (2.) The *sine* of the angle between the normal and the incident ray bears to the *sine* of the angle between the normal and the refracted ray, a ratio which is constant for the same pair of media.

For a theoretical demonstration of these laws, we must refer to the art. Optics, where it will be shown that the ratio involved in the second law is always equal to the ratio of the velocity of the wave in the first medium to the velocity in the second; in other words, the *sines* of the angles in question are *directly* proportional to the velocities.

Refraction is to or from the normal according to relative values of the velocities.

32. Hence sonorous rays, in passing from one medium into another, are bent in towards the normal, or the reverse, according as the velocity of propagation in the former exceeds or falls short of that in the latter. Thus, for instance, sound is refracted *towards* the perpendicular when passing into air from water, or into carbonic acid gas from air; the converse is the case when the passage takes place the opposite way.

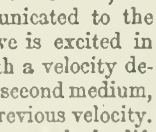

Fig. 6.

Limiting angle and total reflexion.

33. It further follows, as in the analogous case of light, that there is a certain angle termed the *limiting angle*, whose *sine* is found by dividing the less by the greater velocity, such that all rays of sound meeting the surface separating two different bodies will not pass onward, but suffer total reflexion back into the first body, if the velocity in that body is less than that in the other body, and if the angle of incidence exceeds the limiting angle.

The velocities in air and water being respectively 1090 and 4700 feet, the limiting angle for these media may be easily shown to be slightly above $15\frac{1}{2}°$. Hence, rays of sound proceeding from a distant source, and therefore nearly parallel to each other, and to PO (fig. 6), the angle POM being greater than $15\frac{1}{2}°$, will not pass into the water at all, but suffer total reflexion. Under such circumstances, the report of a gun, however powerful, would be inaudible by an ear placed in the water.

Acoustic lenses.

34. As light is concentrated into a focus by a convex glass lens (for which the velocity of light is less than for the air), so sound ought to be made to converge by passing through a convex lens formed of *carbonic acid* gas. On the other hand, to produce convergence with water or hydrogen gas, in both which the velocity of sound exceeds its rate in air, the lens ought to be *concave*. These results have been confirmed experimentally by Sondhaus and Hajech, who also succeeded in verifying the law of the equality of the index of refraction to the ratio of the velocities of sound.

Laws of reflexion.

35. When a wave of sound falls on a surface separating two media, in addition to the refracted wave transmitted into the new medium, which we have just been considering, there is also a fresh wave formed in the new medium, and travelling in it in a different direction, but, of course, with the same velocity. This *reflected* wave is subject to the same laws as regulate the reflexion of light, viz., (1.) the coincidence of the planes of incidence and of reflexion, and (2.) the equality of the angles of incidence and reflexion, that is, of the angles made by the incident and reflected rays with the normal.

Reflexion by a spheroid.

36. As in an ellipse (fig. 7), the normal PG at any point bisects the angle SPH (S, H being the foci), rays of sound diverging from S, and falling on the spheroidal surface formed by the revolution of the ellipse about the longest diameter AB, will be reflected to H. Also, since SP + PH is always = AB, the times in which the different rays will reach H will all be equal to each other, and hence a crash at S will be heard as a crash at H.

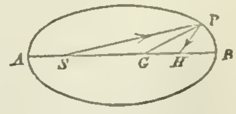

Fig. 7.

Reflexion by parabolic surfaces.

37. At any point P of a parabola (fig. 8) of which S is the focus, and AX the axis, the normal PG bisects the angle SPX, PX being drawn parallel to AX.

Hence rays of sound diverging from S, and falling on the paraboloid formed by the revolution of the parabola about its axis, will all be reflected in directions parallel to the axis. And *vice versa* rays of sound XP, XQ, &c., from a very distant source, and parallel to the axis of a paraboloid, will be reflected into the focus. Consequently, if two reflecting paraboloids be placed at a considerable distance from and opposite to each other, with their axis coincident in direction (fig. 9), the tick of a watch placed at the focus S of one will be heard distinctly by an ear at S′ the focus of the other.

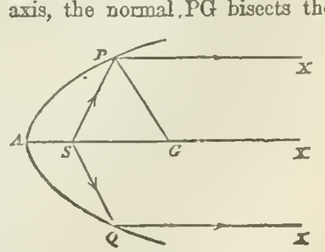

Fig. 8.

38. As a luminous object may give a succession of images when placed between two or more reflecting surfaces, so also in like circumstances may a sound suffer repetition.

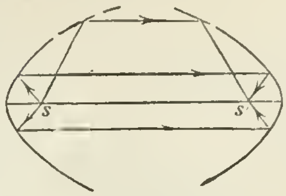

Fig. 9.

To these principles are easily traceable all the peculiarities of echoes. A wall or steep cliff may thus send back, somewhat reduced in intensity, a shout, the report of a pistol, &c. The time which elapses between the sound and its echo may be easily deduced from the known velocity of sound in air, if the distance of the wall be given. Thus, for a distance of 37 yards, the interval will be found by dividing the double of that or 74 yards by 370 yards, the velocity of sound at 50° Fahr., to amount to $\frac{1}{5}$ of a second. Hence, if we assume that the rate at which syllables can be distinctly uttered is five per second, the wall must be at a distance exceeding 37 yards to allow of the echo of a word of one syllable reaching the ear *after* the word has been uttered. 74 yards for a word of *two* syllables, and so on.

If the reflecting surface consists of one or more walls, cliffs, &c., forming together a near approach in shape to that of a prolate spheroid or of a double parabolic surface, then two points may be found, at one of which if a source of sound be placed, there will be produced, by convergence, a distinct echo at the other. As examples of this may be mentioned the whispering gallery in St Paul's, London, and the still more remarkable case of the Cathedral of Girgenti in Sicily mentioned by Sir John Herschel.

39. On similar principles of repeated reflexion may be explained the well-known fact that sounds may be conveyed to great distances with remarkably slight loss of intensity, on a level piece of ground or smooth sheet of water or ice, and still more so in pipes, chimneys, tunnels, &c. Thus, in one of Captain Parry's Polar expeditions, a conversation was on one occasion carried on, at a distance of $1\frac{1}{4}$ mile, between two individuals separated by a frozen sheet of water. M. Biot heard distinctly from one end of the train of pipes $\frac{3}{5}$ of a mile long, previously referred to. a low whisper proceeding from the opposite end.

Practical illustrations are afforded by the system of communication by means of tubing now so extensively adopted in public and private buildings, and by the *speaking trumpet* and the *ear trumpet*.

40. The prolonged roll of thunder, with its manifold varieties, is partly to be ascribed to reflexion by mountains, clouds, &c.; but is mainly accounted for on a different acoustic principle, viz., the comparatively low rate of transmission of sound through air, as was first shown by Dr Hooke at the close of the 17th century. The explanation will be more easily understood by adverting to the case of a volley fired by a long line of troops. A person situated at a point in that line produced, will first it is evident hear the report of the nearest musket, followed by that of the one following, and so down to the last one in the line, which will close the prolonged roll thus reaching his ear; and as each single report will appear to him less intense according as it proceeds from a greater distance, the roll of musketry thus heard will be one of gradually decreasing loudness. But if he were to place himself at a relatively great distance right opposite to the centre of the line, the separate reports from each of the two wings would reach him nearly at the same moment, and hence the sound of the volley would now approach more nearly to that of a single loud crash. If the line of soldiers formed an arc of a circle having its centre in his position, then the distances gone over by the separate reports being equal, they would reach his ear at the same absolute instant of time, and with exactly equal intensities; and the effect produced would be strictly the same as that of a single explosion, equal in violence to the sum of all the separate discharges, occurring at the same distance. It is easy to see that, by varying the form of the line of troops and the position of the observer, the sonorous effect will be diversified to any extent desired. If then we keep in view the great diversity of form exhibited by lightning-flashes, which may be regarded as being lines, at the points of which are generated explosions at the same instant of time, and the variety of distance and relative position at which the observer may be placed, we shall feel no difficulty in accounting for all those acoustic phenomena of thunder to which Hooke's theory is applicable.

Part IV.

The Principles of Musical Harmony.

41. A few words on the subject of *musical harmony* must be introduced here for the immediate purposes of this article, further details being reserved for the special article on that subject.

Sounds in general exhibit three different qualities, so far as their effect on the ear is concerned, viz., *loudness*, *pitch*, and *timbre*.

Loudness depends on extent of vibration.

Loudness depends, *cæt. par.*, on the violence with which the vibrating portions of the ear are excited; and therefore on the *extent* or *amplitude* of the vibrations of the body whence the sound proceeds. Hence, after a bell has been struck, its effect on the ear gradually diminishes as its vibration becomes less and less extensive. By the theory of vibrations, loudness or intensity is measured by the *vis-viva* of the vibrating particles, and is consequently proportional to the square of their maximum velocity or to the square of their maximum displacement. Helmholtz, however, in his remarkable work on the perception of tone, observes that notes differing in pitch differ also in loudness, where their *vis viva* is the same, the higher note always exhibiting the greater intensity.

Pitch depends on rapidity of vibration.

42. Difference of *pitch* is that which finds expression in the common terms applied to notes: *Acute, shrill, high, sharp, grave, deep, low, flat.* We will point out presently in what manner it is established that this quality of sound depends on the rapidity of vibration of the particles of air in contact with the external parts of the ear. The pitch of a note is higher in proportion to the number of vibrations of the air corresponding to it, in a given time, such as one second. If n denote this number, then, by § 13, $n = \frac{V}{\lambda}$, and hence, V being constant, the pitch is higher the less the length λ of the wave.

Timbre.

43. *Timbre*, or, as it is termed by German authors, *klang-farbe*, rendered by Tyndall into *clang-colour* or *clang-tint*, but for which we would substitute the expression *acoustic colour*, denotes that peculiarity of impression produced on the ear by sounds otherwise, in pitch, loudness, &c., alike, whereby they are recognisable as different from each other. Thus human voices are readily interdistinguishable; so are notes of the same pitch and intensity, produced by different instruments. The question whence arises this distinction must be deferred for the present.

44. Besides the three qualities above mentioned, there exists another point in which sounds may be distinguished among each other, and which, though perhaps reducible to difference of timbre, requires some special remarks, viz., that by which sounds are characterised, either as *noises* or as *musical notes*. A musical note is the result of regular,

periodic vibrations of the air-particles acting on the ear, and therefore also of the body whence they proceed, each particle passing through the same phase at stated intervals of time. On the other hand, the motion to which *noise* is due is irregular and flitting, alternately fast and slow, and creating in the mind a bewildering and confusing effect of a more or less unpleasant character. Noise may also be produced by combining in an arbitrary manner several musical notes, as when one leans with the fore-arm against the keys of a piano. In fact, the composition of regular periodic motions, thus effected, is equivalent to an irregular motion.

45. We now proceed to state the laws of musical harmony, and to describe certain instruments by means of which they admit of being experimentally established. The chief of these laws are as follow:—

(1.) The notes employed in music always correspond to certain definite and invariable ratios between the numbers of vibrations performed in a given time by the air when conveying these notes to the ear, and these ratios are of a very simple kind, being restricted to the various permutations of the first four prime numbers 1, 2, 3, 5, and their powers.

(2.) Two notes are in *unison* whose corresponding vibrations are executed exactly at the same rate, or for which (denoting by n, n_1 the numbers per second) $\frac{n_1}{n} = 1$. This ratio or *interval* (as it is termed) is the simplest possible.

(3.) The next *interval* is that in which $\frac{n_1}{n} = 2$, and is termed the *octave*.

(4.) The interval $\frac{n_1}{n} = 3$ is termed the *twelfth*, and if we reduce the higher note of the pair by an 8^ve^, *i.e.*, divide its number of vibrations by 2, we obtain the interval $\frac{n_2}{n} = \frac{3}{2}$, designated as the interval of the *fifth*.

(5.) The interval $\frac{n_1}{n} = 5$ has no particular name attached to it, but if we lower the higher note by two 8^ves^ or divide n_1 by 4, we get the interval $\frac{n_3}{n} = \frac{5}{4}$, or the interval of the *major third*.

(6.) The interval $\frac{n_1}{n} = \frac{5}{3}$ is termed the *major sixth*.

(7.) The interval $\frac{n_1}{n} = \frac{2 \times 3}{5} = \frac{6}{5}$ is termed the *minor third*.

(8.) The interval $\frac{n_1}{n} = \frac{2 \times 2}{3} = \frac{4}{3}$ is termed the *fourth*.

(9.) The interval $\frac{9}{8}$ which, being $= \frac{\frac{3}{2} \times \frac{3}{2}}{2}$, may be regarded as formed by taking in the first place a note one-fifth higher than the key-note or fundamental, *i.e.*, higher than the latter by the interval $\frac{3}{2}$, thence ascending by another fifth, which gives us $\frac{3}{2} \times \frac{3}{2}$ and lowering this by an octave, which results in $\frac{9}{8}$, which is called the *second*.

(10.) The interval $\frac{15}{8}$ or $\frac{3}{2} \times \frac{5}{4}$ may be regarded as the major third $\left(\frac{5}{4}\right)$ of the fifth $\left(\frac{3}{2}\right)$, and is called the interval of the *seventh*.

46. If the key-note or fundamental be denoted by C, and the notes, whose intervals above C are those just enumerated, by D, E, F, G, A, B, C, we form what is known in music as the natural or *diatonic* scale, in which therefore the intervals reckoned from C are successively

$$\frac{9}{8}, \frac{5}{4}, \frac{4}{3}, \frac{3}{2}, \frac{5}{3}, \frac{15}{8}, 2,$$

and therefore the intervals between each note and the one following are

$$\frac{9}{8}, \frac{10}{9}, \frac{16}{15}, \frac{9}{8}, \frac{10}{9}, \frac{9}{8}, \frac{16}{15}$$

Of these last intervals the *first*, *fourth*, and *sixth* are each $= \frac{9}{8}$, which is termed a *major tone*. The *second* and *fifth* are each $= \frac{10}{9}$, which is a ratio slightly less than the former, and hence is called a *minor tone*. The *third* and *seventh* are each $= \frac{16}{15}$, to which is given the name of *semi-tone*.

By interposing an additional note between each pair of notes whose interval is a major or a minor tone, the resulting series of notes may be made to exhibit a nearer approach to equality in the intervals successively separating them, which will be very nearly *semi-tones*. This sequence of twelve notes forms the *chromatic* scale. The note interposed between C and D is either C sharp (C♯) or D flat (D♭), according as it is formed by *raising* C a semi-tone or *lowering* D by the same amount.

47. Various kinds of apparatus have been contrived with a view of confirming experimentally the truth of the laws of musical harmony as above stated.

Savart's toothed wheel apparatus.

Savart's toothed wheel apparatus consists of a brass wheel, whose edge is divided into a number of equal projecting teeth distributed uniformly over the circumference, and which is capable of rapid rotation about an axis perpendicular to its plane and passing through its centre, by means of a series of multiplying wheels, the last of which is turned round by the hand. The toothed wheel being set in motion, the edge of a card or of a funnel-shaped piece of common note paper is held against the teeth, when a note will be heard arising from the rapidly succeeding displacements of the air in its vicinity. The pitch of this note will, agreeably to the theory, rise as the rate of rotation increases, and becomes steady when that rotation is maintained uniform. It may thus be brought into unison with any sound of which it may be required to determine the corresponding number of vibrations per second, as for instance the note A_3, three 8^ves^ higher than the A which is indicated musically by a small circle placed between the second and third lines of the G clef, which A is the note of the tuning-fork usually employed for regulating concert-pitch. A_3 may be given by a piano. Now, suppose that the note produced with Savart's apparatus is in unison with A_3, when the experimenter turns round the first wheel at the rate of 60 turns per minute or one per second, and that the circumferences of the various multiplying wheels are such that the rate of revolution of the toothed wheel is thereby increased 44 times, then the latter wheel will perform 44 revolutions in a second, and hence, if the number of its teeth be 80, the number of taps imparted to the card every second will amount to 44×80 or 3520. This, therefore, is the number of vibrations corresponding to the note A_3. If we divide this by 2^3 or 8, we obtain 440 as the number of vibrations answering to the note A. This, however, tacitly assumes that the bands by which motion is transmitted from wheel to wheel do not *slip* during the experiment. If, as is always more or less the case, slipping occurs, a different mode for determining the rate at which the toothed wheel revolves, such as is employed in the syren of De la Tour (*vide* below), must be adopted.

If, for the single toothed wheel, be substituted a set of four with a common axis, in which the teeth are in the ratios 4 : 5 : 6 : 8, and if the card be rapidly passed along their edges, we shall hear distinctly produced the fundamental chord C, E, G, C_1 and shall thus satisfy ourselves that the intervals C, E; C_1 G, and C C_1 are (as they ought to be) $\frac{5}{4}$, $\frac{3}{2}$, and 2 respectively.

48. The *syren* of Seebeck is the simplest form of apparatus thus designated, and consists of a large circular disc of pasteboard mounted on a central axis, about which it may be made to revolve with moderate rapidity. This disc is perforated with small round holes arranged in circles about the centre of the disc. In the first series of circles, reckoning from the centre, the openings are so made as to divide the respective circumferences, on which they are found, in aliquot parts bearing to each other the ratios of the numbers 2, 4, 5, 6, 8, 10, 12, 16, 20, 24, 32, 40, 48, 64. The second series consists of circles each of which is formed of two sets of perforations, in the first circle arranged as 4 : 5, in the next as 3 : 4, then as 2 : 3, 3 : 5, 4 : 7. In the outer series is a circle divided by perforations into four sets, the numbers of aliquot parts being as 3 : 4 : 5 : 6, followed by others which we need not further refer to.

The disc being started, then by means of a tube held at one end between the lips, and applied near to the disc at the other, or more easily with a common bellows, a blast of air is made to fall on the part of the disc which contains any one of the above circles. The current being alternately transmitted and shut off, as a hole passes on and off the aperture of the tube or bellows, causes a vibratory motion of the air, whose rapidity depends on the number of times per second that a perforation passes the mouth of the tube. Hence the note produced with any given circle of holes rises in pitch as the disc revolves more rapidly; and if, the revolution of the disc being kept as steady as possible, the tube be passed rapidly across the circles of the first series, the notes heard are found to produce on the ear, as required by theory, the exact impression corresponding to the ratios 2 : 4 : &c., *i.e.*, of a series of notes, which, if the lowest be denoted by C, form the sequence C C_1 E_1 G_1 C_2 &c., &c. In like manner, the first circle in which we have two sets of holes dividing the circumference, the one into say 8 parts, and the other into 10, or in ratio 4 : 5, the note produced is a compound one, such as would be obtained by striking on the piano two notes separated by the interval of a major third $\left(\frac{5}{4}\right)$. Similar results, all agreeing with the theory, are obtainable by means of the remaining perforations.

A still simpler form of syren may be constituted with a good spinning top, a perforated card disc, and a tube for blowing with.

49. The syren of Cagnard de la Tour is founded on the same principle as the preceding. It consists of a cylindrical chest of brass, the base of which is pierced at its centre with an opening in which is fixed a brass tube projecting outwards, and intended for supplying the cavity of the cylinder with compressed air or other gas, or even liquid. The top of the cylinder is formed of a plate perforated near its edge by holes distributed uniformly in a circle concentric with the plate, and which are cut obliquely through the thickness of the plate. Immediately above this fixed plate, and almost in contact with it, is another of the same dimensions, and furnished with the same number, n, of openings similarly placed, but passing obliquely through in an opposite direction from those in the fixed plate, the one set being inclined to the left, the other to the right.

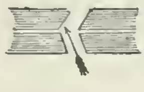

Fig. 10.

This second plate is capable of rotation about a steel axis perpendicular to its plane and passing through its centre. Now, let the movable plate be at any time in a position such that its holes are immediately above those in the fixed plate, and let the bellows by which air is forced into the cylinder (air, for simplicity, being supposed to be the fluid employed) be put in action; then the air in its passage will strike the side of each opening in the movable plate in an oblique direction (as shown in fig. 10), and will therefore urge the latter to rotation round its centre. After $\frac{1}{n}$th of a revolution, the two sets of perforations will again coincide, the lateral impulse of the air repeated, and hence the rapidity of rotation increased. This will go on continually as long as air is supplied to the cylinder, and the velocity of rotation of the upper plate will be accelerated up to a certain maximum, at which it may be maintained by keeping the force of the current constant.

Now, it is evident that each coincidence of the perforations in the two plates is followed by a non-coincidence, during which the air-current is shut off, and that consequently, during each revolution of the upper plate, there occur n alternate passages and interceptions of the current. Hence arises the same number of successive impulses of the external air immediately in contact with the movable plate, which is thus thrown into a state of vibration at the rate of n for every revolution of the plate. The result is a note whose pitch rises as the velocity of rotation increases, and becomes steady when that velocity reaches its constant value. If, then, we can determine the number m of revolutions performed by the plate in every second, we shall at once have the number of vibrations per second corresponding to the audible note by multiplying m by n.

For this purpose the steel axis is furnished at its upper part with a screw working into a toothed wheel, and driving it round, during each revolution of the plate, through a space equal to the interval between two teeth. An index resembling the hand of a watch partakes of this motion, and points successively to the divisions of a graduated dial. On the completion of each revolution of this toothed wheel (which, if the number of its teeth be 100, will comprise 100 revolutions of the movable plate), a projecting pin fixed to it catches a tooth of another toothed wheel and turns it round, and with it a corresponding index which thus records the number of turns of the first toothed wheel. As an example of the application of this syren, suppose that the number of revolutions of the plate, as shown by the indices, amounts to 5400 in a minute of time, that is, to 90 per second, then the number of vibrations per second of the note heard amounts to $90n$, or (if number of holes in each plate = 8) to 720.

Dove's syren.

50. Dove, of Berlin, has produced a modification of the syren by which the relations of different musical notes may be more readily ascertained. In it the fixed and movable plates are each furnished with four concentric series of perforations, dividing the circumferences into different aliquot parts, as *p. ex.*, 8, 10, 12, 16. Beneath the lower or fixed plate are four metallic rings furnished with holes corresponding to those in the plates, and which may be pushed round by projecting pins, so as to admit the air-current through any one or more of the series of perforations in the fixed plate. Thus, may be obtained, either separately or in various combinations, the four notes whose vibrations are in the ratios of the above numbers, and which therefore form the fundamental chord (CEGC_1). The inventor has given to this instrument the name of the *many-voiced syren*.

Helmholtz's double syren.

51. Helmholtz has further adapted the syren for more extensive use, by the addition to Dove's instrument of another chest containing its own fixed and movable per-

forated plates and perforated rings, both the moveable plates being driven by the same current and revolving about a common axis. Annexed is a figure of this instrument (fig. 11).

Vibrographs.

52. The relation between the pitch of a note and the frequency of the corresponding vibrations has also been studied by *graphic* methods. Thus, if an elastic metal slip or a pig's bristle be attached to one prong of a tuning-fork, and if the fork, while in vibration, is moved rapidly over a glass plate coated with lamp black, the attached slip touching the plate lightly, a wavy line will be traced on the plate answering to the vibrations to and fro of the fork. The same result will be obtained with a stationary fork and a movable glass plate; and, if the time occupied by the plate in moving through a given distance can be ascertained, and the number of complete undulations exhibited on the plate for that distance, which is evidently the number of vibrations of the fork in that time, is reckoned, we shall have determined the numerical vibration-value of the note yielded by the fork. Or, if the same plate be moved in contact with two tuning-forks, we shall, by comparing the number of sinuosities in the one trace with that in the other, be enabled to assign the ratio of the corresponding numbers of vibrations per second. Thus, if the one note be an octave higher than the other, it will give double the number of waves in the same distance. The motion of the plate may be simply produced by dropping it between two vertical grooves, the tuning-forks being properly fixed to a frame above.

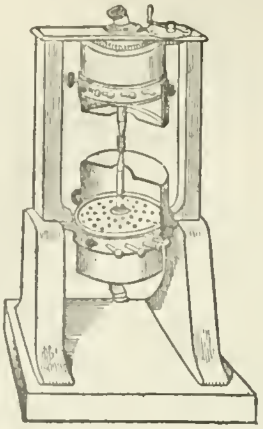

Fig. 11.

The Phonautograph.

53. Greater accuracy may be attained with the so-called *Vibrograph* or *Phonautograph* (Duhamel's or Kœnig's), consisting of a glass cylinder coated with lamp-black, or, better still, a metallic cylinder round which a blackened sheet of paper is wrapped. The cylinder is mounted on a horizontal axis and turned round, while the *pointer* attached to the vibrating body is in light contact with it, and traces therefore a wavy circle, which, on taking off the paper and flattening it, becomes a wavy straight line. The superiority of this arrangement arises from the comparative facility with which the number of revolutions of the cylinder in a given time may be ascertained. In Kœnig's phonautograph, the axis of the cylinder is fashioned as a screw, which works in fixed nuts at the ends, causing a sliding as well as a rotatory motion of the cylinder. The lines traced out by the vibrating pointer are thus prevented from overlapping when more than one turn is given to the cylinder.

Any sound whatever may be made to record its trace on the paper by means of a large parabolic cavity resembling a speaking-trumpet, which is freely open at the wider extremity, but is closed at the other end by a thin stretched membrane. To the centre of this membrane is attached a small feather-fibre, which, when the reflector is suitably placed, touches lightly the surface of the revolving cylinder. Any sound (such as that of the human voice) transmitting its rays into the reflector, and communicating vibratory motion to the membrane, will cause the feather to trace a sinuous line on the paper. If, at the same time, a tuning-fork of known number of vibrations per second be made to trace its own line close to the other, a comparison of the two lines gives the number corresponding to the sound under consideration.

Part V.

Stationary Waves.

Stationary waves produced by two opposite progressive waves.

54. We have hitherto, in treating of the propagation of waves of sound, assumed that the medium through which it took place was unlimited in all directions, and that the source of sound was single. In order, however, to understand the principles of the production of sound by musical instruments, we must now direct our attention to the case of two waves from different sources travelling through the same medium in opposite directions. Any particle of the medium being then affected by two different vibrations at the same instant will necessarily exhibit a different state of motion from that due to either wave acting separately from the other, and we have to inquire what is the result of this mutual *interference* (as it is termed) of the two given waves. Supposing, as sufficient for our purpose, that the given waves are of equal lengths and of equal amplitudes, in other words, that the corresponding notes are of the same pitch and equally loud; and supposing, further, that they are advancing in exactly opposite directions, we shall now show that the result of the mutual interference of two such waves is the production of a *stationary wave*, that is, taking any line of particles of the medium along the direction of motion of the component waves, certain of them, such as a, c, e . . . at intervals each $=\frac{\lambda}{2}$, will remain constantly in their usual undisturbed positions. All the particles situated between a and c will vibrate (transversely or longitudinally, as the case may be) to and fro in the same direction as they would if affected by only one of the interfering waves, but with different amplitudes of vibration, ranging from zero at a to a maximum at b and thence to zero at c. Those between c and e will vibrate in like manner, but always in an opposite direction to the similarly placed particles in ac, and so on alternately.

Fig. 12.

The annexed figures will represent to the eye the states of motion at intervals of time $=\frac{1}{4}$ of the time T of a complete vibration of the particles. In fig. 13, 1, the particles in ac are at their greatest distances from their undisturbed positions (*above* or *to the right*, according as the motion is *transversal* or *longitudinal*). In fig. 13, 2, they are all in their undisturbed positions. In fig. 13, 3, the displacements are all reversed relatively to fig. 13, 1. In fig. 13, 4, the particles are again passing through their equilibrium positions, resuming the positions indicated in fig. 13, 1, after the time T.

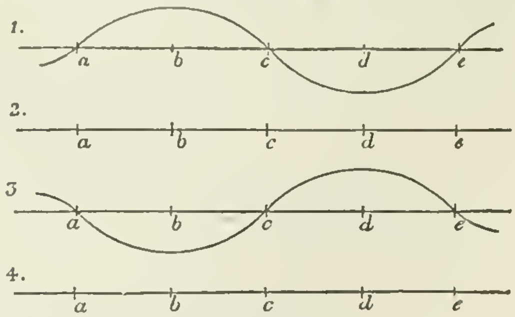

Fig. 13.

Nodes and ventral segments.

The points ace, &c., which remain stationary are termed *nodes*, and the vibrating parts between them *ventral segments*.

Proof.

54*a*. *Proof.* In fig. 14, 1, the full curved line represents the two interfering waves at an instant of time such that, in their progress towards each other, they are then coincident. It is obvious that the particles of the medium will at the moment in question be displaced to double the extent of the displacement producible by either wave alone, so that the *resultant* wave may be represented by the *dotted* curve. In fig. 14, 2, the two interfering waves, represented by the full and dotted curves respectively, have each

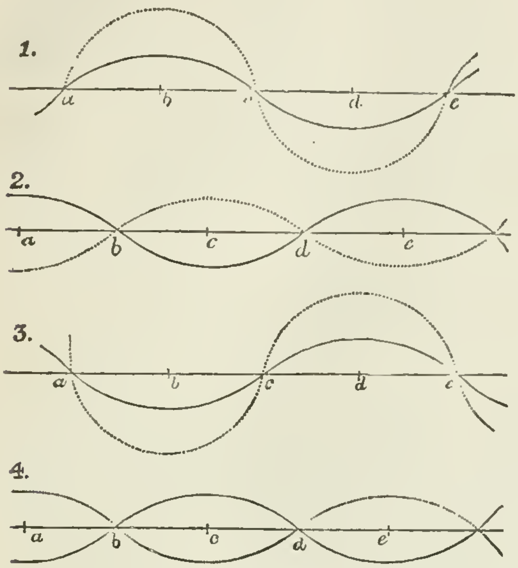

Fig. 14.

passed over a distance $= \frac{1}{4}\lambda$, the one to the right, the other to the left, and it is manifest that any disturbance of the medium, producible by the one wave, is completely neutralised by the equal and opposite action of the other. Hence, the particles of the medium are now in their undisturbed positions. In fig. 14, 3, a further advance of the two waves, each in its own direction, over a space $= \frac{1}{4}\lambda$, has again brought them into coincidence, and the result is the wave represented by the dotted line, which, it will be remarked, has its *crests*, where, in fig. 1, are found *troughs*. In fig. 14, 4, after a further advance $= \frac{1}{4}\lambda$, we have a repetition of the case of fig. 14, 2, the particles are now again unaffected by the waves. A still further advance of $\frac{1}{4}\lambda$, or of λ reckoned from the commencement, brings us back to the same state of things as subsisted in fig. 14, 1. An inspection and inter-comparison of the dotted lines in these figures are now sufficient to establish the accuracy of the laws, before mentioned, of *stationary waves*.

Part VI.

Musical Strings.

ical gs.

55. We have in musical strings an instance of the occurrence of stationary waves.

Let AB (fig. 15) be a wire or string, supposed meanwhile to be fixed only at one extremity B, and let the wire be, at any part, excited (whether by passing a violin bow across or by friction

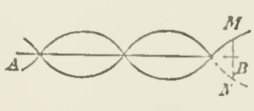

Fig. 15.

along it), so that a wave (whether of transversal or longitudinal vibrations) is propagated thence towards B. On reaching this point, which is fixed, reflexion will occur, in consequence of which the particles there will suffer a complete reversal of velocity, just as when a perfectly elastic ball strikes against a smooth surface perpendicularly, it rebounds with a velocity equal and opposite to that it previously had. Hence, the displacement due to the incident wave being BM, the displacement after reflexion will be BN equal and opposite to BM, and a reflected wave will result, represented by the faint line in the fig., which will travel with the same velocity, but in the opposite direction to the incident wave fully lined in the fig. The interference of these two oppositely progressing waves will consequently give rise to a stationary wave (fig. 16), and if we take on the wire distances BC, CD, DE, &c. $= \frac{1}{2}\lambda$,

Fig. 16.

the points B, C, D, E, . . . will be *nodes*, each of which separate portions of the wire vibrating in opposite directions, *i.e.*, *ventral segments.*

56. Now, it is obvious that, inasmuch as a node is a point which remains always at rest while other parts of the medium to which it belongs are vibrating, such point may be absolutely fixed without thereby interfering with the oscillatory motion of the medium. If, therefore, a length AB of wire be taken equal to any multiple of $\frac{\lambda}{2}$, A may be fixed as well as B, the motion remaining the same as before, and thus we shall have the usual case of a musical string. The two extremities being now both fixed, there will be repeated reflexions at both, and a consequent persistence of two progressive waves advancing in opposite directions and producing together the stationary wave above figured.

57. We learn from this that a musical string is susceptible of an infinite variety of modes of vibration corresponding to different numbers of subdivision into ventral segments. Fundamental and harmonics.

Thus, it may have but *one* ventral segment (fig. 17), or but two nodes formed by its fixed extremities. In this case, the note emitted by it is the lowest which can possibly be

Fig. 17.

obtained from it, or, as it is called, its *fundamental* note. If l denote the length of the wire, by what has been already proved, $l = \frac{\lambda}{2}$, and therefore the length of the wave $\lambda = 2l$. Hence, V being the velocity of propagation of the wave through the wire, the number n_1 of vibrations performed in the unit of time with the fundamental note is $\frac{V}{2l}$.

The next possible sub-division of the wire is into *two* ventral segments, the three nodes being the two fixed ends A, B, and the middle point C (fig. 18). Hence, $l = \lambda$, and the number of vibrations $n_2 = \frac{V}{l}$ or double of those of the fundamental. The note, therefore, now is an 8^{ve} higher.

Fig. 18.

Reasoning in a like manner for the cases of three, four, &c., ventral segments, we obtain the following general law, which is applicable alike to *transversely* and to *longitudinally* vibrating wires:

A wire or string fixed at both ends is capable of yielding, in addition to its fundamental note, any one of a series of notes corresponding to 2, 3, 4 times, &c., the number of vibrations per second of the fundamental, viz., the octave, twelfth, double octave, &c.

These higher notes are termed the *harmonics* or (by the Germans) the *overtones* of the string.

It is to be remarked that the overtones are in general fainter the higher they are in the series, because, as the number of ventral segments or independently vibrating parts of the string increases, the extent or amplitude of the vibrations diminishes. May be heard together.

58. Not only may the fundamental and its harmonics

be obtained independently of each other, but they are also to be heard simultaneously, particularly, for the reason just given, those that are lower in the scale. A practised ear easily discerns the coexistence of these various tones when a pianoforte or violin string is thrown into vibration. It is evident that, in such case, the string, while vibrating as a whole between its fixed extremities, is at the same time executing subsidiary oscillations about its middle point, its points of trisection, &c., as shown in fig. 19, for the fundamental and the first harmonic.

Fig. 19.

59. The easiest means for bringing out the harmonics of a string consists in drawing a violin-bow across it near to one end, while the feathered end of a quill or a hair-pencil is held lightly against the string at the point which it is intended shall form a node, and is removed just after the bow is withdrawn. Thus, if a node is made in this way, at $\frac{1}{3}$ of AB from A, the note heard will be the twelfth. If light paper rings be strung on the cord, they will be driven by the vibrations to the nodes or points of rest, which will thus be clearly indicated to the eye.

Comparison of fundamentals of strings vibrating transversely and longitudinally.

60. The formula $n_1 = \frac{V}{2l}$ shows that the pitch of the fundamental note of a wire of given length rises with the velocity of propagation of sound through it. Now we have learned (§ 28) that this velocity, in ordinary circumstances, is enormously greater for a wire vibrating longitudinally than for the same wire vibrating transversely. The fundamental note, therefore, is far higher in pitch in the former than in the latter case.

As, however, the quantity V depends, for longitudinal vibrations, solely on the nature of the medium, the pitch of the fundamental note of a wire rubbed along its length depends—the material being the same, brass for instance—on its length, not at all on its thickness, &c.

But as regards strings vibrating transversely, such as are met with in our instrumental music, V, as we have seen (§ 27), depends not only on the nature of the substance used, but also on its thickness and tension, and hence the pitch of the fundamental, even with the same length of string, will depend on all those various circumstances.

61. If we put for V its equivalent expressions before given, we have for the fundamental note of transversely vibrating strings:

$$n = \frac{\sqrt{gc}}{2l} \quad \text{or } n = \frac{1}{2l}\sqrt{\frac{gP}{w}},$$

whence the following inferences may be easily drawn:

If a string, its tension being kept invariable, have its length altered, the fundamental note will rise in pitch in exact proportion with its diminished length, that is, n varies then inversely as l.

Hence, on the violin, by placing a finger successively on any one of the strings at $\frac{8}{9}, \frac{4}{5}, \frac{3}{4}, \frac{2}{3}, \frac{3}{5}, \frac{8}{15}, \frac{1}{2}$, we shall obtain notes corresponding to numbers of vibrations bearing to the fundamental the ratios to unity of the following, viz., $\frac{9}{8}, \frac{5}{4}, \frac{4}{3}, \frac{3}{2}, \frac{15}{8}$, 2, which notes form, therefore, with the fundamental, the complete scale.

62. By *tightening* a musical string, its length remaining unchanged, its fundamental is rendered higher. In fact, then, n is proportional to the square root of the tension. Thus, by quadrupling the tension, the note is raised an octave. Hence, the use of keys in tuning the violin, the pianoforte, &c.

63. Equal lengths of strings of the same density and equally stretched, but of different thicknesses, give fundamentals which are higher in pitch in proportion to diminution of thickness (*i.e.*, n varies inversely as the thickness). Thus, of two strings of same kind of gut, same length and same tension, if one be twice as thick as the other, its fundamental will be an octave lower. Hence, three of the strings of the violin, though all of gut, have different fundamentals, because unequally thick.

64. Equally long and equally stretched strings or wires of different thickness and different material, have fundamentals higher in pitch the less the weights of the strings; n here varies inversely as the square root of the weight w of a given length of the string.

$n \propto \frac{1}{\sqrt{\text{weight of given length}}}$.

65. If, in last case, the thicknesses of the strings which are to be compared together are equal, then n varies inversely as the square root of the density.

$n \propto \frac{1}{\sqrt{\text{density}}}$.

Hence, in the violin and in the pianoforte, the lower notes are obtained from wires formed of denser material. Thus, the fourth string of the violin is formed of gut covered with silver wire.

Melde's experimental illustration.

66. A highly ingenious and instructive method for illustrating the above laws of musical strings, has been recently contrived by M. Melde, and consists simply in attaching to the ventral segment of a vibrating body, such as a tuning-fork or a bell-glass, a silk or cotton thread, the other extremity being either fixed or passing over a pulley and supporting weights by which the thread may be stretched to any degree required. The vibrations of the larger mass are communicated to the thread which, by proper adjustment of its length and tension, vibrates in unison and divides itself into one or more ventral segments easily discernible by a spectator. If the length of the thread be kept invariable, a certain tension will give but one ventral segment; the fundamental note of the thread is then of same pitch as the note of the body to which it is attached. By reducing the tension to $\frac{1}{4}$ of its previous amount, the number of ventral segments will be seen to be increased to two, indicating that the first harmonic of the thread is now in unison with the solid, and consequently that its fundamental is an octave lower than it was with the former tension; thus confirming the law that n varies as $\sqrt{P}$. In like manner, on further lowering the tension to $\frac{1}{9}$, three ventral segments will be formed, and so on.

The law that, *cæt. par.*, n varies inversely as the thickness may be tested by forming a string of four lengths of the single thread used before, and consequently of double the thickness of the latter, when, for the same length and tension, the compound thread will exhibit double the number of ventral segments presented by the single thread.

The other laws admit of similar illustration.

Part VII.

Stiff Rods, Plates, &c.

Rod, fixed at one end, vibrating transversely.

67. If, instead of a string or thin wire, we make use of a rod or narrow plate, sufficiently stiff to resist flexure, we may cause it to vibrate transversely when fixed at one end only. In this case the number of vibrations corresponding to the fundamental note varies as the thickness directly, and as the square of the length inversely. The annexed figures represent the modes of vibration corresponding to the fundamental and the first two overtones, the rod passing to and fro between the positions AGKC and AHLD. In all cases A

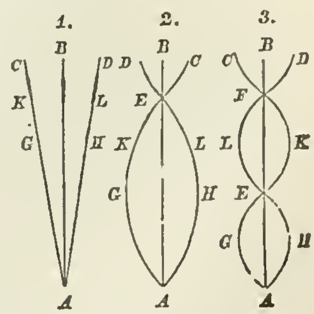

Fig. 20.

being fixed is necessarily a node, and B being free is the middle of a ventral segment. We have thus a succession of cases in which the rod contains $\frac{1}{2}$, $\frac{3}{2}$, $\frac{5}{2}$, &c. ventral segments. The numbers of vibrations per second are as the squares of these, or, as 1 : 9 : 25 : &c. The reason of this is, that (taking the case of fig. 20, 3) the part FB, which may be regarded as an independent rod fixed at the end F, is evidently $\frac{1}{5}$ of the length of AB, and consequently, since $n \propto \frac{1}{l^2}$, has a proper note of 5^2 or 25 times the rapidity of vibration in fig. 20, 1.

By attaching, with a little bees' wax, stiff hog's bristles to one prong of a tuning-fork, or to the edge of a bell-glass, or even a common jar, and clipping them on trial to suitable lengths, we shall find that, on drawing a note in the usual way from the tuning-fork or glass, the bristles will divide into one or more separately vibrating segments, as in the above figs.

Tuning-fork.

68. The *tuning-fork* itself may be regarded as belonging to the class of stiff rods. When emitting its fundamental note, it vibrates, as in fig. 21, with nodes at b and d and extreme positions $abcde$ and $fbgdh$.

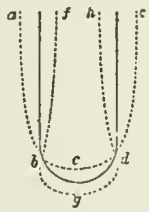

Fig. 21.

Thin plates. Chladni's figures.

69. The transversal vibrations of thin square, circular, and other plates of metal or glass, are interesting, because, if these are kept in a horizontal position, light dry sand or powder sifted over the upper surface, will be thrown off the ventral segments to the nodal lines, which will thus be rendered manifest to the eye, forming what are termed *Chladni's figures.* As in the case of a musical string, so here we find that the pitch of the note is higher for a given plate the greater the number of ventral segments into which it is divided; but the converse of this does not hold good, two different notes being obtainable with the same number of such segments, the position of the nodal lines being, however, different.

70. The upper line of annexed figures shows how the sand arranges itself in three cases, when the plates are square. The lower line gives the same in a sort of

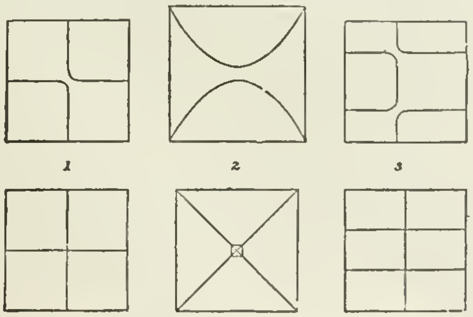

Fig. 22.

idealised form, and as usually to be found in acoustical works. Fig. 22, 1 corresponds to the lowest possible note of the particular plate used; Fig. 22, 2 to the *fifth* higher; Fig. 22, 3 to the *tenth* or octave of the *third*, the numbers of vibration in the same time being as 2 to 3 to 5.

If the plate be small, it is sufficient, in order to bring out the simpler sand-figures, to hold the plate firmly between two fingers of the same hand placed at any point where at least two nodal lines meet, for instance the centre in (1) and (2), and to draw a violin bow downwards across the edge near the middle of a ventral segment. But with larger plates, which alone will furnish the more complicated figures, a clamp-screw must be used for fixing the plate, and, at the same time, one or more other nodal points ought to be touched with the fingers while the bow is being applied. In this way, any of the possible configurations may be easily produced.

Circular plates.

71. By similar methods, a circular plate may be made to exhibit nodal lines dividing the surface by diametral lines into four or a greater, but always *even*, number of sectors, an odd number being incompatible with the general law of stationary waves that the parts of a body adjoining a nodal line on either side must always vibrate oppositely to each other.

Another class of figures consists of circular nodal lines along with diametral (fig. 23).

Fig. 23.

Circular nodal lines unaccompanied by intersecting lines cannot be produced in the manner described; but may be got either by drilling a small hole through the centre, and drawing a horse-hair along its edge to bring out the note, or by attaching a long thin elastic rod to the centre of the plate, at right angles to it, holding the rod by the middle and rubbing it lengthwise with a bit of cloth powdered with resin, till the rod gives a distinct note; the vibrations are communicated to the plate, which consequently vibrates transversely, and causes the sand to heap itself into one or more concentric rings.

Theory of Chladni's figures.

72. The theory of the vibrations of plates has not yet been put on a quite satisfactory basis. The following law may, however, be regarded as confirmed by experiment, viz., that when two different plates of the same substance present the same nodal configuration, the numbers of vibrations are to each other directly as the thicknesses, and inversely as the superficial areas.

Vibrations of membranes.

73. Paper, parchment, or any other thin membrane stretched over a square, circular, &c., frame, when in the vicinity of a sufficiently powerful vibrating body, will, through the medium of the air, be itself made to vibrate in unison, and, by using sand, as in previous instances, the nodal lines will be depicted to the eye, and seen to vary in form, number, and position with the tension of the plate and the pitch of the originating sound. The membrana tympani or drum of the ear has, in like manner and on the same principles, the property of repeating the vibrations of the external air which it communicates to the internal parts of the ear.

Longitudinal vibrations of rods.

74. Rods vibrating longitudinally are, as we have already remarked, subject to the laws of stationary waves. If, for instance, a wooden rod fixed at one end, be rubbed near the top between the finger and thumb previously coated with powdered resin, it will yield a fundamental note when it so vibrates as to have only *one* node (at the fixed extremity) and half a ventral segment reaching from that extremity to the other, that is, when the length l of the rod is $\frac{1}{4}\lambda$, or $\lambda = 4l$, and therefore $n = \frac{V}{4l}$. But it may also give overtones corresponding to 2, 3, &c. nodes, the free end being always the middle of a ventral segment, and for which therefore the lengths of waves are $\frac{4l}{3}$, $\frac{4l}{5}$, &c. (as will be easily seen by referring to figs. in § 67, which may equally represent transversal and longitudinal displacements). Hence, the fundamental and harmonics of a rod such as we are now considering, have vibrations whose rates are as the successive odd numbers.

A series of like rods, each fixed at one end into a block of wood, and of lengths bearing to each other, the ratios $1 : \frac{8}{9}$: &c. (as in § 61), will give the common scale when rubbed in the manner already mentioned. This follows from the fundamental having $n = \frac{V}{4l}$, and therefore $n \propto \frac{1}{l}$.

Glass rods or tubes may also be made to vibrate longitudinally by means of a moist piece of cloth; but it is advisable to clamp them firmly at the centre, when each half will vibrate according to the same laws as the wooden rods above. The existence of a motion of the particles of glass to and fro in the direction of its length may be well exhibited, by allowing a small ball of stone or metal suspended by a string to rest against one extremity of the rod, when, as soon as the latter is made to sing by friction, the ball will be thrown off with considerable violence.

Part VIII.

Theory of Pipes.

Air is the essential source of sound in pipes.

75. The *longitudinal* vibrations of air enclosed in pipes are of greater practical importance than those of other bodies, because made available to a very great extent for musical purposes. In the flute, horn, trumpet, and other wind instruments, it is the contained air that forms the essential medium for the production of sound, the wood or metal enclosing it having no other effect but to modify the *timbre* or acoustic colour of the note.

Principles of Bernouilli's theory.

76. In dealing with the theory of pipes, we must treat the air precisely in the same manner as we have dealt with elastic rods vibrating lengthwise, a pipe stopped at both ends being regarded as equivalent to a rod fixed at both ends, a pipe open at both ends to a rod free at both ends, and a pipe stopped at one end and open at the other to a rod fixed at one end and free at the other. When therefore the air within the pipe is anywhere displaced along the length of the pipe, two waves travel thence in opposite directions, and being reflected at the extremities of the pipe, there results a stationary wave with one or more fixed nodal sections, on one side of which the air is at any moment being displaced in one direction, while on the other side it is displaced in the opposite. Hence, when the air on both sides of the node is moving in towards it, there is condensation going on at the node, followed by rarefaction on the reversal of the motion of the air. The full lines in annexed figs. are curves of *displacements*, the dotted lines curves of *velocity* and *density* (*vid.* § 10 and 14).

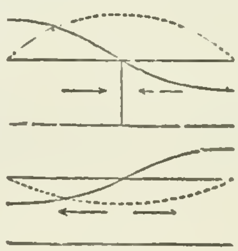

Fig. 24.

As a stopped end prevents any motion of the air, a nodal section is always found there. And as, at the open end, we may conceive the internal air to be maintained at the same density as the external air, we may assume that such end coincides with the middle of a ventral segment.

From these assumptions, which form the basis of Bernouilli's Theory of Pipes, we infer:

77. That in a pipe stopped at both ends, as in a rod fixed at both ends, the fundamental note (fig. 25, 1), corresponds to $\lambda = 2l$, and therefore to $n = \frac{V}{2l}$, V denoting the velocity of sound in air, and the overtones to numbers of vibrations $= 2n$, $3n$, and so on. Fig. 25, 2, represents the octave.

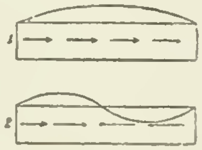

Fig. 25.

Open pipe

78 That in a pipe open at both ends the same holds good as in the previous case. For (fig. 26, 1) $AC = \frac{1}{4}\lambda$ $\therefore \lambda = 4\ AC = 2l$, and in fig. 26, 2, $AD = \frac{1}{4}\lambda$, and also $= \frac{1}{4}\ l\ \therefore\ \lambda = l$, or $\frac{1}{2}$ its value for the fundamental; and similarly for the other harmonics.

Pipe stopped at one end only

79. That in a pipe open at one end and stopped at the other (or, as it is usually termed, a *stopped* pipe, case § 77, being purely imaginary), the fundamental note has $n = \frac{V}{4l}$, and the overtones correspond to $3n$, $5n$. . . .

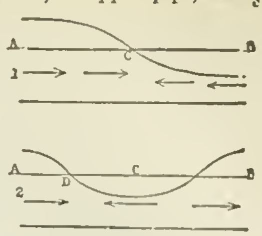

Fig. 26

For, in fig. 27, 1, AB or $l = \frac{1}{4}\lambda$, and in fig. 27, 2, CB or $\frac{1}{4}\lambda$ is evidently $= \frac{1}{3}$ AB or $\frac{1}{3}\ l$, whence $\lambda = \frac{4}{3}l$, which being $\frac{1}{3}$ of value of λ in previous case, shows that the number of vibrations is three times greater. Similarly for the other overtones.

80. It follows from the above, that a given pipe (whether open or stopped) may be made to emit, in addition to or in combination with its fundamental, a series of overtones, which, in an open pipe, follow the natural numbers, and hence are the octave, twelfth, &c., but, in a *stopped pipe*, follow the *odd* numbers, so as to want the octave and other notes represented by the even numbers. The succession of overtones may be practically obtained by properly regulating the force of the blast of air by which the air-column is put into vibration.

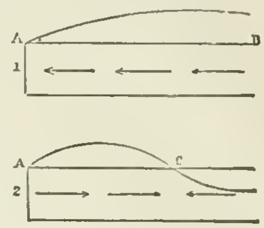

Fig. 27.

81. If the fundamental notes of two pipes of equal lengths, but of which one is open, the other stopped, be compared together, they will be found to differ in pitch by an octave, the stopped being the lower. This fact is in keeping with the theory, for the numbers of vibrations being respectively $\frac{V}{2l}$ and $\frac{V}{4l}$, are in the ratio of 2 to 1

Notes of open and stopped pipes of equal length.

82. By altering the length of the same pipe, we can vary the pitch of the fundamental at pleasure, since n varies inversely as l. This is effected in the flute and some other wind instruments by means of openings along part of the pipe, which, being closed or opened by means of keys and of the fingers, increase or diminish the length of the vibrating air-column. In this manner the successive notes of the scale are usually obtained within the range of an octave. The scale is further extended by bringing into play the higher harmonics.

83. Since in an open pipe $n = \frac{V}{2l}$, and therefore $l = \frac{V}{2n}$, if for V we put 1090 ft., and for n 264, which is the number of vibrations per second usually assigned to the note C, we get $l = 2$ ft. very nearly. This, accordingly, is the length of the so-called C open pipe. The C stopped pipe must, by what has been stated above, be 4 feet in length.

Length of C pipe

84. Conversely it is obvious that the velocity V of sound in air, and generally in any gas, may be deduced from the equation $V = 2nl$, and that if two pipes of equal length contain respectively air and any other gas, the velocities in the two media being to each other directly as the number of vibrations of the notes they respectively emit, we may, from the well-ascertained value of the velocity in air, determine in this way the velocities in other gases, and thence the values of their coefficients γ (*vid.* § 21).

85. While the inferences drawn by means of Bernouilli's theory agree, to a certain extent, with actual observation, there are discrepancies between the two which point to the existence of some flaw in one or both of the hypotheses on which the theory rests. In truth, the conditions assumed by Bernouilli are such as do not fully occur in

practice. The stopped extremity of a pipe is always to some extent of a yielding nature, and does not therefore exactly coincide with a nodal surface; nor can the internal air immediately adjoining the open end be perfectly free from variation of density during the vibrations of the whole mass, particularly so at the *embouchure*, where the blast is introduced by which the tone is originated It would appear from recent experiments that the pitch of a pipe is somewhat lower than the above theory would indicate.

86. The reed-pipe differs in many respects from the simple pipe which we have been considering. A small elastic strip of metal, fixed at one extremity (the *reed*), lies over a slit of the same shape, and is set in transverse vibration by a current of air acting underneath. If, as is the case in the accordion and harmonium, the reed is unprovided with a pipe, the pitch of its note is regulated altogether by the dimensions of the reed, in conformity with the law of tranversely vibrating plates; although, it is to be remarked, the note is really due to the vibrations of the air which alternately escapes through the slit of the reed, and is prevented doing so exactly as often as the reed executes a movement to and fro. The proper note of the reed itself is very poor and faint.

87. In the reed-pipe there is added above the reed a pipe the air in which partakes of the vibratory motion, and improves the quality of the sound. The pitch is, however, not affected by this pipe, unless it exceed a certain length l, when the pitch begins to fall, and continues to do so as l is increased, till, when the length of pipe is $2l$, the note is again restored to its original pitch, &c.

88. M. Weber, to whom we are indebted for these and other curious facts respecting reed pipes, has explained them thus:—If the reed be exactly at that part of the vibrating air-column where the air-displacements are at their maximum, and where consequently the air suffers no variation of density during the vibratory motion of the column, the oscillations of the reed are not at all affected by the air-vibrations, and consequently the pitch of the reed-pipe is the same as that of the reed itself. But if the reed be situated at any other part of the air-column, and especially at a nodal section, where the air is undergoing alternate condensation and rarefaction, then, when the air-blast from the wind chest pushes in the reed, the air in the pipe is in the act of rarefaction, and consequently tends to accelerate the reed inwards, whereas the elasticity of the reed tends in an opposite direction. When, again, the reed is passing to the other extreme of its vibration, the air in the pipe is in the act of condensation, and tends to accelerate the reed outwards or in the opposite direction to the elasticity of the reed. Hence the reed is affected just as if its elasticity, and therefore the rapidity of its vibrations, were diminished, and thus the pitch is lowered.

Part IX.

Singing Flames.

89. The *chemical* or *gas harmonicon*, which consists of a small flame of hydrogen or of coal gas, burning at the lower part of the interior of a glass tube, and giving out a very distinct note, exhibits considerable analogy with the reed-pipe. For, as Sondhaus seems to have established, the primary cause of the note lies in the oscillations of the gas within the burner and the feeding-pipe, which therefore play exactly the same part as does the reed portion of the reed-pipe. The air in the glass tube being heated by the flame ascends, and the pressure above the flame being thence diminished, the flame is forced upwards by the gas beneath, until an influx of atmospheric air at the top of the tube forces the flame back. Thus a periodic agitation of the flame ensues, accompanied by a corresponding disturbance of the air-column in the glass tube. The size of the flame and its position within the tube must be so regulated as to bring out the best possible note, which will then be found to be the same as the air in the tube would itself emit, according to the laws of pipes, allowance being made for the high temperature of the air. A series of tubes may thus be arranged of suitable lengths to give the common scale. It sometimes happens, particularly with short tubes, that the note will not come out spontaneously, all that is required, then, is either by blowing gently at the top of the tube, or by singing in unison with the *expected* note, to give to the air the requisite initial movement.

The flame, which burns steadily with a yellowish light before the tube sounds, will, as soon as the note is heard, be seen to flicker up and down, changing rapidly from yellow to blue and blue to yellow, its intensity also changing periodically. These fluctuations are best seen by viewing the image of the flame reflected by a small plane mirror, held in the hand and moved to and fro. Before the note is heard, the image of the then quiescent flame, being impressed on different points of the retina, appears as a continuous luminous strip; but, when the harmonicon speaks, the various images become quite detached from one another, showing that the portion of the retina over which the reflected light passes is sensibly affected only at certain points of it, which evidently correspond to the instants of time at which the flame, in its periodical fluctuations, is at its brightest.

Naked flames.

90. Naked flames, that is, flames unaccompanied by tubes, may also give out musical notes, and many singular instances are mentioned by Tyndall and others of their sensitiveness to external sounds.

Flame manometer.

91. Koenig of Paris has constructed an apparatus intended to indicate the modes of vibration of the different parts of vibrating bodies, such as columns of air, &c., by means of flames, and to which he has given the name of the *Flame Manometer*. We will here describe its application to the case of organ-pipes. An open pipe has three apertures along one side, one at the middle, o (fig. 28), *i.e.*, at a node of the fundamental tone, and the two others, a, b, half way between o and the extremities of the pipe, and coinciding therefore with the nodes of the first overtone or octave. These openings are closed by thin flexible membranes forming the ends of small boxes or *capsules*, the spaces within which communicate by caoutchouc tubes with a coal-gas reservoir, and also by separate tubes with small gas burners arranged on a vertical stand. The gas being introduced, and the three flames kindled and adjusted to equal heights of about $\frac{3}{4}$ of an inch; if the pipe be made now to utter its first overtone, the flame connected with o will remain stationary and of the same brightness as before, but those communicating with a and b will become longer and thinner, and assume a bluish and faint luminosity. But, if the fundamental be brought out of the pipe, then it is o's flame that is violently affected, while those of a and b are scarcely affected at all. If the flames be originally made less in height (say $\frac{1}{3}$ inch), those of a and b in the former case, and of o in the latter, will be extinguished. These results are due to the condensations and rarefactions of the air in the pipe which are at their maximum at a node, causing the membrane placed there to vibrate outwards and inwards, and hence to force more or less of the gas into the burner.

Fig. 28.

In order to compare together the notes of different pipes, four plane reflecting surfaces are connected together in the form of a cube, which is mounted on a vertical axis about which it is capable of being turned round. Each pipe is furnished with one opening, a membrane, &c. (as above), at its middle. As pointed out (§ 87), if any of the pipes be made to sound, the reflector being at the same time put in motion, a series of separate images will be seen. On sounding another pipe, whose fundamental is an octave higher, we shall have a second line of images separated from each other by half the interval of those in the former series. This is best observed when the two flames are placed in the same vertical line. If the note of the second pipe is a fifth higher than the first, and consequently its vibrations to those of the first as 3 to 2, then the same space which contains two images of the lower note will contain three of the higher, and so on, for other combinations. When more complicated ratios are to be tested, it is preferable to connect both capsules with the same burner, either with or without the reflector.

Part X.

Communication of Vibrations.

92. The communication of sonorous vibrations from one body to another plays so essential a part in acoustics that a few words must here be given to the subject. It appears to be well established that while the vibrations of a solid are in general most readily communicated to other solids in contact with it, they are not so to liquids, and still less so to air and other aeriform fluids. Thus, a tuning-fork is inaudible at any moderate distance unless applied to a table, by whose extended surface the air can be more intensely affected. So likewise a musical string sounds very poorly unless connected with a resonant cavity or wooden chest, to the wood of which it first imparts its vibratory motion, which then produces stationary waves in the continued air.

93. A few years ago M. Kundt made known a method founded on the communicability of vibration, by which the velocities of sound in different media may be compared together with great facility. Take a glass tube 3 feet or upwards in length, drop into it a small quantity of the fine powder of the club-moss or lycopodium, and turn the tube round so as to spread the powder over the internal surface of the tube. Stop both ends of the tube with corks, clamp it at its centre, and rub one of its halves lengthwise with a moist cloth, so as to cause the glass to sound a note. It will then be found that, the air within the tube taking up the motion, and a stationary wave being formed in it, the powder is driven off from the ventral segments and forms little heaps at the nodes. The dust-heaps are, by the laws of stationary waves, separated therefore from each other by intervals each equal to half the length of an air-wave, or $\frac{\lambda}{2}$. If, then, the number of heaps $=m$, and the length of the tube $=l$; $\lambda = \frac{2l}{m}$.

But, by the laws of longitudinal vibrations of rods, the length λ' of the glass-wave $=4\left(\frac{l}{2}\right)=2l$. Hence $\frac{\lambda'}{\lambda}=m$, that is, the number of dust-heaps is equal to the ratio of the lengths of a wave of sound in glass and in air, and consequently to the ratio of the velocities of sound in those media. (For the vibrations being in unison, their number in a given time must be the same for the glass and the air, *i.e.*, $\frac{V}{\lambda'}=\frac{V}{\lambda'}$; V, V′ being the velocities).

Kundt found 16 to be the number of heaps; prior experiments of a different kind had, as we have before mentioned, given this as the number of times that the velocity of sound in glass exceeds its velocity in air.

Instead of producing the air-vibrations by friction of the tube containing the air, it is preferable to make use of a smaller tube or rod, furnished with a cork at one end, which fits like a piston into the tube, and projecting at its outer end through an opening in the cork which closes the air-tube. The rod thus inserted is the one which is rubbed longitudinally and communicates its vibrations to the air in the enclosing tube. By means of an apparatus of this kind, Kundt determined the ratio to the velocity of sound in air of its velocity in various solids, and also (replacing the air in the tube by different gases) of its velocity in these gases.

Part XI.

Interference of Sound.

94. When two or more sonorous waves travel through the same medium, each particle of the air being simultaneously affected by the disturbances due to the different waves, moves in a different manner than it would if only acted on by each wave singly. The waves are said mutually to interfere. We shall exemplify this subject by considering the case of two waves travelling in the same direction through the air. We shall then obviously be led to the following results:—

95. If the two waves are of equal length λ, and are in the same phase (that is, each producing at any given moment the same state of motion in the air-particles), their combined effect is equivalent to that of a wave of the same length λ, but by which the excursions of the particles are increased, being the sum of those due to the two component waves respectively. Two w[illegible] of equ[illegible] lengths

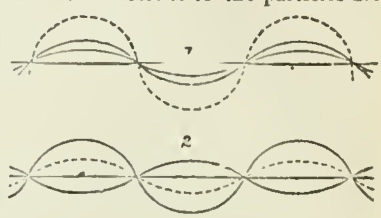

Fig. 29.

If the two interfering waves, being still of same length λ, be in opposite phases, or so that one is in advance of the other by $\frac{\lambda}{2}$, and consequently one produces in the air the opposite state of motion to the other, then the resultant wave is one of the same length λ, but by which the excursions of the particles are decreased, being the difference between those due to the component waves. If the amplitudes of vibration which thus mutually interfere are moreover equal, the effect is the total mutual destruction of the vibratory motion.

Thus we learn that two musical notes, of the same pitch, conveyed to the ear through the air, will produce the effect of a single note of the same pitch, but of increased loudness, if they are in the same phase, but affect the ear very slightly, if at all, when in opposite phases. If the difference of phase be varied gradually from zero to $\frac{1}{2}\lambda$, the resulting sound will gradually decrease from a maximum to a minimum.

96. Among the many experimental confirmations which may be adduced of these proportions, we will mention the following:— Experi-me[illegible] illus[illegible]

Vibrati[illegible] plate.

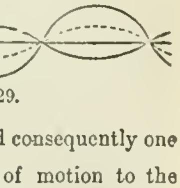

Fig. 30.

Take a circular plate, such as is available for the production of Chladni's figures (§ 71), and cut out of a sheet of pasteboard a piece of the shape ABOCD (fig. 30), consisting of two circular quadrants of the same diameter as the plate. Let, now, the plate be made in the usual manner to vibrate so as to exhibit two nodal lines coinciding with two rectangular diameters. If the ear be placed right above the centre of the plate, the sound will be scarcely audible. But, if the pasteboard be interposed so as to intercept the vibrating segments AOB, DOC, the note becomes much more distinct. The reason of this is, that the segments of the plate AOD, BOC always vibrate in the same direction, but oppositely to the segments AOB, DOC. Hence, when the pasteboard is in its place, there are two waves of same phase starting from the two former segments, and reaching the ear after equal distances of transmission through the air, are again in the same phase, and produce on the ear a conjunct impression. But when the pasteboard is removed, then there is at the ear opposition of phase between the first and the second pair of waves, and consequently a minimum of sound.

97. A tubular piece of wood shaped as in fig. 31, and having a piece of thin membrane stretched over the opening at the top C, some dry sand being strewn over the membrane, is so placed over a circular or rectangular vibrating plate, that the ends A, B lie over the segments of the plate, such as AOD, COB in the previous fig., which are in the same state of motion. The sand at C will be set in violent movement. But if the same ends A, B, be placed over oppositely vibrating segments (such as AOD, COD), the sand will be scarcely, if at all, affected.

Fig. 31.

98. If a tuning-fork in vibration be turned round before the ear, four positions will be found in which it will be inaudible, owing to the mutual interference of the oppositely vibrating prongs of the fork. On interposing the hand between the ear and either prong of the fork when in one of those positions, the sound becomes audible, because then one of the two interfering waves is cut off from the ear. This experiment may be varied by holding the fork over a glass jar into which water is poured to such a depth that the air-column within reinforces the note of the fork when suitably placed and then turning the fork round.

99. Helmholtz's double syren (§ 51) is well calculated for the investigation of the laws of interference of sound. For this purpose a simple mechanism is found in the instrument, by means of which the fixed upper plate can be turned round and placed in any position relatively to the lower one. If, now, the apparatus be so set that the notes from the upper and lower chest are in unison, the upper fixed plate may be placed in four positions, such as to cause the air-current to be cut off in the one chest at the exact instant when it is freely passing through the other, and *vice versa*. The two waves, therefore, being in opposite phases, neutralise one another, and the result is a faint sound. On turning round the upper chest into any intermediate position, the intensity of the sound will increase up to a maximum, which occurs when the air in both chests is being admitted and cut off contemporaneously.

100. If two pipes, in exact unison, and furnished with flame manometers, are in communication with the same wind-chest, and the two flames be placed in the same vertical line, on introducing the current from the bellows, we shall find that the two lines of reflected images will be so related that each image in one lies between two images in the other. This shows that the air-vibrations in one pipe are always in an opposite phase to the other, or that condensation is taking place in the one when rarefaction occurs in the other. This arises from the current from the bellows passing alternately into the one and the other pipe. There will also be a remarkable collapse of the sound when both pipes communicate with the wind-chest compared with that produced from one pipe alone.

101. If the two interfering waves are such as produce vibrations whose numbers per second are n, n' respectively, these being to each other in the ratio of two integers m, m' when expressed in its lowest terms, then the lengths of the waves λ, λ' being inversely as n to n', will be to each other as $m' : m$, and consequently $m\lambda = m'\lambda'$. Particles therefore of the air separated by this distance from each other will be in the same phase, that is, the length of the *resultant* wave will be $m\lambda$ or $m'\lambda'$, and if N denote the corresponding number of vibrations $N = \frac{n}{m}$ or $\frac{n'}{m'}$.

Thus, for the fundamental and its octave $\frac{n}{n'} = \frac{1}{2}$, and therefore $N = n$ or $\frac{n}{2}$; that is, the note of interference is of the same pitch as the fundamental.

For the fundamental and its major third, $\frac{n}{n'} = \frac{4}{5}$. Hence $N = \frac{n}{4}$ or $\frac{n'}{5}$, that is, the resulting sound is two octaves lower than the fundamental. Fundamental and major third.

For the fundamental and its major sixth, $\frac{n}{n'} = \frac{3}{5}$; N therefore $= \frac{n}{3}$ or $\frac{n'}{5}$, and the resulting sound is a twelfth below the lower of the two interfering notes. Fundamental and major sixth.

If m and m' differ by 1, then $N = n - n'$; for $m - m'$ or $1 = \frac{n}{N} - \frac{n^1}{N}$. Hence, if the ratio of the vibrations of two interfering sounds is expressible in its lowest terms by numbers whose difference is unity, the resulting note has a number of vibrations simply equal to the difference of those of the interfering notes. Case of $m - m' = 1$.

The results stated in this section may be tested on a harmonium. Thus, if the notes B, C, at the extreme right of the instrument be struck together, there will be heard an interference note four octaves lower in pitch than the above C, because the interval in question being a semitone, is $\frac{16}{15}$, and, consequently, by last case, the interference note is lower than the C by interval $\frac{1}{16}$.

Other notes may be heard resulting from the mutual interference of the overtones.

102. When two notes are not quite in tune, the resulting sound is found to alternate between a maximum and minimum of loudness recurring periodically. To these periodical alternations has been given the name of *Beats*. Their origin is easily explicable. Suppose the two notes to correspond to 200 and 203 vibrations per second; at some instant of time, the air-particles, through which the waves are passing, will be similarly displaced by both, and consequently the joint effect will be a sound of some intensity. But, after this, the first or less rapidly vibrating note will fall behind the other, and cause a diminution in the joint displacements of the particles, till, after the lapse of $\frac{1}{6}$ of a second, it will have fallen behind the other by $\frac{1}{2}$ a vibration. At this moment, therefore, opposite displacements will be produced of the air-particles by the two notes, and the sound due to them will be at a minimum. This will be followed by an increase of intensity until the lapse of another sixth of a second, when the less rapidly vibrating note will have lost another half-vibration relatively to the other, or one vibration reckoning from the original period of time, and the two component vibrations will again conspire and reproduce a maximum effect. Thus, an interval of $\frac{1}{3}$ of a second elapses between two successive maxima or beats, and there are produced three beats per second. By similar reasoning it may be shown that the number of beats per second is always equal to the difference between the numbers of vibrations in the same time corresponding to the two interfering notes. The more, therefore, these are out of tune, the more rapidly will the beats follow each other. Beats.

Beats are also heard, though less distinctly, when other concords such as *thirds*, *fifths*, &c., are not perfectly in tune; thus, 200 vibrations and 303 vibrations per second, which form, in combination, an imperfect fifth, produce beats occurring at the rate of three per second.

103. The phenomena of beats may be easily observed with two organ-pipes put slightly out of tune by placing the hand near the open end of one of them, with two musical strings on a resonant chest, or with two tuning-forks of same pitch held over a resonant cavity (such as a glass jar, *vid.* § 97), one of the forks being put out of tune by loading one prong with a small lump of bees'-wax. In the last instance, if the forks are fixed on one solid piece of wood which can be grasped with the hand, the beats will be actually felt by the hand. If one prong of each fork be furnished with a small plain mirror, and a beam of light from a luminous point be reflected successively by the two mirrors, so as to form an image on a distant screen, when one fork alone is put in vibration, the image will move on the screen and be seen as a line of a certain length. If both forks are in vibration, and are perfectly in tune, this line may either be increased or diminished permanently in length, according to the difference of phase between the two sets of vibrations. But if the forks be not quite in tune, then the length of the image will be found to fluctuate between a maximum and a minimum, thus making the beats sensible to the eye. The vibrograph (§ 52, 53) is also well suited for the same purpose, and so in an especial manner is Helmholtz' double syren (§ 51), in which, by continually turning round the upper box, a note is produced by it more or less out of tune with the note formed by the lower chest, according as the handle is moved more or less rapidly, and most audible beats ensue. The gas harmonica and the flame manometer also afford excellent illustrations of the laws of beats.

The number of vibrations of a note found by beats.

104. Advantage has been taken of these laws for the purpose of determining the absolute number of vibrations per second corresponding to any given note in music, whence may be derived the number for all the other notes (§ 45). The human ear may be regarded as most correctly appreciating two notes differing by an octave. Two tuning-forks then are taken, giving respectively the note A and its lower octave, and a number of other forks are prepared intermediate in pitch to these, say 54, and by means of bees'-wax these are so tuned, that the first gives four beats with the A fork, the second four beats with the fourth, and so on up to the last, which also gives four beats with the A_{-1} fork. Now, if n = the unknown number of vibrations for the note A, $n-4$, $n-8$ . . . $n-55\times 4$, will be the numbers for all the successive forks down to the A_{-1} fork, which being an octave below A, we have $\frac{n-55\times 4}{n}=\frac{1}{2}$ and consequently $n=440$.

Tuning by beats.

105. Beats also afford an excellent practical guide in the tuning of instruments, but more so for the higher notes of the register, inasmuch as the same number of beats, that is, the same difference between the numbers of vibrations, for two notes of high pitch, indicates greater deviation from perfect unison, than it does for two notes of low pitch. Thus, two low notes of 32 and 30 vibrations respectively, whose interval is therefore $\frac{32}{30}$ or $\frac{16}{15}$ *i.e.*, a semitone, give two beats per second, while the same number of beats are given by notes of 32×16 (four octaves higher than the first of the preceding) or 512 and 514 vibrations, which are only slightly out of tune.

106. As the interval between two notes, and consequently the number of beats increases, the effect on the ear becomes more and more unpleasant, and degenerates at last into an irritating rattle. With the middle notes of the musical register, this result occurs when the number of beats comes up to 20 or 30 per second, the musical interval between the two interfering notes being then between half and a whole tone. Helmholtz attributes the disagreeable impression of beats on the ear to the same physiological cause to which is due the painful effect on the eye of a faint flickering light, as, for instance, the light streaming through a wooden paling with intervening openings when the individual affected is passing alongside. In this case, the retina, which, when continuously receiving the same amount of light, thereby loses its sensitiveness in a great degree, is unable to do so.

It is, however, remarked by the above-mentioned author that the same number of beats, which has so irritating an effect when due to two notes in the middle of the register, is not attended by the same result when due to notes of much lower pitch. Thus, the notes C, D forming a tone give together 33 beats per second, while a note two octaves lower than C also gives 33 beats with its fifth; yet the former combination forms a discord, the latter a most pleasing concord.

Difference tones.

107. When the number of beats reaches to 132 or upwards per second, the result is a continuous and not unpleasing impression on the ear, and it was formerly held that the effect was always equivalent to that of a note having that number of vibrations. Helmholtz has shown that this opinion is inaccurate, except when the interfering tones are very loud, and consequently accompanied by very considerable displacements of the particles of the vibrating medium. These resultant tones being, as to their vibration-number, equal to the difference between the numbers corresponding to the two primaries, are termed *difference-tones*, and may be best observed with the double syren. The same author was led also, on theoretical grounds, to surmise the formation of *summation-tones* by the interference of two loud primaries, the number of resultant vibrations being then equal to the sum of the numbers for the two components, and appealed for experimental proof to his syren. But, at the last meeting of the British Association (1872), Koenig, the celebrated Parisian acoustician, maintained that the notes of the syren, thus held to be summation-tones, were in reality the *difference-tones* of the harmonics.

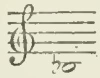
Summation-tones.

Helmholtz's explanation of acoustic colour

108. By reference to the laws of the interference of vibrations, Helmholtz has been enabled to offer a highly satisfactory explanation of the cause whence arises difference of quality or timbre or acoustic colour between different sounds. He has shown conclusively that there are but few sounds which are of a perfectly simple character, that is, in which the fundamental is not accompanied by one or more overtones. Now, when a note is simple, there can be no jarring on the ear, because there is on room for interference of sound. Hence, the softness of the tuning-fork when its fundamental is reinforced by a resonant cavity, and also of the flute. The same character of softness belongs also to those instruments in which the powerful harmonics are limited to the vibration ratios 2, 3 . . . 6 (§ 57, 80); because the mutual interference of the fundamental and their harmonics give rise to concords only. The piano, the open organ pipe, the violin, and the softer tones of the human voice, are of this class. But if the *odd* harmonics alone are present, as in the narrow stopped organ pipe, and in the clarionet, then the sound is poor, and even nasal; and if the higher harmonics beyond the sixth or seventh are very marked, the result is very harsh (as in reed-pipes).

109. The *human voice* (for a description of the organ in which it originates, we refer to Art. *Physiology—Voice and Speech*) is regarded by the best authorities as being analogous to a reed-pipe, the vocal chords forming the reed, and the cavity of the mouth the pipe, and, like the reed, is rich in harmonics, as many as sixteen having been detected in a bass voice. But their number and relative intensities differ much in different individuals, or even in the same person at different times; and it is on this variety that, agreeably to Helm-

holtz's theory of timbre, the peculiarities depend by which any one voice may be unmistakably distinguished from every other. Voices in which overtones abound are sharp, and even rough; those in which they are few or faint, are soft and sweet. In every voice, however, the number and relative intensity of the overtones depend on the form assumed by the cavity of the mouth, which acts relatively to the vocal chords precisely as a *resonator* does to a tuning-fork, or a pipe to a reed. This may be easily tested by holding a tuning-fork before the open mouth, when, by giving to the cavity a suitable form, the fundamental or some overtone of the fork may be heard distinctly reverberated from the interior of the mouth. Each vowel sound, as Helmholtz has shown, is simply the result of the reinforcements by the air in the cavity of the mouth, and its prolongation towards the larynx, of one or in some cases two overtones of determinate pitch, contained in the sound which proceeds from the vocal chords. Koenig assigns the following notes as characteristic of the simpler vowel sounds (adopting the foreign pronunciation):—To U, the note B♭ below the line in the G clef, corresponding to 225 vibrations per second; to O, the next higher octave, consequently of double the number of vibrations, and thence ascending by octaves for A, E, and I, the last of which is therefore characterised by a note of 3600 vibrations per second.



The above theory of vowel sounds may be satisfactorily confirmed by means of tuning-forks, vibrating in front of resonant cavities, which can, by suitable combination, be made to utter any vowel sound.

Works on Acoustics.

Chladni, *Traité d'Acoustique.* Paris, 1809.

Herschel, Sir John, *Encycl. Metrop.*, art. "Sound." London, 1830.

Tyndall, *Lectures on Sound*, 2d edit. London, 1869.

Helmholtz, *Die Lehre von der Tonempfindungen*, 3d edit. Braunschweig, 1870, of which there is a French translation, and an English one is promised.

Besides the above, some account of the subject is to be found in such general works on Physics as Ganot's, 14th edit., Paris, 1870, of which a translation is published by Longmans, London; Deschanel's *Natural Philosophy*, translated by Prof. Everett, London, 1873; Jamin, *Cours de Physique*, 3d edit., Paris, 1871; Wülner, *Physik*, 2d edit., Leipzig, 1870. (D. T.)

ALPHABETICAL INDEX.

The numerals refer to the sections.

ACQUI, a town of Northern Italy, in the province of Alessandria, 18 miles S.S.W. of the city of that name, on the left bank of the Bormida. It is a place of great antiquity; and its hot sulphur baths, which are still much frequented, were known to the Romans, who gave the place the name of *Aquæ Statiellæ*. There are still to be found numerous ancient inscriptions, and the remains of a Roman aqueduct. The town is the seat of a bishop, and has a fine cathedral, several convents, and a royal college. Good wine is produced in the vineyards of the district, and great attention is given to the rearing of silk-worms. There are also considerable silk manufactures. Population, 8600.

ACRE, a measure of surface, being the principal denomination of land-measure used in Great Britain. The word (akin to the Saxon *acer*, the German *acker*, and the Latin *ager*, a field) did not originally signify a determinate quantity of land, but any open ground. The English standard or imperial acre contains 4840 *square yards*, or 10 square chains, and is also divided into *roods*, of which it contains 4, the rood again being divided in 40 *perches*. The imperial acre has, by the Act 5 Geo. IV. c. 74, superseded the acres, of very different extent, that were in use in different parts of the country. The old Scottish acre was equal to 1·26118345 imperial acres. The Irish acre contains 7840 square yards. The acre is equivalent to ·40467, *i.e.*, about $\frac{2}{5}$ths, of the French *hectare* (now the basis of superficial measurement in Germany, Italy, and Spain, as well as in France), ·7 of the Austrian *joch*, ·37 of the Russian *desätine*, and 1·62 ancient Roman *jugera*. The *hectare* corresponds to 2 acres 1 rood 35·38 perches.

ACRE, AKKA, or ST JEAN D'ACRE, a town and seaport of Syria, and in ancient times a celebrated city. No town has experienced greater changes from political revolutions and the calamities of war. According to some this was the *Accho* of the Scriptures; and its great antiquity is proved by fragments of houses that have been found, consisting of that highly sun-burnt brick, with a mixture of cement and sand, which was only used in erections of the remotest ages. It was known among the ancients by the name of *Ace*, but it is only from the period when it was taken possession of by Ptolemy Soter, king of Egypt, and received from him the name of *Ptolemais*, that history gives any certain account of it. When the empire of the Romans began to extend over Asia, Ptolemais came into their possession. It is mentioned by Strabo as a city of great importance; and fine granite and marble pillars, monuments of its ancient grandeur, are still to be seen. During the Middle Ages Ptolemais passed into the hands of the Saracens. They were expelled from it in 1110 by the Crusaders, who made it their principal port, and retained it until 1187, when it was recovered by Saladin. In 1191 it was retaken by Richard I. of England and Philip of France, who purchased this conquest by the sacrifice of 100,000 troops. They gave the town to the knights of St John of Jerusalem, from whom it received the name of St Jean D'Acre. In their possession it remained for a century, though subject to continual assaults from the Saracens. It was at this time a large and extensive city, populous and wealthy, and contained numerous churches, convents, and hospitals, of which no traces now remain. Acre was finally lost to the Crusaders in 1291, when it was taken by the Saracens after a bloody siege, during which it suffered severely. From this time its prosperity rapidly declined. In 1517 it fell into the hands of the Turkish sultan, Selim I.; and in the beginning of the 18th century, with the exception of the residences of the French factors, a mosque, and a few poor cottages, it presented a vast scene of ruin. Towards the end of that century Acre was much strengthened and improved by the Turks, particularly by Djezzar Pacha, and again rose to some importance. It is memorable in modern history for the gallantry with which it was defended in 1799 by the Turks, assisted by Sir Sydney Smith, against Bonaparte, who, after spending sixty-one days before it, was obliged to retreat. It continued to enjoy an increasing degree of prosperity till 1832. Though fettered by imposts and monopolies, it carried on a considerable foreign trade, and had resident consuls from most of the great states of Europe. On the revolt of Mehemet Ali, the pacha of Egypt, Acre was besieged by his son, Ibrahim Pacha, in the winter of 1831–32. The siege lasted five months and twenty-one days, and, before the city was taken, its public and private buildings were mostly destroyed. Its fortifications were subsequently repaired and improved by the Egyptians, in whose hands it remained until 3d Nov. 1840, when the town was reduced to ruins by a three hours' bombardment from the British fleet, acting as the allies of the sultan. The Turks were again put in possession of it in 1841.

Acre is situated on a low promontory, at the northern extremity of the Bay of Acre. The bay affords no shelter in bad weather; and the port is scarcely capable of containing a dozen boats. Vessels coming to this coast, therefore, generally frequent the anchorage of Caiffa, on the south side of the bay. Acre is 80 miles N.N.W. of Jerusalem, and 27 S. of Tyre. Population, 10,000.

ACROBAT (from ἀκροβατέω, to walk on tiptoe), a rope-dancer. Evidence exists that there were very skilful performers on the tight-rope (*funambuli*) among the ancient Romans. Modern acrobats generally use a long pole, loaded at the ends, and by shifting this are enabled to maintain, or readily to recover, their equilibrium. By an extension of the meaning of the term, acrobatic feats now include trapèze leaping and similar performances.

ACROCERAUNIA, in *Ancient Geography*, a promontory in the N.W. of Epirus, which terminates the Montes Ceraunii, a range that runs S.E. from the promontory along the coast for a number of miles, and is supposed to have derived its name from being often struck with lightning. The cape (now called *Glossa* by the Greeks, and *Linguetta* by the Italians) is in lat. 40° 25′ N.

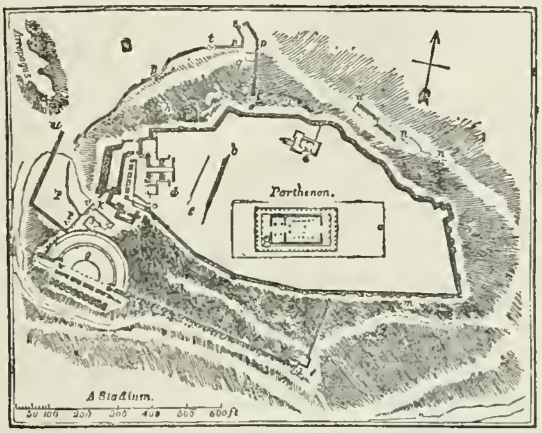
ACROGENÆ is the name applied to a division of acotyledonous or cryptogamous plants, in which leaves are present along with vascular tissue. In the higher divisions of Acrogens, as ferns and lycopods, the tissue consists of scalariform vessels, while in the lower divisions spiral cells are observed, which take the place of vessels. The term Acrogen means summit-grower, that is, a plant in which the stem increases specially by the summit. This is not, however, strictly accurate.

ACROLITH (ἀκρόλιθοι), statues of a transition period in the history of plastic art, in which the trunk of the figure was of wood, and the head, hands, and feet of marble. The wood was concealed either by gilding or, more commonly, by drapery, and the marble parts alone were exposed. Acroliths are frequently mentioned by Pausanias, the best known specimen being the Minerva Areia of the Platæans.

ACRON, a celebrated physician, born at Agrigentum in Sicily, who was contemporary with Empedocles, and must therefore have lived in the 5th century before Christ. The successful measure of lighting large fires, and purifying the air with perfumes, to put a stop to the pestilence that raged in Athens (430 B.C.), is said to have originated with him; but this has been questioned on chronological grounds. Pliny is mistaken in saying that Acron was the founder of the sect of the Empirici, which did not exist until the 3d century before Christ. The error probably arose from a desire on the part of the sect to establish for itself a greater antiquity than that of the Dogmatici. Suidas gives the titles of several works written by Acron.

on medical subjects, in the Doric dialect, but none of these now exist.

ACROPOLIS (Ἀκρόπολις), a word signifying the upper town, or chief place of a city, a citadel, usually on the summit of a rock or hill. Such buildings were common in Greek cities; and they are also found elsewhere, as in the case of the Capitol at Rome, and the Antonia at Jerusalem; but the most celebrated was that at Athens, the remains of which still delight and astonish travellers. It was enclosed by walls, portions of which show traces of extreme antiquity. It had nine gates; the principal one was a splendid structure of Pentelican marble, in noble Doric architecture, which bore the name of *Propylaia.* Besides other beautiful edifices, it contains the Παρθενών, or temple of the virgin goddess Athene, the most glorious monument of ancient Grecian architecture.



Ground plan of the Acropolis of Athens.

a, Pedestal of Rome and Augustus.
b, c, d, Sites of temples of Minerva, Diana, and Venus.
e, Erectheium.
f, Dionysiac theatre.
g, Odeon of Herodes.

i, Ruined mosque.
k, l, Gate and portico.
m, Choragic monument of Thrasycles, now church of our lady of the grotto.
n, n, Remains of Pelasgic wall.
p, u, Walls of outworks, &c.
s, Gate to Propylæa.
q, r, t, Forts.
u, v, Ancient walls.

ACROSTIC (from ἄκρος and στίχος, meaning literally the extremity of a verse), is a species of poetical composition, so constructed that the initial letters of the lines, taken consecutively, form certain names or other particular words. This fancy is of considerable antiquity, one of the most remarkable examples of it being the verses cited by Lactantius and Eusebius in the 4th century, and attributed to the Erythræan sibyl, the initial letters of which form the words Ἰησοῦς Χριστὸς Θεοῦ υἱὸς σωτήρ: "Jesus Christ, the Son of God, the Saviour," with the addition, according to some, of σταυρός, "the cross." The initials of the shorter form of this again make up the word ἰχθύς, to which a mystical meaning has been attached (Augustine, *De Civitate Dei*, 18, 23), thus constituting another kind of acrostic. The arguments of the comedies of Plautus, with acrostics on the names of the respective plays, are probably of still earlier date. Sir John Davies (1570–1626) wrote twenty-six elegant *Hymns to Astræa*, each an acrostic on "Elizabetha Regina;" and Mistress Mary Fage, in *Fame's Roule*, 1637, commemorated 420 celebrities of her time in acrostic verses. The same form of composition is often to be met with in the writings of more recent versifiers. Sometimes the lines are so combined that the final letters as well as the initials are significant. Edgar Allan Poe, with characteristic ingenuity, worked two names—one of them that of Frances Sargent Osgood—into verses in such a way that the letters of the names corresponded to the first letter of the first line, the second letter of the second, the third letter of the third, and so on.

Generally speaking, acrostic verse is not of much value, and is held in slight estimation. Dr Samuel Butler says, in his "Character of a Small Poet," "He uses to lay the outsides of his verses even, like a bricklayer, by a line of rhyme and acrostic, and fill the middle with rubbish." Addison (*Spectator*, No. 60) found it impossible to decide whether the inventor of the anagram or the acrostic were the greater blockhead; and, in describing the latter, says, "I have seen some of them where the verses have not only been edged by a name at each extremity, but have had the same name running down like a seam through the middle of the poem." And Dryden, in *Mac Flecknoe*, scornfully assigned Shadwell the rule of

> "Some peaceful province in acrostic land."

The name acrostic is also applied to alphabetical or "abecedarian" verses. Of these we have instances in some of the Hebrew psalms (*e.g.*, Ps. xxv. and xxxiv.), the successive verses of which begin with the letters of the alphabet in their order. The structure of Ps. cxix. is still more elaborate, each of the verses of each of the twenty-two parts commencing with the letter which stands at the head of the part in our English translation. Alphabetical verses have been constructed with every word of the successive lines beginning with the successive letters of the alphabet.

By an extended use of the term acrostic, it is applied to the formation of words from the initial letters of other words. Ἰχθύς, referred to above, is an illustration of this. So also is the word "Cabal," which, though it was in use before, with a similar meaning, has, from the time of Charles II., been associated with a particular ministry, from the accident of its being composed of Clifford, Ashley, Buckingham, Arlington, and Lauderdale. Akin to this are the names by which the Jews designated their Rabbis; thus Rabbi Moses ben Maimon (better known as Maimonides), was styled "Rambam," from the initials R. M. B. M.; Rabbi David Kimchi (R. D. K.), "Radak," &c.

A species of puzzle, scarcely known twenty years ago, but very common now (see *English Catalogue*, 1863–71, *s. v.* Acrostics), is a combination of enigma and double acrostic, in which words are to be guessed whose initial and final letters form other words that are also to be guessed. Thus Sleep and Dream may have to be discovered from the first and last letters of Sound, Lover, Europe, Elia, and Palm, all expressed enigmatically.

ACT, in *Dramatic Literature*, signifies one of those parts into which a play is divided to mark the change of of time or place, and to give a respite to the actors and to the audience. In Greek plays there are no separate acts, the unities being strictly observed, and the action being continuous from beginning to end. If the principal actors left the stage the chorus took up the argument, and contributed an integral part of the play, though chiefly in the form of comment upon the action. When necessary, another *drama*, which is etymologically the same as an *act*, carried on the history to a later time or in a different place, and thus we have the Greek trilogies or groups of three dramas, in which the same characters reappear. The Roman poets first adopted the division into acts, and suspended the stage business in the intervals between them. Their number was usually five, and the rule was at last laid down by Horace in the *Ars Poetica*—

> "Neve minor, neu sit quinto productior actu
> Fabula, quæ posci vult, et spectata reponi."

> "If you would have your play deserve success,
> Give it five acts complete, nor more nor less."
> —*Francis.*

On the revival of letters this rule was almost universally observed by dramatists and that there is an inherent convenience and fitness in the number five is evident from the fact that Shakespeare, who refused to be trammelled by merely arbitrary rules, adopts it in all his plays. Some critics have laid down rules as to the part each act should sustain in the development of the plot, but these are not essential, and are by no means universally recognised. In comedy the rule as to the number of acts has not been so strictly adhered to as in tragedy, a division into two acts or three acts being quite usual since the time of Molière, who first introduced it.

It may be well to mention here Milton's *Samson Agonistes* as a specimen in English literature of a dramatic work founded on a purely Greek model, in which, consequently, there is no division into acts.

ACT, in *Law*, is an instrument in writing for declaring or justifying the truth of anything; in which sense records, decrees, sentences, reports, certificates, &c., are called *acts*. The origin of the legal use of the word *Act* is in the *acta* of the Roman magistrates or people, of their courts of law, or of the senate, meaning (1) what was done before the magistrates, the people, or the senate; (2) the records of such public proceedings.

ACT OF PARLIAMENT. An Act of Parliament may be regarded as a declaration of the Legislature, enforcing certain rules of conduct, or defining rights and conferring them upon or withholding them from certain persons or classes of persons. The collective body of such declarations constitutes the statutes of the realm or written law of the nation, in the widest sense, from Anglo-Saxon times to the present day. It is not, however, till Magna Charta that, in a more limited constitutional sense, the statute-book is generally held to open, and the Parliamentary records only begin to assume distinct outlines late in the reign of Edward I. The maladministration of the common law by the royal judges had gradually taught the people the necessity of obtaining written declarations of their rights—often acknowledged, still oftener violated. Insensibly almost, the Commons, whose chief function it originally was to vote supplies to the crown, began to couple their grants with petitions for the redress of grievances. The substance of these petitions and of the royal responses was in time made the groundwork of Acts which, as framed by court redactors, and appearing annexed to proclamation-writs after the dissolution of Parliament, were frequently found seriously to misrepresent its will. To check this evil an Act was passed (8 Henry IV.), authorising the Commons to be represented at the engrossing of the Parliament roll; but even this surveillance was not enough, for in the beginning of the reign of Henry V. it was enacted, at the instance of the Commons, that in regard to their petitions the royal prerogative should in future be limited to granting or refusing them *simpliciter*. In this way it became a fixed constitutional principle that an Act of Parliament, to be valid, must express concurrently the will of the entire Legislature. It was not, however, till the reign of Henry VI. that it became customary, as now, to introduce bills into Parliament in the form of finished Acts; and the enacting clause, regarded by constitutionalists as the first perfect assertion, in words, of popular right, came into general use as late as the reign of Charles II. It is thus expressed:—"Be it enacted by the King's most excellent Majesty, by and with the advice and consent of the Lords Spiritual and Temporal and Commons in this present Parliament assembled, and by the authority of the same." The use of the preamble with which Acts are usually prefaced, is thus quaintly set forth by Lord Coke,—"The rehearsal or preamble of the statute is a good meane to find out the meaning of the statute, and, as it were, a key to open the understanding thereof." Originally, the collective Acts of each session formed but one statute, to which a general title was attached, and for this reason an Act of Parliament is always cited as the chapter of a particular statute—*e.g.*, 24 and 25 Vict. c. 101. Titles were, however, prefixed to individual Acts as early as 1488. Since 33 Geo. III. c. 13, an Act of Parliament is complete whenever it receives the royal assent, and takes effect from that date, unless the Act itself fix some other. British Acts require no formal promulgation, for it is presumed that every subject of the realm is cognisant of the resolutions of Parliament, either by himself or his representative therein.

Modern Acts of Parliament are—1. *Public*. These are binding on all citizens, and are *ex officio* cognisable by the judges. Since 1850 every Act is held to be public unless the contrary be expressly declared. 2. *Private Acts*. These relate to particular classes, persons, or places. Private Acts are (1.) Personal, viz., those which relate to name, naturalisation, estate, &c., of particular persons. (2.) Local, affecting bridges, canals, docks, turnpikes, railways, &c. To prevent such Acts from being unduly passed, the promoters of private bills are required to comply with the standing orders of the two Houses, by which private bill procedure is regulated. Acts of Parliament, for convenience of reference, are classified as Public General Acts, Local and Personal Acts declared Public, Private Acts printed, and Private Acts not printed. Public General Acts (if no exception be expressed), extend to Great Britain and Ireland, exclusively only of the Channel Islands and the Isle of Man.

The first complete edition of English Acts of Parliament published by state authority appeared between the years 1810 and 1824. It includes the early charters, and ends with the reign of Queen Anne. Many private editions of the statutes had appeared previous to that of the Record Commissioners. The practice of printing Acts of Parliament commenced in the reign of Richard III. The charters and Acts were written in Latin till the *Statutum de Scaccario*, 51 Henry III. (1266), which is in French. The Acts of Edward I. are indiscriminately in Latin or French; but from the fourth year of Henry VII. Acts are exclusively in English.

Scotch Acts.—The earliest attempts at a written record of the proceedings of the Parliament of Scotland consisted of detached instruments or indentures, and the next step was the entering of these detached instruments on a roll for more permanent preservation. No such record, however, is preserved before the disputed succession, which commenced in 1289. The earliest roll of *placita in parliamento* is dated 1292; but the *Blak Buik*, containing a series of proceedings in Parliament from 1357 to 1402, is the most important of the earliest records of Parliament. The original books of Parliament of the reigns of James I. and James II. are not preserved, but from the year 1466 down to the Union a voluminous, but not unbroken, series has been preserved. Down to the reign of James V., scarcely any Act in the original registers is distinguished by a title or rubric; and even after that period the practice has not in this respect been uniform. In like manner there is no numeration of the Acts of Parliament during this period. The language of the earliest Scotch records is in Latin; but as early as 1398 some of the proceedings of Parliament or the Council-General were written in Scots, and subsequently to 1424 always in that language. Unlike the English Acts, French was never used in Scotch legislation. In 1541 a selection of the Acts of James V. was printed. The first edition of the Acts was published in 1566, the second in 1597, the third in 1681; and the great national work, the complete record of Parliament, has just been completed, with a general index to the whole Acts from 1124 to 1707, which forms the great repertory of the legal, constitutional, and political history of Scotland. In 1540 an Act was passed requiring all the Acts of Parliament to be pronounced in presence of the king and the estates,—the assent of the king being indicated by his touching them with the sceptre; and in 1641 it was ordained that the Acts passed in 1640 be published in the king's name, and with the consent of the estates. But during the civil war the Acts of Parliament were passed in name of the estates alone. These Acts, however, were rescinded after the restoration of Charles II. by Act 1661, c. 126, because "the power of making laws is an essential privilege of the royal prerogative." In 1457 an Act was passed for proclaiming the Acts of Parliament in the shires and burghs, that none be ignorant; and in 1581 it was ordained that Acts need not be proclaimed at the market-cross of the head burgh of each shire, but at the market-cross of Edinburgh only, the lieges obeying them forty days thereafter. The clerk of register was always bound to give extracts of Acts to the lieges in their particular affairs. In 1425 a committee, consisting of an equal number of each estate, was appointed to amend the books of law; and in 1567 a commission was issued to codify the laws, civil and municipal, dividing them into heads like the Roman law,—the heads as they are ready to be brought to Parliament to be confirmed. Lord Bacon recommended the Scotch Acts for their "excelent brevity." His lordship's praise applies very properly to the Acts down to the reign of Queen Mary and the early part of the reign of James VI.; but the logomachy of subsequent legislation is intolerable to the consulter.

Irish Acts may be said to commence A.D. 1310, in the reign of Edward II., and to close with the union with the British Parliament in 1801. From the former date, however, there is a break till 1429. In 1495 *Poyning's Law* provided that no bill should be introduced into the Irish Parliament which has not previously received the royal assent in England; and till 1782 the Parliament of Ireland remained in tutelage to that of England. Since 1801 it has been incorporated with the Parliament of Great Britain.

ACT OF SEDERUNT, in *Scotch Law*, an ordinance for regulating the forms of procedure before the Court of Session, passed by the judges in virtue of a power conferred by an Act of the Scotch Parliament, 1540, c. 93. In former times this power was in several instances clearly exceeded, and such Acts of Sederunt required to be ratified by the Scotch Parliament; but for more than a century and a half Acts of Sederunt have been almost exclusively confined to matters relating to the regulation of judicial procedure. Many recent statutes contain a clause empowering the court to make the necessary Acts of Sederunt. A quorum of nine judges is required to pass an Act of Sederunt.

ACTS OF THE APOSTLES, the fifth among the canonical books of the New Testament. What has to be said on this book will naturally fall under the following heads: The state of the text; the authorship; the object of the work; the date and the place of its composition.

The State of the Text.—The Acts is found in two MSS. generally assigned to the 4th century, the *Codex Sinaiticus*, in St Petersburg, and the *Codex Vaticanus*, in Rome; in one MS. assigned to the 5th century, the *Codex Alexandrinus*, in the British Museum; in two MSS. belonging to the 6th century, the *Codex Bezæ*, in Cambridge, and the *Codex Laudianus*, in Oxford; and in one of the 9th century, the *Codex Palimpsestus Porfirianus*, in St Petersburg, with the exception of chapter first and eight verses of chapter second. Large fragments are contained in a MS. of the 5th century, the *Codex Ephræmi*, in Paris. Fragments are contained in five other MSS., none of which is later than the 9th century. These are all the uncial MSS. containing the Acts or portions of it.

The MSS. in Oxford and Cambridge differ widely from the others. This is especially the case with the Cambridge MS., the *Codex Bezæ*, which is said to contain no less than six hundred interpolations. Scrivener, who has edited this MS. with great care, says, "While the general course of the history and the spirit of the work remain the same as in our commonly received text, we perpetually encounter long passages in *Codex Bezæ* which resemble that text only as a loose and explanatory paraphrase recalls the original form from which it sprung; save that there is no difference in the language in this instance, it is hardly an exaggeration of the facts to assert that Codex D [*i.e.*, *Codex Bezæ*] reproduces the *textus receptus* of the Acts much in the same way that one of the best Chaldee Targums does the Hebrew of the Old Testament, so wide are the variations in the diction, so constant and inveterate the practice of expanding the narrative by means of interpolations." Scrivener here assumes that the additions of the *Codex Bezæ* are interpolations, and this is the opinion of nearly all critics. There is one, however, Bornemann, who thinks that the *Codex Bezæ* contains the original text, and that the others are mutilated. But even supposing that we were quite sure that the additions were interpolations, the *Codex Bezæ* makes it more difficult to determine what the real text was. Scrivener, with good reason, supposes that the *Codex Bezæ* is derived from an original which would most likely belong to the third century at the latest.

Authorship of the Work.—In treating this subject we begin with the external evidence.

The first mention of the authorship of the Acts in a well-authenticated book occurs in the treatise of Irenæus against heresies, written between the years 182 and 188 A.D. Irenæus names St Luke as the author, as if the fact were well known and undoubted. He attributes the third Gospel to him, and calls him "a follower and disciple of apostles" (*H.* iii. 10, 1). He states that "he was inseparable from Paul, and was his fellow-worker in the gospel" (*H.* iii. 14, 1). The next mention occurs in the *Stromata* of Clemens Alexandrinus, written about 195 A.D., where part of St Paul's speech to the Athenians is quoted with the words, "Even as Luke also, in the Acts of the Apostles, records Paul as saying" (*Strom.* v. xii. 82, p. 696, Pott). The Acts of the Apostles is quoted by Tertullian as Scripture, and assigned to St Luke (*Adv. Mar.* v. 2 and 3). Origen speaks of "Luke who wrote the Gospel and the Acts" (Eus. *H. E.* vi. 25); and Eusebius includes the Acts of the Apostles in his summary of the books of the New Testament (*Hist. Eccl.* iii. 25). The Muratorian canon, generally assigned to the end of the second or beginning of the third century, includes the Acts of the Apostles, assigns it to St Luke, and says that he was an eye-witness of the facts recorded. There is thus unanimous testimony up to the time of Eusebius that St Luke was the author of the Acts. This unanimity is not disturbed by the circumstance that some heretics rejected the work, for they did not deny the authorship of the book, but refused to acknowledge it as a source of dogmatic truth.

After the time of Eusebius we find statements to the effect that the Acts was little known. "The existence of this book," Chrysostom says, "is not known to many, nor the person who wrote and composed it." And Photius, in the ninth century, says, "Some maintain that it was Clement of Rome that was the writer of the Acts, others that it was Barnabas, and others that it was Luke the Evangelist."

Irenæus makes such copious quotations from the Acts that we can feel sure that he had before him substantially our Acts. We cannot go further back than Irenæus with certainty. If, as we shall see, the writer of the Acts was also the writer of the third Gospel, we have Justin Martyr's testimony (about 150 A.D.) for the existence of the third Gospel in his day, and therefore a likelihood that the Acts existed also. But we have no satisfactory evidence that Justin used the Acts, and there is nothing in the Apostolic Fathers, nor in any work anterior to the *Letter of the Churches of Vienne and Lyons*, written probably soon after 177 A.D., to prove the existence of the Acts.

The weight of external evidence therefore goes entirely for St Luke as the author of the Acts. But it has to be noticed, that the earliest testimony is more than a hundred years later than the events described in the Acts. We have also to take into account that Irenæus was not critical. We find him calling the *Pastor of Hermas* Scripture; Clemens Alexandrinus also calls the *Pastor* inspired; and Origen not merely attributes inspiration to the work, but makes the author of it the Hermas mentioned in the Epistle to the Romans. All scholars reject the testimony of Irenæus, Clemens Alexandrinus, and Origen in this matter. The question arises, How far are we to trust them in others of a similar nature?

We turn to the internal evidence. And in the very commencement we find the author giving himself out as the person who wrote the third Gospel. This claim has been almost universally acknowledged. There is a remarkable similarity of style in both. The same peculiar modes of expression continually occur in both; and throughout both there exist continual references backward and forward, which imply the same authorship. There are some difficulties in the way of this conclusion. Two of these deserve special notice. If we turn to the last chapter of the Gospel, we find it stated there (ver. 13) that two disciples met Jesus on the day of the resurrection, as they were going to Emmaus. Towards nightfall (ver. 29) he entered the village with them; and as he reclined with them, he became known to them, and disappeared. Whereupon "at that very hour" (ver. 33) they rose up and returned to Jerusalem. They found the eleven assembled, and told them what had happened to them. "While they were saying these things, he himself stood in the midst of them" (ver. 36) The apostles gave him a piece of fish, and he ate it. "But he said to them" (ver. 44), so the narrative goes on, and it then relates his speech; and at ver. 50 it says, "He led them out to Bethany," and then disappeared from them. This disappearance was final; and if the words used in the Gospel make us hesitate in determining it to be his ascension, such hesitation is removed by the opening words of the Acts. According to the Gospel, therefore, all the events now related took place, or seem to have taken place, on the day of the resurrection, or they may possibly have extended into the next morning, but certainly not later. The Acts, on the contrary, states that Jesus was seen by the disciples for forty days, and makes him deliver the speech addressed to his disciples and ascend into heaven forty days after the resurrection. The other instance is perhaps still more singular. In the Acts we have three accounts of the conversion of St Paul—the first by the writer himself, the other two by St Paul in his speeches. The writer states that (ix. 4, 7) when the light shone round Paul, he fell to the ground, "but the men who were journeying with him stood dumb." St Paul himself says (xxvi. 14) that they all fell to the ground. The writer says (ix. 7) that St Paul's companions heard the voice, but saw no one. St Paul himself says (xxii. 9) that his companions saw the light, but did not hear the voice of him who spake to him. And finally, all these accounts differ in their report of what was said on the occasion. Notwithstanding these differences, even these very accounts contain evidence in them that they were written by the same writer, and they do not destroy the force of the rest of the evidence. The case would be quite different if Baur, Schwegler, and Wittichen were right in supposing that the Gospel of Luke contained documents of opposite tendencies. It would then be necessary to assume different authors for the different parts of the Gospel, and still another for the Acts. But this theory falls to the ground if the Tübingen theory of tendencies is rejected.

The Acts itself claims to be written by a companion of St Paul. In chap. xvi. 10, the writer, without any previous warning, passes from the third person to the first. St Paul had reached the Troad. There he saw a vision inviting him to go to Macedonia. "But when he saw the vision, straightway *we* sought to go out into Macedonia." The use of the "we" continues until Paul leaves Philippi. In chap. xx. Paul returns to Philippi, and the "we" is resumed, and is kept up till the end of the work. Irenæus (*H.* iii. 14, 1) quotes these passages as proof that Luke, the author, was a companion of the apostle. The minute character of the narrative, the accurate description of the various journeyings, the unimportance of some of the details, and the impossibility of contriving all the incidents of the shipwreck without experiencing them, are strong reasons for believing that we have the narrative of an eye-witness. And if we allow this much, we can scarcely help coming to the conclusion that this eye-witness was the author of the work; for the style of this eye-witness is exactly the style of the writer who composed the previous portions. Some have supposed that we have here the personal narrative of Timothy or of Silas; but this supposition would compel us to believe that the writer of the Acts was so careless as to tack documents together without remembering to alter their form. Such a procedure on the part of the skilful writer of the Acts is unlikely in the highest degree The "we" is introduced intentionally, and can be accounted for only in two ways: either by supposing that the writer was an eye-witness, or that he wished to be thought an eye-witness, and borrowed the narrative of an eye-witness to facilitate the deception. Zeller has adopted this latter alternative; and this latter alternative is the only possible one for those who assign a very late date to the Acts.

We may test the writer's claim to be regarded as a companion of St Paul by comparing his statements with those of the other books of the New Testament. As might be expected, the great facts recorded in the Gospels are reproduced accurately in the Acts. There is only one marked difference. St Matthew says (xxvii. 5, 7) that Judas cast the traitor's money into the temple, and the priests bought with it a field for the burial of strangers. St Peter in Acts (i. 18) says, that Judas himself purchased a field with the reward of his iniquity. St Matthew says that he went and hanged himself, St Peter that he fell headlong and burst in the middle. St Matthew says, or rather seems to say, that the field was called the field of blood, because it was purchased with blood-money; St Peter seems to attribute the name to the circumstance that Judas died in it.

The Acts is divided into two distinct parts. The first deals with the church in Jerusalem, and especially narrates the actions of St Peter. We have no external means of testing this portion of the narrative The Acts is the only work from which information is got in regard to these events. The second part pursues the history of the apostle Paul; and here we can compare the statements made in the Acts with those made in the Epistles. Now here again we have a general harmony. St Paul travels in the regions where his Epistles show that he founded churches. The friends of St Paul mentioned in the Acts are also the friends acknowledged in the Epistles. And there are many minute coincidences. At the same time, we learn from this comparison that St Luke is not anxious to give minute details. Timothy probably visited Athens while St Paul was there. This we learn from 1 Thess. iii. 1, but no mention is made of this visit in the Acts. Again, we gather from the Epistles to the Corinthians that St Paul paid a visit to Corinth, which is not recorded in the Acts. Moreover, no mention is made of Titus in the Acts. These, however, are slight matters; and it must be allowed that there is a general agreement. But attention has been drawn to two remarkable exception These are the account given by St Paul of his visits to Jerusalem in the Epistle to the Galatians and that given by St Luke; and the character and mission of the apostle Paul, as they appear in his letters and as they appear in the Acts.

In regard to the first point, St Paul himself says in the Epistle to the Galatians, that after his conversion straightway he held no counsel with flesh and blood, nor did he go up to Jerusalem to the apostles who were before him; but he went away to Arabia and returned to Damascus; that then after three years he went up to Jerusalem to seek for Cephas, and he remained with him fourteen days. He at that time saw only two apostles,—Peter, and James the brother of the Lord. He then went away to Syria and Cilicia, and was unknown by face to the churches of Judea. He says that fourteen years after this he went up to Jerusalem with Barnabas, taking Titus with him. On this occasion he went up by revelation. St Paul introduces these facts for a purpose, and this purpose is that he might prove his independence as an apostle. He had acted solely on the revelation given to himself. He had neither required nor obtained sanction from the other apostles. He was an apostle, not sent forth from men nor through men, but through Jesus and God. When we turn to the Acts, we find that no mention is made of the journey to Arabia. He stays some days at Damascus, and then begins to preach the gospel. He continues at this work a considerable time; and then, in consequence of the plots of the Jews, he secretly withdraws from Damascus and proceeds to Jerusalem. The brethren there are suspicious in regard to him, and their fears are not quieted until Barnabas takes him to the apostles; and after this introduction he goes in and out amongst them, and holds discussions with the Hellenists. Finally, when the Hellenists attempt to kill him, the brethren send him to Tarsus. In the Epistle to the Galatians St Paul does everything for himself, instigated by his inward feelings. In the Acts he is forced out of Antioch, and sent by the brethren to Tarsus. In the Galatians St Paul stays only a fortnight, and sees only St Peter and St James of the apostles, and was unknown by face to the churches of Judea. In the Acts Barnabas takes him to the *apostles*, and he continues evidently for a period much longer than a fortnight, going in and out amongst them. Then in chap. xi. 30, he goes up a second time to Jerusalem,—a visit which seems inconsistent with the narrative in the Epistle to the Galatians. And finally, when he goes up to Jerusalem, the Acts does not represent him going up by an independent revelation, but as being sent up; and it says nothing of his taking an independent part, but represents him as submitting to the apostles.

This, however, leads us to the treatment of the character of St Paul by the writer of the Acts. Some of the Tübingen critics assert that the writer shows ill-will to St Paul, but they are evidently wrong. On the contrary, the character of the apostle as given in the Acts is full of grand and noble traits. Yet still there are some singular phenomena in the Acts.. St Paul claimed to be an apostle by the will of God. He had as good a right to be an apostle as St Peter or St James. Yet the writer of the Acts never calls him an apostle in the strict sense of the term. He is twice called an apostle, namely, in Acts xiv. 4 and 14. On both occasions his fellow-apostle is Barnabas; but Barnabas was not one of the twelve, and not an apostle in the strict sense of the term. And even in these verses the reading is doubtful. The *Codex Bezæ* omits the word *apostle* in the 14th verse, and makes the 4th liable to suspicion by inserting an addition to it. St Luke also brings prominently forward as the proper mark of an apostle, that he should have companied with the Lord from his baptism to his ascension, and describes the filling up of the number of the twelve by the election of Matthias. And if St Luke's narrative of St Paul's conversion be minutely examined, it will be perceived that not only does he not mention that St Paul saw Jesus, but the circumstances as related scarcely permitted St Paul to see Jesus. He was at once dazzled by the light, and fell to the ground. In this prostrate condition, with his eyes shut, he heard the voice; but at first he did not know whose it was. And when he opened his eyes, he found that he was blind. The words of Ananias imply that St Paul really did see Jesus, but St Luke abstains from any such statement. And St Paul is not treated by the Jewish Christians in the Acts as an independent apostle. He is evidently under submission to the apostles at Jerusalem.

Furthermore, the point on which St Paul specially insists in the Epistle to the Galatians is, that he was appointed the apostle to the Gentiles as St Peter was to the circumcision, and that circumcision and the observance of the Jewish law were of no importance to the Christian. St Paul's words on this point in all his letters are strong and decided. But in the Acts it is St Peter that opens up the way for the Gentiles. In St Peter's mouth occurs the strongest language in regard to the intolerable nature of the law. Not a word is said of the quarrel between St Peter and St Paul. The brethren in Antioch send St Paul and Barnabas up to Jerusalem to ask the opinion of the apostles and elders. St Paul awaits the decision of the apostles, and St Paul and Barnabas carry back the decision to Antioch. And throughout the whole of the Acts St Paul never stands forth as the champion of the Gentiles. He seems continually anxious to reconcile the Jewish Christians to himself, by observing the law of Moses. He circumcises Timothy, and he performs his vows in the temple. And he is particularly careful in his speeches to show how deep his respect for the law of Moses is In this regard the letters of St Paul are very different from his speeches as given in the Acts. In the Epistle to the Galatians he claims perfect freedom for himself and the Gentiles from the observance of the law; and neither in it nor in the Epistle to the Corinthians does he take any notice of the decision to which the apostles are said to have come in their meeting at Jerusalem. And yet the narrative of St Luke implies a different state of affairs from that which it actually states in words; for why should the Jews hate St Paul so much more than the other apostles if there was nothing special in his attitude towards them?

We may add to this, that while St Luke gives a rather minute account of the sufferings of St Peter and the church in Jerusalem, he has not brought prominently forward the perils of St Paul. St Paul enumerates some of his sufferings in the second Epistle to the Corinthians (chap. xi. 23–28). St Luke has omitted a great number of these. Thus, for instance, St Paul mentions that he was thrice shipwrecked. St Luke does not notice one of these shipwrecks, that recorded in the Acts having taken place after the Epistles to the Corinthians were written. Some also think that St Luke details several occurrences which are scarcely in harmony with the character of St Paul. They say that the dismissal of John Mark, as recorded in the Acts, is a harsh act. St Paul's remark, "I wist not that he is the high priest" (xxiii. 5), they regard as doubtful in point of honesty. And the way by which he gained the Pharisees to his side, in opposition to the Sadducees, they describe as an expedient unworthy the character of this fearless apostle (xxiii. 6).

St Luke occasionally alludes, in the Acts, to events which took place outside of the church. We can test his accuracy in recording these events by comparing his narrative with the narratives of historians who treat of the same period. These historians are Josephus, Tacitus, and Suetonius. Now, here again we find that the accounts in the Acts generally agree. Indeed, Holtzmann has noticed that all the external events mentioned in the Acts are also to be found in Josephus. We may therefore omit Tacitus and Suetonius, and confine ourselves to Josephus. Three narratives deserve minute examination. The first is the death of Herod Agrippa. Josephus says (*Ant.* xix. 8, 2) that Herod was at Cæsarea celebrating a festival in honour of the Cæsar. On the second day of the spectacle, the king put on a robe made entirely of silver, and entered the theatre early in the day. The sun's rays fell upon the silver, and a strong impression was produced on the people, so that his flatterers called out that he was a god. He did not check their impiety, but soon, on looking up he saw an owl perched above his head on a rope. He at once recognised in the bird the harbinger of evil. Immediately he was attacked by violent pains in the bowels, and after five days' illness died. The Acts says that Herod was addressing a deputation of Tyrians and Sidonians in Cæsarea, seated on the tribunal and arrayed in a royal robe. The people called out, "The voice of a god, and not of a man." "Immediately an angel of the Lord struck him because he gave not God the glory, and becoming worm-eaten, he died" (xii. 21–23). Both accounts agree in representing Herod as suddenly struck with disease because he did not check the impiety of his flatterers, but they agree in almost nothing else; and it is difficult to conceive that the one writer knew the account of the other. Which account is most to be trusted, depends upon the answer given to the question which is the more credible historian.

The second case relates to the Egyptian mentioned in the question of the tribune to St Paul, in Acts xxi. 38, "You are not then the Egyptian who, some time ago, made a disturbance, and led into the wilderness the four thousand of the sicarii?" Josephus mentions this Egyptian, both in his *Antiquities* (xx. 8, 6) and in the *Jewish War* (ii. 13, 5). In the *Jewish War* (ii. 13, 3), Josephus describes the sicarii, and then passes on, after a short section, to the Egyptian. He states that he collected thirty thousand people, led them out of the wilderness "to the mount called the Mount of Olives, which," he says (*Ant.* xx. 8, 6) in words similar to those in Acts i. 12, "lies opposite to the city five furlongs distant." On this Felix attacked him, killed some, captured others, and scattered the band. The Egyptian, however, escaped with some followers. Hence the question in the Acts. There are some striking resemblances between the words used by both writers. The numbers differ; but St Luke gives the numbers of the sicarii, Josephus the numbers of the entire multitude led astray.

The third case is the one which has attracted most attention. In the speech which Gamaliel delivers, in Acts v. 35–39, it is said, "Some time before this, Theudas rose up, saying that he was some one, to whom a number of about four hundred men attached themselves, who was cut off, and all who followed him were broken up and came to nought. After him rose up Judas the Galilean, in the days of the registration, and he took away people after him; and he also perished, and all that followed him were scattered." On turning to Josephus we find that both Theudas and Judas the Galilean are mentioned. The circumstances related of both are the same as in the Acts, but the dates are different. According to Josephus, Theudas gave himself out as a prophet, in the reign of Claudius, more than ten years after the speech of Gamaliel had been delivered, while Judas appeared at the period of the registration, and therefore a considerable time before Theudas. To explain this difficulty, some have supposed that there may have been another Theudas not mentioned by Josephus, or that Josephus is wrong in his chronology. Others suppose that St Luke made a mistake in regard to Theudas, and is right in regard to Judas. Keim maintains that St Luke has made the mistake, and suggests that possibly it may be based upon the passage of Josephus; and Holtzmann has gone more minutely into this argument. Holtzmann draws attention to the nature of the sections of Josephus which contain the references to Theudas and Judas (*Ant.* xx. 5, 1, 2). He says that nearly all the principal statements made in these short sections emerge somewhere in the Acts: the census of Quirinus, the great famine, Alexander as a member of a noble Jewish family, and Ananias as high priest. Moreover, St Luke has preserved the order of Josephus in mentioning Theudas and Judas; but Josephus says "the sons of Judas," whereas St Luke says "Judas." "Is it not likely," Holtzmann argues, "that St Luke had before his mind this passage of Josephus, but forgot that it was the sons of Judas that were after Theudas, and not the father?" He adds also, that in the short passage in the Acts there are five peculiar expressions, identical or nearly identical with the expressions used by Josephus, and comes to the conclusion that St Luke knew the works of Josephus. He finds further traces of this knowledge in the circumstance that, in Acts xiii. 20–21, St Luke agrees in his statements with Josephus where both differ from the Old Testament. He also adduces certain Greek words which he supposes St Luke derived from his reading of Josephus. Max Krenkel, in making an addition to this argument, tries to show, from a comparison of passages, that St Luke had Josephus before his mind in the narrative of the childhood of Christ; and he supposes that the expedient attributed to the apostle Paul, of setting the Pharisees against the Sadducees (Acts xxiii. 6), is based upon a similar narrative given in Josephus (*Bell. Jud.* ii. 21, 3, and *Vita*, 26 ff.). The importance of this investigation is great; for if Holtzmann and Krenkel were to prove their point, a likelihood would be established that the Acts of the Apostles, or at least a portion of it, was written after 93 A.D., the year in which the *Antiquities* of Josephus was published, according to a passage occurring in the work itself. Meanwhile, the fact that important portions of the narrative must have been written by an eye-witness of the events recorded, combined with the unity of style and purpose in the book, are cogent arguments on the other side.

The speeches in the Acts deserve special notice. The question occurs here, Did St Luke follow the plan adopted by all historians of his age, or is he a singular exception? The historians of his age claimed the liberty of working up, in their own language, the speeches recorded by them. They did not dream of verbal accuracy, even when they had the exact words of the speakers before them, they preferred to mould the thoughts of the speakers into their own methods of presentation. Besides this, historians do not hesitate to give to the characters of their history speeches which they never uttered. The method of direct speech is useful in producing a vivid idea of what was supposed to pass through the mind of the speaker, and therefore is used continually to make the narrative lively. Now it is generally believed that St Luke has followed the practice of his contemporaries. There are some of his speeches that are evidently the summaries of thoughts that passed through the minds of individuals or of multitudes. Others unquestionably claim to be reports of speeches really delivered. But all these speeches have, to a large extent, the same style as that of the narrative. They have passed to a large extent through the writer's mind, and are given in his words. They are, moreover, all of them the merest abstracts. The speech of St Paul at Athens, as given by St Luke, would not occupy more than a minute and a half in delivery. The longest speech in the Acts, that of the martyr Stephen, would not take more than ten minutes to deliver. It is not likely that either speech lasted so short a time. But this circumstance, while destroying their verbal accuracy, does not destroy their authenticity; and it must strike all that, in most of the speeches, there is a singular appropriateness, there is an exact fitting-in of the thoughts to the character, and there are occasionally allusions of an obscure nature, which point very clearly to their authenticity. The one strong objection urged against this inference, is that the speeches of St Peter and St Paul show no doctrinal differences, such as are said to appear in the Epistles; but the argument has no force, unless it be proved that St Paul's doctrine of justification is different from the creed of St Peter or St James.

Not the least important of the questions which influence critics in determining the authorship of the Acts is that of miracles. Most of those who think that miracles are impossible, come to the conclusion that the narratives containing them are legendary, and accordingly they maintain that the first portion of the Acts, relating to the early church in Jerusalem and to St Peter, is in the highest degree untrustworthy. The writer, it is maintained, had no personal knowledge of those early days, and received the stories after they had gone through a long process of transmutation. They appeal, for instance, to the account of the Pentecost, where the miracle of speaking with tongues is described. They say that it is plain, on a comparison of the Epistle to the Corinthians with the Acts, that St Paul meant one thing by the gift of tongues, and the writer of the Acts another. And the inference is at hand that, if the writer had known St Paul, he would have known what the gift of tongues was; and the possibility of such a mistake, it is said, implies a considerable distance from the time of the apostles and the primitive church. They point also to the curious parallelism between the miracles of St Peter and those of St Paul. St Peter begins his series of miracles by healing a lame man (iii. 2); so does St Paul (xiv. 8). St Peter exorcises evil spirits (v. 16; viii. 7); so does St Paul (xix. 15; xvi. 18). If St Peter deals with the magician Simon, St Paul encounters Elymas. If St Peter punishes with death (v. 1 ff.), St Paul punishes with blindness (xiii. 6 ff.). If St Peter works miracles by his shadow (v. 15), not less powerful are the aprons and napkins of St Paul (xix. 12). And, finally, if St Peter can raise Tabitha from the dead (ix. 36), St Paul is equally successful in the case of Eutychus (xx. 9). It is easy to see, also, that since there is no contemporary history with which to compare the statements in the Acts, and since many of the statements are of a summary nature, and very few dates are given, a critic who believes the narratives legendary will have no difficulty in finding many elements in the narratives confirmatory of his belief. But to those who believe in miracles the rest of the narrative seems plain and unvarnished. The parallelism between the miracles of St Peter and St Paul is accounted for by the fact that they acted in similar circumstances, and that actual events were at hand on which to base the parallelism. At the same time, some who believe in the possibility of miracles think that the Acts presents peculiar difficulties in this matter. They say that the healing by means of shadows and aprons is of a magical nature; that the death of Ananias and Sapphira, and the other destructive miracles, are out of harmony with the rest of the miracles of the New Testament; and that the earthquakes that release St Peter and St Paul seem purposeless. The difficulties on this head, though real, are not however of great importance, nor do they tell very seriously against the received opinion that St Luke is the author of the work.

We have thus given a general summary of the questions which come up in investigating the authorship of the Acts, and of the arguments used in settling this point. The conclusions based upon this evidence are very different. Some join the traditional opinion of the church to the modern idea of inspiration, and maintain that St Luke was the author of the work, that every discrepancy is merely apparent, and that every speech contains the real and genuine words of the speaker. Others maintain that St Luke is the writer, and that the book is justly placed in the canon; that the narrative is, on the whole, thoroughly trustworthy, and that neither its canonicity nor credibility is affected by the existence of real discrepancies in the narrative. Others hold that St Luke is the author, but that we have got in the book an ordinary narrative, with portions credible and portions incredible; that for the early portions of the work he had to trust mainly to his memory, dulled by distance from the scene of action and by lapse of time, and that he has given what he knew with the uncritical indifference to minute accuracy in time, circumstance, and word, which characterises all his contemporaries. Others maintain that St Luke is the author, but that, being a credulous and unscientific Christian, he recorded indeed in honesty all that he knew, but that he was deluded in his belief of miracles, and is often inaccurate in his statement of facts. Others think that St Luke was not the author of the work. He may have been the original author of the diary of the Apostle Paul's travels in which the "we" occurs; but the author of the Acts did not write the diary, but inserted it into his narrative after altering it for a special purpose, and the narrative was written long after St Paul and St Luke were dead. Others think that in the Acts we have the work of Timothy or of Silas, or of some one else. A considerable number imagine that St Luke had different written documents before him while composing, and a very few think that the work is the work of more than one writer. But as we have intimated, the weight of testimony is in favour of St Luke's authorship.

Purpose.—We have seen that the Acts of the Apostles is the work of one author possessed of no inconsiderable skill. This author evidently omits many things that he knew; he gives a short account of others of which he could have supplied accurate details, and, as in the case of St Paul, he has brought forward one side of the character prominently, and thrown the other into the shade. What motive could have led him to act thus? What object had he in inserting what he has inserted, and omitting what he has omitted? Most of the answers given to these questions have no important bearing on the question of the authorship of the Acts. But the case is different with the answer of the Tübingen school. The Tübingen school maintains that St Paul taught that the law was of no avail to Jew and Gentile, and that, therefore, the observance of it was unnecessary; that St Peter and the other apostles taught that the observance of the law was necessary, and that they separated from St Paul on this point; and that the early Christians were divided into two great classes—those who held with St Paul, or the Gentile Christians, and those who held with St Peter, or the Jewish Christians. They further maintain that there prevailed a violent controversy between these two parties in the church, until a fusion took place towards the middle of the second half of the second century, and the Catholic Church arose. At what stage of this controversy was the Acts written? is the question they put. St Peter, we have seen, is represented in the Acts as opening the church to the Gentiles. St Peter and the rest of the apostles at Jerusalem admit the Gentiles on certain gentle conditions of refraining from things offered to idols, from animals suffocated, from blood, and from fornication. What could be the object of such statements but to convince the Jewish Christians that they were wrong in pertinaciously adhering to their entire exclusion of the Gentiles, or insisting on their observance of the entire law? But St Paul is represented as observing the law, as sent forth by St Peter and the other apostles, as going continually to the Jews first, and as appearing in the temple and coming up with collections for the Jerusalem church. Was not this also intended to reconcile the Jewish Christians to St Paul? Then the great doctrines of St Paul all but vanish—free grace, justification by faith alone, redemption through the blood of Christ,—all that is characteristic of St Paul disappears, except his universalism, and that is modified by the decree of the apostles, the circumcision of Timothy, and St Paul's observance of the law. The object of all this, they affirm, must be to reconcile the Jewish party by concessions. But there is said to be also another object, of minor importance indeed, but still quite evident and falling in with the other. Throughout the Acts St Paul is often accused of turning the world upside down and causing disturbances. The Jewish Christians may have thought that St Paul was to blame in this matter, and that St Paul's opinions were peculiarly calculated to stir up persecution against the Christians. The stories in the Acts were devised to convince them that they were mistaken in this supposition. On every occasion in which St Paul is accused before magistrates, and especially Roman magistrates, he is acquitted. Gallio, the town-clerk of Ephesus, Lysias, Felix, and Festus, all declare that St Paul has done nothing contrary to the law. And while the Romans thus free him from all blame, it is the Jews who are always accusing him.

We have here reproduced the argument of Zeller, who has given the most thorough exposition of an opinion held also by Baur, Schwegler, and others. The argument fails to have effect if the assumption that St Paul and St Peter differed radically is rejected. It also suffers from the circumstance, that there is no historical authentication of the church being in such a state in the first half of the second century, that this attempt at reconciliation could take place within it. Moreover, the writing of a fictitious production seems an extraordinary means for any one to employ in order to effect reconciliation, especially if, as Zeller imagines, the church in Rome was specially contemplated. The church in Rome and the other Christian churches had St Paul's Epistles to the Romans, Corinthians, and Galatians before them They could be in no doubt as to what were his sentiments. They must also have had some history of his career; and no object could be effected by attempting to palm upon them a decree of apostles which never existed, or a history of St Peter and St Paul contradicted by what they knew of both.

Overbeck, finding this solution of Zeller unsatisfactory, thinks that the object of the Acts is to help the Gentile-Christian Church of the first half of the second century, now far removed from Paulinism and strongly influenced by Judaism, to form a clear idea of its own past, especially of its own origin and of its founder St Paul. It is thus, he maintains, an historical novel, somewhat like the *Clementines*, devised to realise the state of the church at an earlier period.

It would be tedious to enumerate all the other objects which have been set forth as the special aim of the Acts. Some think that it was a work written for the private use of Theophilus, and aimed, therefore, at giving him the special information which he required. Others think that it is intended to describe the spread of the gospel from Jerusalem to Rome. Others believe that the writer wished to defend the character of the Apostle Paul. Some of the more recent members of the Tübingen school think that it was intended to distort the character of St Paul, and that the image of him given in the Acts is an intermediate stage between the real Paul and the caricature supposed by them to be made of him under the name of Simon in the *Clementines*.

Date.—There are no sure data for determining the date. Appeal used to be made to Acts viii. 26, "Unto the way which goeth down from Jerusalem to Gaza, which is desert." But most probably it is the way which is here said to be desert or lonely. But even if the word "desert" or "lonely" be applied to Gaza, we get nothing out of it. Accordingly, in the absence of data very various dates have been assigned. Some think that it was written at the time mentioned in the last chapter of Acts, when St Paul had been two years in Rome. Some think that it must have been written after the fall of Jerusalem, as they believe that the gospel was written after that event. Irenæus thought that it was written after the death of St Peter and St Paul (*H.* iii. 1). Others think that St Luke must have written it at a late period of his life, about the year 80 A.D. The Tübingen school think that it was written some time in the second century, most of them agreeing on the second or third decade of that century, about 125 A.D. They argue that a late date is proved by the nature of the purpose which occasioned the work, by the representation which it gives of the relation of the Christians to the Roman state, and by the traces of Gnosticism (xx. 29), and of a hierarchical constitution of the church (i. 17, 20; viii. 14, ff.; xv. 28; xx. 17, 28) to be found in the Acts.

Place.—There is no satisfactory evidence by which to settle the place of composition. Later fathers of the church and the subscriptions of late MSS. mention Achaia, Attica, Alexandria, Macedonia, and Rome. And these places have all had their supporters in modern times. Some have also tried to show that it was written in Asia Minor, probably at Ephesus. The most likely supposition is that it was written at Rome; Zeller has argued with great plausibility for this conclusion.

There is a large literature on the subject of this article, but the most important treatises are those of Schwanbeck, Schneckenburger, Lekebusch, Zeller, Trip, Klostermann, and Œrtel. Zeller's work deserves special praise for its thoroughness. Various other writers have discussed the subject in works dealing with this among others; as Baur in his *Paulus;* Schwegler in his *Nachapostolisches Zeitalter;* Ewald in his *History of Israel;* Renan in his *Apostles;* Hausrath in his *New Testament History;* and, in a more conservative manner, Neander, Baumgarten, Lechler, Thiersch, and Lange. Of commentaries, the best on the Tübingen side is that of De Wette, remodelled by Overbeck, and that of the more conservative Meyer is especially good. In English we have an able treatment of the subject in Dr Davidson's *Introduction to the Study of the New Testament;* we have commentaries by Biscoe, Humphry, Hackett, Cook, Wordsworth, Alford, and Gloag; and dissertations by Paley, Birks, Lewin, Conybeare, and Howson.

There are various other treatises claiming to be Acts of Apostles. One or two of these must have existed at an early date, though, no doubt, they have since received large interpolations. But most of them belong to a late period, and all of them are acknowledged to be apocryphal. They are edited by Tischendorf in his *Acta Apostolorum Apocrypha* (Lipsiæ, 1851), and have been translated, with an introduction giving information as to their origin and dates, by Mr Walker, in vol. xvi. of the *Ante-Nicene Library.* (J. D.)

ACTA CONSISTORII, the edicts of the consistory or council of state of the Roman emperors. These edicts were generally expressed in such terms as these: "The august emperors, *Diocletian* and *Maximian*, in council declare, That the children of decurions shall not be exposed to wild beasts in the amphitheatre."—The senate and soldiers often swore, either through flattery or on compulsion, upon the edicts of the emperor. The name of a senator was erased by Nero out of the register, because he refused to swear upon the edicts of Augustus.

ACTA DIURNA, called also *Acta Populi*, *Acta Publica*, and simply *Acta* or *Diurna*, was a sort of Roman gazette, containing an authorised narrative of the transactions worthy of notice which happened at Rome—as assemblies, edicts of the magistrates, trials, executions, buildings, births, marriages, deaths, accidents, prodigies, &c. Petronius has given us an imitation specimen of the *Acta Diurna*, one or two extracts from which may be made to show their style and contents. The book-keeper of Trimalchio pretends to read from the *Acta Urbis:*—"On the 30th of July, on the Cuman farm, belonging to Trimalchio, were born 30 boys and 40 girls; there were brought into the barn from the threshing-floor 125,000 bushels of wheat; 500 oxen were broken in.—On the same day the slave Mithridates was crucified for having slandered the tutelar deity of our friend Gaius.—On the same day 100,000 sesterces, that could not be invested, were put into the money-box.—On the same day a fire broke out in the gardens of Pompey, which arose in the steward's house," &c. The *Acta* differed from the *Annals* (which were discontinued in B.C. 133) in this respect, among others, that only the greater and more important matters were given in the latter, while in the former things of less note also were recorded. The origin of the *Acta* is attributed to Julius Cæsar, who first ordered the keeping and publishing of the acts of the people by public officers. Some trace them back as far as Servius Tullius, who it was believed ordered that the next of kin, on occasion of a birth, should register the event in the temple of Venus, and on occasion of a death, should register it in the temple of Libitina. The *Acta* were drawn up from day to day, and exposed in a public place to be read or copied by all who chose to do so. After remaining there for a reasonable time they were taken down and preserved with other public documents.

ACTA SENATUS, among the Romans, were minutes of the discussions and decisions of the senate. These were also called *Commentarii Senatus*, and, by a Greek name, *ὑπομνήματα*. Before the consulship of Julius Cæsar, minutes of the proceedings of the senate were written and occasionally published, but unofficially. Cæsar first ordered the minutes to be recorded and published authoritatively. The keeping of them was continued by Augustus, but the publication was forbidden. Some prominent senator was usually chosen to draw up these *Acta*.

ACTÆON, in *Fabulous History*, son of Aristæus and Autonoë, a famous hunter. He was torn to pieces by his own dogs. Various accounts are given of this occurrence; but the best known story is that told by Ovid, who represents him as accidentally seeing Diana as she was bathing, when she changed him into a stag, and he was pursued and killed by his dogs.

ACTIAN GAMES, in *Roman Antiquity*, solemn games instituted by Augustus, in memory of his victory over Antony at Actium. See ACTIUM.

ACTINIA, a genus of cœlenterate animals, of which the sea-anemone is the type. See ACTINOZOA

ACTINISM (from ἀκτίς, a ray), that property of the solar rays whereby they produce chemical effects, as in photography. The actinic force is greatest in the blue and violet rays of the spectrum.

ACTINOMETER (*measurer of solar rays*), a thermometer with a large bulb, filled with a dark-blue fluid, and enclosed in a box, the sides of which are blackened, and the whole covered with a thick plate of glass. It was the invention of the late Sir John Herschel, and was first described in the *Edinburgh Journal of Science* for 1825. It is used for measuring the heating power of the sun's rays, the amount of which is ascertained by exposing the bulb for equal intervals of time in sunshine and shade alternately.

ACTINOZOA, a group of animals, of which the most familiar examples are the sea-anemones and "coral insects" of the older writers. The term was first employed by de Blainville, to denote a division of the Animal Kingdom having somewhat different limits from that to which its application is restricted in the present article; in which it is applied to one of the two great divisions of the CŒLENTERATA, the other being the *Hydrozoa*.

The *Actinozoa* agree with the *Hydrozoa* in the primitive and fundamental constitution of the body of two membranes, an *ectoderm* and an *endoderm*,—between which a middle layer or *mesoderm* may subsequently arise,—in the absence of a completely differentiated alimentary canal, and in possessing thread-cells, or nematocysts; but they present a somewhat greater complexity of structure.

This is manifest, in the first place, in their visceral tube, or "stomach," as it is often called, which is continued from the margins of the mouth, for a certain distance, into the interior cavity of the body, but which is always open at its fundus into that cavity. And, secondly, in the position of the reproductive elements, which, in the *Hydrozoa*, are always developed in parts of the body wall which are in immediate relation with the external surface, and generally form outward projections: while, in the *Actinozoa*, they are as constantly situated in the lateral walls of the chambers into which the body cavity is divided. In consequence of this arrangement, the ova, or sexually generated embryos, of the *Actinozoa* are detached into the interior of the body, and usually escape from it by the oral aperture; while those of the *Hydrozoa* are at once set free on the exterior surface of that part of the body in which they are formed.

The *Actinozoa* comprise two groups, which are very different in general appearance and habit, though really similar in fundamental structure. These are—

1. The *Coralligena* or sea-anemones, coral animals, and sea-pens; and 2. The *Ctenophora*.

(1.) The *Coralligena*.—A common sea-anemone presents a subcylindrical body, terminated at each end by a disk. The one of these discoidal ends serves to attach the ordinarily sedentary animal; the other exhibits in the centre a mouth, which is usually elongated in one direction, and, at each end, presents folds extending down into the gastric cavity. This circumstance greatly diminishes the otherwise generally radial symmetry of the disk, and of the series of flexible conical tentacles which start from it; and, taken together with some other circumstances, raises a doubt whether even these animals are not rather bilaterally, than radially, symmetrical. Each tentacle is hollow, and its base communicates with one of the chambers into which the cavity of the body is divided, by thin membranous lamellæ, the so-called mesenteries, which radiate from the oral disk and the lateral walls of the body to the parietes of the visceral tube. The inferior edges of the mesenteries are free, and arcuated in such a manner as to leave a central common chamber, into the circumference of which all the intermesenteric spaces open, while above, it communicates with the visceral tube. The tentacles may be perforated at their extremities, and, in some cases, the body wall itself exhibits apertures leading into the intermesenteric spaces. The free edges of the mesenteries present thickenings, like the hem of a piece of linen, each of which is much longer than the distance between the gastric and the parietal attachment of the mesentery, and hence is much folded on itself. It is full of thread cells. The mesoderm, or middle layer of the body, which lies between the ectoderm and the endoderm, consists of a fibrillated connective tissue, containing fusiform or stellate nucleated cells, and possesses longitudinal and circular muscular fibres. These are prolonged into the mesenteries, and attain a great development in the disk of attachment, which serves as a sort of foot like that of a limpet.

The question whether the *Coralligena* possess a nervous system and organs of sense, hardly admits of a definite answer at present. It is only in the *Actinidæ* that the existence of such organs has been asserted; and the nervous circlet of *Actinia*, described by Spix, has been seen by no later investigator, and may be safely assumed to be non-existent. But Professor P. M. Duncan, F.R.S., in a paper "On the Nervous System of *Actinia*," recently communicated to the Royal Society, has affirmed the existence of a nervous apparatus, consisting of fusiform ganglionic cells, united by nerve fibres, which resemble the sympathetic nerve fibrils of the *Vertebrata*, and form a plexus, which appears to extend throughout the pedal disk, and very probably into other parts of the body. In some of the *Actinidæ* (*e.g.*, *Actinia mesembryanthemum*), brightly coloured bead-like bodies are situated on the oral disk outside the tentacles. The structure of these "chromatophores," or "bourses calicinales." has been carefully investigated by Schneider and Röttekem, and by Professor Duncan. They are diverticula of the body wall, the surface of which is composed of close-set "bacilli," beneath which lies a layer of strongly-refracting spherules, followed by another layer of no less strongly refracting cones. Subjacent to these Professor Duncan finds ganglion cells and nerve plexuses. It would seem, therefore, that these bodies are rudimentary eyes.

At the breeding season the ova or spermatozoa are evolved in the thickness of the mesenteries, and are discharged into the intermesenteric spaces, the ova undergoing their development within the body of the parent. The yelk, usually, if not always, enclosed in a vitelline membrane, undergoes complete division, and the outer wall of the ciliated blastodermic mass which results becomes invaginated, the embryo being thereby converted into a double walled sac—the external aperture of which is the future mouth, while the contained cavity represents the body cavity. In this stage the larval *Actinia* represents the *Gastrula* condition of sponges and *Hydrozoa*. The edges of the oral aperture grow inwards, giving rise to a circular fold, which is the rudiment of the visceral tube. This is at first connected with the body wall by only two mesenteries, which are seated at opposite ends of one of the transverse diameters of the body. As the mesenteries increase in number, the tentacles grow out as diverticula of the intermesenteric spaces.

In all the *Coralligena*, the development of which has been observed, the embryo is converted into a simple actinozoon in a similar manner; but from this point they diverge in two directions. In one great group, the mesenteries, and the tentacles which arise from the intermesenteric chambers, increase in number to six; and then, in the great majority of cases, the intermesenteric spaces undergo subdivision by the development of new mesenteries, according to curious and somewhat complicated numerical laws, until their number is increased to some multiple of five or six. In these *Hexacoralla* (as they have been termed by Haeckel) the tentacles also usually remain rounded and conical. In the other group, the *Octocoralla*, the mesenteries and the tentacles increase to eight, but do not surpass that number; and the tentacles become flattened and serrated at the edges, or take on a more or less pennatifid character.

There are no *Octocoralla* which retain the simple individuality of the young actinozoon throughout life: but all increase by gemmation. and give rise to compound organisms. which may be arborescent. and fixed by the root end of the common stem. as in the *Alcyonidæ* and *Gorgonidæ*: or may possess a central stem which is not fixed. and gives off lateral branches which undergo comparatively little subdivision. as in the *Pennatulidæ*.

The body cavities of the zoöids of these compound *Octocoralla* are in free communication with a set of canals which ramify through the *cœnosarc*. or common fabric of the stem and branches by which they are borne. and which play the part of a vascular system.

Except in the case of *Tubipora*, the zoöids and the superficial cœnosarc give rise to no continuous skeleton: but the deep or inner substance of the cœnosarc may be converted into a solid rod-like or branching stem.

In the *Hexacoralla*. on the other hand, one large group, that of the *Actinidæ*. consists entirely of simple organisms,—organisms that is. in which the primitive actinozoon attains its adult condition without budding or fission; or if it bud or divide, the products of the operation separate from one another No true skeleton is formed. all are to some extent locomotive, and some (*Minyas*) float freely by the help of their contractile pedal region. The most remarkable form of this group is the genus *Cereanthus*, which has two circlets, each composed of numerous tentacles, one immediately around the oral aperture, the other at the margin of the disk. The foot is elongated, subconical, and generally presents a pore at its apex. Of the diametral folds of the oral aperture, one pair is much longer than the other, and is produced as far as the pedal pore. The larva is curiously like a young hydrozoon with free tentacles, and at first possesses four mesenteries, whence it may be doubted whether *Cereanthus* does not rather belong to the *Octocoralla*.

The *Zoanthidæ* differ from the *Actinidæ* in little more than their multiplication by buds, which remain adherent, either by a common connecting mass or cœnosarc or by stolons; and in the possession of a rudimentary, spicular skeleton.

On the other hand, the proper stone-corals (as contradistinguished from the red coral) are essentially *Actiniæ*, which become converted into compound organisms by gemmation or fission, and develope a continuous skeleton.

The skeletal parts[1] of the *Actinozoa*, to which reference has been made, consist either of a substance of a horny character; or of an organic basis impregnated with earthy salts (chiefly of lime and magnesia), but which can be isolated by the action of dilute acids; or finally, of calcareous salts in an almost crystalline state, forming rods or corpuscles, which, when treated with acids, leave only an inappreciable and structureless film of organic matter. The hard parts of all the *Aporosa*, *Perforata*, and *Tabulata* of Milne Edwards are in the last-mentioned condition; while, in the *Octocoralla* (except *Tubipora*) the *Antipathidæ*, and *Zoanthidæ*, the skeleton is either horny, or consists, at any rate, to begin with, of definitely formed spicula, which contain an organic basis, and frequently present a laminated structure. In the organ coral (*Tubipora*), however, the skeleton has the character of that of the ordinary stone-corals, except that it is perforated by numerous minute canals.

The skeleton appears, in all cases, to be deposited within the mesoderm, and in the intercellular substance of that layer of the body. Even the definitely shaped spicula of the *Octocoralla* are not the result of the metamorphosis of cells. In the simple aporose corals the calcification of the base and side walls of the body gives rise to the cup or *theca;* from this the calcification radiates inwards, in correspondence with the mesenteries, and gives rise to as many vertical *septa*, the spaces between which are termed *loculi;* while, in the centre, either by union of the septa or independently, a pillar, the *columella*, grows up. From the sides of adjacent septa scattered processes of calcified substance, or *synapticulæ*, may grow out toward one another, as in the *Fungidæ;* or the interruption of the cavities of the loculi may be more complete by the formation of shelves stretching from septum to septum, but lying at different heights in adjacent loculi. These are *interseptal dissepiments*. Finally, in the *Tabulata*, horizontal plates, which stretch completely across the cavity of the theca, are formed one above the other and constitute *tabular dissepiments*.

In the *Aporosa* the theca and septa are almost invariably imperforate; but in the *Perforata* they present apertures, and in some madrepores the whole skeleton is reduced to a mere network of dense calcareous substance. When the *Hexacoralla* multiply by gemmation or fission, and thus give rise to compound massive or aborescent aggregations, each newly-formed coral polype developes a skeleton

[1] See Kölliker's *Icones Histologicæ*, 1866.

of its own, which is either confluent with that of the others, or is united with them by calcification of the connecting substance of the common body. This intermediate skeletal layer is then termed *cœnenchyma.*

The *Octocoralla* (excepting *Tubipora*) give rise to no *thecæ* and their dependencies, the skeleton of each polype, and of the superficial portion of the polyparium, being always composed of loose and independent spicula. But in many, as the *Gorgonidæ*, *Pennatulidæ* (and in the *Antipathidæ* among the *Hexacoralla*), the central part of the common stem of the compound organism becomes hardened, either by conversion into a mere horny axis (which may be more or less impregnated with calcareous salts) without spicula; or the cornification may be accompanied by a massive development of spicula, either continuously or at intervals; or the main feature of the skeleton may, from the first, be the development of spicula, which become soldered together by a subcrystalline intermediate deposit, as in the red coral of commerce (*Corallium rubrum*).

It has seemed advisable to say thus much concerning the hard parts of the *Actinozoa* in this place, but the details of the structure and development of the skeleton of the *Coralligena* will be discussed under CORALS and CORAL REEFS.

The *Tabulata*, or Millepores, and the *Rugosa*, an extinct and almost exclusively Palæozoic group of stone-coral forming animals, are usually referred to the *Coralligena*. Judging by the figures given by Agassiz[1] of living Millepores, the polypes which cover its surface are undoubtedly much more similar to coryinform *Hydrozoa* than they are to any *Actinozoon.* But it is to be observed, firstly, that we have no sufficient knowledge of the intimate structure of the polypes thus figured; and, secondly, that the figures show not the least indication of the external reproductive organs which are so conspicuous in the *Hydrozoa*, and which surely must have been present in some one or other of the Millepores examined, were they really *Hydrozoa.* As regards the *Rugosa*, the presence of septa is a strong argument against their belonging to any group but the *Actinozoa*, though it is not to be forgotten that a tendency to the development of septiform prominence is visible in the walls of the gastric passages of certain calcareous sponges.

Phenomena analogous to the "alternation of generations," which is so common among the *Hydrozoa*, are unknown among the great majority of the *Actinozoa*. But Semper[2] has recently described a process of sexual multiplication in two species of *Fungiæ*, which he ranks under this head. The *Fungiæ* bud out from a branched stem, and then become detached and free, as is the habit of the genus. To make the parallel with the production of a *Medusa* from a *Scyphistoma* complete, however, the stem should be nourished by an asexual polype of a different character from the forms of *Fungiæ* which are produced by gemmation. And this does not appear to be the case.

Dimorphism has been observed by Kölliker to occur extensively among the *Pennatulidæ.* Each polypary presents at least two different sets of zoöids, some being fully developed, and provided with sexual organs, while the others have neither tentacles nor generative organs, and exhibit some other peculiarities.[3] These abortive zoöids are either scattered irregularly among the others (*e.g.*, *Sarcophyton*, *Veretillum*), or may occupy a definite position (*e.g.*, *Virgularia*).

(2.) The *Ctenophora.*—These are all freely swimming, actively locomotive, marine animals, which do not multiply by gemmation, nor form compound organisms such as the polyparies of the *Coralligena.* Like the latter they are composed of a cellular ectoderm and endoderm, between which a mesoderm, containing stellate connective tissue corpuscles and muscular fibres, is interposed. But, in most parts of the organism, the mesoderm acquires a great thickness and a gelatinous consistency; so that the body of one of these animals differs in this respect from that of an *Actinia* in the same way as the body of a *Cyanœa* differs from that of a *Hydra.* The bilateral symmetry, which is obscure in most of the *Coralligena*, becomes obvious in the *Ctenophora*, in which the parts are disposed symmetrically on each side of a vertical plane passing through the longitudinal axis of the body. The oral aperture is situated at one end of this axis (or its oral pole), while at the opposite extremity (or aboral pole) there is very generally situated a sac containing solid mineral particles—the *lithocyst.*

The oral aperture leads into a visceral tube, which undoubtedly performs the functions of a stomach. Nevertheless, as in the *Coralligena*, it is open at its aboral end, and its cavity is thus placed in direct communication with a chamber, whence canals are given off which penetrate the gelatinous mesoderm. Of these canals, one continues the direction of the axis of the body, and usually ends by two apertures at the aboral pole. The others take a direction in a plane more or less at right angles with the axis; and after branching out, terminate in longitudinal canals, which lie beneath the series of locomotive paddles, or come into relation with the tentacles when such organs are developed. In addition to these, two canals frequently extend along the sides of the stomach towards the oral pole. The paddle-like locomotive plates are disposed in eight longitudinal series (*ctenophores*) on the outer surface of the body. They are thick at the base; thin and, as it were, frayed out into separate filaments, at their free edges; and each plate is set transversely to the long axis of the series of which it forms a part. The ovaria and testes are developed in the side walls of the longitudinal canals. It is clear, therefore, that these canals answer to the intermesenteric spaces of an *Actinia;* that the common cavity into which they and the stomach open answers to the common cavity of the body of the *Actinia;* that the apertures at the aboral pole answer to the terminal aperture of *Cereanthus;* and that the wide interspaces between the longitudinal canals represent the mesoderm of the Actinian mesenteries immensely thickened.

In their development the *Ctenophora* resemble the *Coralligena* in all essential respects, though they differ from them in some details. Thus the process of yelk division goes on at a different rate in the two moieties of the egg, so that the vitellus becomes divided into one set of small and another set of large cells, whereof the latter become overlaid by the former, and give rise to a large-celled hypoblast, enclosed within a small-celled epiblast. But in the manner in which the body cavity is formed, and the visceral tube (which becomes the stomach) is developed, the *Ctenophora* resemble the *Actiniæ.* The paddles make their appearance at four points of the circumference of the body, in the form of elevations beset with short cilia; but each of these divides into two, and thus the eight definitive series are constituted.

There is a general agreement among anatomists respecting the structure of the *Ctenophora* thus far; but the question whether they possess a nervous system and sensory organs or not, is, as in the case of the *Coralligena*, one upon which there exists great diversity of opinion. Grant originally described a nervous ganglionated ring, whence longitudinal cords proceed in *Cydippe* (*Pleurobrachia*);

[1] *Contributions to the Natural History of the United States.* Vol. iii. Plate xv.

[2] *Ueber Generations-Wechsel bei Steinkorallen.* Leipzig, 1872.

[3] *Abhandlungen der Senkenbergischen Naturforschenden Gesellschaft*, bd. vii. viii.

but his observation has not been verified by subsequent investigations. According to Milne Edwards, followed by others (among whom I must include myself), the nervous system consists of a ganglion, situated at the aboral pole of the body, whence nerves radiate, the most conspicuous of which are eight cords which run down the corresponding series of paddles; and a sensory organ, having the characters of an otolithic sac, is seated upon the ganglion. Agassiz and Kölliker, on the other hand, have denied that the appearances described (though they really exist) are justly interpreted. And again, though the body, described as an otolithic sac, undoubtedly exists in the position indicated in all, or most, of the *Ctenophora*, the question has been raised whether it is an auditory or a visual organ.

These problems have been recently reinvestigated with great care, and by the aid of the refined methods of modern histology, by Dr Eimer,[1] who describes a nervous system, consisting of extremely delicate varicose ultimate nerve fibrils, which traverse the mesoderm in all directions, and are connected here and there with ganglionic corpuscles. These nerves are only discernible with high magnifying powers, as they are for the most part isolated, and are collected into bundles only beneath the longitudinal canals. The mass which lies beneath the lithocyst is composed of cells, but these have none of the special characters of nerve cells. Eimer states that he has traced the filaments, which he considers to be nerves, into direct continuity with muscular fibres; and, around the mouth, into subepidermal bodies, which he regards as rudimentary forms of tactile corpuscles. The lithocyst is recognised as an auditory organ, and, in addition, eye-spots are described.

With a fundamental similarity of organisation, the form of the body varies extraordinarily in the *Ctenophora*. One of the genera which is commonest on our coasts—*Cydippe* (*Pleeobrachia*)—is spheroidal; others (*Beroë*) are more ovate; others are provided with large lobular processes (*Eucharis*), while an extreme modification, in which the body is ribbon shaped, is seen in *Cestum*.

The *Ctenophora* are divisible into two very unequal groups:[2]

I. *Eurystomata*, in which the large oral aperture occupies the truncated extremity of the oval body.
    1. *Beroidæ*.

II. *Stenostomata*, in which the oral aperture and the gastric sac are small relatively to the size of the body.
    2. *Saccatæ*.
    3. *Lobatæ*.
    4. *Tæniatæ*.

1. *Beroidæ*.
The body is ovate, truncated at the oral pole, the aboral being more or less acuminate and mobile. The digestive cavity occupies a large portion of the body. The oral margin is simple in *Beroë* and *Idyia*; but in *Rangia* the interradial spaces are notched, and in each a short process projects. The radial canals are connected by a circumoral canal. No tentacles are present. The ctenophores of *Pandora* do not extend over more than half the body, as in the embryos of *Cydippe*. The development of the *Beroidæ* is unaccompanied by metamorphosis.

2. *Saccatæ*.
The circumoral canal is absent. The oral aperture is laterally compressed, its long axis being at right angles to the plane of the tentacles, which are present in all the genera, and which are either simple (*Cydippe*), or furnished with lamellar and filamentous appendages (*Hormiphora*). The ctenophores are equal in length, or the lateral ones are fully developed, while the intermediate are shorter.

3. *Lobatæ*.
The oral and aboral pole, or the oral only, bear lobate appendages. *Bolina* has a pair of oral lappets, into which the radial canals are prolonged. The ctenophores corresponding to these lobes are the longest, while the middle ones are much shorter, and are prolonged on to an auricle or finger-like lobe. The tentacles are represented by a tuft of short processes on either side of the mouth. The young *Bolina* has the form of *Cydippe*, and like it bears a pair of long-fringed tentacles. The aboral region, bearing the lateral ctenophores, grows more rapidly than the oral, so as ultimately to project in two principal lobes, by which the similar outgrowth of the median aboral regions with its ctenophores is arrested, the auricles being the dwarfed representatives of these regions. These auricles in *Eucharis* are longer, so that the ctenophores are all of equal length. The tentacles of this genus are placed at the oral pole; the oral lobes are equivalent to the median ctenophores of *Cydippe*. *Eurhamphæa* has the oral lobes small, the body elongated, terminated by two conical projections, on which the median ctenophores are prolonged.

4. *Tæniatæ*.
The body of *Cestum* is laterally compressed and elongated in a direction which corresponds to one of the transverse diameters of *Cydippe*, the ribbon-like band thus formed being sometimes three or even four feet long. The tentacles are near the oral pole; the canals are ten in number; the medio-lateral canals terminate in trunks which follow the oral margin of the ribbon, and thus correspond to the circular canal of *Beroë*.

[2] Haeckel, "*Generelle Morphologie*," ii. lx.

Many *Actinozoa* (*Pennatulidæ*, *Ctenophora*) are phosphorescent; but the conditions which determine the evolution of light have not been determined.

All *Actinozoa* are marine animals, and the distribution of many of the families (*Actinidæ*, *Turbinolidæ*, *Pennatulidæ*, *Beroïdæ*) is extremely wide, and bears no ascertainable relation to climate. (T. H. H.)

ACTION, *in Law*, is the process by which redress is sought in a court of justice for the violation of a legal right. The word is used by jurists in three different senses. Sometimes it is spoken of as a right—the right, namely, of instituting the legal process; sometimes, and more properly, it means the legal process itself; and sometimes the particular form which it assumes. The most universally recognised division of actions is the division established by the Roman lawyers into actions *in rem* and *in personam*. An action *in rem* asserts a right to a particular thing as against all the world; an action *in personam* asserts a right only as against a particular person. For the sake of convenience, the law relating to actions ought to form a separate section by itself in a properly constructed code.

In Roman law the action passed through three historical stages—

In the first period, which was brought to an end by the *Lex Æbutia*, about 573 A.U.C., the system of *legis actiones* prevailed. These were five in number,—the *actio sacramenti, per judicis postulationem, per condictionem, per manus injectionem, per pignoris captionem*. The first was the primitive and characteristic action of the Roman law, and the others were little more than modes of applying it to cases not contemplated in the original form, or of carrying the result of it into execution when the action had been decided.

ACTION, in *English Law*, means the form of civil process hitherto observed in the Courts of Common Law. The procedure in the Court of Chancery is totally distinct, but some account of the former may be desirable in order to explain the new form of action introduced for all the civil courts by the Judicature Act of 1873:—

Actions at law are divided by Blackstone into three classes, according to the relief which they are respectively intended to obtain. *Real* actions are those "whereby the plaintiff claims title to have any lands or tenements, rents, commons, or other hereditaments." In *personal* actions the claim is "for debt or personal duty, or damages in lieu thereof," or for "satisfaction in damages for some injury done to person or property." *Mixed* actions were supposed to partake of the nature of both of these; that is to say, there was a demand both for real property and for personal damages, as in the case of an action for waste. The distinction has long ceased to be of any value. Blackstone speaks of real actions as being in his time pretty generally laid aside, and successive enactments have obliterated the distinctions altogether. The statute 3 & 4 Will. IV. c. 27, abolished all the real and mixed actions, except three real actions, and ejectment, which was a mixed action. The Common Law Procedure Act of 1860 has assimilated the procedure in the former to an ordinary action, and the Common Law Procedure Act of 1852 now regulates the proceedings in ejectment. In these and other respects the three Common Law Procedure Acts of 1852, 1854, and 1860, very greatly simplified the proceedings in an action at law. The first of these rendered it unnecessary any longer to select a *form* of action in prosecuting a claim, and abolished many of the technicalities which had accompanied the older forms. The divisions now observed may be regarded as indicating, not so much forms of action in the old sense, as the character of the injury sustained and the relief sought.

Action (under the Supreme Court of Judicature Act, 1873). By this Act, which establishes one supreme court in place of the Superior Courts of Common Law and the High Court of Chancery, action is the name given to the proceeding in the High Court of Justice, which takes the place of the old actions at common law, suits instituted by bill or information in the Court of Chancery, causes *in rem* in the Court of Admiralty, or by citation in the Court of Probate. For these various modes of obtaining redress the Act substitutes one uniform proceeding, which retains most of the essential features of the common law action. The form of action established by the Act is in some measure a compromise between the old action at law and Chancery suit. It may be described as putting an end to the unintelligible and even misleading formulæ of the one and reducing the prolixity and redundance of the other. (E. R.)

ACTIUM, in *Ancient Geography*, a promontory in the north of Acarnania, at the mouth of the Sinus Ambracius, opposite the town of Nicopolis, built by Augustus on the north side of the strait. Eastwards from the promontory the strait widens out and forms a safe harbour. On the promontory was an ancient temple of Apollo (who is hence called by Virgil *Actius*), which was enlarged by Augustus. Actium became famous on account of Augustus's victory over Antony and Cleopatra (B.C. 31), and for the quinquennial games he instituted there, called *Actia* or *Ludi Actiaci*. *Actiaca Æra* was a computation of time from the battle of Actium. There was on the promontory a small town, or rather village, also called *Actium*.

ACTON, a large village in Middlesex, about eight miles west of St Paul's. It was once much frequented because of its saline springs, but these have long lost their repute. Acton being near the metropolis and easily accessible by the Great Western Railway, and the price of building land being low, numerous villas have been erected in the neighbourhood. The population of the parish increased from 3151 in 1861 to 8306 in 1871.

ACTON, Sir John Francis Edward, son of Edward Acton, who practised as a physician at Besançon, was born there in 1736, and succeeded to the title and estates in 1791, on the death of his cousin in the third degree, Sir Richard Acton. He served in the navy of France, and afterwards in that of Tuscany, and commanded a frigate in the joint expedition of Spain and Tuscany against Algiers in 1774. His gallantry in rescuing three or four thousand Spanish soldiers from slavery led to his advancement. Entering the Neapolitan service, he gained the favour of Queen Mary Caroline, became commander-in-chief of the land and sea forces, then minister of finance, and ultimately prime minister. His policy was devised in concert with the English ambassador Hamilton, and, of course, was hostile to France and to the French party in Italy. He has been held responsible for the arbitrary and despotic measures which, in 1798–99, filled the prisons of Naples with political prisoners, and even brought some of them to the scaffold. In 1803 Acton was for a short time deprived of the reins of government at the demand of France; but he was speedily restored to his former position, which he held till, in Feb. 1806, on the entry of the French into Naples, he had to flee with the royal family into Sicily. He died at Palermo on the 12th Aug 1811, leaving by his wife (eldest daughter of his brother, General Joseph Edward Acton, whom he had married by papal dispensation) three children, of whom the second, Charles Januarius Edward, was made Cardinal Santa Maria della Pace in 1842. It may be well to state that Sir John has very frequently been confounded with his above-mentioned brother, born in 1737, who was also employed in the Neapolitan service.

ACTUARY, in ancient Rome, was the name given to the clerks who recorded the *Acta Publica* of the Senate, and also to the officers who kept the military accounts and enforced the due fulfilment of contracts for military supplies. In its English usage the word has undergone a gradual limitation of meaning. At first it seems to have denoted any clerk or registrar; then more particularly the secretary and adviser of any joint-stock company, but especially of an insurance company; and it is now applied specifically to one who makes those calculations as to the probabilities of human life, on which the practice of life assurance and the valuation of reversionary interests, deferred annuities, &c., are based. The first mention of the word in law is in the Friendly Societies Act of 1819, where it is used in the vague sense, "actuaries, or persons skilled in calculation." The word has been used with precision since the establishment of the "Institute of Actuaries of Great Britain and Ireland" in 1848. The "Faculty of Actuaries in Scotland" was formed at Edinburgh in 1856, and incorporated by royal charter in 1868. The registrar in the Lower House of Convocation is also called the actuary.

ACUÑA, Christoval d', a Spanish Jesuit, born at Burgos in 1597. He was admitted into the society in 1612, and, after some years spent in study, was sent as a missionary to Chili and Peru, where he became rector of the College of Cuença. In 1639 he was appointed by the Jesuits to accompany Pedro Texeira in his second exploration of the Amazon, in order to take scientific observations, and draw up a report that might be sent to Spain. The journey lasted for ten months; and, on their arrival at Peru, no ship being ready to convey the explorer to Spain, Acuña employed himself in the preparation of a narrative of his journey. This was published at Madrid in 1641, under the title *Nuevo Descubrimiento del Gran Rio de las Amazonas, &c.* The King of Spain received Acuña coldly, and, it is said, even tried to suppress his book, fearing that the Portuguese, who had revolted from Spain, would avail themselves of the information which it contained. A translation into French was published by Gomberville in 1682; and a translation from the French into English appeared in 1698. After occupying the positions of procurator of the Jesuits at Rome, and *calificador* (censor) of the Inquisition at Madrid, Acuña returned to South America, where he died, probably soon after the year 1675.

ACUPRESSURE, in *Surgery* (*acus*, a needle, *premo*, I press), a method of restraining hæmorrhage, introduced in 1869 by the late Sir J. Y. Simpson. The closure of the vessel near the bleeding point is attained by the direct pressure of a metallic needle, either alone or assisted by a loop of wire. The advantages claimed by the originator of this method over the old silk ligature were, that the needles can be removed within forty-eight hours after introduction, allowing the wound to heal rapidly; and that, being metallic and non-porous, they do not cause irritation and suppuration like the silk ligature. The catgut ligature, which is rapidly absorbed, is gradually superseding both the silk ligature and the acupressure needle. A volume entitled *Acupressure*, by Sir J. Y. Simpson, was published in 1864.

ACUPUNCTURE, the name of a surgical operation among the Chinese and Japanese, which is performed by pricking the part affected with a silver needle. They employ this operation in headaches, lethargies, convulsions, colics, &c.; and it has more lately been introduced into British practice for the cure of some forms of neuralgia.

ADAFUDIA, a large town of Western Africa, in the country of the Felattahs, in 13° 6′ N. lat., 1° 3′ E. long., about 400 miles S.E of Timbuctoo. It is surrounded by a mud wall The neighbouring country is rich and fertile. The trade in native merchandise is said to be as great as that of Abomey, the capital of Dahomey; and there is also a considerable traffic in slaves. Population, about 24,000.

ADAL, a region in Eastern Africa, with a coast line extending, between 11° 30′ and 15° 40′ N. lat., from the Gulf of Tajurrah to the neighbourhood of Massowah. For about 300 miles it borders on the Red Sea, the coast of which is composed of coral rock. It stretches inland to the mountain terraces, to the west of which lie the Abyssinian table-lands of Shoa and Tigré, with a breadth near Massowah of only a few miles, but widening towards the south to 200 or 300 miles. The northern portion of this region, known as the Afar country, is traversed by two routes to Abyssinia—the one from Zulla near Massowah, and the other from Amphilla Bay. The former of these was selected for the British Abyssinian expedition of 1868, Annesley Bay being the place of debarkation and base of operations. There is a third route to Abyssinia through Adal, that from Tajurrah to Ankobar, the capital of Shoa, said to be preferred for trading purposes, as being less steep than the others. The river Hawash flows through the southern district of Adal in a N.E. direction, but is lost in Lakes Abbebad and Aussa. Near this river is Aussa, the chief town of the country. Volcanic rocks occur in various parts of this district; and two mountains, 4000 feet high, are mentioned, which have sent down streams of lava on all sides to the distance of 30 miles. The country contains two great salt plains or basins,—that of Asali in its northern portion, and Aussa in the south. The remarkable salt lake of Bahr Assal, near Tajurrah, is 570 feet below the level of the sea. The country as a whole is barren and uncultivated. A little barley is reared on the higher terraces, and some districts afford pasturage for domestic animals, large quantities of butter being annually sent to Massowah. In some parts of Adal the elephant is not uncommon. The salt of Asali and Aussa is a valuable article of commerce. There is no fixed government, the country being inhabited by various independent tribes, all speaking the Afar language and professing the Mahometan religion, and most of them of nomadic habits.

ADALBERT, Saint, one of the founders of Christianity in Germany, known as the Apostle of the Prussians, was born of a noble family in Slavonia, about 955; was educated at the monastery of Magdeburg; and, in 983, was chosen Bishop of Prague. The restraints which he tried to impose on the newly-converted Bohemians by prohibiting polygamy, clerical incontinency, and similar sins, raised against him so strong a feeling of hatred, that he was forced, in 988, to retire to Rome, where he resided at the monasteries of Monte Basino and St Alexis. In 993 he returned to his flock, in obedience to the command of the Pope. Finding little amendment, however, in their course of living, he soon afterwards went again to Rome, and obtained permission from the Pope to devote himself to missionary labours, which he carried on chiefly in North Germany and Poland. While preaching in Pomerania (997), he was thrust through the heart by a heathen priest.

ADALBERT, Archbishop of Bremen and Hamburg, born of the noble Saxon family of the Counts of Wettin, was one of the most remarkable ecclesiastics of the 11th century. Through the friendship of the emperor Henry III. he was elevated in 1043, when only about thirty years old, to the see of Bremen and Hamburg, which included the whole of Scandinavia, and he accompanied the monarch in his journey to Rome (1046). Here it is said that he was offered and that he refused the papal throne. The refusal certainly cannot have arisen from lack of ambition; for on his return in 1050, with a commission as legate to the northern courts from Pope Leo IX., he immediately set about carrying out the emperor's wishes by establishing himself in an independent patriarchate of the north. For this purpose he sought by every means to augment his already great influence, he adorned his two cathedrals, and enlarged and fortified the town of Bremen so that it might rival Rome. There was much in his favour, and he might even have succeeded in entirely separating the church of the north from the see of Rome, had it not been for the death of Henry III., and the opposition of Cardinal Hildebrand. Henry IV. being a minor at the time of his father's death, Adalbert was associated with Archbishop Hanno of Cologne as guardian and regent; and during the absence of the latter on a mission to Rome, he sought, by granting every indulgence, to gain the favour of the young prince, and so to be able to exercise an absolute power in the state (1062–65). The Archbishops of Mayence and Cologne secured his banishment from court after the government had been assumed by Henry in person (1066); and about the same time his diocese was invaded by the "natural enemies" of Bremen, the Saxon nobles. In 1069, however, he was recalled, and reinstated in his former position. He died at Goslar in 1072, having done much during his last years to inflame the Saxons' hatred of Henry, which resulted soon afterwards in their revolt.

ADAM, אָדָם, an appellative noun, meaning the first man. In Genesis ii. 7, 25, iii. 8, 20, iv. 1, &c., it assumes the nature of a proper name, and has the article, *the man*, the only one of his kind; yet it is appellative, correctly speaking. In Genesis i. 26, 27, v. 2, it is simply appellative, being applied to both progenitors of the human race; not to the first man alone as in the second, third, and fourth chapters. The etymology of the word is uncertain, but it is probably connected with a root signifying *red*, so that the idea is one *red* or *ruddy*.

The early part of Genesis contains two accounts of man's creation. These narratives need not be examined at present farther than man's origin is concerned. In Genesis i. 26, 27, we read, "And God said, Let us make man in our image, after our likeness; and let them have dominion over the fish of the sea, and over the fowl of the air, and over the cattle, and over all the earth, and over every creeping thing that creepeth upon the earth. So God created man in his *own* image; in the image of God created he him; male and female created he them." At the end of the sixth day of creation man appears, the noblest of earth's inhabitants. In Genesis ii. 7, 8, we also read, "And the Lord formed man *of* the dust of the ground, and breathed into his nostrils the breath of life; and man became a living soul. And the Lord God planted a garden eastward in Eden: and there he put the man he had formed." The woman's creation is thus narrated in subsequent verses of the same chapter—20, 21, 22, 23, "And Adam gave names to all cattle, and to the fowl of the air, and to every beast of the field: but for Adam there was not found an help meet for him. And the Lord God caused a deep sleep to fall upon Adam, and he slept: and he took one of his ribs, and closed up the flesh instead thereof. And the rib, which the Lord God had taken from man, made he a woman, and brought her unto the man. And Adam said, This *is* now bone of my bones, and flesh of my flesh: she shall be called Woman, because she was taken out of man." Between these accounts some discrepancy exists. The first represents the man and woman to have been created together, after the various creatures which the earth sustains on its surface; the second makes Adam to have been created first, then the various animals, with the woman last of all. The creation of animals separates the origin of the man and the woman. The first narrator states that man was made in the image and form of God, without explaining his meaning more particularly. Hence interpreters differ in attempting to define it. The language need not be restricted either to man's *spirit* or to his *body*, but may refer to his united whole, including spiritual qualities and bodily form. The ancient Hebrew did not think of God without a certain form, but transferred the human one to him, divesting it of grossness, and giving it an ethereal luminousness of surpassing glory. The image of God, therefore, in which Adam is said to have been created, includes the whole man, with special reference to the spiritual nature within him. We cannot tell whether the writer thought of immortality as involved in the God-likeness. He may have done so. But the second account teaches that man was only mortal at first, because he is sent out of Paradise lest he should become immortal by eating of the tree of life.

The narrative in the first chapter is arranged according to a definite plan. Six days are allotted to the creation of the heavens and earth, with all their furniture animate and inanimate. After due preparation had been made by the formation of light, atmosphere, and land separated from water, life is called into existence, first vegetable, then animal, terminating in man the lord of this lower world. The narrative in chapters ii.–iv. does not present such orderly progress. In it man is the central figure, to whom all is subordinated. He is created first. For him plants and trees are made to spring up. He is placed in a delightful garden. The Lord God perceiving his solitary condition creates the beasts of the field and the fowls of the air; but when brought to the protoplast, they were insufficient to supply his mental void, so that woman was made, in whom he found a suitable partner. A number of questions connected with the first pair, not necessarily entering into the writer's main purpose in describing man's origin, but complementary and new, are, the means by which the ground yielded vegetable productions, the materials from which the man and the woman were formed, the cause of their intimate union, the place of their abode, the simplicity of their condition, and the way in which animals first received their names. By these traits preparation is made for the history of what befell the protoplasts in their primitive abode.

According to the second narrative, Jehovah planted a garden in Eden, eastward, and put the first man there. A spring or stream rising in Eden, and flowing through the garden, supplied it with water. In issuing from the garden it divided itself into four rivers, each having its own course. The writer gives their names, and the countries washed by three of them. This garden, usually termed *Paradise* after the Septuagint and Vulgate, has been eagerly sought for; but it has baffled curiosity. Though two of the rivers, the Euphrates and Tigris, are well known, the other two, Pison and Gihon, can only be identified with difficulty. They seem to be rivers of Northern India. The Tigris and Euphrates took their rise in the high land of Northern Armenia; the Pison, *i.e.*, Indus, rises in the Himalayas; and the Gihon, *i.e.*, Oxus, is connected with Ethiopia or Cush. The writer appears to have considered them all as having their source in the northern highlands of Asia, and flowing south, and therefore he placed Eden somewhere in the north of Asia. The names of two rivers belonging to a foreign tradition, and little known to the Hebrews because intercourse with India was then remote, were associated with those of two known ones incorporated in the national tradition. If the interpreter had to do with pure history, it might not be amiss to search for Eden in some definite locality; but, as the case stands, the examination would probably be fruitless.

The garden has two remarkable productions—the tree of life, and the tree of knowledge of good and evil. The former derives its name from the virtue of its fruit to impart perpetual life or immortality. The fruit of the latter communicates the knowledge of good and evil. It awakens moral consciousness. The one had to do with physical, the other with spiritual life. Such were the miraculous powers of the two trees in the midst of the garden.

The third chapter gives an account of the first pair falling away from the state in which they were created. What that state was may be clearly gathered from the words. It was one of innocent simplicity. The protoplasts had a child-like unconsciousness of evil; no knowledge of right and wrong, virtue and vice. They were in the happy condition of infancy. Their moral existence had not begun. Perfection, uprightness, righteousness, could not be predicated of them. But the world presents vice and its concomitant misery in strong colours. Misery and evil abound. The eyes of an Oriental especially must have been vividly struck with the phenomena of toilsome work, the pains of child-bearing, the slavery of woman, and the inevitable necessity of death. The Hebrews, accordingly, meditated on the cause. The writer seeks to connect with the problem incidental phenomena, as the love of man and wife, the form of the serpent different from that of other animals, the mutual hatred of man and serpents, &c. It is an old question, the introduction of evil into the world. As all the posterity of the first pair participate in sin and suffering, the cause must be looked for in connection with these. Yet it must not proceed from themselves. God had made them innocent and happy. The origin of evil must come from without. A serpent becomes the instrument of their temptation. That cunning and mischievous animal seduces them. The writer thought of nothing but the creature itself. Those who suppose that the devil employed the serpent as his instrument, or that the devil alone is spoken of, are confronted by the fact that the idea of Satan was of later introduction among the Hebrews than the age of the writer. The curse pronounced on the tempter sufficiently shows that none but the agent expressly named was thought of.

Are these narratives of the creation, primal abode, and fall of man, literal history? So some have always believed, with Augustine and the Reformers. The difficulties in the way of this interpretation are great. As it cannot be carried out consistently, its advocates resort to various expedients. They forsake the literal for the figurative wherever necessity demands. Thus they put a figurative construction on the language of the curse, because they allege that a literal one would be frigid, utterly unworthy of the solemn occasion, highly inconsistent with the dignity of the speaker and the condition of the parties addressed. Sometimes they even incline to regard the narrative as a sort of poem, or give it a poetical character. The atmosphere in which the accounts move is different from the literal one. Instead of assuming that God created the world and all it contains in a moment of time, and in harmonious arrangement, the first writer attributes creation to six successive days, represents the Almighty as addressing the newly-formed existences, looking upon them with satisfaction, pronouncing them good, and resting on the seventh day. He naturally chose the six days of the Hebrew week, with which he was familiar, for successive gradations of the creative power. In the second account we find a speaking serpent, God walking in a human way in the cool of the day through the garden, his jealousy of the aspiring Adam who had attained a higher knowledge, his cursing the serpent, and cherubim with a flaming sword. To explain all this as literal history, were to attribute other perfections to the

Deity than infinite power, spirituality, and wisdom. Hence the Church of England, according to Horsley, does not demand the literal understanding of the document contained in the second and third chapters, as a point of faith.

Are the narratives allegorical? So Philo[1] interprets them, followed by the Greek fathers of Alexandria, Clement and Origen,[2] as well as by Ambrose. In modern times Coleridge read the whole as an allegory.[3] So did Donaldson in his *Jashar*. There is no indication, however, that allegories were intended. Had this been the case, the truths meant to be conveyed would have been easily discovered. The embarrassment and capriciousness of the allegorical interpreters prove that they have followed a wrong method. The outward form is set aside, and an idea discovered beneath it with which the envelope has no necessary connection. Both should be retained; the shell suggesting the kernel, and the kernel showing itself to be the necessary evolution of central ideas.

According to another interpretation, more commonly accepted among scholars at the present day, both accounts are supposed to be, like the early records of other nations, traditional and mythical. This does not imply that they are fables or fictions; far from it. It is true that the oldest traditions of peoples are mainly subjective, the result of the national mind; but they are nevertheless real. Variable, developed in different forms, influenced by the characteristics of the people and by their intercourse with others, they are all that constitutes the earliest history of nations, the shapings of oral tradition before written records appeared. A mythological age stands at the head of all national histories; and that of the Hebrews seems to be no exception. The two narratives present philosophical mythi in a historical form. They represent the best ideas of the Hebrews at a certain stage of their history in explanation of the creation of man, his primeval abode and state, and the cause of his degeneracy. The first account is plain and simple. It assigns a high dignity to man, and traces all human beings to a single pair, in harmony with the best evidence of modern science that points to unity of origin, rather than to different centres of creation. There is a naturalness in the narrative that cannot be mistaken, while the writer adheres to generalities. (See Gabler's *Einleitung* to *Eichhorn's Urgeschichte*, vol. i. p. 11, &c.; and Gesenius's article "Adam," in *Ersch und Gruber's Encyklopædie*, vol. i.)

On the other hand, the narrator in the second, third, and fourth chapters manifests a more reflective spirit, seeking to explain causes, and to trace connections. Supplying particulars wanting in the older narrative, and correcting others, he enters into details, and though more anthropomorphic, has a finer perception of circumstances associated with the protoplasts. Tholuck himself admits his narrative to be a mythus. It is usual to designate the first writer the Elohist; the second, the Jehovist; because the one commonly uses Elohim as the name of God; the other Jehovah, or Jehovah Elohim in the second and third chapters.

The Adam in the second and third chapters, according to this view, is the progenitor and representative of humanity, who brought misery into the world by self-will. He is ideal man, becoming historical in every individual who, as soon as his moral nature is awakened, feels the power and the possibility of rising higher through reason and perception. Adam's procedure repeats itself in each individual, who has his paradise, eats of the tree of knowledge, and feels within him the roots of apostasy from God. On the other hand, his restoration and happiness are supposed to be in his own power. His salvation is practicable through the victory of reason over instinct, of faith over sense.[4]

The traditions of ancient nations present analogies to the creation of man given in the first chapter of Genesis. The Etrurian comes nearest to the Hebrew. There creation takes place in six periods of a thousand years each, and men appear in the last, after the earth, sun, moon, and stars, with all living things on the surface of the globe, had been brought into existence by God.[5] The Persian mythology, in like manner, makes Ormuzd, the god of light, create by his word *Honover* the visible world in six periods of a thousand years each, and man is formed last. The name of the first man is Kaiomorts.[6] The Chaldee myth, given by Berosus, presents little resemblance to the Hebrew narrative. Bel, the highest god, divided the darkness, and cut the woman, who ruled over the monstrous creatures found at first in *the-all*, into two halves, out of which heaven and earth were formed. After that he cut off his own head. The blood trickling down was taken by other gods and mixed with earth, from which men were formed, who are therefore wise, and partakers of the divine intelligence.[7] The Phenician myth is still more unlike the Hebrew account.[8] But Ovid's teaching is that man was made in the image of the gods, and was intended to be ruler of the earth.[9] The Egyptian theology has no point of contact with the Hebrew.[10] The Indian accounts are very numerous, but often discrepant. Their likeness to the Hebrew narrative is remote; for the play of imagination appears in them to excess and absurdity. Among those myths in which the formation of men is described without allusion to any primordial distinction of castes, we may quote two. Prajapati, *i.e.*, the universe which was soul and only one, formed animals from his breaths, *a man* from his soul. The soul is the first of the breaths. Since he formed a man from his soul, therefore they say, "man is the first of the animals, and the strongest." The soul is all the breaths: for all the breaths depend upon the soul. Since he formed man from his soul, therefore they say, "man is all the animals;" for all these are man's.[11] Manu's account of the creation is that men of the four castes proceeded separately from different parts of Brahma's body prior to the division of that body into two parts. The doctrine of emanation appears in the Indian cosmogonies, as also that of absorption. Thus Brahma is reabsorbed into the supreme spirit, according to Manu.[12] According to the Bamians in India, God having made the world and the creatures belonging to it, created man, who came forth from the earth at the divine voice, his head appearing first, then his whole body, into whom life was conveyed. God gave him for companion a woman, and the two lived together as man and wife, feeding on the fruits of the ground. They had four sons of different temperaments, for whom God made four women, and the four quarters of the earth were peopled by their progeny.[13]

The paradisiacal state of the first pair, and their loss of it as described in the second and third chapters of Genesis, have their parallels in the myths of ancient nations. According to the Persian traditions, Meschia and Meschiane, the progenitors of mankind, were created for happiness in

this world and the next, on condition that they were good, and did not worship Dews. At first they acted according to their original nature, acknowledging that all beings were derived from Ormuzd. But they were seduced by an evil spirit, and clothed themselves in black for thirty days. After that they went out to hunt, and found a white goat, of whose milk they drank. In this they sinned against their body, and were punished. The evil spirit or Dew presented himself to them again, giving them fruits to eat, by which they forfeited a hundred enjoyments. At first they covered themselves with the skins of dogs, and ate the flesh of these animals. They hunted and made themselves clothing of the skins of deer.[1]

Abriman is represented as a poisonous serpent, and springs in this form from heaven to earth.[2] Dews often take the same form.[3]

The tree *Hom* among them is similar to the tree of life. It imparts immortality, and is called the king of trees.[4]

The holy mountain or paradise of Persian tradition is *Albordj*, the abode of Ormuzd and the good spirits, which sends forth great rivers.[5] This means the Hindu Koosh mountains where was *Airjana veedjo*, the first seat of the Aryan race. Here we have mention of a district *Heden;* and Zoroaster is said to have been born in *Hedenesch*, but elsewhere in *Airjana veedjo*.[6]

According to the religion of Lama or the Calmucks, men lived in the first age of the world 80,000 years. They were holy and happy. But their happiness came to an end. A plant, sweet as honey, sprang out of the earth, of which a greedy man tasted, and made others acquainted with it. A sense of shame was awakened, and therefore they began to make themselves coverings of the leaves of trees. Their age and size decreased. Virtue fled, and all manner of vice prevailed.[7] The paradisiacal state of Thibetan mythology is one of perfection and spirituality. But the desire to eat of a sweet herb, *schima*, put an end to that condition. Shame sprang up within the fallen; the need of clothing was felt. They were driven to agriculture by necessity. Virtue fled, murder, adultery, and all other vices succeeded.[8]

Among the Indians, the holy mountain of the north, the seat of the gods, and the source of the great rivers, was *Meru*.[9] The tree *Parijata*, brought from heaven to earth by Krishna, with its heavenly flower and fruit, scares away hunger, thirst, disease, old age, &c.[10]

The Greek myths are remotely parallel. Hesiod describes the primitive state as one free from toil, sickness, and all kinds of evil. Mortals were contented with easily obtained, though poor, sustenance. But cunning Prometheus deceived Zeus, and stole fire from heaven. The latter, by way of punishment, sent a beautiful woman, Pandora, whom Epimetheus accepted as a gift. Having with her a vessel into which all sorts of misery had been put, she opened it out of curiosity, and evils flew forth in abundance, filling the earth. Hope alone remained at the bottom.[11]

The story is supplemented and modified in the *Theogony*. There Prometheus is twice punished, and woman becomes the source of man's evils, merely as the original mother of the race. There is also a reconciliation between Zeus and Prometheus.[12]

In Æschylus mankind are presented in the ignorance of infancy till Prometheus implanted in them the power of intellect, and the capability of knowledge. The fire from heaven is not the cause of the evils that broke in upon them; rather is it the teacher of every art, and the opener up of infinite resources; but Prometheus himself must endure fearful punishment for his self-will, in paying too much regard to mortals. Still there is an intimation of future reconciliation between the opposing powers, Zeus and Prometheus.

The points of similarity between the Old Testament and this Greek representative of man's fall are tolerably plain. In both there is an original state marked by freedom from sorrow, by complete earthly enjoyment and undisturbed peace with God. Both attach the origin of evil to the act of a free being putting himself in opposition to God—evil being the punishment of that act, arising by means of a woman. As the Old Testament narrative implies that the step taken by man was not a mere degeneracy, so Æschylus's description admits that it was for humanity the beginning of a richer and higher life, since man's proper destiny could not be worked out in a condition of childlike incapacity. Pandora reminds us of Eve; Epimetheus of Adam. Prometheus and the serpent both wish to make men like God in knowledge and happiness.[13] The tragic poet seems to regard Prometheus as the archetype of man, so that his fate is theirs. Like every strong-willed mortal, Prometheus flounders on the rock of presumption. He persists in acting contrary to the commands of Deity, and endures torture till he submits to a higher will, accepting the symbols of repentance and restraint within certain limits. Thus, like Adam, he is the representative of humanity.

The fundamental difference between the Hebrew and Greek narratives is, that the distinction between God and the world, spirit and nature, maintained with all sharpness in the one, is not carried out in the other. On the contrary, the Greek myth mixes the two spheres, so that the world appears as the original, independent element, of which spirit and deity are mere products. In the Hebrew narrative the spiritual features are presented clearly and simply; in the Greek they are indistinct, because transferred to the sensuous world and covered with a luxuriant growth of outer nature.[14]

Ovid paints the golden age in the manner of Hesiod, but with more details. It was pervaded by innocent simplicity, and the successive ages became still worse, till moral corruption reached such a height in the last or iron age that Jupiter sent a flood to destroy all mankind.[15]

Plato in his *Symposium*[16] explains the sexual and amatory inclination of the man and the woman by the fact that there were at first androgynous beings, whom Zeus separated into men and women. The two sexes were originally united.

In Corrodi's *Beiträge* (xviii. p. 14), the Indian *Ezour Vedam* is quoted, in which the first man is called *Adimo*, from whose body came Brahma, Vishnu, and Schiva. This statement is repeated by Knobel and others. But the *Ezour Vedam* (a corrupt pronunciation of Yajur Veda) is a spurious Veda from the pen of some Jesuit missionary.[17] Though it mentions Adimo (which simply means *the first*) in vol. i. p. 195, &c., and vol. ii. 205, genuine Indian mythology recognises no such name of the first man.

The second narrative, in some of its ideas, seems de-

rived from Eastern Asia. Several features disclose this; such as the covering of fig leaves, the springing of four rivers from a common source, and the names of two of them which point to India. The tree of life and the seducing spirit have their place in the Persian and Indian religions. But its essence is adapted to the Hebrew theology, and contains genuine Hebrew traits; though it stands tolerably isolated in the circle of ideas which the Old Testament presents. Not till the Book of Wisdom do we find express reference to it (chap. ii. 23, 24), though the tree of life is spoken of in the Proverbs. Yet there is diversity amid similarity. As elaborated by the Hebrew mind, the narrative is a profound theory, with noble features worthy of the subject. Its verisimilitude is apparent. It shows a thoughtful contemplation of human nature, a fine sense of its capacities and weakness, of its aspirations and needs. Its lines are drawn with great discernment. The problem need expect no better solution in this life; for its depths cannot be fathomed by the sounding-line of a finite understanding. Here is the one philosophy of the subject that has taken the deepest hold of the human mind, engrafting itself on the religious systems of very different races, and enlisting the sympathies of the most civilised nations. Originating in the East, it has been transferred to the West, where it lives in pristine vigour. It is the essence of the best ideas and traditions of Eastern Asia, improved and enlarged by the Hebrew mind at a certain period. The more the narrative is examined, the more clearly will it appear the result of enlightened reason. It embodies national traditions of Hebrew reflectiveness. Free from the pantheism and dualism inherent in the mythologies of other peoples, the monotheism which distinguished the Hebrews as the depositaries of a divine truth pervades it. The tradition has two sides. It represents the transition of man to freedom and humanity, as Schiller describes it; his elevation by the awakening exercise of reason; his advance from nature's cradling-season to a consciousness of the divine within him; but it represents at the same time the inclination to follow his own will, to aspire to the forbidden contrary to his better conviction, to push reason beyond the limits within which alone it can be legitimately used; in short, to break away from the will of God in self-sufficient independence. While the fact was one of the most fortunate in man's history, it was also one of the saddest. When moral good was made possible, moral evil was introduced. A knowledge of the one brings that of the other.[1]

After Adam fell, God drove him from paradise, whose gates were guarded by cherubim to prevent access to the tree of life. The protoplasts had first three sons—Cain, Abel, Seth; then other sons and daughters. Adam died at the age of 930. According to the Elohist, the later race of men descended from Seth, the first born (Genesis v.); according to the Jehovist from Cain, who was the first born (Genesis iv.) A Jewish tradition represents him as buried in Hebron with the patriarchs; a Christian one makes Golgotha his resting-place.

A number of absurd fables, the fancies of Jewish writers, have gathered round the simple narratives of the Old Testament, and are incorporated in the Talmud. In these Adam is said to have been made as a man-woman out of dust collected from every part of the earth; his head reached to heaven, and the splendour of his face surpassed the sun. The very angels feared him, and all creatures hastened to pay him devotion. The Lord, in order to display his power before the angels, caused a sleep to fall upon him, took away something from all his members, and when he awoke commanded the parts that had been removed to be dispersed over the globe, that the whole earth might be inhabited by his seed. Thus Adam lost his size, but not his completeness. His first wife was Lilith, mother of the demons. But she flew away through the air; and then the Lord created Eve from his rib, brought her to Adam in the most beautiful dress, and angels descending from heaven played on heavenly instruments; sun, moon, and stars dancing. He blessed the pair, and gave them a feast upon a table of precious stone. Angels prepared the most costly viands. But Adam's glory was envied by the angels; and the seraph Sammael succeeded in seducing him. The pair were driven out of paradise into the place of darkness, and wandered through the earth.[2]

According to the Koran, God created man of dried clay like an earthen vessel, animating the figure, and enduing it with an intelligent soul. When he had placed him in paradise, he formed Eve out of his left side. All the angels worshipped the new man except Eblis, who refused and became an unbeliever. Satan caused them to forfeit paradise, and turned them out of their state of happiness. On Adam's repentance, God pitied him, and had him taught the divine commandments by the archangel Gabriel; whereupon he was conducted to Arafat, a mountain near Mecca, and found Eve after a separation of 200 years. He was buried on Mount Abukais, near Mecca.[3] Many other fables of the later Jews respecting Adam are collected by Eisenmenger, and those of the Mahometans by Herbelot.

In the emanation systems of the Christian Gnostics and Manichæans, as well as in the gnosis of the Mandæans, Adam is represented as one of the first and holiest æons. Both catholic and heretical literature indulged in fictions respecting Adam. *A Life of Adam* was translated from the Ethiopic into German by Dillmann, in Ewald's *Jahrbuch*, v. *The Testament of Adam*, current in Syriac and Arabic, was published by Renan in the *Journal Asiatique*, série v. tom. 2. Both these seem to be derived from the *Spelunca Thesaurorum*, which exists in MS. in the Syriac tongue. The Sethites, a Gnostic sect, had *Apocalypses of Adam*; other Gnostics had a *Gospel of Eve*. *A Book of the Repentance of Adam* and *A Book concerning the Daughters of Adam*, are condemned in the decree of Gelasius. George Syncellus cites a Greek *Life of Adam*; and a fragment from *The Greek Book of Adam*, in a Florentine MS., is given in the *Literaturblatt des Orients* for 1850. Thus the Adam-literature is copious.[4] The *Book of Adam*, published by Norberg in 1816, is improperly so termed. It is a Mandæan or Sabian work, *Sidra Rabba*, which is now better known, since Petermann's critical edition of 1867, and Nöldeke's researches into the language. (S. D.)

ADAM OF BREMEN, ecclesiastical historian, was born in Upper Saxony, and in 1067, probably on the invitation of Archbishop Adalbert, came to Bremen, where he was appointed canon and *magister scholarum*. He died in 1076. His *Gesta Hammaburgensis Ecclesiæ Pontificum*, containing a history of the diocese of Hamburg and Bremen from 788 till the death of Adalbert in 1072, is of great importance as the chief source of information in regard to the state of the northern kingdoms during the period of which it treats. It is supposed to have been compiled partly from written documents and partly from the oral communications of the Danish king, Svend Estrithson. Its statements are generally trustworthy, though the chronology is sometimes confused, and the geographical informa-

tion often erroneous. The style is clear and interesting, though somewhat prolix. It was first published from MSS. at Copenhagen in 1579. The best edition is that of Lappenberg in Pertz's *Monumenta Germaniæ*. A supplement to the *Gesta*, a geographical work of considerable value, entitled *De Situ Daniæ et Reliquarum quæ trans Daniam sunt Regionum Natura*, was published at Stockholm in 1615, and at Leyden in 1629.

ADAM, ALEXANDER, Rector of the High School, Edinburgh, was born on the 24th of June 1741, near Forres, in Morayshire. From his earliest years he showed uncommon diligence and perseverence in classical studies, notwithstanding many difficulties and privations. In 1757 he went to Edinburgh, where he studied at the University with such success that in eighteen months he was appointed head-master of Watson's Hospital, being at the time only nineteen. He was confirmed in the office of Rector of the High School on the 8th of June 1768, on the retirement of Mr Matheson, whose substitute he had been for some time before. From this period he devoted himself entirely to the duties of his office, and to the preparation of the numerous works he published in classical literature. His popularity and success as a teacher are strikingly illustrated in the facts that his class increased more than fourfold during his incumbency, and that an unusually large proportion of his pupils attained to eminence, among them being Sir Walter Scott, Lord Brougham, and Jeffrey. He succeeded in introducing the study of Greek into the curriculum of the school, notwithstanding the opposition of the University headed by Principal Robertson. In 1780 the University of Edinburgh conferred upon Mr Adam the honorary degree of Doctor of Laws. He died on the 18th December 1809, after an illness of five days, during which he occasionally imagined himself still at work, his last words being,—"But it grows dark; you may go." Dr Adam's first publication was his *Principles of Latin and English Grammar* (1772). This was followed by his *Roman Antiquities* (1791), his *Summary of Geography and History* (1794), and his *Latin Dictionary* (1805). The MS. of a projected larger Latin dictionary, which he did not live to complete, lies in the library of the High School.

ADAM, MELCHIOR, German divine and biographer, was born at Grottkaw in Silesia after 1550, and educated in the college of Brieg, where he became a Protestant. He was enabled to pursue his studies there by the liberality of a person of quality, who had left several exhibitions for young students. In 1598 he went to Heidelberg, where, after holding various scholastic appointments, he became conrector of the gymnasium. In 1615 he published the first volume of his *Vitæ Germanorum Philosophorum*, &c. This volume was followed by three others; that which treated of divines was printed in 1619; his lives of lawyers and of physicians were published in 1620. All the learned men whose history is contained in these four volumes lived in the 16th or beginning of the 17th century, and are either Germans or Flemings; but he published in 1618 the lives of twenty divines of other countries in a separate volume, entitled *Decades duæ continentes Vitas Theologorum Exterorum Principum*. All his divines are Protestants. His industry as a biographer is commended by Bayle, who acknowledges his obligations to Adam's labours. Lutherans and Catholics accuse him of unfairness, but the charge is at least exaggerated. He died in 1622.

ADAM, ROBERT, architect, the second son of William Adam of Maryburgh, in Fife, was born in 1728. He studied at the University of Edinburgh, and probably received his first instruction in architecture from his father, who, whether a professional architect or not, gave proofs of his skill and taste in the designs of Hopetoun House and the Edinburgh Royal Infirmary. In 1754 young Adam visited the Continent, and spent three years in Italy for the purpose of examining the ruins of Roman architecture. The magnificence of the public baths erected at Rome in the time of Diocletian having impressed him with the idea that there had been a marked revival of architectural art during that emperor's reign, he resolved to visit the ruins of the private palace Diocletian had erected at Spalatro in Dalmatia. In company with Clerisseau, a French architect, he sailed from Venice in July 1754, and in a few weeks, with the help of two experienced draughtsmen, had completed plans and views of the fragments, from which he was afterwards able to execute a design of the entire building. The results were published in the *Ruins of the Palace of Diocletian*, &c. (1764). After his return to England he rose to the highest eminence in his profession, and was appointed architect to the king in 1762. Six years later he entered Parliament as representative of the county of Kinross, but he still continued to devote himself to the duties of his profession, resigning only his court appointment. In 1773-78 he and his brother James, also an architect of considerable note, published from time to time large folio engravings with letterpress description of their designs, the most important being,—Lord Mansfield's house at Caenwood; Luton House, Bedfordshire; the Register House, Edinburgh, &c. Among their later works may be mentioned the buildings erected in London by the two brothers, and hence called the Adelphi (ἀδελφοί), which proved an unsuccessful speculation; Portland Place, London; and the Infirmary of Glasgow. The leading characteristics of all these designs are lightness and elegance; and, though grave faults may be found with his style, it cannot be denied that English architecture, especially that of the streets of London, owes very much to Robert Adam. He continued actively engaged in his profession until his death in 1792. James, his brother and associate in labour, died in 1794.

ADAM, RIGHT HON. WILLIAM, nephew of the preceding, eldest son of John Adam, Esq. of Blair-Adam, Kinross-shire, was born on the 2d August 1751, studied at the Universities of Edinburgh and Glasgow, and passed at the Scotch bar in 1773. Soon after he removed to England, where he entered Parliament in 1774, and in 1782 was called to the Common-law bar. He withdrew from Parliament in 1795, entered it again in 1806 as representative of the united counties of Clackmannan and Kinross, and continued a member, though with some interruptions, till 1811. A popular though not an eloquent speaker, Mr Adam soon took a prominent place in the House, making himself of importance by his sound judgment and firm general adherence to the Whig party. A duel in 1779 between him and Mr Fox, in which the latter was slightly wounded, did not interrupt their close and steady friendship. They both belonged to the small but noble band that opposed the encroachments of the Government on the Constitution during the period of the French Revolution. One of Mr Adam's most valuable parliamentary efforts was the agitation which he successfully raised, in March 1794, against the severe punishment awarded in the Scotch criminal court to certain persons who had been convicted of sedition. At the English bar he was as successful as any one can be who does not devote himself entirely to the profession. Though known to be much engaged in Parliament, and with the management of the pecuniary affairs of the Prince of Wales and the Duke of York, he obtained a very considerable practice. He was successively Attorney and Solicitor General to the Prince of Wales, one of the managers of the impeachment of Warren Hastings, and one of the counsel who defended the first Lord Melville when impeached (as Mr Dundas). During his party's brief tenure of office in 1806 he was Chancellor of the Duchy of Cornwall, and was afterwards a privy councillor and lord-lieutenant of Kinross-shire. In 1814 he became a baron of Exchequer in Scotland, and in the following year was appointed chief commissioner of the newly-established Jury-Court for the trial of civil causes, over which he presided with much ability and acceptance till 1830, when it ceased to exist as a separate court, and became merged in the permanent supreme tribunal. Though little versed in the technicalities of law, he was in all practical matters an able manager; he was a shrewd observer of all that passed around him, and a most agreeable companion. He died at Edinburgh on the 17th February 1839.

ADAM'S BRIDGE, or *Rama's Bridge*, a chain of sandbanks, extending from the island of Manaar, near the N.W. coast of Ceylon to the island of Ramesceram, off the Indian coast, and lying between the Gulf of Manaar on the S.W. and Palk Strait on the N.E. It is more than 30 miles long, and offers a serious impediment to navigation. Some of the sandbanks are dry; and no part of the shoal has a greater depth than 3 or 4 feet at high water, except three tortuous and intricate channels, a few feet deep, which in calm weather permit the passage of boats and small vessels.

ADAM'S PEAK, a lofty mountain in Ceylon, about 45 miles E. from Colombo, in N. lat. 6° 55′, E. long. 80° 30′. It rises steeply to a height of 7240 feet, and commands a magnificent prospect. Its conical summit terminates in an oblong platform, 74 feet by 24, on which there is a hollow, resembling the form of a human foot, 5 feet 4 inches by 2 feet 6 inches; and this has been consecrated as the footprint of Buddha. The margin of this supposed footprint is ornamented with gems, and a wooden canopy protects it from the weather. It is held in high veneration by the Cingalese, and numerous pilgrims ascend to the sacred spot, where a priest resides to receive their offerings, and bless them on their departure. By the Mahometans the impression is regarded as that of the foot of Adam, who here, according to their tradition, fulfilled a penance of one thousand years, while the Hindoos claim it as that of their god Siva.

ADAMAWA, a country of Central Africa, lies between 7° and 11° N. lat., and 11° and 16° E. long., about midway on the map between the Bight of Biafra and Lake Chad. Its boundaries cannot be strictly defined; but it stretches from S.W. to N.E. a distance of 200 miles, with a width of from 70 to 80 miles. This region is watered by the Benuwe and the Faro. The former, which ultimately unites with the Niger, flows through Adamawa, first in a northerly, then in a westerly direction; and is joined by the Faro, which rises in the south, 22 miles from Yolla, the capital of the country. Near their confluence the Benuwe is 800 yards wide, with a depth of about 11 feet; the Faro has a breadth of 600 yards, but is generally very shallow. Both rivers are subject to extraordinary floods, beginning in the end of September, and lasting forty days, during which the swamps of the adjacent country are covered for a great distance on both sides, and the Benuwe rises at least 30 feet. The most fertile parts of the country are the plains near the Benuwe, about 800 feet above the level of the sea. Further from that river the land rises to an elevation of 1500 feet, and is diversified by numerous hills and groups of mountains. Mount Alantika, about 25 miles S.S.E. of Yolla, is the loftiest mountain in Adamawa, and rises from the plain, an isolated mass, to the height of 9000 feet. The country, which is exceedingly rich, and is covered with luxuriant herbage, has many villages, and a considerable population. The grain known as *Holcus sorghum* or *durra*, ground-nuts, yams, and cotton are the principal products; and the palm and banana abound. Elephants are very numerous, and ivory is largely exported. In the eastern part of the country the rhinoceros is met with, and the rivers swarm with crocodiles, and with a curious mammal called the *ayu*, bearing some resemblance to the seal. Yolla, the capital of Adamawa, is situated, in N. lat. 9° 28′, E. long. 12° 13′, in the fertile plain between the Benuwe and the Faro. The houses are built of clay, and surrounded by court-yards, in which grain is grown; so that the town, though containing only about 12,000 inhabitants, is spread over a large extent of ground, and is 3 miles long from east to west. *Turkedi* (a dark-coloured cotton cloth), beads, salt, and calico are the principal articles exposed in the markets. Here and throughout Adamawa cotton is generally used as a medium of barter. A very large proportion of the population are slaves, many private individuals holding as many as 1000, while the governor is said to receive annually about 5000 in tribute. The government of Adamawa is in the hands of a Mahometan ruler, who owns a nominal allegiance to the Sultan of Sokoto, but is in reality an independent sovereign. Formerly the country was called Fumbina, and was possessed by various African tribes, until it was overrun by the Fulbe, a Mahometan people. It has not been entirely subjected by them, but they have detached settlements at various places; and numerous governors, as well of the Fulbe as of outlying pagan tribes, are in subjection to the ruler of Yolla. (See Barth's *Travels in Central Africa*, vol. ii.)

ADAMITES, or ADAMIANS, a sect of heretics that flourished in North Africa in the 2d and 3d centuries. Basing itself probably on a union of certain gnostic and ascetic doctrines, this sect pretended that its members were re-established in Adam's state of original innocency. They accordingly rejected the form of marriage, which, they said, would never have existed but for sin, and lived in absolute lawlessness, holding that, whatever they did, their actions could be neither good nor bad. During the Middle Ages the doctrines of this obscure sect, which did not at first exist long, were revived in Europe by the Brethren and Sisters of the Free Spirit, who in the 14th century were better known throughout Germany as Beghards. This name was originally borne by a religious party that was formed in the Netherlands a century earlier. The two sects came into contact on the Rhine frontier, associated with each other, gradually approximated in doctrine, and were at last identified by the application to both of the one name; though a distinct sect of Beghards, free from the excesses of the brethren, continued to exist in the Netherlands. *Picard* is simply another form which *Beghard* assumed in the harsh pronunciation of the Bohemians, and the common method of accounting for it by supposing a leader Picard has no sufficient warrant. The principal seat of the Picards in Bohemia was a small island in the river Luschnitz, where they lived in a state of nature, and had wives in common. In 1421 they were almost exterminated by Ziska, the leader of the Hussites, who committed many of them to the flames. In 1849 it appeared that the sect existed in a district of Austria, though small in number, and not ostentatious of its peculiar practices. (Rüdinger *de Eccl. Frat. in Bohem.*, &c.; Bossuet's *Variations of Protestant Churches.*)

ADAMNAN or ADOMNAN, SAINT, born in Ireland about the year 624, was elected Abbot of Iona in 679, on the death of Failbhe. While on a mission to the court of King Aldfrid of Northumberland (700–1), he was led to adopt the Roman rule in regard to the time for the observance of Easter; and on his return to Iona he tried to enforce the change upon the monks, but without success. It is said that the disappointment caused his death, which occurred in 703 or 704. Adamnan wrote a *Life of St Columba*, which, though abounding in fabulous matter, is of great interest and value. The best edition is that of Reeves published by the Irish Archæological and Celtic Society in 1857. Adamnan's other well-known work, *De Situ Terræ Sanctæ*, was based. according to Bede, on information received from Arculf, a French bishop, who, on his return from the Holy Land, was wrecked on the west coast of Britain, and was entertained for a time at Iona. This was first published by Gretser at Ingolstadt in 1619. (*Kalendars of the Scottish Saints*, by Bishop Forbes, 1872.)

ADAMS, John, a distinguished statesman of the United States of North America. He was born on the 19th or (new style) 30th of October 1735, in that part of the township of Braintree, in Massachusetts, which on a subsequent division was called Quincy. His parents were of that class, then abounding in New England, who united the profession of agriculture with that of some one of the mechanic arts. His ancestor Henry had emigrated from Devonshire in the year 1632, and had established himself at Braintree with six sons, all of whom married: from one descended the subject of this memoir, and from another that Samuel Adams who, with John Hancock, was by name proscribed by an Act of the British Parliament, for the conspicuous part he acted in the early stages of the opposition to the measures of the mother country. When about fifteen years of age, his father proposed to his son John either to follow the family pursuits, and to receive in due time, as his portion, a part of the estate which they had cultivated. or to have the expense of a learned education bestowed upon him, with which, instead of any fortune, he was to make his way in future life. The son chose the latter alternative; and having received some preparatory instruction, was admitted a student at Harvard College in the year 1751. After graduating in 1755, he removed to the town of Worcester, where, according to the economical practice of that day in New England, he became a tutor in a grammar school, and at the same time was initiated into the practice of the law in the office of Mr Putnam, then an attorney and a colonel of militia, and subsequently a general of some celebrity in the revolutionary war. A letter he wrote at the early age of nineteen, shows a degree of foresight which, like many other predictions, may have led to its own accomplishment. It is dated 12th October 1754, and says—"Soon after the Reformation, a few people came over to this New World for conscience' sake. Perhaps this apparently trivial incident may transfer the great seat of empire to America. It looks likely to me; for if we can remove the turbulent Gallic (the French in Canada), our people, according to the exactest computation, will in another century become more numerous than England itself. Should this be the case, since we have, I may say, all the naval stores of the nation in our hands, it will be easy to obtain the mastery of the seas, and then the united force of all Europe will not be able to subdue us. The only way to keep us from setting up for ourselves is to disunite us."

He was admitted to practice in the year 1758, and gradually rose to the degree of eminence which a local court can confer; and obtained distinction by some essays on the subject of the canon and feudal law, which were directed to point to the rising difference which commenced between the mother country and the colonies, soon after the peace of 1763 had delivered the latter from all disquietude respecting the establishments of France in the adjoining province of Canada. His character rose, both as a lawyer and a patriot, so as to induce Governor Barnard, who wished to gain him over to the royal party, to offer him the office of advocate-general in the Admiralty Court, which was deemed a sure step to the highest honours of the bench. Two years after, he was chosen one of the representatives of his native town to the congress of the province. His first prominent interference in political affairs was at a meeting at Braintree in 1765, to oppose the Stamp Act. The resolutions he proposed were not only carried unanimously, but were afterwards adopted verbatim by more than forty other towns. In 1768 he found it necessary to remove to Boston, owing to the increase of his legal practice.

His professional integrity was soon after exhibited in the defence of Captain Preston and some soldiers, who were tried before a Boston jury on a charge of murder, April 1770. In this case Adams was counsel for the defence; and being considered by the people, then in an inflamed state against the troops, as a determined friend of liberty, his eloquence obtained a verdict of acquittal without lessening his popularity.

When it was determined, in 1774, to assemble a general congress from the several colonies, Mr Adams was one of those solicited for the purpose by the people of Massachusetts. Before departing for Philadelphia to join the congress, he parted with the friend of his youth, his fellow-student and associate at the bar, Jonathan Sewall, who had attained the rank of attorney-general, and was necessarily opposed to his political views. Sewall made a powerful effort to change his determination, and to deter him from going to the congress. He urged, that Britain was determined on her system, and was irresistible, and would be destructive to him and all those who should persevere in opposition to her designs. To this Adams replied: "I know that Great Britain has determined on her system, and that very fact determines me on mine. You know I have been constant and uniform in opposition to her measures; the die is now cast; I have passed the Rubicon; to swim or sink, live or die, survive or perish with my country, is my unalterable determination." The conversation was then terminated by Adams saying to his friend, "I see we must part; and with a bleeding heart, I say, I fear for ever. But you may depend upon it, this adieu is the sharpest thorn on which I ever set my foot."

When the continental congress was assembled Mr Adams became one of its most active and energetic leaders. He was a member of that committee which framed the Declaration of Independence, and one of the most powerful advocates for its adoption by the general body; and by his eloquence obtained the unanimous suffrages of that assembly. Though he was appointed chief-justice in 1776, he declined the office, in order to dedicate his talents to the general purpose of the defence of the country.

In 1777 he, with three other members, was appointed a commissioner to France. He remained in Paris about a year and a half, when, in consequence of disagreements among themselves, in which Adams was not implicated, all but Franklin were recalled. In the end of 1779 he was charged with two commissions,—one as a plenipotentiary to treat for peace, the other empowering him to form a commercial treaty with Great Britain. When he arrived in Paris, the French Government viewed with jealousy the purpose of the second commission; and Count de Vergennes advised him to keep it secret, with a view to prevail on the congress to revoke it. Mr Adams refused to communicate to the count his instructions on that subject; and an altercation arose, from a claim made by France for a discrimination in favour of French holders of American paper money in the liquidation of it. The count complained to Congress, transmitted copies of Mr Adams's letters, and instructed the French minister at Philadelphia to demand his recall. The demand was rejected, but afterwards four others were joined with him in the commission. Whilst these negotiations were in progress he went to Holland, and there, in opposition to the influence and talents of the British minister, Sir Joseph Yorke, succeeded both in negotiating a loan, and in procuring the assistance of that country in the defence against Great Britain. He formed a commercial treaty with that republic, and joined in the ephemeral association called "the armed neutrality."

In 1785 Mr Adams was appointed ambassador to the court of his former sovereign, where his conduct was such as to secure the approbation of his own country, and the respect of that to which he was commissioned. Whilst in London, he published his work entitled *Defence of the American Constitution*, in which he combated ably the opinions of Turgot, Mably, and Price, in favour of a single legislative assembly; and thus perhaps contributed to the division of power and the checks on its exercise, which became established in the United States. At the close of 1787 he returned, after ten years devoted to the public service, to America. He received the thanks of Congress, and was elected soon after, under the presidency of Washington, to the office of Vice-President. In 1790 Mr Adams gave to the public his *Discourses* on Davila, in which he exposed the revolutionary doctrines propagated by France and her emissaries in other countries. On the retirement of Washington, the choice of President fell on Mr Adams, who entered on that office in May 1797. At that time the Government was entangled by the insolent pretensions of the French demagogues, and by their partisans in many of the states. Great differences of opinion arose between the individuals at the head of affairs: one party, with Mr Hamilton at their head, was disposed to resist the pretensions of France by open hostilities; whilst Mr Adams was disinclined to war, so long as there was a possibility of avoiding it with honour. Owing to this division of his own friends, rather than to a want of public confidence, at the conclusion of the four years for which the President is chosen, Mr Adams was not re-elected. Perhaps this was in some measure owing to the preponderance of the slave states, in which Mr Jefferson, his rival, and a proprietor of slaves, had a fellow-feeling among the chief of the people.

He retired with dignity, at 65 years of age, to his native place, formed no political factions against those in power, but publicly expressed his approbation of the measures which were pursued by him who had been his rival, who had become his successor in power, but had never ceased to be his firmly-attached friend.

The last public occasion on which Mr Adams appeared, was as a member of the convention for the revision of the constitution of Massachusetts, in which some slight alterations were requisite, in consequence of the province of Maine being separated from it.

He seems to have enjoyed his mental faculties to the close of his protracted life; and even on the last day of it, two hours only before its final close, on the 4th July 1826, the fiftieth anniversary of the Act of Independence, he dictated to a friend, as a sentiment to be given at the public dinner of the day, "Independence for ever." By a very singular coincidence Jefferson, his rival and friend, died a few hours earlier on the same day.

Mr Adams was considered a sound scholar, well versed in the ancient languages, and in many branches of general literature. His style in writing was forcible and perspicuous, and, in the latter years of his life, remarkably elegant. In person he was of middling stature; his manners spoke the courtesy of the old school; and his address, at least when he was in England, was dignified and manly.

ADAMS, John Quincy, eldest son of the preceding, was born at Braintree on the 11th July 1767. The greater part of his education was received in Europe, which he visited in company with his father in 1778, and again in 1780, when he attended for a time the university of Leyden. When only fifteen years old he went, as secretary, with Francis Dana on his unsuccessful mission to St Petersburg. Returning home after an interval spent in Holland, London, and Paris, he graduated at Harvard in 1788; and, after spending three years in a lawyer's office, was admitted to the bar in 1791. Three successive series of letters, on political subjects, contributed to a Boston newspaper, attracted much attention, and Washington appointed him ambassador to the Hague in 1794. An appointment to a similar post in Portugal, made just before the expiry of Washington's presidency, was set aside by his father, who sent him instead to Prussia, giving him the promotion by the express advice of Washington. During his residence as ambassador at Berlin, he succeeded in negotiating a commercial treaty with Prussia. On Jefferson becoming President (1801), Adams was recalled, and resumed the practice of law in Boston. In 1802 Suffolk county returned him a member of the Massachusetts Senate, and in the following year he was elected to Congress. Indebted for his position to the Federal party, Adams supported their views for four years, but separated from them by voting for Jefferson's proposed *embargo*. This course involved him in much controversy, and cost him his seat in the Senate. During his retirement he added to the employment arising from his profession the duties of the professorship of rhetoric and belles lettres at Harvard University, which he held for three years (1806–9). His lectures—the first ever read in an American university—were published in 1810, and were much thought of at the time, though now almost forgotten. In the winter following the resignation of his professorship, he visited Washington; and, in an interview with Jefferson, brought a charge against some of the Federal leaders of a design to dissolve the union, and form a separate confederation for the north. The charge was afterwards repeated in the newspapers; and, though resting on slender grounds, greatly affected the confidence of the other states in the New England representatives. In 1809 Madison, having obtained after some delay the concurrence of the Senate, entrusted Adams with the embassy to St Petersburg,—an appointment which the latter accepted against the wishes of his father, and continued to hold, though offered a seat on the judicial bench of New England some time after his arrival in Russia. When war broke out between England and the United States, Adams induced the Czar to make an offer of intervention, which, however, the English Government declined to accept. Independent negotiations were thereupon carried on for six months at Ghent (the representatives of America being Adams, Russell, and Clay), and resulted in the treaty of peace which was signed 24th December 1814. After serving for two years (1815–17) as minister in London, he again entered the arena of home politics as secretary of state under Monroe. In this office he distinguished himself specially by his arrangement of the treaty with Spain, which defined the boundaries of the ceded territories of Florida and Louisiana. An elaborate report on weights and measures gained for him also a name for scientific acquirements. In 1825 the election of a President fell, according to the constitution of the States, to the House of Representatives, since no one of the candidates had secured an absolute majority of the electors chosen by the States, and Adams, who had stood second to Jackson in the electoral vote, was chosen in preference to Jackson, Clay, and Crawford. The administration of Adams was marked by the imposition of a high tariff on foreign goods, with the view of promoting internal industry, and by the unsuccessful attempt to purchase Cuba from Spain. Notwithstanding the efforts of Clay, and the special claim he himself made on the voters of Virginia on account of his discovery of the so-called New England "plot" twenty years before, Adams failed to secure his re-election in 1829. Defeated by Jackson, who had 178 votes to his 83, he retired to Quincy, where his father's fortune, increased by his own efforts, afforded him an ample competency. Two years later he was returned to Congress by the district in which he lived, and which he continued to represent until his death. Having been chosen merely on account of his determined resistance to secret societies, his position was independent of party politics, and correspondingly strong. He stood for the office of governor, and then for that of senator, of Massachusetts, but was on both occasions defeated by Davis. As chairman of the committee on manufactures, he strove to devise a middle policy in regard to tariffs, but his greatest effort at this period—perhaps the greatest service of his whole political life—was in connection with the abolition of slavery. In every form which the question took, he was the bold and determined advocate of abolition, gradually gathering an influential party around him, and so preparing for the triumphs, most of which have been won since his death. He himself witnessed, in 1845, the abolition of the "gag-rule," restricting the right of petition to Congress on the subject of slavery, which he had persistently opposed during the nine years it was in force. He died of paralysis on 23d February 1848, having been seized two days previously while attending the debates of Congress. Adams wrote a number of works, which are now of little importance. The style is fluent, but has none of the vigour and elegance of his father's. During his whole lifetime he kept a very voluminous journal, some portions of which have been published.

ADAMS, Richard, M.A., divine. Two contemporaries of the same name are frequently confounded with each other. The more eminent was son of the Rev. Richard Adams, rector of Worrall, in Cheshire. The family records seven clergymen of the Church of England in succession. The present worthy was born at Worrall, but the loss of the registers leaves the date uncertain. It is usually, but erroneously, stated that he studied at Cambridge University. He was admitted a student of Brazenose College, Oxford, March 24, 1646, and became a fellow, having proceeded through the usual degrees. It was at Brazenose he formed his life-long friendship with John Howe, who had a profound veneration for Adams. In 1655 he was appointed to the rectory of St Mildred's, Bread Street, London—John Milton being a parishioner. From this he was ejected by the Act of Uniformity of 1662. Thereupon he continued his ministry as opportunity offered, and at length was settled as pastor of a congregation in Southwark. This Richard Adams is a typical example of the consistent and meek labourers of the early and struggling period of Nonconformity. His holy and beautiful life inspired Howe's noblest eloquence in his funeral sermon. He died in a ripe old age, on 7th Feb. 1698. His principal literary work is his contribution of annotations on Philippians and Colossians to Pool's celebrated *Annotations*. Along with Veal he edited the works of Charnock. (A. B. G.)

ADAMS, Samuel, American statesman, born at Boston, Sept. 27, 1722, was second cousin to John Adams. He studied at Harvard, but, owing to his father's misfortunes in business in connection with a banking speculation,—the "manufactory scheme,"—he had to leave before completing his course, and to relinquish his intention of becoming a Congregational clergyman. He received his degree, however, and it is worthy of note, as showing the tendency of his political opinions, that his thesis was a defence of the affirmative reply to the question, "Whether it be lawful to resist the supreme magistrate, if the commonwealth cannot otherwise be preserved?" The failure of the banking scheme above referred to, in consequence of the limitations imposed by English law, made Adams still more decided in his assertion of the rights of American citizens, and in his opposition to Parliament. He gave up his business, in which he had little success, and became tax-collector for the city of Boston, whence he was called by his political opponents, "Samuel the publican." In all the proceedings which issued at last in the declaration of independence Adams was a conspicuous actor. He took part in the numerous town meetings, drafted the protest which was sent up by Boston against the taxation scheme of Grenville (May 1764); and, being chosen next year a member of the general court of Massachusetts, soon became one of the leaders in debate. Upon his entry into the House he was appointed clerk, and had thus much influence in arranging the order of business and in drawing up papers. Attempts were more than once made by the English governor to win him over by the offer of a place, but Adams proved inflexible. His uncompromising resistance to the British Government continued; he was a prominent member of the continental Congress at Philadelphia, and was one of those who signed the Declaration of Independence in 1776. He was a member of the convention which settled the constitution of Massachusetts, and became president of its Senate. From 1789 to 1794 he was lieutenant-governor of the State, and governor from 1794 to 1797, retiring in the latter year partly on account of age, but partly also because the Federalists were then in the ascendant, and he himself was inclined to the Jefferson or Republican party. He died on the 3d Oct. 1803. In an oration on American independence, delivered in Philadelphia, 1st Aug. 1776, Adams characterises the English as "a nation of shopkeepers." The oration was translated into French, and published at Paris; and it is therefore not unlikely that Napoleon's use of this phrase was not original.

ADAMS, Thomas—"*the prose Shakspeare of Puritan theologians*," as Southey named him—has left as few personal memorials behind him as the poet himself. The only facts regarding the commonplaces of his biography are furnished by epistles-dedicatory and epistles to the reader, and title-pages. From these we learn that he was, in 1612, "a preacher of the gospel at Willington," in Bedfordshire, where he is found on to 1614, and whence issued his *Heaven and Earth Reconciled*, *The Devil's Banquet*, and other works; that in 1614–15 he was at Wingrave, in Buckinghamshire, probably as vicar, and whence a number of his works went forth in quick succession; that in 1618 he held the preachership at St Gregory's, under St Paul's Cathedral, and was "observant chaplain" to Sir Henrie Montague, the Lord Chief-Justice of England; that during these years his epistles show him to have been on the most friendly terms with some of the foremost men in state and church; and that he must have died before the Restoration of 1660. His "occasionally" printed sermons, in small quartos, when collected in 1630, placed him beyond all comparison in the van of the preachers of England. Jeremy Taylor does not surpass him in brilliance of fancies, nor Thomas Fuller in wit. His numerous works display great learning, classical and patristic, and are unique in their abundance of stories, anecdotes, aphorisms, and puns. He was a Puritan in the church, in distinction from the Nonconformist Puritans, and is evangelically, not dry-doctrinally, Calvinistic in his theology. His works have been recently collected by Drs Joseph Angus and Thomas Smith (3 vols. 8vo, 1862). (A. B. G.)

ADAMSON, Patrick, a Scottish prelate, Archbishop of St Andrews, was born in the year 1543, in the town of Perth, where he received the rudiments of his education. He afterwards studied philosophy, and took his degree of master of arts at the University of St Andrews. In 1564 he set out for Paris as tutor to the eldest son of Sir William Macgill. In the month of June of the same year, Mary Queen of Scots being delivered of a son, afterwards James VI. of Scotland and I. of England, Mr Adamson wrote a Latin poem, in which he gave the prince the title of king of France and England. This proof of his loyalty involved him in difficulties. The French court was offended, and ordered him to be arrested; and he was confined for six months. He was released only through the intercession of Queen Mary and some of the principal nobility, who interested themselves in his behalf. As soon as he recovered his liberty, he retired with his pupil to Bourges. He was in this city during the massacre at Paris; and the same persecuting spirit prevailing among the Catholics at Bourges as at the metropolis, he lived concealed for seven months in a public-house, the aged master of which, in reward for his charity to heretics, was thrown from the roof, and had his brains dashed out. Whilst Mr Adamson lay thus in his sepulchre, as he called it, he wrote his Latin poetical version of the book of Job, and his tragedy of Herod in the same language. In the year 1573 he returned to Scotland, and, having entered into holy orders, became minister of Paisley. In the year 1575 he was appointed one of the commissioners, by the General Assembly, to settle the jurisdiction and policy of the church; and the following year he was named, with Mr David Lindsay, to report their proceedings to the Earl of Morton, then regent. About this time the earl appointed him one of his chaplains; and, on the death of Archbishop Douglas, promoted him to the archiepiscopal see of St Andrews. This gave rise to a protracted conflict with the Presbyterian party in the Assembly. Soon after his promotion, he published a catechism in Latin verse, dedicated to the king, a work highly approved even by his enemies, who nevertheless still continued to persecute him with great violence. In 1578 he submitted himself to the General Assembly, which procured him peace but for a very little time; for, the year following, fresh accusations were brought against him. A Provincial Synod was held at St Andrews in April 1586; the archbishop was here accused and excommunicated. He appealed to the king and the states, but this availed him little. At the next General Assembly, a paper being produced containing the archbishop's submission, he was absolved from the excommunication. In 1588 fresh accusations were brought against him. The year following he published the Lamentations of the prophet Jeremiah in Latin verse, which he dedicated to the king, complaining of his hard usage. Towards the end of the same year he published a translation of the Apocalypse in Latin verse, and a copy of Latin verses. The king was unmoved by his application, and granted the revenue of his see to the Duke of Lennox, so that the prelate and his family were literally reduced to the want of bread. During the remaining part of his unfortunate life he was supported by charitable contributions, and died in 1592. He had previously made a written recantation of his alleged errors in regard to Episcopacy, though the genuineness of this is doubted by Spottiswoode. (See Cunningham's *Church History of Scotland*, vol. i.) The character of this prelate has been variously represented, according to the sentiments of religion and politics which prevailed. But there is little doubt that he encouraged and supported, under the authority of the king, oppressive and injurious measures. The panegyric of the editor of his works, Mr Wilson, is extravagant and absurd. He says that "he was a miracle of nature, and rather seemed to be the immediate production of God Almighty than born of a woman."

ADANA, a city of Asia Minor, the capital of the province of the same name, on the right bank of the Sihun, about 30 miles from the sea, in N. lat. 37° 1′, E. long. 35° 18′. It is built on the site of the ancient *Antiochia ad Sarum*. Its position, commanding the passage of the mountains to the north of Syria, rendered it important as a military station in the contest between the Egyptians and the Turks in 1832. After the defeat of the Turkish army at Konieh, it was taken possession of by Ibrahim Pacha, and continued to be held by the Egyptians till the treaty of July 1840 restored it to the Porte. In the streets of the town there are numerous beautiful fountains, supplied with water from the river, which is here spanned by a stately bridge of fifteen arches, said to have been erected by Justinian. In winter the climate is mild and healthy, but in summer the heat is so great that the principal inhabitants betake themselves to various cool retreats in the neighbouring mountains. The adjoining plain of Adana is rich and fertile. The chief productions of the province are cotton, corn, sesame, and wool, which are largely exported. The population of the town is 20,000

ADANSON, Michel, a celebrated French naturalist, descended from a Scottish family which had at the Revolution attached itself to the fortunes of the house of Stuart, was born the 7th of April 1727, at Aix, in Provence, where his father was in the service of M. de Vintimille, archbishop of that province. On the translation of this prelate to the archbishopric of Paris, about the year 1730, the elder Adanson repaired thither with his five children, who were all provided for by their father's patron. A small canonry fell to the lot of Michel, the revenue of which defrayed the expenses of his education at the college of Plessis. While there he was distinguished for great quickness of apprehension, strength of memory, and mental ardour; but his genius took no particular bent, until he received a microscope from the celebrated Tuberville Needham, who was struck with admiration of the talents and acquirements he displayed at a public examination. From that time to the last hour of his life he persevered with a zeal almost unexampled in the observation and study of nature. On leaving college, his youthful ardour was well employed in the cabinets of Reaumur and Bernard de Jussieu, as well as in the Jardin des Plantes. Such was his zeal, that he repeated the instructions of the professors to his less apt fellow-students; and before completing his nineteenth year he had actually described (for his own improvement) 4000 species of the three kingdoms of nature. In this way he soon exhausted the rich stores of accumulated knowledge in Europe; and having obtained a small appointment in the colony of Senegal, he resigned his canonry, and embarked on the 20th of December 1748 for Africa. Senegal, from the unhealthiness of its climate, was a *terra incognita* to naturalists; and this determined his choice of that country as a field for exploration. His ardour remained unabated during the five years of his residence in Africa. He collected and described, in greater or less detail, an immense number of animals and plants; collected specimens of every object of commerce; delineated maps of the country; made systematic meteorological and astronomical observations; and prepared grammars and dictionaries of the languages spoken on the banks of the Senegal. On his return to Paris in February 1754 he found himself without resources, but fortunately secured the patronage of M. de Bombarde, who encouraged him in the publication of the scientific results of his travels. In his *Histoire Naturelle du Sénégal* (Paris, 1757) he made use of a small portion of the materials at his disposal; and the work has a special interest from the essay on Shells, printed at the end of it, where Adanson proposed his *universal method*, a system of classification distinct from those of Buffon and Linnæus. He founded his classification of all organised beings on the consideration of each individual organ. As each organ gave birth to new relations, so he established a corresponding number of arbitrary arrangements. Those beings possessing the greatest number of similar organs were referred to one great division, and the relationship was considered more remote in proportion to the dissimilarity of organs. The chief defect of this method consists in presupposing a knowledge of species and their organisation altogether beyond the existing stage of knowledge. It gives, however, distinct ideas of the degree of affinity subsisting between organised beings, independent of all physiological science. Until the appearance of this work, the Testacea had scarcely been made the subject of serious study. Adanson's methodical distribution, founded on not less than twenty of the partial classifications already alluded to, is decidedly superior to that of any of his predecessors. For the first time there was presented in this department of natural history a classification of the animals themselves, and not merely of the shells which contain them. Like every first attempt, however, it had its imperfections, which arose chiefly from ignorance of the anatomical structure of the animals. It was owing to this that he omitted, in his arrangement of the *Mollusca*, all molluscous animals without shells. He abandoned his original plan of publishing his Senegal observations in eight volumes, and applied himself entirely to his *Familles des Plantes*, which he published in 1763. Here he developed the principle of arrangement above mentioned, which, in its adherence to natural botanical relations, was based on the system of Tournefort, and had been anticipated to some extent nearly a century before by Ray. The success of this work was hindered by its innovations in the use of terms, which were ridiculed by the defenders of the popular sexual system of Linnæus; but it did much to open the way for the establishment, by means principally of Jussieu's *Genera Plantarum* (1789), of the natural method of the classification of plants. In 1774 Adanson submitted to the consideration of the Academy of Sciences an immense work, containing what may be called the *universal application of his universal method*; for it extended to all known beings and substances. This work consisted of 27 large volumes of manuscript, employed in displaying the general relations of all these matters, and their distribution; 150 volumes more, occupied with the alphabetical arrangement of 40,000 species; a vocabulary, containing 200,000 words, with their explanations; and a number of detached memoirs, 40,000 figures, and 30,000 specimens of the three kingdoms of nature. The committee to which the inspection of this enormous mass was intrusted strongly recommended Adanson to separate and publish all that was peculiarly his own, leaving out what was merely compilation. He obstinately rejected this advice; and the huge work, at which he continued to labour, was never published. He had been elected a member of the Academy of Sciences in 1759, and he latterly subsisted on a small pension it had conferred on him. Of this he was deprived on the dissolution of the Academy by the Constituent Assembly, and was consequently reduced to such a depth of poverty as to be unable to appear before the French Institute when it invited him to take his place among its members. Government afterwards conferred upon him a pension sufficient to relieve the simple wants of the great naturalist. He died, after months of severe suffering, on the 3d of August 1806, requesting, as the only decoration of his grave, a garland of flowers gathered from the 58 families he had differentiated—"a touching though transitory image," says Cuvier, "of the more durable monument which he has erected to himself in his works." His zeal for science, his unwearied industry, and his talents as a philosophical observer, are conspicuous in all his writings. The serenity of his temper, and the unaffected goodness of his heart, endeared him to the few who knew him intimately. On his return from Africa in 1754, he laid before the French Indian Company a scheme for the settlement of a colony in Senegal, where articles of African produce might be cultivated by free negroes. His propositions were unheeded by his countrymen, and by a misdirected patriotism he refused to present them to the Abolitionists of England. A similar feeling led him to refuse to settle in Austria, Russia, or Spain, on the invitation of the sovereigns of those countries. His most important works are his *Natural History of Senegal* and his *Families of Plants*. He contributed a number of papers to the Memoirs of the Academy of Sciences, on the Ship-worm, the Baobab tree (the largest tree known, to which, in honour of Adanson, Linnæus gave the name *Adansonia digitata*), the origin of the varieties of cultivated plants, gum-producing trees, and the *Oscillatoria Adansonia*, an animal regarded by him as a spontaneously moving plant. Besides these essays, he contributed several valuable articles in natural history to the earlier part of the Supplement to the first *Encyclopédie*; and he is also the reputed author of an essay on the *Electricity of the Tourmaline* (Paris, 1757), which bears the name of the Duke of Noya Caraffa.

ADAPTATION, in *Biology*, is the process by which an organism or species of organisms becomes modified to suit the conditions of its life. Every change in a living organism involves adaptation; for in all cases life consists in a continuous adjustment of internal to external relations. The term is usually restricted, however, to imply such modifications as arise during the life of an individual, when an external change directly generates some change of function and structure. Thus, since the adjustments of organisms arise partly in direct response to causes acting on the individual, and partly in response to causes acting not directly on the individual but on the species as a whole, adaptation is to be regarded as the complement of natural selection. While natural selection acts primarily on the species, adaptation acts only indirectly, through the *inheritance* of modifications directly generated in the individual. All adaptation is limited, since an organ can only vary to a certain limited extent from its congenital structure. Adaptations are sometimes distinguished as *indirect* (for instance, by Haeckel, *Generelle Morphologie*, vol. ii.), which are directly generated in an organism, but only become apparent in its offspring. These form an important class, and seem to suggest that the phenomena of adaptation, thoroughly understood, would go far to explain all the difficult cases of so-called spontaneous variation.

ADDA, the ancient *Addua*, a river of Northern Italy, formed by the union of several small streams, near the town of Bormio, in the Rhætian Alps, flows westward through the Valtellina into the Lake of Como, near its northern extremity. Issuing from the Lecco arm of the lake, it crosses the plain of Lombardy, and finally, after a course of about 150 miles, joins the Po, 8 miles above Cremona. The Adda was formerly the boundary between the territories of Venice and Milan; and on its banks several important battles have been fought, notably that of Lodi, where Napoleon defeated the Austrians in 1796.

ADDER, the common viper (*Vipera communis*). The death adder (*Acanthopis tortor*) of Australia, and the puff adder (*Clotho arietans*) of South Africa, are both highly poisonous.

ADDINGTON, HENRY, VISCOUNT SIDMOUTH, prime minister of England, eldest son of Dr Anthony Addington, was born at Reading on the 30th May 1757. He was educated at Winchester and at Brazenose College, Oxford. In 1784 he was called to the bar at Lincoln's Inn, but being elected about the same time member of Parliament for Devizes, he did not enter on legal practice. He was already on terms of intimacy with the younger Pitt, his father having been Lord Chatham's medical adviser (a circumstance that secured for young Addington the nickname in Parliament of "the Doctor"); and he attached himself, as was natural, to the party of the great commoner.

His fidelity to Pitt received a speedy and ample acknowledgment when he was elected, in May 1789, speaker of the House, in succession to Grenville. For a period of twelve years he discharged the duties of the chair to the general satisfaction of all parties, if with no very marked ability. In 1801, when Pitt resigned on the question of Catholic emancipation, Addington succeeded him in the offices of prime minister and chancellor of the exchequer. He was head of the party that had come to be known as "the king's friends," and took office, it is said, on the urgent personal solicitation of his majesty. The most memorable event of his brief administration was the negotiation of the peace of Amiens, which was concluded on terms that were considered very favourable. It proved, however, but a short-lived truce, the ambition of the First Consul necessitating a renewal of hostilities in May 1803. From this period Pitt assumed a critical attitude towards the ministry, and at length he joined Fox and the opposition in demanding more vigorous measures for the defence of the country. The result was that Addington was compelled to resign, and Pitt was restored to power in May 1804. Addington abstained from all factious opposition, and indeed gave a general support to the Government. In January 1805 he joined the cabinet as president of the council, accepting at the same time the dignity of a peerage, which he had previously declined. He resigned office, however, in July of the same year, in consequence of the share he took in the prosecution of Lord Melville having estranged him from Pitt. After the death of the latter in 1806, he became lord privy seal, and subsequently lord president in the cabinet of Fox and Grenville, but resigned office in 1807. He became a third time lord president under Mr Perceval in 1812, and in June of the same year received the seals of the Home Office under the administration of Lord Liverpool. He held this position for ten eventful years, during which he received his full share of the hostile criticism to which home secretaries are peculiarly exposed. His administration had the merit of being vigorous, fearless, and consistent; but it frequently occasioned great irritation, and all but provoked rebellion. The policy of repression which he pursued in regard to the reform meeting at Manchester in 1819, was not justifiable even according to the limited ideas of liberty prevalent at that time. Lord Sidmouth resigned office in 1822, retaining his seat in the cabinet, however, until 1824. He died on the 15th Feb. 1844, at the advanced age of 87. (*Life and Correspondence of Lord Sidmouth*, by Dean Pellew, 3 vols. 8vo, 1847; *Life of William Pitt* by Lord Stanhope, 4 vols. p. 8vo, 1867.)

ADDISON, Joseph, was the eldest son of Lancelot Addison, Dean of Lichfield, and was born at his father's rectory of Milston in Wiltshire, on the 1st day of May 1672 After having passed through several schools, the last of which was the Charter-house, he went to Oxford when he was about fifteen years old. He was first entered of Queen's College, but after two years was elected a scholar of Magdalen College, having, it is said, been recommended by his skill in Latin versification. He took his master's degree in 1693, and held a fellowship from 1699 till 1711.

The eleven years extending from 1693, or his twenty-first year, to 1704, when he was in his thirty-second, may be set down as the first stage of his life as a man of letters. During this period, embracing no profession, and not as yet entangled in official business, he was a student, an observer, and an author; and though the literary works which he then produced are not those on which his permanent celebrity rests, they gained for him in his own day a high reputation. He had at first intended to become a clergyman; but his talents having attracted the attention of leading statesmen belonging to the Whig party, he was speedily diverted from his earlier views by the countenance which these men bestowed on him. His first patron (to whom he seems to have been introduced by Congreve) was Charles Montague, afterwards Earl of Halifax, who was himself a dabbler in literature, and a protector of literary men; and he became known afterwards to the accomplished and excellent Somers. While both of them were quite able to estimate justly his literary merits, they had regard mainly to the services which they believed him capable of rendering to the nation or the party; and accordingly they encouraged him to regulate his pursuits with a view to public and official employment. For a considerable time, however, he was left to his own resources, which cannot have been otherwise than scanty.

His first literary efforts were poetical. In 1693 a short poem of his, addressed to Dryden, was inserted in the third volume of that veteran writer's *Miscellanies*. The next volume of this collection contained his translation, in tolerable heroic couplets, of "all Virgil's *Fourth Georgic*, except the story of Aristæus." Two and a half books of Ovid were afterwards attempted; and to his years of early manhood belonged also his prose *Essay on Virgil's Georgics*, a performance which hardly deserved, either for its style or for its critical excellence, the compliment paid it by Dryden, in prefixing it to his own translation of the poem. The most ambitious of those poetical assay-pieces is the *Account of the Greatest English Poets*, dated April 1694, and addressed affectionately to Sacheverell, the poet's fellow-collegian, who afterwards became so notorious in the party-quarrels of the time. This piece, spirited both in language and in versification, is chiefly noticeable as showing that ignorance of old English poetry which was then universal. Addison next, in 1695, published one of those compositions, celebrating contemporary events, and lauding contemporary great men, on which, during the half-century that succeeded the Revolution, there was wasted so much of good writing and of fair poetical ability. His piece, not very meritorious even in its own class, was addressed "To the King," and commemorates the campaign which was distinguished by William's taking of Namur. Much better than the poem itself are the introductory verses to Somers, then lord keeper. This production, perhaps intended as a remembrancer to the writer's patrons, did not at once produce any obvious effect: and we are left in considerable uncertainty as to the manner in which about this time Addison contrived to support himself. He corresponded with Tonson the bookseller about projected works, one of these being a Translation of Herodotus. It was probably at some later time that he purposed compiling a Dictionary of the English Language. In 1699 a considerable collection of his Latin verses was published at Oxford, in the *Musæ Anglicanæ*. These appear to have interested some foreign scholars; and several of them show curious symptoms of his characteristic humour.

In the same year, his patrons, either having still no office to spare for him, or desiring him to gain peculiarly high qualifications for diplomatic or other important business, provided for him temporarily by a grant, which, though bestowed on a man of great merit and promise, would not pass unquestioned in the present century. He obtained, on the recommendation of Lord Somers, a pension of £300 a year, designed (as Addison himself afterwards said in a memorial addressed to the crown) to enable him "to travel, and qualify himself to serve His Majesty." In the summer of 1699 he crossed into France, where, chiefly for the purpose of learning the language, he remained till the end of 1700; and after this he spent a year in Italy. In Switzerland, on his way home, he was stopped by receiving notice that he was to be appointed envoy to Prince Eugene, then engaged in the war in Italy. But his Whig friends were already tottering in their places; and, in March 1702, the death of King William at once drove them from power and put an end to the pension. Indeed Addison asserted that he never received but one year's payment of it, and that all the other expenses of his travels were defrayed by himself. He was able, however, to visit a great part of Germany, and did not reach Holland till the spring of 1703. His prospects were now sufficiently gloomy: he entered into treaty, oftener than once, for an engagement as a travelling tutor; and the correspondence in one of these negotiations has been preserved. Tonson had recommended him as the best person to attend in this character the son of the Duke of Somerset, commonly called "The Proud." The duke, a profuse man in matters of pomp, was economical in questions of education. He wished Addison to name the salary he expected; this being declined, he announced, with great dignity, that he would give a hundred guineas a year; Addison accepted the munificent offer, saying, however, that he could not find his account in it otherwise than by relying on his Grace's future patronage; and his Grace immediately intimated that he would look out for some one else. Towards the end of 1703 Addison returned to England.

Works which he composed during his residence on the Continent were the earliest that showed him to have attained maturity of skill and genius. There is good reason for believing that his tragedy of *Cato*, whatever changes it may afterwards have suffered, was in great part written while he lived in France, that is, when he was about twenty-eight years of age. In the winter of 1701, amidst the stoppages and discomforts of a journey across the Mount Cenis, he composed, wholly or partly, his *Letter from Italy*, which is by far the best of his poems, if it is not rather the only one among them that at all justifies his claim to the poetical character. It contains some fine touches of description, and is animated by a noble tone of classical enthusiasm. While in Germany he wrote his *Dialogues on Medals*, which, however, were not published till after his death. These have much liveliness of style, and something of the gay humour which the author was afterwards to exhibit more strongly; but they show little either of antiquarian learning or of critical ingenuity. In tracing out parallels between passages of the Roman poets and figures or scenes which appear in ancient sculptures, Addison opened the easy course of inquiry which was afterwards prosecuted by Spence; and this, with the apparatus of spirited metrical translations from the classics, gave the work a likeness to his account of his travels. This account, entitled *Remarks on Several Parts of Italy*, &c., he sent home for publication before his own return. It wants altogether the interest of personal narrative: the author hardly ever appears. The task in which he chiefly busies himself is that of exhibiting the illustrations which the writings of the Latin poets, and the antiquities and scenery of Italy, mutually give and receive. Many of the landscapes are sketched with great liveliness, and there are not a few strokes of arch humour. The statistical information is very meagre; nor are there many observations on society; and politics are no further meddled with than to show the moderate liberality of the writer's own opinions.

With the year 1704 begins a second era in Addison's life, which extends to the summer of 1710, when his age was thirty-eight. This was the first term of his official career; and, though very barren of literary performance, it not only raised him from indigence, but settled definitively his position as a public man. His correspondence shows that, while on the Continent, he had been admitted to confidential intimacy by diplomatists and men of rank; immediately on his return he was enrolled in the Kitcat Club, and brought thus and otherwise into communication with the gentry of the Whig party. Although all accounts agree in representing him as a shy man, he was at least saved from all risk of making himself disagreeable in society, by his unassuming manners, his extreme caution, and that sedulous desire to oblige, which his satirist Pope exaggerated into a positive fault. His knowledge and ability were esteemed so highly, as to confirm the expectations formerly entertained of his usefulness in public business; and the literary fame he had already acquired soon furnished an occasion for recommending him to public employment. Though the Whigs were out of office, the administration which succeeded them was, in all its earlier changes, of a complexion so mixed and uncertain, that the influence of their leaders was not entirely lost. Not long after Marlborough's great victory at Blenheim, it is said that Godolphin, the lord treasurer, expressed to Lord Halifax a desire to have the great duke's fame extended by a poetical tribute. Halifax seized the opportunity of recommending Addison as the fittest man for the duty; stipulating, we are told, that the service should not be unrewarded, and doubtless satisfying the minister that his protegé possessed other qualifications for office besides dexterity in framing heroic verse. *The Campaign*, the poem thus written to order, was received with extraordinary applause; and it is probably as good as any that ever was prompted by no more worthy inspiration. It has, indeed, neither the fiery spirit which Dryden threw into occasional pieces of the sort, nor the exquisite polish that would have been given by Pope, if he had stooped to make such uses of his genius; but many of the details are pleasing; and in the famous passage of the Angel, as well as in several others, there is even something of force and imagination.

The consideration covenanted for by the poet's friends was faithfully paid. A vacancy occurred by the death of another celebrated man, John Locke; and in November 1704, Addison was appointed one of the five commissioners of appeal in Excise. The duties of the place must have been as light for him as they had been for his predecessor; for he continued to hold it with all the appointments he subsequently received from the same ministry. But there is no reason for believing that he was more careless than other public servants in his time; and the charge of incompetency as a man of business, which has been brought so positively against him, cannot possibly be true as to this first period of his official career. Indeed, the specific allegations refer exclusively to the last years of his life; and, if he had not really shown practical ability in the period now in question, it is not easy to see how he, a man destitute alike of wealth, of social or fashionable liveliness, and of family interest, could have been promoted, for several years, from office to office, as he was, till the fall of the administration to which he was attached. In 1706 he became one of the under-secretaries of state, serving first under Hedges, who belonged to the Tory section of the Government, and afterwards under Lord Sunderland, Marlborough's son-in-law, and a zealous follower of Addison's early patron, Somers. The work of this office, however, like that of the commissionership, must often have admitted of performance by deputy. For in 1707, the Whigs having become stronger, Lord Halifax was sent on a mission to the Elector of Hanover; and, besides taking Vanbrugh the dramatist with him as king-at-arms, he selected Addison as his secretary. In 1708 he entered Parliament, sitting at first for Lostwithiel, but afterwards for Malmesbury, which, being six times elected, he represented from 1710 till his death. Here unquestionably he did fail. What part he may have taken in the details of business we are not informed; but he was always a silent member, unless it be true that he once attempted to speak and sat down in confusion. In 1709 Lord Wharton, the father of the notorious duke, having been named lord-lieutenant of Ireland, Addison became his secretary, receiving also an appointment as keeper of records. This event happened only about a year and a half before the dismissal of the ministry; and the Irish secretary would seem to have transacted the business of his office chiefly in London. But there are letters showing him to have made himself acceptable to some of the best and most distinguished persons in Dublin; and he escaped without having any quarrel with Swift, his acquaintance with whom had begun some time before. In the literary history of Addison those seven years of official service are almost a blank, till we approach their close. He defended the Government in an anonymous pamphlet on *The Present State of the War;* he united compliments to the all-powerful Marlborough with indifferent attempts at lyrical poetry in his opera of *Rosamond;* and, besides furnishing a prologue to Steele's comedy of *The Tender Husband*, he perhaps gave some assistance in the composition of the play. Irish administration, however, allowed it would seem more leisure than might have been expected. During the last few months of his tenure of office Addison contributed largely to the *Tatler*. But his entrance on this new field does nearly coincide with the beginning of a new section in his history.

Even the coalition-ministry of Godolphin was too Whiggish for the taste of Queen Anne; and the Tories, the favourites of the court, gained, both in parliamentary power and in popularity out of doors, by a combination of lucky accidents, dexterous management, and divisions and double-dealing among their adversaries. The real failure of the prosecution of Addison's old friend Sacheverell, completed the ruin of the Whigs; and in August 1710 an entire revolution in the ministry had been completed. The Tory administration which succeeded kept its place till the queen's death in 1714, and Addison was thus left to devote four of the best years of his life, from his thirty-ninth year to his forty-third, to occupations less lucrative than those in which his time had recently been frittered away, but much more conducive to the extension of his own fame, and to the benefit of English literature. Although our information as to his pecuniary affairs is very scanty, we are entitled to believe that he was now independent of literary labour. He speaks, in an extant paper, of having had (but lost) property in the West Indies; and he is understood to have inherited several thousand pounds from a younger brother, who was governor of Madras. In 1711 he purchased, for £10,000, the estate of Bilton, near Rugby,—the place which afterwards became the residence of Mr Apperley, better known by his assumed name of "Nimrod."

During those four years he produced a few political writings. Soon after the fall of the ministry, he contributed five numbers to the *Whig Examiner*, a paper set up in opposition to the Tory periodical of the same name, which was then conducted by the poet Prior, and afterwards became the vehicle of Swift's most vehement invectives against the party he had once belonged to. These are certainly the most ill-natured of Addison's writings, but they are neither lively nor vigorous. There is more spirit in his allegorical pamphlet, the *Trial and Conviction of Count Tariff.*

But from the autumn of 1710 till the end of 1714 his principal employment was the composition of his celebrated Periodical Essays. The honour of inventing the plan of such compositions, as well as that of first carrying the idea into execution, belongs to Richard Steele, who had been a school-fellow of Addison at the Charter-house, continued to be on intimate terms with him afterwards, and attached himself with his characteristic ardour to the same political party. When, in April 1709, Steele published the first number of the *Tatler*, Addison was in Dublin, and knew nothing of the design. He is said to have detected his friend's authorship only by recognising, in one of the early papers, a critical remark which he remembered having himself communicated to Steele. He began to furnish essays in a few weeks, assisted occasionally while he held office, and afterwards wrote oftener than Steele himself. He thus contributed in all, if his literary executor selected his contributions correctly, more than 60 of the 271 essays which the work contains. The *Tatler* exhibited, in more ways than one, symptoms of being an experiment. The projector, imitating the news-sheets in form, thought it prudent to give, in each number, news in addition to the essay; and there was a want, both of unity and of correct finishing, in the putting together of the literary materials. Addison's contributions, in particular, are in many places as lively as anything he ever wrote; and his style, in its more familiar moods at least, had been fully formed before he returned from the Continent. But, as compared with his later pieces, these are only what the painter's loose studies and sketches are to the landscapes which he afterwards constructs out of them. In his invention of incidents and characters, one thought after another is hastily used and hastily dismissed, as if he were putting his own powers to the test, or trying the effect of various kinds of objects on his readers; his most ambitious flights, in the shape of allegories and the like, are stiff and inanimate; and his favourite field of literary criticism is touched so slightly, as to show that he still wanted confidence in the taste and knowledge of the public.

The *Tatler* was dropped at the beginning of 1711, but only to be followed by the *Spectator*, which was begun on the 1st day of March, and appeared every week-day till the 6th day of December 1712. It had then completed the 555 numbers usually collected in its first seven volumes. Addison, now in London and unemployed, co-operated with Steele constantly from the very opening of the series; and the two, contributing almost equally, seem together to have written not very much less than five hundred of the papers. Emboldened by the success of their former adventure, they devoted their whole space to the essays. They relied, with a confidence which the extraordinary popularity of the work fully justified, on their power of exciting the interest of a wide audience by pictures and reflections drawn from a field which embraced the whole compass of ordinary life and ordinary knowledge, no kind of practical themes being positively excluded except such as were political, and all literary topics being held admissible, for which it seemed possible to command attention from persons of average taste and information. A seeming unity was given to the undertaking, and curiosity and interest awakened on behalf of the conductors, by the happy invention of the Spectator's Club, in which Steele is believed to have drawn all the characters. The figure of Sir Roger de Coverley, however, the best even in the opening group, is the only one that was afterwards elaborately depicted; and Addison was the author of all the papers in which his oddities and amiabilities are so admirably delineated. To him, also, the *Spectator* owed a very large share of its highest excellences. His were many, and these the most natural and elegant, if not the most original, of its humorous sketches of human character and social eccentricities, its good-humoured satires on ridiculous features in manners, and on corrupt symptoms in public taste; these topics, however, making up a department in which Steele was fairly on a level with his more famous coadjutor. But Steele had neither learning, nor taste, nor critical acuteness sufficient to qualify him for enriching the series with such literary disquisitions as those which Addison insinuated so often into the lighter matter of his essays, and of which he gave an elaborate specimen in his celebrated and agreeable criticism on *Paradise Lost.* Still further beyond the powers of Steele were those speculations on the theory of literature and of the processes of thought analogous to it, which, in the essays "On the Pleasures of the Imagination," Addison prosecuted, not, indeed, with much of philosophical depth, but with a sagacity and comprehensiveness which we shall undervalue much unless we remember how little of philosophy was to be found in any critical views previously propounded in England. To Addison, further, belong those essays which (most frequently introduced in regular alternation in the papers of Saturday) rise into the region of moral and religious meditation, and tread the elevated ground with a step so graceful as to allure the reader irresistibly to follow; sometimes, as in the "Walk through Westminster Abbey," enlivening solemn thought by gentle sportiveness; sometimes flowing on with an uninterrupted sedateness of didactic eloquence; and sometimes shrouding sacred truths in the veil of ingenious allegory, as in the majestic "Vision of Mirza." While, in a word, the *Spectator*, if Addison had not taken part in it, would probably have been as lively and humorous as it was, and not less popular in its own day, it would have wanted some of its strongest claims on the respect of posterity, by being at once lower in its moral tone, far less abundant in literary knowledge, and much less vigorous and expanded in thinking. In point of style, again, the two friends resemble each other so closely as to be hardly distinguishable, when both are dealing with familiar objects, and writing in a key not rising above that of conversation. But in the higher tones of thought and composition, Addison showed a mastery of language raising him very decisively, not above Steele only, but above all his contemporaries. Indeed, it may safely be said, that no one, in any age of our literature, has united, so strikingly as he did, the colloquial grace and ease which mark the style of an accomplished gentleman, with the power of soaring into a strain of expression nobly and eloquently dignified.

On the cessation of the *Spectator*, Steele set on foot the *Guardian*, which, started in March 1713, came to an end in October, with its 175th number. To this series Addison gave 53 papers, being a very frequent writer during the latter half of its progress. None of his essays here aim so high as the best of those in the *Spectator;* but he often exhibits both his cheerful and well-balanced humour, and his earnest desire to inculcate sound principles of literary judgment. In the last six months of the year 1714, the *Spectator* received its eighth and last volume; for which Steele appears not to have written at all, and Addison to have contributed 24 of the 80 papers. Most of these form, in the unbroken seriousness both of their topics and of their manner, a contrast to the majority of his essays in the earlier volumes; but several of them, both in this vein and in one less lofty, are among the best known, if not the finest, of all his essays. Such are the "Mountain of Miseries;" the antediluvian novel of "Shallum and Hilpa;" the "Reflections by Moonlight on the Divine Perfections."

In April 1713 Addison brought on the stage, very reluctantly, as we are assured, and can easily believe, his tragedy of *Cato*. Its success was dazzling; but this issue was mainly owing to the concern which the politicians took in the exhibition. The Whigs hailed it as a brilliant manifesto in favour of constitutional freedom. The Tories echoed the applause, to show themselves enemies of despotism, and professed to find in Julius Cæsar a parallel to the formidable Marlborough. Even with such extrinsic aids, and the advantage derived from the established fame of the author, *Cato* could never have been esteemed a good dramatic work, unless in an age in which dramatic power and insight were almost extinct. It is poor even in its poetical elements, and is redeemed only by the finely solemn tone of its moral reflections, and the singular refinement and equable smoothness of its diction.

The literary career of Addison might almost be held as closed soon after the death of Queen Anne, which occurred in August 1714, when he had lately completed his 42d year. His own life extended only five years longer; and this closing portion of it offers little that is pleasing or instructive. We see him attaining the summit of his ambition, only to totter for a little and sink into an early grave. We are reminded of his more vigorous days by nothing but a few happy inventions interspersed in political pamphlets, and the gay fancy of a trifling poem on Kneller's portrait of George I.

The lord justices who, previously chosen secretly by the Elector of Hanover, assumed the government on the Queen's demise, were, as a matter of course, the leading Whigs. They appointed Addison to act as their secretary. He next held, for a very short time, his former office under the Irish lord-lieutenant; and, early in 1715, he was made one of the lords of trade. In the course of the same year occurred the first of the only two quarrels with friends, into which the prudent, good-tempered, and modest Addison is said to have ever been betrayed. His adversary on this occasion was Pope, who, only three years before, had received, with an appearance of humble thankfulness, Addison's friendly remarks on his *Essay on Criticism;* but who, though still very young, was already very famous, and beginning to show incessantly his literary jealousies, and his personal and party hatreds. Several little misunderstandings had paved the way for a breach, when, at the same time with the first volume of Pope's *Iliad*, there appeared a translation of the first book of the poem, bearing the name of Thomas Tickell. Tickell, in his preface, disclaimed all rivalry with Pope, and declared that he wished only to bespeak favourable attention for his contemplated version of the *Odyssey*. But the simultaneous publication was awkward; and Tickell, though not so good a versifier as Pope, was a dangerous rival, as being a good Greek scholar. Further, he was Addison's under-secretary and confidential friend; and Addison, cautious though he was, does appear to have said (quite truly) that Tickell's translation was more faithful than the other. Pope's anger could not be restrained. He wrote those famous lines in which he describes Addison under the name of Atticus; and, as if to make reconciliation impossible, he not only circulated these among his friends, but sent a copy to Addison himself. Afterwards, he went so far as to profess a belief that the rival translation was really Addison's own. It is pleasant to observe that, after the insult had been perpetrated, Addison was at the pains, in his *Freeholder*, to express hearty approbation of the *Iliad* of Pope; who, on the contrary, after Addison's death, deliberately printed the striking but malignant lines in the Epistle to Dr Arbuthnot. In 1715 there was acted, with little success, the comedy of *The Drummer, or the Haunted House*, which, though it appeared under the name of Steele, was certainly not his, and was probably written in whole or chiefly by Addison. It contributes very little to his fame. From September 1715 to June 1716, he defended the Hanoverian succession, and the proceedings of the Government in regard to the rebellion, in a paper called the *Freeholder*, which he wrote entirely himself, dropping it with the fifty-fifth number. It is much better tempered, not less spirited, and much more able in thinking, than his *Examiner*. The finical man of taste does indeed show himself to be sometimes weary of discussing constitutional questions; but he aims many enlivening thrusts at weak points of social life and manners; and the character of the Fox hunting Squire, who is introduced as the representative of the Jacobites, is drawn with so much humour and force that we regret not being allowed to see more of him.

In August 1716, when he had completed his 44th year, Addison married the Countess-Dowager of Warwick, a widow of fifteen years' standing. She seems to have forfeited her jointure by the marriage, and to have brought her husband nothing but the occupancy of Holland House at Kensington. We know hardly anything positively in regard to the affair, or as to the origin or duration of his acquaintance with the lady or her family. But the current assertion that the courtship was a long one is very probably erroneous. There are better grounds for believing the assertion, transmitted from Addison's own time, that the marriage was unhappy. The countess is said to have been proud as well as violent, and to have supposed that, in contracting the alliance, she conferred honour instead of receiving it. To the uneasiness caused by domestic discomfort, the most friendly critics of Addison's character have attributed those habits of intemperance, which are said to have grown on him in his later years to such an extent as to have broken his health and accelerated his death. His biographer, Miss Aikin, who disbelieves his alleged want of matrimonial quiet, has called in question, with much ingenuity, the whole story of his sottishness; and it must at any rate be allowed that all the assertions which tend to fix such charges on him in the earlier parts of his life, rest on no evidence that is worthy of credit, and are in themselves highly improbable. Sobriety was not the virtue of the day; and the constant frequenting of coffee-houses, which figures so often in the *Spectator* and elsewhere, and which was really practised among literary men as well as others, cannot have had good effects. Addison, however, really appears to have had no genuine relish for this mode of life; and there are curious notices, especially in Steele's correspondence, of his having lodgings out of town, to which he retired for study and composition. But, whatever the cause may have been, his health was shattered before he took that which was the last, and certainly the most unwise step, in his ascent to political power.

For a considerable time dissensions had existed in the ministry; and these came to a crisis in April 1717, when those who had been the real chiefs passed into the ranks of the opposition. Townshend was dismissed, and Walpole anticipated dismissal by resignation. There was now formed, under the leadership of General Stanhope and Lord Sunderland, an administration which, as resting on court-influence, was nicknamed the "German ministry." Sunderland, Addison's former superior, became one of the two principal secretaries of state; and Addison himself was appointed as the other. His elevation to such a post had been contemplated on the accession of George I., and prevented, we are told, by his own refusal; and it is asserted, on the authority of Pope, that his acceptance now was owing only to the influence of his wife. Even if there is no ground, as there probably is not, for the allegation of Addison's inefficiency in the details of business, his unfitness for such an office in such circumstances was undeniable and glaring. It was impossible that a Government, whose secretary of state could not open his lips in debate, should long face an opposition headed by Robert Walpole. The decay of Addison's health, too, was going on rapidly, being, we may readily conjecture, precipitated by anxiety, if no worse causes were at work. Ill health was the reason assigned for retirement, in the letter of resignation which he laid before the king in March 1718, eleven months after his appointment. He received a pension of £1500 a year.

Not long afterwards the divisions in the Whig party alienated him from his oldest friend. The Peerage Bill, introduced in February 1719, was attacked, on behalf of the opposition, in a weekly paper, which was called the *Plebeian*, and written by Steele. Addison answered it temperately enough in the *Old Whig;* provocation from the *Plebeian* brought forth angry retort from the *Whig;* Steele charged Addison with being so old a Whig as to have forgotten his principles; and Addison sneered at Grub Street, and called his friend "Little Dicky."[1] How Addison felt after this painful quarrel we are not told directly; but the *Old Whig* was excluded from that posthumous collection of his works for which his executor Tickell had received from him authority and directions. In that collection was inserted a treatise on the evidences of the faith, entitled *Of the Christian Religion.* Its theological value is very small; but it is pleasant to regard it as the last effort of one who, amidst all weaknesses, was a man of real goodness as well as of eminent genius.

The disease under which Addison laboured appears to have been asthma. It became more violent after his retirement from office, and was now accompanied by dropsy. His deathbed was placid and resigned, and comforted by those religious hopes which he had so often suggested to others, and the value of which he is said, in an anecdote of doubtful authority, to have now inculcated in a parting interview with his stepson. He died at Holland House on the 17th day of June 1719, six weeks after having completed his 47th year. His body, after lying in state, was interred in the Poets' Corner of Westminster Abbey.

The *Biographia Britannica* gives an elaborate memoir of him; particulars are well collected in the article under his name in the *Biographical Dictionary of the Society for the Diffusion of Useful Knowledge;* and a good many new materials, especially letters, will be found in *The Life of Joseph Addison*, by Lucy Aikin, 1843. (W. S.)

An edition of Addison's works, in four volumes quarto, was published by Baskerville at Birmingham in 1761. Dibdin characterises this as a "glorious performance." A complete edition in six volumes, with notes, by Richard Hurd, appeared in 1811. An American edition (New York, 1854), in six volumes, with notes, by G. W. Greene, contains several pieces collected for the first time. An edition of the *Spectator*, with valuable notes by Henry Morley, appeared in 1871.

ADEL or SOMAULI, an extensive tract of country, stretching eastward from the neighbourhood of Tajurrah to Cape Guardafui, between 43° and 51° E. long., with a breadth not accurately ascertained. Zeila and Berbera are the chief ports on the coast, and have some trade with the opposite shores of Arabia, exporting spices, ivory, gold dust, cattle, and horses, and receiving Indian commodities in exchange. The country, which is marshy and unhealthy, is inhabited by the Somauli, who are governed by an Iman, and are Mahometans.

ADELAAR, CORT SIVARTSEN, surnamed the Eagle, a famous naval commander, was born at Brevig in Norway in 1622. At the age of fifteen he became a cadet in the Dutch fleet under Van Tromp, and after a few years entered the service of the Venetian Republic, which was engaged at the time in a war with Turkey. In 1645 he had risen to the rank of captain; and after sharing in various victories as commander of a squadron, he achieved his most brilliant success at the Dardanelles, on the 13th May 1654, when, with his own vessel alone, he broke through a line of 37 Turkish ships, sank 15 of them, and burned others, causing a loss to the enemy of 5000 men. The following day he entered Tenedos, and compelled the complete surrender of the Turks. On returning to Venice he was crowned with honours, and became admiral-lieutenant in 1660. Numerous tempting offers were made to him by other naval powers, and in 1661 he left Venice to return to the Netherlands. Next year he was induced, by the offer of a title and an enormous salary, to accept the command of the Danish fleet from Frederick III. Under Christian V. he took the command of the combined Danish fleets against Sweden, but died suddenly (5th November

[1] On this point, however, see Macaulay's Essay on *The Life and Writings of Addison.*

1675) at Copenhagen, before the expedition set out. When in the Venetian service, Adelaar was known by the name of Curzio Suffrido Adelborst.

ADELAIDE, the capital of the British colony of South Australia and of the county of the same name, situated on the Torrens, seven miles from Port Adelaide, with which it is connected by railway. The river, which is spanned at this point by several bridges, divides the city into two parts —North Adelaide, the smaller of the two, but containing the chief private houses, occupying a gentle slope on the right bank; and South Adelaide, the commercial centre of the town, lying on a very level plain on the left. The streets of Adelaide are broad, and regularly laid out. Among its public buildings are the Government offices and the governor's house, the post office, the jail, five banks, the railway station, and a theatre. It is the seat of a Protestant Episcopal and also of a Roman Catholic bishop, and contains places of worship belonging to these bodies, as well as to the Presbyterians, the Methodists, the Unitarians, the Baptists, and other denominations. Adelaide possesses a botanical garden, and is surrounded by extensive public grounds, known as the "Park Lands," containing over 1900 acres. It is lighted with gas, and is supplied with water from a reservoir some miles up the Torrens. The corporation consists of a mayor and eight councillors, two from each of the four wards; and there are also two auditors, a town clerk, and other officials. The chief manufactures are woollen, starch, soap, beer, flour, leather, earthenware, and iron goods. There is a good retail trade in European produce; and in the vicinity are iron and copper mines. Adelaide was founded in 1836, and incorporated in 1842. It received its name in honour of Queen Adelaide. Population, 27,208. Lat. 34° 55′ S., long. 138° 38′ E.

Port Adelaide is situated in a low marshy position, on a small inlet of the Gulf of St Vincent. Its harbour is safe and commodious; but a bar at the mouth, where the depth of water varies with the tide from 8 to 16 feet, prevents large vessels from entering. It is a free port, and has good wharfs and warehouse accommodation. In 1867, 364 vessels of 119,654 tons arrived at, and 376 of 125,559 tons departed from, Port Adelaide. The chief imports were drapery, iron goods and machinery, beer, wine, spirits, and paper; and the exports, grain, copper and lead ores, wool, tallow, and other native products. Population, 2482.

ADELSBERG, a market town of Austria, in the province of Carniola, 26 miles SW. of Laibach, and about the same distance E. of Trieste. About a mile from the town is the entrance to the famous stalactite cavern of Adelsberg, the largest and most magnificent in Europe. The cavern is divided into four grottoes, with two lateral ramifications which reach to the distance of about a mile and a half from the entrance. The river Poik enters the cavern 60 feet below its mouth, and is heard murmuring in its recesses. In the Kaiser-Ferdinand grotto, the third of the chain, a great ball is annually held on Whitmonday, when the chamber is brilliantly illuminated. The Franz-Joseph-Elisabeth grotto, the largest of the four, and the farthest from the entrance, is 665 feet in length, 640 feet in breadth, and more than 100 feet high. Besides the imposing proportions of its chambers, the cavern is remarkable for the variegated beauty of its stalactite formations, some resembling transparent drapery, others waterfalls, trees, animals, or human beings, the more grotesque being called by various fanciful appellations. These subterranean wonders were known in the Middle Ages, but the cavern remained undiscovered in modern times until 1816, and it is only in still more recent times that its vast extent has been fully ascertained and explored.

ADELUNG, Friedrich von, a distinguished philologist, nephew of John Christoph Adelung, was born at Stettin on the 25th February 1768. After studying philosophy and jurisprudence at Leipsic he accompanied a family to Italy, where he remained for several years. At Rome he obtained access to the Vatican library, a privilege which he utilised by collating and editing some valuable old German MSS. that had been taken from Heidelberg. On his return he became private secretary to Count Pahlen, whom he accompanied from Riga to St Petersburg. In 1803 he became instructor to the younger brothers of the Czar, the arch-dukes Nicholas and Michael, and gave such satisfaction to the empress-mother that she entrusted him with the care of her private library. In 1824 he became director of the Oriental Institute in connection with the foreign office, and in the year following president of the Academy of Sciences. He died on the 30th January 1843. Adelung's chief literary works were—a *Biography of Baron Herberstein* (St Petersburg, 1817), a *Biography of Baron de Meyerberg* (1827), a treatise on the *Relations between the Sanscrit and the Russian Languages* (1815), and an *Essay on Sanscrit Literature* (1830), a second edition of which appeared in 1837, under the title *Bibliotheca Sanscrita*.

ADELUNG, Johann Christoph, a very eminent German grammarian, philologist, and general scholar, was born at Spantekow, in Pomerania, on the 8th August 1732, and educated at the public schools of Anclam and Closterbergen, and the university of Halle. In the year 1759 he was appointed professor at the gymnasium of Erfurt, but relinquished this situation two years after, and went to reside in a private capacity at Leipsic, where he continued to devote himself for a long period to the cultivation of letters, and particularly to those extensive and laborious philological researches which proved so useful to the language and literature of his native country. In 1787 he received the appointment of principal librarian to the elector of Saxony at Dresden, with the honorary title of Aulic Counsellor. Here he continued to reside during the remainder of his life, discharging with diligence and integrity the duties of his situation, and prosecuting his laborious studies to the last with indefatigable industry and unabated zeal. Possessing a naturally robust constitution, he was able to devote, it has been said, fourteen hours daily to literary toil, down even to the period of his death. He died at Dresden on the 10th of September 1806. The life of a mere scholar is generally destitute of interest; and that of Adelung, which was spent entirely in literary seclusion, presents no variety of incident to the pen of the biographer. Of his private character and habits few memorials have been preserved, but in these few he is represented as the man of an amiable disposition. He was a lover of good cheer, and spared neither pains nor expense in procuring a variety of foreign wines, of which his cellar, which he facetiously denominated his *Bibliotheca Selectissima*, is said to have contained no less than forty different kinds. His manners were easy and affable, and the habitual cheerfulness of his disposition rendered his society most acceptable to a numerous circle of friends. The writings of Adelung are very voluminous, and there is not one of them, perhaps, which does not exhibit some proofs of the genius, industry, and erudition of the author. But although his pen was usefully employed upon a variety of subjects in different departments of literature and science, it is to his philological labours that he is principally indebted for his great reputation; and no man ever devoted himself with more zeal and assiduity, or with greater success, to the improvement of his native language. In a country subdivided into so many distinct sovereign states, possessing no common political centre, and no national institution whose authority could command deference in matters of taste,—in a country whose indigenous literature was but of recent growth, and where the dialect of the people was held in contempt at the several courts, it was no easy task for a single writer to undertake to fix the standard of a language which had branched out into a variety of idioms, depending in a great measure upon principles altogether arbitrary. Adelung effected as much in this respect as could well be accomplished by the persevering labours of an individual. By means of his excellent grammars, dictionary, and various works on German style, he contributed greatly towards rectifying the orthography, refining the idiom, and fixing the standard of his native tongue.[1] Of all the different dialects he gave a decided preference to that of the margraviate of Misnia, in Upper Saxony, and positively rejected everything that was contrary to the phraseology in use among the best society of that province, and in the writings of those authors whom it had produced. In adopting this narrow principle he is generally thought to have been too fastidious. The dialect of Misnia was undoubtedly the richest, as it was the earliest cultivated of any in Germany; but Adelung probably went too far in restraining the language within the limits of this single idiom, to the exclusion of others from which it might have, and really has, acquired additional richness, flexibility, and force. His German dictionary has been generally regarded as superior to the English one of Johnson, and certainly far surpasses it in etymology. Indeed, the patient spirit of investigation which Adelung possessed in so remarkable a degree, together with his intimate knowledge of the ancient history and progressive revolutions of the different dialects on which the modern German is based, peculiarly qualified him for the duties of a lexicographer. No man before Jacob Grimm did so much for the language of Germany. Shortly before his death he issued the very learned work, at which he had been labouring quietly for years, entitled *Mithridates; or, a General History of Languages, with the Lord's Prayer, as a specimen, in nearly five hundred languages and dialects.* The hint of this work appears to have been taken from a publication, with a similar title, published by the celebrated Conrad Gesner in 1555; but the plan of Adelung is much more extensive. Unfortunately he did not live to finish what he had undertaken. The first volume, which contains the Asiatic languages, was published immediately after his death; the other three were issued under the superintendence of Professor Vater (1809–17). Of the very numerous works by Adelung, in addition to translations, the following are of greatest importance:—

Geschichte der Streitigkeiten zwischen Dänemark und den Herzogen von Holstein-Gottorp. Frankf., Leipsic, 1762, 4to.—*Pragmatische Staatsgeschichte Europens von dem Ableben Kaiser Karls des 6ten an.* Vols. i.–ix. Gotha, 1762–9, 4to.—*Mineralogische Belustigungen.* Vols. i.–vi. Copenhagen and Leipsic, 1767–71, 8vo.—*Glossarium Manuale ad Scriptores mediæ et infimæ Latinitatis, ex magnis Glossariis Caroli du Fresne Domini Ducange et Carpentarii, in compendium redactum.* Tomi vi. Halle, 1772–84.—*Versuch eines vollständigen grammatisch-kritischen Wörterbuchs der Hoch Teutschen Mundart.* 1774–86, 5 vols. 4to.—*Ueber die Geschichte der Teutschen Sprache, über Teutsche Mundarten und Teutsche Sprachlehre.* Leipsic, 1781, 8vo.—*Ueber den Ursprung der Sprache und den Bau der Wörter. Ibid.* 1781, 8vo.—*Teutsche Sprachlehre, zum Gebrauch der Schulen in den Königl. Preuss. Landen.* Berlin, 1781. —*Lehrgebäude der Teutschen Sprache.*—*Versuch einer Geschichte der Cultur des Menschlichen Geschlechts.* 1782, 8vo.—*Beyträge zur Bürgerlichen Geschichte, zur Geschichte der Cultur, zur Naturgeschichte, Naturlehre, und dem Feldbaue.* Leipsic, 1783, 8vo.—*Fortsetzung und Ergänzungen zu Christ. Gottl. Jöchers allgemeinem Gelehrten Lexico.* Leipsic, 1784, 2 vols. 4to.—*Ueber den Teutschen Styl.* Berlin, 1785, 3 vols. 8vo.—*Vollstandige Anweisung zur Teutschen Orthographie.* Leipsic, 1786, 2 vols.—*Auszug aus dem Grammatisch-kritischen Wörterbuch der Hohen Teutschen Mundart.* Leipsic, 1793, 1 vol.; 1795, 2 vols. 8vo.—*Mithridates, oder Allgemeine Sprachenkunde.* 3 vols. Berlin, 1806-1812.

[1] The period in which High German as a written language approached nearest perfection is, according to him, the short interval between 1740 and 1760.

ADEN, a town and seaport of Yemen in Arabia, belonging to Britain, situated on a peninsula of the same name, 100 miles east of the strait of Bab-el-Mandeb. The peninsula of Aden consists chiefly of a mass of barren and desolate volcanic rocks, extending five miles from east to west, and three from its northern shore to Ras Sanailah or Cape Aden, its most southerly point, it is connected with the mainland by a neck of flat sandy ground only a few feet high; and its greatest elevation is Jebel Shamshan, 1776 feet above the level of the sea. The town is built on the eastern coast, in what is probably the crater of an extinct volcano, and is surrounded by precipitous rocks that form an admirable natural defence. There are two harbours, an outer, facing the town, protected by the island of Sirah, but now partially choked with mud; and an inner, called Aden Back-bay, or, by the Arabs, Bander Tuwayyi, on the western side of the peninsula, which, at all periods of the year, admits vessels drawing less than 20 feet. On the whole, Aden is a healthy place, although it suffers considerably from the want of good water, and the heat is often very intense. From its admirable commercial and military position, Aden early became the chief entrepôt of the trade between Europe and Asia. It was known to the Romans as *Arabia Felix* and *Attanæ*, and was captured by them, probably in the year 24 B.C. At the commencement of the 16th century it fell into the hands of the Portuguese, who, however, were expelled by the Turks in 1538. In the following century the Turks themselves relinquished their conquests in Yemen, and the Sultan of Senna established a supremacy over Aden, which was maintained until the year 1730, when the Sheik of Lahej, throwing off his allegiance, founded a line of independent sultans. In 1837 a ship under British colours was wrecked near Aden, and the crew and passengers grievously maltreated by the Arabs. An explanation of the outrage being demanded by the Bombay Government, the Sultan undertook to make compensation for the plunder of the vessel, and also agreed to sell his town and port to the English. Captain Haines of the Indian navy was sent to complete these arrangements, but the Sultan's son, who now exercised the powers of government, refused to fulfil the promises that his father had made. A combined naval and military force was thereupon despatched, and the place was captured on the 16th January 1839. It became an outlying portion of the Presidency of Bombay. The withdrawal of the trade between Europe and the East, caused by the discovery of the passage round the Cape of Good Hope, and the misgovernment of the native rulers, had gradually reduced Aden to a state of comparative insignificance; but about the time of its capture by the British, the Red Sea route to India was re-opened, and commerce soon began to flow in its former channel. Aden was made a free port, and was chosen as one of the coaling stations of the Peninsular and Oriental Steamship Company; and at present its most valuable import is coal for the use of the steamers. It has, however, a considerable trade in the products of Arabia—coffee, gum, feathers, dyes, pearls, and ivory; and in return receives silk and cotton goods, grain, and provisions. In 1871–72 the value of its imports was £1,404,169; and of its exports, £885,919. In the same year 535 steamers (643,982 tons), 94 sailing vessels (90,516 tons), and 898 native craft visited the port. The town has been fortified and garrisoned by the British; and its magnificent water-tanks, which had been permitted to fall into ruins, have been partially restored. It contains nearly 30,000 inhabitants, as compared with less than 1000 in 1839. Lat. 12° 46′ N.; long. 45° 10′ E.

ADERNO, a city of Sicily, in the province of Catania, near the foot of Mount Etna, 17 miles N.W. of Catania. It is built on the site of the ancient *Adranum*, portions of the massive walls of which are still visible, and numerous

Roman sepulchres have been found in the vicinity. The modern city has a clean appearance, but the situation is unhealthy. It is remarkable for the number of its convents and nunneries, and has several churches, the chief of which is supported by beautiful pillars of polished lava. On the river Simeto, near the town, there is a series of beautiful cascades. Population, 12,999.

ADERSBACH ROCKS, a remarkable group of isolated columnar rocks in a valley of the Riesengebirge, on the frontier of Bohemia and Prussian Silesia, 9 miles W.N.W. of Braunau. The mountain, for several miles, appears divided into detached masses by perpendicular gaps, varying in depth from 600 to 1200 feet. These masses are from a few feet to several hundred yards in diameter. The part called the labyrinth consists of smaller masses of columnar form, confusedly piled on one another, and rising to heights of from 100 to 200 feet. From their fantastic shapes the rocks have received various fanciful appellations. Some geologists have supposed that their remarkable structure is the result of subterranean commotion; but the generally-received opinion is, that the whole area had once been a tabular mass of sandstone of unequal hardness, and that the soft parts, which formed perpendicular seams, have been worn away by water and atmospheric changes, leaving the harder portions in their natural position. The recesses of this wild region frequently afforded a place of refuge to the distressed inhabitants of the district during the Thirty Years' War.

ADHESION, a term used to denote the physical force in virtue of which one body or substance remains attached to the surface of another with which it has been brought into contact. It is to be distinguished from *cohesion*, which is the mutual attraction that the particles of the same body exert on each other; and it differs from *chemical attraction* or *affinity*, since the properties of the substances it affects remain unchanged after it takes place. It is a force that the molecules of the adhering bodies exert on each other, and must not be confounded with a contact which is due to mere mechanical pressure, such as that which a piece of caoutchouc tubing exerts by its elasticity on a body that distends it. A very familiar instance of adhesion occurs in the wetting of solid bodies. It often, indeed generally, happens that, when a solid and a liquid touch each other, a film of the latter adheres to the former, and neither falls nor can be shaken off. This arises from the adhesion of the liquid to the solid being a stronger force than the cohesion of the particles of the liquid. It is also stronger than the force of gravitation; and the liquid can only be removed by being forcibly rubbed off, or by the process of evaporation. The force of adhesion may be determined by poising a plate of metal on a balance, and afterwards ascertaining what additional force will be required to detach it from the surface of a liquid. But this can only be done in the few cases in which the liquid does not wet the solid (otherwise the measurement would be that of the cohesive force of the liquid), and does not act on it chemically. The phenomena of CAPILLARY ATTRACTION (*q.v.*) depend on adhesion. Sometimes, when a solid and a liquid are brought into contact, the adhesive force overcomes the cohesion of the particles of the solid, so that it loses its solid form, and is dissolved or held in solution. Solid bodies, too, as well as liquids, adhere to solids. Smooth surfaces (of lead, for instance, or of dissimilar metals) will adhere; and if two plates of polished glass be laid together, it will scarcely be possible to separate them without breaking them. If the solids are pressed together, the adhesive force is generally greater; but it has been shown to be dependent to a very slight extent only on the pressure of the atmosphere. To a looser kind of adhesion, whereby one body is prevented from moving smoothly on the surface of another, we give the name of *friction*. The force of this increases with pressure, which may be the effect of gravitation or the result of mechanical appliances. If it be desired that solids should adhere permanently, this is commonly effected by the intervention of other substances—the cements, mortars, and solders—in a liquid or viscid state, which, when they "set" or become solid, adhere closely to the bodies united by means of them. The principle of the processes of plating, gilding, &c., is similar to this. The adhesive force of cements, &c., is sometimes very great. The common experiment of splitting a thin sheet of paper into two is an illustration of it. The paper is pasted carefully between two pieces of cloth, which are pulled asunder after the paste has dried. The adhesion of the paste to the paper and to the cloth is so strong that the paper is thus separated into two sheets, which can easily be detached from the cloth by wetting it. Again, air and other gases adhere to solids. A dry needle, placed carefully on the surface of still water, will float, resting on a cushion of air; and when thermometers are filled with mercury, the liquid has to be boiled in them to expel the air that adheres to the glass.

ADIAPHORISTS (ἀδιάφορος, *indifferent*), a name applied to Melancthon and his supporters in a controversy which arose out of the so-called Leipsic Interim (1548), and raged until 1555. In 1547 Charles V. had drawn up the Augsburg Interim, with a view to provide for the temporary government of the Church until a general council could be called. This gave great dissatisfaction both to the more advanced and to the more moderate reformers; and the object of Melancthon's Leipsic Interim was to reconcile all parties, if possible, by declaring that certain rites and observances of the Roman Catholic Church and the jurisdiction of the Roman Catholic bishops being *adiaphora* (things indifferent), might be lawfully recognised. On the other hand, the Catholics were required to accept the Protestant formula of the doctrine of justification, leaving out the words *sola fide*, which, it was said, might belong to the *adiaphora*. In the controversy that followed, Melancthon's chief opponent was his former colleague, Matth. Flacius, on whose removal from Wittenburg to Magdeburg the latter place became the head-quarters of the extreme Lutherans.

ADIGE (German, *Etsch*), the ancient *Athesis*, a large river of Italy, formed by several rivulets which rise in the Rhætian Alps, and unite near Glarus. After flowing eastward to the neighbourhood of Botzen, it receives the Eisach, and becomes navigable. It then turns to the south, and leaving the Tyrol, enters Lombardy 13 miles S. of Roveredo. After traversing Northern Italy in a course first southerly, but then easterly, it falls into the Adriatic at Porto-Fossone, a few miles N. of the Po. The most considerable towns on its banks are Trent and Roveredo in the Tyrol, and Verona and Legnago in Italy. It is navigable from the heart of the Tyrol to the sea, and has in Lombardy a breadth of 200 yards and a depth of from 10 to 16 feet, but the strength of the current renders its navigation very difficult, and lessens its value as a means of transit between Germany and Northern Italy. The Adige has a course of about 220 miles.

ADIPOCERE (from *adeps*, fat, and *cera*, wax), a substance into which animal matter is sometimes converted, deriving its name from the resemblance it bears to both fat and wax. When the Cemetery of the Innocents at Paris was removed in 1786–87, great masses of this substance were found where the coffins containing the dead bodies had been placed very closely together. At the bottom of the coffin, in these cases, there appeared, loosely enveloped in linen, a shapeless mass, of a dingy white colour, flattened as though it had undergone great pressure. The whole body had been converted into this fatty matter, except the bones, which remained, but were extremely brittle. Fourcroy, who had observed the substance before, and had given it the name of adipocere, read a paper on the subject before the Academy of Sciences in 1789. Chemically, adipocere is found to consist principally of margarate of ammonia. A similar substance, found in peat, is known as *bog-butter*.

ADIPOSE (*adeps*, fat), a term in *Anatomy*, signifying fatty; as adipose tissue, adipose cell, &c.

ADIRONDACK MOUNTAINS, a group of mountains in the N. of the state of New York, North America, lying between Lakes Champlain and Ontario. They rise from an extensive plateau about 2000 feet above the level of the sea, and are chiefly of granite formation. Mount Marcy, the highest summit, has an altitude of 5337 feet, and others of the group are from 4000 to 5000 feet high. The two principal streams which take their rise in this region—the Hudson flowing south, and the Richelieu flowing northwards from Lake Champlain—afford abundant means of conveying from the mountains the valuable timber, chiefly pine, with which they are covered. Extensive deposits of magnetic iron ore, of great value, have been discovered; and a village, called Adirondack, has recently sprung up, where smelting is extensively prosecuted. Emerson, in his poem *Adirondacks*, has familiarised the literary world with the scenery of these mountains.

ADIT (from *adire*, to go to), a passage or door. The doors of porticoes in ancient theatres were called adits. In mines the name is given to a gallery or passage, nearly horizontal, by which water is carried off. Ores also are sometimes removed by the adit. Some works of this kind are of great magnitude. The great Cornish adit at Gwennap, near Falmouth, extends, with its branches, to from 30 to 40 miles in length, and drains a tract of 5500 acres.

ADJUDICATION, in *Scottish Law*, the name of that action by which a creditor attaches the heritable, *i.e.*, the real, estate of his debtor, or his debtor's heir, in order to appropriate it to himself either in payment or security of his debt. The term is also applied to a proceeding of the same nature by which the holder of an heritable right, labouring under any defect in point of form, gets that defect supplied by decree of a court.

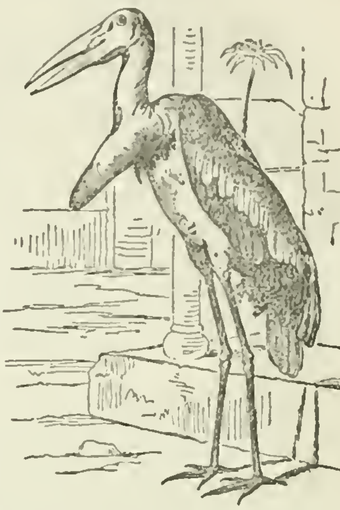
ADJUDICATION in Bankruptcy, in *English Law*, is equivalent to the Scotch award of sequestration.

ADJUSTMENT, in *Commerce*, the settlement of a loss incurred at sea on insured goods. If the policy be what is called an *open one*, and the loss of the goods be total, the insurer must pay for them at the value of prime cost, which includes not only the invoice price of the goods, but all duties paid, the premium of insurance, and all expenses incurred on them when put on board. If the policy be a *valued one*, and a total loss be incurred, then they are settled for at the valuation fixed at the time of the insurance, unless the insurers can prove that the insured had not a real interest in the goods, or that they were overvalued. In case of a partial loss, the value of the goods must be proved. (See Arnould *On Marine Insurance*.)

ADJUTAGE, a short tube or nozzle, inserted in an orifice, by means of which liquids flow from a vessel more freely.

ADJUTANT, a military officer whose duty it is to assist the commanding officer of a regiment or battalion. Every battalion of infantry, regiment of cavalry, and brigade of artillery, has an adjutant, who keeps the regimental books, records, and correspondence; acts as the commanding officer's representative in matters of regimental detail; superintends the drill of recruits; keeps the roster (*i.e.*, register of order of service) for all duties; details the guards, piquets, detachments, &c., that are furnished by the regiment; and is responsible for the receipt of the daily divisional or brigade order from the superior staff-officer, and the preparation and issue of regimental orders. The *Adjutant-General* is the staff-officer specially charged with all matters relating to the discipline and drill of the army.

ADJUTANT, the *Ciconia Argala*, or *Leptoptilos Argala*, a species of stork found in tropical India. It is of great size, sometimes six or even seven feet in height, the body and legs bearing nearly the same proportion as in the common stork. The bill is long and large; while the head, neck, and pouch are bare, or covered only with a few scattered hairs. At the back of its neck there is a second pouch-like appendage, which the bird inflates during flight. The general colour of the body is an ashen gray above and white below. The adjutant is extremely voracious, and, feeding on offal, reptiles, and other vermin, acts the part of a scavenger. It is often to be seen in camps and parade-grounds; hence its name. A similar bird, which, however, has been differentiated as



Ciconia Marabou, occurs in different parts of Africa—*Marabou* being the native Senegal name. The brilliant white marabou feathers of commerce are the under feathers of the tail and wings of both species, but those of the *C. Argala* are the most valuable.

ADJYGURH, a town and fort of India, in the presidency of Bengal, 130 miles S.W. of Allahabad. The fort is situated on a very steep hill, more than 800 feet above the town; and contains the ruins of temples adorned with elaborately-carved sculptures. It was captured by the British in 1809. The town is a neatly-built place, but subject to malaria. Population, 5000.

ADMINISTRATOR, in *English Law*, he to whom the ordinary or judge of the ecclesiastical court, now the Court of Probate, acting in the queen's name, commits the administration of the goods of a person deceased, in default of an executor. The origin of administrators is derived from the civil law. Their establishment in England is owing to a statute made in the 31st year of Edward III. Till then no office of this kind was known besides that of executor; in default of whom, the ordinary had the disposal of goods of persons intestate, &c.

ADMINISTRATOR, in *Scottish Law*, a person legally empowered to act for another whom the law presumes incapable of acting for himself, as a father for a pupil child.

ADMIRAL, a great officer or magistrate, who has the government of a navy and the hearing of all maritime causes.

There can be little doubt of the Asiatic origin of the name given to this officer, which does not appear to have been known in the languages of Europe before the time of the Holy Wars. *Amir*, in Arabic, is a chief or commander of forces; it is the same word as the *ameer* of the peninsula of India (as *ameer al omrah*, the chief of lords or princes), and the *emir* of the Turks or Saracens, who had and still have their *emir* or *ameer'l dureea*, commander of the sea, *amir'l asker dureea*, commander of the naval armament. The incorporation of the article with the noun appears, we believe, for the first time in the Annals of Eutychius, patriarch of Alexandria, in the 10th century, who calls the Caliph Omar *Amirol munumim*, i.e., *Imperator fidelium.* Spelman says, "In regno Saracenorum quatuor prætores statuit, qui *admiralli* vocabantur." The *d* is evidently superfluous, and is omitted by the French, who say *Amiral.* The Spanish write *Almirante;* the Portuguese the same. Milton would seem to have been aware of the origin of the word when he speaks of "the mast of some great ammiral." It is obvious, then, that the supposed derivations of ἁλμυρος from the Greek, *aumer* from the French, and *aen mereal* from the Saxon, are fanciful and unauthorised etymologies.

Anciently there were three or four admirals appointed for the English seas, all of them holding the office *durante beneplacito*, and each of them having particular limits under his charge and government, as admiral of the fleet of ships from the mouth of the Thames, northward, southward, or westward. Besides these, there were admirals of the Cinque Ports. We sometimes find that one person had been admiral of all the fleets—Sir John de Beauchamp, 34 Edw. III., being the first who held the post; but the title of *Admiralis Angliæ* does not occur till the reign of Henry IV., when the king's half-brother, Sir Thomas Beaufort (created Earl of Dorset 5th July 1411), a natural son of John of Gaunt, was made admiral of the fleet for life, and admiral of England, Ireland, and Aquitaine for life. It may be observed that there was a title above that of admiral of England, which was *locum tenens regis super mare*, the king's lieutenant-general of the sea. This title is first mentioned in the reign of Richard II. Before the use of the word *admiral* was known, the title of *custos maris* was made use of.

Of the rank of admiral there are three degrees—admiral, vice-admiral, rear-admiral. Each of these degrees formerly comprised three grades, distinguished by red, white, and blue flags—the red being the highest degree in each rank of admiral, vice-admiral, and rear-admiral.

It may be remarked that for nearly a century there was no admiral of the red squadron. According to a vulgar error, that flag had been taken from us by the Dutch in one of those arduous struggles for naval superiority which that nation was once able to maintain against the naval power of England. But the fact is, the red flag was laid aside on the union of the two crowns of England and Scotland, when the union flag was adopted in its place, and was usually hoisted by the admiral commanding in chief. The red flag was revived on the occasion of the promotion of naval officers in November 1805, in consequence of the memorable victory off Trafalgar. The three degrees of red, white, and blue flag-officers were abolished by order in council on 5th August 1864, and the white ensign was thenceforward adopted as the sole flag for the ships of the royal navy proper. Captains are now promoted to be rear-admirals, rear-admirals to be vice-admirals; and vice-admirals to be admirals *simpliciter*—the numbers of each rank being regulated by orders in council passed on and subsequently to 22d February 1870. (See NAVY.) For biographical information, see Campbell's *Lives of the British Admirals*, 8 vols. 8vo, 1817; O'Byrne's *Naval Biographical Dictionary*, 8vo, 1849.

ADMIRAL OF THE FLEET is a mere honorary distinction, which gives no command, but merely an increase of half-pay, his being £3, 7s. a day, and that of an admiral £2, 2s. The title has been sometimes conferred on the senior admiral on the list of naval officers, and was a short time held by the Duke of Clarence, afterwards William IV. In 1851 were appointed, for the first time, two admirals of the fleet, Sir Thomas Byam Martin, G.C.B., and Sir George Cockburn, G.C.B., the last having been appointed for his long and highly-distinguished services. The number of admirals of the fleet now (1874) authorised to be borne is three. If the admiral of the fleet should happen to serve afloat, he is authorised to carry the union flag at the main-top-gallant-mast head, which was the case when the Duke of Clarence escorted Louis XVIII. across the Channel to take possession of the throne of France.

The comparative rank of flag-officers and officers in the army has been settled as follows by his Majesty's order in council, in the reign of George IV:-

The admiral and commander-in-chief of the fleet has the rank of a field-marshal in the army; admirals with flags at the main take rank with generals of horse and foot; vice-admirals with lieutenant-generals; rear-admirals with major-generals; commodores of the first and second class with broad pendants with brigadier-generals.

On the active list of admirals there were in 1873 three admirals of the fleet, thirteen admirals, fifteen vice-admirals, and twenty-five rear-admirals.

In addition to these, there were on the reserved list forty admirals and thirty-four vice-admirals; on the retired list forty-three admirals, fifty-five vice-admirals, and sixty-two rear-admirals. As to the numbers to be borne permanently on these lists, and the regulations according to which admirals are retired and reserved, under Mr Childers' retirement scheme, see NAVY.

ADMIRAL (THE LORD HIGH) OF ENGLAND, an ancient officer of high rank in the state, who not only is vested with the government of the navy, but who, long before any regular navy existed in England, presided over a sovereign court, with authority to hear and determine all causes relating to the sea, and to take cognizance of all offences committed thereon.

The period about which this officer first makes his appearance in the governments of European nations corroborates the supposition of the office having been adopted in imitation of the Mediterranean powers at the return of the Christian heroes from the Holy Wars. According to Moreri, Florent de Varenne, in the year 1270, was the first admiral known in France; but by the most approved writers of that nation the title was unknown till, in 1284, Enguerand de Coussy was constituted admiral. The first admiral by name that we know of in England was W. de Leybourne, who was appointed to that office by Edward I. in the year 1286, under the title of *Admiral de la mer du Roy d'Angleterre.* Mariana, in his *History of Spain*, says that Don Sancho, having resolved to make war on the barbarians (Moors), prepared a great fleet; and as the Genoese were at that time very powerful by sea, and experienced and dexterous sailors, he sent to Genoa to invite, with great offers, Benito Zacharias into his service; that he accepted those offers, and brought with him twelve ships; that the king named him his admiral (*almirante*), and conferred on him the office for a limited time. This happened in the year 1284. Several Portuguese authors observe that their office of *almirante* was derived from the Genoese, who had it from the Sicilians, and these from the Saracens; and it appears from Souza's *Historia Genealogica da Caza Real*, that in 1322 Micer Manuel Piçagow was invited from Genoa into Portugal, and appointed to the office of *almirante*, with a salary of 3000 pounds (*livras*) a year, and certain lands, &c., on condition that he should furnish on his part twenty men of Genoa, all experienced in sea affairs, and qualified to be *alcaidis* (captains) and *arraises* (masters) of ships: all of which terms, *almirante*, *alcaidi*, and *arrais*, are obviously of Arabic derivatión.

Edward I., who began his reign in 1272, went to the Holy Land, and visited Sicily on his return. He must therefore have had an opportunity of informing himself concerning the military and naval science of the various countries bordering on the Mediterranean—an opportunity which so able and warlike a prince would not neglect, but whether the title and office of admiral existed in England before his time, as some are inclined to think, or whether W. de Leybourne was first created to that office in 1286, as before mentioned, we believe there is no authentic record to enable us to decide. Supposing him, however, to be the first, Edward may either have adopted the office and title from the Genoese, or the Sicilians, or the Spaniards, or the French; or even had it directly from the Saracens, against whom he had fought, and with whom he had afterwards much amicable intercourse. It would seem, howe-that the office was in Edward's time to some extent honorary; for that monarch, in 1307, orders the lord mayor of London, at his peril and without delay, to provide a good ship, well equipped, to carry his pavilions and tents; and in the same year another order is addressed to the *Viccomes Kantiæ* to provide for immediate passage across the seas *tot et tales pontes et claias*, as the constable of Dover Castle should demand, without one word being mentioned of the admiral. (Rymer, vol. iii. p. 32.) It is to be observed, however, that at this time the royal fleets were made up of royal and private ships, and that the admiral would not be charged with the transport of such things as those mentioned unless the fleet was intended to co-operate with the land forces.

From the 34th Edward II. we have a regular and uninterrupted succession of admirals. In that year Edward Charles was appointed admiral of the north, from the mouth of the river Thames northward, and Gervase Allard admiral of the west, from the mouth of the Thames westward; and these two admirals of the north and the west were continued down to the 34th Edward III., when Sir John de Beauchamp, lord warden of the Cinque Ports, constable of the Tower of London and of the Castle of Dover, was constituted *High Admiral of England*. Nine years afterwards the office was again divided into north and west, and so continued until the 10th Richard II., when Richard, son of Alain, Earl of Arundel, was appointed Admiral of England. Two years after this it was again divided as before; and in the 15th year of the same reign, Edward, Earl of Rutland and Cork, afterwards Duke of Albemarle, was constituted *High Admiral of the North and West;* and after him the Marquis of Dorset and Earl of Somerset, son of John of Gaunt, Duke of Lancaster. Percy, Earl of Winchester next succeeded to the same title, which once more was dropped in the 2d of Henry IV., and divided as before. Sir Thomas Beaufort was twice appointed by Henry IV. admiral of England; and on the accession of Henry V. he was reappointed by letters patent dated 3d June 1413. In the 14th Henry VI., John Holland, Duke of Exeter, was created admiral of England, Ireland, and Aquitaine, for life; and in the third year of Edward VI., John Dudley, Earl of Warwick, was constituted high admiral of England, Ireland, Wales, Calais, Boulogne, the marches of the same, Normandy, Gascony, and Aquitaine, also captain-general of the navy and seas of the king, &c. In the 27th Elizabeth, Charles, Lord Howard, had all the aforesaid titles, with the addition of captain-general of the navy and seas of the said kingdoms.

On the 20th November 1632 the office of high admiral was for the first time put in commission, all the great officers of state being the commissioners. During the Commonwealth a committee of Parliament managed the affairs of the Admiralty. At the Restoration, in 1660, the Duke of York was constituted *Lord High Admiral of England.* The commission was revoked in 1673, and King Charles II. held the Admiralty in his own hands, and managed it by the great officers of his privy council till 1684, when the Duke of York was re-instated. Charles took this occasion of reserving for his own use all the droits and perquisites claimed by the lord high admiral.

Annexed is a list of lord high admirals and first lords of the Admiralty from the time of Charles the Second to the year 1874:—

FIRST LORDS OF THE ADMIRALTY FROM 1660.

	Date of Appointment.
James Duke of York,*	June 6, 1660.
King Charles the Second,	June 14, 1673.
Prince Rupert,	July 9, 1673.
Sir Henry Capell, Kt.,	May 14, 1679.
Daniel Finch, Esq.,	Feb. 14, 1680.
Daniel Lord Finch,	Jan. 20, 1681.
Daniel Earl of Nottingham,	April 17, 1684.
James Duke of York (and as James II.),†	May 17, 1684.
Arthur Herbert, Esq.,	March 8, 1689.
Thomas Earl of Pembroke and Montgomery,	Jan. 20, 1690.
Charles Lord Cornwallis,	March 10, 1692.
Anthony Viscount Falkland,	April 15, 1693.
Edward Russell, Esq.,	May 2, 1694.
Edward Earl of Orford,	June 5, 1697.
John Earl of Bridgewater,	May 31, 1699.
Thomas Earl of Pembroke and Montgomery,	April 4, 1701.
George Prince of Denmark,‡	May 20, 1702.
Thomas Earl of Pembroke and Montgomery,‡	Nov. 29, 1708.
Edward Earl of Orford,	Nov. 8, 1709.
Sir John Leake, Kt.,	Oct. 4, 1710.
Thomas Earl of Strafford,	Sept. 30, 1712.
Edward Earl of Orford,	Oct. 14, 1714.
James Earl of Berkeley,	March 19, 1717.
Lord Viscount Torrington,	Aug. 2, 1727.
Sir Charles Wager, Kt.,	June 21, 1733.
Daniel Earl of Winchelsea and Nottingham,	March 19, 1741.
John Duke of Bedford,	Dec. 27, 1744.
John Earl of Sandwich,	Feb. 16, 1748.
George Lord Anson,	June 22, 1751.
Richard Earl Temple,	Nov. 17, 1756.
Daniel Earl of Winchelsea and Nottingham,	April 6, 1757.
George Lord Anson,	July 2, 1757.
George Dank Earl of Halifax	June 17, 1762.
George Grenville, Esq.,	Oct. 13, 1762.
John Earl of Sandwich,	April 20, 1763.
John Earl of Egmont,	Sept. 16, 1763.
Sir Charles Saunders, K.B.,	Sept. 15, 1766.
Sir Edward Hawke, K.B.,	Dec. 11, 1766.
John Earl of Sandwich,	Jan. 12, 1771.
Hon. Augustus Keppel,	April 1, 1782.
Augustus Viscount Keppel,	July 18, 1782.

Right Hon. George Joachim Goschen,	March 13, 1871.

* Lord High Admiral of England.
† Lord High Admiral and Lord General.
‡ Lord High Admirals of Great Britain.

Prince George of Denmark, when lord high admiral, having surrendered, by a formal instrument, all the rights, profits, perquisites, and advantages whatsoever, appertaining to the office, for the benefit and use of the public, with the exception of the sum of £2500 a-year, to be disposed of in such manner and for such particular uses as her Majesty, under her sign manual, should direct; and the salary of the lord high admiral, which had hitherto been no more than 300 marks, was now fixed, by warrant under privy seal, at £7000 a-year. This sum, by 1st George II., was divided equally among seven commissioners, an arrangement which continued from that time, except that the pay of the commissioner who stood first in the patent was made up from other funds to £3000 a-year, and in the year 1806 was further increased to £5000 a-year. Since the surrender above mentioned, all the *droits of admiralty*, as they are called, with all the fees, emoluments, and perquisites whatsoever, have been taken from the admiral and applied to public purposes.

These droits and perquisites are by no means inconsiderable. As enumerated in the patent, they consist of flotsam, jetsam, ligan, treasure, deodands, derelicts, found within the admiral's jurisdiction; all goods picked up at sea; all fines, forfeitures, ransoms, recognisances, and pecuniary punishments; all sturgeons, whales, porpoises, dolphins, and grampuses and all such large fishes; all ships and goods of the enemy coming into any creek, road, or port, by stress of weather, mistake, or ignorance of the war; all ships seized at sea, salvage, &c., together with his shares of prizes; which shares were afterwards called *tenths*, in imitation probably of the French, who gave their admiral, for supporting the dignity of his office, *son droit de dixième*. All prizes are now wholly given up by the crown to the captors, and such share of the *droits* as from circumstances may be thought proper The lord high admiral also claimed and enjoyed as his due the cast ships; and the subordinate officers of the navy, as their perquisites, all other decayed and unserviceable stores.

Though by Act of 2 William and Mary, stat. 2, c. 2 (extended by the 1 Geo. IV. c. 90, and 7 and 8 Geo. IV. c. 65), the lords commissioners of the admiralty are vested with all and singular authorities, jurisdictions, and powers which have been and are vested, settled, and placed in the lord high admiral of England for the time being, to all intents and purposes as if the said commissioners were lord high admiral of England, yet there is this remarkable difference in the two patents by which they are constituted, that the patent of the lord high admiral mentions very little of the military part of his office, but chiefly details his judicial duties as a magistrate; whilst, on the contrary, the patent to the lords commissioners of the admiralty is very particular in directing them to govern the affairs of the navy, and is almost wholly silent as to their judicial powers.

These powers, as set forth in the patent to the Earl of Pembroke in 1701, are, the power to act by deputy; to take cognisance of all causes, civil and maritime, within his jurisdiction; to arrest goods and persons; to preserve public streams, ports, rivers, fresh waters, and creeks whatsoever within his jurisdiction, as well for the preservation of the ships as of the fishes; to reform too strait nets and unlawful engines, and punish offenders; to arrest ships, mariners, pilots, masters, gunners, bombardiers, and any other persons whatsoever able and fit for the service of the ships, as often as occasion shall require, and wheresoever they shall be met with; to appoint vice-admirals, judges, and other officers, *durante beneplacito;* to remove, suspend, or expel them, and put others in their places, as he shall see occasion; to take cognisance of civil and maritime laws, and of death, murder, and mayhem.

It was by no means necessary that the lord high admiral should be a professional man. Henry VIII. made his natural son, the Duke of Richmond, lord high admiral of England when he was but six years old. When the high admiral, however, went to sea in person, he had usually a commission under the great seal appointing him admiral and captain-general of the fleet, sometimes with powers to confer knighthood, and generally to punish with life and limb. Such a commission was granted by Henry VIII. to Sir Edward Howard, who executed indenture with the king to furnish 3000 men, 18 captains, 1750 soldiers, 1232 mariners and gunners; his own pay to be 10s. and that of a captain 1s. 6d. a-day. The rest had 5s. per mensem as wages, and 5s. for victuals each man, together with certain dead shares.

It appears, from Mr Pepys' *Naval Collections*, that the lord high admiral did anciently wear, on solemn occasions, a gold whistle, set with precious stones, hanging at the end of a gold chain.

The salary of the first lord commissioner is £4500 a-year, and of each of the naval lords £1500, in addition to the half-pay of their rank. The civil lord gets £1000, and the parliamentary secretary £2000 a-year.

The opening paragraph of the *Black Book of the Admiralty* has the following noteworthy instruction as regards the deputies and officers to be chosen by the lord high admiral:—

"When one is made admirall, hee must first ordaine and substitute for his lieutenants, deputies, and other officers under him, some of the most loyall, wise, and discreete persons in the maritime law and auncient customes of the seas which hee can any where find, to the end that by the helpe of God and their good and just government, the office may be executed to the honour and good of the realme."

Had this precept been always acted on, there would probably have been less occasion than has presented itself for the many reorganisations which the administration of the lord high admiral's administrative office has undergone. As it has been, the necessity for periodical changes has been urgent and unavoidable. From the time of which Macaulay wrote, that the king (James II.) was the only honest man in his dockyards, down to the present date, the need has been incumbent on successive first lords and high admirals to lay the axe to the root of a tree which, in some shape or other, has not ceased to bring forth evil fruit. The soil favoured corruption, and no efficient means were employed to prevent its growth. A root and branch reformation was urgently needed, though it was not applied except in particular instances. Till the great French war of 1793–1815 led to the formation of a navy board of commissioners to superintend the work and management of the dockyards; of a victualling board, to see to the provisioning of the fleet; and of sick and hurt commissioners, to look after the sick and wounded —the administrative departments of the navy were left to nominees of the lord high admiral or first lord, the said nominees deriving "no small advantage" from the arrangement. Under the departmental boards things certainly improved from what they were in the time of Charles II.; but they fell far short of what was desirable, and, by the vagueness of their administrative principle, opened a door for irresponsible wrong-doing, which in the end made them exceedingly bad instruments of government. These boards continued till 1832, when Sir James Graham, then first lord of the admiralty, introduced sweeping changes. He abolished the several intangible boards which administered under the shelter of the board of admiralty, and appointed in their stead five principal officers of the navy, who were afterwards included in the admiralty patent. These officers were—a surveyor or architect and constructor of the navy; a storekeeper-general, charged with oversight and purchase of the material for dockyards and ships; an accountant-general, charged with the duty of seeing that all wages and cash paid were duly brought to account; a comptroller of victualling and transport services, charged with the maintenance of the victualling establishments of the navy, and of sufficient supplies of provisions and clothing for the fleet, and with the oversight of the transport arrangements for men and stores; and a physician of the navy, afterwards called medical director-general, charged with the oversight of all hospitals and of all sanitary arrangements of the navy. Each of these officers administered the department entrusted to him in every particular, not only in respect of stock, but of replenishment and account of stock. A lord of the admiralty was told off to supervise the permanent head and to represent his department at the board. These alterations were in many respects very beneficial. Altered circumstances required some modification of the original scheme of duties; and the addition of three principal officers—the director of works, the director of transports (who, after the Crimean war, relieved the comptroller of victualling of his transport duties), and the registrar of contracts. In 1860 the office of surveyor of the navy was abolished, and that of controller of the navy, with larger powers over dockyard management, was revived. In 1869, Mr Childers, first lord of the admiralty, made changes which tended to subordinate the members of the board of admiralty more effectually to the first lord, constituting him in effect minister of marine; and to render departmental officers at once more individually responsible and more intimate with the controlling members of the board. ' He increased the power and functions of the controller of the navy, giving him a seat at the board, and charging him with the stock-keeping attributes of the storekeeper-general, whose purchasing functions were transferred to a new officer—the superintendent of contracts, the head of the contract and purchase department, and his accounting functions to the accountant-general. The office of storekeeper-general was abolished. The office of comptroller of victualling was also abolished—the storekeeping functions being transferred to a new officer, the superintendent of victualling—the purchasing function to the head of the purchase department, the accounts to the accountant-general. The other officers remained; but in the case of each this modification of business ensued, viz., that all stores whatever required by any of them were to be obtained through the agency of one supply or purchase department; that all accounts whatever were to be rendered to the accountant-general. The departmental officers of the admiralty at the present time (1874) are—the controller of the navy, without a seat at the board (who has on his staff a chief naval architect, a chief engineer, a surveyor of dockyards, a superintendent of naval stores, and a director of ordnance)—the director-general of the medical department, the director of works, the director of transports, the hydrographer, the superintendent of contracts, the superintendent of victualling. The department of the two permanent secretaries of the admiralty (one a naval officer, the other a civilian) undertakes the conduct of all business relating to the *personnel* of the navy and the ordering of the fleets.

To control the departmental officers, and to advise the responsible first lord, there are the following members of the board of admiralty, viz., the parliamentary or financial secretary, who has oversight of all business relating to finance, estimates, expenditure, and accounts, and who is the *alter ego* of the first lord in Parliament; the first naval lord, who, assisted by two other naval "lords," takes oversight of the *personnel* and of all executive functions of the fleet; and a civilian lord, who assists the financial secretary, and has particular oversight also of naval civil establishments and of the works department.

A list of secretaries of the admiralty from 1684 to the present time is given below:—

FIRST SECRETARIES TO THE ADMIRALTY.

	From	To
Samuel Pepys, Esq., . . .	May 1684	Feb. 1689.
Phineas Bowles, Esq., . . .	March 1689	Dec. 1689.
James Sotherne, Esq., . . .	Dec. 25, 1689	Sept. 24, 1694.
Josiah Barchett, Esq., . . .	Sept. 25, 1694	Oct. 10, 1741.
Thomas Corbet, Esq., . . .	Oct. 10, 1741	...
John Cleveland, Esq., . . .	...	...
Philip Stevens, Esq. (then one of the Board), ...	June 18, 1763	March 3, 1795.
Evan Nepean, Esq., ...	March 3, 1795	Jan. 21, 1804.
William Marsden, Esq., . .	Jan. 21, 1804	June 24, 1807.
Hon. W. W. Pole, ...	June 24, 1807	Oct. 8, 1809.
John Wilson Croker, Esq., .	Oct. 9, 1809	Nov. 29, 1830.
Captain the Hon. George Elliott,	Nov. 29, 1830	Dec. 24, 1834.
Right Hon. George R. Dawson,	Dec. 24, 1834	April 27, 1835.
Charles Wood, Esq., M.P., .	April 27, 1835	Oct. 4, 1839.
R. More O'Ferrall, Esq., . .	Oct. 4, 1839	June 9, 1841.
John Parker, Esq., M.P., . .	June 9, 1841	Sept. 10, 1841.
Hon. Sidney Herbert, . . .	Sept. 10, 1841	Feb. 1845.
Right Hon. H. T. L. Corry, M.P.,	Feb. 1845	July 13, 1846.
Henry G. Ward, Esq., M.P., .	July 13, 1846	May 1, 1849.
John Parker, Esq., M.P., . .	May 21, 1849	March 3, 1852.
Augustus Stafford, Esq., . .	March 3, 1852	Jan. 6, 1853.
Bernal Osborne, Esq., M.P., .	Jan. 6, 1853	March 8, 1858.
Right Hon. H. T. L. Corry, M.P.,	March 9, 1858	June 30, 1859.
Rear-Admiral Lord C. G. Paget, C.B., M.P., ...	June 30, 1859	April 29, 1866.
Hon. Thomas G. Baring, M.P.,	April 30, 1866	July 15, 1866.
Lord Henry G. Lennox, M.P.,	July 16, 1866	Dec. 17, 1868.
W. E. Baxter, Esq., M.P., .	Dec. 18, 1868	March 16, 1871.
Geo. J. Shaw Lefevre, Esq., M.P.,	March 17, 1871	...

As regards the navies of foreign countries, their government is in the hands of ministers or departments variously constituted. The Russian Admiralty is a highly-organised bureau, divided into departments after the English manner, and under the supreme control of a high admiral, usually a Grand Duke of the Imperial House. The German Admiralty was, till 1872, a branch of the War Office, though governed by a vice-admiral under a naval prince of the reigning family. In 1872 it was severed from the War Office, though remaining an appanage thereof, and a general of the army was placed at its head. The French minister of marine, assisted by a permanent staff, controls the navy of France on a highly centralised system of administration; but the departments are well organised, and work well. The Italian fleet is governed on principles analogous to the French, but with a large admixture of the English representative element. The American navy is governed by a secretary of the navy, a cabinet minister, to whom the departmental heads are responsible, and under whose orders they work. (F. W. R.)

ADMIRALTY, HIGH COURT OF. This is a court of law, in which the authority of the lord high admiral is exercised in his *judicial* capacity. Very little has been left on record of the ancient prerogative of the admirals of England. For some time after the first institution of the office they judged all matters relating to merchants and mariners, which happened on the main sea, in a summary way, according to the laws of Oleron (so called because promulgated by Richard I. at that place). These laws, which were little more than a transcript of the Rhodian laws, became the universally-received customs of the western part of the world. "All the seafaring nations," says Sir Leoline Jenkins, "soon after their promulgation, received and entertained these laws from the English, by way of deference to the sovereignty of our kings in the British ocean, and to the judgment of our countrymen in sea affairs."

In the patents granted to the early admirals between the latter years of the reign of Henry III. and the close of that of Edward III., no mention is made of marine perquisites or of civil power, nor does it appear that the admirals enjoyed either; but after the death of the latter, new and extraordinary powers were granted to them, and it would appear that they usurped others. The preamble to the 13 Richard II. stat. 1, c. 5, sets forth that "a great and common clamour and complaint hath been oftentimes made before this time, and yet is, for that the admirals and their deputies hold their sessions within divers places of this realm, as well within the franchise as without, accroaching to them greater authority than belongeth to their office, in prejudice of our lord the king and the common law of the realm, and in diminishing of divers franchises, and in destruction and impoverishing of the common people;" and the statute therefore directs that the admirals and their deputies shall not meddle from henceforth of any thing done within the realm, but only of a thing done upon the sea. Two years afterwards (15 Rich. II. c. 3), in consequence, as stated in the preamble of the statute, "of the great and grievous complaint of all the commons," it was ordained that the admiral's court should have no cognisance of any contracts, pleas, or quarrels, or of any thing done or arising within the bodies of counties, whether by land or by water, nor of wreck of the sea; but that the admiral should have cognisance of the death of a man, and of mayhem done in great ships being and hovering in the main stream of great rivers, yet only beneath the bridges of the same rivers nigh to the sea. He may also arrest ships in the great flotes for the great voyages of the king and of the realm, saving always to the king all manner of forfeitures and profits thereof coming, and have jurisdiction over the said flotes, but during the said voyages only. But if the admiral or his lieutenant exceed that jurisdiction, then, by 2 Henry IV. c. 11, the statute and the common law may be holden against them; and if a man pursues wrongfully in the admiralty court, his adversary may recover double damages at common law.

and the pursuant, if attainted, shall incur the penalty of £10 to the king.

The place which, according to Spelman, is absolutely subject to the jurisdiction of the admiral is the sea; which, however, comprehends public rivers, fresh waters, creeks, and all places whatsoever, within the ebbing and flowing of the sea, at the highest water, the shores or banks adjoining, from all the first bridges to the seaward; and in these, he observes, the admiralty hath full jurisdiction in all causes, criminal and civil, except treasons and the right of wreck. Lord Coke observes (5 Rep. 107), that between the high-water mark and the low-water mark the admiral hath jurisdiction *super aquam, ad plenitudinem maris*, and as long as it flows, though the land be *infra corpus comitatus* at the reflow, so as of one place there is *divisum imperium* interchangeably.

But though the statute restraineth the lord high admiral that he shall not hold plea of a thing rising in the body of a county, he is not restrained from making execution upon the land, but is empowered to take either body or goods upon the land; otherwise his jurisdiction would often prove a dead letter. He also can and does hold his court in the body of a county. So, likewise, the civil power may apprehend and try persons who may have been guilty of offences cognisable at common law, though committed in the fleet, in any port or harbour of Great Britain, or at sea, provided such persons have not already been tried for such offences either by court-martial or in the admiralty court; and in all ports, harbours, creeks, &c., lying in any county, the high admiral and the sheriff, or coroner, as the case may be, have concurrent jurisdiction.

By the 6 and 7 Will. IV. c. 53 the admiralty jurisdiction is extended to Prince of Wales' Island, Singapore, and Malacca; and under the 3 and 4 Vict. c. 65, the court has jurisdiction in the following cases:—

Whenever a vessel is arrested by process issuing from the said court, or the proceeds of any vessel are brought into the registry, to take cognisance of all claims in respect of any mortgage of such vessel.

To decide all questions as to the title to, or ownership of, such vessel, or the proceeds thereof remaining in the registry, arising in any cause of possession, salvage, damage, wages, or bottomry, instituted in the said court.

To decide all claims and demands whatsoever in the nature of salvage, or in the nature of towage, or for necessaries supplied to any foreign vessel, and enforce the payment of the same, whether such vessel may have been in the body of the county or upon the high seas at the time when the service was rendered, or damage received, or necessaries furnished, in respect of which claim is made.

To decide all matters and questions concerning booty of war on shore, or the distribution thereof, which it shall please her Majesty, by the advice of the privy council, to refer to the judgment of the said court, who shall proceed therein as in cases of prize of war.

And under § 40 of the 9 and 10 Vict. c. 99, to decide on all claims and demands whatsoever in the nature of salvage for services performed, whether on sea or land.

The high court of Admiralty has jurisdiction upon the high seas all over the world. It has an instance jurisdiction which is civil, and a prize jurisdiction in time of war. The latter jurisdiction does not extend to the admiralty courts of Ireland or Scotland, which never had prize commissions sent to them. It is of the highest importance in war time, when questions of seizure or detention of neutral ships arise, to have but one court of which to inquire concerning all causes, so as to expedite the action of the Foreign Office in dealing with representations from neutral powers. The causes which arise in time of peace are causes of collisions, of seamen's wages, bottomry, wearing unlawful colours, salvage, and causes of possession, where one part owner or minor claims to have security from those other owners who are going to send the ship on a foreign voyage that the ship shall return again. Causes under the Slave Act treaties are also cognisable here. The evidence is all documentary. In 1803 there were 1125 prize cases before the court; in 1804, 1144; in 1806, 2286; in 1807, 2789; and so on, above 1000 causes each year, down to the year 1811.

The criminal jurisdiction, which formerly comprehended all crimes whatever committed at sea, from larceny to homicide, which were triable at common law at the assizes if committed on shore, was much modified upon the report of the select committee on the high court of admiralty in 1833. Such offences are now triable at common law on surrender to the jurisdiction; but the judge of the admiralty court may still sit with other commissioners of oyer and terminer. He has no longer any independent criminal jurisdiction.

The instance jurisdiction is permanent; the prize jurisdiction is by virtue of a special commission, *pro re natâ*. Its issue is one of the first acts done on the outbreak of war. Appeals formerly lay from the civil decisions to the high court of delegates or specially-appointed commissioners; from the prize decisions to the prize commissioners. By the Acts 2 and 3 Will. IV. c. 92, and 3 and 4 Will. IV. c. 41, all appeals from admiralty court decisions of any kind lie to the sovereign, who is authorised to refer them to the judicial committee of the privy council.

The lord high admiral was assisted in his *judicial* functions by the following principal officers:—1. The vice-admiral; 2. The judge; 3. The registrar; 4. The advocate-general; 5. The counsel and judge-advocate; 6. The solicitor; 7. The procurator; 8. The marshal,—which officers are continued.

1. *The Vice-Admiral.* This officer is the admiral's deputy or lieutenant mentioned in the statutes of 13th and 15th Richard II., and was the person, most probably, who presided in the court. At present the office of vice-admiral of England is a perfect sinecure, generally conferred on some naval officer of high rank and distinguished character in the service. The salary of £434, 1s. 9d. per annum, attached to it in addition to half-pay, was abolished by order in council, 22d February 1870. The salary and office of rear-admiral of England were abolished by the same order in council. The salary was £342, 9s. per annum. Each county of England has its vice-admiral, which is little more than an honorary distinction, though the patent gives to the holder all the powers vested in the admiral himself. Similar powers were also granted to the judges of the admiralty county courts; but this was found so inconvenient and prejudicial to those who had suits to commence or defend before them, that the Duke of York, when lord high admiral, in 1663 caused instructions to be drawn up in order to assign to each his province, whereby the whole judicial power remained with the judge, and the upholding of the rights of the admiral, and levying and receiving the perquisites, &c., appertained to the vice-admiral.

Each of the four provinces of Ireland has its vice-admiral. There is one vice-admiral for all Scotland, and one for the Shetland and Orkney Islands. The governor of most of our colonies had a commission of vice-admiral granted to him by the lord high admiral or lords commissioners of the admiralty, and generally a commission from the king under the great seal, grounded on the 11 and 12 William III. c. 7, and further confirmed by 46 Geo. III. c. 54, by which he was authorised to try all treasons, piracies, felonies, robberies, murders, conspiracies, and other offences, of what nature or kind soever, committed on the seas, where the parties were taken into custody in places remote from England. The court consisted of seven persons at the least, of whom the governor, the lieutenant-governor, the vice-admiral, the flag-officer, or commander-in-chief of the squadron, the members of the council, the chief-justice, judge of the vice-admiralty court, captains of men-of-war, and secretary of the colony, were specially named in the commission; but any three of these, with four others selected from known merchants, factors, or planters, captains, lieutenants, or warrant officers of men-of-war, or captains, masters, or mates of merchant ships, constituted a legal court of piracy. By the 12 and 13 Vict. c. 96, all persons charged in any colony with offences committed on the sea may be dealt with in the same manner as if the offences had been committed on waters within the local jurisdiction of the courts of the colony.

The vice-admiralty courts in the colonies are of two descriptions. The one has power to inquire into the causes of detention of enemies or neutral vessels, to try and condemn the same for the benefit of the captors, as well as to take cognisance of all matters relating to the office of the lord high admiral. The other has only power to institute inquiries into misdemeanours committed in merchant vessels, and to determine petty suits, &c., and to guard the privileges of the admiral. The former are usually known by the name of *prize courts*, the latter by that of *instance courts*. Appeals from vice-admiralty courts abroad lay formerly to the high court of admiralty in England, and from that, if need were, to the high court of delegates, or in prize cases to the prize commissioners. By an Act of her present Majesty, all such appeals lie direct to the sovereign, who refers them to the judicial committee of the privy council.

The following are the colonies and foreign possessions in which vice-admiralty courts are now (1874) established. Others are constituted as occasion may require, in case of war:—

Aden. (*Slave trade jurisdiction only.*)
Antigua, Montserrat, and Barbuda.
Australia, South.
Australia, West.
Bahamas.
Barbadoes.
Bermuda.
Bombay.
British Columbia.
British Guiana.
Calcutta.
Canada.
Cape of Good Hope.
Ceylon.
Dominica.
Falkland Islands.
Gambia.
Gibraltar.
Gold Coast.
Grenada.
Halifax, Nova Scotia.
Honduras.
Hong Kong.
Jamaica.
Labuan.
Lagos.
Madras.
Malta.
Mauritius.
Montserrat.
Natal.
Nevis.
New Brunswick.
Newfoundland.
New South Wales.
New Zealand.
Prince Edward's Island.
Quebec.
Queensland.
St Christopher.
St Helena.
St Lucia.
St Vincent.
Sierra Leone.
The Straits Settlements. (*Prince of Wales' Island, Singapore, and Malacca.*)
Tasmania.
Tobago.
Tortola and Virgin Islands.
Trinidad.
Vancouver's Island.
Victoria.
Zanzibar. (*Limited slave trade jurisdiction only.*)

By the provisions of the Vice-admiralty Courts Act of 1863, The governor of a colony is *ex officio* vice-admiral, and the chief-justice *ex officio* judge of the vice-admiralty court.

In none of the patents to the lord high admiral, vice-admiral, or judge, is any mention made of prize jurisdiction. Lord Mansfield had occasion to search into the records of the court of admiralty in Doctors' Commons, to ascertain on what foundation this jurisdiction was exercised by the judge of the admiralty; but he could not discover any prize-act books farther back than 1643; no sentences farther back than 1648. The registrar could go no farther back than 1690. "The prior records," says his lordship, "are in confusion, illegible, and without index." The prize jurisdiction may therefore be considered as of modern authority, and distinct altogether from the ancient powers given to the admiral. To constitute the authority for trying prize causes, a commission under the great seal issues to the lord high admiral at the commencement of every war, to will and require the court of admiralty, and the lieutenant and judge of the said court, his surrogate or surrogates, to proceed upon all manner of captures, seizures, and reprisals, of all ships and goods that are or shall be taken; and to hear and determine according to the course of the admiralty, or the law of nations; and a warrant issues to the judge of the admiralty accordingly.

The admiralty court being in this respect a court in which foreigners of all nations may become suitors, an appeal may be had from its decisions to a committee of the lords of the privy council, who hear and determine according to the established laws of nations.

At the breaking out of a war, the lord high admiral also receives a special commission from the crown, under the great seal, to empower him to grant letters of marque and reprisals against the enemy, he having no such power by his patent. These letters are either general or special: general, when granted to private men to fit out ships at their own charge to annoy the enemy; special, when in the case of any of our merchants being robbed of their estates or property by foreigners, the king grants them letters of reprisal against that nation, though we may be in amity with it. Before the latter can be sued for, the complainant must have gone through the prosecution of his suit in the courts of the state whose subjects have wronged him; where, if justice be denied, or vexatiously delayed, he must first make proof of his loses and charges in the admiralty court here; whereupon, if the Crown is satisfied he has pursued all lawful means to obtain redress, and his own interceding should produce no better effect, special letters of reprisal are granted; not, however, as must be evident, until a very strong case has been made out. This custom, which we may now consider as obsolete, seems to be a remnant of the law of ancient Greece, called *androlepsia*, by which, if a man was slain, the friends and relations of the deceased might seize on any three citizens of the place where the murderer took refuge, and make them slaves, unless he was delivered up. Both Oliver Cromwell and King Charles II. granted letters of reprisal. In 1638 the Duc d'Epernon seized on the ship "Amity" of London, for the service of the French king against the Spaniards, promising full satisfaction; but none being made, the owners obtained letters of reprisal from the Protector, and afterwards, in 1665, from Charles II. In 1666 Captain Butler Barnes had letters of reprisal against the Danes. The Dutch having burnt six English merchant vessels in the Elbe, within the territories of Hamburg, which city, instead of giving any assistance or protection, hindered the English from defending themselves, letters of reprisal were granted to the sufferers against that city. Lastly, one Justiniani, a noble Genoese, being indebted in a large sum to Joseph Como, a merchant in London, which he had several years solicited for without obtaining satisfaction, Captain Scott, commander of his Majesty's ship the "Dragon," stationed at that time in the Mediterranean, received orders to make reprisals upon the ships of that republic; upon which the debt was paid.

2. *The Judge.*—The patents to the judge of the admiralty and vice-admiralty courts run pretty nearly in the same manner as those of the lord high admiral, and point out the several matters of which he can take cognisance. The Parliament of 1640 established the office of judge of the admiralty court in three persons, with a salary of £500 a-year to each. At the Restoration there were two judges of the high court of admiralty, which sometimes proved inconvenient; for when they differed in opinion, no judgment could be had. These judges, before the Revolution, held their appointment only during pleasure. At that period, and under the provisions of the Bill of Rights, Sir Charles Hedges was constituted judge under the great seal of England, *quamdiu se bene gesserit*, with a salary of £400 a-year, and an additional £400 out of the proceeds of prizes and perquisites of the admiralty; but in the year 1725 the latter sum was diminished from the ordinary estimate by the House of Commons. The salary of Sir James Marriott, from 1778 to 1782, during the American war, was £800 a year, and £3700 added for fees. From 1794 to 1798, the salary was £1780, and £2500 for fees. During the sixteen years that Sir William Scott (Lord Stowell) was judge,

from 1798 to 1814, the salary was £2500, and the fees averaged £2800 a-year. Under the 3 and 4 Vict. c. 66, § 1, the salary is fixed at £4000 per annum. All fees of whatever kind, formerly payable to the judge, are now paid to the consolidated fund.

The court of admiralty is at present (1873), and pending the erection of the new law courts, held in Westminster. In the time of Henry IV. it was held in Southwark, either at a quay on the south side of the Thames, or in the erewhile church of St Margaret-on-Hill, most likely the former. Stow, in his *Survey* (A.D. 1598), says—"A part of this parish church of St Margaret is now a court, wherein the assizes and sessions be kept; and the court of admiralty is also there kept." Pepys also, in his *Diary* (17th March 1663), describes the court as sitting there. But it is probable that the sittings in St Margaret's Church were commenced shortly before Stow's time; for in the Rolls of Parliament, 11 Hen. IV. No. 61, the Commons complain that people are summoned by the officers of the admiral *à Loundres à le Key de William Horton, Suthwerke.* Further, it would appear from an appeal made to the king, Henry IV., that the rule then was for the admiral's court to be held upon some wharf or quay within the flux and reflux of the tide. In the reign of Henry VIII., Horton's Quay, near London Bridge, is mentioned in the records of the high court of admiralty (3d Nov. 1541) as its usual place of sitting.

The judges of the vice-admiralty courts in certain of the colonies, limited by 41 George III. c. 96, are allowed a salary not exceeding to each the sum of £2000 a-year, to be paid out of the consolidated fund of Great Britain; together with profits and emoluments not exceeding to each the further sum of £2000 per annum. out of the fees to be taken by the said judges, of which a table is directed to be hung up in some conspicuous place in the court; and no judge is to take any fee beyond those specified, directly or indirectly, on pain of forfeiture of his office, and being proceeded against for extortion; and on his retirement from office after six years' service, or from some permanent infirmity, the Crown may, by authority of the Act above mentioned, grant unto such judge an annuity for the term of his life not exceeding £1000 per annum. This liberal provision puts the judges of the colonial courts of vice-admiralty above all suspicion of their decisions being influenced by unworthy motives—a suspicion they were not entirely free from when their emoluments depended mainly on their fees.

During the war of 1793–1815 a session of oyer and terminer to try admiralty causes was held at the Old Bailey, now the central criminal court, twice a-year. The commission for this purpose was of the same nature with those which are granted to the judges when they go on circuit; that is to say, to determine and punish all crimes, offences, and misdemeanours, and abuses; the *end* of both being the same, their *limits* different; the one relating to things done upon the land, the other to things done upon the water. The lords commissioners of the admiralty, all the members of the privy council, the chancellor and all the judges, the lords of the treasury, the secretary of the admiralty, the treasurer and commissioners of the navy, some of the aldermen of London. and several doctors of the civil law, were the members of this commission; any four of whom made a court.

The proceedings of the court, now probably obsolete, were continued *de die in diem*, or, as the style of the court was, from tide to tide.

3. *The Registrar of the Admiralty* formerly held his place by patent from the Crown. The patent was issued under the great seal of the court of admiralty, and the appointment was afterwards confirmed by patent under the great seal of the United Kingdom. The appointment was for life, and was often granted in reversion. The registrar had no salary, the amount of his emoluments depending on the captures, droits, &c., condemned by the court. which during the war of 1793–1815 were so enormous that in 1810 an Act was passed for regulating the offices of registrars of admiralty and prize courts, by which it is enacted "that no office of registrar of the high court of admiralty, or of the high court of appeals for prizes, or high court of delegates in Great Britain, shall, after the expiration of the interest now vested in possession or reversion therein, be granted for a longer term than during pleasure, nor be executed by deputy; that an account be kept in the said offices respectively of all the fees, dues, perquisites, emoluments, and profits received by and on account of the said registrars, out of which all the expenses of their offices are to be paid; that one-third of the surplus shall belong to the registrar and to his assistant (if an assistant should be necessary), and the remaining two-thirds to the consolidated fund of Great Britain, to be paid quarterly into the exchequer; the account of such surplus to be presented to the court at least fourteen days before each quarter-day, and verified on oath." Under the 3 and 4 Vict. c. 66, § 2, a yearly salary of £1400 is substituted for "all fees, dues, perquisites, emoluments, and profits," and which may be increased in time of war to £2000. The duties of the registrar are—1. To keep a public registry, to give attendance therein, and to preserve in a regular manner the registers, acts, records, and documents belonging to the office; 2. To attend all sittings of the court of admiralty, and to attend the judge at chambers; 3. To draw and sign all warrants, monitions, commissions, &c., issuing from the court; to attend other courts with minutes, &c., of the admiralty court when required: 4. To have the custody of all moneys paid into court or paid out of court.

4. *The Advocate-General.*—This officer is appointed by warrant of the lords commissioners of the admiralty. His duties are—to appear for the lord high admiral in his court of admiralty, court of delegates, and other courts; to move and debate in all causes wherein the rights of the admiral are concerned; for which he had anciently a salary of 20 marks (£13, 6s. 8d.) a-year. In May 1803, Dr William Battine, who was appointed in 1791, had an addition of £200 to his salary, "for his extraordinary trouble and attendance during the present hostilities." His salary was continued to him and his successor, Dr Arnold, till 1816; since that time the allowance has been reduced to its original amount of £13, 6s. 8d. Formerly the admiral's advocate was always retained as leading counsel, but after the droits were transferred to the crown, he was gradually supplanted by the king's advocate, who was generally retained in all cases, the admiralty advocate acting only as junior counsel; and while the former during the war made sometimes from £15,000 to £20,000 a-year, the latter rarely received from his professional duties more than from £1500 to £2000 a-year.

5. *The Counsel and Judge-Advocate for the affairs of the Admiralty and Navy* is the law officer who is chiefly consulted on matters connected with the military duties of the lord high admiral. He advises also on all legal questions. His salary is £100 a-year, besides his fees, which in time of war may be reckoned to amount to from £1200 to £1800 a-year. Till the present reign the offices of counsel of the admiralty and judge-advocate of the fleet were separate and distinct, the latter being a sinecure appointment, with a salary of £182, 10s. attached to it. The salary is now abolished. The duties are very light, the veritable work of the office being discharged by deputy judges-advocate appointed on each occasion of a court-martial, and by resident law agents at Portsmouth and Plymouth, who receive salaries in lieu of all fees and charges.

6. *The Solicitor to the Admiralty* is also an officer ap

pointed during pleasure by the lords of the admiralty. He is the general legal adviser, in the first instance, of the lords commissioners; and since 1869 there have been added to his other functions those of registrar of public securities and custodian of all public securities and bonds belonging to the admiralty. His salary is £1600 a-year in lieu of all fees, bills, and disbursements, with an allowance of £1300 a-year for assistance of clerks. His office is provided for him.

7. *The Procurator.*—The admiralty's proctor stands precisely in the same situation to the queen's proctor that his advocate does to that of the queen, though there is not quite so great a difference in their emoluments. They act as the attorneys or solicitors in all causes concerning the queen's and the lord high admiral's affairs in the high court of admiralty and other courts. All prize causes are conducted by the queen's proctor. It is supposed that in some years of war, in the early part of the century, the proctor did not receive less than £20,000 a-year.

8. *The Marshal.*—This officer receives his appointment from the lord high admiral or lords commissioners of the admiralty. His appointment is under the seal of the high court of admiralty during pleasure, and is confirmed by letters patent from the Crown. His duties are to arrest ships and persons; to execute all processes or orders issuing from the court; to attend, in person or by deputy, the judge with the silver oar (the ancient emblem of maritime jurisdiction); and formerly also to attend executions. It is also the duty of the marshal or his deputy to arrest, under warrant from the admiralty, any officer not beneath the rank of post captain who may be ordered for trial by court-martial; and to see to the delivery of sentenced prisoners to their place of punishment. His emoluments formerly depended on the number of prizes brought into port for condemnation, and the number of ships embargoed, and might probably be reckoned in time of war, *communibus annis*, from £1500 to £2000 a-year, out of which he had to pay about £400 a-year to a deputy. He had no salary. The office can, however, be no longer performed by deputy, except in case of illness, § 9 of the 3 and 4 Viet. c. 66. The marshal is now paid by a salary of £500, in addition to his travelling expenses.

(F. W. R.)

ADMIRALTY, IRELAND.—For all executive functions Ireland is subject to the jurisdiction and orders of the lord high admiral, or lords commissioners for executing the office, of Great Britain. For judicial purposes, however, an admiralty court sits in the Four Courts, Dublin, having a judge, a registrar, a marshal, and other officers. In peace time and war time alike it exercises only an instance jurisdiction. No prize commission has ever issued to it.

ADMIRALTY, SCOTLAND. At the Union, while the national functions of the lord high admiral were merged in the English office, there remained a separate court of admiralty, with subsidiary local courts, having civil and criminal jurisdictions in maritime questions. The separate courts were abolished in 1831, and their powers merged in the courts of session and justiciary, and the local courts.

ADMIRALTY CHARTS. These useful aids to navigation are constructed in the hydrographic department of the British Admiralty, by specially-appointed surveyors and draughtsmen, and they are issued to the public by order of the lords commissioners of the admiralty. They are divided into various sections as follows:—1. English and Irish Channels and coasts of the United Kingdom; 2. North Sea and adjacent coasts; 3. Baltic Sea; 4. North and west coasts of France, Spain, and Portugal; 5. Mediterranean, Black Sea, and Sea of Azov; 6. Atlantic Ocean and Islands; 7. Arctic Sea and north and east coasts of America; 8. West Indies, Gulf of Mexico, &c.; 9. South America, east coast; 10. West coasts of South and North America; 11. Africa, Madagascar, Mauritius, Red Sea, &c.; 12. East Indies, Arabian coast, &c.; 13. Indian Archipelago, China Sea, Japan, &c.; 14. Australia, New Zealand, &c.; 15. Pacific Ocean islands. They are about 3000 in number, of various sizes and scales, and the prices vary from 6d. to 10s. Accompanying the charts there are books of sailing directions, tables, and lists of lights. Similar charts as those of the British Admiralty are issued by the United States Coast Survey, as well as by the Russian and French governments. The superintendent of the United States Coast Survey issues an annual report, showing the progress of the survey, and containing much valuable information.

ADMIRALTY ISLAND, an island belonging to the United States, about 90 miles long from N. to S., and 25 miles broad, lying between King George III. Archipelago and the mainland, in 58° N. lat., 134° W. long. Its coasts, which are generally steep and rocky, are indented with several accessible and commodious bays. The island has abundance of good water, and is covered with pines, which grow there to a very large size.

ADMIRALTY ISLANDS, a group of about forty islands lying to the N.E. of New Guinea, between 2° and 3° S. lat., and 146° 18′ and 147° 46′ E. long. The largest is about 50 miles in length; the others are very small, and all rise but little above the sea-level. Their exuberant vegetation, and in particular the groves of cocoa-nut trees, give them a very beautiful appearance. The islands were discovered by the Dutch in 1616, but have seldom been visited, access being difficult on account of the surrounding reefs. The natives are tall, and of a tawny colour.

ADOLPHUS, JOHN, historian and barrister, was born in London on the 7th August 1768. He was educated under the care of a grand-uncle, and after making a voyage to the West Indies was enrolled as an attorney about the year 1790. Called to the bar in 1807, he devoted himself to practice in criminal causes, and in a few years attained a leading position among Old Bailey counsel. His masterly defence of Thistlewood and the Cato Street conspirators, for which he had been retained only a few hours before the trial, did much to extend his reputation. He was very skilful in the management of his cases, but his hastiness of temper frequently led to unseemly altercations with other counsel. He held a good position in society, and was on terms of intimacy with the leading literary men of the day. *The History of England from the Accession of George III. to* 1783, which he published in 1802, was favourably noticed in the *Edinburgh Review* for its impartiality and accuracy. A new and enlarged edition of this work, in eight volumes, was in preparation, but only seven volumes were completed when the author died, 16th July 1845. His other literary works were—*Biographical Memoirs of the French Revolution* (1799); *The British Cabinet* (1799); *History of France from* 1790 *to* 1802 (1803); *Memoirs of John Bannister.*

ADOLPHUS, JOHN LEYCESTER, son of the above, also a distinguished barrister (died 1862), was the first to pierce the mask of the author of *Waverley*, in a series of critical letters addressed to Richard Heber, which he published in 1821.

ADONIS, according to some authors, the son of Theias, king of Assyria, and his daughter Smyrna [Myrrha], was the favourite of Venus. He was fond of hunting; and Venus often warned him not to attack the larger wild beasts; but neglecting the advice, he was killed by a wild boar he had rashly wounded. Venus was inconsolable, and turned him into a flower of a blood colour, supposed by some to be an anemone. Adonis had to spend half the year in the lower regions, but during the other half he was permitted to revisit the upper world, and pass the time with Venus. No grief was ever more celebrated than that of Venus for Adonis, most nations round the Mediterranean having perpetuated the memory of it by anniversary ceremonies. "The tale of Adonis (Keightley's *Mythology*) is evidently an eastern myth. His own name and those of his parents refer to that part of the world. He appears to be the same with the Thammuz mentioned by the prophet Ezekiel (viii. 14), and to be a Phœnician personification of the sun, who during part of the year is absent, or, as the legend expresses it, with the goddess of the under world; during the remainder with Astarte, the regent of heaven." Among the Egyptians, Adonis is supposed to have been adored under the name of Osiris, the husband of Isis; but he was sometimes called by the name of Ammuz or Thammuz, *the concealed*, to denote probably his death or burial. It has been thought it is he the Hebrews call *the dead* (Ps. cvi. 28, and Lev. xix. 28), because his worshippers wept for him, and represented him as one dead; and at other times they call him the *image of jealousy* (Ezek. viii. 3, 5), because he was an object of jealousy to other gods. The Syrians, Phœnicians, and Cyprians worshipped Adonis; and Calmet was of opinion that this worship may be identified with that of the Moabitish Baal-peor. Modern critics plausibly connect the divine honours paid to Adonis with the mysterious rites of phallic worship, which, in some shape or other, prevailed so extensively in the ancient world.

ADONIS, in *Ancient Geography*, a small river rising in Mount Lebanon, and falling into the sea at Byblus. When in flood its waters exhibit a deep red tinge; hence the legend that connects it with the wound of Adonis.

> "While smooth Adonis from his native rock,
> Ran purple to the sea, suppos'd with blood
> Of Thammuz yearly wounded."—MILTON.

ADONIS, a genus of ranunculaceous plants, known commonly by the names of Pheasant's Eye and *Flos Adonis*. There are ten or twelve species given by authors, but they may be probably reduced to three or four. There are two indigenous species, *Adonis autumnalis* and *Adonis æstivalis*. They are commonly cultivated. An early flowering species, *Adonis vernalis*, is well worthy of cultivation.

ADOPTIAN CONTROVERSY, a controversy relating to the sonship of Christ, raised in Spain by Elipandus, archbishop of Toledo, and Felix, bishop of Urgel, towards the close of the 8th century. By a modification of the doctrine of Nestorius they maintained that Christ was really the Son of God in his divine nature alone, and that in his human nature he was only the Son of God by adoption. It was hoped that this view would prove more acceptable to the Mahometans than the orthodox doctrine, and Elipandus especially was very diligent in propagating it. Felix was instrumental in introducing it into that part of Spain which belonged to the Franks, and Charlemagne thought it necessary to assemble a synod at Ratisbon (792), before which the bishop was summoned to explain and justify the new doctrine. Instead of this he renounced it, and confirmed his renunciation by a solemn oath to Pope Adrian, to whom the synod sent him. The recantation was probably insincere, for on returning to his diocese he taught adoptianism as before. Another synod was held at Frankfort in 794, by which the new doctrine was again formally condemned, though neither Felix nor any of his followers appeared. A friendly letter from Alcuin, and a controversial pamphlet, to which Felix replied, were followed by the sending of several commissions of clergy to Spain to endeavour to put down the heresy. Archbishop Leidrad of Lyons being on one of these commissions, persuaded Felix to appear before a synod at Aix-la-Chapelle in 799. There, after six days' disputing with Alcuin, he again recanted his heresy. The rest of his life was spent under the supervision of the archbishop at Lyons, where he died in 816. Elipandus, secure in his see at Toledo, never swerved from the adoptian views, which, however, were almost universally abandoned after the two leaders died. The controversy was revived by solitary advocates of the heretical opinions more than once during the Middle Ages, and the questions on which it turns have, in one form or another, been the subject of frequent discussion.

ADOPTION, the act by which the relations of paternity and filiation are recognised as legally existing between persons not so related by nature. Cases of adoption were very frequent among the Greeks and Romans, and the custom was accordingly very strictly regulated in their laws. In Athens the power of adoption was allowed to all citizens who were of sound mind, and who possessed no male offspring of their own, and it could be exercised either during lifetime or by testament. The person adopted, who required to be himself a citizen, was enrolled in the family and *demus* of the adoptive father, whose name, however, he did not necessarily assume. In the interest of the next of kin, whose rights were affected by a case of adoption, it was provided that the registration should be attended with certain formalities, and that it should take place at a fixed time—the festival of the *Thargelia*. The rights and duties of adopted children were almost identical with those of natural offspring, and could not be renounced except in the case of one who had begotten children to take his place in the family of his adoptive father. Adopted into another family, children ceased to have any claim of kindred or inheritance through their natural father, though any rights they might have through their mother were not similarly affected. Among the Romans the existence of the *patria potestas* gave a peculiar significance to the custom of adoption. The motive to the act was not so generally childlessness, or the gratification of affection, as the desire to acquire those civil and agnate rights which were founded on the *patria potestas*. It was necessary, however, that the adopter should have no children of his own, and that he should be of such an age as to preclude reasonable expectation of any being born to him. Another limitation as to age was imposed by the maxim *adoptio imitatur naturam*, which required the adoptive father to be at least eighteen years older than the adopted children. According to the same maxim eunuchs were not permitted to adopt, as being impotent to beget children for themselves. Adoption was of two kinds according to the state of the person adopted, who might be either still under the *patria potestas* (*alieni juris*), or his own master (*sui juris*). In the former case the act was one of *adoption proper*, in the latter case it was styled *adrogation*, though the term adoption was also used in a general sense to describe both species. In adoption proper the natural father publicly sold his child to the adoptive father, and the sale being thrice repeated, the maxim of the Twelve Tables took effect, *Si pater filium ter venunduit, filius a patre liber esto*. The process was ratified and completed by a fictitious action of recovery brought by the adoptive father against the natural parent, which the latter did not defend, and which was therefore known as the *cessio in jure*. *Adrogation* could be accomplished originally only by the authority of the people assembled in the

Comitia, but from the time of Diocletian it was effected by an imperial rescript. Females could not be adrogated, and, as they did not possess the *patria potestas*, they could not exercise the right of adoption in either kind. The whole Roman law on the subject of adoption will be found in Justinian's *Institutes*, lib. i. tit. 11. In Hindoo law, as in nearly every ancient system, wills are almost unknown, and adoptions take their place. The strict law of adoption in India has been relaxed to the extent that a Hindoo widow may adopt when her deceased husband has not done so. Adoption is not recognised in the laws of England and Scotland, though there are legal means by which one may be enabled to assume the name and arms and to inherit the property of a stranger. In France and Germany, which may be said to have embodied the Roman law in their jurisprudence, adoption is regulated according to the principles of Justinian, though with several more or less important modifications, rendered necessary by the usages of these countries respectively. The part played by the legal fiction of adoption in the constitution of primitive society and the civilisation of the race is so important, that Sir Henry S. Maine, in his valuable work on *Ancient Law*, expresses the opinion that, had it never existed, the primitive groups of mankind could not have coalesced except on terms of absolute superiority on the one side, and absolute subjection on the other. With the institution of adoption, however, one people might *feign itself* as descended from the same stock as the people to whose *sacra gentilicia* it was admitted; and amicable relations were thus established between stocks which, but for this expedient, must have submitted to the arbitrament of the sword with all its consequences.

ADOPTION, as a Biblical term, occurs only in the *New Testament*. In Old Testament history the practice was unknown, though cases approximating to it have been pointed out. In the New Testament υἱοθεσία occurs in several passages, on which is founded one of the leading doctrines of theology.

ADORATION (from *os*, *oris*, the mouth, or from *oro*, to pray), an act of homage or worship which, among the Romans, was performed by raising the hand to the mouth, kissing it, and then waving it in the direction of the adored object. The devotee had his head covered, and after the act turned himself round from left to right. Sometimes he kissed the feet or knees of the images of the gods themselves, and Saturn and Hercules were adored with the head bare. By a natural transition the homage that was at first paid to divine beings alone came to be paid to men in token of extraordinary respect. Those who approached the Greek and Roman emperors adored by bowing or kneeling, laying hold of the imperial robe, and presently withdrawing the hand and pressing it to the lips. In eastern countries adoration was performed in an attitude still more lowly. The Persian method, introduced by Cyrus, was to bend the knee and fall on the face at the prince's feet, striking the earth with the forehead, and kissing the ground. Homage in this form was refused by Conon to Artaxerxes, and by Callisthenes to Alexander the Great. In England the ceremony of kissing the king's or queen's hand, and some other acts which are performed kneeling, may be described as forms of adoration. Adoration is applied in the court of Rome to the ceremony of kissing the Pope's foot, a custom which is said to have been introduced by the popes after the example of the Emperor Diocletian. In the Romish Church a distinction is made between *Latria*, a worship due to God alone, and *Dulia* or *Hyperdulia*, the adoration paid to the Virgin, saints, martyrs, crucifixes, the host, &c.

ADOUR, the ancient *Aturus*, a river of France which rises near Barége, in the department of Upper Pyrenees, and, flowing first northwards, then with a circuit to the west, passes through the departments of Gers and Landes, and falls into the Bay of Biscay 3 miles below Bayonne. Its length is about 180 miles, and it is navigable for about 70 miles, as far as St Sever. Bagnères-de-Bigorre, Tarbes, and Dax are the other important towns on its banks.

ADOWA, the capital of Tigré, in Abyssinia, is situated in 14° 12′ N. lat., 39° 3′ E. long., on the left bank of the River Hasam, 145 miles N.E. of Gondar. It is built on the eastern declivity of a hill overlooking a small plain, and has regular streets, ornamented with trees and gardens. The town derives its chief importance from its situation on the route between Massowah and Gondar, which has caused it to become the great entrepôt of traffic between the extensive table-land of Tigré and the coast. Gold and ivory are included in its transit trade, and hardware is manufactured, as well as the coarse cotton cloth which circulates in Abyssinia as the medium of exchange in place of money. Population about 6000.

ADRA, the ancient *Abdera*, a seaport of Spain on the Mediterranean, in the province of Almeria, 60 miles S.E. of Grenada. Lead is extensively wrought in the neighbourhood, and exported to Marseilles. The other exports include wheat and sugar. Population, 7400.

ADRASTUS, in *Legendary History*, was the son of Talaus, king of Argos, and Lysianassa, daughter of Polybus, king of Sicyon. Being driven from Argos by Amphiaraus, Adrastus repaired to Sicyon, where he became king on the death of Polybus. After a time he was reconciled to Amphiaraus, to whom he gave his sister in marriage, returned to Argos, and occupied the throne. He acquired great honour in the famous war against Thebes, which he undertook for the restoration of his son-in-law Polynices, who had been deprived of his rights by his brother Eteocles, notwithstanding the agreement between them. Adrastus, followed by Polynices and Lydeus, his two sons-in-law, Amphiaraus, his brother-in-law, Capaneus, Hippomedon, and Parthenopæus, marched against the city of Thebes, and on his way is said to have founded the Nemean games. This is the expedition of the *Seven Worthies against Thebes* which the poets have made nearly as famous as the siege of Troy. As Amphiaraus had foretold, they all lost their lives in this war except Adrastus, who was saved by the speed of his horse Arion. Ten years after, at the instigation of Adrastus, the war was renewed by the sons of the chiefs that had fallen. This expedition was called the *War of the Epigoni*, and ended in the taking and destruction of Thebes. None of the followers of Adrastus perished in it except his son Ægialeus. The death of this son affected Adrastus so much that he died of grief at Megara, as he was leading back his victorious army.

ADRIA, a city of Italy, in the province of Rovigo, between the rivers Po and Adige. It is a place of great antiquity, and was at an early period a seaport of such importance and celebrity as to give name to the sea on which it stood. Originally an Etruscan colony, it enjoyed for a time remarkable prosperity; but under the Romans it appears never to have been of much importance, and after the fall of the Western Empire it rapidly declined. The dykes which protected the surrounding country from inundation were neglected, the canals became choked, and the mud and other deposits brought down by the waters of the Po and Adige caused a gradual extension of the land into the Adriatic, so that Adria ceased to be a seaport, and is now 16 miles from the sea, on whose shores it formerly stood. By the draining of the neighbouring lands, the modern town has been much improved. It has some trade in grain, cattle, fish, wine, and earthenware, is the seat of a bishopric, and has a museum of Greek and Roman antiquities. A little to the south, extensive remains of the ancient city have been discovered deeply imbedded in the accumulated soil. The population of Adria is 10,000.

ADRIA (ὁ Ἀδρίας—Acts xxvii. 27) in St Paul's time meant all that part of the Mediterranean between Crete and Sicily. This fact is of importance, as it relieves us from the necessity of finding the island of Melita, on which Paul was shipwrecked, in the present Adriatic Gulf.

ADRIAN, a town of the United States, capital of Lenawee co., Michigan, situated on a branch of the Raisin river, and on the Michigan Southern Railway, 73 miles W.S.W. of Detroit. Adrian is the centre of trade for the surrounding district, which is chiefly grain-producing. Its extensive water-power is employed in mills of various kinds. It has several fine churches and other public buildings. Population in 1870, 8438.

ADRIAN, Publius Ælius, Roman emperor. See Hadrian and Roman History.

ADRIAN (sometimes written Hadrian) was the name of six popes:—

Adrian I., son of Theodore, a Roman nobleman, occupied the pontifical chair from 772 to 795. Soon after his accession the territory that had been bestowed on the popes by Pepin was invaded by Desiderius, king of the Longobards, and Adrian found it necessary to invoke the aid of Charlemagne, who entered Italy with a large army, and repelled the enemy. The pope acknowledged the obligation by conferring upon the emperor the title of Patrician of Rome, and Charlemagne made a fresh grant of the territories orginally bestowed by his father, with the addition of Ancona and Benevento. The friendly relations thus established between pope and emperor continued unbroken, though a serious difference arose between them on the question of the worship of images, to which Charlemagne and the Gallican Church were strongly opposed, while Adrian favoured the views of the Eastern Church, and approved the decree of the Council of Nicæa (787), confirming the practice and excommunicating the iconoclasts. It was in connection with this controversy that Charlemagne wrote the so-called *Libri Carolini*, to which Adrian replied by letter, anathematising all who refused to worship the images of Christ, or the Virgin, or saints. Notwithstanding this, a synod, held at Frankfort in 794, anew condemned the practice, and the dispute remained unsettled at Adrian's death. An epitaph written by Charlemagne in verse, in which he styles Adrian "father," proves that his friendship with the pontiff was not disturbed by the controversy in which they were so long engaged.

Adrian II., born at Rome, became pope in 867, at the age of seventy-six. He faithfully adhered to the ambitious policy of his immediate predecessor, Nicholas I., and used every means to extend his authority. His persistent endeavours to induce Charles the Bald to resign the kingdom of Lorraine to the emperor were unsuccessful. Hincmar, archbishop of Rheims, who had crowned Charles, denied the pope's right to interfere in the matter, and maintained that the threatened excommunication of the king's adherents would have no validity. Adrian was for the time more successful in his contest with the patriarch of Constantinople—the sentence of deposition he passed upon Photius being confirmed by a council of the Eastern Church held in 869–70. His arrogant measures were, however, the immediate occasion of the schism between the Greek and Latin churches. Adrian had himself been married, but put away his wife on ascending the papal throne, and a council called by him at Worms in 868 decreed the celibacy of the clergy. He died in 872.

Adrian III., born at Rome, succeeded Martin II. in 884, and died in 885 on a journey to Worms.

Adrian IV. whose name was Nicholas Breakspeare, was born before 1100 A.D. at Langley, near St Albans, in Hertfordshire, and is the only Englishman who has occupied the papal chair. His request to be allowed to take the habit of the monastery of St Albans having been refused by Abbot Richard, he proceeded to Paris, where he studied with diligence, and soon attained great proficiency, especially in theology. Being admitted, after a period of probation, a regular clerk in the monastery of St Rufus, in Provence, he distinguished himself so much by his learning and strict observance of the monastic discipline that he was chosen abbot when the office fell vacant. His merit became known to Pope Eugenius III., who created him cardinal-bishop of Alba in 1146, and sent him two years later as his legate to Denmark and Norway. On this mission he converted many of the inhabitants to Christianity, and erected Upsal into an archiepiscopal see. Soon after his return to Rome, Anastasius, successor of Eugenius, died, and Nicholas was unanimously chosen pope, against his own inclination, in Nov. 1154. On hearing of the election, Henry II. of England sent the abbot of St Albans and three bishops to Rome with his congratulations, which Adrian acknowledged by granting considerable privileges to the monastery of St Albans, including exemption from all episcopal jurisdiction except that of Rome. The bestowal by Adrian of the sovereignty of Ireland upon the English monarch was a practical assertion of the papal claim to dispose of kingdoms. The act, besides facilitating and hastening the subjection of Ireland to England, was also the means of inducing Henry to yield the long-contested point of lay investiture to ecclesiastical offices. The beginning of Adrian's pontificate was signalised by the energetic attempts of the Roman people to recover their ancient liberty under the consuls, but the pope took strong measures to maintain his authority, compelling the magistrates to abdicate, laying the city under an interdict, and procuring the execution of Arnold of Brescia (1155). In the same year he excommunicated William, king of Sicily, who had ravaged the territories of the church, but the ban was removed and the title of King of the Two Sicilies conferred on William in the following year, on the promise of a yearly tribute to the Holy See. With Adrian commenced the long and bitter conflict between the papal power and the house of Hohenstaufen which ended in the humiliation of the latter. Frederick Barbarossa having entered Italy at the head of a large army for the purpose of obtaining the crown of Germany from the hands of the pope, Adrian met him at Sutri. The demand that he should hold the pope's stirrup as a mark of respect was at first refused by Frederick, whereupon the pope on his part withheld from the emperor the *osculum pacis*, and the cardinals ran away in terror. After two days' negotiation, Frederick was induced to yield the desired homage, on the representation that the same thing had been done by his predecessors. His holiness then conducted the emperor to Rome, where the ceremony of coronation took place in the Church of St Peter's. It was in these transactions that the quarrel originated. A letter addressed by the pope to Frederick and the German bishops in 1157 asserted, on the ground of the ceremonies that had taken place, that the emperor held his dominions as a *beneficium*. The expression, being interpreted as denoting feudal tenure, stirred up the fiercest indignation of Frederick and the Germans, and though explanations were afterwards given with the view of showing that the word had not been used in an offensive sense, the breach could not be healed. Adrian was about to pronounce the sentence of excommunication upon Frederick when he died at Anagni on the 1st Sept. 1159.

Adrian V., a Genoese, whose name was Ottoboni Fiesci, occupied the papal throne for only five weeks in 1276. When congratulated on his accession he replied in the well-known words, "I wish you had found me a healthy cardinal rather than a dying pope."

ADRIAN VI., born of humble parentage at Utrecht in 1459, studied at the university of Louvain, of which he became vice-chancellor. He was chosen by the Emperor Maximilian to be tutor to his grandson, the Archduke Charles, through whose interest as Charles V. he was afterwards raised to the papal throne. In 1517 he received the cardinal's hat from Leo X., and in 1519 he was made bishop of Tortosa. After the death of Ferdinand he was for a time regent of Spain. He was chosen pope Jan. 9, 1522; but the election was very displeasing to the people of Rome, as the new pope, in contrast with his predecessor Leo, was known to be very rigid in discipline and frugal in his mode of living. On his accession, contrary to the usual custom, he did not change his name, and he showed his dislike to ostentation in many other ways. In regard to the great fact with which he had to deal—the Reformation—Adrian's conduct showed that he did not fully estimate the gravity of the crisis. Acknowledging the corruptions of the church, he did his utmost to reform certain external abuses; but when his proposed measures failed to win back Luther and the other reformers, he immediately sought to suppress their doctrines by force. He died on the 14th September 1523. So little did the people care to conceal their joy at the event that they wrote on the door of his physician's house the words "the saviour of his country."

ADRIAN, CARDINAL, was born at Corneto, in Tuscany, and studied at Rome. He was sent by Innocent VIII. as nuncio to Britain, to endeavour to reconcile James III. of Scotland and his subjects. That king having died, Adrian remained in England, where Henry VII. presented him to the bishopric of Hereford, and afterwards to that of Bath and Wells; but he never resided in either of these dioceses. On his return to Rome he became secretary to Pope Alexander VI., who employed him in various missions, and subsequently invested him with the purple. It was Adrian in particular that Alexander is said to have meant to poison in order that he might seize on his great wealth, when, as is generally reported, he fell a victim to his own wickedness. Not long after the elevation of Leo X. to the papal chair he was implicated in the conspiracy of Cardinal Petrucci against that pontiff. He confessed his guilt; and pardon being offered only on condition of his payment of a fine of 25,000 ducats, he resolved to fly from Rome. It is supposed that he was murdered by a domestic who coveted his wealth. Adrian was one of the first who sought to restore the Latin tongue from its mediæval corruptions to classical purity. He wrote *De Vera Philosophia*, a religious treatise, printed at Cologne in 1548; *De Sermone Latino*, a learned work, published at Rome in 1515, and repeatedly since; a treatise, *De Venatione*; and some Latin verses.

ADRIANI, GIOVANNI BATTISTA, born of a patrician family of Florence about 1511, was secretary to the republic of Florence, and for thirty years professor of rhetoric at the university. He wrote a history of his own times, from 1536 to 1574, in Italian, which is generally, but according to Brunet erroneously, considered a continuation of Guicciardini. De Thou acknowledges himself greatly indebted to this history, praising it especially for its accuracy. Adriani composed funeral orations on the Emperor Charles V. and other noble personages, and was the author of a long letter on ancient painters and sculptors prefixed to the third volume of Vasari. He died at Florence in 1579.

ADRIANOPLE (called by the Turks EDRENEH), a city of European Turkey, in the province of Rumelia, 137 miles W.N.W. of Constantinople; 41° 41′ N. lat., 26° 35′ E. long. It is pleasantly situated partly on a hill and partly on the banks of the Tundja, near its confluence with the Maritza. Next to Constantinople, Adrianople is the most important city of the empire. It is the seat of a bishop of the Greek Church. The streets are narrow, crooked, and filthy; its ancient citadel, and the walls which formerly surrounded the town, are now in ruins. Of its public buildings the most distinguished are the *Eski-Serai*, the ancient palace of the sultans, now in a state of decay; the famous bazaar of Ali Pacha; and the mosque of the Sultan Selim II., a magnificent specimen of Turkish architecture, which ranks among the finest Mahometan temples. The city has numerous baths, caravanseries, and bazaars; and considerable manufactures of silk, leather, tapestry, woollens, linen, and cotton, and an active general trade. Besides fruits and agricultural produce, its exports include raw silk, cotton, opium, rose-water, attar of roses, wax, and the famous dye known as Turkey red. The surrounding country is extremely fertile, and its wines are the best produced in Turkey. The city is supplied with fresh water by means of a noble aqueduct carried by arches over an extensive valley. There is also a fine stone bridge here over the Tundja. During winter and spring the Maritza is navigable up to the town, but Enos, at the mouth of that river, is properly its seaport. Adrianople was called Uskadama previous to the time of the Emperor Hadrian, who improved and embellished the town, and changed its name to Hadrianopolis. In 1360 it was taken by the Turks, who, from 1366 till 1453, when they got possession of Constantinople, made it the seat of their government. In the campaign of 1829 Adrianople surrendered to the Russians without making any resistance, but was restored after the treaty of peace signed the same year. Population, 140,000.

ADRIATIC SEA, the *Adriaticum Mare* of the ancients, is an arm of the Mediterranean which separates Italy from Triest, Croatia, Dalmatia, and Albania. It extends from 40° to 45° 50′ N. lat. in a N.W. direction. Its extreme north-west portion forms the Gulf of Venice, and on the east side are the gulfs of Triest, Fiume, Cattaro, and Drino. Its greatest length is 450 miles, its mean breadth 90 miles, and its depth varies from 12 to 22 fathoms. The western or Italian coasts are generally low and marshy; but the eastern shores are steep and rocky, and the abounding creeks and inlets, with the numerous islands, afford to mariners many safe natural harbours. The ebbs and flows of the tide in the Adriatic are inconsiderable, though more observable than in the Mediterranean generally; and its saltness is a little greater than that of the ocean. The prevalence of sudden squalls from the N.E. and S.E. renders its navigation hazardous, especially in winter. Except the Po and Adige, no considerable rivers flow into the Adriatic. Its chief emporia of trade are Venice, Triest, and Ancona. The port of Brindisi, on the Italian coast, near the southern extremity of the Adriatic, is rapidly rising in importance as the point of arrival and departure of the Peninsular and Oriental Company's steamers conveying the overland mails between England and the East. The name Adriatic is derived from Adria, between the mouths of the Po and the Adige, and not from Adria in Picenum. (See *Highlands and Islands of the Adriatic*, by A. A. Paton, 2 vols. 8vo, 1849; *Shores of the Adriatic*, by Viscountess Strangford, 1864.)

ADULE or ADULIS, a town on the Red Sea. See ZULLA.

ADULLAM, in *Scripture Geography*, a city in the plain country of the tribe of Judah. The cave Adullam, in which David took refuge after escaping from Gath (1 Sam. xxii. 1), was probably situated among the mountains to the east of Judah, near the Dead Sea. From its being described as the resort of "every one that was in distress," or "in debt," or "discontented," it has often been humorously alluded to, as by the Baron of Bradwardine in *Waverley*, chap. 57.

ADULTERATION

ADULTERATION, the act of debasing a pure or genuine commodity for pecuniary profit, by adding to it an inferior or spurious article, or by taking from it one or more of its constituents. The term is derived from the Latin *adultero*, which in its various inflections signifies to defile, to debase, to corrupt, to sophisticate, to falsify, to counterfeit, &c. The objects of adulteration are fourfold, namely, to increase the bulk or weight of the article, to improve its appearance, to give it a false strength, or to rob it of its most valuable constituents. All these adulterations are manifestly of a designedly fraudulent character, and are therefore properly the subjects of judicial inquiry; but there may be accidental corruptions and adulterations of a commodity, arising from natural or unavoidable causes, as when darnel or ergot become mixed with grain in the fields of the slovenly farmer, or when an article becomes changed and deteriorated from spontaneous decay, or when mineral matters and other impurities are accidentally derived from the machinery or vessels in which the thing is prepared or kept. The recognition of such impurities, and the tracing of them to their source, is of prime importance in pursuing a charge of adulteration. Few articles of commerce, however, are exempt from fraudulent adulteration, and the practice of it has grown with the competition of trade, and the removal of those wholesome restrictions which in former times were so energetically opposed to all kinds of dishonest dealing; for the guilds and companies of all large cities had their corporate regulations for supervising and governing every description of trade and manufacture. The excise, too, including the customs, had until recently control over the quality of all exciseable articles; and although the prime object of this was to protect the revenue of the country, yet it also served to prevent adulteration. In addition to this there were in ancient times ordinances of assize for regulating the price and quality of the common necessaries of life. As far back as the reign of John (1203) there was a proclamation throughout the kingdom for enforcing the legal obligations of assize as regards bread; and in the following reign the statute (51 Hen. III. stat. 6), entitled the Pillory and Tumbrel, was framed for the express purpose of protecting the public from the dishonest dealings of bakers, vintners, brewers, butchers, and others. This statute is deserving of notice as the first in which the adulteration of human food is specially noticed and prohibited; and it seems to have been enforced with more or less of rigour until the time of Anne, when it was repealed (8 Anne, c. 19). According to *Liber Albus*, it was strictly observed in the days of Edward I., for it states that "if any default shall be found in the bread of a baker in the city, the first time, let him be drawn upon a hurdle from the Guildhall to his own house through the great street where there be most people assembled, and through the great streets which are most dirty, with the faulty loaf hanging from his neck; if a second time he shall be found committing the same offence, let him be drawn from the Guildhall through the great street of Cheepe, in the manner aforesaid, to the pillory, and let him be put upon the pillory, and remain there at least one hour in the day; and the third time that such default shall be found, he shall be drawn, and the oven shall be pulled down, and the baker made to forswear the trade in the city for ever." Vintners, spicers, grocers, butchers, regrators, and others, were subject to the like punishment for dishonesty in their commercial dealings—it being thought that the pillory, by appealing to the sense of shame, was far more deterrent of such crimes than fine or imprisonment. But all this has given way to the force of free trade, and now the practice of adulteration has become an art, in which the knowledge of science and the ingenuity of trade are freely exercised. Fifty years ago it attracted the attention of one of the most expert chemists of the day, Mr Accum, who, in his *Treatise on Adulterations of Food, and Culinary Poisons*, declared it to be an "art and mystery." Subsequently to that, in 1851 and the three following years, articles on the adulteration of food appeared in the *Lancet*, and the effect of those articles was to call for a Parliamentary inquiry, which resulted in the Adulteration of Food Act of 1860. That Act of Parliament gave power to certain local authorities in England, Scotland, and Ireland to appoint analysts, having competent medical, chemical, and microscopical knowledge. The penalty for selling an adulterated article, knowing it to be so adulterated, was five pounds, and the costs of the proceedings. But as the statute was permissive, only a few analysts were appointed, and it soon became a dead letter. Attempts were subsequently made to improve the law, and to make it compulsory on local authorities to appoint analysts. One of these was the Bill of 1869, and another was that of 1871—both of which were abandoned by their promoters. In the year 1872, however, an Act was passed, entitled An Act to amend the Laws for the Prevention of Adulteration of Food, Drink, and Drugs. The main features of this Act are the following:—Local authorities in England, Scotland, and Ireland are bound to appoint analysts with competent medical, chemical, and microscopical knowledge. They must also appoint officers or inspectors to purchase articles of food, drink, and drugs within their respective districts, and take them to the analyst for examination. Other purchasers of such articles are permitted, under proper restrictions, to have suspected articles analysed. On receiving a certificate from the analyst, stating that any article is adulterated, the inspector must take the necessary legal proceedings for the purpose of bringing the offender to justice. The penalty on conviction of mixing anything whatever with a drug, with the view of adulterating it, or of mixing any injurious or poisonous ingredient with any article of food or drink, is a sum not exceeding fifty pounds, together with the costs; and for the second offence he shall be guilty of a misdemeanour, and be imprisoned for a period not exceeding six calendar months with hard labour. The penalty for selling an adulterated article with a guilty knowledge is a sum not exceeding twenty pounds, together with the costs; and for a second offence, the justice may order the offender's name, place of abode, and offence to be published in a newspaper, or in any manner he thinks fit, at the expense of the offender. Although the meaning of the term adulteration is not strictly defined in the Act, yet it is declared that the admixture of anything whatever with an article of food, drink, or drug, for the purpose of fraudulently increasing its weight or bulk, is an adulteration within the provisions of the Act. The adulteration of intoxicating liquors is provided for by the Licensing Act 1872 (35 and 36 Vict. c. 94); and in this Act there is a schedule of substances, called "*Deleterious Ingredients*," which are considered to be adulterations: they are *Cocculus indicus*, chloride of sodium or common salt, copperas, opium, Indian hemp, strychnine, tobacco, darnel seed, extract of logwood, salts of zinc or lead, alum, and any extract or compound of any of these. The execution of this Act rests with the police authorities and the Inland Revenue. The penalties for adulteration are very severe, leaving it to the magistrate either to inflict a heavy fine or to send the offender to prison. In the year 1869 an Act was passed to prevent the adulteration of seeds, in fraud of Her Majesty's subjects, and to the great detriment of agriculture (32 and 33 Vict. c. 112), wherein it is declared that the killing of seeds, the dying of them, and the selling of such killed or dyed seeds, with intent to defraud, is punishable with a penalty not exceeding five pounds for the first offence, nor exceeding fifty pounds for a second or subsequent offence, together with the publication of the offender's name, place of abode, and offence in any manner that the justice thinks fit.

Adulteration in other countries is strictly prohibited under penal obligations. The Prussian penal code provides that any person selling adulterated or spoiled goods shall be liable to a penalty up to fifty dollars, or imprisonment for six weeks, with confiscation of goods; and it is not necessary to prove that the seller was aware of the adulteration. In Holland, the Dutch law is very similar to the code Napoleon, and inflicts a punishment of imprisonment for from six days to two years, with a fine of from 16 to 600 francs. The adulteration of bread with copperas or sulphate of zinc is dealt with by imprisonment of from two to five years, and a fine of from 200 to 500 florins. In Paris, malpractices connected with the adulteration of food are investigated by the Conseil de Salubrité and punished. Much valuable information concerning the adulteration of food, drink, and drugs in foreign countries has lately been obtained from the various British legations and consulates abroad, through a circular addressed to them from the Foreign Office. These investigations were commenced by the late Earl of Clarendon, and have been continued by Earl Granville. The results have been published in the *Food Journal* for 1870 and 1871; and they are epitomised at page 193 of the journal of the last mentioned date.

Among the adulterations which are practised for the purpose of fraudulently increasing the weight or bulk of an article are the following:—

1. *Adulterations of Milk.*—This is commonly effected by the addition of water—technically termed Simpson; and it is known by the appearance of the milk, the specific gravity of it, the quantity of cream which rises, and the chemical composition of the milk. Good milk has a rich appearance, and a full pleasant taste. Its specific gravity ranges from 1029 (water being 1000) to 1032—the average being 1030. If, therefore, the density of milk is above 1030, other conditions corresponding, the inference is that the sample is unusually good. Between 1028 and 1030 it is most probably genuine. At from 1026 to 1028 it is of doubtful quality, and below that, unless the amount of cream is enormously large, the sample is not genuine. An instrument, called a *galactometer*, has been constructed to show the specific gravity of milk at a glance; but it must always be remembered that while the addition of water tends to lower the gravity of milk, so also does the presence of much cream, and therefore a sample of skimmed milk may show a high gravity even when diluted with water. The percentage quantity of cream is ascertained by means of an instrument called a *lactometer*. It is a glass tube about 10 or 11 inches long and half an inch in diameter, graduated into 100 parts. Having shaken a sample of milk so as to diffuse the cream throughout its bulk, it is poured into the lactometer to the topmost division; and after standing for 12 hours, to allow the cream to rise, the proportion of it is read off from the divisions on the tube. Good milk shows a range of from 8 to 12 divisions. Conjoined with the preceding test, this affords reliable indication of the quality of the sample. After removing the cream, the gravity should be again taken, and this should not be lower than 1030. The chemical composition of milk varies to some extent with the breed of the cow, its age, the diet upon which it is fed, the time of calving, and the time of milking; for afternoon milk is generally richer than morning, and the last drawn than the first. But taking the results of a large number of analyses by different chemists, it may be said that the average percentage composition of milk is as follows:—Casein or cheese matter, 3·64; butter, 3·55; milk, sugar or lactose, 4·70; saline matter, 0·81; and water, 87·30. If, therefore. 1000 grains of milk be treated with a few drops of acetic acid, and then heated in a flask to about 120° Fahr., the casein of the milk will curdle, and enclose within it all the butter. When it is quite cold, it can easily be filtered, and when dry, the curd and butter should weigh from 75 to 85 grains; and the serum or whey should have a density of about 1029. The addition of mineral matter, as common salt or carbonate of soda, to milk is easily recognised by an examination of the ash or saline constitutents. 1000 grains of good milk evaporated to dryness will produce from 120 to 130 grains of solid matter, of which about 8 grains are mineral; and these are left in the platinum capsule, when the solid matter is incinerated or burnt to an ash. Of this ash about half is phosphate of lime, and 2·7 are alkaline chlorides, the rest being phosphates of magnesia and iron, with a little carbonate of soda. Any notable increase, therefore, in the proportion of ash, or any large diminution of it, will show adulteration. Colouring matter, as annatto, &c., is known by the peculiar tint of the milk; and starchy matters boiled to an emulsion will give their characteristic reactions with iodine, and will furnish a sediment which the microscope will reveal. Fatty emulsions, in imitation of milk, were used during the siege of Paris, on the recommendation of M. Dubrunfaut, who claims to have made a very perfect substitute by emulsifying fatty matter with an artificial whey or serum. This he did by dissolving from 40 to 50 grammes of saccharine matter (lactose, glucose, or cane sugar), and from 20 to 30 grammes of albumen (dried white of egg), and from 1 to 2 grammes of the crystals of carbonate of soda, in half a litre of water, and then emulsifying with from 50 to 60 grammes of olive oil or other fatty substance. This is best done at a temperature of from 120° to 140° Fahr.; and the liquid so prepared has the appearance of cream, and requires to be mixed with twice its volume of water to acquire the consistence of milk. Gelatine may be used instead of albumen, the mixture being even more nearly like rich cream than the former. M. Gaudin says that any kind of fat may be used for this purpose, provided it is purified with superheated steam; and M. Fan states that even horse grease may be so employed. M. Dumas, however, is of opinion that none of these substitutes can take the place of milk for any time as dietetical agents. Milk from diseased animals, especially those affected with pleuropneumonia, and the foot-and-mouth disease, is very unwholesome, and ought not to be drunk. The diseased product is recognised by the presence of abnormal inflammatory globules of the nature of pus, and by a large amount of epithelium cells. Preserved condensed milk is now so commonly used for food, that its properties when good should be known. 100 parts of the specimens at present in the market consist of from 14 to 18 parts of casein, from 12 to 14 of butter, from 44 to 52 of sugar, and from 2·4 to 2·7 of saline matter—making in all from 77 to 81 parts of solid matter—the rest, namely, from 23 to 19 parts, being water. It appears, therefore, that the concentration of the milk has been carried to about one-third of its original bulk, and that sugar has then been added, so that when diluted with twice its volume of water, it makes a sweet-tasting milk of ordinary strength. Good cream should contain rom 25 to 34 parts of butter, about 5 of casein, 2 of sugar 2 of saline matter, and from 62 to 56 parts of water.

2. *Coffee* has from very early times been the subject of sophistication. As far back as 1725, the Act 2 Geo. I. c. 30, took cognizance of the practice, and rendered it penal. In 1803 it was the object of very decisive measures, for by 43 Geo. III. c. 129, the officers of excise were empowered to search for, and to seize any burnt, scorched, or roasted peas, beans, or other grains or vegetable substance prepared in imitation of coffee; and any person manufacturing or selling the same was liable to a penalty of £100; gradually, however, it was found that use of torrefied vegetables in lieu of coffee, was becoming general in spite of these restrictions, and, therefore, in 1822, the Legislature (3 Geo. IV. c. 53) thought it expedient to allow the manufacture and sale of scorched or roasted corn, peas, beans, or turnips, by persons who were not dealers or sellers of coffee or cocoa, provided the same was sold under license in a whole or unground condition, and in its proper name. The penalty for infraction of the law was £100 in the case of a dealer in coffee or cocoa, and £50 in that of a licensed dealer. At that time the use of chicory was not generally known in England, although it had long before been introduced into France as a substitute for coffee; and its use was encouraged by the first Napoleon, who thought thus to strike a blow at English commerce. It was also used in Belgium and the Netherlands, so that travellers who visited Paris, Brussels, or Amsterdam, became acquainted with the substitute, and gradually acquired a taste for it. About the year 1820 the first parcels of chicory were imported into this country, and it would seem that the public demand for it gradually increased; for in 1832 there was a minute of the Treasury nullifying the Acts of George III. and George IV., by allowing grocers and other dealers in coffee and cocoa to sell chicory, provided they did not mix it with coffee. At a later period even this restriction was withdrawn; for by the Treasury minute of 1840, dealers in coffee were permitted to sell a mixture of chicory and coffee, provided a duty of 6d. per lb. was paid on all the chicory imported for home consumption. The use of it being thus legalised, it rapidly came into favour, and English farmers found it profitable to cultivate the root, and to send it into commerce duty free. This roused the attention of the Government, for the duties on chicory and coffee began seriously to fall off. Even the quality of the coffee imported underwent a change; for instead of demanding the fine flavoured varieties, orders were given for a coarse and strong description of plantation coffee, which would stand a good deal of chicory, as the grocers phrased it. All this was brought to the notice of the Lords of the Treasury, and in 1852 they revoked the order of 1840. But so strong was the influence of the trade upon Government, that in the following year the offensive minute was withdrawn, and grocers were again permitted to sell mixtures of coffee and chicory, provided the packet was distinctly labelled "mixture of chicory and coffee." The Treasury even went so far in 1858 as to direct the Commissioners of Inland Revenue, not to object to licensed dealers in coffee keeping and selling mangel-wurzel or beet-root mixed with coffee, provided they observed the same conditions as those laid down in the Treasury minute of 1853 as to chicory and coffee. Up to this time the duty on chicory had been merely nominal; but it was gradually increased until, in 1863, it was equivalent to that levied on coffee, and thus the revenue was protected, while adulteration was encouraged. The extent to which this was practised may be gathered from the Annual Reports of Mr Phillips, the principal chemist of the Inland Revenue Laboratory. During the years 1856 to 1862 inclusive, when the dealers in coffee and chicory were visited by the officers of Excise, the average number of samples of coffee annually examined was 3053, and of these 90, or nearly 3 per cent. were adulterated—the range being from 5·1 per cent. in 1856, to 1·8 per cent. in 1862; and the quantity of chicory in the mixture averaged 24 per cent. In 1860 it was 29 per cent. Now, in all these cases the coffee was sold as pure coffee, with no label upon the package; but when the mixtures of chicory and coffee were asked for, 7·3 per cent. were improperly labelled, and the average proportions of chicory ranged from 39·8 per cent. in 1859, to 22·3 per cent. in 1862—the average for the seven years, before the duties were equalised, being 30·7 per cent. In some cases, however, it reached to nearly 90 per cent.—40 to 50 per cent. being common proportions; and to neutralise the peculiar sweetness, and the earthy flavours which such quantities of chicory induced, it was, and still is the practice, to add more or less of the bitter material called "finings," which is a preparation of burnt sugar or caramel. Even chicory itself is now the subject of adulteration with roasted corn, beans, lupin seeds, acorns, horse-chesnuts, peas, pulse (called "Hambro' powder"), mustard husks, coffee husks (called "flights"), and even spent coffee, besides various roots, as carrots, parsnips, mangel wurzel, beet-root, dandelion, &c. It is even said that spent tan and dried bullocks' livers have been employed for the purpose. The tests for these adulterations are the appearances presented by the tissues of the various vegetables when examined under the microscope, and by the fact that infusion of chicory does not become discoloured when it is treated with iodine, as it contains no starchy matters. Ground coffee, also, is of such a greasy nature, from the presence of volatile oil, that when it is thrown upon water, it floats, and does not readily discolour the water; whereas, all the adulterating agents quickly sink in water, and give it a brown porter-like appearance. It is not difficult indeed to separate, in a rough way, the coffee from its adulterating matters by merely stirring a given weight of the mixture in a tumbler of cold water; after a few minutes, the coffee will be found upon the surface of the water, and the other things at the bottom of it. Chemical analysis also readily discovers the fraud. It might be thought that there was safety in purchasing the coffee-berries entire, but a very ingenious machine has been patented for the manufacture of spurious berries out of common vegetable substances.

3. *Tea.*—Formerly, when the supply of tea to this country was entirely under the control of the East India Company, the adulteration of it in China was rarely practised, as every shipment of it was carefully examined by experienced officers at Canton, who rejected all teas of spurious or doubtful character. At that time, therefore, the adulteration of tea was carried on after it was imported into this country, and there were many legislative enactments prohibiting the practice. By the Act 2 Geo. I. c. 3, every tea dealer was subject to a penalty of £100, if he was convicted of counterfeiting, altering, fabricating, or manufacturing tea, or mixing it with other leaves. Later still, the statutes of 4 Geo. II. c. 14, and 17 Geo. III. c. 29, and 4 Geo. IV. c. 14, dealt more precisely with the subject, and imposed other penalties. At that time the adulterations of tea were effected in a wholesale manner; for according to Mr Phillips, of the Inland Revenue Office, there were in London alone, in 1843, as many as eight manufactories in which the exhausted leaves, obtained from hotels, coffee-houses, and elsewhere, were redried, and faced with rose-pink and blacklead, in imitation of genuine tea. More recently, however, the adulteration of tea has been practised by the Chinese, who find no difficulty in disposing of any kind of spurious tea to English merchants at Canton and Shanghai, who ship it to this country, and lodge it in the bonded warehouses with all the formalities of an honourable transaction, knowing that the difficulties of convicting them under the Adulteration of Food Acts and

Nuisances Removal Acts are almost insurmountable; for, in the first place, the local sanitary authorities have no means of obtaining direct information of the existence of unsound or spurious tea, or other article of food or drink in bonded warehouses; and secondly, if such information reaches them indirectly, they have no legal right of entry for the purpose of examining the tea and taking samples. But supposing both of these difficulties have been surmounted, and the tea has been found on analysis to be spurious, there yet remain the difficulties of obtaining a justice's order for its condemnation, an order from the customs for its removal, and an order which will satisfy the requirements of the wharfinger in whose custody it has been placed. But besides these, there are the difficulties of proving the ownership of the article, and the guilty knowledge of the broker who sells it. In illustration of this, we may refer to the proceedings of the sanitary authorities of the city of London in their endeavour to suppress the importation and sale of spurious tea. In the month of March 1870, Dr Letheby, the food analyst for the city, reported that a large quantity of spurious tea had arrived in London from China, and was lodged in the bonded warehouses of the city. It was described as "Fine Moning Congou" from Shanghai; and it consisted of the redried leaves of exhausted tea, much of which had become putrid before drying. It appears to have been called in China "Ma-loo mixture"—Maloo being the name of the street where it was prepared, and along the sides of which heaps of this trash might often be seen drying in the sun, with dogs and pigs walking over it. Proceedings were taken under the Nuisance Removal Amendment Act (26 and 27 Vict. c. 117), for the purpose of obtaining an order for the condemnation and destruction of the tea; but it was argued for the defence—1*st*, That "tea" was not named in the Act of Parliament; 2*d*, That it was not included under the term "vegetable;" 3*d*, That it was not "food;" and 4*th*, That being in a bonded warehouse, it was not "exposed for sale." The case, however, was so glaring that, after two days' hearing, an order was given by the justice for its destruction; but as a case was granted for the opinion of the Court of Queen's Bench, the order was suspended; and as the application to the Court was never made, the order is still in abeyance. In another case, where many chests of spurious "scented orange Pekoe siftings" were in bond, the order for its condemnation was refuted on the ground that there was not sufficient evidence of the so-called tea being unwholesome, notwithstanding that it was not above one-sixth its proper strength; that it had little or none of the active principles of tea; that it had an unpleasant odour and an acrid taste; that a great portion of it was not tea at all, and that the rest of it was composed of exhausted tea leaves, with just enough good tea to give it a flavour. A like failure of justice occurred in the city in 1866, when measures were taken by the sanitary authorities to prevent the sale of about 350,000 lbs. of rotten and charred tea which had been saved from a fire at Beal's wharf. The adulterations practised by the Chinese are numerous; exhausted tea is redried and glazed in a very deceptive manner. Millions of pounds of leaves of different plants, other than tea, are gathered and mixed with it. Mineral matter too in the form of china clay, fine sand, and iron filings, are ingeniously incorporated with the leaf before curling, so that as much as from 20 to 40 per cent. of impurity is thus mixed with it. The tests, however, for these adulterations are very simple. In the first place, there is the usual trade test of infusion: a quantity of tea, amounting to the weight of a sixpence, is put into a small covered cup, and infused with about four ounces of boiling water for ten minutes. The infusion is then poured off from the leaves, and is examined for colour, taste, and odour—all of which are characteristic. The leaves, too, are examined for soundness, for colour, for size, and for special botanical properties. Impurities like iron filings, sand, or dirt, are easily seen among the leaves, or at the bottom of the cup; and when these are placed upon a coarse sieve and washed with water, the impurities pass through, and may be collected for examination. The leaves, too, betray by their coarseness and botanical characters the nature and quality of the tea; for although the leaves of genuine tea differ much in size and form, yet their venation and general structure are very distinctive. Very young leaves are narrow, convoluted, and downy; those next in size and age have their edges delicately serrated, and the venation is scarcely perceptible; while those of larger size have the venation well marked, there being a series of loops along each side of the leaf extending from the mid-rib to the edge: the serrations also are stronger and deeper, beginning a short distance from the stem and running up the side of the leaf to the apex. In addition to this, the microscopic characters of the surface of the leaf are very characteristic. Further investigations of a chemical nature are sometimes needed to determine the question of adulteration; and these depend on the well-known composition of good tea. In different cases, according to the age of the leaf and its mode of treatment, the proportions of its chief constituents may vary; but in a general way it may be said that the average composition of tea is as follows:—Moisture from 6 to 10 per cent.; astringent matter (tannin), from 25 to 35; gum, from 6 to 7; albuminous matters, from 2 to 3; thein, from 2 to 3; mineral matters (ash), from 5 to 6; and ligneous or woody tissue, from 50 to 60 per cent. Green tea, which is generally made out of young leaves, contains the largest quantity of soluble matters; and these, when fully exhausted from the leaves by successive boiling in water, amount to from 25 to 35 per cent. of the weight of the tea. In ordinary cases, when the tea is merely infused in boiling water, it does not yield above 25 per cent. of extractive. Again, the ash of tea is very characteristic of its quality—old and spurious leaves, as well as tea adulterated with mineral matter, yielding more than 6 per cent. of ash. The chief constituents of the ash of good tea are potash and phosphoric acid, with a little lime, silica, and oxide of iron—there being but a trace of chlorine and sulphuric acid; whereas the ash of old and exhausted leaves contains but little potash and phosphoric acid, in proportion to the lime and silica; and in those cases where tea has been damaged by sea water, the amount of chloride is considerable. Iron filings in tea are easily discovered by means of a magnet, there being in some cases as much as 20 or 30 per cent. of this impurity. Even when incorporated with the leaf before rolling and glazing, the fraud is detected by the attraction of the tea to the magnet.

4. *Cocoa* in its natural state contains so much fatty matter (amounting to rather more than half its weight), that it has long been the practice to reduce it by means of sugar or farinaceous substances. The first of these preparations is called chocolate, and the latter is known by such names as granulated, flake, rock, soluble cocoa, &c. In some cases the mixture is adulterated with mineral matters, as oxide of iron, to give colour. These adulterations are recognised by the appearance and taste of the preparation, by its microscopic characters, by the colour and reaction of its solution, and by the proportions of fat and mineral matters in it.

5. *Bread.*—Especial care has been taken at all times to protect the public from the dishonest dealing of bakers. The assize of bread, for example, is a very ancient institution; for it was the subject of a proclamation in 1202, and it was the chief matter referred to in the notable statute of

the Pillory and Tumbrel (51 Henry III. stat. 16) already mentioned. In the city of London, according to "*Liber Albus*," the assize of bread was an important institution. It was always made immediately after the feast of St Michael in each year, and very specific instructions were given for the guidance of the four discreet men who were to perform it; for their decision regulated the business of the baker in respect of the price and quality of bread, &c., for the current year; and woe to him if he disregarded it—there being numerous instances in "*Liber Albus*" of the pillory and the thew in cases where bread had been found adulterated or of short weight. In the time of Anne, the assize of bread was still further regulated (8 Anne, c. 19), and in the year 1815 it was abolished by the statute 55 Geo. III. c. 99. Especial provision, however, was made to guard against the frauds of adulteration, for several Acts of Parliament, especially 31 Geo. II. c. 29 and 1 and 2 Geo. IV. c. 50, prohibited the use of alum and other spurious articles in bread under severe penalties. At the present time, the chief adulterations of bread are with alum or sulphate of copper for the purpose of giving solidity to the gluten of damaged or inferior flour, or with chalk or carbonate of soda to correct the acidity of such flour, or with boiled rice or potatoes to enable the bread to carry more water, and thus to produce a large number of loaves per sack of flour. In practice 100 lbs. of flour will make from 133 to 137 lbs. of bread, a good average being 136 lbs.; so that a sack of flour of 280 lbs. should yield 95 four-pound loaves. But the art of the baker is exercised to increase the number, and this is accomplished by hardening the gluten in the way already mentioned, or by means of a gummy mess of boiled rice, three or four pounds of which, when boiled for two or three hours in as many gallons of water, will make a sack of flour yield at least 100 four-pound loaves. Such bread, however, is always dropsical, and gets soft and sodden at the base on standing, and quickly becomes mouldy. A good loaf should have kindness of structure, being neither chaffy, nor flaky, nor crummy, nor sodden. It should also be sweet and agreeable to the palate and the nose, being neither sour nor mouldy. It should keep well, and be easily restored to freshness by heating it in a closed vessel. And a slice of it, subjected to a temperature of from 260° to 280° Fahr. should hardly be discoloured, and should not lose more than 37 or 38 per cent. of its weight. When steeped in water, it should give a milky sweet solution, and not a ropy acid liquid. The recognition of alum and sulphate of copper in bread requires practice and skilful manipulation, it being surrounded with difficulties. The most easily applied process is that described by Mr Horsley. He makes a tincture of logwood, by digesting a quarter of an ounce of the freshly cut chips in five ounces of methylated spirit for eight hours, and filters. A teaspoonful of this tincture is put with a like quantity of a saturated solution of carbonate of ammonia into a wine-glassful of water; and the mixed solutions, which are of a pink colour, are then poured into a white-ware plate or dish. A slice of the suspected bread is allowed to soak in it for five minutes, after which it is placed upon a clear plate to drain, and, if alum be present, it will, in the course of an hour or two, acquire a *blue* colour; if the tint be *greenish*, it is a sign of sulphate of copper; whereas pure bread gradually loses its pink colour, but never becomes blue or green. The ash of bread will also furnish evidences of the presence of mineral impurities.

6. *Flour and other Farinaceous Matters.*—The tests for good flour are its sweetness and freedom from acidity and musty flavour. A given weight of the flour, say 500 grains, made into a stiff dough with water, and then carefully kneaded under a small stream of water, will yield a tough elastic gluten, which, when baked in an oven, expands into a clean-looking ball of a rich brown colour, that weighs, when perfectly dry, not less than 50 grains. Bad flour makes a ropy-looking gluten, which is very difficult of manipulation, and is of a dirty brown colour when baked. The ash of flour should not exceed 2 per cent. Other farinaceous matters are recognised under the microscope by the peculiar form, and size, and marking of the individual granules. In this way, the adulterations of oat-meal with barley-meal, and of arrow-root with inferior starches, may be easily detected.

7. *Fatty Matters and Oils* are the subjects of frequent adulteration. Butter and lard, for example, are mixed with inferior fats, and with water, salt, and farina. Most of these impurities are seen when the sample of butter or lard is melted in a glass, and allowed to stand in a warm place for a few hours, when the pure fat will float as a transparent oil, while the water, salt, farina, &c., will subside to the bottom of the glass. Fresh butter generally contains a notable quantity of water, as from 12 to 13 per cent., and sometimes a little salt, and a trace of curd; but these should never exceed two per cent. in the aggregate. Foreign fats are recognised by the granular look of the butter, by its gritty feel, by its taste, and by its odour when warmed. Other tests for these impurities are the melting-point of the sample, and its solubility in a fixed quantity of ether at a temperature of 65° Fahr. 20 grains of the sample, treated with a fluid drachm of ether, in a closed test tube, will look slighty flocculent, and be almost entirely dissolved in the case of good butter; but it will be mealy and liniment-like with lard, granular with dripping, and almost solid with mutton fat. The melting point of different fats is as follows:—Horse grease, 140°; calf fat, 136°; mutton fat, 130°; beef fat, 99°; hog's lard, 81°; and butter, 80°.

Oils are adulterated with inferior kinds, and the fraud is detected by means of the specific gravity of the oil, and its chemical reactions when tested upon a white plate with a drop of concentrated sulphuric acid—the colour and its time of development being the indications of the quality of the oil. The specific gravity of the animal oils are as follows:—Neat's-foot oil, 880; tallow oil, 900; dolphin oil, 918; cod-liver oil, 921 to 926; whale oil, 927; seal oil, 934; porpoise oil, 937. Among the vegetable oils the following are the most important:—Rape or colza oil, 913 to 910; olive oil, 918; filbert oil, 916; beech-nut, 922; walnut, 923; cotton-seed, 923 to 928; poppy, 924; sweet almond, 918 to 922; hazel-nut and hemp-seed, 926; and linseed, 634 to 936.

8. *Isinglass* is often adulterated with gelatine, the fraud being ingeniously contrived so as to retain to a large extent the well-known characters of genuine isinglass; but it may be recognised in the following way: immersed in cold water, the shreds of genuine isinglass become white and opaque like cotton threads, and they swell equally in all directions, whereas those of gelatine become transparent and ribbon-like. Isinglass dissolves completely in boiling water, and makes a slightly turbid solution, which has a faint fishy smell, and is without action on litmus paper; whereas gelatine leaves a quantity of insoluble matter, and the solution smells of glue, and has an acid reaction. Strong acetic acid swells up the shreds of isinglass, and renders them soft and gelatinous; but it hardens gelatine. And, lastly, the ash of genuine isinglass is very small in quantity, and has a reddish colour; whereas that of gelatine is bulky (weighing from 2 to 3 per cent.), and has a perfectly white appearance from the presence of calcareous salts. Genuine isinglass is produced from the swimming-bladder or sound of the sturgeon, but gelatine is a sort of clarified glue obtained from bones, clippings of hides, &c. Boussingault states that the Bouxwiller glue, which is prepared from the

bones of horses slaughtered at that establishment, is transparent, and nearly colourless, and is on that account much sought after by restaurateurs for making jellies. It enters largely, too, into the composition of French gelatine.

9. *Sugar.*—During the last ten or twelve years the manufacture of sugar from starch has been an important branch of industry. The product is sent into commerce under the names of glucose, saccharum, and British sugar; and although it is chiefly used for brewing purposes, it is also employed for adulterating brown sugar, and for making confectionary, jams, marmalades, and fruit jellies. In the year 1870, as much as 25,737 cwt. of this sugar was manufactured for home consumption, and since then the quantity has been increasing. It is produced from rice or other starch, by submitting it to the action of very dilute sulphuric acid at a boiling temperature—the acid being afterwards neutralised with lime, and the solution evaporated to the setting point. The crystals of grape sugar are very small, and are entirely without that sparkling character which distinguishes cane sugar. They are less soluble in water, but more so in alcohol, than cane sugar, and they have only about one-third the sweetening power. Boiled with a solution of caustic potash, they quickly produce a deep brown liquid, and they have the power of reducing the hydrated oxide of copper, when heated therewith in an alkaline solution. These characters are distinctive of it, and will serve to recognise it in the brown sugars of commerce.

10. *Mustard* is generally so acrid and powerful in its flavour that it is commonly diluted with flour, or other farinaceous matter, turmeric being added to improve its appearance. The mixture is recognised by means of the microscope, when the granules of starch and the colouring matters of turmeric are easily seen. Genuine mustard does not contain starch, and therefore does not become blue when it is treated with a solution of iodine.

11. *Spices*, as pepper, cinnamon, curry powder, ginger, cayenne, &c., are more or less the subjects of fraudulent adulteration, which can readily be detected by the microscope, and by an examination of the mineral constituents. Formerly, pepper was ground by the retail dealer, and then there was no excuse for the presence of adulterating agents; but in 1856, the wholesale dealer undertook the business of grinding, and from that time adulteration has been on the increase. In some cases, the article does not contain a trace of pepper, but is made up of gypsum, mustard husk, and a little starch. In the *Ninth Report of the Commissioners of Inland Revenue*, there is a statement by Mr Phillips, the chief chemist of the Excise, that he found a sample of so-called pepper containing 25 per cent. gypsum, the rest being mustard husks and a little cereal starch, without a trace of pepper. Another sample consisted of 16 per cent. gypsum, 44 mustard husks, a little cereal starch, and the rest pepper. Four other samples, closely resembling pepper, so as to deceive an inexperienced eye, were found to contain about 22 per cent. of gypsum, with sand, starch, and mustard husk. Linseed meal and powdered capsicums are likewise used for adulterating pepper. The chief sophistications of ginger powder are sago-meal, ground rice, and turmeric; while the colouring agents of curry powders and cayenne are ferruginous earths, brick dust, and even vermilion and red-lead. Spices, too, are sometimes exhausted of their active properties before they are ground and sold to the public.

12. *Beer, Ale, and Porter.*—The assize of ale is contemporaneous with that of bread, being described as the "*Assisæ Panis et Cervesiæ*," in old documents. In the statute 51 Henry III. c. 16 (1266), they are spoken of as ancient and well-known institutions, the object of them being to regulate the quality and price of these articles. The officers appointed to determine the goodness of ale were called "ale conners," or "ale tasters" (*gustatores cervisiæ*), and were elected annually in the court-leet of each manor, and in the city of London at the ward-mote, according to the advice and assent of the alderman and other reputable men of the ward. Very specific instructions are given in *Liber Albus* of the business of the brewer, and of the penalties for any default thereof—it being ordained that no ale should be sold without having been tasted and approved by the ale conners of the district. Even now these officers are elected in the city of London with the old formalities, but the real duty of examining the quality of ale, beer, and porter has for many years been in the hands of the Excise. As far back as the time of Anne there was a law prohibiting the use of *Cocculus indicus* or any unwholesome ingredient in the brewing of beer, under severe penalties, the brewer being restricted to the use of malt and hops alone; but gradually, as the taste for porter came into fashion (since 1730), and during the French war, when the price of malt was very high, certain colouring matters prepared from burnt sugar were allowed to be used, and this at last became so necessary to the trade, that it was legalised by the Act 51 Geo. III. c. 51. Five years after, however, it was prohibited by the statute 56 Geo. III. c. 58, which declared that after the 5th of July 1817, no brewer, or dealer, or retailer of beer, shall receive, or use, or have in his possession or custody, any liquor, extract, or other material or preparation, for the purpose of darkening the colour of worts or beer, other than brown malt. He was also prohibited from using molasses, honey, liquorice, vitriol, quassia, *Cocculus indicus*, grains of paradise, guinea pepper, or opium, or any extract or preparation of the same, or any substitute for malt or hops, under a penalty of £200; and no chemist or vendor of drugs was permitted to sell, send, or deliver any such things to a brewer or retailer of beer under a penalty of £500. Later still, in 1830, the Act for permitting the general sale of beer and cider by retail in England (1 Will. IV. c. 64), declares that if any person so licensed shall knowingly sell any beer, ale, or porter, made otherwise than from malt and hops, or shall mix, or cause to be admixed, any drugs or other pernicious ingredients with any beer sold in his house or premises, or shall fraudulently dilute or in any way adulterate any such beer, &c., shall for the first offence forfeit and pay a sum of from £10 to £20, and for the second offence shall be adjudged disqualified from selling beer, ale, or porter for two years, or forfeit a sum of from £20 to £50; and the same regulations applied to cider and perry. The execution of these acts rested with the Excise, and it would seem that three classes of adulterations were practised, namely, 1*st*, Those which gave fictitious strength to the beer, as *Cocculus indicus*, tobacco, opium, &c.; 2*d*, Those which improved the flavour and body of the beer, as grains of paradise, capsicum pods, ground ginger, coriander seeds, caraway seeds, sweet flag, liquorice, molasses, and salt; and, 3*d*, Those which gave bitterness, as quassia, chiretta, horehound, gentian, &c. In London the publicans were not in the habit of practising the first kind of adulteration, but confined themselves to the second and third. In the country, however, according to Mr Phillips, it was quite otherwise, especially with brewers who retailed their own beer; for he found that they frequently used tobacco and *Cocculus indicus*. He even thinks that the cases of brutal and purposeless violence which were so often recorded were referable to the maddening influence of these ingredients. By the Act 24 and 25 Vict. c. 22 (1863), when the duty on hops was relieved, these bitters and substitutes were permitted, and so also was sugar, provided the full duty of 12s. 8d. per cwt. was paid upon it. Later still, by the Licensing Act 1872 (35

and 36 Vict. c. 94), provision is made to protect the public from the adulteration of beer; for it prohibits the possession, sale, or use of beer adulterated with *Cocculus indicus*, chloride of sodium (otherwise common salt), copperas, opium, Indian hemp, strychnine, tobacco, darnel-seed, extract of logwood, salts of zinc or lead, alum, and any extract or compound thereof, under a penalty of £20 for the first offence, and £100 for the second offence, together with disqualification of both the dealer and the house for a certain period. The police and the officers of Inland Revenue are empowered to search for and obtain samples of such beer, and the analyst is a person appointed by the Excise. The tests for the adulteration of beer, ale, and porter, are not easily applied except by a skilled chemist; but it may be said that the chief qualities of good beer are its density, sweetness, spirituosity, piquancy, flavour, and frothiness. The density of ale and beer ranges from 1008 to 1020 (water being 1000)—the average being 1015; and in the case of porter it ranges from 1015 to 1020. The amount of alcohol in these beverages ranges from 5 to 9 per cent., the average being about 7. The solid extract is from 4 to 6 per cent., and the ash or mineral matter is from 0·2 to 0·3 per cent. very little of which should be common salt.

13. *Malt.*—The Excise do not permit malt to be adulterated with ungerminated grain; but it is very difficult to determine whether the presence of these grains is accidental or otherwise, as in some wet seasons when barley is badly stacked it will heat or become mouldy, and the grains will lose their vitality. Even if the grain is dried artificially at a temperature of from 140° to 150° Fahr., the vitality of the seed will be destroyed. In some seasons as much as from 34 to 70 per cent. of the grain will be killed. Roasted unmalted grain, instead of the malted, is prohibited by 19 and 20 Vict. c. 34, but there is no doubt that the substitution is largely practised.

14. *Wine and Spirits.*—The denunciations in the Scripture against the use of mixed wine have reference, in all probability, to wines which were fortified or adulterated with stimulating and intoxicating herbs. In this country measures were taken at a very early period to prevent the sale of unsound and unwholesome wine. The Vintners' Company, for example, which was incorporated in the reign of Edward the Third, under the name of the "*Wine Tonners*," had control over the price and purity of the article, there being chosen every year "persons of the most sufficient, most true, and most cunning of the craft (that hold no taverns)," who were to see to the condition of all wines sold by retail, and who were to govern the taverners in all their proceedings. Bad or adulterated wine was thrown into the gutters, and the possessors thereof were set in the pillory. It would seem that the wine which was most adulterated was that called Gascoign; for in the tenth year of the reign of Henry the Sixth (1432), there was a petition to the king on the subject, praying him to amend the same. Stowe, in fact, says "that in the 6th of Henry VI., the Lombardes currupting their sweete wines, when the knowledge thereof came to John Ranwell, maior of London, he, in divers places of the citie, commanded the heades of the buts and other vessels in the open streetes to be broken, to the number of fifty, so that the liquor running forth passed through the citie like a stream of raine water, in the sight of all the people, from whence there issued a most loathsome savour." In modern times the art of adulterating wine has been brought to great perfection; for it consists not merely in the blending of wines of different countries and vintages, but in the use of materials which are entirely foreign to the grape. Port wine, for example, is manufactured from Beni Carlos, Figueras, and red Cape, with a touch of Mountain to soften the mixture and give it richness—the body and flavour being produced by gum-dragon, and the colour by "*berry-dye*," which is a preparation of German bilberries. To this is added the washings of brandy casks ("*brandy cowe*") and a little salt of tartar to form a crust. Sherry of the brown kind and of low price is mingled with Cape and cheap brandy, and is flavoured with "brandy-cowe," sugar-candy, and bitter almonds. If the colour be too high it is lowered by means of blood, and softness is imparted to it by gum-benzoin. Pale sherries are produced by means of plaster of Paris or gypsum, by a process called "plastering," and the effect of it is to remove the natural acids (tartaric and malic), as well as the colour of the wine. In this way a pale, dry, bitter, and sub-acid wine is produced, charged with the sulphates of lime and potash. Large quantities of what are called clarets are manufactured in this country from inferior French wine and rough cider, the colour being imparted to it by turnsol or cochineal. Madeira is produced from Vidonia with a little Mountain and Cape, to which are added bitter almonds and sugar. Even Vidonia and Cape are adulterated with cider and rum—carbonate of soda being used to correct the acidity. Common Sicilian wine is transformed into Tokay, Malaga, and Lachryma Christi. Champagne is produced from rhubarb stalks, gooseberries, and sugar, the product being largely consumed at balls, races, masquerades, and public dinners. Of late, too, since the investigations of Petiot, Thenard, Gall, Hussman, and others, the manufacture of wine from sugar and the refuse husk or mark of the grape has been largely practised, insomuch that a great part of the wine of France and Germany has ceased to be the juice of the grape at all. In point of fact, the processes of blending, softening, fortifying, sweetening, plastering, &c., &c., are carried on to such an extent that it is hardly possible to obtain a sample of genuine wine, even at first hand; and books are written on the subject, in which the plainest directions are given for the fabrication of every kind of wine, there being druggists called "brewers' druggists," who supply the agents of adulteration. These are as follow:—Elderberry, logwood, brazil-wood, red saunders-wood, cudbear, red beet-root, &c., for colour; litharge, lime or carbonate of lime, carbonate of soda, and carbonate of potash, to correct acidity; catechu, logwood, sloe-leaves, and oak-bark, for astringency; sulphate of lime, gypsum, or Spanish earth, and alum for removing colour; cane sugar for giving sweetness and body; glucose or starch sugar for artificial wine; alcohol for fortifying; and ether, especially acetic ether, for giving bouquet and flavour. The tests for these agents are not readily applied, except by the professional chemist; but they are promptly recognised by the stomach and the brain, for good wine, though it may intoxicate, rarely leaves a disagreeable impression. In a general way, it may be said that the specific gravity of genuine wine ranges from 991 to 997; and the amount of alcohol in it never exceeds 20 per cent. by volume. The solid residue in it, when evaporated to perfect dryness, amounts to from 1·33 to 2·15 per cent. in Rhine wines, and in the light wines of France; to from 2·85 to 3·73 per cent. in Teneriffe and Cape; to from 3·49 to 4·54 per cent. in sherry and Madeira; and to from 3·75 to 5·24 in port. Sweet wines, as Lachryma Christi, Muscat, Malaga, Tokay, Bergerac, champagne, and the wines of the Palatinate, contain a much larger percentage of solid matter in them. The ash, or involatile constituents of wine, should range between 0·19 and 0·5 per cent. It should be strongly alkaline, and should consist of carbonate, sulphate, and phosphate of potash, chloride of sodium, carbonate of lime, and a little alumina. As a distinctive mark of genuine wine, the ash is of the greatest value. Again, pure wine gives but slight precipitates with oxalate of ammonia, with acid nitrate of silver, and acid nitrate of baryta. The

colouring matters of wine may be separated and analysed by the process of Mulder, which is too elaborate for description in this place, and so also are the tests for recognising spurious colours, as the test of Vogel, Jacob, and others (solutions of acetate of lead), that of Pelouze and Frenny (basic acetate of lead); of Ness von Esenbeck (solutions of alum and of carbonate of potash); of Batilliat (ammonia); of Filhol (ammonia and sulphide of ammonium); and others. At present, the spectroscope has not furnished, as was expected, any very reliable indications of the nature of the colouring matters of wine. In fact, the whole subject requires fuller investigation. The adulteration of spirits consists mostly in the addition of water and in the use of inferior spirit, recipes being given in the *Publican's Guide*, and other such books, for what is called making up spirits for sale. The recognition of these frauds rests with the Excise, under the Act 35 and 36 Vict. c. 94.

15. *Tobacco and Snuff.*—The adulteration of these articles is prohibited and otherwise provided for by the statutes 5 and 6 Vict. c. 93, and 25 and 26 Vict. c. 7, and 30 and 31 Vict. c. 90. manufacturers of tobacco and snuff being prohibited from using or having in their possession sugar, honey, molasses, treacle, leaves, herbs, or plants, powdered wood, moss, weeds, sea-weeds, or any ground or unground roasted grain, chicory, lime, sand. umbre, ochre, or other earths, nor anything capable of being used to increase the weight of tobacco or snuff, under a penalty of £200—water alone being allowed in the manufacture of tobacco; and water, salt, and alkaline salts, as well as lime in the manufacture of snuffs, under a penalty of £300. But it appears from the reports of the Commissioners of Inland Revenue, that the adulteration of tobacco and snuff is still largely practised. Tobacco is adulterated with molasses, sugar, aloes, liquorice, gum, catechu, oil and lamp-black, alum, tannic acid and iron, logwood, and such leaves as rhubarb, chicory, cabbage, burdock, colts-foot, and excess of salt and water. In the year 1862 it was discovered that certain Irish manufacturers were adulterating their Cavendish and roll-tobacco with liquorice, in imitation of the sweetened Cavendish of North America, and therefore in 1863 the practice was legalised in the case of Cavendish and negro-head by the Manufactured Tobacco Act, 1863. Snuffs are adulterated with excess of alkaline salts, lime, sand, ferruginous earths, fustic, torrefied oat meal, peat-moss, ground velonia cups, bichromate of potash, and chromate of lead. Mr Phillips states, in the *Fourth Report of the Commissioners of Inland Revenue*, that up to 1856 the practice of adulterating snuff was very prevalent, particularly in Ireland—52 per cent. of the samples analysed being found to be illicit; in 1858 and subsequently, however, the proportion has been much less. These adulterations are recognised by drying the sample, and noting the loss of weight, and by the amount and nature of the ash left on incineration. Foreign leaves, &c., are discovered by the aid of the microscope.

16. Among the adulterations which are practised for the purpose of improving the appearance of the article, and giving it a false strength, are the following:—The addition of *alum* or *sulphate of copper* to bread; the facing of black tea with *black lead*, and of green with a mixture of *indigo* or *Prussian blue* with *turmeric* and *china clay;* the treatment of pickles and preserved fruits with a *salt of copper*, which has the property of mordanting and brightening the green colouring matter of vegetables. In some cases the quantity of copper has been so large as to give a coppery appearance to a steel knife or fork kept in the pickle; but at all times the metal may be discovered by the pink colour of the ash, and by its becoming blue when treated with a little strong ammonia. *Ferruginous earths* are added to sauces anchovies, potted meats, and the preparations of cocoa. This also is recognised by the amount and colour of the ash. *Mineral pigments*, as yellow and orange *chromate of lead*, green *arsenite of copper*, &c., are frequently used in colouring confectionery, and have produced serious results to those who have eaten it. Lastly, with a view of giving false strength to the article, *sulphuric acid* has been added to vinegar and lime-juice; *black jack* or *burnt sugar* to coffee and chicory; *catechu* or *terra japonica* to exhausted tea; *Cocculus indicus* to beer and porter; cayenne and mustard husks to pepper, &c.

17. Adulterations are also practised for the purpose of debasing the article, as when the cream is taken from milk by the process of skimming; or when the active principles of spices, &c., have been removed by distillation.

18. Accidental adulterations may occur from the admixture of darnel or ergot with flour: siliceous and earthy matters with substances that are ground in a mill; mould or acari with flour, sugar, cheese. &c.; and copper, zinc, or lead may be accidentally derived from the vessels in which any acid substance or liquid has been prepared or kept. In this manner cider and wine have become tainted with lead; sour milk with zinc; and jellies, jams, and preserves with copper.

19. *Adulteration of Cattle Foods.*—In a recent trial, where the question of adulteration was raised, a linseed-cake maker stated in evidence that his ordinary oil-cake consisted of 50 parts ground sesamé cake, 20 parts of bran. and 30 of linseed and linseed siftings. To prevent the detection of this fraud by an examination of the cake with the naked eye, it is customary to powder the materials very fine by means of a machine called a "Buffein machine," after which they are thoroughly mixed together and pressed into a cake. It would seem, indeed, that pure linseed cake is not saleable, except in a few localities, as in the neighbourhood of Gainsborough, and in the agricultural centres of Lincolnshire and Norfolk, where the genuine cake is appreciated. Elsewhere the adulterated article commands a ready sale, on account of its low price; and thus encouragement is given to the use of all sorts of adulterating agents, as earth-nut, cotton, beech, and sesamé bran, rice-husks, oat-dust, and other such worthless matter. Very recently this important subject has been treated by Dr Voelcker in a paper "On the Characters of Pure and Mixed Linseed Cakes," which was published in the *Journal of the Royal Agricultural Society of England* (vol. ix. part 1). Some of the impurities of linseed cake may be due to the accidental presence of the seeds of various weeds and wild plants, which the careless farmer has allowed to grow upon his land. Most of these, however, are easily removed by one or two siftings, as in the case with clean linseed; but the siftings are not thrown away; they are used for adulterating other samples of linseed—making the second, third, and even fourth qualities of Riga and St Petersburg seed. Occasionally the siftings are sent out to sea in barges to meet the vessels coming from the north with linseed on board; there the mixture is made; and when the vessels reach the port for which they are destined, the cargo is sold for genuine linseed "as imported." But besides these impurities, the linseed cake of commerce contains a large proportion of other cakes, as rape, earth-nut, decorticated and undecorticated cotton seed, beech-nut, hemp-seed, cocoa-nut, cocoa, palm-nut, palm-kernels, niger seed, sesamé or teal seed, poppy, castor oil, bassia, curcas, indigo seed, olive, &c., besides bran, acorns, careb-beans, and the husks or shades of earth-nut, oats, barley, rice, and other refuse. Some of these things are actually poisonous to cattle, as in the case of castor-oil cake, curcas bean, purging flax, wild mustard, wild radish, &c.; others are of doubtful quality, as corn cockle, darnel, indigo seed, earth-nut, &c.; and many are disagreeable to the taste, on

account of rancidity and other properties, as cocoa-nut cake, palm-nut cake, bassia cake, &c.; while many are so charged with woody matters as to be indigestible and irritating in their action, as cotton, olive, palm-nut, husks of rice, cocoa-nut fibre, saw-dust, &c. These impurities are sometimes easily recognised by the naked eye, or by a lens of low power. At other times the colour of the cake is an indication of its impurity. The taste of it also is frequently characteristic; for while linseed has a sweet mucilaginous taste, rape seed is turnipy, mustard acrid, dodder like garlic, bassia bitter, &c. Then, again, the action of a little warm water will develope the flavour of impurities—rape giving off a strong odour of turnip, mustard its well-known acrid flavour, wild radish and other impurities their characteristic smells. When examined chemically it is found that adulterated and dirty cakes show a deficiency of oil and albuminous matter, and a large excess of woody fibre and mineral substance. In good cake the moisture ranges from 10 to 14 per cent., the oil from 10 to 15, the albuminous matter from 25 to 35, the mucilage, sugar, and digestible fibre to from 20 to 30 per cent., the woody fibre to from 9 to 14, and the mineral matter or ash to from 6 to 8 per cent. Cake that has been shipped too fresh is apt to heat and become mouldy; in which case it will lose its fine aroma, and be of inferior quality: it may even be injurious to animals feeding on it.

20. *The Adulteration of Seeds*, in fraud of her Majesty's subjects, and to the great detriment of agriculture, has been provided for by the Act 32 and 33 Vict. c. 112, wherein it is prohibited to kill, dye, or to sulphur seeds, or any way to give them a false appearance, under a penalty of £5 for the first offence, and £50 for the second. But for all this extensive frauds are practised: turnip seed is adulterated with rape, wild mustard or charlock, the vitality of which has been destroyed by kiln-drying at a high temperature; old turnip seed (kiln-dried) is also used for diluting fresh seed; and it is notorious that such seed can be obtained in commerce by the ton. Again, clover seed is often killed and dyed—one of the commonest frauds being to dye trefoil, and to sell it for red clover; the pinkish or yellowish-brown tint and metallic look being given with a weak solution of logwood and alum, or with a strong solution of logwood alone, and then it is shaken up with a little black lead. Another trick is to dye white clover seed with a weak solution of indigo, and thus to make it look like hybrid clover which has a bluish-green colour. When trefoil and white clover seed have become changed by age and have lost their yellowish colour, they are dyed with infusion of turmeric, and then toned down with the fumes of burning sulphur; in fact, these fumes are used to brighten up all sorts of seeds that have become brown by keeping, but they destroy the vitality of the seed.

21. *Adulteration of Drugs.*—This at all times has been considered a serious offence. In the city of London, the president and censors of the College of Physicians have power to search for apothecaries' wares, drugs, and stuffs, and on finding them defective, corrupted, and not meet nor convenient to be ministered in any medicines for the health of man's body, they are to destroy them, and are to correct and punish the offenders by committing them to prison, and amercing them in a penalty not exceeding £20. These wholesome powers were granted to the college by the Acts 14 and 15 Hen. VIII. c. 5, and 32 Hen. VIII. c. 40, and 2 Mary, c. 9; but although they are still in force, and might be advantageously exercised, yet they have long since fallen into disuse; and if it had not been for the laudable efforts of the Pharmaceutical Society of Great Britain, there would have been no practical remedy for the adulteration of drugs. The Society was founded in 1841, for the purpose of advancing the status and education of those who were engaged in the preparation and sale of medicines, and it was incorporated by Royal Charter in 1843. A few years after, in 1852, the qualifications of pharmaceutical chemists were regulated by Act of Parliament (15 and 16 Vict. c. 56), and in 1868 it was further provided, by the 31 and 32 Vict. c. 121, that no person should be permitted to engage in the sale or dispensing of medicines, or to use the title of chemist and druggist, or dispensing chemist, or pharmaceutist, without being duly qualified, and registered as a pharmaceutical chemist. The adulteration of medicine was also prohibited by the incorporation of the Adulteration of Food and Drink Act 1860 (23 and 24 Vict. c. 84), it being declared that such adulteration should be deemed an admixture injurious to health. More recently, in 1872, the Act 35 and 36 Vict. c. 74, renders it penal for any one to adulterate a drug for sale, or to sell such drug. In the first case the penalty is a sum not exceeding £50, together with the costs of the conviction; and for a second offence he shall be guilty of a misdemeanour, and be imprisoned for a period not exceeding six calendar months, with hard labour. In the second case, the seller of an adulterated drug is subject to a penalty not exceeding £20, together with costs; and for a second offence he shall have his name, place of abode, and offence published in any manner that the justice thinks fit. The chief adulterations and debasing of drugs are the following:—In the case of vegetable substances, as jalap, opium, rhubarb, cinchona bark, &c., foreign substances are added to make up for the loss of weight in drying and powdering, there being in many cases a trade allowance of only four per cent. for such loss, whereas in almost all cases it exceeds this. Roots, seeds, and barks, for example, lose from 6 to 9 per cent., scammony 7 per cent., aloes 9, sarsaparilla 10, squills 12, and opium from 15 to 25 per cent. At other times foreign substances are added to assist the grinding, or to improve the appearance of the article. Occasionally the active principles are removed, or the medicine has become worthless from keeping or from faulty preparation. In the case of the alkaloids, inert substances, as sugar, starch, gum, &c., are mixed with them to increase their weight and bulk. Lastly, the activity of a vegetable drug may greatly depend on its mode and place of culture. With respect to mineral preparations, there is even a still larger field for adulteration, insomuch that the purity of the article is entirely regulated by the wholesale price of it. Again, directly after the Act of 1856 (18 and 19 Vict. c. 38), which permitted the sale of methylated spirit—that is, inferior spirit mixed with wood-naphtha, duty free for manufacturing purposes—advantage was taken of it by many chemists and druggists, and the cheap spirit was used for making tinctures and other medicinal preparations. This, however, came at last to be so serious and dangerous a practice, and was withal so great a fraud on the revenue, that means were taken to suppress it by the Act 29 and 30 Vict. c. 64, wherein it is provided that such spirit shall not be used in any medicinal preparation, except in the manufacture of chloroform, ether, and the vegetable alkaloids, or in the preparation of other things whereby the spirit was afterwards entirely dissipated. But Mr Phillips remarks, in the *Ninth Report of the Commissioners of Inland Revenue*, that a few instances have been discovered of the sale of drinks under the names of "Indianna brandee," "medicated whiskee," "pure Islay mountain," "Indian tincture," &c., the exciting principle of all of which was found to be hyponitrous ether prepared from methylated spirit. In the case of a drink called "Hollands whiskee," it was produced by distilling the methylated spirit with a little nitric acid, and then sweetening with treacle, and flavouring with rhubarb, chloroform,

fœnugreek, &c., so as to conceal its real character; and notwithstanding its disagreeable flavour, it got into public favour in some districts, especially in Ireland, and was largely sold as a cheap means of producing intoxication.

22. *The Adulteration of Textile Fabrics.*—Woollen goods have for years past been largely adulterated with refuse fibres called "shoddy" or "mingo." The practice was denounced by Latimer in one of his sermons at Paul's Cross, preached before king Edward in 1635, wherein he spoke of it as the devil's artifice, saying that they were wont to make beds of flock, but now they had turned it into dust, which he aptly called "Devil's dust," and that the cloth worker did so incorporate it to the cloth that it was wonderful to see. The practice is still in vogue, for there is hardly a piece of cheap cloth without it. Shoddy as originally used was merely the fluff or waste from the looms, but now it consists of any kind of woollen rubbish, as old blankets, stockings, &c., pulled to pieces in a machine called the "Devil." Mingo is even a shorter description of fibre, and is made in the same way from old rags. No less than forty millions of pounds of these are made annually in Yorkshire, at an estimated value of eight millions sterling, and all of it is used for adulterating woollen cloth. There is even another kind of refuse called "extract," which is employed for the same purpose. It consists of the wool obtained from the rags of mixed goods; that is, goods which have a cotton or linen warp blended with wool. The cotton is destroyed by chemical agency, chiefly by means of dilute sulphuric acid, and the wool is left intact.

The cotton fabrics and gray goods of Lancashire and Yorkshire are largely adulterated with size and china clay, the object being to give them increased weight and substance. Up to about twenty years ago the sizing of cotton goods was effected with a mixture of fermented flour, paste, and tallow, by which means the tenacity of the warp was increased and the friction of weaving was lessened. To effect this about 20 per cent. of size was used; but in 1854, when tallow became dear in consequence of the Russian war, a substitute was found in china clay. Later still in 1862, when the cotton famine began to be felt, and the long-fibred American cotton grew scarce, it was found necessary to give tenacity to the twist made from shorter fibre by using more size. In this manner as much as from 50 to 90 per cent. of size has got to be used, the greater part of it being china clay, with a certain proportion of hygroscopic matter, such as chloride of magnesium, to keep the material damp and supple. The impurity is easily detected by washing the cloth, and ascertaining the loss of weight before and after the operation. Cheap calicoes are also largely impregnated with lime, which has been used in the process of bleaching, and left in them. A cloud of dust flies out of such fabrics when they are torn. Silk also is made heavier and stouter by the incorporation of dye stuffs used expressly for the purpose. This is generally the case with dark-coloured silks, black and brown, as lighter shades will hardly admit of it; as much indeed as half the weight of the silk may be thus incorporated with it.

23. *Falsification of Coin and Precious Metals.*—In Anglo-Saxon times the debasing or counterfeiting of coin was punished by the loss of the hand. In later times it has been criminal in the highest degree. By the statute 24 and 25 Vict. c. 99, the counterfeiting of gold or silver coin is felony, and in Scotland is a high crime and offence. Hardly less severe is the punishment for debasing, diminishing, lightening, or impairing the value of the current coin of the realm; and very effectual means are taken to secure their standard value when put into circulation. In the first place, an officer is appointed by the Crown to superintend the coinage, and to be answerable for its goodness. (See MINT and COINAGE.) In the second place, the coin is tested, as to its weight and fineness, by persons skilled in the goldsmith's craft. (See ASSAY.) But notwithstanding this, the coins of the realm, as issued from the mint, have often been debased to a considerable extent; for, according to Lord Liverpool, the total debasement of the silver money of this country, from the time of the Conquest to the reign of Elizabeth, was not less than 65 per cent. It is notorious that in Spain, Austria, and Turkey the degradation of the silver coin, even at the present time, is carried to a serious extent. By the Coinage Act 1870 (33 and 34 Vict. c. 10) the composition and weight of all the coins of this country are strictly provided for; and in the case of gold coin, the limits or "remedy" of fineness and weight are exceedingly narrow. The composition of the coin is fixed at eleven-twelfths fine gold, and one-twelfth alloy (copper); so that in 1000 parts of our gold coin there are 916·66 parts of fine gold. This is called its millesimal fineness, and the allowance for error in composition is limited to 0·002 per 1000 parts. The weight of the sovereign is fixed at 123·27447 grains, and the limit of error in weight is the 0·2 of a grain; and in proportion with all other gold coins. In the case of silver coins, the composition is thirty-seven fortieths of fine silver, and three-fortieths of alloy (copper) —the millesimal fineness being therefore 925 parts of silver; the remedy or allowance of fineness is just twice that of gold—namely, 0·004 per 1000 parts. The weight of the silver coin is at the rate of 87·27272 grains per shilling of value; and the remedy or allowance of error is confined to 0·36363 of a grain per shilling. Lastly, the bronze coinage of the country consists of 95 parts copper, 4 tin, and 1 zinc: the weight of a penny being 145·83333 grains; and the allowance for error is 2·91666 grains per penny. The specific gravity of the several descriptions of coin is 17·53 for gold, 10·35 for silver, and 8·89 for bronze. So accurate are the composition and weight of the coins issued from the mint at the present time, that at the last trial of the "Pyx" in July 1871, the jury reported that every piece separately examined (representing many millions sterling) was found to be accurately coined in regard to weight and fineness. In the case of the gold coin, the fineness ranged from 916·2 to 917 parts per 1000. These, indeed, were the extremes of only 2·66 per cent. of the coins examined, the great bulk of them, namely 72·65 per cent. having a fineness of from 916·5 to 916·7 per 1000. Now, when it is considered that the composition of an alloy of gold and copper can be ascertained to the one-ten thousandth part, and that the delicacy of a balance is to the thousandth part of a grain, it must be evident that the accuracy and perfection of coining in this country are remarkably precise. As, however, the weight of gold and silver coin must become less by continual wear, the Acts 22 and 25 Vict. c. 99, and 33 and 34 Vict. c. 10 provide for it. It does not appear that the practice of debasing coin is carried on to any great extent in this country; for in the second Annual Report of the Deputy-Master of the Mint (1871), the chemist of the Mint (Mr W. Chandler Roberts) says that only two sovereigns were submitted to him, the weight of which had been fraudulently reduced by means of a solvent, aided by electricity. In former times, however, the process of "sweating" was very frequently employed.

The adulteration of precious metals was prohibited and provided for by the rules and regulations of the various guilds and corporations which took cognizance of the goldsmiths' craft. As early as the 26th of Henry II. (1180) the Goldsmiths' Company of London was founded, and in 1327, when it was incorporated, it was invested with the privilege and power of inspecting, trying, and regulating all gold and silver wares throughout the kingdom, and of punishing all offenders who were found guilty of working adulterated gold or silver. The chief offenders appear to have been the cutlers, who were charged with covering base metal in such a manner that it could not easily be detected. It was therefore provided that all manner of vessels of gold and silver should be of "good and true alloy;" and power was given to the company to "go from shop to shop to assay if the gold was good," and finding that it was not of the right touch, it was to be seized and forfeited for the king. Subsequently, by the statute of 2 Henry VI. (1424), it was provided that none should work gold unless it be as good as the alloy of the "mystery," and that silver wares should be as good or better than the king's coin. It was further provided, that when the goods were finished they should be brought to the Hall to be assayed; and when found of the right touch it should be stamped with the owner's and assayer's marks, as well as with the "Liberdshede crowned." These powers have been confirmed in numerous Acts of Parliament, the most important of which are the following:—12 Geo. II. c. 26 (1739), which provides that no goldsmith, silversmith, or other trader shall work or make any vessel of gold of less than 22-carat fineness (that is, 22 parts of fine gold to 2 parts of alloy), nor any silver vessel or plate of less than eleven ounces and two pennyweights of fine silver, and 18 pennyweights of alloy, in a pound troy, under a penalty of £10. But this does not extend to jewelry, earrings, gold springs, lockets, &c. It also provides for the proper assaying and stamping of the same. In 1784, the Act 24 Geo. III. c. 53, made provision for imposing a duty on the article assayed and stamped, and from that time the king's or queen's head has appeared as a mark. In 1798, the Act 38 Geo. III. c. 69, gave permission for a lower standard of gold, namely 18-carat gold (that is, 18 parts of fine gold to 6 of alloy); and by the Act 7 and 8 Vict. c. 22 (1844), the penalty for using false stamps, &c., was ameliorated. Lastly, by the Act 17 and 18 Vict. c. 96, three still lower standards of gold were permitted, namely 15-carat gold, 12-carat gold, and 9-carat gold, each of which was to be designated by the number and the decimal. At present, therefore, all gold and silver plate, as well as wedding and mourning rings, must be assayed and stamped before their sale; and other articles may be assayed and stamped in like manner at the option of the maker or dealer. The stamps or marks impressed on gold are the following, namely,—1*st*, The initials of the maker's name; 2*d*, The duty mark (a king's or queen's head); 3*d*, The crown and standard number, indicating the quality of the gold; 4*th*, The assayer's stamp (a leopard's head for Goldsmiths' Hall); and 5*th*, The letter denoting the year of assay. In the case of silver, the stamps are—1*st*, The initial letters of the maker; 2*d*, A lion; 3*d*, The assayer's stamp (in London, a leopard's head); 4*th*, The letter indicating the year of assay; and 5*th*, The duty mark (a king's or queen's head). Silver goods of higher value, that is, with a mixture of 11 ounces and 10 pennyweights of fine silver, instead of 11 ounces and 2 pennyweights, is called new sterling, and is, as formerly, marked with a figure of Britannia, and a lion's head erased. As in olden times, the Goldsmiths' Company have still power to break, cut, or otherwise destroy all gold and silver plate which is below the legal standard. (B. L.)

ADULTERY (from the Latin *adulterium*) is the sexual intercourse of a married person with another than the offender's husband or wife. Among the Greeks, and in the earlier period of Roman law, it was not adultery unless a married woman was the offender. The foundation of the later Roman law with regard to adultery was the *lex Julia de adulteriis coercendis* passed by Augustus about B.C. 17. (See *Dig.* 48, 5; Paull. *Rec. Sent.* ii. 26; Brisson, *Ad Leg. Jul. de Adult.*) In Britain it has been reckoned a spiritual offence, that is, cognisable by the spiritual courts only. The common law took no farther notice of it than to allow the party aggrieved an action of damages. In England, however, the action for "criminal conversation," as it was called, is nominally abolished by 20 and 21 Vict. c. 85, § 59; but by the 33d section of the same Act, the husband may claim damages from one who has committed adultery with his wife in a petition for dissolution of the marriage, or for judicial separation, or in a special petition for the purpose in the Divorce Court. In Scotland damages may be recovered against an adulterer in an ordinary action of damages in the civil court, and the latter may be found liable for the expenses of an action of divorce if joined with the guilty spouse as a co-defender.

Adultery is, both in England and Scotland, a ground of divorce. In England, a *complete* divorce or dissolution of the marriage could, until the creation of the Court of Probate and Divorce by 20 and 21 Vict. c. 85, be obtained only by an Act of Parliament. In Scotland a complete divorce may be effected by proceedings in the Court of Session, as succeeding to the old ecclesiastical jurisdiction of the commissioners. A person divorced for adultery is, by the law of Scotland, prohibited from intermarrying with the paramour. See DIVORCE.

ADVENT, the period of the approach of the nativity, lasting, in the Greek Church, from St Martin's Day (Nov. 11), and, in other churches, from the Sunday nearest to St Andrew's Day (Nov. 30) till Christmas. The observance of it dates from the 4th century, and it has been recognised since the 6th century as the commencement of the ecclesiastical year. With the view of directing the thoughts of Christians to the coming of Christ as Saviour, and to his second coming as Judge, special lessons are prescribed for the four Sundays in Advent. At one time Advent was observed almost as strictly as Lent, but the rule is now relaxed, and in the Church of England fasting is confined to the week in which Ember Day (13th Dec.) occurs. The phrase *second advent* is commonly used to denote our Lord's "appearing the second time, without sin, unto salvation," which is so often spoken of in the New Testament. Various opinions have been held as to the time and manner of this event. In the apostolic churches it was commonly regarded as imminent, though this was not the opinion of the apostle Paul, as may be gathered from 2 Thess. ii. 3, 4. The discussion in later times has centred itself chiefly round the question whether the second advent is pre-millennial or post-millennial.

ADVERTISEMENT (from the French *avertissement*, a giving notice, or announcement) denotes in a general sense any information publicly communicated through the press or otherwise. It is the profit derived from advertisements that supports the larger number of newspapers. While some of these drag out a sickly existence, others derive a large revenue from this source. The duty upon advertisements (which existed in Britain[1] previous to 1853) was not unjustly branded as a tax upon knowledge. It was certainly very unequal and oppressive, being the same upon the sale of an estate worth £100,000 as on a servant's notice wanting a place, upon an advertisement of a sixpenny

[1] There is no duty on advertisements in the United States, Germany, or France. In France, however, there is a duty of 10 per cent. on the raw paper, and a further duty of 20 per cent. on all newspapers printed.

pamphlet and an expensive book. Previous to 1833 the duty on each advertisement was 3s. 6d. in Great Britain, and 2s. 6d. in Ireland; in that year it was reduced to 1s. 6d. in Great Britain, and 1s. in Ireland. In 1832 (the last year of the high duty) the total number of newspaper advertisements in the U. K. was 921,943: viz., 787,649 in England, 108,914 in Scotland, and 125,380 in Ireland; the amount of duty paid in that year being £172,570. In 1841 the number of advertisements had increased to 1,778,957: viz., 1,386,625 for England, 188,189 for Scotland, and 204,143 for Ireland; and the total duty paid amounted to £128,318. In 1851 the amount of duty rose to £175,094, 10s. 8d.; being for England £142,365, 3s. 6d.; Scotland, £19,940, 11s.; Ireland, £12,788, 16s. 2d. In compliance with the all but unanimous voice of the public, this duty was abolished in 1853; since which time the system of advertising has increased to an unprecedented extent, in consequence of the low rate at which short advertisements are now inserted. To advertise advantageously requires both experience and judgment; without a knowledge of the character and circulation of the public journals, much expenditure may be wasted by advertising in papers that have either a limited or inappropriate circulation. The sale of some commodities (such as quack medicines) depends almost wholly on advertising, of which it has been said that if the vender has the courage to continue advertising to the extent of £20,000, he will make his fortune by a drug thoroughly worthless. Advertising often falls disproportionately on books, as it is necessary that new publications should be freely advertised. On small low-priced books the expense is particularly heavy, an advertisement of a one shilling book costing as much as one selling at twenty shillings. From this, and their generally ephemeral character, it may be said that ninety-nine out of a hundred pamphlets are published at a loss.

Interesting information on the subject of advertisements will be found in an article in the *Edinburgh Review* for 1st Feb. 1843, "On the Advertising System," and in the *Quarterly Review* for June 1855, "On the Rise and Progress of Advertisements, from the establishment of the Newspaper Press of this Country till the Present Time." In the latter article it is stated that the first advertisement occurs in the *Mercurius Politicus* for Jan. 1652, the subject of the advertisement being a heroic poem of congratulation on Cromwell's victories in Ireland. A writer in *Notes and Queries* for July 6, 1872, has found two examples of advertisements previous to that date, which occur in the *Mercurius Elencticus* of Oct. 1648. See also *The Newspaper Press*, by James Grant (2 vols., 1871), and the article NEWSPAPERS.

ADVOCATE (from the Latin *advocatus*), a lawyer authorised to plead the causes of litigants in courts of law. The word is used technically in Scotland in a sense virtually equivalent to the English term *barrister;* and a derivative from the same Latin source is so used in most of the countries of Europe where the civil law is in force. The *advocatus* of the Romans meant, as the word implies, a person whose assistance was called in or invoked. The word is not often used among the earlier jurists, and appears not to have had a strict meaning. It is not always associated with legal proceedings, and might apparently be applied to a supporter or coadjutor in the pursuit of any desired object. When it came to be applied with a more specific limitation to legal services, the position of the *advocatus* was still uncertain. It was different from, and evidently inferior to, that of the *juris-consultus*, who gave his opinion and advice in questions of law, and may be identified with the consulting counsel of the present day. Nor is the merely professional advocate to be confounded with the more distinguished *orator*, or *patronus*, who came forward in the guise of the disinterested vindicator of justice. This distinction, however, appears to have arisen in later times, when the profession became mercenary. By the *lex Cincia*, passed about two centuries before Christ, and subsequently renewed, the acceptance of remuneration for professional assistance in lawsuits was prohibited. This law, like all others of the kind, was evaded. The skilful debater was propitiated with a present; and though he could not sue for the value of his services, it was ruled that any *honorarium* so given could not be demanded back, even though he died before the anticipated service was performed. The traces of this evasion of a law may be found in the existing practice of rewarding counsel by fees in anticipation of services. In the Justinian collection we find that legal provision had been made for the remuneration of advocates. (*Dig.* lib. 50, tit. 12, § 10–13; Brissonius, *De Sig. Verb.*; Heineccius *ad Pand.* lib. iii. tit. 1.) The *advocatus fisci*, or fiscal advocate, was an officer whose function, like that of a solicitor of taxes at the present day, was connected with the collection of the revenue. (See generally on this subject Forsyth's *Hortensius*, London, 1849.) The term advocate is of frequent use in the chronicles, capitularies, chartularies, and other records of ecclesiastical matters, during the Middle Ages. (See Du Cange, s.v. *Advocati Ecclesiarum*, who affords a profuse supply of references to authorities.) The term was applied in the primitive church to those who defended the Christians against malignants or persecutors. As the church waxed rich and powerful, its temporal supporters assumed a more important position. The advocate, defender, or patron, was of a temporal rank, corresponding to the power of the ecclesiastical body who sought his advocacy. Princes sought the distinction from Rome; and it was as a relic of the practice of propitiating temporal sovereigns by desiring their protection that Henry VIII. received his title of "Defender of the Faith." The office of advocate to any of the great religious houses, possessed of vast wealth, was one of dignity and emolument, generally held by some feudal lord of power and influence. This kind of protection, however, was sometimes oppressive. In the authorities quoted by Du Cange we find that, so early as the 12th century, the advocates were accused of rapine and extortion; and by a capitulary of the popedom of Innocent III. they are prohibited from taking and usurping rewards and privileges beyond use and wont. The office at length assumed a fixed character in its powers and emoluments; and it became the practice for the founders of churches and other ecclesiastical endowments to reserve the office of advocate to themselves and their representatives. The term advocate was subsequently superseded by the word patron; but a relic of it still exists in the term *advowson*, and the word *advowee*, which is the form in which the Latin *advocatus* found its way into the technicalities of English law. Until lately, advocate was the proper designation of legal practitioners in the Probate and Admiralty courts, and still is the name given to those who practise in what remains of ecclesiastical courts In France, corporations or faculties of avocats were attached to the parliaments and other tribunals. They formed, before the revolution, a part of the extensive and powerful body commonly called the nobility of the robe. It was not necessary that the avocat should be born noble, and his professional rank was little respected by the hereditary aristocracy; but as a middle rank, possessed of great powers and privileges, which it jealously guarded, the profession acquired great influence. In the *Encyclopédie Methodique*, the avocat is called "the tutelary genius of the repose of families, the friend of man, his guide and protector." The avocats, as a body, were reorganised under the empire by a decree of 15th December 1810. (See Camus, *Lettres sur la Profession d'Advocat*; A. Young, *The French Bar.*) In

France there is a distinction between *avocats* and *avoués*. The latter, whose number is limited, act as procurators or agents, representing the parties before the tribunals, draft and prepare for them all formal acts and writings, and prepare their lawsuits for the oral debates. The office of the *avocat*, on the other hand, consists in giving advice as to the law, and conducting the causes of his clients by written and oral pleadings. The number of avocats is not limited; every licentiate of law being entitled to apply to the corporation of avocats attached to each court, and after presentation to the court, taking the oath of office, and passing three years in attendance on some older advocate, to have himself recognised as an advocate. The Faculty of Advocates is the collective term by which the members of the bar are known in Scotland. They professionally attend the supreme courts in Edinburgh; but they are privileged to plead in any cause before the inferior courts, where counsel are not excluded by statute. They may act in cases of appeal before the House of Lords; and in some of the British colonies, where the civil law is in force, it is customary for those who practise as barristers to pass as advocates in Scotland. This body has existed by immemorial custom. Its privileges are constitutional, and are founded on no statute or charter of incorporation. The body formed itself gradually, from time to time, on the model of the French corporations of avocats, appointing like them a dean. or doyen, who is their principal officer. No curriculum of study, residence, or professional training was, until 1856, required on entering this profession; but the faculty have always had the power, believed to be liable to control by the Court of Session, of rejecting any candidate for admission. The candidate undergoes two private examinations—the one in general scholarship, in lieu of which, however, he may produce evidence of his having graduated as master of arts in a Scottish university, or obtained an equivalent degree in an English or foreign university; and the other, at the interval of a year, in Roman, private international, and Scots law. He must, before the latter examination, produce evidence of attendance at classes of Scots law and conveyancing in a Scottish university, and at classes of civil law, public or international law, constitutional law, and medical jurisprudence in a Scottish or other approved university. He has then to undergo the old academic form of the public impugnment of a thesis on some title of the pandects; but this ceremony, called the public examination, has degenerated into a mere form. A large proportion of the candidate's entrance fees (amounting to £339) is devoted to the magnificent library belonging to the faculty, which literary investigators in Edinburgh find so eminently useful.

Lord Advocate, or King's Advocate, is the principal law-officer of the crown in Scotland. His business is to act as a public prosecutor, and to plead in all causes that concern the crown. He is at the head of the system of public prosecutions by which criminal justice is administered in Scotland, and thus his functions are of a far more extensive character than those of the English law-officers of the crown. He is aided by a solicitor-general and subordinate assistants called advocates-depute. The office of king's advocate seems to have been established about the beginning of the 16th century. Originally he had no power to prosecute crimes without the concurrence of a private party; but in the year 1597 he was empowered to prosecute crimes at his own instance. He has the privilege of pleading in court with his hat on.

ADVOCATION, in *Scottish Law*, was a mode of appeal from certain inferior courts to the supreme court. It was abolished in 1868, a simple "appeal" being substituted.

ADVOWSON, or Advowzen (*advocatio*), in *English Common Law*, the right of presentation to a vacant ecclesiastical benefice, is so called because the patron defends or advocates the claims of the person whom he presents. Originally all appointments within a diocese lay with the bishop; but when a landowner founded a church on his estate and endowed it, his right to nominate the incumbent was usually recognised. Where the right of presentation remains attached to the manor, it is called an advowson *appendant*, and passes with the estate by inheritance or sale without any special conveyance. But where, as is often the case, the right of presentation has been sold by itself, and so separated from the manor, it is called an advowson *in gross*. Advowsons are further distinguished into *presentative*, *collative*, and *donative*. In a *presentative* advowson, the patron presents a clergyman to the bishop, with the petition that he be instituted into the vacant living. The bishop is bound to induct if he find the clergyman canonically qualified, and a refusal on his part is subject to an appeal to an ecclesiastical court either by patron or by presentee. In a *collative* advowson the bishop is himself the patron, either in his own right or in the right of the proper patron, which has lapsed to him through not being exercised within the statutory period of six months after the vacancy occurred. No petition is necessary in this case, and the bishop is said to *collate* to the benefice. In a *donative* advowson, the sovereign, or any subject by special licence from the sovereign, confers a benefice by a simple letter of gift, without any reference to the bishop, and without presentation and institution. The incumbent of such a living is to a great extent free from the jurisdiction of the bishop, who can only reach him through the action of an ecclesiastical court. When an ecclesiastical body owned an advowson, it very frequently, by *appropriation*, exercised the right in its own favour, the corporation becoming the incumbent of the living, the actual duties of which were discharged by a *vicar* or *perpetual curate*. An advowson, being property, may be sold, or mortgaged, or seized by the creditors on a bankrupt estate, under certain restrictions intended to prevent simony. A sale is absolutely prohibited during the mortal sickness of the incumbent, or during the existence of a vacancy. There are upwards of 13,000 benefices in the Church of England, the advowsons being distributed as shown in the following list, which may be taken as approximately correct:—Under the patronage of the crown there are 1144 livings; bishops, 2324; deans and chapters, 938; the universities, 770; parochial clergy, 931; and private persons, 7000.

ADYTUM, the most retired and sacred place of ancient temples, into which none but the officiating priests were allowed to enter. The Most Holy Place of the temple of Solomon was of the nature of the pagan adytum; none but the high priest being admitted into it, and he but once a year.

Æ, or AE, a diphthong, compounded of A and E, of frequent occurrence in Latin and in Anglo-Saxon. In the best editions of the classics the form now preferred is *ae*. In English words derived from Latin the diphthong is generally converted into the simple *e*, but it is not unfrequently retained, as in *Æolian*, *mediæval*, &c. In some words it represents the Greek αι, to which the Latin æ corresponds, as in *æsthetics* (αισθητικά).

ÆACUS, in *Mythology*, the son of Jupiter by Ægina. When the isle of Ægina was depopulated by a plague, his father, in compassion to his grief, changed all the ants upon it into men and women, who were called *Myrmidones*, from μύρμηξ, *an ant*. The foundation of the fable is said to be, that when the country had been depopulated by pirates, who forced the few that remained to take shelter in caves, Æacus encouraged them to come out, and by commerce and industry to recover what they had lost. His character for justice and piety was such that, in a time of universal drought, he was nominated by the Delphic oracle to intercede for Greece and his prayer was answered. The ancients also imagined that Æacus, on account of his impartial justice, was chosen by Pluto one of the three judges of the dead, and that it was his province to judge the Europeans.

ÆDILE (*ædilis*), in *Roman Antiquity*, a magistrate whose chief business was to superintend buildings of all kinds, but more especially public ones, as temples, aqueducts, bridges, &c. To the ædiles likewise belonged the care of the highways, public places, weights and measures, &c. They also superintended the markets, fixed the prices of provisions, took cognisance of breaches of decency and public order, and took charge of police matters generally. The custody of the *plebiscita*, or decrees of the people, and *senatus consulta*, or decrees of the senate, was likewise committed to them. They had the inspection of theatres and plays, and were obliged to exhibit magnificent games to the people, usually at their own expense, whereby many of them were ruined. They had the power, on certain occasions, of issuing edicts, and by degrees they procured to themselves a considerable jurisdiction. At first there were only two ædiles, viz., the ædiles of the people, *ædiles plebeii*, or *minores*. They were first created in the same year as the tribunes, B.C. 494; for the tribunes, finding themselves oppressed with the multiplicity of affairs, demanded of the senate to have officers to whom they might entrust matters of less importance; and accordingly two ædiles were created; and henceforward the ædiles were elected every year at the same assembly as the tribunes. But these plebeian ædiles having refused, on a signal occasion, to continue the great games for four days instead of three, on account of the expense, the patricians made an offer to do it, provided they were admitted to the honours of the ædileship. Accordingly two new ædiles were created, from the order of the patricians, in the year of Rome 388. They were called *ædiles curules*, or *majores*, as having a right to sit on a curule chair when they gave audience; whereas the plebeian ædiles only sat on benches. The curule ædiles alone had the right to issue edicts. Otherwise they shared all the ordinary functions of the plebeian ædiles; they had to procure the celebration of the grand Roman games, and to exhibit comedies, shows of gladiators, &c., to the people; and they were also appointed judges in all cases relating to the selling or exchanging of estates. To assist these first four ædiles, Cæsar (B.C. 45) created a new kind, called *ædiles cereales*, so named from their being deputed chiefly to take care of the supply of corn, which was called *donum Cereris*. These ædiles cereales were also taken out of the order of patricians. In the municipal cities and colonies there were ædiles having much the same authority as at Rome. We also read of an *ædilis alimentarius*, expressed in abbreviature by *ædil. alim.*, whose business seems to have been to provide diet for those who were maintained at the public charge, though others assign him a different office. In an ancient inscription we also meet with ædile of the camp, *ædilis castrorum*.

ÆGADES, or ÆGATES, a group of islands off the western coast of Sicily, between Trapani and Marsala, consisting of Marettimo, Levanzo, and Favignana. These islands are rendered historically famous by the great naval victory gained there by the Romans over the Carthaginians in B.C. 241, which put an end to the first Punic war

ÆGEAN SEA, a part of the Mediterranean, now more usually called the Archipelago or Grecian Archipelago, bounded on the north by Thrace and Macedonia, on the west by Greece, and on the east by Asia Minor. The origin of the name is uncertain. Various derivations are given by the ancient grammarians—one from the town of Ægæ; another from Ægea, queen of the amazons, who perished in this sea; and a third from Ægeus, the father of Theseus, who threw himself headlong into it. See ARCHIPELAGO.

ÆGEUS, in *Fabulous History*, the son of Pandion, was king of Athens, and the father of Theseus. He was one of the Athenian heroes, but is notable chiefly for the manner of his death. The Athenians having killed Androgeus, the son of Minos, king of Crete, for carrying away the prize for wrestling from them, Minos made war upon them; and being victorious, imposed this severe condition on Ægeus, that he should annually send into Crete seven of the noblest of the Athenian youths and as many maidens, chosen by lot, to be devoured by the Minotaur. On the fourth year of this tribute the choice fell on Theseus, or, as others say, he himself entreated to be sent. The king at his son's departure gave orders that, as the ship sailed with black sails, it should return with the same in case he perished; but if he came back victorious he should change them for white. When Theseus returned from Crete after killing the Minotaur, he forgot to change the sails in token of his victory, according to the agreement; and his father, who sat on a rock watching the return of the vessel, imagining from the black sails that his son was dead, cast himself headlong into the sea, which was supposed in consequence to have obtained the name of the *Ægean Sea*. The Athenians decreed divine honours to Ægeus, and sacrificed to him as a marine deity and an adopted son of Neptune.

ÆGINA, in *Fabulous History*, the daughter of Asopus, king of Bœotia, was beloved by Jupiter, who carried her from Epidaurus to a desert island called *Œnone* or *Œnopia*, which was afterwards called by her name. See ÆACUS.

ÆGINA, or EGINA, or ENGIA, an island in the Saronic gulf, 20 miles distant from the Piræus, formerly vying with Athens in naval power, and at the sea-fight of Salamis disputing the palm of victory with the Athenians. It was the native country and kingdom of Æacus, who called it *Ægina*, from his mother's name. (Ovid.) The inhabitants were called *Æginetæ* and *Æginenses*. Ægina is triangular in shape, and is about 8 miles long from N.W. to S.E., and about 6 broad, with an area of about 41 square miles. Strabo states its circumference at 180 stadia, or about 22½ English miles. Its western side consists of stony but fertile plains, which are well cultivated, and produce luxuriant crops of grain, with some cotton, vines, almonds, and figs. The rest of the island is mountainous, and rather barren. The southern end rises in the conical Mount Oros, and the Panhellenian ridge stretches to the north, from which fertile narrow valleys descend on either hand. From the absence of marshes, and its insularity, the climate is mild, and the most salubrious of Greece. The ruins of the ancient Ægina extend along two small ports, still protected by well-built ancient moles, and the shores of an open bay, defended by an ancient breakwater, near the N.W. cape of the island. On the land side the city walls are still distinctly traceable, 10 feet in thickness, strengthened by towers at unequal distances, and pierced by three gates. They abutted on those of the ports, which were thus included within the line of fortifications, as at Athens and elsewhere in ancient Greece. Two elegant Doric columns and substructures are all that remain of the buildings noticed by Pausanias within the precincts of a city that was long the greatest and most opulent maritime power of Greece; but the ruins of seventeen Christian churches, still visible, prove that after the glories of the proud city had passed away—after what it suffered from the jealousy of its rival Athens, and from an earthquake about the beginning of our era—a considerable modern town had occupied its site. Some of these may perhaps only date from the time that Ægina remained under its Venetian masters, as does a tower erected at the entrance of the largest port. The Venetians resigned possession of the island to the Turks in 1715, under whom it became the prey of Mainote and other pirates, until the emancipation of Greece made it, in 1828–29, the seat of the Greek government. On a hill near the N.E. corner of the island stands the modern little town of Ægina (as it is pronounced by the modern Greeks). It is separated by a ravine from the hill, on which rise in lonely majesty the ruins of a noble temple, supposed to be that of *Jupiter Panhellenius*, though the point has been disputed. The temple occupies the rocky summit of a hill, in the midst of a forest of pines, at the extremity of the Panhellenian ridge. It was a ruin in the days of Cicero, as mentioned in one of his letters, and seems to have been thrown down by an earthquake at an unknown epoch. This temple is conspicuous from a distance, and was visited by Chandler in the last century; but has been chiefly known to us by the successful excavations of our countrymen Cockerell and Foster, assisted by Baron Haller and M. Linckh of Stuttgard, in 1811. These gentlemen united in clearing away the rubbish which the lapse of 2000 years had accumulated on the basement and floor of the cella; and after twenty days' exertion they were rewarded by the discovery not only of many interesting details relating to Grecian architecture, but also of many statues, in wonderfully energetic attitudes, that had once adorned the fallen pediments of this celebrated temple. These consist of the eleven figures of the eastern and five statues of the western pediment, almost entire, besides fragments of the rest, and two statuettes, and other ornaments of the acroteria. These sculptures supply an important link in the history of ancient art, and connect the schools of early Greece with that of Etruscan sculpture. The efforts of Messrs Cockerell and Foster to secure those treasures to their country are well known, as well as their failure through an unlucky mistake of the agent sent out to purchase them for the British Museum. They now form one of the most interesting acquisitions of the magnificent *Glyptothek* of Munich. The temple stands on a stylobate of 94 feet by 45 feet. The original number of columns in the peristyle was thirty-two, of which twelve were ranged on each side, and six in each front, 17 feet 2 inches high, including the wide spreading ovolo of the capital, and a diameter of 3 feet 3 inches at the base. Two other columns, of 3 feet 2 inches between antæ, are in the pronaos, and two similar in the opisthodomos or *posticum*. The cella had a door at each end; a double row of smaller columns, 2 feet 4 inches in diameter, were within the cella to support its partial roof; but the greatest portion of the cella was open, as this temple was *hypæthral*. There still remain twenty-one columns of the peristyle, with their architraves; six of the eastern front, and continuously with them are five columns of the north side; the four columns of the pronaos and opisthodomos, and the lower part of the shafts of five within the cella. The tympana had been painted of a bright azure, to give relief to the statues; and the drapery of Minerva, the middle figure of each group, had been painted red and blue. The whole of the ornaments on the cornices and upper mouldings of the pediment had been painted in *encaustic*, not carved. The subject of the groups of statuary appears to be the contest for the body of Patroclus, one of the *Æacidæ* (or royal progeny of Ægina of old), as described by Homer. (Cockerell *On the Ægina Marbles;* Brand's *Journal.*) This magnificent structure was erected most probably in the 6th century B.C., but, at all events, undoubtedly belongs to the brilliant period of Æginetan power, when its navy and its commerce were the pride of Greece, and carried its citizens to the remotest shores of the Mediterranean and the Euxine. Silver money is said to have been struck at Ægina long before it was coined even at Athens. The victory of Salamis was in a great measure owing to the thirty ships of Ægina, and the voice of grateful Greece assigned to her warriors on that eventful day the prize of valour. Yet not long after, the rivalry of Athens began to cloud the prosperity of the haughty islanders, whose fleet she had before defeated; and Ægina at length sunk under the enmity of a relentless commercial rival, that banished her citizens and supplied their place with Attic colonists. After the close of the Peloponnesian war Lysander restored the banished inhabitants, but Ægina never recovered its ancient prosperity.

ÆGINETA, Paulus, a celebrated surgeon of the island of Ægina, whence he derived his name. According to Le Clerc's calculation. he lived in the 4th century; but Abulfaragius the Arabian places him with more probability in the 7th. His knowledge in surgery was very great, and his works are deservedly famous. The title of the most important of them, as given by Suidas, is Ἐπιτομῆς Ἰατρικῆς Βιβλία Ἕπτα (*Synopsis of Medicine in Seven Books*). The sixth book, which treats of surgery, is particularly interesting. The whole work in the original Greek was published at Venice in 1528, and another edition appeared at Basle in 1538. Several Latin translations have been published, and an excellent English version, with commentary, by Dr F. Adams (1844–48). Ægineta is the first writer who takes notice of the cathartic property of rhubarb, and, according to Dr Milward, is the first in all antiquity who deserves the title of accoucheur.

ÆGIS, in *Classical Mythology*, a name given to the shield or buckler of Jupiter. The goat Amalthæa, which had suckled that god, being dead, he is said to have covered his buckler with the skin, or used the skin as a buckler; whence the appellation *ægis*, from αἴξ, αἰγός, *goat*. Jupiter afterwards restored the animal to life, covered it with a new skin, and placed it among the stars. A full description of the ægis of Jupiter is given by Homer, *Il.* v. 738, *sqq.* Apollo is also represented as bearing the *ægis*, and Minerva still more frequently. After Perseus killed Medusa, Minerva nailed her head in the middle of the ægis, which thenceforth had the faculty Medusa herself had during her life of converting all who looked on it into stone. Later writers regard the ægis sometimes as a buckler, but oftener as a cuirass or breastplate. The ægis of Pallas, described by Virgil (*Æn.* lib. viii. v. 435), must have been a cuirass, since the poet says expressly that Medusa's head was on the breast of the goddess. But the ægis of Jupiter, mentioned a little before (v. 354), seems from the description to have been a buckler. The ægis appears to have been really the goat's skin used, as well as the skins of other animals, as a belt to support the shield. When so used it would usually be fastened on the right shoulder, and would partially envelope the chest as it passed obliquely round in front and behind to be attached to the shield under the left arm. Hence, by transference, it would be employed to denote at times the shield which it supported, and at other times a *lorica* or *cuirass*, the purpose of which it in part served. Illustrations of the assumption of the ægis by the Roman emperors may be seen in ancient statues and cameos.

ÆGISTHUS, in *Ancient History*, was the son of Thyestes by his own daughter Pelopea, who to conceal her shame exposed him in the woods. Some say he was taken up by a shepherd and suckled by a goat; whence he was called *Ægisthus*. After he grew up he was recognised by his father, and on the death of the latter he became king of Mycenæ. He did not join the expedition against Troy; and after the departure of the expedition he seduced Clytemnestra, the wife of Agamemnon, and lived with her during the siege of Troy. Afterwards, with her assistance, he slew her husband, and reigned seven years in Mycenæ. He was slain, together with Clytemnestra, by Orestes.

ÆGOSPOTAMI, in *Ancient Geography*, a small river in the Thracian Chersonesus, running south-east, and falling into the Hellespont to the north of Sestos,—with a town of the same name, and a station or road for ships, at its mouth. Here the Athenians under Conon, through the fault of his colleague Philocles, received a signal overthrow from the Lacedemonians under Lysander (B.C. 405), which involved the taking of Athens, and put an end to the Peloponnesian war. The town does not appear to have existed till after the date of the battle.

ÆLFRIC, "the Grammarian," as he has been called, is one of the most voluminous of our old English writers before the Conquest. He flourished at the latter end of the 10th century and the beginning of the 11th. Of his personal history little can be learned, and his birth and death are alike involved in obscurity. We know that he was a pupil of Ethelwold, the friend of Dunstan, at Abingdon. On Ethelwold's advancement to the see of Winchester, Ælfric accompanied him, and filled the office of chief instructor in the diocese. For the use of his scholars he wrote his Latin and English *Grammar and Glossary* and his *Colloquium*. The last of these is in Latin, with an old English interlinear translation, in which the Latin is rendered word for word. It is interesting for its account of ancient manners, and shows that Ælfric made use of the conversational method in his teaching. The words in his Glossary are not arranged alphabetically, but grouped together into classes. Ælfric afterwards removed to Cerne Abbey, in Dorsetshire, where he composed his *Homilies*, the work on which his fame as an author chiefly depends. They are 80 in number, and were edited by Thorpe in 1844-46 for the Ælfric Society. In composing them, Ælfric drew largely from the fathers. Their style is very simple and pleasing, and obscure words are carefully avoided in order to adapt them to the capacity even of the most ignorant. Subsequent writers made great use of them, and not a few are to be found unabridged in the transition (semi-Saxon) English of the succeeding centuries. They excited great attention about the time of the Reformation, and were appealed to—especially the "Paschal Homily"—to prove that the doctrines of the English Church before the Conquest were at variance with those held by the Church of Rome. Among Ælfric's other works may be mentioned his *Treatise on the Old and New Testaments*, and his *Abridgment of the Pentateuch and the Book of Job*. Of the rest of his life we have little on which we can rely. He attained to the dignity of abbot, but he seems to be a different person from Ælfric, archbishop of Canterbury (995-1006), with whom he is sometimes confounded.

ÆLIA CAPITOLINA, a name given to the city built by the Emperor Hadrian, A.D. 134, near the spot where the ancient Jerusalem stood, which he found in ruins when he visited the eastern parts of the Roman empire. A Roman colony was settled here, and a temple was dedicated to Jupiter Capitolinus. Hence the name Capitolina, to which Hadrian prefixed that of his own family.

ÆLIANUS, CLAUDIUS, born at Præneste, in Italy. He taught rhetoric at Rome, under the Emperor Alexander Severus, according to Perizonius, but more probably under Hadrian. He was surnamed Μελίγλωσσος, "Honey-tongued," on account of the ease and accuracy with which he spoke and wrote Greek; and he was also named "the Sophist," from his being a teacher of rhetoric. He loved retirement, and devoted himself to study. He greatly admired and studied Plato, Aristotle, Isocrates, Plutarch, Homer, Anacreon, Archilochus, &c.; and, though a Roman, gives preference to the writers of the Greek nation, and employs the Greek language in his works. His curious and entertaining work entitled *Varia Historia* has been frequently republished, as well as his treatise *De Natura Animalium*. A very useful edition of the latter was published by Schneider, at Leipsic, in 1784, in 8vo; another at Jena, in 1832, by Fr. Jacobs. The collected edition of his works, by Gesner, 1556, fol., contains another work ascribed to him, named *Epistolæ Rusticæ*.

ÆMILIUS, PAULUS, the name of a celebrated family of the Æmilia Gens. See PAULUS.

ÆMILIUS, PAULUS, or PAOLO EMILIO, a celebrated historian, born at Verona, who obtained such reputation in Italy that he was invited into France by the cardinal of Bourbon, in the reign of Charles VIII., in order to write the history of the kings of France in Latin, and was presented to a canonry in Notre Dame. He enjoyed the patronage and support of Louis XII. He died at Paris on the 5th of May 1529. His work entitled *De Rebus gestis Francorum* was translated into French by Renard in 1581, and has also been translated into Italian and German.

ÆNEAS, in *Fabulous History*, a Trojan prince, the son of Venus and Anchises. He plays a conspicuous part in the *Iliad*, and is represented, along with Hector, as the chief bulwark of the Trojans. Homer always speaks of Æneas and his descendants as destined to reign at Troy after the destruction of Priam and his house. Virgil has chosen him as the hero of his great epic, and the story of the *Æneid*, though not only at variance with other traditions, but inconsistent with itself, can never lose its place as a biography of the mythical founder of the Latin power. Æneas is described in the *Æneid* as escaping from the destruction of Troy, bearing his aged father on his shoulders, carrying in one hand his household gods, while with the other he leads his little son Ascanius or Iülus. His wife Creüsa is separated from them and lost in the tumult. After a perilous voyage he lands in Africa, and is kindly received by Dido, queen of Carthage; who, on his forsaking her to seek a new home, destroys herself. Again escaping the dangers of the sea, he arrives in Italy, where he lands in Latium, and forms an alliance with Latinus, the king of the country, marries his daughter Lavinia, and founds a city which he calls, after her, Lavinium. Turnus, king of the Rutuli, a rejected suitor of Lavinia, makes war on Latinus, and both are slain in battle. The story of the *Æneid* ends with the death of Turnus. According to Livy, on the death of Latinus, Æneas assumes the sovereignty of Latium, and the Trojan and Latin powers are united in one nation. After a reign of three years, Æneas falls in a battle with the Rutuli, assisted by Mezentius, king of Etruria, and is supposed to be carried up into heaven, because his body cannot be found. After his death or disappearance he receives divine honours.

ÆNEAS SYLVIUS, POPE. See PIUS II.

ÆOLIÆ INSULÆ, the modern LIPARI ISLANDS, a group of islands between Italy and Sicily. They are so called from Æolus, the god of the winds, who was supposed to rule over them; but they are also frequently termed *Insulæ Vulcaniæ*, or *Hephæstiæ*, from their volcanic eruptions, and *Insulæ Liparcorum*, from *Lipara* (modern Lipari), the chief of the group. According to Pliny, the other islands are *Hiera*, now *Vulcano; Strongyle*, now *Stromboli; Didyme*, now *Salina; Phœnicusa*, now *Felicudi; Euonymus*, probably *Panaria;* and *Ericusa*, now *Alicudi*. Besides these there are several small islets. Homer mentions only one Æolian island (*Od.* x. 1).

ÆOLIAN HARP, named from Æolus, god of the wind, a musical instrument consisting of cat-gut strings stretched over a wooden sound-box. When exposed to a current of air, the strings produce a variety of pleasing harmonic sounds in strange succession and combination.

ÆOLIS, or ÆOLIA, in *Ancient Geography*, a country of Asia Minor, settled by colonies of Æolian Greeks. The name in its limited sense was applied to the coast extending from the river Hermus to the promontory of Lectum, on the north side of the entrance to the Gulf of Adramyttium, and lying between Ionia to the S. and Troas to the N. In its wider acceptation it comprehended Troas and the coasts of the Hellespont to the Propontis, where there were likewise several Æolian colonies.

ÆOLUS, in *Heathen Mythology*, the god and father of the winds, was variously represented as the son of Hippotes, or of Neptune by a daughter of Hippotes, or of Jupiter. In the *Odyssey* he is mentioned as the king of the Æolian isle to whom Jupiter had given the superintendence and distribution of the winds. Later poets make him the god and father of the winds, who dwelt in one of the Æolian islands—according to some in Stromboli, according to others in Lipari, while others place his residence at Rhegium in Italy. He is represented as having authority over the winds, which he confined in a vast cavern. Strabo and some other writers consider him to have had a real existence; and derive the fable of his power over the winds from his skill in meteorology and the management of ships.

> Hic vasto rex Æolus antro,
> Luctantes ventos tempestatesque sonoras
> Imperio premit, ac vinclis et carcere frenat.
> Illi indignantes magno cum murmure montis
> Circum claustra fremunt; celsâ sedet Æolus arce
> Sceptra tenens, mollitque animos, et temperat iras:
> Ni faciat, maria ac terras cœlumque profundum
> Quippe ferant rapidi secum, verrantque per auras.
>
> *Æneid*, lib. i. 52.
>
> Here Æolus, in cavern vast,
> With bolt and barrier fetters fast
> Rebellious storm and howling blast.
> They with the rock's reverberant roar
> Chafe blustering round their prison door.
> He, throned on high, the sceptre sways,
> Controls their moods, their wrath allays.
> Break but that sceptre, sea and land,
> And heaven's etherial deep,
> Before them they would whirl like sand,
> And through the void air sweep.
>
> *Conington's Translation.*

Through Hippotes, Æolus is usually represented as descended from Æolus, one of the sons of Hellen, and the mythological ancestor of the Æolian tribes.

ÆON (αἰών), a space of time. was often used in Greek to denote indefinite or infinite duration; and hence, by metonymy, for a being that exists for ever. In the latter sense it was chiefly used by the Gnostic sects to denote those eternal beings or manifestations which emanated from the one incomprehensible and ineffable God. See Gnosticism.

ÆPINUS, Franz Maria Ulrich Theodor, a distinguished German natural philosopher, was born at Rostock in Saxony in 1724, and died at Dorpat in August 1802. He was descended from John Æpinus (*b.* 1499—*d.* 1553), the first to adopt the Greek form (αἰπεινός) of the family name, a leading theologian and controversialist at the time of the Reformation. After studying medicine for a time, Francis Æpinus devoted himself to the physical and mathematical sciences, in which he soon gained such distinction that he was admitted a member of the Berlin Academy of Sciences. In 1757 he settled in St Petersburg as member of the Imperial Academy of Sciences and professor of physics, labouring there and pursuing his favourite studies with great success till his death. He enjoyed the special favour of the Empress Catharine II., who appointed him tutor to her son Paul, and endeavoured, without success, to establish normal schools throughout the empire under his direction. Æpinus is best known by his researches, theoretical and experimental, in electricity and magnetism. His principal work, *Tentamen Theoriæ Electricitatis et Magnetismi*, published at St Petersburg in 1759, may be regarded as the first systematic and successful attempt to apply mathematical reasoning to these subjects. Adopting Franklin's theory of positive and negative electricities, or electric forces, he investigated the relations of these fully, and especially the conditions of their equilibrium; and many of the conclusions he arrived at do not depend for their value and importance on the theory of Franklin. Æpinus himself extended the theory, holding that the particles of the electric fluid repel each other, attract the particles of all bodies, and are attracted by them, with a force inversely proportional to the distance; that the fluid resides in the pores of the surfaces of bodies, moving readily through some, called conductors or non-electrics, and with difficulty through others; and that electric phenomena are produced either by the approach of bodies unequally charged, or by the unequal distribution of the fluid in the same body. He propounded a kindred theory of magnetism, a magnetic fluid being supposed to exist corresponding to the electric fluid, but acting on, and acted on by, the particles of iron only. It is to be added that Æpinus was the first to perceive and define, with any measure of clearness, the affinity between electricity and magnetism. There is a remarkable similarity between portions of the work above named and a paper by Cavendish—the result of independent investigations—given in the *Philosophical Transactions* for 1771. In 1787 the Abbé Haüy published an exposition of Æpinus's theories. Æpinus did not confine himself to one or two departments of natural science. He published a treatise, in 1762, *On the Distribution of Heat at the Surface of the Earth;* and he was also the author of valuable memoirs on different subjects in astronomy, mechanics, optics, meteorology, and pure mathematics, contained in the journals of the learned societies of St Petersburg and Berlin. His discussion of the effects of parallax in the transit of a planet over the sun's disc excited great interest, having appeared (in 1764) between the dates of the two transits of Venus that took place during last century.

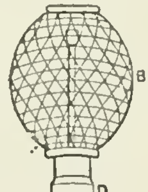
ÆQUI, an ancient and warlike people of Italy, inhabiting the upper valley of the Anio, who, in confederacy with the Volsci, carried on a long series of hostilities with the early Romans, but were finally subdued in the year 302 B.C.

ÆRARIANS, a class in ancient Rome, composed of citizens who had suffered the severest kind of degradation the censors could inflict, but concerning whose exact position we have no precise information. Though heavily taxed, they did not enjoy the rights of citizenship beyond their liberty and the general protection of the state. They could not vote in assemblies or serve in the army, and were deprived of and excluded from all posts of honour and profit. Romans of the higher classes, as well as the plebeians, were liable to become Ærarians. The name may be derived from *æs, æris,* money, since they were mere tax-payers; or, which is more probable, it may refer to the list of them which the censors gave in to the *ærarium* or public treasury.

ÆRARIUM, the public treasury at ancient Rome. It contained the moneys and accounts of the state, and also the standards of the legions, the public laws engraven on brass, the decrees of the senate, and other papers and registers of importance. The place where these public treasures were deposited, from the time of the establishment of the republic, was the temple of Saturn, on the eastern slope of the Capitoline hill. In addition to the common treasury, supported by the general taxes and charged with the ordinary expenditure, there was a reserve treasury, also in the temple of Saturn, the *ærarium sanctum* (or *sanctius*), maintained chiefly by a tax of 5 per cent. on the value of all manumitted slaves, which was not to be had recourse to or even entered, except in the extreme necessity of the state. Under the emperors the senate continued to have at least the nominal management of the *ærarium*, while the emperor had a separate exchequer, called the *fiscus*. But after a time, as the power of the emperors increased and their jurisdiction extended till the senate existed but in form and name, this distinction virtually ceased. Besides creating the *fiscus*, Augustus also established a military treasury (*ærarium militare*), containing all moneys raised for and appropriated to the maintenance of the army. The later emperors had a separate *ærarium privatum*, containing the monies allotted for their own use, distinct from the *fiscus*, which they administered in the interests of the empire.

AERATED WATERS. Waters impregnated with an unusually large proportion of carbonic acid, or other gaseous substances, occur abundantly in springs throughout the world; and, in addition to their gaseous constituents, generally hold in solution a large percentage of different salts. The manufacture of aerated waters arose out of the attempt to imitate these by artificial means, but till about the beginning of the present century such efforts did not meet with great success. The earliest method of producing acidulated water was that which still obtains in the preparation of effervescing draughts, such as are made from "Seidlitz" powders. These powders consist of separate portions of sodium bicarbonate and tartaric acid, which, on being dissolved together in water, form sodium tartrate and liberate carbonic acid, which bubbles up through the water. In recent years "granular" effervescent preparations have been introduced, in which the acid and salt are mixed in a dry state, and produce their reaction on being dissolved. The popular preparation termed effervescent citrate of magnesia, and several others under a variety of names, consist essentially of sodium bicarbonate and tartaric acid, to which a little citric acid is sometimes added. A limit, however, is set to the use of waters so aerated on account of the purgative action of the alkaline earths they necessarily contain.

In the manufacture of common aerated waters the carbonic acid is prepared apart from the pure water in which it is to be dissolved. There are essentially only two methods on which the manufacture is conducted, although there is an endless variety in the apparatus used. In the first process, which may be distinguished as the method of chemical pressure, the carbonic acid gas saturates the water by its own pressure, passing directly from the chamber in which it is produced and purified into the cylinder or cylinders containing the water to be aerated. The small apparatus frequently used in private houses and hospitals may be taken as an illustration of this method. The most common form consists of two strong glass globes A and B, protected by netting in case of breakage. Into the globe A are placed the materials for generating carbonic acid, usually in this case tartaric acid and sodium bicarbonate. When charged with these materials, a metal tube C, accurately fitted to the aperture in the globe, is inserted. The globe B is inverted and filled with water, and in this position the globe A is screwed tightly up by the joint D, the metal tube reaching to near the top of globe B. On placing the apparatus upright, a proportion of water escapes through the metal tube into globe A, acts on the charge it contains, and evolves carbonic acid, which passes up the tube and saturates the water in B. As the pressure of the gas augments, the quantity absorbed increases, and when fully saturated the aerated water may be drawn off by the cock E. In manufacturing on a large scale, a combination of globes or cylinders is used for producing continuous action, and less expensive sources of carbonic acid than sodium bicarbonate and tartaric acid are employed. The second or mechanical pressure process is that generally followed in the manufacture in this country. In this process the gas is prepared in a lead chamber by the action of sulphuric acid on chalk, and is washed by passing through water into the gas-holder in which it is collected. By the action of a force-pump, water, filtered when necessary, and carbonic acid, are pressed, in due proportions, into a very strong copper cylinder, tinned internally, termed a receiver or saturator, in which an agitator is kept revolving. A pressure gauge is attached to the receiver, and when the index indicates from 120 to 140 ℔ pressure per square inch, what is termed aerated water, and very frequently does duty for soda-water, is ready for drawing off at the bottling apparatus. Real soda-water is best prepared by adding to the water before aeration a proportion of sodium bicarbonate equal to about 30 or 36 grains per pint of water. Potash-water, Seltzer, lithia, Carrara, bromide of potassium, and a host of other waters, are similarly prepared, the various salts being used in different proportions, according to the taste and experience of manufacturers. Lemonade, and other aerated drinks flavoured with fruit syrups, have the proportion of syrup placed in the bottle to which simple aerated water taken from a receiver, indicating a pressure of 80 to 100 ℔ per square inch, is added. From a syrup composed of 14 ℔ of sugar, 2½ oz. of tartaric acid, 3½ oz. of citric acid, and 4½ drachms of essence of lemon, dissolved in 2½ gallons of water, 30 dozen bottles of an excellent quality of lemonade can be prepared. On account of the rapidity with which the gas escapes on the removal of pressure, special arrangements are required for the bottling and corking processes, and the frequent explosion of bottles necessitates guards to protect the bottler. A dexterous bottler will fill and cork 5000 bottles in ten hours. The consumption of aerated waters, especially in hot climates, is very great.



AEROE, or Ärroe, an island of Denmark, in the Little Belt, lying 7½ miles S. of Funen, between Alsen and Langeland. It is of an irregular triangular shape, about 15 miles long and 8 broad at the widest points, with a hilly surface, but a fertile and well-cultivated soil. Population, 10,200; chief town, Aeroeskjobing, on the east coast.

AEROLITE (ἀήρ, air, and λίθος, a stone), a stony or metallic body, which, falling through the atmosphere, reaches the earth's surface. These meteoric stones generally contain a considerable proportion of iron; indeed, the iron in some of these substances exceeds the siliceous matter, and some have then given them the name of meteoric irons. A remarkable aerolite that fell at Ægospotami, in 467 B.C., was, according to Pliny, to be seen in his day, and was then as large as a waggon. In 1492 one fell at Ensisheim, in Alsace, that weighed 270 ℔.; and, not to mention others, one of 12 ℔ weight is reported to have fallen in California in August 1873, which penetrated the earth to the depth of 8 feet, and when dug up was so hot that it could not be handled. Aerolites often reach the earth in groups or showers, as at L'Aigle, in Normandy, in 1803; at New Concord, Ohio, in May 1860; and at Dhurmsala, in the Punjaub, in July the same year. The area on which a shower of aerolites falls is usually elliptical, the largest stones being near one end of the ellipse, the major axis of which extends in some cases to a length of eighteen or twenty miles. See Meteor.

AERONAUTICS

adual covery naviga- n.

IN every stage of society men have sought, by the combination of superior skill and ingenuity, to attain those distinct and obvious advantages which nature has conferred on the different tribes of animals, by endowing them with a peculiar structure and a peculiar force of organs. The rudest savage learns from his very infancy to imitate the swimming of a fish, and plays on the surface of the water with agility and perseverance. But an art so confined in its exercise, and requiring such a degree of bodily exertion, could not be considered of much avail. It must have been soon perceived (even if the discoveries of the arts of natation and navigation were not absolutely simultaneous), that the fatigue of impulsion through the water could be greatly diminished by the support and floating of some light substance. The trunk of a tree would bear its rude proprietor along the stream; or, hollowed out into a canoe and furnished with paddles, it might enable him even to traverse a river. From this simple fabric the step was not great to the construction of a boat or barge, impelled by the force of oars. But it was a great advance to fix masts and apply sails to the vessel, and thus substitute the power of wind for that of human labour. The adventurous sailor, instead of plying on the narrow seas or creeping timidly along the shore, could now launch with confidence into the wide ocean. Navigation, in its most cultivated form, may be fairly regarded as one of the sublimest triumphs of human genius, industry, courage, and perseverance.

alogy ween vigation l flying y very ue.

Having by his skill achieved the conquest of the waters that encompass the habitable globe, it was natural for man to desire likewise the mastery of the air in which we breathe. In all ages, therefore, great ingenuity has been expended in efforts at flying, all of which have as yet resulted in failure. But the analogy between sailing on the water and sailing in the air is not so close as many enthusiasts have supposed it to be. There is a general resemblance, inasmuch as in both cases the propulsion must be made by means of a fluid. But in the one case the fluid is inelastic, in the other elastic; and the physicist or mathematician knows how vastly different are the properties of liquids, even in fundamental points, from those of aeriform or gaseous bodies. Again, in the one case the vessel floats on the surface of the water, in the other it must float totally immersed in the aerial fluid. A ship, while sailing, is acted on by two fluids—the water supports it and the air propels it; but a ship sailing in the air would be only under the action of the one fluid that surrounds it on all sides. These few considerations—and many more might be added—indicate the essential distinctions between the two cases; and a very little thought shows that it is not so remarkable as it at first sight appears, that the invention of the art of sailing on the water should be lost in prehistoric antiquity, while that of sailing in the air is not a century old; and that while navigation is one of the most perfect of the arts, the power of directing a body floating in the air still remains unattained. Many have argued, that because navigation is an accomplished fact, therefore the navigation of the air must be possible; and without denying the truth of the conclusion, it is worth while at the outset of this article to point out the fallacy of the reasoning. It is true that there is no reason to despair of the attainment of aerial navigation, as the history of invention and science records many victories as great and at one time apparently as far off; still, it is as well to notice how little assistance the old discovery affords towards the solution of the new: it may, indeed, even be that progress has been retarded by the false analogy, for we may feel pretty certain that if ever the air is navigated, it will be by ships presenting little resemblance to those that traverse the ocean.

The subject of aerostation is scarcely ever alluded to by the classical writers, and the fable of Dædalus and Icarus, and the dove of Archytas, form almost all we have to record in relation to flying previous to the dark ages. Dædalus, an Athenian, killed his nephew Talus through jealousy of his talents, and fled with his son Icarus to Crete, where he built the celebrated labyrinth for Minos, the king. But having offended Minos, so that he was imprisoned by him, he made wings of feathers, cemented with wax, for himself and his son, so that they might escape by flight. He gave his son directions to fly neither too low nor too high, but to follow him. Icarus, however, becoming excited, forgot his father's advice, and rose so high that the heat of the sun melted the wax of his wings, and he fell into the sea near Samos, the island of Icaria and the Icarian sea being named after him. Dædalus accomplished his flight in safety. (Ovid, *Met.* lib. viii. Fab. iii.) The explanation of the myth may be, as has been supposed, that Dædalus used sails, which, till then, according to Pausanius and Palæphatus, were unknown, and so was enabled to escape from Minos' galleys, which were only provided with oars; and that Icarus was drowned near the island Icaria. But the whole story of Dædalus is so fanciful a romance, that it is scarcely worth while even to speculate upon what the infinitesimal fragment of truth that lay at the bottom of it may have been.

Archytas of Tarentum was a well-known geometer and astronomer, and he is apostrophised by Horace (*Ode* 28, lib. i.) The account of his flying pigeon or dove we owe to Aulus Gellius (*Noctes Atticæ*), who says "that it was the model of a dove or a pigeon formed in wood, and so contrived as by a certain mechanical art and power to fly: so nicely was it balanced by weights, and put in motion by hidden and enclosed air." Gellius gives as his authorities "many men of eminence among the Greeks," whom he does not mention by name, and Favorinus the philosopher.

Archytas thus has been regarded as holding to aeronautics much about the same position as Archimedes does to the mechanical sciences; but while the claim of the latter rests on real discoveries and great contributions to knowledge, the former owes his position merely to an unsupported and untrustworthy tradition. When the fire-balloon was invented, it was only natural that many should see in the "hidden and enclosed air" of Archytas' dove a previous discovery of the hot-air balloon. It is quite possible that Archytas may have rarefied the air in his dove by heat, and so made it ascend; but in this case it certainly could not have been made of wood. But if the dove ever was made to appear to fly, it is much the more probable that this effect was produced, as in the scenes at theatres, by means of fine strings or wires invisible to the spectators.

The ancients seem to have been convinced of the impossibility of men being able to fly, and they appear to have made no attempts in this direction at all. The power of flying was attributed only to the most powerful of the divinities; and it was regarded as only secondary to Jupiter's prerogative of flashing the lightning and hurling the thunderbolt.

The history of aerostatics in the Middle Ages, like that of every other subject relating even remotely to science or knowledge of any kind, is little better than a record of the falsehoods or chimeras circulated by impostors or enthusiasts. Truth was completely obscured by ignorance and fanaticism, and every person of superior talents and acquirements was believed to deal in magic, and to perform his feats of skill chiefly through the secret aid granted him by the prince of darkness; and in a later and comparatively recent period, those wretched creatures whom the unfeeling credulity of our ancestors, particularly during the prevalence of religious fanaticism, stigmatised and murdered under the denomination of witches, were supposed to work all their enchantments, to change their shapes at will, and to transport themselves through the air with the swiftness of thought, by a power derived from their infernal master, to whom was thus assigned the privilege of conferring the gift of aerial navigation upon his servants.

During the darkness of the Middle Ages every one at all distinguished for his knowledge in physics was generally reputed to have obtained the power of flying in the air. Friar Bacon did not scruple to claim the invention; and the credulity and indulgent admiration of some authors have lent to these pretensions more credit than they really deserved. Any one who takes the trouble to examine the passages of Bacon's obscure and ponderous works will find that the propositions advanced by him are seldom founded on reality, but ought rather to be considered as the illusions of a lively fancy. Albertus Magnus, who flourished in the first half of the 13th century, was reputed to have discovered the art; and to give an idea of the state of the physical sciences at that time, it is worth while to quote the following recipes from his *De Mirabilibus Naturæ*:—"Take one pound of sulphur, two pounds of willow-carbon, six pounds of rock-salt ground very fine in a marble mortar; place, when you please, in a covering made of flying papyrus to produce thunder. The covering, in order to ascend and float away, should be long, graceful, well filled with this fine powder; but to produce thunder, the covering should be short, thick, and half full." (Quoted in *Astra Castra*, p. 25.) Regiomontanus, the first real mathematician after the partial revival of learning, is said, like Archytas, to have formed an artificial dove, which flew before the Emperor Charles V. at his public entry into Nuremberg; but the date of Regiomontanus' death shows this to have been impossible.

Attempts at flying.

Attempts at flying have, as a rule, been made by a somewhat low class of projectors, who have generally united some little share of ingenuity to a smattering of mechanics. At the beginning of the 16th century an Italian alchemist visited Scotland, and was collated by James IV. to the abbacy of Tungland, in Galloway. Having constructed a set of wings, composed of various plumage, he undertook from the walls of Stirling Castle to fly through the air to France. This feat he actually attempted, but he soon came to the ground, and broke his thigh-bone by the violence of the fall—an accident he explained by asserting that the feathers of some fowls were employed in his wings, and that these had an affinity for the dunghill, whereas, if composed solely of eagles' feathers, they would have been attracted to the air. This anecdote has furnished to Dunbar, the Scottish poet, the subject of one of his rude satires. In 1617, Fleyder, rector of the grammar school at Tübingen, delivered a lecture on flying, which he published eleven years afterwards. A poor monk, however, ambitious to reduce the theory to practice, provided himself with wings; but his machinery broke down, and falling to the ground, he broke his legs and perished. Bishop Wilkins (*Mathematical Magick*, 1648) says it was related that "a certain English monk called Elmerus, about the Confessor's time," flew by means of wings from a tower a distance of more than a furlong; that another person flew from St Mark's steeple at Venice; and another, at Nuremberg. He also quotes Busbequius to the effect that a Turk also attempted something of the kind at Constantinople. It would probably not be very difficult to make a long list of such narrations, in some of which the experimenter is related to have been successful, and in others to have failed; but the evidence is in no case very good, and we may feel certain that all the traditions of attempts with a successful issue are false.

Borelli shows the impossibility of man flying by the aid of wings.

In Borelli's posthumous work, *De Motu Animalium*, published at Rome in 1680-81, he calculated the enormous strength of the pectoral muscles in birds; and his proposition cciv. (vol. i. pp. 322-326) is entitled "Est impossibile, ut homines propriis viribus artificiosè volare possint," in which he clearly points out the impossibility of man being able by his muscular strength to give motion to wings of sufficient extent to keep him suspended in the air. But Borelli did not, of course, as has sometimes been stated, demonstrate the impossibility of man's flying otherwise than merely by means of his own muscular power.

Sailing the air

A very slight consideration of the matter shows that, although the muscles of man may not be of sufficient strength to enable him to use wings, this objection does not apply against the possibility of making a flying chariot in which the motive power should be produced mechanically as in a watch, or a boat to float in the atmosphere. Both these projects have therefore always engaged the attention of abler men than has the art of flying, and it was only the ignorance of the nature and force of the atmosphere, as well as of the properties of all aeriform bodies, that caused so long a time to elapse before the invention of the balloon.

Albert of Saxony

Albert of Saxony, a monk of the order of St Augustine, and a commentator on the physical works of Aristotle, seems first to have comprehended (though in a very vague and erroneous manner) the principles on which a body might be made to float in the atmosphere. Adopting, of course, Aristotelian views with regard to the nature of the elements, he considered that, as fire is more attenuated, and floats above our atmosphere, therefore a small portion of this ethereal substance, enclosed in a light hollow globe, would raise it to a certain height and keep it suspended in the air; and that, if more air were introduced, the globe would sink like a ship when water enters by a leak.

Francis Mendoza

Long afterwards Francis Mendoza, a Portuguese Jesuit, who died in 1626, at the age of forty-six, embraced this theory, and he held that the combustible nature of fire was no real obstacle, as its extreme levity and the extension of the air would prevent it from supporting inflammation.

Casper Schott

Casper Schott, also a Jesuit, adopted the same speculation, only that he replaced the fire by the thin ethereal substance which he believed floated above our atmosphere; but, of course, the difficulty of procuring any of this ether was a sufficient obstacle.

Alchemical notions

Lauretus Laurus

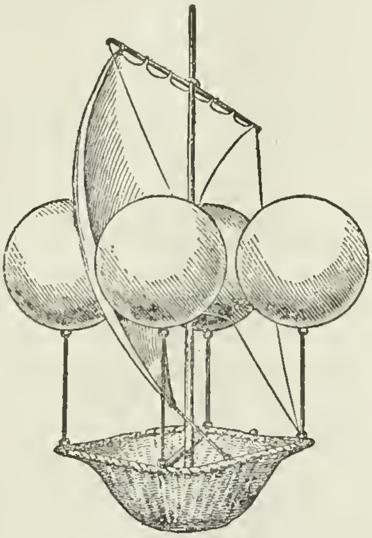
Similar notions have been revived at different times. They were likewise often blended with the alchemical tenets so generally received in the course of the 15th, 16th, and part of the 17th centuries. Thus Schott quotes Lauretus Laurus to the effect that if swans' eggs or leather balls be filled with nitre, sulphur, or quicksilver, and be exposed to the sun, they will ascend. It was also believed that dew was of celestial origin, being shed by the stars, and that it was drawn up again in the course of the day to heaven by the heat of the sun. Thus Laurus states that hens' eggs filled with dew and exposed to the solar heat will rise. He was so grossly ignorant, however, of the principles of motion, that it is not worth while even to allude to his other assertions.

Romance of Cyrano de Bergerac.

Cyrano de Bergerac (born 1620) wrote a philosophical romance entitled *Histoire Comique des Estats et Empire de la Lune*, and *Les Estats et Empire du Soleil* (from which Swift is supposed to have derived the idea of writing portions of *Gulliver's Travels*). To equip himself for performing the journey to the moon, the French traveller fastens round his body a multitude of very thin flasks filled with the morning's dew; the heat of the sun, by its attractive power on the dew, raised him up to the middle region of the atmosphere, whence, some of the flasks being broken, the adventurer sank again to the ground. Other aeronautical ideas occur in the romance.

Cardan proposed that ascensional power might be applied as in a rocket; and one Honoratus Fabry has described a huge apparatus, consisting of long tin pipes, worked by air compressed by the action of fire.

The most noted scheme for navigating the air promulgated previously to the successful experiments of the Montgolfiers, is due to a Jesuit, Francis Lana, and was proposed by him in a work entitled *Prodromo dell'Arte Maestra*, Brescia, 1670. His idea, though useless and unpractical in so far that it could never be carried out, is yet deserving of notice, as the principles involved are sound; and this can be said of no earlier attempt. His project was to procure four copper balls of very large dimensions, yet so extremely thin that after the air was exhausted from them they would be lighter than the air displaced, and so would rise; and to those four balls he proposed to attach a boat, with sails, &c., and which would carry up a man. He submitted the whole matter to calculation, and proposed that the globes should be about 25 feet in diameter and $\frac{1}{225}$th of an inch in thickness; this would give from all four balls a total ascensional force of about 1200 ℔, which would be quite enough to raise the boat, sails, passengers, &c. But the obvious objection to the whole scheme is, that it would be quite impossible to construct a globe of so large a size and of such small thickness which would even support its own weight without falling to pieces if placed on the ground, much less bear the external atmospheric pressure when the internal air was removed. Lana himself noticed the latter objection, but he thought that the spherical form of the copper shell would, notwithstanding its extreme thinness, enable it, after the exhaustion was effected, to sustain the enormous pressure, which, acting equally on every point of the surface, would tend to consolidate rather than to break the metal. Of course this assumed the ball to be absolutely spherical, a state of affairs as impossible as indifferent equilibrium actually is. He proposed to exhaust the air from the globes by attaching each to a tube 36 feet long, fitted with a stopcock, and so produce a Torricellian vacuum. He was thus apparently ignorant of the invention of the air-pump by Otto Guericke about 1650; and though his project is noteworthy as the hydrostatics of it is correct, still Lana displays his ignorance of philosophical facts known in his day, quite as much as his originality; and his proposition has, since Montgolfier's discovery, received a greater share of notice than it deserves.



Lana's Aeronautical Machine.

So late as 1755, and not long before the invention of balloons, a very fanciful scheme was proposed by Joseph Galien, a Dominican friar, and professor of philosophy and theology in the papal university of Avignon. This visionary proposed to collect the diffuse air of the upper regions, and to enclose it in a huge vessel extending more than a mile every way, and intended to carry fifty-four times as much weight as did Noah's ark. It is unnecessary to notice at greater length this absurd chimera, which is merely mentioned here at all because it is sometimes referred to, though only on account of the magnitude of the fantastic scheme.

False ideas with regard to the atmosphere.

It is proper here to remark, that nearly all the early projectors imagined that the atmosphere was of no great height, and that it covered the earth like a shallow ocean, having a well-defined boundary; and the aerial vessels which they proposed were intended to float on the surface of this ocean, exactly as ships do on the sea, with their upper portions in the ether or diffuse air, or whatever the fluid might be, that lay above. And these ideas were, of course, not dispelled till after the invention of the barometer and the discovery of the law of the decrease of atmospheric pressure with elevation.

Confused ideas of Bacon on aeronautics.

Some writers have stated that Francis Bacon first published the true principles of aeronautics. This assertion we cannot help noticing, because it has really no foundation except in the propensity, fostered by indolence, which would gladly refer all the discoveries ever made to a few great names. They mistake, indeed, the character of Bacon who seek to represent him as an inventor. His claim to immortality rests chiefly on the profound and comprehensive views which he took of the bearings of the different parts of human knowlege; for it would be difficult to point out a single fact or observation with which he enriched the store of physical science. On the contrary, being very deficient in mathematical learning, he disregarded or rejected some of the noblest discoveries made in his own time.

We can find only two passages in Bacon's works which can be considered as referring to aeronautics, and they both occur in that collection of loose facts and inconclusive reasonings which he has entitled *Natural History*. The first is styled *Experiment Solitary, touching Flying in the Air*, and runs thus—"Certainly many birds of good wing (as kites and the like) would bear up a good weight as they fly; and spreading feathers thin and close, and in great breadth, will likewise bear up a great weight, being even laid, without tilting up on the sides. *The farther extension of this experiment might be thought upon.*" The second passage is more diffuse, but less intelligible; it is styled *Experiment Solitary, touching the Flying of unequal Bodies in the Air:*—"Let there be a body of unequal weight (as of wool and lead or bone and lead); if you throw it from you with the light end forward, it will turn, and the weightier end will recover to be forwards, unless the body be over long. The cause is, for that the more dense body hath a more violent pressure of the parts from the first impulsion, which is the cause (though heretofore not found out, as hath been often said) of all violent motions; and when the hinder part moveth swifter (for that it less endureth pressure of parts) than the forward part can make way for it, it must needs be that the body turn over; for (turned) it can more easily draw forward the lighter part." The fact here alluded to is the resistance that bodies experience in moving through the air, which, depending on the quantity of surface merely, must exert a proportionally greater effect on rare substances. The passage itself, however, after making every allowance for the period in which it was written, must be deemed confused, obscure, and unphilosophical.

Discovery of the balloon.

We now come to the discovery of the balloon, which was due to Stephen and Joseph Montgolfier, sons of Peter Montgolfier, a large and celebrated papermaker at Annonay, The brothers Montgolfier.

a town about 40 miles from Lyons. The brothers had observed the suspension of clouds in the atmosphere, and it occurred to them that if they could enclose any vapour of the nature of a cloud in a large and very light bag, it might rise and carry the bag with it into the air. They accordingly made experiments, inflating bags with smoke from a fire placed underneath, and found either that the smoke or some vapour emitted from the fire did ascend and carry the bag with it. Being thus assured of the correctness of their views, they determined to have a public ascent of a balloon on a large scale. They accordingly invited the States of Vivarais, then assembled at Annonay, to witness their aerostatic experiment; and on June 5, 1783, in the presence of a considerable concourse of spectators, a linen globe of 105 feet in circumference was inflated over a fire fed with small bundles of chopped straw, and when released rapidly rose to a great height, and descended, at the expiration of ten minutes, at the distance of about 1½ mile. This was the discovery of the balloon. The brothers Montgolfier imagined that the bag rose because of the levity of the smoke or other vapour given forth by the burning straw; and it was not till some time later that it was recognised that the ascending power was due merely to the lightness of heated air compared to an equal volume of air at a lower temperature. Air, like all other fluids, expands by heat, and thereby becomes rarefied, so that any volume of hot air weighs less than the corresponding volume of air at a lower temperature. If, then, the air inside the balloon be so heated that it, together with the balloon, weighs less than the air displaced, the balloon will rise till it arrives at such a height that it and the enclosed air are equal in weight to that of the displaced air, when equilibrium will be obtained. In Montgolfier's first balloon, no source of heat was taken up with it, so that the air inside rapidly cooled, and the balloon soon descended.

Ascent of the first air-balloon.

The news of the experiment at Annonay rapidly spread over Europe, and at Paris attracted so much attention that M. Fäujas de Saint-Fond, a naturalist, set on foot a subscription for paying the expense of repeating the experiment. The balloon was constructed by two brothers of the name of Robert, under the superintendence of M. Charles, professor of natural philosophy in Paris, and afterwards a member of the Academy of Sciences. It had at first been suggested to copy the process of Montgolfier, but Charles proposed the application of hydrogen gas, which was adopted. The filling of the balloon, which was made of thin silk varnished with a solution of elastic gum, and was about 13 feet in diameter, was commenced on August 23, 1783, in the Place des Victoires. The hydrogen gas was obtained by the action of dilute sulphuric acid upon iron filings, and was introduced through leaden pipes; but as the gas was not passed through cold water, great difficulty was experienced in filling the balloon completely; and altogether about 500 lb of sulphuric acid and twice that amount of iron filings were used. Bulletins were issued daily of the progress of the inflation; and the crowd was so great that on the 26th the balloon was moved to the Champ de Mars, a distance of 2 miles. This was done secretly, in the middle of the night, to avoid the crowd; and the appearance of the balloon being thus removed, preceded by lighted torches and escorted by a detachment of soldiers, is described as having been very remarkable. On the next day, August 27, an immense concourse of people covered the Champ de Mars, and every spot from which a view could be obtained was crowded. About five o'clock a cannon was discharged as the signal for the ascent, and the balloon when liberated rose to the height of about 3000 feet with great rapidity. A shower of rain which began to fall directly after the balloon had left the earth in no way checked its progress; and the excitement was so great, that thousands of well-dressed spectators, many of them ladies, stood exposed, watching it intently the whole time it was in sight, and were drenched to the skin. The balloon, after remaining in the air for about three-quarters of an hour, fell in a field near Gonesse, about 15 miles off, and terrified the peasantry so much that it was torn into shreds by them. Hydrogen gas was at this time known by the name of inflammable air; and balloons inflated with gas have ever since been called by the people air-balloons, the kind invented by the Montgolfiers being designated fire-balloons. French writers have also very frequently styled them after their inventors, *Charlières* and *Montgolfières*.

Ascent of sheep, cock, and duck.

On the 19th of September 1783 Joseph Montgolfier repeated the Annonay experiment at Versailles, in the presence of the king, the queen, the court, and an immense number of spectators. The inflation was commenced at one o'clock, and completed in eleven minutes, when the balloon rose to the height of about 1500 feet, and descended after eight minutes, at a distance of about two miles, in the wood of Vaucresson. Suspended below the balloon, in a cage, had been placed a sheep, a cock, and a duck, which were thus the first aerial travellers. They were quite uninjured, except the cock, which had its right wing hurt in consequence of a kick it had received from the sheep; but this took place before the ascent. The balloon, which was painted with ornaments in oil colours, had a very showy appearance. See Plat

Ascent of M. Pilâtre de Rozier and the Marquis d'Arlandes.

The first human being who ascended in a balloon was M. François Pilâtre de Rozier, a young naturalist, who, two years afterwards, was killed in an attempt to cross the English Channel in a balloon. On October 15, 1783, and following days, he made several ascents (generally alone, but once with a companion, M. Girond de Villette), in a captive balloon (*i.e.*, one attached by ropes to the ground), and demonstrated that there was no difficulty in taking up fuel and feeding the fire, which was kindled in a brazier suspended under the balloon, when in the air. The way being thus prepared for aerial navigation, on November 21, 1783, M. Pilâtre de Rozier and the Marquis d'Arlandes first trusted themselves to a free fire-balloon. The experiment was made from the Jardin du Chateau de la Muette, in the Bois de Boulogne. The machine employed, which was a large fire-balloon, was inflated at about two o'clock, and leaving the earth at this time, it rose to a height of about 500 feet, and passing over the Invalides and the Ecole Militaire, descended beyond the Boulevards, about 9000 yards from the place of ascent, having been between twenty and twenty-five minutes in the air. The result was completely successful; and it is scarcely necessary to add, the excitement in Paris was very great.

Only ten days later, viz., on December 1, 1783, MM. Charles and Robert ascended from Paris in a balloon inflated with hydrogen gas. The balloon, as in the case of the small one of the same kind previously launched from the Champ de Mars, was constructed by the brothers Robert. It was 27 feet in diameter, and the car was suspended from a hoop surrounding the middle of the balloon, and fastened to a net which covered the upper hemisphere. The balloon ascended very gently from the Tuileries at a quarter to two o'clock, and after remaining for some time at an elevation of about 2000 feet, it descended in about two hours at Nesle, a small town about 27 miles from Paris, when M. Robert left the car, and M. Charles made a second ascent by himself. He had intended to have replaced the weight of his companion by a nearly equivalent quantity of ballast; but not having any suitable means of obtaining such ready at the place of descent, and it being just upon sunset, he gave the word to let go, and the balloon being thus so greatly lightened, ascended very rapidly to a height of about 2 miles. After staying in the air about half-an-hour, he descended 3 miles from the place of ascent, although he believed the distance traversed, owing to different currents, to have been about 9 miles. In this second journey M. Charles experienced a violent pain in his right ear and jaw, no doubt produced by the rapidity of the ascent. He also witnessed the phenomenon of a double sunset on the same day; for when he ascended, the sun had set in the valleys, and as he mounted he saw it rise again, and set a second time as he descended.

All the features of the modern balloon as now used are more or less due to Charles, who invented the valve at the top, suspended the car from a hoop, which was itself attached to the balloon by netting, &c. The M. Robert who accompanied him in the ascent was one of the brothers who had constructed it.

On January 19, 1784, the largest balloon on record (if the contemporary accounts are correct) ascended from Lyons. It was more than 100 feet in diameter, about 130 feet in height, and when distended had a capacity, it is said, of over half-a-million cubic feet. It was called the *Flesselles* (from the name of its proprietor or owner, we believe), and after having been inflated from a straw fire in seventeen minutes, it rose with seven persons in the car, viz., Joseph Montgolfier, Pilâtre de Rozier, Count de Laurencin, Count de Dampierre, Prince Charles de Ligne, Count de Laport d'Anglefort, and M. Fontaine, the last gentleman having leaped into the car just as the machine had started. The fire was fed with trusses of straw, and the balloon rose majestically to the height of about 3000 feet, but descended again after the lapse of about a quarter of an hour from the time of starting, in consequence of a rent in the upper part.

It is proper here to state that researches on the use of gas for inflating balloons seem to have been carried on at Philadelphia nearly simultaneously with the experiments of the Montgolfiers; and when the news of the latter reached America, Messrs Rittenhouse and Hopkins, members of the Philosophical Academy of Philadelphia, constructed a machine consisting of forty-seven small hydrogen gas-balloons attached to a car or cage. After several preliminary experiments, in which animals were let up to a certain height by a rope, a carpenter, one James Wilcox, was induced to enter the car for a small sum of money; the ropes were cut, and he remained in the air about ten minutes, and only then effected his descent by making incisions in a number of the balloons, through fear of falling into the river, which he was approaching.

The improvements that have been made in the management and inflation of balloons in the last ninety years have only had reference to details, so that as far as essential principles are concerned the subject is now in pretty much the same state as it was in 1783. We have therefore arrived at a point in the history of the balloon where it is well to consider how much the Montgolfiers and Charles owed to their predecessors; and it is proper here to state that, although we have assigned the invention to the two brothers, Stephen and Joseph—as no doubt they both conducted the early experiments together—still there is reason to believe that the share of the latter was very small. Stephen, however, although the originator of balloons, does not appear ever to have ascended himself, and Joseph did not repeat the ascent just mentioned in the *Flesselles*. The Montgolfiers had studied Priestley's *Experiments relating to different kinds of Air*, whence they first conceived the possibility of navigating the atmosphere; but their experiment was so simple as to require scarcely any philosophical knowledge. They had seen smoke ascend, and thought that if they could imprison it in a bag, the bag might ascend too; and the observation and reasoning were both such as might occur to anybody. This does not detract from their merit; it, on the contrary, adds to it. The fact that millions of persons must have observed the same thing, and had *not* derived anything practical therefrom, only enhances the glory of those who in such well-worn tracts did make a discovery; but the simplicity of the invention shows that it is needless to inquire whence the brothers were led to make it, and how far any part of the credit is due to their predecessors. It is scarcely possible to imagine anything more remarkable than that the fact that a light bag held over a fire would ascend into the air was not discovered till 1783, notwithstanding that men in all ages had seen smoke ascend from fire (though, of course, the fire-balloon does not ascend for exactly the same reason that smoke does). It might be supposed that the connection of the Montgolfiers with a paper manufactory gave them facilities for constructing their experimental balloons of thin paper; and perhaps such was the case, although we can find no evidence of it. With regard to Charles's substitution of hydrogen gas, there are anticipations that must be noticed. As early as 1766 Cavendish showed that this gas was at least seven times lighter than ordinary air, and it immediately occurred to Dr Black, of Edinburgh, well known as the discoverer of latent heat, that a thin bag filled with hydrogen gas would rise to the ceiling of a room. He provided, accordingly, the allantois of a calf, with the view of showing at a public lecture such a curious experiment; but for some reason it seems to have failed, and Black did not repeat it, thus allowing a great discovery, almost within his reach, to escape him. Several years afterwards a similar idea occurred to Tiberius Cavallo, who found that bladders, even when carefully scraped, are too heavy, and that China paper is permeable to the gas. But in 1782, the year before the invention of the Montgolfiers, he succeeded in elevating soap-bubbles by inflating them with hydrogen gas. The discovery of fire-balloons might have taken place almost at any time in the world's history, but the substitution of hydrogen gas for heated air could not have been made previously to the latter half of the last century; and although all the honour of an independent discovery belongs to the Montgolfiers, Charles, by his substitution of "inflammable air" for heated air, merely showed himself acquainted with the state of chemical science of his day. Charles never again ascended after his double expedition on the 1st of December 1783.

Dr Black's experiments

Cavallo inflated soap bubbles with hydrogen gas in 1782.

We now return to the history of aerial navigation, and commence with an account of the first ascents of balloons in this country. Although the news of the Annonay and subsequent experiments in France rapidly spread all over Europe, and formed a topic of general discussion, still it was not till five months after the Montgolfiers had first publicly sent a balloon into the air that any aerostatic experiment was made in England. In November 1783 Count Zambeccari, an Italian, who happened to be in London, made a balloon of oil-silk, 10 feet in diameter, and weighing 11 lb. It was publicly shown for several days, and on the 25th it was three-quarters filled with hydrogen gas, and launched from the Artillery ground at one o'clock. It descended after two hours and a half near Petworth, in Sussex, 48 miles from London. This was the first balloon that ascended from English ground. On February 22, 1784, a hydrogen gas balloon, 5 feet in diameter, was let up from Sandwich, in Kent, and descended at Warneton, in French Flanders, 75 miles distance. This was the first balloon that crossed the Channel. The difficulties and dangers of aerial navigation having been surmounted by the end of the year

1783, the ascents of balloons were now multiplied in all quarters. It will therefore be sufficient to notice very briefly only the more remarkable of the succeeding ascents.

The Chevalier Paul Andreani, of Milan, constructed a fire-balloon 68 feet in diameter, and on February 25, 1784, ascended from Milan with two brothers of the name of Gerli, and remained in the air for about twenty minutes. This is usually regarded as the first ascent in Italy (but see Monck Mason's *Aeronautica*, p. 247). Andreani ascended again on March 13, with two other persons.

On the 2d of March M. Jean Pierre Blanchard, who had been for some years before occupied with projects for flying, made his first voyage from Paris in a balloon 27 feet in diameter, and descended at Billancourt, near Sèvres. Just as the balloon was about to ascend, a young man jumped into the car, and, drawing his sword, declared his determination to ascend with Blanchard. He was ultimately removed by force. The episode is worth noting, as it has sometimes been stated that the young man was Napoleon Bonaparte, but this is untrue; his name was Dupont de Chambon. Blanchard made subsequently, it is said, more than thirty aerial voyages, and he is one of the most celebrated of the earlier aeronauts. He also crossed the English Channel, as noticed further on.

On July 15, 1784, the Duc de Chartres and the two brothers Robert ascended from St Cloud; but the neck of the balloon becoming choked up with an interior balloon filled with common air, intended to regulate the ascending and descending power, they were obliged to make a hole in the balloon, in order to allow of the escape of the gas, but they descended in safety.

The first person who rose into the air from British ground appears to have been Mr J. Tytler,[1] who ascended from the Comely Gardens, Edinburgh, on August 27, 1784, in a fire-balloon of his own construction. He descended on the road to Restalrig, about half-a-mile from the place where he rose. A brief account appeared in a letter, under date August 27, in the *London Chronicle*, and we have seen a picture of the balloon copied in some journal from a "ticket in the British Museum." Mr Tytler's claims were for a long time entirely overlooked, the honour being invariably assigned to Lunardi, till attention was called to them by Mr Monck Mason in 1838. After Lunardi's successful ascents in 1785, Mr Tytler addressed a set of verses to him (quoted in *Astra Castra*, p. 108), in a note, to which he gives a modest account of his own "misfortunes," describing his two "leaps." This is, perhaps, the most correct name for them, as his apparatus having been damaged at different times, he merely heated the air in the balloon, and went up without any furnace, being seated in an ordinary basket for carrying earthenware. He reached a height of from 350 to 500 feet.

Although by a few days Tytler has the precedence, still his attempts and partial success were all but totally unknown; whereas Lunardi's experiments excited an enormous amount of enthusiasm in London, and it was he that practically introduced aerostation into this country in the face of very great disadvantages. We have already referred to the extraordinary apathy displayed in England with regard to aerostatic experiments, one consequence of which was that their introduction was due to a foreigner. Vincent Lunardi was secretary to Prince Caramanico, the Neapolitan ambassador, and his published letters to his guardian, the Chevalier Compagni, written while he was carrying out his project, and detailing all the difficulties, &c., he met with as they occurred, are very interesting, and give a vivid account of the whole matter. His balloon was 33 feet in circumference, and was exposed to the public view at the Lyceum in the Strand, where it was visited by upwards of 20,000 people. It was his original intention to have ascended from Chelsea Hospital, but the conduct of a crowd at a garden at Chelsea, which destroyed the fire-balloon of a Frenchman named De Moret, who announced an ascent on August 11, but was unable to keep his word, led to the withdrawal of the leave that had been granted. Ultimately, after some difficulties had been arranged, he was permitted to ascend from the Artillery ground, and on September 15, 1784, the inflation with hydrogen gas took place. It was intended that Mr Biggin, an English gentleman, should accompany Lunardi; but the crowd becoming impatient, the latter judged it prudent to ascend with the balloon only partially full rather than risk a longer delay, and accordingly Mr Biggin was obliged to leave the car. Lunardi therefore ascended alone, in presence of the Prince of Wales and an enormous crowd of spectators. He took up with him a pigeon, a dog, and a cat, and the balloon was provided with oars, by means of which he hoped to raise or lower it at pleasure. Shortly after starting, the pigeon escaped, and one of the oars became broken and fell to the ground. In about an hour and a half he descended at South Mimms, in Hertfordshire, and landed the cat, which had suffered from the cold: he then ascended again, and descended, after the lapse of about three-quarters of an hour, at Standon, near Ware, where he had great difficulty in inducing the peasants to come to his assistance; but at length a young woman, taking hold of one of the cords, urged the men to follow her example, which they then did. The excitement caused by this ascent was immense, and Lunardi at once became the star of the hour. He was presented to the king, and was courted and flattered on all sides. To show the enthusiasm displayed by the people during his ascent, he tells himself, in his sixth letter, how a lady, mistaking the oar which fell for himself, was so affected by his supposed destruction that she died in a few days; but, on the other hand, he says he was told by the judges "that he had certainly saved the life of a young man who might possibly be reformed, and be to the public a compensation for the death of the lady;" for the jury were deliberating on the fate of a criminal, whom they must ultimately have condemned, when the balloon appeared, and every one became inattentive, and to save time they gave a verdict of acquittal, and the whole court came out to view the balloon. The king also was in conference with his ministers; but on hearing that the balloon was passing, he broke up the discussion, remarking that they might resume their deliberations, but that perhaps they might not see Lunardi again; upon which he, Mr Pitt, and the other ministers viewed the balloon through telescopes. The balloon was afterwards exhibited in the Pantheon. In the latter part of the following year (1785) Lunardi made several very successful ascents from Kelso, Edinburgh, and Glasgow (in one of which he traversed a distance of 110 miles): these he has described in a second series of letters. He subsequently returned to Italy, where we believe he still followed the practice of aerostation, and made many ascents. He died on July 31, 1806, at Lisbon, according to the *Gentleman's Magazine*, but a contemporary newspaper gives Genoa as the place, and adds that he died in a state of very great indigence.

Lunardi's example was soon followed by others, and on October 16, 1784, Blanchard ascended from Little Chelsea with Mr Sheldon, and having deposited the latter at Sunbury, rose again alone, and descended at Romney Marshes. On November 12, Mr James Sadler, sen., ascended from Oxford, and there is every reason to believe that he made a previous ascent from the same place on October 12, four

ascents
England

[1] Mr Tytler contributed largely to, and, indeed, appears to have been virtually editor of, the second edition (1778-83) of the *Encyclopaedia Britannica*.

days previous to Blanchard's (see Monck Mason, p. 274, where it is stated that he attempted to ascend in a fire-balloon on September 12, but that the balloon was burnt). On November 30, 1784, Blanchard again ascended, accompanied this time by Dr J. Jeffries, an American physician. On January 4, 1785, Mr Harper ascended from Birmingham; and on January 7, Blanchard and Dr Jeffries achieved the feat of crossing the Channel from Dover to Calais. At seven minutes past one the balloon left Dover Castle, and in their passage they had a most magnificent view of both shores. When about one-third across they found themselves descending, and threw out every available thing from the boat or car. When about three-quarters across they were descending again, and had to throw out not only the anchor and cords, but also to strip and throw away part of their clothing, after which they found they were rising, and their last resource, viz., to cut away the car, was rendered unnecessary. As they approached the shore the balloon rose, describing a magnificent arch high over the land. They descended in the forest of Guinnes.

ccari.

On March 23, 1785, Count Zambeccari, who had, as we have seen, launched the first balloon from English ground, ascended for the first time with Admiral Vernon from London. Shortly afterwards he returned to his own country, and there applied himself assiduously to the practice of aerial navigation. He twice, in 1803 and 1804, descended into the Adriatic, and both times only escaped after undergoing much danger. Descending in a fire-balloon on September 21, 1812, after a voyage from Bologna, the shock of the grapnel catching in a tree caused the balloon to catch fire; and to save themselves from being burnt, Zambeccari and his companion, Signor Bonaga, leaped from the car. The former was killed on the spot, but the latter, though fearfully injured, escaped with his life.

r
de

On June 15, 1785, Pilâtre de Rozier made his last fatal voyage from Boulogne. It was his intention to have repeated the exploit of Blanchard and Jeffries in the reverse direction, and have crossed from Boulogne to England. For this purpose he had contrived a double balloon, which he expected would combine the advantages of both kinds—a fire-balloon, 10 feet in diameter, being placed underneath a gas-balloon of 37 feet in diameter, so that by increasing or diminishing the fire in the former it might be possible to ascend or descend without waste of gas. Rozier was accompanied by M. P. A. Romain, and for rather less than half-an-hour after the aerostat ascended all seemed to be going on well, when suddenly the whole apparatus was seen in flames, and the unfortunate adventurers came to the ground from the supposed height of more than 3000 feet. Rozier was killed on the spot, and Romain only survived about ten minutes. A monument was erected on the place where they fell, which was near the sea-shore, about four miles from the starting-point. The Marquis de la Maisonfort had accompanied Rozier to Boulogne, intending to ascend with him, but M. Romain there insisted on a prior promise. Either the upper balloon must have been reached by the flames, and the gas taken fire, or the gas must have poured down into the lower balloon, and so have caused the explosion.

We must not omit to mention that on June 4, 1784, Madame Thible ascended from Lyons in a fire-balloon with M. Fleurand, in the presence of King Gustavus of Sweden, then travelling under the name of Count Haga. Madame Thible is very likely the only woman who ever ascended in a fire-balloon. The first Englishwoman who ever ascended into the air was Mrs Sage, who accompanied Mr Biggin in his voyage from London on June 29, 1785.

anti-

Accounts are given of an ascent at Constantinople, made in the presence of the Sultan, by a Persian physician, accompanied by two Bostangis, early in the year 1786, who, crossing the sea which divides Europe from Asia, descended about 30 leagues from the coast.

Most of the subsequent ascents merely undertaken for pleasure, and of no permanent

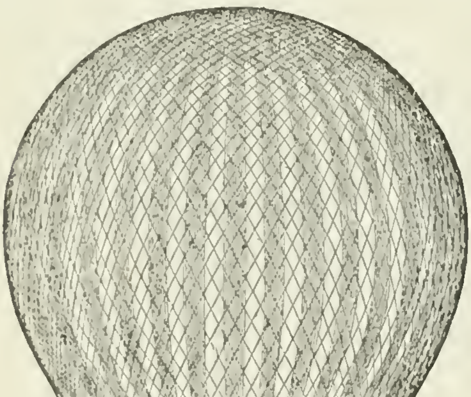
We have now given a brief account of all the noteworthy voyages that took place within the first two or three years after the discovery of the balloon by Montgolfier. Ascents were multiplied from this time onwards, and it is impossible to give even a list of the many hundreds that have taken place since: this omission is, however, of slight importance, as henceforth the balloon became little better than a toy, let up to amuse people at *fêtes* or other public occasions. When the first ascents were made in France, the glow of national vanity was lighted up, and the most brilliant expectations were felt with regard to aerostation, and the glory to the nation that would accrue therefrom. These anticipations have not been realised, and the balloon at this moment has received no great improvement since the time of Charles, except the substitution of ordinary coal-gas for hydrogen, which has rendered the inflation of a balloon at any gas-works a comparatively simple matter, bearing in mind the elaborate contrivances required for the generation of hydrogen in sufficient quantities. But in one respect the balloon has been of real service, viz., to science, in rendering the attainment of observations in the higher strata of the atmosphere not only possible but practicable. In regard to such matters the balloon is unique, as the atmosphere is the great laboratory of nature, in which are produced all the phenomena of weather, the results of which we perceive on the earth; and no observations made on mountain-sides can take the place of those made in the balloon, as what is required is the knowledge of the state of the upper atmosphere itself, free from the disturbing effects of the contiguity of the land. Although, therefore, in what follows, we shall notice any particularly remarkable ascents, we shall chiefly confine ourselves to the few that have been undertaken for the sake of advancing science, and which alone are of permanent value. It will be necessary to make one exception to this rule, however, in the case of the parachute, the experiments with which require some notice, although they have been put to no useful purpose. The balloon has also been used in warfare as a means of observing the movements of the enemy; and the applications of it to this purpose deserve notice, although we think not so much use has been made of the balloon in this direction as might have been.

Substitution of coal-gas for hydrogen by Mr Green.

The substitution of coal-gas for hydrogen is due to Mr Charles Green, the veteran aeronaut, who made several hundred ascents, the first of which took place on July 19, 1821, the coronation day of George IV. In this ascent ordinary coal-gas was first used; and every balloon, with very few exceptions, that has ascended since this date has been so inflated. Pall Mall was first lighted by gas in 1807, and at the end of 1814 the general lighting of London by gas commenced; so that coal-gas could not have been available for filling balloons long before it was actually used.

Subsequent famous ascents (non-scientific).

Leaving out of consideration the ascents undertaken for scientific objects (very many of which were remarkable for the height attained or the distance traversed, and which will be specially noticed further on), we proceed to mention the most noteworthy ascents that have taken place and that have not ended fatally (these latter will be referred to separately). Mr Crosbie, a gentleman who was the first to ascend from Ireland (January 19, 1785), on the 19th July 1785 attempted to cross St George's Channel to England, but fell into the sea; he was saved by some vessels that came to his rescue. Lunardi also fell into the sea, about a mile and a half from the shore, after an ascent from Edinburgh in December 1785; he was rescued by a fishing-boat. Richard Maguire was the second person who ascended from Ireland. Mr Crosbie had inflated his balloon on May 12, 1785, but it was unable to take him up, when Mr Maguire, a student at the university, who was present, offered to ascend. His offer was accepted, and he made the ascent. For this he was knighted by the Lord-Lieutenant (Monck Mason, p. 266). On July 22, 1785, Major Money ascended from Norwich. The balloon was blown out to sea, and he was obliged to descend into the water. After remaining there seven hours he was rescued by a revenue cutter which had been despatched to his assistance. Mr James Sadler attempted to cross St George's Channel on the 1st of October 1812, and had nearly succeeded, when, in consequence of a change in the wind, he was forced to descend into the sea off Liverpool. After remaining in the water some time, he was rescued by a fishing-boat. But on July 22, 1817, Mr Windham Sadler, his second son, succeeded in crossing the Channel from Dublin to Holyhead. On May 24, 1837, Mr Sneath ascended from near Mansfield in a fire-balloon, and descended safely. At half-past one o'clock on November 7, 1836, Mr Robert Hollond, Mr Monck Mason, and Mr Charles Green ascended from Vauxhall Gardens, and descended at about two leagues from Weilburg, in the duchy of Nassau, at half-past seven the next morning, having thus traversed a distance of about 500 miles in 18 hours; Liége was passed in the course of the night, and Coblentz in the early morning. A full account of this trip is given by Mr Monck Mason in his *Aeronautica* (1838). The balloon in which the journey was performed (a very large one, containing about 85,000 cubic feet of gas), was subsequently called the *Nassau Balloon*, and under that name became famous, and ascended frequently.



The Great Nassau Balloon.

Equestrian ascents.

We ought also, perhaps, to notice a curious ascent made by Mr Green on July 29, 1828, from the Eagle Tavern, City Road, on the back of a favourite pony. Underneath the balloon was a platform (in place of a car) containing places for the pony's feet, and some straps went loosely under his body, to prevent his lying down or moving about. Everything passed off satisfactorily, the balloon descending safely at Beckenham; the pony showed no alarm, but quietly ate some beans with which its rider supplied it in the air. Equestrian ascents have since been repeated. In 1852, Madame Poitevin, who had made several such journeys in Paris, ascended from Cremorne Gardens, London, on horseback (as "Europa on a bull"); but after the first journey its repetition was stopped in England by application to the police courts, as the exhibition outraged public feeling. Lieutenant Gale was killed at Bordeaux on Sept. 8, 1850, in descending after an equestrian ascent, through mismanagement in landing of the horse. M. Poitevin, descending in 1858, after an equestrian ascent from Paris, was nearly drowned in the sea near Malaga. Among remarkable balloon ascents must also be noticed that of Mr Wise, from St Louis, on June 23, 1859, in which a distance of 1120 miles was traversed.

Nadar's balloon.

In 1863, Nadar, a well-known photographer at Paris, constructed an enormous balloon, which he called "Le Géant." It was the largest gas-balloon ever constructed, containing over 200,000 cubic feet of gas. Underneath it was placed a smaller balloon, called a compensator, the object of which was to prevent loss of gas during the voyage. The car had two stories, and was, in fact, a model of a cottage in wicker-work, 8 feet in height by 13 feet in length, containing a small printing-office, a photographic department, a refreshment-room, a lavatory, &c. The first ascent took place at five o'clock on Sunday, October 4, 1863, from the Champ de Mars. There were thirteen persons in the car, including one lady, the Princess de la Tour d'Auvergne, and the two aeronauts Louis and Jules Godard. In spite of the elaborate preparations that had been made and the stores of provisions that were taken up, the balloon descended at nine o'clock, at Meaux, the early descent being rendered necessary, it was said, by an accident to the valve-line. A second ascent was made a fortnight later. viz., on October 18; there were nine passengers, including Madame Nadar. The balloon descended at the expiration of seventeen hours, near Nienburg in Hanover, a distance of about 400 miles. A strong wind was blowing, and the balloon was dragged over the ground a distance of 7 or 8 miles. All the passengers were bruised, and some more seriously hurt. The balloon and car were then brought to England, and exhibited for some time at the Crystal Palace at the end of 1863 and beginning of 1864. The two ascents of Nadar's balloon excited an extraordinary amount of enthusiasm and interest, vastly out of proportion to what they were entitled to. The balloon was larger than any of the same kind that had previously ascended; but this was scarcely more than just appreciable to the eye, as the doubling the contents of a balloon makes comparatively slight addition to its diameter. M. Nadar's idea was to obtain sufficient money, by the exhibition of his balloon, to carry out a plan of aerial locomotion he had conceived possible by means of the principle of the screw; in fact, he spoke of "Le Géant" as "the last balloon." He also started *L'Aeronaute*, a newspaper devoted to aerostation, and published a small book, which was translated into English under the title *The Right to Fly*. Nadar's ascents had not the remotest connection with science, although he claimed that they had; nor was his knowledge, as shown in his writings, sufficient to have enabled him to advance it in any way.

Eugene Godard's large fire balloon.

Directly after Nadar's two balloon ascents, M. Eugene Godard constructed what was perhaps the largest aerial machine that has ever been made. It was a Montgolfier or fire-balloon, of nearly half-a-million cubic feet capacity (more than double the capacity of Nadar's). The balloon *Flesselles*, 1783, is said to have slightly exceeded this size. The air was heated by an 18 feet stove, weighing, with the chimney, 980 lb. This furnace was fed by straw; and the "car" consisted of a gallery surrounding it. Two ascents of this balloon were made from Cremorne Gardens, on July 20 and July 28, 1864. After the first journey the balloon descended at Greenwich, and after the second at Walthamstow, where it was injured by being blown against a tree. Notwithstanding the enormous size of the balloon, M. Godard asserted that it could be inflated in half an hour, and the inflation at Cremorne did not occupy more than an hour. The ascent of the balloon was a very striking sight, the flames roaring up the chimney of the furnace into the enormous globe above. The trusses of straw were suspended by ropes from the gallery below the car, and were drawn up and placed in the furnace as required. This was the first fire-balloon seen by the inhabitants of London, and it was the second ascent of this kind that had been made in this country, Mr Sneath's ascent at Mansfield having been the first, as Mr Tytler's experiment at Edinburgh in 1784 was a leap, not an ascent, as no source of heat was taken up. In spite of the rapidity with which the inflation was effected, few who saw the ascent could fail to receive an impression most favourable to the gas-balloon in the matter of safety, as a rough descent, with a heated furnace as it were in the car, could not be other than most dangerous.

In the summer of 1873 the proprietors of the New York *Daily Graphic*, an illustrated paper, determined to construct a very large balloon, and enable Mr Wise, the well-known American aeronaut, to realise his favourite scheme of crossing the Atlantic Ocean to Europe. It was believed by many that a current from west to east existed constantly at heights above 10,000 feet, but this seems very uncertain. Mr Green having stated that he had met with such a current, Mr Glaisher made a point of investigating the directions of the wind at different heights in his ascents, but found that they were as capricious as near the ground. The same result was found by others, and a comparison of the courses of the balloons sent up from Paris during the siege will show that no constant current exists. The American project came to nothing owing to the quality of the material of which the balloon was made. The size was said to be such as to contain 400,000 cubic feet, so that it would lift a weight of 14,000 lb. On September 12, 1873, during its inflation, Mr Wise declared the material of which it was made was so bad that he could not ascend in it, though the other two persons who were to accompany him agreed to go. When, however, 325,000 feet of gas had been put into the balloon, a rent was observed, and the whole rapidly collapsed. Although this accident was greatly regretted at the time, it seems pretty certain, from what subsequently took place, that the aeronauts would not have succeeded in their object, and a serious mishap was probably avoided. On October 6, 1873, Mr Donaldson and two others ascended from New York in the balloon after it had been repaired, and effected a perilous descent in Connecticut. During the autumn of 1873 a great amount of discussion took place both in England and America about the existence of the westerly current and the subject of aerostation. In September 1873 Mr Barnum, the well known American showman, visited England with the view of eliciting whether, in the opinion of those best qualified, there was sufficient probability of a successful result to induce him to undertake the construction of a suitable balloon.

By aeronauts (omitting the pioneers Lunardi, Zambeccari, and others who have been already spoken of) we mean persons who have followed ballooning as a business or trade. Of these, perhaps the best known and most successful have been Blanchard, Garnerin, the Sadlers, Mr Charles Green, Mr Wise, Mr Coxwell, and the brothers Godard. Blanchard made, it is said, thirty-six ascents, his first having taken place on March 2, 1784. His wife also made many ascents; she was killed on July 7, 1819. Garnerin is said to have ascended more than fifty times; he introduced night ascents with fireworks, &c., the first of which took place on August 4, 1807. We shall have occasion to refer to him again when we treat of parachutes. Mr James Sadler made about sixty ascents, the first of which took place on October 12, 1784. His two sons, John and Windham, both followed in their father's steps; the latter was killed in 1817. In the minds of most Englishmen the practice of ballooning will, for a long time, be associated with the name of Mr Charles Green, the most celebrated of English aeronauts, who, having made his first ascent on July 19, 1821, only died in the year 1870, at a very advanced age. He is credited with 526 ascents by Mr Turnor; and from advertisements, &c., we see that in 1838 he had made 249. Mr Green may be said to have reduced ballooning to routine, and he made more ascents than any other person has ever accomplished. He accompanied Mr Welsh in his scientific ascents, and to him is also due the invention of the *guide rope*, which he used in many of his voyages with success. It merely consisted of a rope not less than 1000 feet in length, which was attached to the ring of the balloon (from which the car is suspended), and hung down so that the end of it was allowed to trail along the surface of the ground, the object being to prevent the continual waste of gas and ballast that takes place in an ordinary balloon journey, as such an expenditure is otherwise always going on, owing to the necessity of keeping the balloon from getting either too high or too low. If a balloon provided with a guide rope sinks so low that a good deal of the rope rests on the earth, it is relieved of so much weight and rises again; if, on the contrary, it rises so high that but a little is supported by the earth, a greater weight is borne by the balloon, and equilibrium is thus produced. Mr Green frequently used the guide rope, and found that its action was satisfactory, and that it did not, as might be supposed, become entangled in trees, &c. It was used in the Nassau journey, but more recent aeronauts have dispensed with it. Still, in crossing the sea or making a very long journey, where the preservation of the gas was of great importance, it could not fail to be valuable. Mr Green had, in his time, more experience in the management than has fallen to the lot of any one else, and he brought to bear on the subject a great amount of skill and practical knowledge. There is also a plain matter-of-fact style about his accounts of his ascents that contrasts very favourably with the writings of some other aeronauts. Mr Coxwell, who has made several hundred ascents, first ascended in 1844, under the name of Welis. He it was who, as aeronaut, accompanied Mr Glaisher in most of his scientific ascents, 1862–65. The Godard family have made very many ascents in France, and are well known in all countries in connection with aeronautics. It was to two of the Godards that the management of the military balloons in the Italian campaign was entrusted; it was M. Jules Godard who succeeded in opening the valve in the dangerous descent of Nadar's balloon in Hanover in 1863, and it was Eugene Godard who constructed perhaps the largest Montgolfier ever made, an account of the ascensions of which has been given above. M. Dupuis Delcourt was also a well-known aeronaut; he has written on the subject of aerostation, and his balloons were employed by MM. Bixio and Barral in their scientific ascents. In America Mr Wise is *par excellence* the aeronaut; he has made several hundred ascents, and many of them are distinguished for much skill and daring. He also appears to have pursued his profession with more energy and capacity than has any other aeronaut in recent times, and his *History* of *Aerostation* shows him to possess much higher scientific attainments than balloonists usually have. In fact, Mr Wise stands alone in this respect, as nearly all professional aeronauts are destitute of scientific knowledge.

The number of fatal accidents that have occurred in the history of balloons is not very great, and nearly all have resulted either from the use of the fire-balloon, or from want of knowledge, or carelessness on the part of the aeronauts themselves. We have already referred to the accidents that closed the careers of Pilâtre de Rozier and Zambeccari. On November 25, 1802, Signor Olivari, at Orleans, and on July 17, 1812, Herr Bittorff, at Mannheim, perished in consequence of the accidental combustion of their *Montgolfières*. On April 7, 1806, M. Mosment ascended from Lille upon a platform, from which he accidentally fell and was killed. On July 7, 1819, Madame Blanchard ascended from Paris at night with fireworks attached to the car, a spark from one of which ignited the gas in the balloon, and she was precipitated to the ground and killed. Lieut. Harris ascended from London on May 25, 1824, but, through mismanagement of the valve-line, he allowed all the gas to escape suddenly from the balloon, which descended with terrible velocity. He was killed by the fall, but his companion, Miss Stocks, escaped almost uninjured. In an ascent from Blackburn on September 29, 1824, by Mr Windham Sadler, the balloon, in rising, struck against a chimney, and the aeronaut fell over the side of the car and was killed. On July 24, 1837, Mr Cocking descended from a balloon in a parachute, which struck the ground with such violence that he was killed on the spot. In descending with a horse on September 8, 1850, Lieut. Gale was killed; and in 1863 Mr Chambers was killed at Nottingham, his death arising from suffocation by the gas that poured out at the neck of the balloon, which was not separated from the car by a sufficient interval.

The number of persons who have ascended in balloons.

The number of accidents that have occurred bears but a very small proportion to the number of successful ascents that have been made. Mr Monck Mason, in his *Aeronautica*, gives a list of the names, with the dates and places of their ascent, of all persons who, as far as he could find, had ascended previously to 1838. His list contains 471 names, which are distributed among the inhabitants of the different countries as follows:—England, 313; France, 104; Italy, 18; Germany and the German States, 17; Turkey, 5; Prussia, 3; Russia, 2; Poland, 2; Hungary, 2, Denmark, 1; Switzerland, 1; and the United States, 3. Among these are the names of 49 women, of whom 28 are English, 17 French, 3 German, and 1 Italian. Some of the persons had ascended a great number of times; thus Mr Charles Green's ascents alone amounted to more than 249; and those of the members of the same family to 535. Mr Mason calculated that the whole number of ascents executed by Englishmen was 752. Of the 471 adventurers only nine were killed, and of these six owed their fate to the dangers attendant on the use of the fire-balloon, and one to bravado. The great number of our own countrymen that appear in the above list is no doubt partially due to the fact that it was compiled by an Englishman, to whom English newspapers and other records were more accessible; still there is no reason to doubt that a much greater number of Englishmen have ascended than inhabitants of any other country, as balloons as an amusement at fêtes, &c., have been more common here. The number of Englishmen who have ascended might now be estimated at from 1500 to 2000.

We can call to mind but three fatal casualties that have taken place since Mr Mason compiled his list, viz., Mr Cocking's parachute accident, Mr Gale's death in 1850, and Mr Chambers' death in 1863.

Scientific ascents.

We come now to an account of the use to which the balloon has been applied for the advancement of science. The ascents that have been made are by Sacharof, Biot, and Gay-Lussac in 1804, by Bixio and Barral in 1850, by Mr Welsh in 1852, by Mr Glaisher in 1862-66, and MM. Flammarion and De Fonvielle in 1867-68. We shall give a brief account of these ascents, because, as has been remarked, with a few exceptions, they form the only useful purpose to which the balloon has been applied. The general description of the phenomena, &c., met with in a high ascent, and the general results found, are referred to in the account of Mr Glaisher's experiments, as not only are his accounts more detailed, but the number of ascents made by him is much in excess of that of all the others put together.

The Academy of Sciences at St Petersburg, entertaining the opinion that the experiments made on mountain-sides by De Luc, De Saussure, Humboldt, and others must give results different from those made in free air at the same heights, resolved in 1803 that a balloon ascent should be made for the purpose of making scientific researches. Accordingly, on January 30, 1804, M. Sacharof, a member of the academy, ascended, with M. Robertson as aeronaut, in a balloon belonging to the latter, which was inflated with hydrogen gas. The ascent was made at a quarter past seven, and the descent effected at a quarter to eleven. No great height was reached, as the barometer never sank below 23 in., corresponding to less than $1\frac{1}{2}$ mile. The experiments were not very systematically made, and the chief results were the filling and bringing down several flasks of air collected at different elevations, and the supposed observation that the magnetic dip was altered. A telescope was fixed in the bottom of the car pointing vertically downwards, so that the travellers might be able to ascertain exactly the spot over which they were floating at any moment. M. Sacharof found that, on shouting downwards through his speaking-trumpet, the echo from the earth was quite distinct, and at his height was audible after an interval of about ten seconds. M. Sacharof's account is given in the *Philosophical Magazine* (Tilloch's), vol. xxi. pp. 193–200 (1805).

At the commencement of 1804 Laplace proposed to the members of the French Academy of Sciences that balloons should be employed for the purpose of solving certain physical problems, adding that, as the government had placed funds at their disposal for the prosecution of useful experiments, he thought they might be well applied to this kind of research. The proposition was supported by Chaptal the chemist, who was then minister of the interior, and accordingly the necessary arrangements were speedily effected, the charge of the experiments being given to MM. Gay-Lussac and Biot.

The principal object of this ascent was to determine if the magnetic force experienced any appreciable diminution at heights above the earth's surface, De Saussure having found that such was the case upon the Col du Géant. On August 24, 1804, MM. Gay-Lussac and Biot (the former eminent as a chemist and the latter as a natural philosopher) ascended from the Conservatoire des Arts at ten o'clock in the morning. Their magnetic experiments were incommoded by the rotation of the balloon, but they found that, up to the height of 13,000 feet, the time of vibration of a magnet was appreciably the same as on the earth's surface. They found also that the air became drier as they ascended. The height reached was about 13,000 feet, and the temperature declined from 63° Fahr. to 51°. The descent was effected about half-past one, at Meriville, 18 leagues from Paris.

Ascent of Gay-Lussac and Biot, August 1804.

In a second experiment, which was made on September 16, 1804, M. Gay-Lussac ascended alone. The balloon left the Conservatoire des Arts at 9.40 A.M., and descended at 3.45 P.M. between Rouen and Dieppe. The chief result obtained was that the magnetic force, like gravitation, did

Ascent of M. Gay-Lussac, September 16, 1804.

not experience any sensible variation at heights from the earth's surface which we can attain to. Gay-Lussac also brought down air collected at the height of nearly 23,000 feet, and on analysis it appeared that its constitution was the same as that of air collected at the earth's surface. At the time of leaving the earth the thermometer stood at 82° Fahr., and at the highest point reached (23,000 feet) it was 14°·9 Fahr. Gay-Lussac remarked that at his highest point there were still clouds above him.

From 1804 to 1850 there is no record of any scientific ascents in balloons having been undertaken. In the latter year MM. Bixio and Barral made two ascents for this purpose. They ascended from the Paris Observatory on June 29, 1850, at 10.27 A.M., the balloon being inflated with hydrogen gas. The day was a rough one, and the ascent took place suddenly, without any previous attempt having been made to test the ascensional force of the balloon. When liberated, it rose with great rapidity, and becoming fully inflated it pressed upon the network, bulging out at the top and bottom. As the ropes by which the car was suspended were too short, the balloon soon covered the travellers like an immense hood. In endeavouring to secure the valve-rope, a rent was made in the balloon, and the gas escaped so close to the faces of the voyagers as almost to suffocate them. Finding that they were descending then too rapidly, they threw overboard everything available, including their coats, and only excepting the instruments. The ground was reached at 10h. 45m., near Lagny. Of course no observations were made.

July 1850. MM. Bixio and Barral determined to ascend again without delay, and accordingly, on July 27, 1850, they repeated the experiment. The ascent was remarkable on account of the extreme cold met with. At about 20,000 feet the temperature was 15° Fahr., the balloon being enveloped in cloud; but on emerging from the cloud, at 23,000 feet, the temperature sank to −38° Fahr., no less than 53° Fahr. below that experienced by Gay-Lussac at the same elevation. The existence of these very cold clouds served to explain certain meteorological phenomena that were observed on the earth both the day before and the day after the ascent. Some pigeons were taken up in this, as in most other high ascents, and liberated; they showed a reluctance to leave the car, and then fell heavily downwards.

Welsh's as- ...s in ... In July 1852 the committee of the Kew Observatory resolved to institute a series of balloon ascents, with the view of investigating such meteorological and physical phenomena as require the presence of an observer at a great height in the atmosphere. Mr Welsh, of the Kew Observatory, was the observer, and Mr Green's great Nassau balloon was employed, Mr Green himself being the aeronaut. Four ascents were made in 1852, viz., on August 17, August 26, October 31, and November 10, when the respective heights of 19,510, 19,100, 12,640, and 22,930 feet were attained. A siphon barometer, dry and wet bulb thermometers, aspirated and free, and a Regnault's hygrometer were taken up. Some air collected at a considerable height was found on analysis not to differ appreciably in its composition from air collected near the ground. The original observations are printed *in extenso* in the *Philosophical Transactions* for 1853, pp. 311–346. The lowest temperatures met with in the four ascents were respectively 8°·7 Fahr. (19,380 feet); 12°·4 Fahr. (18,370); 16°·4 Fahr. (12,640); −10°·5 Fahr. (22,370); the decline of temperature being very regular.

...sh As-...ation ...oints ...oon ...mittee. At the meeting of the British Association for the Advancement of Science held at Aberdeen in 1859, a committee was appointed for the purpose of making observations in the higher strata of the atmosphere by means of the balloon. For the first two years nothing was effected, owing to the want both of an observer and of a suitable balloon. In 1861, at Manchester, the committee was reappointed, and it then consisted of Colonel Sykes (chairman), Mr Airy, Sir David Brewster, Mr Fairbairn, Admiral Fitzroy, Mr Gassiot, Mr James Glaisher, Sir J. Herschel, Dr Lee, Dr Lloyd, Dr W. A. Miller, Dr Robinson, and Dr Tyndall. Some unsuccessful experiments were made with a balloon of Mr Green's, and also with one hired from the proprietors of Cremorne Gardens, which turned out to be in a hopelessly leaky condition; the trained observers also, on whom the committee had relied, failed to perform their duties. In this state of affairs, Mr Coxwell, an aeronaut who had made a good many ascents, was communicated with, and he agreed to construct a new balloon, of 90,000 cubic feet capacity, on the condition that the committee would undertake to use it, and pay £25 for each high ascent made especially for the committee, the latter defraying also the cost of gas, &c., so that the expense of each high ascent amounted to nearly £50. An observer being still wanted, Mr Glaisher, a member of the committee, offered himself to take the observations, and accordingly the first ascent was made on July 17, 1862, from the gas-works at Wolverhampton, this town being chosen on account of its central position in the country. Altogether, Mr Glaisher made twenty-eight ascents, the last having taken place on May 26, 1866. Of these only seven were specially high ascents, although six others were undertaken for the objects of the committee alone. On the other occasions Mr Glaisher availed himself of public ascents from the Crystal Palace and other places of entertainment, merely taking his place like the other passengers. In the last six ascents another aeronaut, Mr Orton, and a smaller balloon, were employed. The dates, places of ascent, and greatest heights (in feet) attained in the twenty-eight ascents were—1862: July 17, Wolverhampton, 26,177; July 30, Crystal Palace, 6937; August 18, Wolverhampton, 23,377; August 20, Crystal Palace, 5900; August 21, Hendon, 14,355; September 1, Crystal Palace, 4190; September 5, Wolverhampton, 37,000; September 8, Crystal Palace, 5428. 1863: March 31, Crystal Palace, 22,884; April 18, Crystal Palace, 24,163; June 26, Wolverton, 23,200; July 11, Crystal Palace, 6623; July 21, Crystal Palace, 3298; August 31, Newcastle-upon-Tyne, 8033; September 29, Wolverhampton, 16,590; October 9, Crystal Palace, 7310. 1864: January 12, Woolwich, 11,897; April 6, Woolwich, 11,075; June 13, Crystal Palace, 3543; June 20, Derby, 4280; June 27, Crystal Palace, 4898; August 29, Crystal Palace, 14,581; December 1, Woolwich, 5431; December 30, Woolwich, 3735. 1865: February 27, Woolwich, 4865; October 2, Woolwich, 1949; December 2, Woolwich, 4628. 1866: May 26, Windsor, 6325. Of these, all the ascents from Wolverhampton (four in number) and from Woolwich (seven in number) were undertaken wholly for the committee, and Mr Glaisher was merely accompanied by the aeronaut, whose business it was to manage the balloon. The expense of the special high ascents (about £50 for each, as stated above) rendered it desirable, when possible, to take advantage of the desire felt by many to accompany Mr Glaisher in his journey, and admit one or two other travellers; and of this kind were one or two of the ascents from the Crystal Palace, though the majority, in which the elevation attained frequently fell short of a mile, were the ordinary public ascents advertised beforehand. It is not possible here to give any complete account of the results obtained, and it would be superfluous, as the observations, both as made and after reduction, are printed in the *British Association Reports*, 1862–66. It will be enough, after explaining the objects of the experiments, &c., to describe briefly one or two of the most remarkable ascents, and then state the kind of conclusions that follow from them as a whole.

The primary object was to determine the temperature of the air, and its hygrometrical state at different elevations to as great a height as could be reached; and the secondary objects were—(1) to determine the temperature of the dew-point by Daniell's and Regnault's hygrometers, as well as by the dry and wet bulb thermometers, and to compare the results; (2) to compare the readings of an aneroid barometer with those of a mercurial barometer up to the height of 5 miles; (3) to determine the electrical state of the air, (4) the oxygenic condition of the atmosphere, and (5) the time of vibration of a magnet; (6) to collect air at different elevations; (7) to note the height and kind of clouds, their density and thickness; (8) to determine the rate and direction of different currents in the atmosphere; and (9) to make observations on sound.

The instruments used were mercurial and aneroid barometers, dry and wet bulb thermometers, Daniell's dew-point hygrometer, Regnault's condensing hygrometer, maximum and minimum thermometers, a magnet for horizontal vibration, hermetically sealed glass tubes exhausted of air, and an electrometer. In one or two of the ascents a camera was taken up.

One end of the car was occupied by the aeronaut; near the other, in front of Mr Glaisher, was placed a board or table, the extremities of which rested on the sides of the car; upon this board was placed suitable framework to carry the several thermometers, hygrometers, magnet, aneroid barometer, &c.; a perforation through it admitted the lower branch of the mercurial barometer to descend below, leaving the upper branch at a convenient height for observing. A watch was placed directly opposite to Mr Glaisher, the central space being occupied by his note-book. The aspirator (for Regnault's hygrometer) was fixed underneath the centre of the board, so as to be conveniently workable by either feet or hands. Holes were cut in the board to admit the passage of the flexible tubes required for Regnault's hygrometer and the dry and wet bulb thermometers.

Mr Glaisher's ascent on July 17, 1862.

The first ascent was made, as has been stated, from Wolverhampton on July 17, 1862, and the journey was remarkable on account of a warm current that was met with at a great elevation. The weather, previous to the ascent, had been bad for a long time, and it had been delayed in consequence. The wind was still blowing from the west, and considerable difficulty was experienced in the preliminary arrangements, so that no instrument was fixed before starting. The balloon left at 9.43 A.M., and a height of 3800 feet was reached before an observation could be taken. At 4000 feet clouds were entered, and left at 8000 feet. The temperature of the air at starting was 59° Fahr., at 4000 feet it was 45°, and it descended to 26° at 10,000 feet, from which height to that of 13,000 feet there was no diminution. While passing through this space Mr Glaisher put on additional clothing, feeling certain that a temperature below zero would be attained before the height of 5 miles was reached; but at the elevation of 15,500 feet the temperature was 31°, and at each successive reading, up to 19,500, it *increased*, and was there 42°. The temperature then decreased rapidly, and was 16° at 26,000 feet. On descending it increased regularly to 37°·8 at 10,000 feet. A very rough descent, in which nearly £50 worth of instruments were broken, was effected near Oakham, in Rutlandshire, Mr Coxwell having judged it prudent to descend on account of the proximity, as he supposed, of the Wash. In coming down, a cloud was entered at an elevation of 12,400 feet, and proved to be more than 8000 feet in thickness. The rise of temperature met with in this ascent was most remarkable.

The weather on the day (Aug. 18, 1862) of the third ascent was favourable, and there was but little wind. All the instruments were fixed before leaving the earth. A height of more than 4 miles was attained, and the balloon remained in the air about two hours. When at its highest point there were no clouds between the balloon and the earth, and the streets of Birmingham were distinctly visible. The descent was effected at Solihull, 7 miles from Birmingham. On the earth the temperature of the air was 67°·8, and that of the dew-point 54°·6; and they steadily decreased to 39°·5 and 22°·2 respectively at 11,500 feet. The balloon was then made to descend to the height of about 3000 feet, when both increased to 56°·0 and 47°·5 respectively. On throwing out ballast the balloon rose again, and the temperature declined pretty steadily to 24°·0, and that of the dew-point to −10°·0, at the height of 23,000 feet. During this ascent Mr Glaisher's hands became quite blue, and he experienced a qualmish sensation in the brain and stomach, resembling the approach of sea-sickness; but no further inconvenience, besides such as resulted from the cold and the difficulty of breathing, was experienced. This feeling of sickness never occurred again to Mr Glaisher in any subsequent ascent.

Ascen[t] from [Wol]verhan[p]ton, A[ug.] 18, 18[62].

Ascen[t] from [Crys]tal P[alace], Augu[st 20,] and f[rom] Hend[on,] Augu[st] 1862.

The ascent from the Crystal Palace on August 20, 1862, was merely an ordinary one for the public amusement, in which Mr Glaisher took a place in the car. In these low ascents from places of entertainment, in which other persons also were passengers, the large board stretching right across the car could not be used. A smaller frame was therefore made, which could be screwed on to the edge of the car, to carry the watch, siphon barometer, aneroid barometer, dry and wet bulb thermometers, gridiron thermometer,[1] and Daniell's and Regnault's hygrometers, which comprised all the instruments usually taken up in these low ascents. In the first low ascent, July 30, this framework was fixed inside the car; but as it seemed possible that the warmth proceeding from the voyagers might influence the readings of the instruments, it was always afterwards fixed outside, and projected beyond the car, so that all the instruments were freely exposed to the surrounding air. The ascent on August 20 was a low one, and presented no remarkable feature except that the balloon was nearly becalmed over London. The earth was left at 6.26 P.M., and the air was so quiet that at the height of three-quarters of a mile the balloon was still over the Crystal Palace. At 7h. 47m. it was over London, and moving so slowly that it was thought desirable to ascend above the clouds in hopes of meeting with a more rapid current of air. At 8h. 5m. the voyagers were above the clouds, and it became quite light again, darkness having come on whilst hovering over London, at which time the gradual illumination by the lights in the streets formed a most wonderful sight, and one never to be forgotten. The roar, or rather loud hum, proceeding from the great city was also most remarkable. After having been above the clouds some time, the lowing of cattle and other agricultural sounds were heard. Accordingly, the valve-line was pulled, and the balloon descended below the clouds, when the light of London was seen in the distance as a misty glare. The darkness increased as the balloon descended very slowly, and it at length touched the ground so gently in the middle of a field at Mill Hill, near Hendon, that those in the car were scarcely aware of the contact. There were twelve voyagers altogether, and when with some trouble sufficient countrymen were collected to take their places and enable

[1] This was a thermometer with a bulb shaped like a gridiron, so as to have a very great surface exposed to the air. It was thought that the ordinary pea-sized bulb would not permit of the thermometer being sufficiently delicate to register the rapid changes of temperature due to the quick motion of the balloon, as it requires some little time for such a thermometer to take up the temperature of the surrounding medium.

them to leave the car, it was resolved to anchor the balloon for the night and to make an ascent in the early morning. Accordingly, at 4.30 A.M., on August 21, the earth was left, there being altogether five persons in the car. It was a dull, warm, cloudy morning, with the sky overcast. In about an hour the height of 3 miles was attained, and the temperature had fallen to 23°, having been 58° on the earth before leaving. The aspect of the clouds under formation before and during the rising of the sun was marvellous in the extreme, and baffled description. There were seen shining masses of cloud in mountain chains, rising perpendicularly from the plain, with summits of dazzling whiteness, forming vast ravines, down which the balloon appeared to glide, or pass through their sides, into other valleys, until, as the balloon rose far above, all appeared a mighty sea of white cloud. The descent was effected about a quarter past seven, and the transition from the magnificent scene above the clouds to the ugly prospect of the dreary earth as seen early on a dull morning, with a uniform leaden sky, was most depressing. The place of descent was near Biggleswade.

The most noteworthy fact in connection with the ascent, September 1, 1862, was, that from the balloon the clouds were observed to be forming below, and seen to be following the whole course of the Thames from the Nore to Richmond. The clouds were above the river following all its windings, and extending neither to the right nor to the left. It was about the time of high water at London Bridge, and the phenomenon was no doubt connected with the warm water from the sea.

As in the ascent, September 5, 1862, the greatest height ever reached was attained, it is desirable to give the account of it in some detail, and in Mr Glaisher's own words. It is only necessary to premise that it was intended on this occasion to ascend as high as possible. The following is an extract from Mr Glaisher's account (*British Association Report*, 1862, pp. 383–385):—

This ascent had been delayed owing to the unfavourable state of the weather. The balloon left at 1h. 3m. P.M. The temperature of the air was 59°, and the dew-point 50°. At the height of 1 mile it was 41°, dew-point 38°; and shortly afterwards we entered a cloud of about 1100 feet in thickness, in which the temperature of the air fell to $36\frac{1}{2}$°, the dew-point being the same, thus indicating that the air was here saturated with moisture. On emerging from the cloud at 1h. 17m. we came upon a flood of strong sunlight, with a beautiful blue sky, without a cloud above us, and a magnificent sea of cloud below, its surface being varied with endless hills, hillocks, mountain chains, and many snow-white masses rising from it. I here tried to take a view with the camera; but we were rising with too great rapidity, and going round and round too quickly, to enable me to do so. The flood of light, however, was so great that all I should have needed would have been a momentary exposure, as Dr Hill Norris had kindly furnished me with extremely sensitive dry plates for the purpose. We reached 2 miles in height at 1h. 21m. The temperature had fallen to the freezing-point, and the dew-point to 26°. We were 3 miles high at 1h. 28m., with a temperature of 18°, and dew-point 13°. At 1h. 39m. we had reached 4 miles, and the temperature was 8°, and dew-point − 15°; in ten minutes more we had reached the fifth mile, and the temperature had passed below zero, and then read − 2°, and at this point no dew was observed on Regnault's hygrometer when cooled down to − 30°; but a dew-point obtained from the readings of dry and wet gave − 36°. Up to this time I had taken observations with comfort. I had experienced no difficulty in breathing, whilst Mr Coxwell, in consequence of the necessary exertions he had to make, had breathed with difficulty for some time. At 1h. 51m. the barometer reading was 11·05 inches, but this requires a subtractive correction of 0·25 inch, as found by comparison with Lord Wrottesley's standard barometer just before starting. I afterwards read the dry thermometer as − 5°; this must have been about 1h. 52m. or later; I could not see the column of mercury in the wet bulb thermometer; nor afterwards the hands of the watch, nor the fine divisions on any instrument. I asked Mr Coxwell to help me to read the instruments, as I experienced a difficulty in seeing. In consequence, however, of the rotatory motion of the balloon, which had continued without ceasing since the earth had been left, the valve-line had become twisted, and he had to leave the car and mount into the ring above to adjust it. At this time I looked at the barometer, and found it to be 10 inches, still decreasing fast; its true reading therefore was $9\frac{3}{4}$ inches, implying a height of 29,000 feet. Shortly afterwards I laid my arm upon the table, possessed of its full vigour, and on being desirous of using it, I found it powerless—it must have lost its power momentarily. I tried to move the other arm, and found it powerless also. I then tried to shake myself, and succeeded in shaking my body. I seemed to have no limbs. I then looked at the barometer, and whilst doing so my head fell on my left shoulder. I struggled and shook my body again, but could not move my arms. I got my head upright, but for an instant only, when it fell on my right shoulder, and then I fell backwards, my back resting against the side of the car, and my head on its edge; in this position my eyes were directed towards Mr Coxwell in the ring. When I shook my body I seemed to have full power over the muscles of the back, and considerable power over those of the neck, but none over either my arms or my legs; in fact, I seemed to have none. As in the case of the arms, all muscular power was lost in an instant from my back and neck. I dimly saw Mr Coxwell in the ring, and endeavoured to speak, but could not; when in an instant intense black darkness came: the optic nerve finally lost power suddenly. I was still conscious, with as active a brain as at the present moment whilst writing this. I thought I had been seized with asphyxia, and that I should experience no more, as death would come unless we speedily descended: other thoughts were actively entering my mind, when I suddenly became unconscious as on going to sleep. I cannot tell anything of the sense of hearing; the perfect stillness and silence of the regions 6 miles from the earth (and at this time we were between 6 and 7 miles high) is such that no sound reaches the ear.

My last observation was made at 1h. 54m. at 29,000 feet. I suppose two or three minutes fully were occupied between my eyes becoming insensible to seeing fine divisions and 1h. 54m., and then that two or three minutes more passed till I was insensible; therefore I think this took place at about 1h. 56m. or 1h. 57m. Whilst powerless I heard the words 'temperature' and 'observation,' and I knew Mr Coxwell was in the car speaking to me, and endeavouring to arouse me; therefore consciousness and hearing had returned. I then heard him speak more emphatically, but I could not see, speak, or move. I heard him again say, 'Do try—now do.' Then I saw the instruments dimly, then Mr Coxwell, and very shortly saw clearly. I rose in my seat and looked round, as though waking from sleep, though not refreshed by sleep, and said to Mr Coxwell, 'I have been insensible.' He said, 'You have; and I too, very nearly.' I then drew up my legs, which had been extended before me, and took a pencil in my hand to begin observations. Mr Coxwell told me that he had lost the use of his hands, which were black, and I poured brandy over them.

"I resumed my observations at 2h. 7m., recording the barometer reading at 11·53 inches and temperature − 2°. I suppose that three or four minutes were occupied from the time of my hearing the words 'temperature' and 'observation' till I began to observe. If so, then returning consciousness came at 2h. 4m., and this gives seven minutes for total insensibility. I found the water in the vessel supplying the wet bulb thermometer, which I had by frequent disturbances kept from freezing, was one solid mass of ice; and it did not all melt until after we had been on the ground some time.

"Mr Coxwell told me that whilst in the ring he felt it piercingly cold; that hoar-frost was all round the neck of the balloon; on attempting to leave the ring he found his hands frozen, and he had to place his arms on the ring and drop down; that he thought for a moment I had lain back to rest myself; that he spoke to me without eliciting a reply; that he then noticed my legs projected and my arms hung down by my side; that my countenance was serene and placid, without the earnestness and anxiety he had noticed before going into the ring, and then it struck him I was insensible. He wished to approach me, but could not, and he felt insensibility coming over himself; that he became anxious to open the valve, but in consequence of his having lost the use of his hands he could not, and ultimately did so by seizing the cord with his teeth, and dipping his head two or three times, until the balloon took a decided turn downwards.

"No inconvenience followed this insensibility, and when we dropped it was in a country where no conveyance of any kind could be obtained, so that I had to walk between 7 and 8 miles.

"The descent was at first very rapid; we passed downwards 3 miles in nine minutes; the balloon's career was then checked, and it finally descended in the centre of a large grass field at Cold Weston, $7\frac{1}{4}$ miles from Ludlow.

"In this ascent six pigeons were taken up. One was thrown out at the height of 3 miles, when it extended its wings and dropped as a piece of paper; a second, at 4 miles, flew vigorously round and round, apparently taking a dip each time; a third was thrown out between 4 and 5 miles, and it fell downwards as a stone; a fourth was thrown out at 4 miles on descending; it flew in a circle, and shortly alighted on the top of the balloon. The two remaining pigeons were brought down to the ground. One was found to be dead, and the other, a carrier, was still living, but would not leave the hand when I attempted to throw it off, till, after a quarter of an hour, it began to peck a piece of ribbon which encircled its neck, and was then jerked off the finger, and flew with some vigour towards Wolverhampton. One of the pigeons returned to Wolverhampton on Sunday, the 7th, and this is the only one that has been heard of."

Mr Glaisher found from his observation-book that the last observation was made at 29,000 feet, and that at this time the balloon was ascending at the rate of 1000 feet per minute; and that when he resumed his observations, it was descending at the rate of 2000 feet per minute, the interval being thirteen minutes. This gives 36,000 or 37,000 feet for the greatest height attained. Two other series of considerations led to the latter height, and there can be no doubt that the altitude of 37,000 feet, or 7 miles, was attained on this occasion.

Ascent from the Crystal Palace on April 18, 1863.

In the ascent, April 18, 1863, 24,000 feet of elevation was reached. It was remarkable for the rapidity of the descent. At 2h. 44m., the balloon being then at a height of 10,000 feet, Mr Coxwell suddenly caught sight of Beachy Head, and Mr Glaisher, looking over the edge of the car, saw the sea, apparently immediately underneath. There was no time to be lost, and Mr Coxwell hung on to the valve-line, telling Mr Glaisher to leave his instruments and do the same. The earth was reached at 2h. 48m., the two miles of descent having been effected in four minutes. The balloon struck the ground near Newhaven with a terrible crash, but, from the free use of the valve-line, it was so crippled that it did not move afterwards. All the instruments, of the value of more than £25, including some that were unreplaceable, were broken, and Mr Glaisher was hurt. In the descent, after the first high ascent on July 17, 1862, the earth was struck with so much violence that most of the instruments were broken, and Mr Glaisher (who was closed in by his observing-board) was a good deal hurt then. In subsequent ascents, therefore, boxes were used filled with small mattresses, in which the instruments could be hurriedly placed, and the board was so arranged that it could be turned over and hung outside the car. These improvements had the effect of diminishing the danger to himself and the chance of breakage of the instruments, but in the Newhaven descent there was not sufficient time to put them in practice.

Ascent from Wolverton, June 26, 1863.

The circumstances met with in the ascent, June 26, 1863, were so remarkable that a short account cannot be omitted. The morning was at first very bright and fine, but between 11 and 12 o'clock a change took place; the sky became covered with clouds, and the wind rose and blew strongly, so that great difficulty was experienced in completing the inflation. At 1h. 3m. the balloon left; in four minutes, at 4000 feet high, cloud was entered. Mr Glaisher expected soon to break through it, and enter into bright sunshine as usual, but nothing of the sort took place, as, on emergence, clouds were seen both above and below. At 9000 feet the sighing and moaning of the wind were heard, and Mr Glaisher satisfied himself that this was due, not to the cordage of the balloon, but to opposing currents. At this time the sun was seen faintly, but instead of its brilliance increasing, although the balloon was then two miles high, a fog was entered, and the sight of the sun lost. The balloon next passed through a dry fog, which was left at 12,000 feet, and after the sun had been seen faintly for a little time, a wetting fog was entered.

"At 15,000 feet," Mr Glaisher proceeds, "we were still in fog, but it was not so wetting. At 16,000 feet we entered a dry fog; at 17,000 feet saw faint gleams of the sun, and heard a train. We were now about 3 miles high; at this time we were not in cloud, but clouds were below us; others were on our level at a distance, and yet more above us. We looked with astonishment at each other, and said as we were rising steadily we surely must soon pass through them. At 17,500 feet we were again enveloped in fog, which became wetting at 18,500 feet; we left this cloud below at 19,600 feet. At 20,000 feet the sun was just visible. We were now approaching 4 miles high; dense clouds were still above us; for a space of 2000 to 3000 feet we met with no fog, but on passing above 4 miles our attention was first attracted to a dark mass of cloud, and then to another on our level; both these clouds had fringed edges—they were both nimbi. Without the slightest doubt both these clouds were regular rain-clouds. Whilst looking at them we again lost sight of everything, being enveloped in fog whilst passing upwards through 1000 feet. At 22,000 feet we again emerged, and were above clouds on passing above 23,000 feet. At six minutes to 2 o'clock we heard a railway train; the temperature here was 18°. I wished still to ascend to find the limits of this vapour, but Mr Coxwell said, 'We are too short of sand; I cannot go higher; we must not even stop here.' I was therefore most reluctantly compelled to abandon the wish, and looked searchingly around. At this highest point, in close proximity to us, were rain-clouds; below us dense fog. I was again reminded that we must not stop. With a hasty glance everywhere, above, below, around, I saw the sky nearly covered with dark clouds of a stratus character, with cirri still higher, and small spaces of blue sky between them. The blue was not the blue of 4 or 5 miles high as I had always before seen it, but a faint blue, as seen from the earth when the air is charged with moisture."

In the downward journey an even more remarkable series of circumstances was met with; for a fall of rain was passed through, and then *below it* a snow-storm. the flakes being entirely composed of spiculæ of ice and innumerable snow-crystals. On reaching the ground near Ely the lower atmosphere was found to be thick, misty, and murky. At Wolverton the afternoon was cold, raw, and disagreeable for a summer's day. The fact of rain-clouds extending layer above layer to a height of 4 miles, was one never hitherto regarded as possible; and the occurrence of rain and snow, and the latter underneath the former, and all happening on a day in the very middle of summer, formed a series of most curious and unexpected phenomena

Mr Glaisher having, in one of his descents, which took place near sunset, observed that the temperature was the same through a very considerable height, it occurred to him that after dark it was quite possible that, for some elevation above the earth's surface, the temperature might even increase with increase of height; and to determine this he arranged for some ascents to be made after sunset, so that the temperature during the night might be observed. For this purpose he procured a couple of Davy lamps, which answered their object satisfactorily. Accordingly, on October 2, 1865, an ascent was made from Woolwich Arsenal, the time of starting being about three-quarters of an hour after the sun had set. The temperature on the earth was 56°, and it steadily increased to 59°·6 at the height of 1900 feet. This was established conclusively by repeated ups and downs, the temperature falling as the balloon descended. The view of London lighted up, as seen from the balloon in this ascent, the night being clear, was most wonderful. A second night ascent was made from the same place on December 2; 1865, and the balloon left the earth $2\frac{3}{4}$ hours after sunset. On this occasion the temperature did not rise, but the decrease, though steady, was small. In an ascent from Windsor on May 29, 1866, the balloon was kept up till half-past eight o'clock, and the temperature was found to decrease as the earth was approached during the last 900 feet. In this last ascent no paid aeronaut was employed, as Mr Westcar, of the Royal Horse Guards, undertook the management of the balloon. In the preceding five ascents Mr Orton, of Blackwall, was employed as aeronaut.

It has been found necessary in the present notice to allude merely to the more striking points noticed in Mr Glaisher's twenty-eight ascents. The number of observations made by him was of course great, and it is only necessary here to repeat that they are to be found in the *Reports of the British Association for the Advancement of Science.*

1862–66. It appeared as one of the results of the experiments that the rate of the decline of temperature with elevation near the earth was very different when the sky was clear from what was the case when it was cloudy; and the equality of temperature at sunset and increase with height after sunset were very remarkable facts which were not anticipated, and which have an important bearing on the theory of refraction, as astronomical observations are usually made at night. Even at the height of 5 miles, cirrus clouds were seen high in the air, apparently as far above as they seem when viewed from the earth, and the air must there be so exceedingly dry that it is hard to believe that their presence can be due to moisture at all. The results of the observations differed very much, and no doubt the atmospheric conditions depended not only on the time of day, but also on the season of the year, and were such that a vast number of ascents would be requisite to determine the true laws with anything approaching to certainty and completeness. It is also clear that England is a most unfit country for the pursuit of such investigations, as, from whatever place the balloon started, it was never safe to be more than an hour above the clouds for fear of reaching the sea. It appeared from the observations that an aneroid barometer could be trusted to read as accurately as a mercurial barometer to the heights reached. The time of vibration of a horizontal magnet was taken in very many of the ascents, and the results of ten different sets of observations proved undoubtedly that the time of vibration was longer than on the earth. In almost all the ascents the balloon was under the influence of currents of air in different directions. The thickness of these currents was found to vary greatly. The direction of the wind on the earth was sometimes that of the whole mass of air up to 20,000 feet, whilst at other times the direction changed within 500 feet of the earth. Sometimes directly opposite currents were met with at different heights in the same ascent, and three or four streams of air were encountered moving in different directions. Ignoring the different currents of air which caused the balloon to change its direction, and at times to move in entirely opposite directions, and simply taking into account the places of ascent and descent, the distances so measured were always very much greater than the horizontal movement of the air as measured by anemometers. For example, on January 12, 1862, the balloon left Woolwich at 2h. 8m. P.M., and descended at Lakenheath, 70 miles distant from the place of ascent, at 4h. 19m. P.M. At the Greenwich Observatory, by Robinson's anemometer, during this time the motion of the air was 6 miles only. With regard to physiological observations, Mr Glaisher found that the number of pulsations increased with elevation, as also the number of inspirations. The number of his pulsations was generally 76 per minute before starting, about 90 at 10,000 feet, 100 at 20,000 feet, and 110 at higher elevations. But a good deal depended on the temperament of the individual. This was also the case in respect to colour; at 10,000 feet the faces of some would be a glowing purple, whilst others would be scarcely affected; at 4 miles high Mr Glaisher found the pulsations of his heart distinctly audible, and his breathing was very much affected, so that panting was produced by the very slightest exertion; at 29,000 feet he became insensible. In reference to the propagation of sound, it was at all times found that sounds from the earth were more or less audible according to the amount of moisture in the air. When in clouds at 4 miles high, a railway train was heard; but when clouds were far below, no sound ever reached the ear at this elevation. The discharge of a gun was heard at 10,000 feet. The barking of a dog was heard at the height of 2 miles, while the shouting of a multitude of people was not audible at heights exceeding 4000 feet.

The majority of Mr Glaisher's experiments were made in the summer, partly because public ascents took place at this time of the year, and partly because the weather was more settled. But some special ascents were made in the winter; these were found to be very troublesome and costly, owing to the time that was wasted before a suitable day occurred, and to the boisterous weather, which damaged the balloon. Altogether the number of ascents bore but a small ratio to the number of days spent over them. Sometimes it was necessary to wait at Wolverhampton a whole week after the day fixed for the ascent, owing to the unfavourable state of the weather and the necessity of keeping the light gas required for the balloon in a separate gasometer (as the lightest gas is the worst in illuminating power), added to the cost and difficulty. When balloons ascend as public exhibitions from places of entertainment it is very rarely that a height of a mile is reached, although, in the absence of instruments, it is not unusual for the aeronaut to exaggerate the elevation, as the passengers have no reason for disputing what is told them. This must be borne in mind when physiological or other phenomena are described by voyagers unprovided with instruments. We have noticed the observations made in Mr Glaisher's ascents at greater length, because they are almost the only ones that have been made in which the height and other matters are determined with certainty. A quantity of air was collected in two large bags at the height of 12,000 feet in the ascent on January 12, 1864, and submitted to Professor Tyndall, but he has never made public the analysis of it.

In the years 1867 and 1868 M. Flammarion made eight or nine ascents from Paris for scientific purposes. The heights reached were not great, but the general result of the observations was to confirm those made by Mr Glaisher. See M. Flammarion in *Voyages Aériens*, Paris, 1870, or *Travels in the Air*, London, 1871. Observations were also made in some balloon ascents by M. de Fonvielle, which are noticed in the works just referred to. Ascents of M. Flammarion, 1867–68.

The balloon had not been discovered very long before it received a military status, and soon after the commencement of the French revolutionary war an aeronautic school was founded at Meudon; Guyton de Morveau, the chemist, and Colonel Coutelle being the persons in charge. Four balloons were constructed for the armies of the north, of the Sambre and Meuse, of the Rhine and Moselle, and of Egypt. In June 1794 Coutelle ascended with the adjutant and general to reconnoitre the hostile army just before the battle of Fleurus, and two reconnaissances were made, each occupying four hours. It is generally stated that it was to the information so gained that the French victory was due. The balloon corps was in constant requisition during the campaign, but it does not appear that, with the exception of the reconnaissances just mentioned, any great advantages resulted, except in a moral point of view. But even this was of importance, as the enemy were much disconcerted at having their movements so completely watched, while the French were correspondingly elated at the superior information it was believed they were gaining. An attempt was made to revive the use of balloons in the African campaign of 1830, but no opportunity occurred in which they could be employed. It is said that in 1849 a reconnoitring balloon was sent up from before Venice, and that the Russians used one at Sebastopol. In the French campaign against Italy in 1859 the French had recourse to the use of balloons, but this time there was not any aerostatic corps, and their management was entrusted to the brothers Godard. Several reconnaissances were made, and one of especial interest the day before the battle of Solferino. No information of much importance seems, however, to have been gained thereby. The Fleurus re- Use of balloons for military purposes. Reconnaissances before the battle of Fleurus. At Solferino.

connaissance was made in a balloon inflated with hydrogen gas, while at Solferino a fire-balloon was employed. Each system has its advantages and disadvantages; the gas-balloon requires several hours for inflation, but then it can remain in the air any length of time; the fire-balloon can be inflated rapidly, but it will not stay in the air more than five or ten minutes unless a furnace is taken up, the use of which is impracticable in even a moderate wind; besides, the fire-balloon must be of very large dimensions, and only one person could, as a rule, ascend at a time, and he would have to be occupied with the fire: the use of fire-balloons also is always attended with some danger. M. Eugene Godard, who was engaged in the management of the balloons in the Italian campaign, wrote to the *Times*, in August 1864, expressing his opinion of the superiority of fire-balloons for war purposes, as they are so easily inflated and are not destroyed or compelled to descend even if pierced by several balls; and this was also, we believe, the opinion of the Austrians who made experiments with war balloons.

In the late American war balloons were a good deal used by the Federals. There was a regular balloon staff attached to M'Clellan's army, with a captain, an assistant-captain, and about 50 non-commissioned officers and privates. The apparatus consisted of two generators, drawn by four horses each; two balloons, drawn by four horses each, and an acid-cart, drawn by two horses. The two balloons used contained about 13,000 and 26,000 feet of gas, and the inflation usually occupied about three hours. (See Captain Beaumont's Account, vol. xii. of the *Royal Engineers' Papers.*) We are not aware of the value set by the officers in command on the information obtained by this means; but as we believe balloons were employed till the conclusion of the war, it is clear that some importance was attached to their use. In 1862 or 1863 one or two experiments to test the use of balloons in making reconnaissances were made at Aldershot, but nothing came of them.

When the Montgolfiers first discovered the balloon, its great use in military operations was at once prophesied; but these anticipations have not been realised. On the other hand, however, there can be no doubt that the balloon has never had a fair trial, being viewed coldly by officers enamoured of routine, and when used, being often left unsupplied with suitable appointments. It is probable that a future still remains for the balloon in this direction.

The paramount value of the balloon during the recent siege of Paris must be fresh in the minds of all. It was by it alone that communication was kept up between the besieged city and the external world, as the balloons carried away from Paris the pigeons which afterwards brought back to it the news of the provinces. The total number of balloons that ascended from Paris during the siege, conveying persons and despatches, was sixty-four—the first having started on September 23, 1870, and the last on January 28, 1871. Gambetta effected his escape from Paris, on October 7, in the balloon *Armand-Barbès*, an event which doubtless led to the prolongation of the war. Of the sixty-four balloons only two were never heard of; they were blown out to sea. One of the most remarkable voyages was that of the *Ville d'Orléans*, which, leaving Paris at eleven o'clock on November 21, descended fifteen hours afterwards near Christiania, having crossed the North Sea. Several of the balloons on their descent were taken by the Prussians, and a good many were fired at while in the air; but we do not hear of any being injured from this cause. The average size of the balloons was from 2000 to 2050 metres, or from 70,000 to 72,000 cubic feet. The above facts we have extracted from *Les Ballons du Siège de Paris*, a sheet published by Bulla & Sons, Paris; compiled by the brothers Tissandier, well-known French aeronauts, and giving the name, size, and times of ascent and descent of every balloon that left Paris, with the names of the aeronaut and generally also those of the passengers, the weight of despatches, the number of pigeons, &c. Only those balloons, however, are noticed in which some person ascended. A similar list of sixty-two balloons is given by Mr Glaisher in the introduction to the second edition of *Travels in the Air* (1871). It was, however, published too soon after the conclusion of the siege to be quite so complete as the sheet of the MM. Tissandier.

It is perhaps worth stating that the balloons were manufactured and despatched (generally from the platforms of the Orleans or the Northern Railway) under the direction of the Post-Office. The aeronauts employed were mostly sailors, who did their work very well. No use whatever was made in the war of balloons for purposes of reconnaissance. The exceedingly important part played by the balloon in the siege of Paris would alone, if it had been of no other utility, render it one of the most valuable inventions of the last century.

The principle of the parachute is so simple that the idea must have occurred to persons in all ages. Father Loubere, in his History of Siam, published two centuries ago, tells of a person who frequently diverted the court by the prodigious leaps he used to take, having two parachutes or umbrellas fastened to his girdle. In 1783 a certain M. le Normand practically demonstrated the efficiency of a parachute by descending from a high house at Lyons; but he merely regarded it as a useful means whereby to escape from fire. To Blanchard is due the idea of using it as an adjunct to the balloon. As early as 1785 he had constructed a parachute, to which was attached a basket. In this he placed a dog, which descended safely to the ground when the parachute was released from a balloon at a considerable elevation. It is stated that he descended himself from a balloon in a parachute in 1793; but, owing to some defect in its construction, he fell too rapidly, and broke his leg.

Para-chutes.

Blanchard.

André Jaques Garnerin was the first person who successfully descended from a balloon in a parachute, and he repeated this experiment so often that he may be said to have first demonstrated the practicability of using the machine; and, in fact, that he invented it in a practical and suitable form. In 1793 Garnerin had been taken prisoner at Marchiennes, and he was confined for between two and three years in the fortress of Bude, in Hungary. While in captivity he elaborated in his mind the means of descending from a balloon by means of a parachute; and on October 22, 1797, he made his first public experiment. He ascended from the park of Monceau at Paris, and when at the height of about $1\frac{1}{2}$ mile he released the parachute, which was attached to the balloon in place of a car; the balloon, relieved suddenly of so great a weight, rose very rapidly till it burst, while the parachute descended very fast, making violent oscillations all the way. Garnerin, however, reached the earth in safety upon the plain of Monceau. In 1802 Garnerin came to England and made a good many ascents in all parts of the country, many of which excited much enthusiasm, as can be seen from the contemporary accounts; and on September 21, 1802, he repeated his parachute experiment in England.

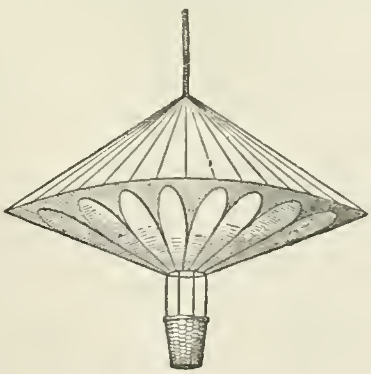
Garnerin.

The parachute was dome-shaped, and bore a resemblance to a large umbrella. The case or dome was made of white canvas, and was 23 feet in diameter. At the top was a truck or round piece of wood 10 inches in diameter, with a hole in its centre, fastened to the canvas by 32 short pieces of tape. The parachute was suspended from a hoop attached to the netting of the balloon, and below the parachute was placed a cylindrical basket, 4 feet high and $2\frac{1}{4}$ feet in diameter, which contained the aeronaut. The ascent took place at about six o'clock from North Audley Street, London:

and, at a height of about (it is believed) 8000 feet, Garnerin separated the parachute from the balloon. For a few seconds his fate seemed certain, as the parachute retained the collapsed state in which it had originally ascended, and fell very rapidly. It suddenly, however, expanded, and the rapidity of its descent was at once checked, but the oscillations were so violent that the car, which was suspended 20 feet below, was sometimes on a level with the rest of the apparatus. Some accounts state that these oscillations increased, others that they decreased as the parachute descended, and the latter seems most probable. It came to the ground in a field at the back of St Pancras Church, the descent having occupied rather more than ten minutes. Garnerin was hurt a little by the violence with which the basket containing him struck the earth; but a few cuts and a slight nausea represented all the ill effects of his fall. He made, certainly, one other descent in a similar way (as that just described is stated to have been his third), and we believe several others on the Continent, but this was the only one he effected in England.

Jordaki Kuparento, a Polish aeronaut, is the only person who ever made any real use of a parachute. He ascended from Warsaw on July 24, 1808, in a fire-balloon, which, at a considerable elevation, took fire; but being provided with a parachute, he was enabled to effect his descent in safety.

The next experiment made with a parachute was that which resulted in the unfortunate death of Mr Robert Cocking. So early as 1814 this gentleman had lectured on the subject before the City Philosophical Society, and also before the Society of Arts. He always retained an interest in ballooning, and made two ascents—one with Mr Sadler, and the other on September 27, 1836, with Mr Green. The success of the balloon trip of Messrs Hollond, Mason, and Green, seems to have incited Mr Cocking to demonstrate practically the truth of his views. He accordingly constructed a suitable parachute on his principles, and having succeeded in obtaining the consent of Messrs Hughes and Gye, the proprietors of Vauxhall Gardens, to permit the ascent to be made there, he prevailed on Mr Green to ascend in his great Nassau balloon with the parachute attached. The great defect of Garnerin's umbrella-shaped parachute was its violent oscillation during descent, and Mr Cocking considered that if the parachute were made of a conical form (vertex downwards), the whole of this oscillation would be avoided; and if it were made of sufficient size, there would be resistance enough to check too rapid a descent. He therefore constructed a parachute on this principle, the radius of which at its widest part was about 17 feet. It was stated in the public announcements previous to the experiment that the whole weighed 223 lb; but from the evidence at the inquest it appeared that the weight must have been over 400 lb. Mr Cocking's weight was 177 lb, which was so much additional. On July 24, 1837, the trial took place; and the Nassau balloon, with Mr Green and Mr Spencer, a solicitor, in the car, and having suspended below it the parachute, in the car of which was Mr Cocking, rose from the ground at twenty-five minutes to eight in the evening. A good deal of difficulty was experienced in rising to a suitable height, partly in consequence of the resistance to the air offered by the expanded parachute, and partly owing to its weight. Mr Cocking wished the height to be 8000 feet; but when the balloon reached the height of 5000 feet, it being then nearly over Greenwich, Mr Green called out to Mr Cocking that he should be unable to ascend to the requisite height if the parachute was to descend in daylight. Mr Cocking accordingly let slip the catch which was to liberate him from the balloon. The parachute for a few seconds descended very rapidly but still evenly, until suddenly the upper rim seemed to give way, and the whole apparatus collapsed (taking a form resembling an umbrella turned inside out, and nearly closed), and the machine descended with great rapidity, oscillating very much. When about two or three hundred feet from the ground, the basket became disengaged from the remnant of the parachute, and Mr Cocking was found in a field at Lee, literally dashed to pieces.



Cocking's Parachute.

Mr Green and Mr Spencer, who were in the car of the balloon, had also a narrow escape. At the moment the parachute was disengaged they crouched down in the car, and Mr Green clung to the valve-line, to permit the escape of the gas. The balloon shot upwards, plunging and rolling, and the gas pouring from both the upper and lower valves, but chiefly from the latter, as the great resistance of the air checked its egress from the former. Mr Green and Mr Spencer applied their mouths to tubes communicating with an air-bag with which they had had the foresight to provide themselves, otherwise they would certainly have been suffocated by the gas. Notwithstanding this precaution, however, the gas almost totally deprived them of sight for four or five minutes. When they came to themselves they found they were at a height of about four miles, and descending rapidly. They effected, however, a safe descent near Maidstone.

Many objections were made, after the result, to the form of Mr Cocking's parachute; but there is little doubt that had it been constructed of sufficient strength, and perhaps of somewhat larger size, it would have answered its purpose. As it was, the upper rim was made of tin, which soon gave way. Mr Wise, the American aeronaut, made some experiments on parachutes of both forms (Garnerin's and Cocking's), and found that the latter always were much more steady, descending generally in a spiral curve.

Mr Hampton's parachute descents.

In 1839 Mr Hampton made three descents in a parachute, on Garnerin's pattern, from his balloon, the "Albion." He followed Garnerin's example in attaching the parachute to the netting of the balloon, so that when the connection between the two was severed the latter was left to its own devices. Mr Hampton took measures, however, that it should descend soon after the parachute, and it was generally found no great distance off, and returned to him. All his parachute descents were safely performed, although in one he was a good deal shaken.

Hampton's Parachute.

We may remark that a descending balloon half-full of gas either does rise, or can with a little management be made to rise, to the top of the netting and take the form of a parachute, thus materially lessening the rapidity of descent. Mr Wise, in fact, having noticed this, once purposely exploded his balloon when at a considerable altitude, and the resistance offered to the air by the envelope of the balloon was sufficient to enable him to reach the ground without injury. And a similar thing took place in one of Mr Glaisher's high scientific ascents (April 18, 1863), when, at a height of about 2 miles, the sea appeared directly underneath; the gas was let out of the balloon as quickly as possible, and the velocity of descent was so great, that the 2 miles of vertical height were passed through in four minutes. On the balloon reaching the ground at Newhaven, close to the shore, it was found to be nearly empty. The balloon had, in fact, for the last mile or more, merely acted as a parachute; the shock was a severe one, and all the instruments were broken, but nothing serious resulted to the occupants of the car.

Numerous attempts have been made both to direct balloons and contrive independent flying machines. After the invention of the balloon by the brothers Montgolfier, it was at once thought that no very great difficulty would be found in devising a suitable steering apparatus; in fact, it was supposed that to rise into the air and remain there was the chief difficulty, and that, this being accomplished, the power of directing the aerostat would be a secondary achievement that must follow before long. Accordingly, in most of the early balloons the voyagers took up oars, sails, or paddles, which they diligently worked while in the air; sometimes they thought an effect was produced, and sometimes not. If we consider the number of different currents in the atmosphere, it is no wonder that some should have announced with confidence that their course was changed from that of the wind by means of the sails or oars that they used, in fact, it is not very often that the whole atmosphere up to a considerable height is moving *en masse* in the same direction, so that generally the course taken by the balloon, as determined merely by joining the places of ascent and descent, is not identical with the direction of the wind, even when it is the same at both places. Although there is no reason why balloons should not be so guided by means of mechanical appliances attached to them as to move in a direction making a small angle with that of the wind, still it must have been evident to any one who has observed a balloon during inflation on a windy day, that any motion in which it would be exposed to the action of a strong current of air must result in its destruction. It has therefore gradually become recognised that the balloon is scarcely a step at all towards a system of aerial navigation; and many have thought that the principles involved in the construction of a flying machine must be very different from the simple statical equilibrium that subsists when a balloon is floating in the air. "To navigate the air the machine must be heavier than the air," has frequently been regarded as an axiom; and there can be no doubt that an apparatus constructed of such light material as is necessary for a balloon must either be destroyed or become ungovernable in a high wind. Recently, however, M. Dupuy de Lôme, an eminent French engineer, has constructed and made experiments with a balloon which he considers satisfies some of the conditions. The balloon is spindle-shaped, the longer axis being horizontal, and it contains about 120,000 cubic feet. The car is suspended below the middle of the balloon, and there are provided a rudder and a screw. The rudder consists of a triangular sail placed beneath the balloon and near the rear, and is kept in position by a horizontal yard, about 20 feet long, turning round a pivot in its forward extremity; the height of the sail is 16 feet, and its surface 160 square feet. Two ropes for working the rudder extend forward to the seat of the steerer, who has before him a compass fixed to the car, the central part of which will contain fourteen men. The screw is carried by the car, and is driven by four or eight men working at a capstan. A trial was made with the machine on February 2, 1872, on a windy day, and M. de Lôme considered that he had been enabled by his screw and rudder to alter his course about 12°. (See *Report of the Aeronautical Society*, 1872).

Whatever difficulties may present themselves in regulating the horizontal movement of the balloon, there can be no doubt that the vertical motion could be obtained by means of a screw or other mechanical means; and the power of being able to ascend or descend without loss of ballast would be a considerable gain. In the opinion of many, however, the balloon is not worth improvement; and as ballooning is now generally practised merely as a spectacle by which the aeronaut or showman gains his living, it is not likely that any advancement will be made.

Of flying machines, in which both buoyancy and motion were proposed to be obtained by purely mechanical means, the number has been very great. Most of the projects have been chimerical, and were due to persons possessed of an insufficient knowledge of the principles of natural philosophy, both theoretically and practically. They serve, however, to show how great a number of individuals must have paid attention to the matter, and even at the present time several patents are taken out annually on the subject. We do not propose here to give an account of any of these projects, for but few have ever passed beyond projects, but will merely refer to Mr Henson's aerial carriage, which in 1843 attracted some attention. The apparatus was an elaborate one, and its principal feature was the great expanse of the sustaining planes. The machine was to advance with its front edge a little raised, the effect of which would be to present its under surface to the air over which it was passing; the resistance of this air, acting on it like the strong wind on the sails of a windmill, would, it was thought, prevent the descent of the machine. Mr Henson invented a steam-engine of great lightness, but he proposed that the machine should be started down an inclined plane, so that the steam-engine would only have to make up for the velocity lost by the resistance of the air. The scheme never came to anything.

Hens aeria riage

In the still air of a room it is, of course, not difficult to attach an apparatus to a balloon so as to direct its motion, and even models of flying machines have been made which, when tried in a room, seemed moderately successful. Some instruments which would very nearly support themselves in the air were shown at the Aeronautical Society's exhibition at the Crystal Palace. A good deal would be accomplished if an accurate knowledge of the exact motion of a bird's wing could be obtained; in fact, until this is known, or until sufficient experiments on the resistance experienced by different-shaped laminæ with different motions are made, there seems little chance of the construction of a satisfactory flying machine, unless means can be found to make a steam-engine of much less weight than is at present necessary.

In 1865 the Aeronautical Society of Great Britain was founded, the officers being—President, the Duke of Argyle; Treasurer, Mr J. Glaisher; and Secretary, Mr Brearey. It has published an annual report every year since [1873], containing selections from the papers read to the society, and abstracts of the discussions that took place thereon at the meetings. The numerous papers submitted to this society bear witness to the great number of minds that are engaged on the solution of the problem of aerial navigation. Of course, not a few of the methods proposed are the fanciful projects of ignorant men, but some show the careful thought and elaborate experiment of trained engineers and other qualified persons. In 1868 the society held an exhibition of flying machines, &c., at the Crystal Palace, which was visited by many persons. A fire-balloon of a M. de la Marne, which should have ascended during this exhibition

Aeron cal S of Gr Brita

caught fire and was burnt. In 1871 a series of experiments was made at Penn's factory (Greenwich) on the resistance of different shaped planes placed at different angles, in a current of air produced by a rotary fan. Investigations of this kind not only form the first step towards obtaining data for a true knowledge of the exact nature of flying, but are also independently of high scientific interest. The chief object of the society is to bring together those persons who are interested in the subject of aeronautics (except balloonists by trade, who are ineligible), and to encourage those who, possessing suitable acquirements, are devoting their time to the investigation of the question.

Aerostatic societies have also been founded in other countries; but although they have been inaugurated with considerable *éclat*, more than one have already terminated a short-lived career. The Vienna society seems, however, to have been unusually active during the recent exhibition of 1873.

The principle in virtue of which a balloon ascends is exactly the same as that which causes a piece of wood or other material to float partially immersed in water, and may be stated as follows, viz., that if any body float in equilibrium in a fluid, the weight of the body is equal to the weight of the fluid displaced. By the "fluid displaced" is meant the fluid which would occupy the space actually occupied in the fluid by the body if the body were removed. When the fluid is inelastic and incompressible, *i.e.*, a liquid, as water, its density is the same throughout, and bodies placed in it either rise to the surface and float there partially immersed, or sink to the bottom. Thus, suppose a body only one-third as heavy as water (in other words, whose specific gravity is one-third) was floating on the surface of water, then, as the weight of the body must be equal to that of the water it displaces, it is clear that one-third of the body must be immersed. In the case, however, of an elastic or gaseous fluid, such as air, the density gradually decreases as we recede from the surface of the earth, for each layer has to support the weight of all above it, and as air is elastic or compressible, the layers near the earth are more pressed upon, and therefore denser than those above. Thus, if a body lighter than the air it displaces be set free in the atmosphere, it rises to such a height that the air there is so attenuated that the weight of it displaced is equal to that of the body, when equilibrium takes place, and the body ascends no higher. In all cases, therefore, a body floating in the air is totally immersed, and it can never get beyond the atmosphere, and float, as it were, upon its surface.

To find, therefore, how high any body (lighter than the air it displaces), such as a balloon, of given capacity and weight, will rise, it is only necessary to calculate at what height the volume of a quantity of air equal to the given capacity will be equal in weight to the given weight. Leaving temperature out of the question, the law of the decrease of density in the atmosphere is such that the density at a height x is equal to $e^{-\frac{g}{k}x}$ × the density at the earth's surface, g being the measure of gravity, and k also a constant; the value of $\frac{k}{g}$ is called the height of the homogeneous atmosphere, viz., it is equal to what would be the height of the atmosphere if it were homogeneous throughout, and of the same density as at the earth's surface. Its value may be taken at about 26,000 feet. Thus, let V be the volume of a balloon and its appurtenances, car, ropes, &c. (viz., the number of cubic feet, or whatever the unit of solidity may be, that it displaces), and let W be its weight (including that of the gas), then it will rise to a height x such that

$$W = Vg \times \text{density of air},$$
$$= Vg\sigma_0 e^{-\frac{g}{k}x},$$

g being the value of the force of gravity, and σ_0 being the density of the air at the surface of the earth. This equation is not quite accurate, for several reasons—(1) because the decrease of temperature that results from increase of elevation has not been taken into account; (2) because g has been taken to measure the force of gravity on the earth's surface, whereas it should represent the force at a height x; this is easily corrected by replacing g by g', where $g' = g\frac{a^2}{(a+x)^2}$, a being the radius of the earth, but as a is about 4000 miles, and x is never likely in any ordinary question to exceed 10 miles, we can replace g' by g without introducing sensible error, for the correction due to this cause would be much less than other uncertainties that must arise; and (3) because W and V could not both remain constant. If the balloon be not fully inflated on leaving, so that the gas contained in it can expand, then V, the volume of air displaced, will increase; while, if the balloon be full at starting, the envelope must either be strong enough to resist the increased pressure of the gas inside, due to the removal of some of the pressure outside (owing to the diminished density of the air), or some of the gas must be allowed to escape. The former alternative of the second case could not be complied with, as the balloon would burst; some of the gas must therefore escape, and so W is diminished. The weight of gas of which the balloon is thus eased cannot properly be omitted from the calculation, if x be considerable; but a good approximation is obtained without it, as the weight of the gas that escapes will generally bear a small proportion to the weight of balloon, car, grapnel, passengers, &c. The true equation (except as regards temperature) is therefore, for a balloon full at starting—

$$W - \frac{ga^2 v_0 \rho_0 (1 - e^{-\frac{g'}{k}x})}{(a+x)^2} = \frac{ga^2 V_0 \sigma_0 e^{-\frac{g'}{k}x}}{(a+x)^2},$$

v_0 denoting the volume actually occupied by the gas, g' denoting $g\frac{a^2}{(a+x)^2}$, viz., gravity at height x, and ρ_0 being the density of the gas on the ground. It will generally be sufficient, especially when temperature is omitted, to take the formula in the approximate form written previously. As the volume of air displaced by the car, ropes, passengers, &c., is usually trifling compared to that displaced by the balloon itself, no great error can arise from taking $v_0 = V_0$. As an example, let us find how high a balloon of 100,000 cubic feet capacity would rise if inflated with pure hydrogen gas, carrying with it a weight of 3000 lb (this including the weight of the balloon itself and appurtenances). A cubic foot of air, at temperature 32° Fahr., and under a pressure of 29·922 in., weighs ·080728 lb, and a cubic foot of hydrogen weighs ·005592 lb, so that (supposing the barometer reading on the earth to be 29·922 in., and the temperature of the air to be 32°) at the surface of the earth the balloon, &c., weighs 3559 lb, and the weight of the air displaced is 8073 lb. The balloon will therefore approximately rise to such a height x that 100,000 cubic feet of air shall there weigh 3559 lb; and x is given in feet by the equation

$$e^{-\frac{x}{26,000}} = \frac{3559}{8073},$$

or $$x = 26,000\,(\log 8073 - \log 3559),$$

the logarithms being hyperbolic; if common or Briggian logarithms be used, the result must be multiplied by 2·30258 . . . (the reciprocal of the modulus). In the above case we find $x =$ about 21,000 feet, and as at this height rather more than half the gas will have escaped (it having been supposed that the balloon was full at starting). This only reduces the value 3559 by about 300, and the result of taking it into account is only to increase the height just found by about 200 feet. If 2000 lb out of the 3000 were thrown away during the ascent, the balloon would reach a height of about 10 miles; the weight of the gas that escapes is here important, as, if it be not taken into account, the height given by the formula is only about 8 miles.

In actual aerostation, as at present practised, ordinary coal gas is used, which is many times heavier than hydrogen, being, in fact, usually not less than half the specific gravity of air. Even when balloons are inflated with hydrogen, generated by the action of sulphuric acid on zinc filings, the gas is very far from pure, and its density is often double that of pure hydrogen, and even greater.

The hydrostatic laws relating to the equilibrium of floating bodies were known long previous to the invention of the balloon in 1783, but it was only in the latter half of the 18th century that the nature of gases was sufficiently understood to enable these principles to have been acted on. As we have seen, both Black and Cavallo did make use of them on a small scale, and if they had thought it possible to make a varnish impervious to the passage of hydrogen gas they could have easily anticipated the Montgolfiers. As it was, no sooner was the fire-balloon invented, than Charles at once suggested and practically carried out the idea of the hydrogen or inflammable air balloon.

Mathematical theory of the motion of a balloon; the last problem that engaged the attention of Euler.

The mathematical theory of the rate of ascent of a balloon possesses remarkable historic interest, from the fact that it was the last problem that engaged the attention of the greatest mathematician of the last century, Euler. The news of the experiment of the Montgolfiers at Annonay on June 5, 1783, reached the aged mathematician (he was in his 77th year) at St Petersburg, and with an energy that was characteristic of him he at once proceeded to investigate the motion of a globe lighter than the air it displaced. For many years he had been all but totally blind, and was in the habit of performing his calculations with chalk upon a black board. It was after his death, on September 7, 1783, that this board was found covered with the analytical investigation of the motion of an aerostat. This investigation is printed under the title, *Calculs sur les Ballons Aérostatiques faits par feu M. Léonard Euler, tels qu'on les a trouvés svr son ardoise, après sa mort arrivée le 7 Septembre* 1783, in the *Memoirs of the French Academy* for 1781 (pp. 264–268). The explanation of the earlier date is that the volume of memoirs for 1781 was not published till 1784. The peculiarity of Euler's memoir is that it deals with the motion of a closed globe filled with a gas lighter than air, whereas the experiments of the Montgolfiers were made with balloons inflated with heated air. The explanation of this must be that either an imperfect account reached Euler, and that he supplied the details himself as seemed to him most probable, or that he, like the Montgolfiers themselves, attributed the rising of the balloon to the generation of a special gas given off by the chopped straw with which the fire was fed. The treatment of the question by Euler presents no particular point of importance—indeed, it could not; but the fact of its having given rise to the closing work of so long and distinguished a life, and having occupied the last thoughts of so great a mind, confers on the problem of the balloon's motion a peculiar interest.

We now proceed to the investigation of the vertical motion of a balloon inflated with gas, the horizontal motion, of course, being always equal to that of the current in which it is placed. In supposing, therefore, the balloon to be ascending vertically into a perfectly calm atmosphere, there is no loss of generality. There are two cases of the problem, viz., when the balloon is only partially filled with gas at starting, and when it is quite filled. The motion in the former case we shall investigate first, as the balloon will ascend till it becomes completely full, and then the subsequent motion will belong to the second case. We may remark that it is usual in investigations relating to the motions of a balloon to regard it in the way that Euler did, viz., as a *closed* inextensible bag, capable of bearing any amount of pressure. In point of fact, the neck or lower orifice of the balloon is invariably open while it is in the air, so that the pressure inside and outside is practically always the same, and when the balloon continues ascending after it has become quite full, the gas pours out of the neck or is allowed to escape by opening the upper valve. It is to be noticed that we have not thought it necessary to transform the formulæ obtained in such wise that they may be readily adapted to numerical calculations as they stand, as our object is rather to exhibit the nature of the motion, and clearly express the conditions that are fulfilled in the case of a balloon, than deduce a series of formulæ for practical use. We shall, however, indicate the simplifications allowable in practical applications. The effect of temperature, though important, is neglected, as the connection between it and height is still unknown. It was chiefly to determine this relation that Mr Glaisher's ascents were undertaken, and at the conclusion of the first eight he deduced an empirical law which seemed to accord pretty well with the observations; the succeeding twenty ascents, however, failed to confirm this law. In fact, it is evident, even without observation, that the rate of the decline of temperature when the sky is clear must differ from what it is when cloudy, and that, being influenced to a great amount by radiation of heat from the earth's surface, it will vary from hour to hour. Under these circumstances, as our object is not to deduce a series of practical rules for calculating heights, &c., we have supposed the temperature to remain constant throughout the atmosphere. The assumption of any law of decrease would considerably complicate the equations. Perhaps the simplest law, mathematically considered, would be to assume the curve of descent of temperature to be $y = e^{-cx}$. The curve Mr Glaisher deduced from his eight ascents was a portion of a hyperbola, the constants being determined empirically.

Let M = the mass of the balloon, car, netting, gas, passengers, &c., on starting.
- V_0 = the capacity of the envelope of the balloon when full.
- v_0 = the volume of gas at the pressure of the air introduced into the balloon before starting.
- v = the volume (supposed less than V_0) occupied by the gas at the height x.
- ρ_0 = density of the gas in the balloon on the earth.
- ρ = " " " at the height x.
- σ_0 = density of the air on the earth.
- σ = " " at the height x.
- u = the initial upward velocity of the balloon (which is introduced for the sake of complete generality, but is always zero).
- u_0 = the velocity (vertically upwards, as all horizontal motion is ignored) at height x.

Then the equation of motion at any time previous to the balloon becoming completely filled is

$$Mu\frac{du}{dx} = \sigma v g' - Mg' - \lambda u^2 e^{-\frac{k}{a}x},$$

the last term being due to the resistance of the air, which is assumed to vary directly as the square of the velocity and as the density of the air. In very slow motions the resistance appears from experiments to vary pretty nearly as the velocity; and when the motion is very swift, as in the case of a rifle-bullet, as the cube of the velocity; but when the motion is neither very rapid nor very slow, the law of the square of the velocity probably represents the truth very fairly. By g' is denoted the value of gravity at the height x, so that

$$g' = g\frac{a^2}{(a+x)^2}$$

a being, as above, the radius of the earth. In the exponential term, we shall replace g' by g, as no sensible error can result therefrom. The value of σv is constant, as by Boyle's and Marriotte's law it always $=\sigma_0 v_0$. Writing, therefore, for brevity—

$$\sigma_0 v_0 - \mathrm{M} = c,$$

$$\frac{2\lambda}{\mathrm{M}} = \alpha, \quad \frac{2cg}{\mathrm{M}} = \beta, \quad \frac{g}{k} = n, \quad \frac{\alpha}{n} = m,$$

the equation of motion takes the form

$$\frac{du^2}{dx} + \alpha e^{-nx}u^2 = \beta\frac{a^2}{(a+x)^2};$$

whence, following the usual rule for the integration of linear differential equations of the first order, and writing X for e^{-nx}, for convenience of printing,

$$u^2 e^{-m\mathrm{X}} = \beta a^2 \int e^{-m\mathrm{X}}\frac{dx}{(a+x)^2}$$

$$= \beta a^2\left\{-\frac{e^{-m\mathrm{X}}}{a+x} + \alpha\int\frac{e^{-nx-m\mathrm{X}}dx}{a+x}\right\}$$

$$= \beta a^2\left\{-\frac{e^{-m\mathrm{X}}}{a+x} + \alpha\int\frac{dx}{a+x}\left(e^{-nx} - me^{-2nx} + \frac{m^2}{1.2}e^{-3nx} - \ldots\right)\right\}$$

$$= \beta a^2\Big[-\frac{e^{-m\mathrm{X}}}{a+x} + \alpha\{e^{na}\mathrm{Ei}(-na-nx)$$

$$-me^{2na}\mathrm{Ei}(-2na-2nx)$$

$$+\frac{m^2}{1.2}e^{3na}\,\mathrm{Ei}(-3na-3nx) - \ldots\}\Big] + \mathrm{C}.$$

Herein put $x=0$, so that $u=u_0$, and we have

$$u_0^2 e^{-m} = \beta a^2\Big[-\frac{e^{-m}}{a} + \alpha\{e^{na}\mathrm{Ei}(-na) - me^{2na}\mathrm{Ei}(-2na)$$

$$+\frac{m^2}{1.2}e^{3na}\mathrm{Ei}(-3na)\ldots\}\Big] + \mathrm{C};$$

whence, by subtraction,

$$u^2 e^{-m\mathrm{X}} - u_0^2 e^{-m} = \beta a^2\Big[\frac{e^{-m}}{a} - \frac{e^{-m\mathrm{X}}}{a+x} + \alpha\{e^{na}\mathrm{Ei}(-na-nx)$$

$$-me^{2na}\mathrm{Ei}(-2na-2nx) + \ldots - e^{na}\mathrm{Ei}(-na) + me^{2na}\mathrm{Ei}(-2na) - \ldots\}\Big]$$

therefore

$$u^2 = u_0^2 e^{-m(1-\mathrm{X})} + \beta a^2\Big[\frac{e^{-m(1-\mathrm{X})}}{a} - \frac{1}{a+x}$$

$$+\alpha e^{m\mathrm{X}}\{e^{na}\mathrm{Ei}(-na-nx) - e^{na}\mathrm{Ei}(-na) - me^{2na}\mathrm{Ei}(-2na-2nx)$$

$$+me^{2na}\mathrm{Ei}(-2na) + \frac{m^2}{1.2}e^{3na}\mathrm{Ei}(-3na-3nx)$$

$$-\frac{m^2}{1.2}e^{3na}\mathrm{Ei}(-3na) + \ldots\}\Big]$$

in which Ei x is used to denote the exponential integral of x, viz.: $\int_{-\infty}^{x}\frac{e^x}{x}dx$, according to a recognised notation. The values of the integral Ei x, which may be regarded as a known function, have been tabulated (see *Philosophical Transactions* for 1870, pp. 367–388).

We thus have, except for temperature, the complete solution of the problem of the motion of the balloon so far as velocity and height are concerned; it would not be possible to connect the time and the height except by the performance of another integration, for the practicability of which it would be necessary to submit to some loss of generality, viz., we should have to regard x as small as compared to a, and take λ as small, and so on. The equation last written gives the motion until the height (say h) is attained at which the balloon becomes quite full, after which the gas begins to escape, and we have the second case of the problem.

Before proceeding, however, to the discussion of this second case, it is worth while to examine the solution more carefully, leaving out of consideration quantities that make no very great difference in the practical result, for the sake of simplicity. Supposing, then, gravity to be constant at all heights, and λ to be zero, the equation of motion takes the simple form

$$\frac{d.u^2}{dx} = \beta$$

whence $u^2 - u_0^2 = \beta x$;

and we see, what is pretty evident from general reasoning, that if a balloon, partially filled, rises at all, it will at least rise to such a height that it will become completely full.

The letters meaning the same as before, the equation of motion of a balloon completely filled at starting is Motion of a balloon full at starting

$$\Big\{\mathrm{M} - \mathrm{V}_0(\rho_0 - \rho)\Big\}u\frac{du}{dx} = g\frac{a^2}{(a+x)^2}\Big\{\mathrm{V}_0\sigma - \mathrm{M} + \mathrm{V}_0(\rho_0 - \rho)\Big\}$$
$$-\lambda u^2 e^{-nx},$$

or substituting for ρ and σ their values

$$\Big\{\mathrm{M} - \mathrm{V}_0\rho_0(1-e^{-nx})\Big\}u\frac{du}{dx} = g\frac{a^2}{(a+x)^2}\Big\{\mathrm{V}_0\sigma_0 e^{-nx} - \mathrm{M}$$

$$+\mathrm{V}_0\rho_0(1-e^{-nx})\Big\} - \lambda u^2 e^{-nx}.$$

The integral of this differential equation could be obtained in series as before, only that the resulting equations would be more complicated. As we do not propose to discuss the formulæ obtained, it will be sufficient for our purpose to deduce an approximate solution by neglecting $\mathrm{V}_0\rho_0(1-e^{-nx})$ compared to M, viz., neglecting the mass of the gas that has escaped during the ascent compared to the mass of the whole balloon and appurtenances. It must be borne in mind, however, that when coal gas is used, and the ascent is to a great height, the mass of gas that escapes is by no means insensible. The equation thus becomes

$$\tfrac{1}{2}\mathrm{M}\frac{du^2}{dx} + \lambda e^{-nx}u^2 = \frac{ga^2}{(a+x)^2}\Big\{\mathrm{V}_0\sigma_0 e^{-nx} - \mathrm{M}\Big\}$$

or

$$\frac{du^2}{dx} + \alpha e^{-nx}u^2 = \frac{\gamma a^2}{(a+x)^2}\Big\{\mathrm{V}_0\sigma_0 e^{-nx} - \mathrm{M}\Big\}$$

γ being $\frac{2g}{\mathrm{M}}$. This is an equation which can be integrated in exactly the same way as that previously considered, viz., by multiplying by a factor $e^{-m\mathrm{X}}$, and integrating at once; thus,

$$u^2 e^{-m\mathrm{X}} = \mathrm{V}_0\sigma_0\gamma a^2\int\frac{e^{-nx-m\mathrm{X}}dx}{(a+x)^2} - \mathrm{M}\gamma a^2\int\frac{e^{-m\mathrm{X}}dx}{(a+x)^2} + \mathrm{C}$$

$$= \mathrm{V}_0\sigma_0\gamma a^2\Big\{-\frac{e^{-nx-m\mathrm{X}}}{a+x} + \int\frac{dx}{a+x}\left(-ne^{-nx-m\mathrm{X}} + \alpha e^{-2nx-m\mathrm{X}}\right)\Big\}$$

$$-\mathrm{M}\gamma a^2\Big\{-\frac{e^{-m\mathrm{X}}}{a+x} + \alpha\int\frac{e^{-m\mathrm{X}-nx}dx}{a+x}\Big\} + \mathrm{C}$$

$$= \mathrm{V}_0\sigma_0\gamma a^2\Big[-\frac{e^{-nx-m\mathrm{X}}}{a+x}$$

$$-n\{e^{na}\,\mathrm{Ei}(-na-nx) - me^{2na}\mathrm{Ei}(-2na-2nx) + \ldots\}$$

$$+\alpha\{e^{2na}\mathrm{Ei}(-2na-2nx) - me^{3na}\mathrm{Ei}(-3na-3nx) + \ldots\}\Big]$$

$$-M\gamma a^2\left[-\frac{\epsilon^{-nx}}{a+x}+\alpha\left\{\epsilon^{na}\mathrm{Ei}(-na-nx)\right.\right.$$
$$\left.\left.-m\epsilon^{2na}\mathrm{Ei}(-2na-2nx)+\ldots\right\}\right]+C,$$

and C is determined as before by putting $x = 0$, when we have $u = u_0$.

In this case u_0 is not zero, except when the balloon starts from the earth quite full. The general case is, when the balloon is only partially filled on leaving; the previous equations then hold until a height h, at which it becomes quite full, when the motion changes, and is as just investigated. Then u_0 becomes the velocity at the height h, and everything is measured from this height as if from the surface of the earth, a being then the radius of the earth $+ h$, ρ_0, σ_0 the densities at height h, and ρ, σ at height $x + h$, &c. We have therefore, except as regards time, completely determined the motion of a balloon inflated with gas in an atmosphere of constant temperature. The introduction of temperature would modify the motion considerably, but in the present state of science it cannot be taken into account.

The general principle of the equilibrium of a fire-balloon is, of course, identical with that of a gas-balloon; but the motion is different, as the degree of buoyancy at each moment varies with the temperature of the air within the balloon, and therefore with the heat of the furnace by which the air is warmed. Dry air expands $\frac{1}{273}$d part of its volume for every increase of temperature of 1° centigrade, or $\frac{1}{491}$th of its volume for every increase of temperature of 1° Fahr. If, therefore, the air in an envelope or bag be heated 60° Fahr. more than the surrounding air, the air within the bag will expand $\frac{60}{491}$th of its volume, and this air must therefore escape. The air within the bag weighs less, therefore, than the air it displaces by the $\frac{60}{551}$th part of the latter; and if the weight of this be greater than the weight of the bag and appurtenances, the latter will ascend. It is, therefore, always easy to calculate approximately the ascensional power of a fire-balloon if the temperature of the surrounding air be known, and also the mean temperature of the air within the balloon. Thus, let the balloon contain V cubic feet of hot air at the temperature t' (Fahr.), and let the temperature of the surrounding air be t (Fahr.) Also, suppose the weight of the balloon, car, &c., is W ℔, and let the barometer reading be h inches, then the ascensional power is equal to the weight of the air displaced − weight of the heated air − W ℔, viz.,

$$\frac{h}{29{\cdot}922}\left\{\frac{V\times{\cdot}080728}{1+\dfrac{t-32}{491}}-\frac{V\times{\cdot}080728}{1+\dfrac{t'-32}{491}}\right\}\text{℔}-\text{W ℔},$$

·080728 ℔ being the weight of a cubic foot of air at temperature 32°, under the pressure of one atmosphere, viz., when the reading of the barometer is 29·922 in. Of course, the motion depends upon the temperature of the air in the balloon as due to the furnace, if the latter is taken up with the balloon; but if the air in the balloon is merely warmed, and the balloon then set free by itself, the problem is an easy one, as the rate of cooling can be determined approximately; but it is destitute of interest. We have said that dry air increases its volume by $\frac{1}{491}$th part for every increase of 1° (Fahr.), but the air is generally more or less saturated with moisture. This second atmosphere, formed of the vapour of water, is superposed over that of the air, as it were, and, in a very careful consideration of the question, should be taken into account. Even, however, when the air is completely saturated with moisture but little difference is produced; so that for all practical purposes the presence of the vapour of water in the air may be ignored. Of course the amount of vapour depends on the dew-point, and tables of the pressure of the vapour of water at different temperatures are given in most modern works on heat; but, as has been stated, the matter, in an aeronautical point of view, is of very little importance. At first it was supposed that the cause of the ascent of the balloon of the Montgolfiers was traceable to the generation of gas and smoke from the damp straw which was set light to; but the advance of science showed that the fire-balloon owed its levity merely to the rarefaction of the air produced by the heat generated.

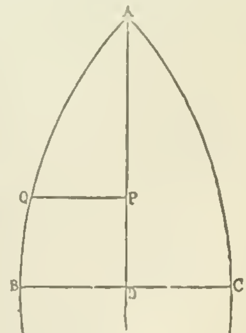
A formula giving the height, in terms of the readings of the barometer and thermometer, on the surface of the earth, and at the place the height of which is required, is easily obtained from the principles of hydrostatics. The formula given by Laplace, reduced to English units, is—

$$Z=\log\left(\frac{h}{h'}\right)\times 60159\left(1+\frac{t+t'-64}{900}\right)(1+{\cdot}002837\cos 2\,L)\left(1+\frac{z+52251}{20886900}\right).$$

Z being the height required in feet, h, h' the heights of the barometer in inches at the lower and upper stations, t, t' the temperatures (Fahr.) of the air at the lower and upper stations, L the latitude, z the approximate altitude, and 20,886,900 the earth's mean radius in feet. This was the formula used by Mr Glaisher for the reduction of his observations. It is open to the obvious defect that the temperature is assumed uniform, and equal to the mean of the temperatures at the upper and lower stations; but till the law of decline of temperature is better determined, perhaps this is as good an approximation to the truth as we can have without introducing needless complication in the formula.

Shape of gore of a balloon.

A sphere is not a developable surface—*i.e.*, it cannot be divided in any manner so as to admit of its being spread out flat upon a plane, so that no spherical balloon could be made of *stiff* plane material. However, the silk or cotton of which balloons are manufactured is sufficiently flexible to prevent any deviation from the sphere being noticeable. Balloons are made in *gores*, a gore being what, in spherical trigonometry, is called a *lune*, viz., the surface enclosed between two meridians. The approximate shape of these gores is very easy to calculate. Thus, let A B E C be a gore, then the sides A B E, A C E, are not arcs of circles, but curves of sines, viz., P Q bears to D B the ratio that sin A P does to sin A D, or, which comes to the same thing, supposing A D = 90°, and A P = x°, then P Q = B D sin x°. It is thus easy, by means of a table of natural sines, to form a pattern gore, whatever the required number of gores may be. Thus, supposing there are to be n gores, then B C must be $\frac{1}{n}$th of the circumference—viz., $\frac{2}{n}$ths of A E; and B D and A D being given, any number of points can be found on the curve A B E in the manner indicated above. A slight knowledge of spherical trigonometry shows the reason for the above rule. Balloons, as usually constructed, are spherical, except for the neck, which is made to slope down, so that the whole



Balloon Gore.

shape resembles rather that of a pear. The pattern gore should originally be made as if for a spherical balloon, and afterwards the slight modification necessary for the formation of the neck should be applied.

The gores are sewn together, and a small portion of the upper end of each is cut away, so as to leave an aperture at the top of the balloon of from 1 to 3 feet in diameter. This space is occupied by the valve, which is generally made of strong wood, and consists of two semicircular shutters hinged to a diameter of the circular frame, and kept closed by a spring. The valve is opened by pulling a string, technically called the valve-line, which passes down through the balloon and out at the lower orifice in which the neck terminates. The net-work which, like the gores, is attached to the circumferences of the valve, passes over the surface of the balloon, and supports the ring or hoop from which the car is suspended by half a dozen strong ropes, of perhaps 4 or 5 feet in length. The network is thus stretched between the valve and the ring. It is very important that all the ropes by which the car hangs from the ring should be so adjusted that each may bear pretty nearly the same weight, as otherwise the whole netting and balloon will be strained, and perhaps to a serious extent. The car is usually merely a large basket made of wicker-work. The neck of the balloon should be 7 or 8 feet above the car, so that the aeronaut can easily reach it by mounting into the ring. The best material for the envelope is silk; but on account of the expense cotton or alpaca is generally used: in all cases it must be varnished, in order to render it more impervious to the gas. The grapnel or anchor is a large five-pronged hook attached to the ring by a rope 100 or 120 feet long. The first care of the aeronaut on leaving the earth is to lower the grapnel gently to the full extent that the rope will permit. Thus, when the balloon is in the air, the grapnel hangs down below it, and when the descent is being effected, is the first thing to touch the ground. If the descent is well managed, and the balloon is moving downwards slowly, the weight of which it is relieved when the grapnel is supported by the earth checks any further descent, and the wind carries the balloon along horizontally, the grapnel trailing over the ground until it catches in some obstruction and is held fast. The balloon is then in much about the same position as a kite held by a string, and if the wind be strong, plunges about wildly, striking the ground and rebounding, until the aeronaut, by continued use of the valve-line, has allowed sufficient gas to escape to deprive it of all buoyancy and prevent its rising again.

The chief danger attending ballooning lies in the descent; for if a strong wind be blowing, the grapnel will sometimes trail for miles over the ground at the rate of ten or twenty miles an hour, catching now and then in hedges, ditches, roots of trees, &c.; and, after giving the balloon a terrible jerk, breaking loose again, till at length some obstruction, such as the wooded bank of a stream, affords a firm hold. If the balloon has lost all its buoyant power by the escape of the gas, the car also drags over the ground. But even a very rough descent is usually not productive of any very serious consequences; as, although the occupants of the car generally receive many bruises, and are perhaps cut by the ropes, it rarely happens that anything worse occurs. On a day when the wind is light (supposing that there is no want of ballast) nothing can be easier than the descent, and the aeronaut can decide several miles off on the field in which he will alight. It is very important to have a good supply of ballast, so as to be able to check the rapidity of the descent, as in passing downwards through a wet cloud the weight of the balloon is enormously increased by the water deposited on it; and if there is no ballast to throw out to compensate this accession of mass, the velocity is sometimes very great. It is also convenient, if the district upon which the balloon is descending appear unsuitable for landing, to be able to rise again. The ballast consists of fine baked sand, which becomes so scattered as to be inappreciable before it has fallen far below the balloon. It is taken up in bags containing about ½ cwt. each. The balloon at starting is liberated by a spring catch which the aeronaut releases, and the ballast should be so adjusted that there is nearly equilibrium before leaving, else the rapidity of ascent is too great, and has to be checked by parting with gas. It is almost impossible to liberate the balloon in such a way as to avoid giving it a rotary motion about a vertical axis, which continues during the whole time it is in the air. This rotation makes it difficult for those in the car to discover in what direction they are moving; and it is only by looking down along the rope to which the grapnel is suspended that the motion of the balloon over the country below can be traced. We may mention that the upward and downward motion at any instant is at once known by merely dropping over the side of the car a small piece of paper: if the paper ascends or remains on the same level or stationary, the balloon is descending; while, if it descends, the balloon is ascending. This test is so delicate that it sometimes showed the motion at a particular instant with more precision than did Mr Glaisher's very delicate instruments.

Contrivances are often proposed by which the valve might be opened in less crude ways than by merely pulling a string attached to it; by which the jerks produced by the catching of the grapnel might be diminished, &c. These improvements are not adopted, because simplicity is requisite before everything. Any mechanical contrivance might be broken and rendered useless by the first blow of the car on the earth; whereas the primitive arrangements in use are such that scarcely any rough treatment can impair their efficiency.

The most important works that have appeared on the subject of aerostation are—

Dædalus, or Mechanical Motions, by Bishop Wilkins, London, 1648; *A Treatise on the Nature and Properties of Air and other Permanently Elastic Fluids*, by Tiberius Cavallo, London, 1781; *Account of the First Aerial Voyage in England, in a Series of Letters to his Guardian*, by Vincent Lunardi, London, 1784; *History and Practice of Aerostation*, by Tiberius Cavallo, London, 1785; *Annals of some Remarkable Aerial and Alpine Voyages, including those of the author*, by T. Forster, London, 1832; *Aeronautica*, by Monck Mason, London, 1838; *A System of Aeronautics, comprehending its Earliest Investigations*, by John Wise, Philadelphia, 1850; *Astra Castra, Experiments and Adventures in the Atmosphere*, by Hatton Turnor, London, 1865; *Voyages Aériens*, par J. Glaisher, C. Flammarion, W. de Fonvielle, et G. Tissandier, Paris, 1870; the same translated into English and published, edited by James Glaisher, under the title, *Travels in the Air*, London, 1871.

All the above books we have seen ourselves, and used in the preparation of the present article. *Astra Castra* is a work of 530 pp. large quarto; it consists chiefly of extracts from other works and writings, and it is useful as affording data for a history rather than as a history itself. On pp. 463–465 is a list of books and papers on aeronautics, which seems fairly complete up to the date 1864. In the list are also included memoirs and papers which we have not noted in the last paragraph, as the most important of them are referred to under their special subjects in the course of this article. We should advise any one desirous of studying the history of aeronautics to consult Mr Turnor's list in *Astra Castra*, which is the most perfect we have met with. He has marked with an asterisk those works that may be consulted by the public in the library of the Patent Office, which contains, besides books, a valuable collection of prints and broadsheets on the subject of aerostation. (J. G.)

ÆRTSZEN, Pieter, called "Long Peter" on account of his height, an historical painter of great merit as regards both drawing and colouring, was born at Amsterdam in 1520, and died in 1573. When a youth he distinguished himself by painting homely scenes, in which he reproduced articles of furniture, cooking utensils, &c., with marvellous fidelity, but he afterwards cultivated historical painting. Several of his best works—altar-pieces in various churches—were destroyed in the religious wars of the Netherlands. An excellent specimen of his style on a small scale, a picture of the crucifixion, may be seen in the Antwerp Museum. Ærtszen was a member of the Academy of St Luke, in whose books he is entered as *Langhe Peter, schilder.* Three of his sons attained to some note as painters.

ÆS is commonly translated *brass*, but the æs of the Romans, like the χαλκός of the Greeks, was used to signify not only pure copper, but also a *bronze*, or alloy of copper and tin. *Brass*, in the modern acceptation of an alloy of copper and *zinc*, was unknown to the ancients. The cutting instruments of the ancient Greeks, Romans, and Egyptians were originally of bronze. The Romans borrowed their arms, as well as their money, from the Etruscans. Analysis of the bronzes of these nations shows that they contained about 12 per cent. of tin, which gave them hardness and the capability of receiving a good edge. As the most ancient coined money of the Romans was of copper or bronze, *æs* came to be used for money in general, even after the introduction of silver and gold coinage; and *æs alienum* was used to signify *borrowed money, debt. Æs equestre, Æs hordearium, Æs militare,* were terms for the pay of Roman soldiers (previous to the introduction of the regular *stipendium*), which was furnished, it would appear, not from the public treasury, but by certain private persons as decreed by the state. The first, which amounted to 10,000 asses, was the purchase-money of the horse of an *eques.* The second, amounting to 2000 asses, was the pay of an *eques,* and was furnished by unmarried women, widows, and orphans, if possessed of a certain amount of property. The *æs militare*, reckoned by Niebuhr at 1000 asses a year, was the pay of a foot soldier.

ÆSCHINES, an Athenian philosopher, said to have been the son of a sausage-maker. He was continually with Socrates; which occasioned that philosopher to say that the sausage-maker's son was the only person who knew how to pay a due regard to him. It is alleged that poverty obliged him to go to Sicily to the court of Dionysius; and that he met with great contempt from Plato, but was extremely well received by Aristippus, to whom he showed some of his dialogues, receiving from him a handsome sum of money. He did not venture to profess philosophy at Athens, Plato and Aristippus being in such high esteem; but he opened a school, in which he taught philosophy to maintain himself. He afterwards wrote orations for the forum. Phrynicus, in Photius, ranks him amongst the best orators, and mentions his orations as the standard of the pure Attic style. Hermogenes has also spoken very highly of him. He wrote, besides, several dialogues:—1. Concerning virtue, whether it can be taught; 2. Eryxias, or Erasistratus: concerning riches, whether they are good; 3. Axiochus: concerning death, whether it is to be feared,—but those extant on the several subjects are not genuine remains. M. le Clerc has given a Latin translation of them, with notes and several dissertations, entitled *Silvæ Philologicæ.*

ÆSCHINES, a celebrated Grecian orator, was born in Attica 389 years before the Christian era. According to his own account, he was of distinguished birth; according to that of Demosthenes, he was the son of a courtesan, and a humble performer in a company of comedians. But whatever was the true history of his birth and early life, his services as a soldier, and his talents, which were considerable, procured him great applause; and, as a public speaker, he became a formidable rival to Demosthenes himself. The two orators, inspired probably with mutual jealousy and animosity, became at last the strenuous leaders of opposing parties. Æschines had almost from the first advocated peace with Philip of Macedon, and having been sent on several embassies to negotiate with the king, had been treated with much respect. He was, in consequence, accused by Demosthenes of having received money as a bribe when he was employed on one of these embassies. He indirectly retaliated by bringing an accusation against Ctesiphon, the friend of Demosthenes, for having moved a decree, contrary to the laws, to confer on Demosthenes a golden crown as a mark of public approbation. A numerous assembly of judges and citizens met to hear and decide the question. Each orator employed all his powers of eloquence; but Demosthenes, with superior talents, and with more justice on his side, was victorious; whereupon Æschines went into exile. According to Plutarch, the resentment of Demosthenes was now softened into generous kindness: for when Æschines was going into banishment, he requested him to accept of a sum of money; which made him exclaim, "How do I regret leaving a country where I have found an enemy so generous, that I must despair of ever meeting with a friend who shall be like him!" But this story seems more than doubtful. Æschines, after staying some years in Asia Minor, opened a school of eloquence at Rhodes. He is said to have commenced his lectures by reading to his audience the two orations which had been the cause of his banishment. His own oration received great praise, but that of Demosthenes was heard with boundless applause. In so trying a moment, when vanity must be supposed to have been deeply wounded, he is reported to have said, with a noble generosity of sentiment, "What would you have thought if you had heard him thunder out the words himself!" Æschines afterwards removed to Samos, where he died in the 75th year of his age. Three only of his orations are extant. His eloquence is of a very high order, and as an orator he is second only to Demosthenes.

ÆSCHYLUS, the father of the Greek tragic drama, was born in the year 525 B.C., in the Attic demos of Eleusis. The period of his youth and manhood coincides, therefore, with that great uprising of the national spirit of the Greeks, caused by the successive attempts of Darius, king of Persia, and his son Xerxes, to enslave their European neighbours on the north and west shores of the Ægean; and it was no doubt as much for the advantage of his poetical faculty as for the development of his manhood, that he took an active part in those famous military achievements by which the march of the insolent Asiatic hosts was repelled. The father of Attic tragedy helped, in the year 490, to drive the captains of Darius into the marshes of Marathon, and, ten years later, encompassed with ruin the multitudinous armament of Xerxes within the narrow strait of Salamis. The glories of this naval achievement, the bard who had helped to win it with his sword afterwards lived to celebrate with the lyre, and left to the world the play of the *Persians*, as a great national record of combined poetry and patriotism almost unique in history. Of his subsequent career at Athens only a few scanty notices remain, and those chiefly connected with the representation of his plays. We know that he composed seventy plays, and that he gained the prize for dramatic excellence thirteen times; further, that the Athenians esteemed his works so highly as to allow some of them to be represented after his death,—a privilege, in their dramatic practice, altogether anomalous. We know, also, that in the course of his life he paid one or two visits to Sicily, to which country he was attracted no doubt, by the same literary influence in the person of its ruler Hiero, that drew thither Bacchylides, Simonides, and other notable men of that rich epoch. There can, at the same time, be little doubt that one cause of his visits to that island may have been a want of sympathy as to political matters between him and the Athenian public; for while the Athenians, from the time of Cleisthenes (A.C. 510), had been advancing by rapid and decided steps to the full expansion of the democratic principle, it is evident, from some passages in his plays, especially from the whole tone and tendency of the *Eumenides*, that the political leanings of the poet of the *Prometheus* were towards aristocracy, and that, in the days of Pericles, he foresaw, with a sorrowful fear, the ripeness of those democratic evils which within so short a period led Xenophon to seek a new fatherland in Sparta, and opened to the Macedonian a plain path to the sovereignty of Greece. But whatever may have have been his motives for retiring from the scene of so many literary triumphs (and the gossipers of ancient times have of course transmitted to us their pleasant inventions on this point), it is certain that, in the year A.C. 456, two years after the representation of his great trilogy, the *Orestiad*, he died at Gela, in Sicily, in the sixty-ninth year of his age; and the people of Gela, rejoicing in his bones, as Ravenna does in those of the banished Dante, inscribed the following memorial on his tomb:—

> "Here Æschylus lies, from his Athenian home
> Remote, 'neath Gela's wheat-producing loam;
> How brave in battle was Euphorion's son,
> The long-haired Mede can tell who fell at Marathon."

And thus he lives among posterity, celebrated more as a patriot than as a poet; as if to witness to all times that the great world of books, with all its power, is but a small thing unless it be the reflection of a greater world of action. Of the seventy plays which an old biographer reports him to have composed, only seven remain, with a few fragments of little significance save to the keen eye of the professed philologist. These fragments, however, are sufficient to justify the high esteem in which he was held by the Athenian public, and by that greatest of all the great wits of a witty age and a witty people, Aristophanes. In the grand trilogy which exhibits, in three consecutive tragedies, the story of the murder of Agamemnon, and its moral sequences, we have a perfect specimen of what the Greek tragedy was to the Greeks, as at once a complex artistic machinery for the exhibition of national legend, and a grave pulpit for the preaching of important moral truths; nor could a more worthy founder than Æschylus of such a "sacred opera" be imagined. His imagination dwells habitually in the loftiest region of the stern old religious mythology of primeval Greece; his moral tone is pure, his character earnest and manly, and his strictly dramatic power (notwithstanding the very imperfect form of the drama in his day), as exhibited more especially in the *Agamemnon*, in the *Eumenides*, and in some parts of the *Prometheus*, is such as none of his famous successors, least of all Euripides, could surpass. Of his other plays, the *Seven against Thebes* is a drama, as Aristophanes expressed it, "full of war," and breathes in every line the spirit of the age and of the people that saved Europe from the grasp of oriental despotism; the *Persians*, though weak in some parts, contains some fine choral poetry, and a description of the battle of Salamis, that will belong to the poetry of the world so long as the world lasts; while the *Suppliants* presents much in a tasteful translation that makes us lament the loss of the missing piece of the trilogy to which it belonged, no less than the blundering of the thoughtless copyists of the middle ages, by whose pen it has been so egregiously defaced. For in ancient times the flowing rhetorical Euripides was found a more useful model for the schools of eloquence than the lofty, stern, and sometimes harsh, and occasionally it may be obscure, Æschylus: therefore the text of the latter has been comparatively neglected, and much work was left for the tasteful philologist before many parts of his noblest choruses could be rendered legible. Of the editions of Æschylus, the most notable in the earlier times of modern scholarship is that of Stanley; in more recent times, that of Schütz, who undertook the work of restoration with much learning and great boldness. The impulse given by this scholar was moderated by Wellauer, who, in his edition, along with some happy emendations, principally endeavoured to vindicate the authority of the manuscript readings from the large license of conjectural critics; and now from the remains of the great Hermann has been published a text that should present the just medium between the timidity of Wellauer and the rashness of mere conjectural criticism, though it is much to be feared that the learned German has been not seldom led astray by the itch of emendation, which is the old besetting sin of critical scholarship. Of English poetical translations there are the old one by Potter, and recent ones by Blackie, Plumptre, and Swanwick. There is also a translation in literal prose by Buckley. (J. S. B.)

ÆSCULAPIUS, in the *Heathen Mythology*, the god of medicine, was the son of Apollo and the nymph Coronis. He was educated by the centaur Chiron, who taught him the art of healing; and his skill enabled him to cure the most desperate diseases. But Jupiter, enraged at his restoring to life Hippolytus, who had been torn in pieces by his own horses, killed him with a thunderbolt. According to Cicero, there were three deities of this name: the first, the son of Apollo, worshipped in Arcadia, who invented the probe and bandages for wounds; the second, the brother of Mercury, who was killed by lightning; and the third, the son of Arsippus and Arsinoe, who was the first to teach tooth-drawing and purging. At Epidaurus, Æsculapius's statue was of gold and ivory, with a long beard, the head surrounded with rays, a knotty stick in one hand, and the other entwined with a serpent: the figure was seated on a throne of the same materials as the statue, and had a dog lying at its feet. The Romans crowned him with laurel, to represent his descent from Apollo; and the Phliasians represented him as beardless. The cock, the raven, and the goat were sacred to this deity. His chief temples were at Pergamos, Smyrna, Tricca, a city in Thessaly, and the isle of Coos; in all which places votive tablets were hung up, showing the names of those cured and the diseases of which they were healed by his assistance. But his most famous shrine was at Epidaurus, where, every five years, games were celebrated in his honour, nine days after the Isthmian games at Corinth.

ÆSIR (plural of *As*, or *Ass*, god), the gods of the Northmen of Scandinavia and Iceland. There were twelve chief gods or Æsir besides Odin (the *All-faðir*, All-father), viz., Thor, Baldur, Niörd, Frey, Tŷ or Tŷr, Bragi, Heimdal, Höd, Vidar, Ull, Forsetti, Loki or Lopt. The chief goddesses of ASGARD (*q.v.*), the Odinic Olympus, were—Frigg, Freyia, Nanna, Sif, Saga, Hel, Gefion, Eir, Hlin, Lofn, Vör, Snotra. The names of the Æsir, considered in the primary old northern significance of the words, convey in most instances an allusion to their characteristics; but it is impossible to decide whether they merely personify certain physical powers in nature, and abstract ideas of definite mental conditions, or whether they were originally borne by individuals connected with the pre-historic ages of the people. It is probable that the ideas underlying the myths connected with the Æsir have a mixed origin, and may be referred to a blending of physical, material, and historical elements. Our knowledge of northern mythology has been derived principally from the fragmentary remains of ancient Scandinavian songs, first collected in Iceland in the 11th century, and embodied in the 13th century with numerous other prose and poetic myths in a compilation now known to us as the *Eddas*. From these highly interesting but frequently obscure sources we are able to reproduce to a certain extent the image and conception of each of the Æsir, as they presented themselves to the imagination of their early northern worshippers.

In *Thor*, who seems to have been a god of that earlier Phœnician form of nature-worship which was superseded in Scandinavia and Northern Germany by the faith of Odin, we have the impersonation of the disturbing and destructive agencies in the universe. He is the son of heaven and earth—of Odin, the All-father, and of Frigg or Fiörgvin, the vivifying—and is the strongest of the Æsir. From his hammer flashed the lightning, and his chariot wheels sent thunder rolling through the clouds as he went on his way, cleaving mountains, loosening the pent-up streams and fires, and slaying all giants and misshapen monsters. Ever busily engaged in these labours, he seldom tarried in Asgard with the other Æsir, but dwelt in his mansion, Bilskirnir, in the densest gloom of the clouds. With his mallet he consecrated the newly-wedded, and hence the sign of the mallet or hammer was made by the Northmen when they took an oath and bound themselves by vows, whether of marriage or any other obligation. The early Christian missionaries of Norway, finding the faith in Thor too strong to be suddenly uprooted, tried to transfer many of his characteristics to their zealous royal convert, St Olaf, who was said to have resembled the old northern god in his comeliness of person, his bright red beard, hot, angry temper, and personal strength; while some of the monks of a later period endeavoured to persuade the Northmen that in Thor their forefathers had worshipped the Christ, the strong and mighty Saviour of the oppressed, and that his mallet was the rude image of the cross. Slaves and all thralls killed in battle were believed to be under the protection of Thor, who, as god of the Finns before the spread of the As religion, was honoured as their special guardian against the tyranny of their new masters.

In *Baldur* the Northmen honoured all that was beautiful, eloquent, wise, and good, and he was the spirit of activity, joy, and light; but his name signifies the strong in mind, and the earliest conception of Baldur is that of mental rather than physical or material perfection. His wife, Nanna, reflected these attributes in a less degree. On his life depended the activity and happiness of all the Æsir, excepting only Loki, the earthly fire or incarnation of evil, and hence this As, from envy of the beauty and innocence of Baldur, brought about his death, and hindered his release from the power of Hel, the goddess of death.

According to the myth, the Æsir, distressed at Baldur's presentiment of his own approaching end, joined his mother, Frigg, in exacting an oath from animals, plants, and minerals, not to injure him. The mistletoe alone among plants had been forgotten, and when this was discovered by Loki he pulled a wand of it, and hastening to the assembly of the Æsir, where all were engaged in the sport of shooting at Baldur, as he was supposed to be invulnerable, he gave it to Hod, the blind god of brute strength, and directed him how to aim it. The mistletoe pierced Baldur through, and he fell dead to the ground in the presence of the Æsir, who, foreseeing the evil that would befall them, since light and purity had been taken from them, gave way to sorrow and fear. When all their efforts to release Baldur from Hel had been thwarted by the machinations of Loki, they resolved to avenge themselves. Having captured their foe, they confined him within a mountain-cave, and hung above his head a venomous snake, to drop its poison on his face; but his wife, Sigyn, stood by him, and caught the drops in a cup, and it was only while she emptied the goblet that the venom touched him, when he shrank aside, and caused the earth to be shaken as with an earthquake. There Loki will remain till Ragnaröck, the twilight of the world, when the Æsir, the earth and all dwellers therein, will be destroyed by the powers of evil, the rescuers and companions of Loki. Only Odin, the All-father, will survive, and gather around him on Ida's plain, where Asgard had once stood, the Æsir, regenerate and purified by Surt's black fire, and then a new and better world will arise, in which Baldur will again come with his unconscious slayer, Hod, and all evil will cease, and light and darkness will dwell together in unity.

Under one form of the myth of Baldur's death he is the bright god of day or summer, and Höd, the blind and the strong, is dark night or fiercely-raging winter, his pre-ordained foe and destroyer. After that final purification by suffering or fire, and the regeneration to which the Northmen looked as the means of the ultimate adjustment of the disturbed balance between evil and good, and from which they did not exempt their gods, the influence of good was to prevail. Baldur would reappear, and Loki, the consuming power of evil, be no more heard of.

Loki, in the beginning of time, under the name of Lodthur, flame, and as the foster-brother of the All-father, had united with him in imparting blessings to the universe, and had given blood and a fair colour to Ask and Embla, from which the first men were created. Afterwards he left the council of the Æsir, and like a fallen angel wandered away into regions of space, desolating and consuming all things that came in contact with his fierce flame. Descending into the bowels of the earth, where his presence is made manifest by volcanic fires, he consorted with evil giantesses, by whom he became the father of Hel, pallid death; of Angurboda, the announcer of sorrow; and of the wolf Fenrir, and the serpent of Midgard, which are ever threatening the destruction of the world and the peace of the Æsir.

Loki can assume all forms. As sensuality he courses through the veins of men, and as heat and fire he pervades nature, causing death and destruction. After the introduction of Christianity, the attributes and mystic deeds of Loki were transferred to Satan by the people of Scandinavia, amongst whose descendants his name still retains its evil reputation. In Iceland an *ignis fatuus* is known as Loki's burning; and in Jutland, when there is a dazzling light or a waving motion in the air which impedes the sight of distant objects, the peasants say, "Loki is *sowing his oats*."

Niörd, supposed to be the Nerthus known to the Romans, and his children Frey or Fricco and Freyia, appear to have been honoured in the north before the time of Odin, and to have been worshipped by peoples powerful enough to have been admitted into friendly alliance with his followers. Niörd is said to have lived in Vanaheim, and to have ruled over the Vanir, or light elves, long before he became one of the Æsir. He is god of the ocean, the ruler of winds and stiller of waves, and to him the seafarer and fisherman raise altars and make prayers. His attributes and powers seem to point to the existence of a superior knowledge of navigation among those ancient races of Scandinavia who have been idealised in the imagination of the Northmen as good, bright, and agile elves and water-sprites—the *Liós Alfar*—or Vanir of their mythology. Niörd's son *Frey* is the god of rain, plenty, and fruitfulness; and his worship, according to the early northern chronicler, Adam of Bremen, was accompanied with phallic rites. His sister and wife, Freyia, who holds a high place among the Æsir, is the goddess of love; but her influence, unlike her husband's, is not always beneficent, and varies with the form which she assumes in operating on the minds of men. Her chariot is drawn by cats, as emblematic of fondness and passion, and a hog attends upon her and upon Frey, whose name, like her own, implies fructification or enjoyment.

The Swedes paid especial honour to Frey, while the Norwegians worshipped Thor (who was in all respects his opposite) as their chief As. The latter must also have received divine honours amongst the Germans, as his name is included in the form of objurgation used by the early Saxon missionaries; but this fact and the German name of the fifth day of the week—Donners-tag, the Thunderer's day—are the only evidences still extant of the early worship of Thor in Germany.

By their alliance with Niörd and his children the Æsir secured fertility to the earth and mankind, and the intervention of mild gentle agencies in nature to counteract the destructive influence of Thor's power.

In *Tý* or *Týr* we have the Mars of the Northmen. It is he who gives victory, and although he is as wise as he is brave, it is he who stirs men to strife, and not to peace. His name, which signifies honour, is found in the names of the days of the week in O. Nor., Dan., A.-S., and in our own "Tuesday;" and shows that, like Thor and Frey or Freyia, whose memory is perpetuated in our Thursday and Friday, the worship of this bravest of the Æsir was widely spread among peoples of Northern origin.

In *Bragi* the Northmen honoured the originator of their Skaldic poetry, the god of eloquence and wise utterances. At guilds and at grave-feasts the Bragi-cup was drunk; and at the funeral of kings or jarls the heir was not permitted to take his father's seat till the "Bragarfull" was brought in, when, rising to receive it, he drank the contents of the cup, and was led to the high seat of honour. At guild feasts the Bragi-cup was signed with Thor's mallet, and was drunk after the company had drained Odin's cup for victory, and Niörd's and Frey's cup for a bountiful year.

The peculiarity of Bragi's cup was that, on drinking it, a vow —held to be inviolable—was made to perform some deed worthy of a skald's song. Bragi's wife, Idun, as the guardian of the casket which contained apples that gave to those who ate them perpetual youth, was specially cherished by the other Æsir. In her abduction by the giant Thiassi, and her removal to the nether world through Loki's craft, her mute grief, and her release in the spring, we have an analogy with the myth of Proserpine; and like her she presides over fresh verdure.

Heimdal, whose attribute is the rainbow, is the god of watchfulness, the doorkeeper of the Æsir; while *Vidar*, the strongest of the gods after Thor, is the impersonation of silence and caution; *Ull* decides the issue of single combats, and *Forsetti* settles all quarrels.

In the goddesses *Lofn* and *Vör* lovers find protectors; the former unites the faithful, the latter punishes the faithless. *Gefion*, to whom the Danes owe the formation of the island Seeland, watches over maidens, and knows the decrees of fate. *Hlin* guards those whom *Frigg*, the queen and mother of heaven, is desirous of freeing from peril; Frigg herself, as Odin's wife and the mother of the Æsir, knows the destinies of men, but is silent in regard to them. As goddess of the earth, she is known as Frygga, the fertile summer earth, and Rinda the frost-hardened surface, and is attended by *Fulla*, the full, *Eir*, the young goddess of healing, and many other goddesses.

Saga, whose name is derived from *Segja*, to narrate, is the goddess of history and narration. Odin and she pledge each other daily in golden cups filled from the copious ever-flowing streams of her abode, *Sockquabek* (from Sökk, abyss, in allusion to the abundant streams of narrative). *Snotra* is the goddess of sagacity and elegance, from whom men and women seek good sense and refinement of manners. The Norns and the Valkyriur, if not actually goddesses, are closely connected with the Æsir. The three principal Norns or Nornir are Urd, past time; Verdandi, present time; and Skulld, future time. They and the Valkyriur, who are known under many names, twist and spin the threads of destiny, and make known what has been decreed from the beginning of time.

From this brief outline it may be seen that in their Æsir the Northmen recognised the creators, sustainers, and regulators of the world as it now is, from whom emanated the thought and life that pervade and animate all nature, and the efforts to subject it to the spiritual will. With Odin and the Æsir the intellectual life of the northern people began; and although they ascribed to them human forms and acts, these were seldom without something higher and nobler than what pertains to mortals; and while they recognised the existence of a state of chaos and darkness before this world began with the creation of the Æsir, they anticipated the advent of another state, in which gods, like men, would receive their award at the hands of a supreme All-father. (E. C. O.)

ÆSOP, the fabulist, is supposed to have been born about the year 620 B.C., but the place of his birth is uncertain, that honour being claimed alike by Samos, Sardis, Mesembria in Thrace, and Cotiæum in Phrygia. He was brought, while young, to Athens as a slave, and having served several masters, was eventually enfranchised by Iadmon the Samian. He thereupon visited Crœsus, king of Lydia, at whose court he is represented by Plutarch as reproving Solon for his discourteous manner towards the king. During the usurpation of Pisistratus he is said to have visited Athens, and composed the fable of *Jupiter and the Frogs* for the instruction of the citizens (Phædrus, i. 2). As the ambassador of Crœsus at Delphi he was charged with the payment of the large sum of four minæ to each of the citizens; but in consequence of some dispute, he declined to distribute the money. The Delphians, incensed at his conduct, accused him of sacrilege, and threw him headlong from a precipice, about 564 B.C. A pestilence which ensued being attributed to this crime, the people declared their willingness to make compensation for his death; which, in default of a nearer connection, was claimed and received by Iadmon, the grandson of his old master (Plut. *de sera Num. Vind.*, p. 556, Herodot. ii. 134). None of Æsop's works are extant. The popular stories regarding him are derived from a life prefixed to a book of fables purporting to be his, collected by Maximus Planudes, a monk of the 14th century, in which he is represented as a monster of ugliness and deformity, a notion utterly without foundation, and doubtless intended to heighten his wit by the contrast. That this life, however, was in existence a century before Planudes's time, appears by a manuscript of it found at Florence, and published in 1809. In Plutarch's *Convivium*, where Æsop is a guest, though there are many jests on his original servile condition, there are none on his appearance; and it would seem that the ancients were not usually restrained by delicacy in this point, since the personal defects of Socrates, and his resemblance to old Silenus, afford ample matter for merriment and raillery in the *Symposium* of Plato. We are told, besides, that the Athenians erected in honour of Æsop a noble statue by the famous sculptor Lysippus, a circumstance which alone would be sufficient to confute the absurd fiction of his deformity; but more to the point is the statement of Pliny (xxxvi. 12), that he was the *Contubernalis* of Rhodopis, his fellow-slave, whose extraordinary beauty passed into a proverb:

Ἅπανθ' ὅμοια, καὶ Ῥοδῶπις ἡ καλή·

The obscurity in which the history of Æsop is involved has induced some to deny his existence altogether; and Giambattista Vico, in his *Scienza Nuova*, chooses rather to consider him as an abstraction, an excess of scepticism which is quite unreasonable. Whether Æsop left any written fables has been more justly disputed, and Bentley inclines to the negative. Thus Aristophanes (*Vespæ*, v. 1259) represents Philocleon as learning his fables in conversation, and not from a book; and Socrates essayed to versify such as he remembered (Plat. *Phæd.* p. 61). Others, again, are of opinion that a collection had been made of them before the time of Socrates (*Mus. Crit.* i. 408). It is, however, certain that fables bearing Æsop's name were popular at Athens during the most brilliant period of its literary history; though the discrepancies of authors in quoting the same fables seem in favour of Bentley's hypothesis. (Compare Aristot. *De Part. Anim*

iii. 2; and Lucian, *Nigr.* 32). The original fables were in prose, and were turned into verse by several writers; the first, after the example of Socrates, being Demetrius Phalereus. Next appeared an edition in elegiac verse, often cited by Suidas, but the author's name is unknown; then Babrius, an excellent Greek poet, turned them into choliambics (i.e. *limping* iambics); but of ten books, a few fables only are preserved entire. Of the Latin writers of Æsopean fables, Phædrus is the most celebrated.

> "Æsopus auctor quam materiam reperit,
> Hanc ego polivi versibus senariis."
> PHÆD.

The fables now extant in prose under Æsop's name are entirely spurious, as is proved by Bentley in his *Dissertation on the Fables of Æsop*, and have been assigned an oriental origin. The identification of Æsop with the Arabian philosopher and fabulist Lokman (who is made by some traditions the contemporary of the psalmist David) has frequently been attempted; and the Persian accounts of Lokman, which among other things describe him as an ugly black slave, appear to have been blended by the author of the *Life*, published by Planudes, with the classical stories respecting Æsop. The similarity of the fables ascribed to each renders it probable that they were derived from the same Indo-Persian source, or from the Chinese, who appear to have possessed such fables in very remote antiquity. A complete collection of the Æsopean fables, 231 in number, was published at Breslau by J. G. Schneider in 1810.

ÆSOP, a Greek historian, whose life of Alexander the Great is preserved in a Latin translation by Julius Valerius. It is a work of no credit, abounding in errors.

ÆSOP, CLODIUS, a celebrated actor, who flourished about the 670th year of Rome. He and Roscius were contemporaries, and the best performers who ever appeared upon the Roman stage; the former excelling in tragedy, the latter in comedy. Cicero was on intimate terms with both actors, and put himself under their direction to perfect his action. Æsop performed many friendly services to Cicero, especially during the period of his banishment. He appears to have spared no pains to improve himself in his art, and to have always studied his part with the greatest care. On the stage his declamation was emphatic and his action vehement, and he became entirely absorbed in his part. Plutarch mentions it as reported of him, that while he was representing Atreus deliberating how he should revenge himself on Thyestes, he forgot himself so far in the heat of action that with his truncheon he struck and killed one of the servants crossing the stage. His age and the time of his death are uncertain; but he made his last appearance on the stage in B.C. 55, at the dedication of Pompey's theatre, on which occasion his voice failed him. Æsop lived in a somewhat expensive manner; but he nevertheless contrived to leave an ample fortune to his spendthrift son. This is the son of Æsop mentioned by Horace (*Sat.* iii. 3, 239) as taking a pearl from the ear-drop of Cæcilia Metella, and dissolving it in vinegar, that he might have the satisfaction of swallowing eight thousand pounds' worth at a draught.

ÆSTHETICS is the term now employed to designate the theory of the Fine Arts—the science of the Beautiful, with its allied conceptions and emotions. The province of the science is not, however, very definitely fixed, and there is still some ambiguity about the meaning of the term, arising from its etymology and various use. The word æsthetic, in its original Greek form (αἰσθητικός), means anything that has to do with perception by the senses, and this wider connotation was retained by Kant, who, under the title Transcendental Æsthetic, treats of the *a priori* principles of all sensuous knowledge. The limitation of the term to the comparatively narrow class of sensations and perceptions occupied with the Beautiful and its allied properties is due to the Germans, and primarily to Baumgarten, who started from the supposition that, just as truth is the end and perfection of pure knowledge or the understanding, and good that of the will, so beauty must be the supreme aim of all sensuous knowledge. Yet, spite of these sources of vagueness in the subject and its name, some considerable part of the theory can be looked upon as pretty clearly defined, and it may be possible, by means of careful reflection on this ascertainable quantity, to indicate, roughly at least, the extent and boundaries of a complete system of æsthetic doctrine.

A very brief survey of what has been written under the name æsthetics is sufficient to show that it includes, as its first and foremost problem, the determination of the nature and laws of Beauty, including along with the Beautiful, in its narrower signification, its kindred subjects, the Sublime and the Ludicrous. To discover what it is in things which makes them beautiful or ugly, sublime or ludicrous, is one constant factor in the æsthetic problem. Intimately connected with this objective question is the subjective and psychological inquiry into the nature of the feelings and ideas that have beauty for their object. Further, it will be found that all attempts to construct a complete æsthetic theory aim at determining the highest ends of the Fine Arts (which obviously concern themselves largely, if not exclusively, with the Beautiful), and at marking out the distinctions and tracing the dependencies of natural and artistic beauty. All this part of the field of æsthetic inquiry seems fairly agreed on, and it is only when we approach other sides of the Fine Arts that the precise scope of the science appears obscure. But while there is this measure of agreement as to the proper subject matter of æsthetics, we find two diametrically opposed methods of approaching it, which distinctly colour all parts of the doctrine arrived at, and impose different limitations to the boundaries of the subject. The first is the metaphysical or *a priori* method; the second the scientific or empirical method. The one reasons deductively from ultra-scientific conceptions respecting the ultimate nature of the universe and human intelligence, and seeks to explain the phenomena of beauty and art by help of these. The other proceeds inductively from the consideration of these phenomena, as facts capable of being compared, classified, and brought under certain uniformities. At the same time, it must not be supposed that either method is customarily pursued in complete independence of the other. The most subtle exponent of transcendentalism in art appeals to generalisations drawn from the facts of art; nor have the professedly scientific critics often abstained from introducing conceptions and hypotheses of a metaphysical character.

(A.) METAPHYSICAL PROBLEMS.

Metaphysical speculation in æsthetics centres about the objective nature of beauty, and arises somewhat in the following manner:—The appreciation of the Beautiful is a mode of perception. In estimating a beautiful landscape or a beautiful statue, the mind perceives the beauty as a property of the object. It is, moreover, a single property; the name beautiful always denoting the same essential thing, whatever this may be. Now we find that it is not a simple property of matter known through one particular class of sensations, as colour; and the question arises, what it really is in itself, whether inherent in and inseparable from matter, or something superior to it, and if so, how revealed through it. The directions of this inquiry have been almost as numerous as the systems of metaphysical thought. On the supposition of a real substance matter, independent of all intelligence, human or divine, writers have attempted to discover the essential principle which beautifies it. It has been universally considered by metaphysicians that matter in itself is devoid of beauty, if not positively ugly, and the only question arises as to the extraneous principle which imparts beauty to it. This has been conceived either as a simple force distinct from matter, yet setting it in motion, vivifying it, and reducing it to forms, as by Lévêque; or as a divine being, whose volition directly invests material objects with all their beautiful aspects, as by Reid; or, lastly, as self-existent forms or ideas superinduced upon matter, which are in truth the beauty of objects, as by Plato and his modern followers.

In the prevailing German systems of æsthetics, which are based on an ontological idealism, the independent existence of matter has been denied. These writers conceive an absolute Thought or Idea as the ultimate reality, of which matter and consciousness are but the two sides. Matter is conceived as the negative or limiting principle in the action or self-movement of the Absolute. The problem of objective beauty becomes on this hypothesis the determination of the particular mode in which the Beautiful is a manifestation of the supreme thought; for the Good and the True are equally revelations of the Unconditioned, and it is necessary to mark off beauty from these. Various definitions of the Beautiful, based on this mode of conception, may be found in the systems of Hegel, Weisse, and the Hegelians. The second great problem in the metaphysics of æsthetics is to co-ordinate the species of the æsthetic genus, namely, the Beautiful (in its narrow sense), the Ugly, the Sublime, and the Ridiculous. This has been undertaken by the Hegelians, and their attempts to construct what they call the dialectics of æsthetics are among the most curious products of metaphysical thought. It being assumed that there is some one ontological process running through every manifestation of the æsthetic Idea, these writers have sought to determine how each of the subaltern notions is related to this process. The last problem in the scheme of metaphysical æsthetics relates to the nature and functions of Art, looked at on one side as a reproduction in altered form of the beauty of Nature, and, on the other, as the conscious product of æsthetic intuition in the human mind. First of all, the arts are appreciated and classified according to the several modes in which they body forth the Idea to our minds. Secondly, since the Absolute may be spoken of as revealing itself to human intelligence, so human intelligence may be looked on as groping through long ages after the Absolute, and thus the historical evolution of art finds its place in a complete metaphysic of æsthetics. In concluding this preliminary sketch of the metaphysical systems, it should be added that they can be adequately estimated and criticised only in connection with the whole systems of thought of which they are organic parts. Within the scope of a purely scientific criticism it is only possible to point out any inconsistencies in the application of these ideas to beauty and art, and to show how much or how little they effect, as hypothetical instruments, in helping us more clearly to understand the phenomena.

(B.) Scientific Problems.

In the scientific discussion of æsthetic subjects, the antithesis of subject and object in human cognition is accepted as a phenomenal distinction, without any inquiry into its ontological meaning. Inquirers no longer discuss the essence of beauty, looked on as a transcendental conception above all experience, but seek to determine in what the Beautiful, as a series of phenomena, clearly and visibly consists. Æsthetic speculation becomes, accordingly, more purely psychological. First of all, the unity of beauty is questioned. It is asked whether all objects which appear beautiful are so because of some one ultimate property, or combination of properties, running through all examples of beauty, or whether they are so called simply because they produce some common pleasurable feeling in the mind. This is a question of induction from facts and consequent definition, lying at the very threshold of æsthetic science. It has been most vigorously disputed by British writers on the subject, and many of them have decided in favour of the plurality and diversity of elements in beauty. Again, it has been asked in which category of our experience, objective or subjective, beauty originates. By some it has been referred to an objective source, whether to sensation, as a direct result of physiological action, as by Burke, or to something distinctly perceived by means of sensation, as a certain relation of unity, symmetry, &c., among the parts of an object, its colours, forms, and so on, as probably by Aristotle, Diderot, Hogarth, and most writers. By others the source of beauty has been sought in the inner life of the mind itself, in certain ideas and emotions which have become reflected on external objects by association. This is the doctrine of Alison. A third class recognise both of these sources, attributing the effects of beauty partly to the pleasurable effects of external stimulation, partly to the activities of perception, and partly to multitudinous associations of ideas and feelings from past experience. This class includes Dugald Stewart, Professor Bain, and Mr Herbert Spencer. A third question in the general scientific theory of beauty which is closely related to the last and largely determined by it, is the precise nature of the mental faculty or activity concerned in the perception and appreciation of the Beautiful. This, too, has been widely discussed by English writers,—answers to the other two questions frequently appearing as the necessary implications of the solution of this one. By those who affirm that beauty is a simple property or conjunction of properties in external objects, the subjective perception of this property has been regarded either as a unique faculty (the internal sense), or as the rational principle acting in a certain way. By the school of Alison, who find the source of beauty in a certain flow of ideas suggested by an object, the perception of the same, as a property of the object, would be explained as the result of inseparable association, producing a kind of momentary delusion. And this same effect of association, in producing an apparent intuition of one simple property, would be made use of by those later writers who resolve the nature of beauty into both objective and subjective elements. It is noticeable, too, that while some writers have treated the appreciation of beauty as purely intellectual, others have confined themselves to the emotional element of pleasure. With respect to the Ludicrous and the Sublime, as distinguished from the Beautiful, there seems to have been a tacit agreement that both of these are unique and single properties, whether originally in the object of sense, or reflected on it from the mind; and various theories have been suggested in explanation of the characteristic effects of these properties on human sensibility and thought.

What strikes one most, perhaps, in these discussions is the vagueness due to the great diversity of conception as to the real extent of the Beautiful—the number of objects it may be supposed to denote. While one class of writers appears to limit the term to the highest and most refined examples of beauty in nature and art, others have looked on it as properly including the lower and more vulgarly recognised instances. There is certainly a great want of definiteness as to the legitimate scope of æsthetic theory. It will be seen, too, how closely this point bears on the question of the relativity of æsthetic impressions, whether there is any form of beauty which pleases universally and necessarily, as Kant affirms. The true method of resolving this difficulty would appear to be to look on æsthetic impressions more as a growth, rising, with the advance of intellectual culture, from the crude enjoyments of sensation to the more refined and subtle delights of the cultivated mind. The problem of the universal and necessary would then resolve itself into an inquiry into a general tendency. It would be asked what kinds of objects, and what elements of sensation, idea, and emotion, tend to become conspicuous in æsthetic pleasures, in proportion as the mind advances in general emotional and intellectual culture. Another defect in nearly all the theories of the Beautiful that have been proposed, refers to the precise relation of the intellectual element in the æsthetic impression. In opposing the narrow view, that the appreciation of beauty is a purely intellectual act, a cold intuition of reason, writers have fallen sometimes into another narrowness, in resolving the whole of the effect into emotional elements, or certain species of pleasure. Unless beauty is, as Hutcheson affirmed, a simple property of objects like colour, the perception of it as objective, which all must allow to be a mental fact, can only be explained by means of certain intellectual activities, by force of which the pleasurable effects come to be referred to such a seemingly simple property. The solution of this point would doubtless be found in a more complete discussion of the perceptive or discriminative and assimilative activities of the intellect which are invariably called into play by complex objects, and which correspond to the attributes of proportion, unity in variety, &c., on which so much stress has been laid by the intuitivists. Not only so, but any theory of æsthetic operations must be incomplete which does not give prominence to those more subtle and exalted intellectual activities that are involved in the imaginative side of æsthetic appreciation, as in detecting the curious half-hidden implications which make up the essence of a refined humour, in constructing those vague yet impressive ideas which enter into our intuition of sublimity and infinity, and even in appreciating such seemingly simple qualities as purity of colour and tone, or the perfectly graduated blending of two adjacent colours. Such activities of the mind constitute, among other things, the symbolic aspect of the Beautiful, and give, as Mr Mill suggests, a basis of truth to such seemingly fanciful notions respecting the meaning of beautiful qualities as one finds in the works of Mr Ruskin.

But comparatively little has been done in a purely scientific manner to determine the nature and functions of Art so as to fix the relations of the different arts to simple or natural beauty. Aristotle supplied a few valuable doctrines, which have been rendered still more precise by Lessing and others. Yet there seems even now no consensus of opinion as to the precise aims of art, how far it has simply to reproduce and constructively vary the beauties of nature, or how far to seek modes of pleasurable effect wider than those supplied by natural objects. A theory of art at all comparable in scientific precision to existing theories of morals has yet to be constructed. The few attempts to establish a basis for art of a non-metaphysical kind are characterised by great one-sidedness. Thus, for example, the theory that the function of art is to imitate nature, has been broached again and again with scarcely any reference to music, merely, as it seems, out of an impatience for some one defining property. Without attempting to sketch a complete doctrine of art, a suggestion may be offered as to the right direction of inquiry. First of all, then, the widest possible generalisations on the various emotional susceptibilities to which art can appeal must be collected, from a study both of mental phenomena as a whole, and of all varieties of pleasurable feeling actually ministered by the several forms of art. This would fix the end of the fine arts in the widest sense, marking it off from the ends of utility and morality. Secondly, the highest aims of art, or the ideal of art, would have to be determined by a consideration of the laws of compatibility and incompatibility among these various orders of gratification, the requirements of quantity, variety, and harmony, in any lofty æsthetic impression, and the relative value of the sensational, intellectual, and emotional elements in æsthetic effect. This part of the subject would include the discussion of the value and universal necessity of the real and the ideal in art, truth to nature and imaginative transformation. These conclusions would require verification by means of the widest and most accurate study of the development of the arts, in which could be traced the gradual tentative progress of the artistic mind towards the highest achievements of art, as well as the permanent superiority of all those forms of art which most clearly embody this tendency. This part of the theory of art would clearly connect itself with the problem of the general law or tendency in æsthetic development already referred to. The proper determination of these two ideas, the whole range of possible æsthetic delight, and the direction of the highest, purest, and most permanent delight of cultivated minds, would at once dispose of many narrow conceptions of art, by recognising the need of the widest possible diversity and grades of artistic value, if only as experiments requisite to the discovery of its highest function. At the same time the meaning and limits of the universal and necessary in art would be defined, and the unsuggestive and dreary conflicts between an unbending absolutism and a lawless individualism shown to be irrelevant. The validity of canons of art, and their limitations, would in this manner be fixed, and the impatient exaltation of certain schools and directions of taste reduced to a modest assertion of a purely relative truth. The aims of art as a whole being thus determined, the next thing would be to define and classify the individual arts of painting, music, poetry, &c., according to their respective powers of embodying these aims. This would require a careful consideration of the material or medium of expression employed by each art, and the limitations imposed by it as to the mode of representation. The determination of this part of æsthetic theory, which Lessing commenced, would require not only technical but considerable psychological knowledge. Similarly, any conclusion arrived at on this subject would need to be verified by a reference to the history of the arts, as exemplifying both the successes of a right conception of the scope and possibilities of the particular art, and the failures resulting from a mistaken conception. Many other points, such as the nature of genius, the function and bounds of criticism, the relation of æsthetic culture to intellectual, moral, and social progress, would be included in a complete scheme of art doctrine.

(C.) History of Systems.

In the following brief account of the most important contributions to æsthetic doctrine, only such writings will be recognised as aim at some general conception of Art and the Beautiful. Much that passes in current literature for æsthetic speculation, namely, a certain thoughtful way of criticising special works of art, is simply the application of recognised principles to new cases. Sometimes, however, in the hands of a philosophic critic the mere appreciation of a single poem or the works of a particular artist may become a luminous discussion of some general principle, and this method of constructing æsthetic theory from the criticism of a single work or series of works was rendered very productive by Lessing.

I. *Greek Speculations.*—Ancient Greece supplies us with the first speculations on the Beautiful and the aims of the fine arts. Nor is it surprising that among a people so productive of noble artistic creations, and at the same time so speculative, numerous attempts to theorise on these subjects should have been made. We have in classic writings many allusions to works of an æsthetic character now lost, such as a series on poetry, harmony, and even painting, by Democritus. It is to be gathered, too, from Plato's Dialogues that the Sophists made the principles of beauty a special department in their teaching. The first Greek thinker, however, whose views on these subjects are at all known is Socrates. Accepting Xenophon's account of his views in the *Memorabilia* and the *Symposion*, we find that he regarded the Beautiful as coincident with the Good, and both of them as resolvable into the Useful. Every beautiful object is so called because it serves some rational end, whether the security or gratification of man. It looks as though Socrates rather disparaged the immediate gratification which a beautiful object affords to perception and contemplation, and emphasised rather its power of furthering the more necessary ends of life. Thus he said that pictures and other purposeless works of art, when used to adorn a house, hindered rather than furthered enjoyment, because of the space they took from useful objects. This mode of estimating the value of beauty is, however, no necessary consequence of the theory that the whole nature of beauty is to minister pleasure. It arises from undue attention to mere material comfort as a condition of happiness. The really valuable point which Socrates distinctly brought to light is the relativity of beauty. Unlike his illustrious disciple, he recognised no self-beauty (αὐτὸ τὸ καλόν) existing absolutely and out of all relation to a percipient mind.

Of the precise views of Plato on this subject, even if they were really formed, it is very difficult to gain a just conception from the Dialogues. In some of these, called by Mr Grote the Dialogues of Research, as the *Hippias Major*, he ventures on no dogmatic theory of Beauty, and several definitions of the Beautiful proposed are rejected as inadequate by the Platonic Socrates. At the same time we may conclude that Plato's mind leaned decidedly to a theory of an absolute Beauty, this, indeed, being but one side of his remarkable scheme of Ideas or self-existing Forms. In the *Symposion* he describes how love (Eros) produces aspiration towards the pure idea of beauty. It is only this absolute beauty, he tells us, which deserves the name of beauty; and this is beautiful in every manner; and the ground of beauty in all things. It is nothing discoverable as an attribute in another thing, whether living being, earth, or heaven; for these are only beautiful things, not the Beautiful itself. It is the eternal and perfect existence contrasted with the oscillations between existence and non-existence in the phenomenal world. In the *Phædrus*, again, he treats the soul's intuition of the self-beautiful as a reminiscence of its præ-natal existence, undefiled by union with the body. With respect to the precise forms in which the idea of beauty reveals itself, Plato is very undecided. Of course his theory of an absolute Beauty is incompatible with the notion of its ministering simply a variety of sensuous pleasure, to which he appears to lean in the *Gorgias* and even the *Hippias Major*. Further, his peculiar system of ideas naturally led him to confuse the self-beautiful with other general conceptions of the true and the good, and so arose the Platonic formula καλοκἀγαθία, expressive of the intimate union of the two principles. So far as his writings embody the notion of any distinguishing element in beautiful objects, it is proportion, harmony, or unity among the parts of an object. The superior beauty of proportion is taught in the *Philebus*, and in the *Phædon* it is applied to virtue. As a closely-related view, we see him emphasising unity in its simplest aspect of evenness and purity, the need of variety being overlooked. Thus in the *Philebus* he states his preference for regular and mathematical forms, as the straight line and the circle. So he selected among colours pure white, among tones the pure and equal, and among impressions of touch the smooth. At the same time the Dialogues evince many other tentative distinctions in the Beautiful, as, for example, the recognition in the *Politics* of two opposed classes of beautiful things, those characterised by force and velocity, and those by a certain slowness and softness; which points to a contrast between the stimulative and the restful in sensation, since enlarged upon by English psychologists. Elsewhere he descants on the beauty of the mind, and seems to think, in the *Republic*, that the highest beauty of proportion is seen in the union of a beautiful mind with a beautiful body. In spite of his lofty theory of the origin and nature of beauty, Plato seems to have imperfectly appreciated the worth of art as an independent end in human life and culture. He found the end of art in imitation (μίμησις), but estimated the creative activity of art as a clever knack, little higher in intellectual value than the tricks of a juggler. He tended to regard the effects of art as devoid of all serious value, and as promoting indolence and the supremacy of the sensual elements of human nature. (See the *Sophistes*, *Gorgias*, and *Republic*.) Accordingly, in his scheme for an ideal republic, he provided for the most inexorable censorship on poets, &c., so as to make art as far as possible a mere instrument of moral and political training. As to particular arts, Plato appears to have allowed a certain ethical value to music, in combination with dance and song, if of a certain character, as expressing either the worthy and manly, or the quiet and orderly. With respect to poetry, his views, as expressed in the *Republic* and elsewhere, were very uncertain. Thus at times he condemns tragedy and comedy *in toto*; at other times he admits the claims of a lofty dramatic poetry. He seems not to have fully considered the aims and influences of painting and sculpture, which he constantly disparages.

Aristotle

A loftier conception of the aims of poetry was afforded by the strictures of Aristophanes in the *Frogs* and elsewhere. But the one Greek who, as far as we know, fully appreciated and clearly set forth the ends of the fine arts, considered, independently of ethical and political aims, as the vehicles to the mind of the ideas and delights of beauty, was Aristotle. Unlike Plato, he proceeded less metaphysically and more scientifically to investigate the phenomena of beauty by a careful analysis of the principles of art. In his treatises on poetry and rhetoric, he gives us, along with a theory of these arts, certain principles of beauty in general; and scattered among his other writings we find many valuable suggestions on the same subject. First of all, Aristotle ignores all conceptions of an absolute Beauty, and at the same time seeks to distinguish the Beautiful from the Good. Thus, although in the more popular exposition, the *Rhetoric*, he somewhat incorrectly makes praiseworthiness a distinguishing mark of the Beautiful, regarded as a species of the Agreeable or Desirable, he seeks in the *Metaphysics* to distinguish the Good and the Beautiful thus: the Good is always in action (ἐν πράξει); the Beautiful, however, may exist in motionless things as well (ἐν ἀκινήτοις). Elsewhere he distinctly teaches that the Good and the Beautiful are different (ἕτερον), although the Good, under certain conditions, can be called beautiful. He thus looked on the two spheres as co-ordinate species, having a certain area in common. It should be noticed that the habit of the Greek mind, in estimating the value of moral nobleness and elevation of character by their power of gratifying and impressing a spectator, gave rise to a certain ambiguity in the meaning of τὸ καλόν, which accounts for the prominence the Greek thinkers gave to the connection between the

Beautiful and the Good or morally Worthy. Aristotle further distinguished the Beautiful from the Fit, and in a passage of the *Politics* set Beauty above the Useful and Necessary. Another characteristic of the Beautiful fixed by this thinker in the *Rhetoric* is the absence of all lust or desire in the pleasure it bestows. This is an important point, as suggesting the disinterested and unmonopolising side of æsthetic pleasure. The universal elements of beauty, again, Aristotle finds in the *Metaphysics* to be order (τάξις), symmetry, and definiteness or determinateness (τὸ ὡρισμένον). In the *Poetics* he adds another essential, namely, a certain magnitude, it being desirable, for a synoptic and single view of the parts, that the object, whether a natural body or a work of art, should not be too large, while clearness of perception requires that it should not be too small. At the same time he seems to think that, provided the whole be visible as such, the greater magnitude of an object is itself an element of beauty. This is probably to be understood by help of a passage in the *Politics*, which lays down the need of a number of beautiful parts or aspects in a highly beautiful object, as the human body. With respect to art, Aristotle's views are an immense advance on those of Plato. He distinctly recognised, in the *Politics* and elsewhere, that its aim is simply to give immediate pleasure, and so it does not need to seek the useful like the mechanical arts. The essence of art, considered as an activity, Aristotle found in imitation, which, unlike Plato, he considers not as an unworthy trick, but as including knowledge and discovery. The celebrated passage in the *Poetics* where he declares poetry to be more philosophic and serious a matter (σπουδαιότερον) than philosophy, best shows the contrast between Plato and Aristotle in their estimates of the dignity of artistic labour. In the *Poetics* he tells us that the objects to be imitated by the poet are of three kinds—(1.) Those things or events which have been or still are; (2.) The things which are said to be and seem probable; (3.) The things which necessarily are (εἶναι δεῖ). The last points, as Schasler supposes, to the ideal character of imitation as opposed to mere copying of individual objects or events, and accounts for the lofty value assigned to it by Aristotle. More particularly the objects of imitation in poetry and music, if not in all art, are dispositions (ἤθη), passions, and actions. Aristotle gives us some interesting speculations on the nature of the artist's mind, and distinguishes two varieties of the poetic imagination—the easy and versatile conceptive power of a man of natural genius (ἐνφυής), and the more emotional and lively temperament of an inspired man (μανικός). He gives us no complete classification of the fine arts, and it is doubtful how far his principles are to be taken as applicable to other than the poetic art. He seems, however, to distinguish poetry, music, and dancing—all of which are supposed to imitate some element of human nature, some feeling or action—by the means they employ, namely, rhythm, harmony, melody, and vocal sound. Painting and sculpture are spoken of as imitative arts, but their special aims are not defined. Architecture seems ignored by Aristotle as non-imitative. His peculiar theory of poetry can only be just glanced at here. Its aim, he says, is to imitate dispositions and actions. Metrical form is hardly looked on as an essential. Poetic imitation, as including the selection of the universal in human nature and history, is ably treated; and from this part of Aristotle's theory all modern ideas of poetic truth are more or less derivable. He distinguishes, somewhat superficially, the epic poem, the drama, and a third variety not named, but apparently lyric poetry, by the manner in which the poet speaks in each variety, whether in his own person, or in that of another, or in both alternately. The epic and the dramatic poem require unity of action, a certain magnitude, with beginning, middle, and end, and also those changes of fortune and recognitions that make up the thrilling character of plot. The end of tragedy Aristotle defines as the effecting, by means of pity and fear, of a purification of these passions; and this is perhaps the point of greatest interest for æsthetics in the whole of his theory of poetry. Whether he is referring to any moral influence of tragedy on the emotions, bringing both fear and pity in the spectator's mind to their proper ethical mean, as Lessing and others conceive; whether he simply means the elimination of all painful ingredients in these feelings, either by the recognition of the imaginary nature of the evil represented, or by the simultaneous satisfaction of other and deeper feelings as moral approval or wide human sympathy; or, finally, whether by "purification" we are to understand the grateful relief by artificial means of a recurring emotion needing periodic vent, as Ueberweg argues,—this subtle point may be left to the student to decide. It would be interesting to know how far Aristotle attributed something analogous to this κάθαρσις to the other arts. In the *Politics* he certainly speaks of a purifying effect in certain kinds of music in quieting the wilder forms of excitement. Finally, it might perhaps be conjectured from his definition of the Ludicrous, as something faulty and disgraceful, yet free from pain, and not destructive, that he would find in the laughter of comedy something analogous to this purification, namely, the gradual resolution of the more painful feelings of contempt or disgust into the genial moods of pure hilarity.

Omitting to notice the few valuable remarks on æsthetic subjects of the later Greeks and their Roman contemporaries, one may briefly refer to the views of the Alexandrian mystic and Neo-Platonist Plotinus, not only because of their intrinsic interest, but on account of their resemblance to certain modern systems. His theory is to be found in an essay on the Beautiful in the series of discourses called *Enneades*. His philosophy differs from the Platonic in the recognition of an objective νοῦς, the direct emanation from the absolute Good, in which the ideas or notions (λόγοι), which are the prototypes of real things, are immanent. This Reason, as self-moving, becomes the formative influence reducing matter, which in itself is dead, to form. Matter thus formed becomes a notion (λόγος), and this form is beauty. Objects are ugly so far as they are unacted upon by Reason, and so remain formless. The creative νοῦς is absolute Beauty, and is called the more than beautiful (τὸ ὑπέρκαλλον). There are three degrees or stages of the Beautiful in manifestation, namely, the beauty of subjective νοῦς, or human reason, which is the highest; that of the human soul, which is less perfect through the connection of the soul with a material body; and that of real objects, which is the lowest manifestation of all. As to the characteristic form of beauty, he supposed, in opposition to Aristotle, that a single thing not divisible into parts might be beautiful through its unity and simplicity. He attached special worth to the beauty of colours in which material darkness is overpowered by light and warmth. In reference to artistic beauty, he said that when the artist has λογοι as models for his creations, these may become more beautiful than natural objects. This is a very curious divergence of opinion from the Platonic.

After Plotinus there is little speculation on æsthetic subjects till we come to modern writers. St Augustine wrote a treatise on the Beautiful, now lost, in which he appears to have reproduced Platonic ideas under a Christian guise. He taught that unity is the form of all beauty ("omnis porro pulchritudinis forma unitas est"). Infinite goodness, truth, and beauty are the attributes of the Deity, and communicated by him to things. But passing from these fragmentary utterances, we may consider more fully the modern theories, beginning with the German systems, as being the most metaphysical, and having most affinity with ancient speculation. In German literature the two divisions of metaphysical deduction and critical construction of æsthetic principles are very sharply contrasted, and nearly every writer on the subject is easily referred to one or other of the classes. On the one hand, we have the laborious systematic philosophers, as Kant and Hegel; and on the other, men who entered upon æsthetic speculation either as connoisseurs of some special department, as Winckelmann and Lessing, or even as productive artists—for example, Schiller and Goethe.

II. *German Writers.*—The first of the Germans who attempted to fit a theory of the Beautiful and of Art into a complete system of philosophy was Baumgarten. Adopting the Wolffian principles of knowledge, as modified by Leibnitz, he thought he was completing that system by setting over against logical knowledge, whose object is truth, æsthetic knowledge, which has to do with beauty. The former is conceptive knowledge (*begreifendes Erkennen*), the act of the understanding, and its result as the science of clear conceptions is embodied in logic. Æsthetic has to do, not with clear, but confused conceptions (*verworrene Vorstellungen*), namely, sensuous knowledge. The beautiful is defined by Baumgarten as the perfection of sensuous knowledge, and the ugly is that which struggles against this perfection; and, consistently with this view, he first employed the term æsthetic (*æsthetica*) to denote a theory of the Beautiful. He held that perfection, as harmony of object with its conception or notion (*Begriff*), presents itself under three aspects:—(1.) As truth for pure knowledge; (2.) As beauty for obscure perception; (3.) As goodness for the capacities of desire or will. It will be seen at once by the thoughtful student that this mode of dealing with impressions of beauty, &c., simply as intellectual elements (confused conceptions), must fail to account for their emotional aspects—feeling, which is the very soul of the æsthetic impression, being radically distinct from conception and knowledge. Still Baumgarten did service in separating so sharply the provinces of logic, ethics, and æsthetics, and in connecting the latter with the impressions of the senses. The details of his æsthetics are mostly unimportant. From Leibnitz's theory of a pre-established harmony, and its consequence that the world is the best possible, Baumgarten concluded that nature is the highest embodiment of beauty, and that art must seek as its highest function the strictest possible imitation of nature. Baumgarten had several disciples in this conception of æsthetics, as Sulzer and Moses Mendelssohn.

The next original philosophical scheme of æsthetics is that of Kant. His system of knowledge falls into three branches—the critique of pure reason, which has to determine what are the *a priori* elements in the knowledge of objects; the critique of practical reason, which inquires into the *a priori* determinations of the will; and the critique of judgment, which he regards as a connecting link between the other two, and which has to do with any *a priori* principles of emotion (pleasure and pain), as the middle term between cognition and volition. This judgment Kant divides into the æsthetic, when pleasure or pain is felt immediately on presentation of an object; and the teleological, which implies a pre-existing notion, to which the object is expected to conform. He attempts, in a somewhat strained manner, to define the Beautiful by help of his four categories. In *quality* beauty is that which pleases without interest or pleasure in the existence of the object. This distinguishes it from the simply Agreeable and the Good, the former stimulating desire, and the latter giving motive to the will. In *quantity* it is a universal pleasure. Under the aspect of *relation*, the Beautiful is the form of adaptation (*Zweckmässigkeit*) without any end being conceived. Finally, in *modality* it is a necessary satisfaction, pleasing not by a universal rule, this being unassignable, but by a *sensus communis*, or agreement of taste. Kant is not very consistent in carrying out these distinctions. Thus, for example, he recognises in fitness a particular species of beauty, namely, "adhering" as distinguished from "free" or intrinsic beauty, without recognising that this implies the presence of a notion. So, in discussing the objective validity of our æsthetic impressions, he decides that the highest meaning of beauty is to symbolise moral good and, in even a more fanciful manner than that of Mr Ruskin, he attaches moral ideas, as modesty, frankness, courage, &c., to the seven primary colours of the Newtonian system. Yet he does not admit that the perception of this symbolic function involves any notion. Once more, he attributes beauty to a single colour or tone by reason of its purity. But such a definition of the form of the Beautiful clearly involves some notion in the percipient mind. Kant further applies his four categories, with still less of fruitful suggestion, to the Sublime. The satisfaction of the Sublime is a kind of negative pleasure created through the feeling of a momentary restraint (*Hemmung*) of vital force, and of a subsequent outpouring of the same in greater intensity. The feeling of the inadequacy of the imagination is succeeded by a consciousness of the superiority of reason to imagination. The sentiment is thus a kind of wonder or awe. Sublimity is either mathematical, that of magnitude, or dynamical, that of nature's might. He allows no sublimity to passions, as rage or revenge. Kant has, too, a theory of the Ridiculous, the effect of which he lays, oddly enough in respect to the rest of his doctrine, in a grateful action of the body, the muscles of the diaphragm, &c., giving a sense of health. This action takes place on the sudden relaxation of the understanding when kept in a state of tension by expectation. The cause of laughter, or the Ridiculous, may hence be defined as "the sudden transformation of a tense expectation into nothing." He placed the beauty of nature above that of art, which can be of value only mediately, not as an end in itself. He classifies the arts according as they express the æsthetic idea—whatever this may mean after his exclusion of all definite conception from the perception of beauty. Just as expression in speech consists of articulation, gesticulation, and modulation, answering to thought, intuition (*Anschauung*), and feeling, so we have three kinds of art—(1.) Those proceeding orally (*redende*), oratory and poetry; (2.) Those of visible image (*bildende*), plastic art and painting; and (3.) "the art of the play of feelings," namely, music and "colour art," which last is not defined. Kant's system is very defective, and some of its inconsistencies were pointed out by Herder in his *Kalligone*, who lacked, however, philosophic accuracy. Herder denied Kant's distinctions between the Beautiful, the Good, and the Agreeable, saying that the first must be desired as well as satisfying, and the second be loved as well as prized. Yet herein Kant is decidedly superior to his critic. Herder held, in opposition to Kant, that all beauty includes significance (*Bedeutsamkeit*), and cannot affect us apart from a notion of perfection. But here, too, Kant is to be preferred, since his theory does not assume all beautiful objects to contain some one element or form capable of being detected. Kant's real additions to æsthetic theory consist in the better separation of the Beautiful from the Good and Agreeable, in the prominence given to the emotional side of æsthetic impressions, and in the partial recognition of the relativity of æsthetic judgment, more especially in the case of the Sublime.

After Kant the next philosopher to discuss the metaphysics of the Beautiful and art is Schelling. He sought to engraft art upon his curious system of transcendental idealism in a manner which can only be faintly indicated here. In Schelling's metaphysical system the relation of subject and object is conceived as identity. Each exists, yet not independently of the other, but identified in a higher, the absolute. They may be conceived as two poles representing different directions, but yet inseparably joined. All knowledge rests on this agreement. Either nature, the object, may be conceived as the *prius*, and the subject constructed out of it; or the subject may be taken as the *prius*, and the object constructed from it. These are the two poles of knowledge, and constitute the philosophy of nature and the transcendental philosophy. The latter, like Kant's philosophy of mind, is based on a threefold conception of the powers of human nature. It consists of—(1.) Theoretic philosophy, dealing with perception; (2.) Practical philosophy, discussing the will and freedom; and (3.) The philosophy of art. The aim of the last is thus expressed: The *ego* must succeed in actually perceiving the concord of subject and object, which is half disguised in perception and volition. This concord is seen within the limits of the *ego* in artistic perception only. Just as the product of nature is an unconscious product like a conscious one, in its designfulness, so the product of art is a conscious product like an unconscious one. Only in the work of art does intelligence reach a perfect perception of its real self. This is accompanied by a feeling of infinite satisfaction, all mystery being solved. Through the creative activity of the artist the absolute reveals itself in the perfect identity of subject and object. Art is therefore higher than philosophy. Schelling thus sets the beauty of art far above that of nature. As to the form of the beautiful he is very vague, leaning now to a conception of harmony in the totality of the world (*Weltall*), and now to a Platonic conception of primitive forms (*Urbilder*) of perfection. He has a very intricate classification of the arts, based on his antithesis of object and subject, reality and ideality. A curious feature of Schelling's theory is his application of his one fundamental idea to tragedy. The essence of tragedy is, he thinks, an actual conflict of liberty in the subject with objective necessity, in which both being conquered and conquering, appear at once in the perfect indifference. Antique tragedy he holds, accordingly, to be the most perfect composition of all arts.

Hegel. Passing over Solger, whose æsthetic doctrine is little more than a revival of Platonism, we come to Hegel. His system of philosophy falls into three parts, all based on the self-movement of the idea or absolute:—(1.) The logic discussing the pure universal notions which are the logical evolution of the absolute, as pure thought; (2.) Philosophy of nature—the disruption of thought, the idea, into the particular and external; (3.) Philosophy of the spirit—the return of thought or the absolute from this self-alienation to itself in self-cognisant thought. Just as the absolute, so has spirit a series of three grades to traverse—(*a.*) Subjective spirit or intelligence, relating itself to the rational object as something given; (*b.*) Objective spirit or will, which converts the subjectivised theoretical matter (truth) into objectivity; (*c.*) Absolute spirit, which is the return of the spirit from objectivity to the ideality of cognition, to the perception of the absolute idea. This again has three stages—(1.) Art, in which the absolute is immediately present to sensuous perception; (2.) Religion, which embodies certainty of the idea as above all immediate reality; and (3.) Philosophy, the unity of these. According to this conception, the beautiful is defined as the shining of the idea through a sensuous medium (as colour or tone). It is said to have its life in shining or appearance (*Schein*), and so differs from the true, which is not real sensuous existence, but the universal idea contained in it for thought. He defines the form of the Beautiful as unity of the manifold. The notion (*Begriff*) gives necessity in mutual dependence of parts (unity), while the reality demands the appearance or semblance (*Schein*) of liberty in the parts. He discusses very fully the beauty of nature as immediate unity of notion and reality, and lays great emphasis on the beauty of organic life. But it is in art that, like Schelling, he finds the highest revelation of the Beautiful. Art makes up the deficiencies of natural beauty by bringing the idea into clearer light, by showing the external in its life and spiritual animation. The various forms of art depend on the various combinations of matter and form. In Oriental or symbolical art matter is predominant, and the thought is struggling through with pain so as to reveal the ideal. In the classical form the ideal has attained an adequate existence, form and matter being absolutely commensurate. Lastly, in the romantic form, the matter is reduced to a mere show, and the ideal is supreme. Hegel classifies the individual arts according to this same principle of the relative supremacy of form and matter—(1.) The beginning of art is architecture, in which as a symbolic art the sensuous material is in excess. (2.) Sculpture is less subjected to matter, and, as representing the living body, is a step towards a higher ideality. (3.) Painting, which is the romantic art κατ' ἐξοχήν, expresses the full life of the soul. By the elimination of the third dimension of space, and the employment of a coloured plane, painting rids itself of the coarse material substrate of sculpture, and produces only a semblance of materiality. (4.) In music, which employs pure tone, all the elements of space are suppressed, and hence its content is the inner emotional nature (*Gemüth*). Music is the most subjective of the arts. (5.) Poetry has the privilege of universal expression. It contains all the other arts in itself, namely, the plastic art in the epos, music in the ode, and the unity of both in the drama.

Several systems of æsthetics, more or less Hegelian in character, can only be referred to in passing. Weisse defined æsthetics as the science of the idea of beauty, and explained the Beautiful as the entrance of the universal or of the essence into the limited and finite, that is, the cancelling or annulling of truth (*die aufgehobene Wahrheit*). By thus recognising an internal contradiction in all beauty, he sought to develope, by a curious dialectical process, the ideas of the Ugly, the Sublime, and the Ludicrous. He treats each of these three in immediate contrast to beauty. Ugliness is the immediate existence of beauty. It appears as the negative moment in the Sublime, and in the Ludicrous this negativity is again cancelled and resolved into affirmation so as to constitute a return to the Beautiful. A like attempt to determine the relations of the Ugly, Comic, &c., as moments of the self-revealing idea was made by several Hegelians. Thus Ruge, in his *Abhandlung über das Komische*, teaches that sublimity is the æsthetic idea striving to find itself, together with the satisfaction of this striving. If, however, the idea lose itself, sinking away in a kind of swoon, we have the Ugly. Finally, when the idea recovers from the swoon, its new birth is attended with a feeling of amusement (*Erheiterung*), and then we have the effect of the Ludicrous. Rosenkranz, in his *Æsthetik des Hässlichen*, conceives the Ugly as the negation of the Beautiful, or as the middle between the Beautiful and the Ludicrous, and seeks to trace out its various manifestations in formlessness in nature, incorrectness in artistic representation, and deformity or the disorganisation of the Beautiful in caricature. Schasler, again, seems to hold that the Ugly is co-ordinate with the Beautiful, being the motor principle that drives the Beautiful from the unconditioned rest of the Platonic idea, from the sphere of empty abstractness to actuality. This fundamental contradiction reveals itself as the contrast of matter and spirit, rigid motionlessness and motion, and appears in art as the antithesis of the sublime and graceful (*das Anmuthige*), the latter containing the Naïf, the Pretty, and the Ridiculous. Finally, Theodor Vischer seeks to settle these subtle relationships in this manner: He supposes the Sublime to be the sundering of the æsthetic idea and its sensuous image (*Gebild*) from the state of unity constituting the Beautiful, the idea reaching as the infinite over against the finite of the image. The image now resists the sudden rupture, and in asserting itself as a totality in defiance of the idea becomes the Ugly. The Comic, again, is the result of some partial and apparently involuntary recognition of the rights of the idea by the rebellious image. Schasler says, in criticising the views of Vischer, that it is difficult not to be satirical in describing the dialectic artifices to which the idea is here compelled, little suspecting how easily any similar attempt to adjust relations between these ideas, looked at objectively as movements of the supreme idea, may appear equally naïf and funny to a mind not already oppressed with the resisting burden of its own abstractions.

Theodor Vischer, the last of the Hegelians named here, has produced the largest and most laborious system of metaphysical æsthetics, and a brief account of its scope must be given to complete our history of the German systems. He defines æsthetics as the science of the Beautiful. His system falls into three parts: (1.) Metaphysic of the Beautiful; (2.) The Beautiful as one-sided existence —beauty of nature and the human imagination; (3.) The subjective-objective actuality of the Beautiful—Art. The metaphysic again falls into two parts—the theory of simple beauty, and that of the Beautiful in the resistance of its moments (the Sublime and Ridiculous). He defines the Beautiful as "the idea in the form of limited appearance." His discussions of the various beauties of nature, the organic and inorganic world, are very full and suggestive, and his elaboration of the principles of art (excepting those of music, which he left another to elucidate), is marked by a wide and accurate knowledge. He divides the arts into—(1.) The objective, or eye arts (architecture, sculpture, and painting); (2.) Subjective, or ear arts (music); (3.) Subjective-objective arts, or those of sensuous conception (poetry). He subdivides the first into those of measuring sight (architecture), touching sight (sculpture), and sight proper (painting). Vischer's style is very laboured. His propositions fall into the form of mathematical theorems, and are made exceedingly incomprehensible by the excessive subtleties of his metaphysical nomenclature.

There are several other systems of æsthetics which deserve mention here, but space does not allow of a full account of them. Of these the most important are the theories of Herbart, Schopenhauer, and von Kirchmann. Herbart's views are based on his curious psychological conceptions. He ignores any function in the Beautiful as expressive of the idea, and seeks simply to determine the simplest forms or the elementary judgments of beauty. Schopenhauer's discussions, connecting beauty with his peculiar conception of the universe as volition, are a curious contribution to the subject. As a specimen of his speculations, one may give his definition of tragedy as the representation of the horrible side of life, the scornful dominion of accident, and the inevitable fall of the just and innocent, this containing a significant glimpse into the nature of the world and existence. Von Kirchmann has written a two-volume work on æsthetics, which is interesting as a reaction against the Hegelian method. It professes to be an attempt to base the science on a realistic foundation, and to apply the principles of observation and induction long acted upon in natural science.

The German æsthetic speculations not elaborated into complete systems are too numerous to be fully represented here. Only a few of the most valuable contributions to the theory will be alluded to. Winckelmann's services to the development of plastic art do not directly concern us. Of his theory of plastic beauty, based exclusively on the principles of Greek sculpture, little requires to be said. He first pointed to the real sources of superiority in antique creations, by emphasising the distinction between natural and ideal beauty, the æsthetic value of contour as an ideal element, the beauty of expression as the manifestation of an elevated soul, and consisting of a noble simplicity and a quiet grandeur. But by too exclusive an attention to Greek art, and indeed to sculpture, his theory, as an attempt to generalise on art, lacks completeness, making little room for the many-sidedness of art, and narrowing it down to one, though an exalted, ideal.

Lessing's services to the scientific theory of art are far greater than those of Winckelmann. He is the first modern who has sought to deduce the special function of an art from a consideration of the means at its disposal. In his *Laokoon* he defines the boundaries of poetry and painting in a manner which has scarcely been improved on since. In slight divergence from Winckelmann, who had said that the representation of crying was excluded from sculpture by the ancients as unworthy of a great soul, Lessing sought to prove that it was prohibited by reason of its incompatibility with the conditions of plastic beauty. He reasoned from the example of the celebrated group, the Laokoon. Visible beauty was, he said, the first law of ancient sculpture and painting. These arts, as employing the co-existent and permanent in space, are much more limited than poetry, which employs the transitory and successive impressions of sound. Hence, expression is to poetry what corporeal beauty is to the arts of visible form and colour. The former has to do with actions, the latter with bodies,—that is, objects whose parts co-exist. Poetry can only *suggest* material objects and visible scenery by means of actions; as for example, when Homer pictures Juno's chariot by a description of its formation piece by piece. Painting and sculpture, again, can only suggest actions by means of bodies. From this it follows that the range of expression in poetry is far greater than in visible art. Just as corporeal beauty loses much of its charm, so the visible Ugly loses much of its repulsiveness by the successive and transient character of the poetic medium. Hence poetry may introduce it, while painting is forbidden to represent it. Even the Disgusting may be skilfully employed in poetry to strengthen the impression of the Horrible or Ridiculous; while painting can only attempt this at its peril, as in Pordenone's Interment of Christ, in which a figure is represented as holding its nose. Visible imitation being immediate and permanent, the painful element cannot be softened and disguised by other and pleasing ingredients (the Laughable, &c.), as in poetry. As Schasler says, Lessing's theory hardly makes room for the effects of individuality of character as one aim of pictorial as well as of poetic art. Yet as a broad distinction between the two heterogeneous arts, limiting, on the one hand, pictorial description in poetry, and the representation of the painful, low, and revolting in the arts of vision, it is unassailable, and constitutes a real discovery in æsthetics. Lessing's principles of the drama, as scattered through the critiques of the *Hamburg Dramaturgy*, are for the most part a further elucidation of Aristotelian principles, of great value to the progress of art, but adding comparatively little to the theory. Its conspicuous points are the determination of poetic truth as shadowed forth by Aristotle, and the difference between tragedy and comedy in respect to liberty of invention both of fable and of character; secondly, the reassertion that both fear and pity, and not simply one of these, are the effects of every tragedy, and that it is false dramatic art to attempt to represent either the sufferings of a perfect martyr, or the actions of some monstrous horror of wickedness, as Corneille and the French school had urged; lastly, the interpretation of Aristotle's purification of the passions as referring to this very fear and pity, and pointing to a certain desirable mean between excessive sensibility and excessive callousness. Schasler says that if Lessing had had an Aristotle to lean on in the *Laokoon* as in the *Dramaturgy*, it would have been more valuable. Others might be disposed to say that if he had been as free from the traditions of authority in the *Dramaturgy* as he was in the *Laokoon*, the former might have contained as much in the way of real discovery as the latter.

The partial contributions to æsthetics after Lessing need not long detain us. Goethe wrote several tracts on æsthetic topics, as well as many aphorisms. He attempts to mediate between the claims of ideal beauty, as taught by Winckelmann, and the aims of individualisation. Schiller discusses, in a number of disconnected essays and letters, some of the principal questions in the philosophy of art. He looks at art as a side of culture and the forces of human nature, and finds in an æsthetically cultivated soul the reconciliation of the sensual and rational. His letters on æsthetic education (*Ueber die æsthetische Erziehung des Menschen*) are very valuable, and bring out the connection between æsthetic activity and the universal impulse to play (*Spieltrieb*). This impulse is formed from the union of two other impulses—the material (*Stofftrieb*) and the formal (*Formtrieb*)—the former of which seeks to make real the inner thought, the latter to form or fashion this reality. Schiller's thoughts on this topic are cast in a highly metaphysical mould, and he makes no attempt to trace the gradual development of the first crude play of children into the æsthetic pleasures of a cultivated maturity. He fixes as the two conditions of æsthetic growth, moral freedom of the individual and sociability. The philosophic basis of Schiller's speculation is the system of Kant. Another example of this kind of reflective discussion of art by literary men is afforded us in the *Vorschule der Æsthetik* of Jean Paul Richter. This is a rather ambitious discussion of the Sublime and the Ludicrous, and contains much valuable matter on the nature of humour in romantic poetry. Jean Paul is by no means exact or systematic, and his language is highly poetic. His definitions strike one as hasty and inadequate: for example, that the Sublime is the applied Infinite, or that the Ludicrous is the infinitely Small. Other writers of this class, as Wilhelm von Humboldt, the two Schlegels, Gervinus, though they have helped to form juster views of the several kinds of poetry, &c., have contributed little to the general theory of art. F. Schlegel's determination of the principle of romantic poetry as the Interesting, in opposition to the objectivity of antique poetry, may be cited as a good example of this group of speculations.

No account of German æsthetics can be complete without some reference to the attempts recently made by one or two naturalists to determine experimentally the physical conditions and the net sensational element of artistic impression. Of these, the most imposing is the development by Helmholtz of a large part of the laws of musical composition, harmony, tone, modulation, &c., from a simple physical hypothesis as to the complex character of what appear to us as elementary tones. Another interesting experimental inquiry has been instituted by Fechner into the alleged superiority of "the golden section" as a visible proportion. Zeising, the author of this theory, asserts that the most pleasing division of a line, say in a cross, is the golden section, where the smaller division is to the larger as the latter to the sum. Fechner describes in his contribution *Zur experimentalen Æsthetik* a series of experiments on a large number of different persons, in which he supposes he eliminated all effects of individual association, and decides in favour of the hypothesis. He, however, assumes that this visible form must please primarily, and does not recognise that any constant association growing up in all minds alike would give precisely the same results. Finally, allusion may be made to some ingenious but very forced attempts of Unger and others to discover harmonic and melodious relations among the elementary colours.

III. *French writers on Æsthetics.*—In passing from German to French writers on æsthetical topics we find, as might be expected, much less of metaphysical assumption and a clearer perception of the scientific character of the problem. At the same time, the authors are but few, and their works mostly of a fragmentary character. Passing by the Jesuit André, who sought to rehabilitate Augustin's theory of the Beautiful, we first light on the name of Batteux. In his *Cours de Belles Lettres* (1765) he seeks to determine the aims of art by elucidating the meaning and value of the imitation of nature. He classifies the arts according to the forms of space and time, those of either division being capable of combining among themselves, but not with those of the other. Thus architecture, sculpture, and painting may co-operate in one visible effect; also music, poetry, and the dance. Diderot, again, in the *Encyclopédie*, sought to define beauty by making it to consist in the perception of relations. In his *Essais sur la Peinture* he follows Batteux in extolling naturalness, or fidelity to nature. Another very inadequate theory of beauty was propounded by Père Buffier. He said it is the type of a species which gives the measure of beauty. A beautiful face, though rare, is nevertheless the model after which the largest number is formed. Not unlike this theory is a doctrine propounded by H. Taine. In his work, *De l'Ideal dans l'Art*, he proceeds in the manner of a botanist to determine a scale of characters in the physical and moral man, according to the embodiment of which a work of art becomes ideal. The degree of universality or importance, and the degree of beneficence or adaptation to the ends of life in a character, give it its measure of æsthetic value, and render the work of art, which seeks to represent it in its purity, an ideal work.

The only elaborated systems of æsthetics in French literature are those constructed by the *spiritualistes*, that is, the philosophic followers of Reid and D. Stewart on the one hand, and the German idealists on the other, who constituted a reaction against the crude sensationalism of the 18th century. They aim at elucidating what they call the higher and spiritual element in æsthetic impressions, and wholly ignore any capability in material substance or external sensation of affording the peculiar delights of beauty. The lectures of Cousin, entitled *Du Vrai, du Beau, et du Bien*, the *Cours d'Esthétique* of Jouffroy, and the systematic treatise of Lévêque, *La Science du Beau*, are the principal works of this school. The last, as the most elaborate, will afford the student the best insight into this mode of speculation. The system of Lévêque falls into four parts—(1.) The psychological observation and classification of the effects of the Beautiful on human intelligence and sensibility; (2.) The metaphysic of beauty, which determines whether it has a real objective existence, and if so, what is the internal principle or substance of this objective entity; and further seeks to adjust the relations of the Beautiful, the Sublime, the Ugly, and the Ridiculous in relation to this principle; (3.) The application of these psychological and metaphysical principles to the beauty of nature, animate and inanimate, and to that of the Deity; (4.) Their application to the arts. The influence of the

The sy tems c spiritu istes.

Germans in this mode of systematising is apparent. All the characters of beauty in external objects, as a flower, of which the principal are size, unity and variety of parts, intensity of colour, grace or flexibility, and correspondence to environment, may be summed up as the ideal grandeur and order of the species. These are perceived by reason to be the manifestations of an invisible vital force. Similarly the beauties of inorganic nature are translatable as the grand and orderly displays of an immaterial physical force. Thus all beauty is in its objective essence either spirit or unconscious force acting with fulness and in order. It is curious that Lévêque in this way modifies the strictly spiritual theory of beauty by the admission of an unconscious physical force, equally with spirit or mind, as an objective substratum of the Beautiful. He seeks, however, to assimilate this as nearly as possible to conscious energy, as immaterial and indivisible. The aim of art is to reproduce this beauty of nature in a beautiful manner, and the individual arts may be classified according to the degree of beautiful force or spirit expressed, and the degree of power with which this is interpreted. Accordingly, they are arranged by Lévêque in the same order as by Hegel.

IV. *Italian and Dutch Writers.*—There are a few writers on æsthetic subjects to be found in Italian and Dutch literature, but they have little of original speculation. The Italian, as Pagano and Muratori, follow French and English writers. One Dutch writer, Franz Hemsterhuis (18th century), is worth naming. His philosophic views are an attempt at reconciliation between the sensational and the intuitive systems of knowledge. The only faculty of true knowledge is an internal sense, nevertheless all true knowledge comes *through* the senses. The soul, desiring immediate and complete knowledge, and being limited by its union with the senses, which are incapable of perfectly simultaneous action, strives to gain the greatest number of the elements of cognition or ideas in the shortest possible time. In proportion as this effort is successful, the knowledge is attended with enjoyment. The highest measure of this delight is given by beauty, wherefore it may be defined as that which affords the largest number of ideas in the shortest time.

V. *English Writers.*—In the æsthetic speculations of English writers, we find still less of metaphysical construction and systematisation than in those of French thinkers. Indeed, it may be said that there is nothing answering to the German conception of æsthetic in our literature. The inquiries of English and Scotch thinkers have been directed for the most part to very definite and strictly scientific problems, such as the psychological processes in the perception of the Beautiful. The more moderate metaphysical impulses of our countrymen have never reached beyond the bare assertion of an objective and independent beauty. Hence we find that the German historians regard these special and limited discussions as so many empirical reflections, wholly devoid of the rational element in true philosophy. Schasler speaks of these essays as "empiristic æsthetics," tending in one direction to raw materialism, in the other, by want of method, never lifting itself above the plane of "an æstheticising dilettanteism." English writers are easily divisible into two groups—(1.) Those who lean to the conception of a primitive objective beauty, not resolvable into any simpler ingredients of sensation or simple emotion, which is perceived intuitively either by reason or by some special faculty, an internal sense; (2.) Those who, tracing the genesis of beauty to the union of simple impressions, have been chiefly concerned with a psychological discussion of the origin and growth of our æsthetic perceptions and emotions.

Lord Shaftesbury is the first of the intuitive writers on beauty. His views are highly metaphysical and Platonic in character. The Beautiful and the Good are combined in one ideal conception, much as with Plato. Matter in itself is ugly. The order of the world, wherein all beauty really resides, is a spiritual principle, all motion and life being the product of spirit. The principle of beauty is perceived not with the outer senses, but with an internal—that is, the moral—sense (which perceives the Good as well). This perception affords the only true delight, namely, spiritual enjoyment. Shaftesbury distinguishes three grades of the Beautiful, namely, (1.) Inanimate objects, including works of art; (2.) Living forms, which reveal the spiritual formative force; and (3.) The source from which these forms spring, God.

The intuitists. Shaftesbury.

In his *Inquiry into the Original of our Ideas of Beauty and Virtue*, Hutcheson follows many of Shaftesbury's ideas. Yet he distinctly disclaims any independent self-existing beauty in objects apart from percipient minds. "All beauty," he says, "is relative to the sense of some mind perceiving it." The cause of beauty is not any simple sensation from an object, as colour, tone, but a certain order among the parts, or "uniformity amidst variety." The faculty by which this principle is known is an internal sense which is defined as "a passive power of receiving ideas of beauty from all objects in which there is uniformity in variety." Thus Hutcheson seems to have supposed that beauty, though always residing in uniformity in variety as its form, was still something distinct from this, and so in need of a peculiar sense distinct from reason for the appreciation of it. But his meaning on this point is not clear. This faculty is called a sense, because it resembles the external senses in the immediateness of the pleasure it experiences. The perception of beauty, and the delight attending it, are quite as independent of considerations of principles, causes, or usefulness in the object, as the pleasurable sensation of a sweet taste. Further, the effect of a beautiful object is like the impression of our senses in its necessity; a beautiful thing being always, whether we will or no, beautiful. In the second place, this sense is called internal, because the appreciation of beauty is clearly distinct from the ordinary sensibility of the eye and ear, whether emotional or intellectual and discriminative, many persons who possess the latter intact being totally destitute of the former. Another reason is, that in some affairs which have little to do with the external senses, beauty is perceived, as in theorems, universal truths, and general causes. Hutcheson discusses two kinds of beauty—absolute or original, and relative or comparative. The former is independent of all comparison of the beautiful object with another object of which it may be an imitation. The latter is perceived in an object considered as an imitation or resemblance of something else. He distinctly states that "an exact imitation may still be beautiful though the original were entirely devoid of it;" but, curiously enough, will not allow that this proves his previous definition of beauty as "uniformity amidst variety" to be too narrow. He seems to conceive that the original sense of beauty may be "varied and overbalanced" with the secondary and subordinate kind. Hutcheson spends a good deal of time in proving the universality of this sense of beauty, by showing that all men, in proportion to the enlargement of their intellectual capacity, are more delighted with uniformity than the contrary. He argues against the supposition that custom and education are sources of our perception of beauty, though he admits that they may enlarge the capacity of our minds to retain and compare, and so may add to the delight of beauty.

The next writer of consequence on the intuitive side is Reid. In the eighth of his *Essays on the Intellectual Powers* he discusses the faculty of taste. He held, on the ground of common sense, that beauty must exist in objects independently of our minds. As to the nature of the Beautiful, he taught that all beauty resides primarily in the faculties of the mind, intellectual and moral. The beauty which is spread over the face of visible nature is an emanation from this spiritual beauty, and is beautiful because it symbolises and expresses it. Thus the beauty of a plant resides in its perfection for its end, as an expression of the wisdom of its Creator. Reid's theory of beauty is thus purely spiritual.

The celebrated *Lectures on Metaphysics* of Sir W. Hamilton do not, unfortunately, contain more than a slight preliminary sketch of the writer's theory of the emotional activities. He defines pleasure, following very closely the theory of Aristotle, as "a reflex of the spontaneous and unimpeded exertion of a power of whose energy we are conscious" (vol. ii. p. 440). And, in perfect agreement with this conception, he divides the various feelings according to the faculties or powers, bodily or mental, of which they are the concomitants. In the scheme thus faintly shadowed forth, the sentiments of Taste are regarded as subserving both the subsidiary and the elaborative faculties in cognition, in other words, the Imagination and the Understanding. The activity of the former corresponds to the element of variety in the beautiful object, while that of the latter is concerned with its unity. A beautiful thing is accordingly defined "as one whose form occupies the Imagination and Understanding in a free and full, and, consequently, in an agreeable activity" (p. 512). In this way, the writer conceives, he comprehends all pre-existing definitions of beauty. He explicitly excludes all other varieties of pleasure, such as the sensuous, from the proper gratification of beauty. The æsthetic sentiment is thus regarded as unique and not resolvable into simpler feelings. Similarly, he denies any proper attribute of beauty to fitness. The essence of the sentiment of sublimity he finds, much in the same way as Kant, in a mingled pleasure and pain; "of pleasure in the consciousness of the strong energy, of pain in the consciousness that this energy is vain." He recognises three forms of Sublimity: those of Extension or space, of Protension or time, and of Intension or power. Finally, he thinks that the Picturesque differs from the Beautiful in appealing simply to the imagination. A picturesque object is one whose parts are so palpably unconnected that the understanding is not stimulated to the perception of unity.

A very like interpretation of beauty, as spiritual and typical of divine attributes, has been given by Mr Ruskin in the second volume of his *Modern Painters*. This part of his work, bearing the title "Of Ideas of Beauty," has a very systematic appearance, but is in fact a singularly desultory series of æsthetic ideas put into a very charming language, and coloured by strong emotion. Mr Ruskin distinguishes between the theoretic faculty concerned in the moral perception and appreciation of ideas of beauty and the imaginative or artistic faculty, which is employed in regarding in a certain way and combining the ideas received from external nature. The former, he thinks, is wrongly named the *æsthetic* faculty, as though it were a mere operation of sense. The object of the faculty is beauty, which Mr Ruskin divides into typical and vital beauty. The former is the external quality of bodies that typifies some divine attribute. The latter consists in "the appearance of felicitous fulfilment of function in living things." The forms of typical beauty are—(1.) Infinity, the type of the divine incomprehensibility; (2.) Unity, the type of the divine comprehensiveness; (3.) Repose, the type of the divine permanence; (4.) Symmetry, the type of the divine justice; (5.) Purity, the type of the divine energy; and (6.) Moderation, the type of government by law. Vital beauty, again, is regarded as relative when the degree of exaltation of the function is estimated, or generic if only the degree of conformity of an individual to the appointed functions of the species is taken into account. Mr Ruskin's wide knowledge and fine æsthetic perception make his works replete with valuable suggestions, though he appears wanting in scientific accuracy, and lacks, as Mr Mill has pointed out, all appreciation of the explanatory power of association with respect to the ideal elements of typical beauty.

Of the more analytic writers on the effects of the Beautiful, Addison deserves a passing mention, less, however, for the scientific precision of his definitions, than for the charm of his style. His Essays on the Imagination, contributed to the *Spectator*, are admirable specimens of popular æsthetic reflection. Addison means by the pleasures of imagination those which arise originally from sight, and he divides them into two classes—(1.) Primary pleasures, which entirely proceed from objects before our eyes; and (2.) Secondary pleasures, flowing from ideas of visible objects. The original sources of pleasure in visible objects are greatness, novelty, and beauty. This, it may be said, is a valuable distinction, as pointing to the plurality of sources in the æsthetic impression, but the threefold division is only a very rough tentative, and destitute of all logical value, novelty of impression being always a condition of beauty. The secondary pleasures, he rightly remarks, are rendered far more extended than the original by the addition of the proper enjoyment of resemblance, which is at the basis of all mimicry and wit. Addison recognises, too, the effects of association in the suggestion of whole scenes, and their accompaniments by some single circumstance. He has some curious hints as to the physiological seat of these mental processes, and seeks, somewhat naïvely, to connect these pleasures with teleological considerations.

Lord Kaim[es]

In the *Elements of Criticism* of Lord Kaimes, another attempt is made to affiliate æsthetic phenomena to simpler pleasures of experience. Beauty and ugliness are simply the pleasant and the unpleasant in the higher senses of sight and hearing. By "higher" he means more intellectual, and he conceives these two senses to be placed midway between the lower senses and the understanding. He appears to admit no more general feature in beautiful objects than this pleasurable quality. Like Hutcheson, he divides beauty into intrinsic and relative, but understands by the latter ideas of fitness and utility, which were excluded from the Beautiful by Hutcheson. He illustrates the English tendency to connect mental processes with physiological conditions, by referring the main elements of the feeling of sublimity to the effect of height in objects in compelling the spectator to stand on tiptoe, by which the chest is expanded and muscular movements produced which give rise to the peculiar emotion.

Hogar[th]

Passing by the name of Sir Joshua Reynolds, whose theory of beauty closely resembles that of Père Buffier, we come to the speculations of another artist and painter, Hogarth. He discusses in his *Analysis of Beauty* all the elements of visible beauty, both form and colour, often manifesting great speculative skill, and always showing a wide and accurate knowledge of art. He finds altogether six elements in beauty, namely—(1.) Fitness of the parts to some design, as of the limbs for support and movement; (2.) Variety in as many ways as possible, thus in form, length, and direction of line, shape, and magnitude of figure, &c.; (3.) Uniformity, regularity, or symmetry, which is only beautiful when it helps to preserve the character of fitness; (4.) Simplicity or distinctness, which gives pleasure not in itself, but through its enabling the eye to enjoy variety with ease; (5.) Intricacy, which provides employment for our active energies, ever eager for pursuit, and leads the eye "a wanton kind of chase"; (6.) Quantit[y] or magnitude, which draws our attention, and produces admiration and awe. The beauty of proportion he very acutely resolves into the needs of fitness. Hogarth applies these principles to the determination of degrees of beauty in lines, and figures, and compositions of forms. Among lines he singles out for special honour the serpentine (formed by drawing a line once round from the base to the apex of a long slender cone) as the line of grace or beauty *par excellence.* Its superiority he places in its many varieties of direction or curvature, though he adds that more suddenly curving lines displease by their grossness, while straighter lines appear lean and poor. In this last remark Hogarth tacitly allows another principle in graceful line, namely, gentleness, as opposed to suddenness, of change in direction, though he does not give it distinct recognition in his theory, as Burke did. Hogarth's opinions are of great value as a set off against the extreme views of Alison and the association school, since he distinctly attributes a great part of the effects of beauty in form, as in colour, to the satisfaction of primitive susceptibilities of the mind, though he had not the requisite psychological knowledge to reduce them to their simplest expression. In his remarks on intricacy he shows clearly enough that he understood the pleasures of movement to be involved in all visual perception of form.

Burke's speculations on the Beautiful, in his *Philosophical Inquiry into the Origin of our Ideas of the Sublime and Beautiful*, are curious as introducing physiological considerations into the explanation of the feelings of beauty. They illustrate, moreover, the tendency of English writers to treat the problem as a psychological one. He finds the elements of beauty to be—(1.) Smallness of size; (2.) Smoothness of surface; (3.) Gradual variation of direction of outline, by which he means gentle curves; (4.) Delicacy, or the appearance of fragility; (5.) Brightness, purity, and softness of colour. The Sublime he resolves, not very carefully, into astonishment, which he thinks always contains an element of terror. Thus "infinity has a tendency to fill the mind with a delightful horror." Burke seeks what he calls "efficient causes" for these phenomena in certain affections of the nerves of sight, which he compares with the operations of taste, smell, and touch. Terror produces "an unnatural tension and certain violent emotions of the nerves," hence any objects of sight which produce this tension awaken the feeling of the Sublime, which is a kind of terror. Beautiful objects affect the nerves of sight just as smooth surfaces the nerves of touch, sweet tastes and odours the corresponding nerve fibres, namely, by relaxing them, and so producing a soothing effect on the mind. The arbitrariness and narrowness of this theory, looked at as a complete explanation of beauty, cannot well escape the reader's attention.

Alison, in his well-known *Essays on the Nature and Principles of Taste*, proceeds on an exactly opposite method to that of Hogarth and Burke. He considers and seeks to analyse the mental process which goes on when we experience the emotion of beauty or sublimity. He finds that this consists in a peculiar operation of the imagination, namely, the flow of a train of ideas through the mind, which ideas are not arbitrarily determined, but always correspond to some simple affection or emotion (as cheerfulness, sadness, awe), awakened by the object. He thus makes association the sole source of the Beautiful, and denies any such attribute to the simple impressions of the senses. His exposition, which is very extensive, contains many ingenious and valuable contributions to the ideal or association side of æsthetic effects, both of nature and of art; but his total exclusion of delight (by which name he distinguishes æsthetic pleasure) from the immediate effects of colour, visible form, and tone, makes his theory appear very incomplete. This is especially applicable to music, where the delight of mere sensation is perhaps most conspicuous. He fails, too, to see that in the emotional harmony of the ideas, which, according to his view, make up an impression of beauty, there is a distinct source of pleasure over and above that supplied by the simple feeling and by the ideas themselves.

Jeffrey's *Essay on Beauty* is little more than a modification of Alison's views. He defines the sense of beauty as consisting in the suggestion of agreeable and interesting sensations previously experienced by means of our various pleasurable sensibilities. He thus retains the necessity of ideal suggestion, but at the same time discards the supposed requirement of a *train* of ideas. Jeffrey distinctly saw that this theory excludes the hypothesis of an independent beauty inherent in objects. He fails as completely as Alison to disprove the existence of a sensuous or organic beautiful, and, like him, is avowedly concerned to show the presence of some one, and only one, determining principle in all forms of the Beautiful.

Dugald Stewart

D. Stewart's chief merit in the æsthetic discussions, contained in his *Philosophical Essays*, consists in pointing out this unwarranted assumption of some single quality (other than that of producing a certain refined pleasure) running through all beautiful objects, and constituting the essence of beauty. He shows very ingeniously how the successive transitions and generalisations in the meaning of the term beauty may have arisen. He thinks it must originally have connoted the pleasure of colour, which he recognises as primitive. His criticisms on the one-sided schemes of other writers, as Burke and Alison, are very able, though he himself hardly attempts any complete theory of beauty. His conception of the Sublime, suggested by the etymology of the word, renders prominent the element of height in objects, which he conceives as an upward direction of motion, and which operates on the mind as an exhibition of power, namely, triumph over gravity.

Professor Bain.

Of the association psychologists James Mill did little more towards the analysis of the sentiments of beauty than re-state Alison's doctrine. On the other hand, Professor Bain, in his treatise *The Emotions and the Will*, carries this examination considerably further. He asserts with Stewart that no one generalisation will comprehend all varieties of beautiful objects. He thinks, however, that the æsthetic emotions, those involved in the fine arts, may be roughly circumscribed and marked off from other modes of enjoyment by means of three characteristics—(1.) Their not serving to keep up existence, but being gratifications sought for themselves only; (2.) Their purity from all repulsive ingredients; (3.) Their eminently sympathetic or sharable nature in contrast to the exclusive pleasures of the individual in eating, &c. The pleasures of art are divided, according to Mr Bain's general plan of the mind, into (1.) The elements of sensation—sights and sounds; (2.) The extension of these by intellectual revival—ideal suggestions of muscular impression, touch, odour, and other pleasurable sensations; (3.) The revival, in ideal form also, of pleasurable emotions, as tenderness and power, and in a softened measure of emotions painful in reality, as fear; (4.) The immediate gratification, that is in actual form, of certain wide emotional susceptibilities reaching beyond art, namely, the elating effect of all change of impression under the forms of artistic contrast and variety; and, secondly, the peculiar delight springing from harmony among impressions and feelings, under its several æsthetic aspects, musical harmony and melody, proportion, &c. The details in Mr Bain's exposition are rich and varied in relation to the psychology of the subject. He finds the effect of sublimity in the manifestation of superior power in its highest degrees, which manifestation excites a sympathetic elation in the beholder. The Ludicrous, again, is defined by Mr Bain, improving on Aristotle and Hobbes, as the degradation of something possessing dignity in circumstances that excite no other strong emotion. The pleasure accompanying the impression may be referred either to the elation of a sense of power or superiority ideally or sympathetically excited, or to a sense of freedom from restraint, both of which have in common the element of a joyous rebound from pressure. Thus it will be seen that Professor Bain recognises no new mental principle in æsthetic effects, but regards them as peculiar combinations and transformations, according to known psychological laws, of other and simpler feelings.

An interesting turn has been given to the psychology of æsthetics by Mr Herbert Spencer. In some of his essays, as the one entitled "The Origin and Function of Music," and more fully in the concluding chapter of his *Psychology* (second edition), on the Æsthetic Sentiments, he offers a new theory of the genesis of the pleasures of beauty and art, based on his doctrine of evolution. He takes up Schiller's idea of the connection between æsthetic activity and play, only he deals with this latter not as an ideal tendency, but as a phenomenal reality, seeking to make it the actual starting-point in the order of evolution of æsthetic action. Play or sport is defined as the superfluous and useless exercise of faculties that have been quiescent for a time, and have in this way become so ready to discharge as to relieve themselves by *simulated* actions. Æsthetic activities yield to the higher powers of perception and emotion the substituted exercise which play yields to the lower impulses, agreeing with play in not directly subserving any processes conducive to life, but being gratifications sought for themselves only. This point of affinity between the two classes of pleasures is a valuable addition to æsthetic theory, and helps one to understand how the artistic impulse first arose. At the same time it is doubtful how far all present æsthetic pleasures, as the passive enjoyments of colour and tone, can be interpreted as substituted activities in Mr Spencer's sense. They seem rather to be original and instinctive modes of gratification not dependent on any previous exercises of life-function, except so far as the structure and functions of the senses as a whole may be viewed as the product of multitudinous life-processes in animal evolution. Mr Spencer, moreover, forms a hierarchy of æsthetic pleasures, the standard of height being either the number of powers duly exercised, or what comes to the same thing, the degree of complexity of the emotional faculty thus exercised. The first, and lowest class of pleasures, are those of simple sensation, as tone and colour, which are partly organic and partly the results of association. The second class are the pleasures of perception, as employed upon the combination of colours, &c. The highest order of pleasures are those of the æsthetic sentiments proper, consisting of the multitudinous emotions ideally excited by æsthetic objects, natural and artistic. Among these vaguely and partially revived emotions Mr Spencer reckons not only those of the individual, but also many of the constant feelings of the race. Thus he would attribute the vagueness and apparent depth of musical emotion to associations with vocal tones, built up during the course of vast ages. This graduated scheme is evidently dictated by the assumption that the higher the stage of evolution, the higher the pleasure. Yet Mr Spencer admits that this measure of æsthetic value will not suffice alone, and he adds, that the most perfect form of æsthetic gratification is realised when sensation, perception, and emotion, are present in fullest and most pleasurable action. Mr Spencer's supposition, that much of the pleasure of æsthetic emotion is referrible to transmitted experience, offers a very ingenious, even if not very definite, mode of explaining many of the mysterious effects of tone, and even of colour.

Among works on the history of æsthetic doctrines, the student may be referred to the following :—

In German literature, which contains the most complete histories, Max Schasler's *Kritische Geschichte der Æsthetik*, forming the first two volumes of an æsthetic system, is the fullest. Still he hardly does justice to English writers, there being no mention of Alison and recent thinkers. His stand-point is only definable as a new modification of Hegelianism. Zimmermann's *Geschichte der Æsthetik* is also to be recommended. Lotze's *Geschichte der Æsthetik in Deutschland* is a highly critical *résumé* of German systems, characterised by a good deal of caution, and a desire to mediate between opposing views, and if not very definite in its result, very appreciative and suggestive of the many-sidedness of the subject. In French, Lévêque's work, *La Science du Beau*, contains a very fair account of the most conspicuous systems, ancient and modern. In our own literature, numerous references to other systems are to be found in the essays of Alison ; and Jeffrey attempts a brief historical survey of the doctrines of beauty in his article on the subject. Dugald Stewart's essays mostly fall into critical examination of the chief theories of beauty. Finally, Professor Bain, in his *Compendium of Mental and Moral Science*, supplies a brief but careful account of most of the known theories of the Beautiful. (J. S.)

AETION, a painter, whose famous picture of the marriage of Roxana and Alexander was exhibited at the Olympic games, and gained Aëtion so much reputation that the president of the games gave him his daughter in marriage. The picture is minutely described by Lucian. Aëtion appears from that author to have flourished in the times of Hadrian and the Antonines.

AETIUS, a Roman general of the closing period of the western empire, born at Dorostolus in Mœsia, late in the 4th century. While detained for some time as a hostage in the camp of Rhuas, king of the Huns, he acquired an influence with the barbarians that was afterwards of much advantage to himself, though the same cannot be said of it as regards the empire. He led into Italy an army of 60,000 Huns, which he employed first to support the usurping Emperor John, and, on the death of the latter, to enforce his claim to the supreme command of the army in Gaul upon Placidia, the empress-mother and regent for Valentinian III. Afterwards, when he incurred the disfavour of Placidia for the death of his rival Boniface, he again employed an army of Huns to compel her to reinstate him in his former position. In Gaul he won his military reputation, upholding for nearly twenty years, by combined policy and daring, the falling fortunes of the western empire. His greatest victory was that of Chalons-sur-Marne (20th Sept. 451), in which he utterly routed Attila and the Huns—the number slain on both sides being, according to one computation, 300,000, though this is obviously an exaggeration. This was the last triumph of the empire. Three years later (454) Aëtius presented himself at court to claim the emperor's daughter in marriage for his son Gaudentius; but Valentinian, suspecting him of designs upon the crown, slew him with his own hand.

AETIUS, surnamed "the Atheist," founder of an extreme sect of the Arians, was a native of Cœle-Syria. After working for some time as a coppersmith, he became a travelling doctor, and displayed great skill in disputations on medical subjects; but his controversial power soon found a wider field for its exercise in the great theological question of the time. He studied successively under the Arians, Paulinus, bishop of Antioch, Athanasius, bishop of Anazarbus, and the presbyter Antonius of Tarsus. In 350 he was ordained a deacon by Leontius of Antioch, but was shortly afterwards forced by the orthodox party to leave that town. At the first synod of Sirmium, he won a dialectic victory over the homoiousian bishops Basilius and Eustathius, who sought in consequence to stir up against him the enmity of Cæsar Gallus. In 356 he went to

Alexandria with Eunomius in order to advocate Arianism, but he was banished by Constantius. Julian the apostate recalled him from exile, bestowed upon him an estate in Lesbos, and retained him for a time at his court in Constantinople. Being consecrated a bishop, he used his office in the interests of Arianism by creating other bishops of that party. At the accession of Valens (364) he retired to his estate at Lesbos, but soon returned to Constantinople, where he died in 367. The Anomœan sect of the Arians, of whom he was the leader, are sometimes called after him *Aëtians*. His work *De Fide* has been preserved in connection with a refutation written by Epiphanius.

AETIUS, a Greek physician, born at Amida in Mesopotamia, who lived at the end of the 5th or the beginning of the 6th century. Of his personal history little is known, except that he studied at Alexandria, and was physician to the court at Constantinople with the title *comes obsequii*. He wrote a work entitled *Βιβλία Ἰατρικὰ Ἑκκαίδεκα*, which is mainly a compilation from the works of previous authors. Eight books of this were issued from the Aldine press at Venice in 1534; various other parts have been frequently published; and a Latin translation of the whole, by Cornarius, appeared at Basle in 1542.

ÆTNA. See ETNA.

ÆTOLIA, a country of ancient Greece, bounded on the N. by Epirus and Thessaly, on the E. by the provinces of Doris and Locris, on the S. by the Gulf of Corinth, and separated on the W. from Acarnania by the river Achelous. The part which lay westward of the river Evenus, and south of a line joining Thermum and Stratus in Acarnania, was called old Ætolia, the rest of the country new or acquired Ætolia. The country is in general mountainous and woody, but along the coast from the Achelous to the Evenus, and northward to Mount Aracynthus, is a plain of great fertility; while another extensive and fertile plain stretches north from this mountain along the east bank of the Achelous as far as the northern limit of old Ætolia. The Ætolians were a restless and turbulent people, strangers to friendship or principles of honour, and they were consequently regarded by the other states of Greece as outlaws and public robbers. On the other hand, they were bold and enterprising in war, undaunted in the greatest dangers, and jealous defenders of their liberties. They distinguished themselves above all the other nations of Greece in opposing the ambitious designs of the Macedonian princes, who, after having reduced most of the other states, were forced to grant them a peace upon very honourable terms. The constitution of the Ætolian league was copied from that of the Achæans, and with a view to form, as it were, a counter alliance. The Cleomenic war, and that of the allies, called the Social War, were kindled by the Ætolians with the express purpose of humbling the Achæans. In the latter they held out, with the assistance only of the Eleans and Lacedemonians, for the space of three years, against the united forces of Achaia and Macedon, but were obliged at last to purchase a peace by yielding up to Philip all Acarnania. In order to regain this province they entered into an alliance with Rome against Philip, and proved of great service to the Romans in their war with him; but being dissatisfied with the terms of peace granted by Flaminius, they made war upon the Romans themselves. They were speedily overcome, and only obtained peace on very humiliating terms. After the conquest of Macedon by Æmilius Paullus the Ætolians were reduced to a much worse condition; for not only those among them who had openly declared for Perseus, but those who were only suspected to have secretly favoured him, were sent to Rome to clear themselves before the senate. There they were detained, and never afterwards permitted to return to their native country. Five hundred and fifty of the chief men were barbarously assassinated by the partisans of Rome solely on the suspicion of favouring the designs of Perseus. The Ætolians appeared before Æmilius Paullus in mourning habits, and made loud complaints of such inhuman treatment, but could obtain no redress; on the contrary, ten commissioners, who had been sent by the senate to settle the affairs of Greece, enacted a decree, declaring that those who were killed had suffered justly, since it appeared to them that they had favoured the Macedonian party. From this time those only were raised to the chief honours and employments in the Ætolian republic who were known to prefer the interest of Rome to that of their country, and thus all the magistrates of Ætolia became the creatures and mere tools of the Roman senate. In this state of servile subjection they continued till the destruction of Corinth and the dissolution of the Achæan league, when Ætolia, with the other free states of Greece, was reduced to a Roman province, commonly called the *province of Achaia*. In this state, with little alteration, Ætolia continued under the emperors till the reign of Constantine the Great, who, in his new partition of the provinces of the empire, divided the western parts of Greece from the rest, calling them *New Epirus*, and subjecting the whole country to the *præfectus prætorio* for Illyricum. Under the successors of Constantine Greece was parcelled out into several principalities, especially after the taking of Constantinople by the western princes. About the beginning of the 13th century Theodorus Angelus, a noble Grecian of the imperial family, seized on Ætolia and Epirus. The former he left to Michael his son, who maintained it against Michael Palæologus, the first emperor of the Greeks, after the expulsion of the Latins. Charles, the last prince of this family, dying in 1430 without lawful issue, bequeathed Ætolia to his brother's son, named also Charles; and Acarnania to his natural sons Memnon, Turnus, and Hercules. But great disputes arising about this division, Amurath II., after the reduction of Thessalonica, laid hold of so favourable an opportunity, and expelled all the contending heirs in 1432. The Mahometans were afterwards dispossessed of this country by the famous prince of Epirus, George Castriot, commonly called Scanderbeg, who with a small army opposed the whole power of the Ottoman empire, and was victorious in twenty-two pitched battles. That hero at his death left great part of Ætolia to the Venetians; but they not being able to make head against such a mighty power, the whole country was soon reduced by Mahommed II. It is now included in the kingdom of Greece.

AFANASIEF, ALEKSANDR NIKOLAEVICH, a Russian scholar, distinguished for his researches in Slavonic literature and archæology, was born about 1825. He contributed many valuable articles to the serial literature of his country, but his reputation rests chiefly on two works of more permanent interest. The first was an extensive collection, in eight parts, of *Russian Popular Stories*; the other a treatise, in three volumes, on the *Poetical Views of the Old Slavonians about Nature*, completed just before the author's death, which occurred in the autumn of 1871.

AFER, DOMITIUS, orator, born at Nismes, flourished under Tiberius and the three succeeding emperors. Quintilian makes frequent mention of him, and commends his pleadings. But he disgraced his talents by acting as public accuser in behalf of the emperors against some of the most distinguished personages in Rome. Quintilian, in his youth, assiduously cultivated the friendship of Domitius. He tells us that his pleadings were superior in point of eloquence to any he had ever heard, and that there were public collections of his witty sayings (*dicta*), some of which he quotes. He also mentions two books of his, *On*

Witnesses. Domitius erected a statue in honour of Caligula, on which there was an inscription to the effect that this prince was a second time consul at the age of 27. This he intended as an encomium; but Caligula regarding it as a sarcasm upon his youth and his infringement of the laws, raised a process against him, and pleaded himself in person. Domitius, instead of making a defence, repeated part of the emperor's speech with the highest marks of admiration; after which he fell upon his knees, begged pardon, and declared that he dreaded Caligula's eloquence more than his imperial power. This piece of flattery succeeded so well, that the emperor not only pardoned him, but raised him to the consulship. Afer died in the reign of Nero. A.D. 60.

AFFIDAVIT means a solemn assurance of a matter of fact known to the person who states it, and attested as his statement by some person in authority. Evidence is chiefly taken by means of affidavits in the practice of the Court of Chancery in England. By 3 and 4 Will. IV. c. 42, s. 42, provision is made for appointing commissioners in Scotland and Ireland to take affidavits. The term is generally applied to a statement certified by a justice of peace or other magistrate. Affidavits are sometimes necessary as certificates that certain formalities have been duly and legally performed. They are extensively used in the practice of bankruptcy, and in the administration of the revenue. At one time they were invariably taken on oath, but this practice has been much narrowed. Quakers, Moravians, and Separatists have long been privileged in all cases to make a solemn declaration or affirmation; and now, if any persons called as witnesses, or required or desiring to make an affidavit or deposition, shall refuse or be unwilling from alleged conscientious motives to be sworn, the court or justice may, on being satisfied of the sincerity of such objection, allow such person to make a solemn affirmation or declaration—by 17 and 18 Vict. c. 125, s. 20, extended to all counties in England, Ireland, and Scotland by subsequent statutes. An Act of 1835 (5 and 6 Will. IV. c. 62) substituted declarations for oaths in certain cases; and this statute is extensively observed. The same Act prohibited justices of peace from administering oaths in any matter in which they had not jurisdiction as judges, except when an oath was specially authorised by statute, as in the bankrupt law, and excepting criminal inquiries, Parliamentary proceedings, and instances where oaths are required to give validity to documents abroad. But justices are permitted to take affidavits in any matter by declaration, and a person making a false affidavit in this way is liable to punishment. Affidavits may be made abroad before any British ambassador, envoy, minister, *chargé d'affaires*, secretary of embassy or legation, consul, or consular agent (18 and 19 Vict. c. 42, s. 1)

AFFINITY, in *Law*, as distinguished from consanguinity, is applied to the relation which each party to a marriage, the husband and the wife, bears to the kindred of the other. The marriage having made them one person, the blood relations of each are held as related by affinity in the same degree to the one spouse as by consanguinity to the other. But the relation is only with the married parties themselves, and does not bring those in affinity with them in affinity with each other; so a wife's sister has no affinity to her husband's brother. The subject is chiefly important from the matrimonial prohibitions by which the canon law has restricted relations by affinity. Taking the table of degrees within which marriage is prohibited on account of consanguinity, the rule has been thus extended to affinity, so that wherever relationship to a man himself would be a bar to marriage, relationship to his deceased wife will be the same bar, and *vice versa* on the husband's decease. This rule has been founded chiefly on interpretations of the eighteenth chapter of Leviticus. Formerly by law in England, marriages within the degrees of affinity were not absolutely null, but they were liable to be annulled by ecclesiastical process during the lives of both parties; in other words, the incapacity was only a canonical, not a civil, disability. By an Act passed in 1835 (5 and 6 Will. IV. c. 54), all marriages of this kind not disputed before the passing of the Act are declared absolutely valid, while all subsequent to it are declared null. This renders null in England, and not merely voidable, a marriage with a deceased wife's sister or niece. The Act does not extend to Scotland; but it was made quite clear by a leading decision in 1861 (Fenton *v.* Livingston) that, as "the degrees forbidden in consanguinity are also forbidden in affinity," the marriage of a sister-in-law with a brother-in-law is absolutely null in that country. Nor can a man contract a marriage with his wife's sister so as to be valid in Great Britain, by celebrating his marriage with her in a country where such marriages are lawful (Brook *v.* Brook, 9 *H. L. Cases*, 193).

AFFINITY, CHEMICAL, the property or relation in virtue of which dissimilar substances are capable of entering into chemical combination with each other. Substances that are so related combine always in fixed and definite proportions; the resulting compound differs from its components in its physical properties, with the exception that its weight is exactly the sum of their weights; and the combination is always accompanied with the evolution of heat. In these respects it differs from a mere mechanical mixture; in the latter there is contact without combination, and its properties are a mean or average of those of the substances that compose it. That effect may be given to chemical affinity, the substances must be placed in contact; but mere contact is often insufficient, and combination only takes place on the application of heat, light, electric agency, &c., or through the interposition of some foreign substance. Generally speaking, the affinity is less between substances that closely resemble each other than between those whose properties are altogether dissimilar. The term *elective affinity*, now generally disused, has been employed to indicate the greater affinity which a substance, when brought into contact with other substances, often has for one in preference to another. Advantage is frequently taken of this greater affinity to decompose compound substances. For a full treatment of chemical affinity and combination, see CHEMISTRY.

AFFIRMATION. See AFFIDAVIT.

AFFRE, DENIS AUGUSTE, Archbishop of Paris, was born at St Rome, in the department of Tarn, on the 27th Sept. 1793. When fourteen years of age, having expressed his desire to enter the church, he became a student at the seminary of St Sulpice, of which his maternal uncle, Denis Boyer, was director. His studies being completed before he had reached the age necessary for ordination, he was occupied for some time as professor of philosophy in the seminary at Nantes. He was ordained a priest in 1818, and held his first charge in connection with the church of St Sulpice. After filling a number of ecclesiastical offices, he was elevated to the Archbishopric of Paris in 1840. His tenure of this office, though it was marked by great zeal and faithfulness, will be chiefly remembered by its tragic close. During the insurrection of 1848 the archbishop was led to believe that by his personal interference peace might be restored between the soldiery and the insurgents. He accordingly applied to General Cavaignac, who warned him of the risk he incurred. "My life," the archbishop answered, "is of little importance." Soon afterwards, the firing having ceased at his request, he appeared on the barricade at the entrance to the Faubourg St Antoine, accompanied by M. Albert, of the national guard, bearing a green branch as a sign of peace, and by Sellier, an attached servant. His reception was not very favourable, and he had spoken only a few words, when the insurgents, hearing some shots, and fancying they were betrayed, opened fire upon the national guard, and the archbishop fell. He was removed to his palace, where he died on the 27th June 1848. Next day the National Assembly issued a decree expressing their great sorrow on account of his death; and the public funeral on the 7th July was one of the most striking spectacles of its kind. The archbishop wrote several treatises of considerable value, including one on Egyptian hieroglyphics.

AFGHÂNISTÂN

THIS is the name applied, originally in Persian, to that mountainous region between N.W. India and Eastern Persia, of which the Afghâns are the most numerous and the predominant inhabitants. Afghans, under that and other names, have played no small part in Asiatic history. But the present extensive application of the name *Afghânistân* is scarcely older than the shortlived empire founded by Ahmed Khan in the middle of last century. The Afghans themselves are not in the habit of using the term.

In treating of this country we include a part of the Hazâra mountain region, but not that part of the Oxus basin which is now under Afghan rule, for which see AFGHAN TURKESTAN.

Afghanistan generally may be regarded as a great quadrilateral plateau,—using that term in the technical sense of a region whose lowest tracts even are considerably elevated above the sea-level,—extending from about 62° to 70° E. long., and from 30° to 35° N. lat. This territory corresponds fairly to the aggregate of the ancient provinces of *Aria* (Herât), *Drangiana* (Seistân), the region of the *Paropamisadæ* (Kâbul), and *Arachosia* (Kandahâr), with *Gandaritis* (Peshâwar and Yûzufzai). Though the last territory belongs ethnically to Afghanistan, an important part of it now forms the British district of Peshâwar, whilst the remainder acknowledges no master.

The boundaries of Afghanistan can be stated here only roughly; and, from the area thus broadly defined, many portions will have to be deducted as occupied by independent or semi-independent tribes. But, so understood, they may be thus stated:—

On the north: beginning from east, the great range of Hindu Kush, a western offshoot of the Himâlya, parting the Oxus basin from the Afghan basins of the Kabul river and Helmand. From long. 68° this boundary continues westward in the prolongation of Hindu Kush called Koh-i-Bâbâ. This breaks into several almost parallel branches, enclosing the valleys of the river of Herat and the Murghâb or river of Merv. The half-independent Hazara tribes stretch across these branches and down into the Oxus basin, so that it is difficult here to assign a boundary. We assume it to continue along the range called Safed Koh or "White Mountain," which parts the Herat river valley from the Murghab.[1]

On the east: the eastern base of the spurs of the Sulimâni and other mountains which limit the plains on the west bank of Indus, and the lower valleys opening into these, which plains (the "Derajât") and lower valleys belong to British India. North of Peshâwar district the boundary will be, for a space, the Indus, and then the limit, lying in unknown country, between the Afghan and Dard tribes.

On the south: the eastern part of the boundary, occupied by practically independent tribes, Afghan and Bilûch, is hard to define, having no marked natural indication. But from the Shâl territory (long. 67°), belonging to the Bilûch state of KELAT, westward, the southern limits of the valleys of the Lora river, and then of the Helmand, as far as the Lake of Seistan in lat. 30°, will complete the southern boundary. Thus the whole breadth of Bilûchistân, the ancient *Gedrosia*, a dry region occupying 5° of latitude, intervenes between Afghanistan and the sea.

The western boundary runs from the intersection of the Lake of Seistan with lat. 30°, bending eastward, so as to exclude a part of the plain of Seistan on the eastern bank of the lake, and then crosses the lake to near the meridian of 61°. Thence it runs nearly due north, near this meridian, to a point on the Hari-Rûd, or river of Herat, about 70 miles below that city, where it encounters the spurs of the Safed Koh, which has been given as the northern boundary.

But if we take the limits of the entire Afghan *dominions*, as they at present exist, the western boundary will continue north along the Hari-Rûd to lat. 36°, and the northern boundary will run from this point along the borders of the Turkman desert, so as to include Andkhoi, to Khoja Sâleh ferry on the Oxus. The Oxus, to its source in Great Pamir, forms the rest of the northern boundary. These enlarged limits would embrace the remainder of the Hazara mountain tracts, and the whole of what is now called AFGHAN TURKESTAN, as well as BADAKHSHAN with its dependencies, now tributary to the Afghan Amir.

The extreme dimensions of Afghanistan, as at first defined, will be about 600 miles from east to west, and 450 miles from north to south; and, if we take the whole Afghan dominion, the extent from north to south will be increased to 600 miles. Within both the areas so defined, however, we have included some territory over which the Afghan government has no control whatever, and much over which its authority is respected only when backed by a special exertion of force. Under the former head come the valleys of the Yusufzai clan north of Peshâwar, the Momands, Afrîdîs, Vazîrîs, &c., adjoining that district on the west and south-west, the high-lying valleys of Chitrâl or Kâshkâr, and of the independent Pagans or Kâfirs, among the loftier spurs of Hindu Kush. Under the latter head come the eastern districts of Khost and (partially) of Kurram, the Kâkar country in the extreme south-east, much of the country of the tribes called Eimâk and Hazara in the north-west, and probably Badakhshân with its dependencies.

If we suppose the sea to rise 4000 feet above its existing level, no part of the quadrilateral plateau that we have defined would be covered, except portions of the lower valley of the Kabul river, small tracts towards the Indus, and a triangle, of which the apex should be at the Lake of Seistan in the extreme south-west, and the base should just include Herat and Kandahar, passing beyond those cities to intersect the western and southern boundaries respectively. Isolated points and ridges within this triangle would emerge.

Further, let us suppose the sea to rise 7000 feet above its existing level. We should still have a tract emerging so large that a straight line of 200 miles could be drawn, from the Kûshân Pass of Hindu Kush, passing about 35 miles west of Kabul, to Rangak on the road between Ghazni and Kandahar, which nowhere should touch the submerged portion. And we believe it is certain that a line under

[1] Not to be confounded with the more easterly *Safed Koh* of the Kabul basin.

like conditions, but 250 miles in length, could be drawn at right angles to the former, passing about 25 miles south of Ghazni. The greater part of this latter line, however, would lie in the Hazara country, in which we have no observations.

In the triangular tract that would be submerged according to our first supposition, the lowest level is the Lake of Seistan, 1280 feet above the sea. Herat is 2650: Kandahar, 3490.

The Afghans themselves make a broad distinction between *Kabul*, meaning thereby the whole basin of the Kabul river, and the rest of their country, excluding the former from the large and vague term Khorasan, under which they consider the rest to be comprehended. There is reason for such a distinction in history as well as nature. For the Kabul basin was in old times much more intimately connected with India, and to the beginning of the 11th century was regarded as Indian territory.

Natural Divisions.—Of these, this Kabul basin (1) forms the first. As others we may discriminate—(2.) The lofty central part of the table-land on which stand Ghazni and Kala't-i-Ghilzai, embracing the upper valleys of ancient *Arachosia;* (3.) The upper Helmand basin; (4.) The lower Helmand basin, embracing Girishk, Kandahar, and the Afghan portion of Seistan; (5.) The basin of the Herat river; and (6.) The eastern part of the table-land, draining by streams, chiefly occasional torrents, towards the Indus.

Kabul Basin.—Its northern limit is the range of Hindu Kush, a name which properly applies to the lofty, snowclad crest due north of Kabul, and perhaps especially to one pass and peak. But it has been conveniently extended to the whole line of alpine watershed, stretching westward from the southern end of Pamir, and represents the Caucasus of Alexander's historians. Its peaks throughout probably rise to the region of perpetual snow, and even on most of the passes beds of snow occur at all seasons, and, on some, glaciers. We find no precise height stated for any of its peaks, but the highest probably attain to at least 20,000 or 21,000 feet. The height of the Kushan *Pass* is estimated by Lord at 15,000 feet.

The Kabul river (the ancient *Kophes*) is the most important river of Afghanistan. It may be considered as fully formed about 30 miles east of Kabul, by the junction thereabouts (the confluence does not seem to have been fixed by any traveller) of the following streams:—(*a.*) The *Kabul* stream, rising in the Unai pass towards the Helmand, which, after passing through the city, has been joined by the Logar river flowing north from the skirts of the Ghilzai plateau; (*b.*) A river bringing down from the valleys Ghorband, Parwân, and Panjshîr, a large part of the drainage of Hindu Kush, and watering the fruitful plain of Dâman-i-Koh (the "Hill-skirt"), intersected by innumerable brooks, and studded with vineyards, gardens, and fortalices. This river was formerly called *Bârân*, a name apparently obsolete, but desirable to maintain; (*c.*) The river of *Tagao*, coming down from the spurs of Hindu Kush on the Kafir borders.

Some 30 miles further east, the *Alishang* enters on the left bank, from Laghmân, above which this river and its confluents drain western Kafiristan. Twenty miles further, and not far beyond Jalâlâbâd, the Kabul river receives from the same side a confluent entitled, as regards length, to count as main stream. In some older maps this bears the name of *Kâma*, from a place near the confluence, and in more recent ones *Kûner*, from a district on its lower course. Higher it is called the *river of Kashkar*, and the *Beilam.* It seems to be the *Choaspes*, and perhaps the *Malamantus* of the ancients. It rises in a small lake near the borders of Pamir, and flows in a south-west direction through the length of Kashkar or Chitral, an independent valley-state, whose soil lies at a height of 6000 to 11,000 feet. The whole length of the river to its confluence with the Kabul river cannot be less than 250 miles, *i.e.*, about 80 miles longer than that regarded as the main stream, measured to its most remote source.

The basin of the Kabul river is enclosed at the head by the Paghman range, an offshoot of Hindu Kush, which divides the Kabul valleys from the Helmand. Up the head-waters of the stream that passes Kabul, leads the chief road to Turkestan, crossing for a brief space into the Helmand basin by the easy pass of Unai (11,320 feet), and then over the Koh-i-Baba, or western extension of Hindu Kush, by the Hajjigak passes (12,190 and 12,480 feet), to Bâmiân.

The most conspicuous southern limit of the Kabul basin is the Safed Koh, Spin-gar of the Afghans ("White Mountain," not to be confounded with the western Safed Koh already named), an alpine chain, reaching, in its highest summit, Sîta Râm, to a height of 15,622 feet, and the eastern ramifications of which extend to the Indus at and below Attok. Among the spurs of this range are those formidable passes between Kabul and Jalalabad, in which the disasters of 1841–42 culminated, as well as the famous Khybar passes between Jalalabad and Peshâwar. This southern watershed formed by the Safed Koh is so much nearer the Kabul river than that on the north, that the tributaries from this side, though numerous, are individually insignificant.

After flowing 60 miles (in direct measurement) eastward from the Kuner confluence, the Kabul river issues from the mountains which have hemmed it in, and enters the plain of Peshâwar, receiving, soon after, the combined rivers of Swât (*Soastus*) and Panjkora (*Guræus*), two of the great valleys of the Yusufzai. This combined river is called by the Afghans *Landai Sîn* or Little river, in distinction from the *Abba Sîn* or Indus, and the name seems often to adhere to the lower course of the Kabul river. Both rivers on entering the plain ramify, in delta fashion, into many natural channels, increased in number by artificial cuts for irrigation. Finally the river enters the Indus immediately above the gorge at Attok.

The lowest ford on the Kabul river is a bad one, near Jalalabad, only passable in the dry season. Below the Kuner confluence the river is deep and copious, crossed by ferries only, except at Naoshera, below Peshâwar, where there is usually a bridge of boats. The rapid current is unfavourable to navigation, but from Jalalabad downwards the river can float boats of 50 tons, and is often descended by rafts on blown skins. The whole course of the river, measured by a five-mile opening of the compasses, is as follows:—From source of Kabul stream in Unai pass to Attok, 250 miles; from source either of Logar or of Panjshir to the same, 290 miles; from source of Kashkar river to the same, 370 miles.

A marked natural division of the Kabul basin occurs near Gandâmak, above Jalalabad, where a sudden descent takes effect from a minimum elevation of 5000 feet to one of only 2000. The Emperor Baber says of this:—"The moment you descend, you see quite another world. The timber is different; its grains are of another sort; its animals are of a different species; and the manners and customs of its inhabitants are of a different kind." Burnes, on his first journey, left the wheat harvest in progress at Jalalabad, and found the crop at Gandamak, only 25 miles distant, but 3 inches above ground. Here, in truth, nature has planted the gates of India. The valleys of the upper basin, though still in the height of summer affected by a sun of fierce power, recall the climate and products of the finest part of temperate Europe; the region below is a chain of narrow, low, and hot plains, with climate and vegetation of an Indian character.

Accounts of Kabul strike us by apparent contradiction. Some give scarcely any impression but that of extreme ruggedness and desolation, awful defiles, and bare black crags; others dwell on the abounding orchards, green sward, charming dells, and purling streams. But both aspects are characteristic. The higher spurs, both of Hindu Kush and Safed Koh, are often clad with grand forests of pine, oak, and other alpine trees, and resemble the wooded ranges of Himalya. But the lower hills generally are utterly woodless, and almost entirely naked. In the bottoms, often watered by clear and copious streams, we have those beauties of verdure and fertility on which some writers dwell, and which derive new charms from contrast with the excessive sterility of the hills that frame them.

We cannot speak at equal length of the other natural divisions of Afghanistan, but some chief points will be noticed with the rivers. In general the remainder of the country, regarded by the Afghans as included in Khorasan, exhibits neither the savage sublimity of the defiles of the Kabul region, the alpine forests of its higher ranges, nor its nests of rich vegetation in the valleys, save in the north-east part adjoining Safed Koh, where these characters still adhere, and in some exceptional localities, such as the valley of Herat, which is matchless in richness of cultivation. Generally the characteristics of this country are elevated plateaux of sandy or gravelly surface, broken by ranges of rocky hills, and often expanding in wide spaces of arid waste, which terminate to the south-west in a regular desert of shifting sand. Even in cultivated parts there is a singular absence of trees, and when the crops are not visible this imparts an aspect of great desolation and emptiness to the landscape. Natural wood, however, is found in some parts of West Afghanistan, as in the almost tropical delta of the Helmand, in the Ghûr territory, and on the Herat river below Herat. Generally, indeed, in such cases the trees appear to be mimosas, tamarisks, and the like, with little body of foliage.

Rivers.—Next to the Kabul river in importance, and probably much exceeding it in volume as it certainly does in length, is the *Helmand* (*Etymander*), the only considerable river in its latitude from the Tigris to the Indus. The Helmand has its highest sources in the Koh-i-Baba and Paghman hills, between Kabul and Bamian. Its succeeding course is through the least known tract of Afghanistan, chiefly occupied by Hazaras; indeed, for a length of nearly 300 miles no European has seen the river. This unvisited space terminates at Girishk, where the river is crossed by the principal route from Herat to Kandahar. Till about 40 miles above Girishk the character of the Helmand is said to be that of a mountain river, flowing between scarped rocks, and obstructed by enormous boulders. At that point it enters on a flat country, and extends over a gravelly bed. Here, also, it begins to be used in irrigation. Forty-five miles below Girishk the Helmand receives its greatest tributary, the Arghand-âb, coming past Kandahar from the high Ghilzai country. It here becomes a very considerable river, said to have a width of 300 or 400 yards, and a depth of 9 to 12 feet. But this cannot be at all seasons, as there are fords at long intervals as far down as Pûlalik, 100 miles from the mouth. The desert draws near the left bank in the lower course, and for the last 150 miles the moving sands approach within 1¼ mile. The vegetation on the banks is here of luxuriant tropical character. The whole of the lower valley seems to have been once the seat of a prosperous population, and there is still a good deal of cultivation for 100 miles below Girishk. Even this, however, is much fallen off, and lower down still more so, owing to disorders and excessive insecurity.

The course of the river is more or less south-west from its source till in Seistan it approaches meridian 62°, when it turns nearly north, and so flows on for 70 or 80 miles, till it falls into the lake of Seistan by various mouths. The whole length of the river, measured as before, is about 615 miles. Ferrier considers that it has water enough for navigation at all seasons, from Girishk downwards. At present boats are rarely seen, and those in use are most clumsy; rafts are employed for crossing.

Arghand-âb.—Of this tributary of the Helmand little is known except in its lower course. It rises in the Hazara country, N. W. of Ghazni. It is said to be shallow, and to run nearly dry in height of summer; but when its depth exceeds 3 feet its great rapidity makes it a serious obstacle to travellers. In its lower course it is much used for irrigation, and the valley is cultivated and populous; yet the water is said to be somewhat brackish. Its course may be reckoned about 235 miles.

It is doubtful whether the ancient *Arachotus* is to be identified with the Arghand-ab or with its chief confluent the *Tarnak*, which joins it on the left about 30 miles S.W. of Kandahar. The two rivers run nearly parallel, inclosing the backbone of the Ghilzai plateau. The Tarnak is much the shorter (length about 197 miles) and less copious. The ruins at Ulân Robât, supposed to represent the city *Arachosia*, are in its basin; and the lake known as *Ab-i-Istâda*, the most probable representative of *Lake Arachotus*, is near the head of the Tarnak, though not communicating with it. The Tarnak is dammed for irrigation at intervals, and in the hot season almost exhausted. There is a good deal of cultivation along the river, but few villages. The high road from Kabul to Kandahar passes this way (another reason for supposing the Tarnak to be *Arachotus*), and the people live off the road to eschew the onerous duties of hospitality.

The *Lora* is the most southerly river of Afghanistan, and may be regarded as belonging to the Helmand basin, though it is not known that its waters ever reach that river. It rises near the Kand and Joba peaks in a branch of the Sulimani, and flows nearly east, passing through the large valley of Pishîn, but lying too deep for irrigation. The river has a course of nearly 200 miles, and considerable breadth, but is never for a week together unfordable. In the Shorâwak district (long. 65°-66°) a good deal of irrigation is drawn from it. The river is said to terminate in a lake, on the verge of the sandy desert.

Rivers belonging to the basin of Seistan and the Lower Helmand are the Khash-Rud, the Farrah-Rud, and the Harut.

The *Khâsh-rûd* rises in or near the southern slopes of Siah-Koh (Black Mountain), which forms the southern wall of the valley of Herat, and flows south, in flood reaching the Lake of Seistan, but generally exhausted in irrigation. It is named from Khâsh, a village in the Seistan plain. In the dry season it is everywhere fordable, but in floods caravans may be detained by it several days.

The *Farrah* river flows from the same quarter, and has the same character in floods. It is a larger stream, and at Farrah is said to have a width of 150 yards, with 2 feet of water, and a clear, swift stream. In flood, Khanikoff was struck with the resemblance of this river, rolling its yellow waves violently between steep banks of clay, to the Cyrus at Tiflis.

The *Harût* rises in the mountains S.E. of Herat, and has a course of about 245 miles to the Lake of Seistan. Canals from it supply abundant irrigation to the plains of Sabzvâr and Anârdarah. The river forms a true delta with fifteen branches, giving rise to marsh and much vegetation, especially tamarisk, willow, and poplar. The Harut receives in the plain a considerable affluent, the Khushkek river.

It is possible that confusion of the name of this river with the Hari-Rud, or river of Herat, led to the long prevalent mistake that the latter river flowed south into the Seistan Lake—a mistake as old as Ptolemy, if his *Aria Lacus* be (as it seems) that of Seistan.

The *Hari-rûd* is formed by two chief confluents in the lofty Hazara country, not far from the sources of the river of Balkh. Its early course is, for more than 100 miles and as far as the village of Jâor, westward, at a height of many thousand feet above the sea. It then descends rapidly (it is said with cataracts), but continues in the same direction, receiving numerous streams, to Obeh, where much water begins to be drawn off. Sixty-five miles further it flows past *Herat*, 3 miles to the south of the city. Hereabouts the Kandahar road crosses the river by a masonry bridge of 26 arches. Near this fifteen deep canals are drawn off. A few miles below Herat the river begins to turn N.W.; and after passing for many miles through a woody tract, abounding in game, in which are the preserves of the Herat princes, at the ancient and now nearly deserted town of Kassan, 70 miles from Herat, it turns due north. Though the drainage brought down by this river must be large, so much is drawn off that, below Herat, reaches of it are at times quite dry. Below Kassan it receives fresh supplies, and eventually the Meshed stream. It flows on towards Sarakhs, and dwindles away; but accurate information regarding it is still wanting. The channel is shown, in a map lately published, as passing Sarakhs for some 250 miles, and ending in a swamp adjoining the Daman-i-Koh, on the border of the Turkman desert.

Of the rivers that run towards the Indus, south of the Kabul river, the chief are the Kurram and the Gomal.

The *Kurram* drains the southern flanks of Safed Koh. The middle valley of Kurram, forming the district so called, is highly irrigated, well peopled, and crowded with small fortified villages, orchards, and groves, to which a fine background is afforded by the dark pine forests and alpine snows of Safed Koh. The beauty and climate of the valley attracted some of the Mogul emperors of Delhi, and the remains exist of a garden of Shah Jahan's. The river passes the British frontier, and enters the plain country a few miles above Bann, spreading into a wide bed of sand and boulders, till it joins the Indus near Isa-Khel, after a course of more than 200 miles. By the Kurram valley is one of the best routes from India into Afghanistan. It was travelled by Major Lumsden's party in 1857–58.

The *Gomal*, rising in the Sulimani mountains, though in length equal to the Kurram, and draining, with its tributaries, a much larger area, is little more than a winter torrent, diminishing to a mere rivulet, till December, when it begins to swell. At its exit into the plain of the Derajat a local chief threw a dam across its channel; and it is now only in very wet seasons that its waters reach the Indus, near Dera Ismael Khan. Not long before leaving the hills it receives from the S.W. a tributary, the Zhôb, of nearly equal length and size, coming from the vicinity of the Kand and Joba peaks, in long. 68°.

Lakes.—As we know nothing of the lake in which the Lora is said to end, and the greater part of the lake of Seistan (see that article) is excluded from Afghanistan, there remains only the *Ab-i-Istada*, on the Ghilzai plateau. This is about 65 miles S.S.W. of Ghazni, and stands at a height of about 7000 feet, in a site of most barren and dreary aspect, with no tree or blade of grass, and hardly a habitation in sight. It is about 44 miles in circuit, and very shallow; not more than 12 feet deep in the middle. The chief feeder is the Ghazni river. The Afghans speak of a stream draining the lake, but this seems to be unfounded, and the saltness and bitterness of the lake is against it. Fish entering the salt water from the Ghazni river sicken and die.

Provinces and Towns.—The chief political divisions of Afghanistan in recent times are stated to be Kabul, Jalalabad, Ghazni, Kandahar, Herat, and Afghan Turkestan (*q.v.*), to which are sometimes added the command of the Ghilzais and of the Hazaras. This list seems to omit the unruly districts of the eastern table-land, such as Kurram, Khost, &c. But we must not look for the precision of European administration in such a case.

In addition to Kabul, Ghazni, Kandahar, Herat, described under those articles, there are not many places in Afghanistan to be called towns. We notice the following:—

Jalâlâbâd lies, at a height of 1946 feet, in a plain on the south of the Kabul river. It is by road 100 miles from Kabul, and 91 from Peshawar. Between it and Peshawar intervene the Khybar and other adjoining passes; between it and Kabul the passes of Jagdalak, Khurd-Kabul, &c. The place has been visited by no known European since Sir G. Pollock's expedition in 1842. As it then existed, the town, though its walls had an extent of 2100 yards, contained only 300 houses, and a permanent population of 2000. The walls formed an irregular quadrilateral in a ruinous state, surrounded on all sides by buildings, gardens, the remains of the ancient walls, &c., affording cover to an assailant. The town walls were destroyed by Pollock, but have probably been restored.

The highly-cultivated plain is, according to Wood, 25 miles in length by 3 or 4 miles in breadth; the central part covered with villages, castles, and gardens. It is abundantly watered

The province under Jalalabad is about 80 miles in length by 35 in width, and includes the large district of Laghman, north of the Kabul river, as well as that on the south, which is called Nangnihâr. The former name, properly Lamghân, the seat of the ancient *Lampagœ*, is absurdly derived by the Mahommedans from the patriarch Lamech, whose tomb they profess to show; the latter name is interpreted (in mixed Pushtu and Arabic) to mean "nine rivers," an etymology supported by the numerous streams. The word is, however, really a distortion of the ancient Indian name *Nagarahâra*, borne by a city in this plain long before Islam, and believed to have been the *Nagara* or *Dionysopolis* of Ptolemy. Many topes and other Buddhist traces exist in the valley, but there are no unruined buildings of any moment. Baber laid out fine gardens here; and his grandson (Jalâluddîn) Akbar built Jalalabad. Hindus form a considerable part of the town population, and have a large temple. The most notable point in the history of Jalalabad is the stout and famous defence made there, from November 1841 till April 1842, by Sir Robert Sale.

Istâlif is a town in the Koh Daman, 20 miles N.N.W. of Kabul, which was stormed and destroyed, 29th September 1842, by a force under General M'Caskill, to punish the towns-people for the massacre of the garrison at Charikar, and for harbouring the murderers of Burnes. The place is singularly picturesque and beautiful. The rude houses rise in terrace over terrace on the mountain-side, forming a pyramid, crowned by a shrine embosomed in a fine clump of planes. The dell below, traversed by a clear rapid stream, both sides of which are clothed with vineyards and orchards, opens out to the great plain of the Daman-i-Koh, rich with trees and cultivation, and dotted with turreted castles; beyond these are rocky ridges, and over all the eternal snows of Hindu Kush. Nearly every householder has his garden with a tower, to which the families repair in the fruit season, closing their houses in the town. The town is estimated, with seven villages depending on it, to contain about 18,000 souls.

Chârîkâr (population 5000) lies about 20 miles north of Istalif, at the north end of Koh Daman, and watered by a canal from the Ghorband branch of the Baran river. Hereabouts must have been the *Triodon*, or meeting of the three roads from Bactria, spoken of by Strabo and Pliny. It is still the seat of the customs levied on trade with Turkestan, and also of the governor of the Kohistân or hill country of Kabul, and is a place of considerable trade with the regions to the north. During the British occupation a political agent (Major Eldred Pottinger, famous in the defence of Herat) was posted here with a Gûrkha corps under Captain Codrington and Lieutenant Haughton. In the revolt of 1841, after severe fighting, they attempted to make their way to Kabul, and a great part was cut off. Pottinger, Haughton (with the loss of an arm), and one sepoy only, reached the city then; though many were afterwards recovered.

Kala't-i-Ghilzai has no town, but is a fortress of some importance on the right bank of the Tarnak, on the road between Ghazni and Kandahar, 89 miles from the latter, and at a height of 5773 feet. The repulse of the Afghans in 1842 by a sepoy garrison under Captain Craigie, was one of the most brilliant feats of that war.

Girishk is also a fort rather than a town, the latter being insignificant. It is important for its position on the high road between Kandahar and Herat, commanding the ordinary passage and summer ford of the Helmand. It was held by the British from 1839 till August 1842, but during the latter nine months, amid great difficulties, by a native garrison only, under a gallant Indian soldier, Balwant Singh.

Farrah belongs to the Seistan basin, and stands on the river that bears its name, and on one of the main routes from Herat to Kandahar, 164 miles from the former, 236 miles from the latter. The place is enclosed by a huge earthen rampart, crowned with towers, and surrounded by a wide and deep ditch, which can be flooded, and with a covered way. It has the form of a parallelogram, running north and south, and only two gates. As a military position it is of great importance, but it is excessively unhealthy. Though the place would easily contain 4500 houses, there were but 60 habitable when Ferrier was there in 1845, nor was there much change for the better when Colonel Pelly passed in 1858. Farrah is a place of great antiquity; certainly, it would seem, the *Phra* of Isidore of Charax (1st century), and possibly *Prophthasia*, though this is more probably to be sought in the great ruins of Peshâwarân, farther south, near Lâsh. According to Ferrier, who alludes to "ancient chronicles and traditions," the city on the present site within the great rampart was sacked by the armies of Chinghiz, and the survivors transported to another position, one hour further north, where there are now many ruins and bricks of immense size (a yard square), with cuneiform letters, showing that site again to be vastly older than Chinghiz. The population came back to the southern site after the destruction of the mediæval city by Shah Abbas, and the city prospered again till its bloody siege by Nadir Shah. Since then, under constant attacks, it has declined, and in 1837 the remaining population, amounting to 6000, was carried off to Kandahar. Such are the vicissitudes of a city on this unhappy frontier.

Sabzvâr, the name of which is a corruption of old Persian, *Isphizar*, "horse-pastures," is another important strategic point, 93 miles from Herat and 71 miles north of Farrah, in similar decay to the latter. The present fort, which in 1845 contained a small bazar and 100 houses, must once have been the citadel of a large city, now represented by extensive suburbs, partly in ruins. Water is conducted from the Harut by numerous canals, which also protect the approaches.

Zarni is a town in the famous but little known country of Ghur, to the east of Herat, the cradle of a monarchy (the Ghurid dynasty) which supplanted the Ghaznevides, and ruled over an extensive dominion, including all Afghanistan, for several generations. Zarni, according to Ferrier, was the old capital of Ghur. Ruins abound; the town itself is small, and enclosed by a wall in decay. It lies in a pleasant valley, through which fine streams wind, said to abound with trout. The hills around are covered with trees, luxuriantly festooned with vines. The population in 1845 was about 1200, among whom Ferrier noticed (a remarkable circumstance) some Gheber families. The bulk of the people are *Sûris* and *Taimûnis*, apparently both very old Persian tribes.

CLIMATE.—The variety of climate is immense, as might be expected. At Kabul, and over all the northern part of the country to the descent at Gandamak, winter is rigorous, but especially so on the high Arachosian plateau. In Kabul the snow lies for two or three months; the people seldom leave their houses, and sleep close to stoves. At Ghazni the snow has been known to lie long beyond the vernal equinox; the thermometer sinks to 10° and 15° below zero (Fahr.); and tradition relates the entire destruction of the population of Ghazni by snow-storms more than once.

At Jalalabad the winter and the climate generally assume an Indian character, and the hot weather sometimes brings the fatal *simûm*. The summer heat is great everywhere in Afghanistan, but most of all in the districts bordering on the Indus, especially Sewi, on the lower Helmand, and in Seistan. All over Kandahar province the summer heat is intense, and the simum is not unknown. The hot season throughout the "Khorasan" part of the country is rendered more trying by frequent dust-storms and fiery winds; whilst the bare rocky ridges that traverse the country, absorbing heat by day and radiating it by night, render the summer nights most oppressive. At Girishk, Ferrier records the thermometer in August to have reached 118° to 120° (Fahr.) in the shade. At Kabul the summer sun has much of its Indian power, though the heat is tempered occasionally by breezes from Hindu Kush, and the nights are usually cool. Baber says that, even in summer, one could not sleep at Kabul without a sheepskin, but this seems exaggerated. At Kandahar snow seldom falls on the plains or lower hills; when it does, it melts at once.

At Herat, though 800 feet lower than Kandahar, the summer climate appears to be more temperate; and, in fact, the climate altogether is one of the most agreeable in Asia. In July, Ferrier says he found the heat never to pass 98°, and rarely 91° to 93° (Fahr.) These are not low figures, but must be compared with his register at Girishk, just given. From May to September the wind blows from the N.W. with great violence, and this extends across the country to Kandahar. The winter is tolerably mild; snow melts as it falls, and even on the mountains does not lie long. Three years out of four at Herat it does not freeze hard enough for the people to store ice; yet it was not very far from Herat, and could not have been at a greatly higher level (at Kafir Kala', near Kassan) that, in 1750, Ahmed Shah's army, retreating from Persia, is said to have lost 18,000 men from cold in a single night.

The summer rains that accompany the S.W. monsoon in India, beating along the southern slopes of the Himalya, travel up the Kabul valley, at least to Laghman, though they are more clearly felt in Bajaur and Panjkora, under the high spurs of the Hindu Kush, and in the eastern branches of Safed Koh. Rain also falls at this season at the head of Kurram valley. South of this the Sulimani mountains may be taken as the western limit of the monsoon's action. It is quite unfelt in the rest of Afghanistan, in which, as in all the west of Asia, the winter rains are the most considerable. The spring rain, though less copious, is more important to agriculture than the winter rain, unless where the latter falls in the form of snow. Speaking generally, the Afghanistan climate is a dry one. The sun shines with splendour for three-fourths of the year, and the nights are even more beautiful than the days. Marked characteristics are the great differences of summer and winter temperature and of day and night temperature, as well as the extent to which change of climate can be attained by slight change of place. As Baber again says of Kabul, at one day's journey from it you may find a place where snow never falls, and at two hours' journey, a place where snow almost never melts!

The Afghans vaunt the salubrity and charm of some local climates, as of the Tobah hills above the Kakar country, and of some of the high valleys of the Safed Koh.

The people have by no means that immunity from disease which the bright dry character of the climate and the fine physical aspect of a large proportion of them might lead us to expect. Intermittent and remittent fevers are very prevalent: bowel complaints are common, and often fatal in the autumn. The universal custom of sleeping on the house-top in summer promotes rheumatic and neuralgic affections; and in the Koh Daman of Kabul, which the natives regard as having the finest of climates, the mortality from fever and bowel complaint, between July and October, is great; the immoderate use of fruit predisposing to such ailments. Stone is frequent; eye disease is very common, as are hæmorrhoidal affections and syphilitic diseases in repulsive forms. A peculiar skin disease of syphilitic origin prevails at Kandahar, and native physicians there are said by Bellew to admit that hardly one person in twenty is free from the taint in some form.

NATURAL PRODUCTIONS—*Minerals.*—Afghanistan is believed to be rich in minerals, but few are wrought. Some small quantity of gold is taken from the streams in Laghman and the adjoining districts. Famous silver mines were formerly wrought near the head of the Panjshir valley, in Hindu Kush. Iron of excellent quality is produced in the (independent) territory of Bajaur, north-west of Peshawar, from magnetic iron sand, and is exported. Kabul is chiefly supplied from the Permûli (or Farmûli) district, between the Upper Kurram and Gomal, where it is said to be abundant. Iron ore is most abundant near the passes leading to Bamian, and in other parts of Hindu Kush. Copper ore from various parts of Afghanistan has been seen, but it is nowhere worked.

Lead is found, *e.g.*, in Upper Bangash (Kurram district), and in the Shinwari country (also among the branches of Safed Koh), and in the Kakar country. There are reported to be rich lead mines near Herat scarcely worked. Lead, with antimony, is found near the Arghand-ab, 32 miles north-west of Kala't-i-Ghilzai; in the Wardak hills, 24 miles north of Ghazni; in the Ghorband valley, north of Kabul; and in the Afridi country, near our frontier. Most of the lead used, however, comes from the Hazara country, where the ore is described as being gathered on the surface. An ancient mine of great extent and elaborate character exists at Feringal, in the Ghorband valley. Antimony is obtained in considerable quantities at Shah-Maksud, about 30 miles north of Kandahar.

Silicate of zinc in nodular fragments comes from the Zhob district of the Kakar country. It is chiefly used by cutlers for polishing.

Sulphur is said to be found at Herat, dug from the soil in small fragments, but the chief supply comes from the Hazara country, and from Pirkisri, on the confines of Seistan, where there would seem to be a crater, or fumarole. Sal-ammoniac is brought from the same place. Gypsum is found in large quantities in the plain of Kandahar, being dug out in fragile coralline masses from near the surface.

Coal (perhaps lignite) is said to be found in Zurmat (between the Upper Kurram and the Gomal) and near Ghazni.

Nitre abounds in the soil over all the south-west of Afghanistan, and often affects the water of the *kârez*, or subterranean canals.

VEGETABLE KINGDOM.[1]—The characteristic distribution of vegetation on the mountains of Afghanistan is worthy of attention. The great mass of it is confined to the main ranges and their immediate offshoots, whilst on the more distant and terminal prolongations it is almost entirely absent; in fact, these are naked rock and stone.

Take, for example, the Safed Koh. On the alpine range itself and its immediate branches, at a height of 6000 to 10,000 feet, we have abundant growth of large forest trees, among which conifers are the most noble and prominent, such as *Cedrus Deodara*, *Abies excelsa*, *Pinus longifolia*, *P. Pinaster*, *P. Pinea* (the edible pine), and the larch. We have also the yew, the hazel, juniper, walnut, wild peach, and almond. Growing under the shade of these are several varieties of rose, honeysuckle, currant, gooseberry, hawthorn, rhododendron, and a luxuriant herbage, among which the ranunculus family is important for frequency and number of genera. The lemon and wild vine are also here met with, but are more common on the northern mountains. The walnut and oak (evergreen, holly-leaved, and kermes) descend to the secondary heights, where they become mixed with alder, ash, khinjak, *Arbor-vitæ*, juniper, with species of *Astragalus*, &c. Here also are *Indigoferæ* and dwarf laburnum.

Lower again, and down to 3000 feet, we have wild olive, species of rock-rose, wild privet, acacias and mimosas, barberry, and *Zizyphus;* and in the eastern ramifications of the chain, *Chamærops humilis* (which is applied to a variety of useful purposes), *Bignonia* or trumpet flower, sissu, *Salvadora versica* verbena, acanthus, varieties of *Gesneræ*.

The lowest terminal ridges, especially towards the west, are, as has been said, naked in aspect. Their scanty vegetation is almost wholly herbal; shrubs are only occasional; trees almost non-existent. Labiate, composite, and umbelliferous plants are most common. Ferns and mosses are almost confined to the higher ranges.

In the low brushwood scattered over portions of the dreary plains of the "Khorasan" table-lands, we find leguminous thorny plants of the papilionaceous sub-order, such as camel-thorn (*Hedysarum Alhagi*), *Astragalus* in several varieties, spiny rest-harrow (*Ononis spinosa*), the fibrous roots of which often serve as a tooth-brush; plants of the sub-order *Mimoseæ*, as the sensitive mimosa; a plant of the Rue family, called by the natives *lipâd;* the common wormwood; also certain orchids, and several species of *Salsola*. The rue and wormwood are in general use as domestic medicines—the former for rheumatism and neuralgia; the latter in fever, debility, and dyspepsia, as well as for a vermifuge. The *lipad*, owing to its heavy nauseous odour, is believed to keep off evil spirits. In some places, occupying the sides and hollows of ravines, are found the rose bay (*Nerium Oleander*), called in Persian *khar-zarah*, or ass-bane, the wild laburnum, and various *Indigoferæ*.

In cultivated districts the chief trees seen are mulberry, willow, poplar, ash, and occasionally the plane; but these are due to man's planting.

Uncultivated Products of Value.—One of the most important of these is the gum-resin of *Narthex assafœtida*, which grows abundantly in the high and dry plains of Western Afghanistan, especially between Kandahar and Herat. The depot for it is Kandahar, whence it finds its way to India, where it is much used as a condiment. It is not so used in Afghanistan, but the Seistan people eat the green stalks of the plant preserved in brine. The collection of the gum-resin is almost entirely in the hands of the Kakar clan of Afghans.

In the highlands of Kabul edible rhubarb is an important local luxury. The plants grow wild in the mountains. The bleached rhubarb, which has a very delicate flavour, is altered by covering the young leaves, as they sprout from the soil, with loose stones or an empty jar. The leaf-stalks are gathered by the neighbouring hill people, and carried down for sale. Bleached and unbleached rhubarb are both largely consumed, both raw and cooked.

The walnut and edible pine-nut are both wild growths, which are exported.

The *sanjit* (*Elæagnus orientalis*), common on the banks of water-courses, furnishes an edible fruit. An orchis found in the mountains yields the dried tuber which affords the nutritious mucilage called *salep;* a good deal of this goes to India.

Pistacia khinjak affords a mastic. The fruit, mixed with its resin, is used for food by the Achakzais in Southern Afghanistan. The true pistachio is found only on the northern frontier; the nuts are imported from Badakhshan and Kunduz.

Mushrooms and other fungi are largely used as food, especially by the Hindus of the towns, to whom they supply a substitute for meat.

Manna, of at least two kinds, is sold in the bazaars. One, called *turanjbîn*, appears to exude, in small round tears, from the camel-thorn, and also from the dwarf tamarisk; the other, *sir-kasht*, in large grains and irregular masses, or cakes, with bits of twig imbedded, is obtained from a tree which the natives call *siah chob* (black wood), thought by Bellew to be a *Fraxinus* or *Ornus*.

AGRICULTURE.—In most parts of the country there are two harvests, as generally in India. One of these, called by the Afghans *bahârak*, or the spring crop, is sown in the end of autumn, and reaped in summer. It consists of wheat, barley, and a variety of lentils. The other, called *pâizah* or *tîrmâi*, the autumnal, is sown in the end of spring, and reaped in autumn. It consists of rice, varieties of millet and sorghum, of maize, *Phaseolus Mungo*, tobacco, beet, turnips, &c. The loftier regions have but one harvest.

Wheat is the staple food over the greater part of the country. Rice is largely distributed, but is most abundant in Swat (independent), and best in Peshawar (British). It is also the chief crop in Kurram. In much of the eastern mountainous country *bâjra* (*Holcus spicatus*) is the chief grain. Most English and Indian garden-stuffs are cultivated; turnips in some places very largely, as cattle food.

The growth of melons, water-melons, and other cucurbitaceous plants is reckoned very important, especially near towns; and this crop counts for a distinct harvest.

Sugar-cane is grown only in the rich plains; and though cotton is grown in the warmer tracts, most of the cotton cloth is imported.

Madder is an important item of the spring crop in Ghazni and Kandahar districts, and generally over the west, and supplies the Indian demand. It is said to be very profitable, though it takes three years to mature.

---

[1] Chiefly from Bellew.

Saffron is grown and exported. The castor-oil plant is everywhere common, and furnishes most of the oil of the country. Tobacco is grown very generally; that of Kandahar has much repute, and is exported to India and Bokhara. Two crops of leaves are taken.

Lucerne and a trefoil called *shaftal* form important fodder crops in the western parts of the country, and, when irrigated, are said to afford ten or eleven cuttings in the season. The *komal* (*Prangos pabularia*) is abundant in the hill country of Ghazni, and is said to extend through the Hazara country to Herat. It is stored for winter use, and forms an excellent fodder. Others are derived from the *Holcus sorghum*, and from two kinds of panick. It is common to cut down the green wheat and barley before the ear forms, for fodder, and the repetition of this, with barley at least, is said not to injure the grain crop. Bellew gives the following statement of the manner in which the soil is sometimes worked in the Kandahar district:—Barley is sown in November; in March and April it is twice cut for fodder; in June the grain is reaped, the ground is ploughed and manured, and sown with tobacco, which yields two cuttings. The ground is then prepared for carrots and turnips, which are gathered in November or December.

Of great moment are the fruit crops. All European fruits are produced profusely, in many varieties, and of excellent quality. Fresh or preserved, they form a principal food of a large class of the people, and the dry fruit is largely exported. In the valleys of Kabul, mulberries are dried, and packed in skins for winter use. This mulberry cake is often reduced to flour, and used as such, forming in some valleys the main food of the people.

Grapes are grown very extensively, and the varieties are very numerous. The vines are sometimes trained on trellises, but most frequently over ridges of earth 8 or 10 feet high. The principal part of the garden lands in villages round Kandahar is vineyard, and the produce must be enormous.

Open canals are usual in the Kabul valley, and in eastern Afghanistan generally; but over all the western parts of the country much use is made of the *karez*, which is a subterranean aqueduct uniting the waters of several springs, and conducting their combined volume to the surface at a lower level. Elphinstone had heard of such conduits 36 miles in length.

Animal Kingdom.—As regards vertebrate zoology, Afghanistan lies on the frontier of three regions, viz., the *Eurasian*, the *Ethiopian* (to which region Biluchestan seems to belong), and the *Indo-Malayan*. Hence it naturally partakes somewhat of the forms of each, but is in the main *Eurasian*.

Mammals.—Monkeys are stated by Mr Bellew to exist in Yusufzai, and perhaps extend to some other districts north of the Kabul river; but no species has been named.

Felidæ.—*F. catus*, *F. chaus* (both Eurasian); *F. caracal* (Eur., Ind., Ethiop.), about Kandahar; a small leopard, stated to be found almost all over the country, perhaps rather the cheeta (*F. jubatus*, Ind. and Eth.); *F. pardus*, the common leopard (Eth. and Ind.) The tiger is said to exist in the north-eastern hill country, which is quasi-Indian.

Canidæ.—The jackal (*C. aureus*, Euras., Ind., Eth.) abounds on the Helmand and Argand-ab, and probably elsewhere. Wolves (*C. Bengalensis*) are formidable in the wilder tracts, and assemble in troops on the snow, destroying cattle, and sometimes attacking single horsemen. The hyæna (*H. striata*, Africa to India) is common. These do not hunt in packs, but will sometimes singly attack a bullock: they and the wolves make havoc among sheep. A favourite feat of the boldest of the young men of southern Afghanistan is to enter the hyæna's den, single-handed, muffle and tie him. There are wild dogs, according to Elphinstone and Conolly. The small Indian fox (*Vulpes Bengalensis*) is found; also *V. flavescens*, common to India and Persia, the skin of which is much used as a fur.

Mustelidæ.—Species of Mungoose (*Herpestes*), species of otter, *Mustela erminea*, and two ferrets, one of them with tortoise-shell marks, tamed by the Afghans to keep down vermin; a marten (*M. flavigula*, Indian).

Bears are two: a black one, probably *Ursus torquatus;* and one of a dirty yellow, *U. Isabellinus*, both Himalyan species.

Ruminants.—*Capra ægagrus* and *C. megaceros;* a wild sheep (*Ovis cycloceros* or *Vignei*); *Gazella subgutturosa*—these are often netted in batches when they descend to drink at a stream; *G. dorcas*, perhaps; *Cervus Wallichii*, the Indian barasingha, and probably some other Indian deer, in the north-eastern mountains.

The wild hog (*Sus scrofa*) is found on the Lower Helmand. The wild ass, *Gorkhar* of Persia (*Equus onager*), is frequent on the sandy tracts in the south-west. Neither elephant nor rhinoceros now exists within many hundred miles of Afghanistan; but there is ample evidence that the latter was hunted in the Peshawar plain down to the middle of the 16th century.

Talpidæ.—A mole, probably *T. Europæa; Sorex Indicus; Erinaceus collaris* (Indian), and *Er. auritus* (Eurasian).

Bats, believed to be *Phyllorhinus cineraceus* (Panjab species), *Scotophilus Bellii* (W. India), *Vesp. auritus* and *V. barbastellus*, both found from England to India.

Rodentia.—A squirrel (*Sciurus Syriacus?*); *Mus Indicus* and *M. Gerbellinus;* a gerboa (*Dipus telum?*); *Alactaga Bactriana; Gerbillus Indicus*, and *G. erythrinus* (Persian and Indian); *Lagomys Nepalensis*, a central Asian species. A hare, probably *L. ruficaudatus*.

Birds.—The largest list of Afghan birds that we know of is given by Captain Hutton in the *J. As. Soc. Bengal*, vol. xvi. p. 775, *seqq.;* but it is confessedly far from complete. Of 124 species in that list, 95 are pronounced to be Eurasian, 17 Indian, 10 both Eurasian and Indian, 1 (*Turtur risorius*) Eur., Ind., and Eth.; and 1 only, *Carpodacus* (*Bucanetes*) *crassirostris*, peculiar to the country. Afghanistan appears to be, during the breeding season, the retreat of a variety of Indian and some African (desert) forms, whilst in winter the *avifauna* becomes overwhelmingly Eurasian.

Reptiles.—The following particulars are from Gray:—Lizards—*Pseudopus gracilis* (Eur.), *Argyrophis Horsfieldii, Salea Horsfieldii, Calotes Maria, C. versicolor, C. minor, C. Emma, Phrynocephalus Tickelii*—all Indian forms. A tortoise (*T. Horsfieldii*) appears to be peculiar to Kabul. There are apparently no salamanders or tailed Amphibia. The frogs are partly Eurasian, partly Indian. And the same may be said of the fish; but they are as yet most imperfectly known.

Domestic Animals.—The camel is of a more robust and compact breed than the tall beast used in India, and is more carefully tended. The two-humped Bactrian camel is sometimes seen, but is not a native.

Horses form a staple export to India. The best of these, however, are brought from Maimana and other places on the Khorasan and Turkman frontier. The indigenous horse is the *yâbû*, a stout, heavy-shouldered animal, of about 14 hands high, used chiefly for burden, but also for riding. It gets over incredible distances at an ambling shuffle; but is unfit for fast work, and cannot stand excessive heat. The breed of horses was improving much under the Amir Dost Mahommed, who took much interest in it. Generally, colts are sold and worked too young.

The cows of Kandahar and Seistan give very large quantities of milk. They seem to be of the humped variety, but with the hump evanescent. Dairy produce is important in Afghan diet, especially the pressed and dried curd called *krût* (an article and name perhaps introduced by the Mongols).

There are two varieties of sheep, both having the fat tail. One bears a white fleece, the other a russet or black one. Much of the white wool is exported to Persia, and now largely to Europe by Bombay. Flocks of sheep are the main wealth of the nomad population, and mutton is the chief animal food of the nation. In autumn large numbers are slaughtered, their carcases cut up, rubbed with salt, and dried in the sun. The same is done with beef and camel's flesh.

The goats, generally black or parti-coloured, seem to be a degenerate variety of the shawl-goat.

The climate is found to be favourable to dog-breeding. Pointers are bred in the Kohistan of Kabul and above Jalalabad—large, heavy, slow-hunting, but fine-nosed and staunch; very like the old double-nosed Spanish pointer. There are greyhounds also, but inferior in speed to second-rate English dogs. The *khandi* is another sporting dog, most useful, but of complex breed. He is often used for turning up quail and partridge to the hawk.

INDUSTRIAL PRODUCTS.—These are not important. Silk is produced in Kabul, Jalalabad, Kandahar, and Herat, and chiefly consumed in domestic manufactures, though the best qualities are carried to the Panjab and Bombay.

Excellent carpets—soft, brilliant, and durable in colour—are made at Herat. They are usually sold in India as Persian. Excellent felts and a variety of woven goods are made from the wool of the sheep, goat, and Bactrian camel. A manufacture, of which there is now a considerable export to the Panjab for the winter clothing of our irregular troops, besides a large domestic use, is that of the *postîn*, or sheepskin pelisse. The long wool remains on, and the skin is tanned yellow, with admirable softness and suppleness. Pomegranate rind is a chief material in the preparation.

Rosaries are extensively made at Kandahar from a soft crystallised silicate of magnesia (chrysolite). The best are of a semi-transparent straw colour, like amber. They are largely exported, especially to Mecca.

TRADE.—Practically, there are no navigable rivers in Afghanistan, nor does there exist any wheeled carriage. Hence goods are carried on beasts of burden, chiefly camels, along roads which often lie through close and craggy defiles, and narrow stony valleys among bare mountains, or over waste plains. Though from time immemorial the larger part of the products of India destined for western Asia and Europe has been exported by sea, yet at one time valuable caravans of these products, with the same destination, used to traverse these rugged Afghan roads.

The great trade routes are the following:—

1. From Persia by Mesh'hed to Herat.
2. From Bokhara by Merv to Herat.
3. From the same quarter by Karshi, Balkh, and Khulm, to Kabul.
4. From the Panjab by Peshawar and the Tatara or Abkhanah Passes to Kabul.
5. From the Panjab by the Ghawalâri Pass towards Ghazni.
6. From Sind by the Bolan Pass to Kandahar.

There is also a route from eastern Turkistan by Chitral to Jalalabad, or to Peshawar by Dir: but it is doubtful how far there is any present traffic by it.

Towards Sind the chief exports from or through Afghanistan are wool, horses, silk, fruit, madder, and assafœtida. The staple of local production exported from Kandahar is dried fruit. The horse trade in this direction is chiefly carried on by the Syads of Pishin, Kakars, Bakhtiyaris, and Biluchis. The Syads also do, or did, dabble largely in slave-dealing. The Hazaras furnished the largest part of the victims.

Burnes's early anticipation of a large traffic in wool from the regions west of the Indus has been amply verified, for the trade has for many years been of growing importance; and in 1871–72 2,000,000 ℔ were shipped from Karâchi. The importation to Sind is chiefly in the hands of Shikarpûr merchants. Indeed, nearly all the trade from southern Afghanistan is managed by Hindus. That between Mesh'hed, Herat, and Kandahar is carried on by Persians, who bring down silk, arms, turquoises, horses, carpets, &c., and take back wool, skins, and woollen fabrics.

The chief imports by Peshawar from India into Afghanistan are cotton, woollen, and silk goods; from England, coarse country cloths, sugar and indigo, Benares brocades, gold thread and lace, scarves, leather, groceries, and drugs. The exports are raw silk and silk fabrics of Bokhara, gold and silver wire (Russian), horses, almonds and raisins, and fruits generally, furs (including dressed fox skins and sheep skins), and bullion.

The trade with India was thus estimated in 1862:—

	Exports to India.	Imports from India.	Totals.
By Peshawar............	£156,513	£120,643	£277,156
By Ghawalari Pass.....	130,000	164,000	294,000
By Bolan Pass..........	31,870	18,892	50,762
	£318,383	£303,535	£621,918

But this omits some passes, and the Bolan exports do not include the large item of wool which enters Sind further south.

A relic of the old times of Asiatic trade has come down to our day in the habits of the class of Lohâni Afghan traders, commonly called *Povindahs*, who spend their lives in carrying on traffic between India, Khorasan, and Bokhara, by means of their strings of camels and ponies, banded in large armed caravans, in order to restrict those recurring exactions that would render trade impossible. Bullying, fighting, evading, or bribing, they battle their way twice a year between Bokhara and the Indus. Their summer pastures are in the highlands of Ghazni and Kala't-i-Ghilzai. In the autumn they descend the Sulimani passes. At the Indus, in these days, they have to deposit all weapons; but once across that, they are in security. They leave their families and their camels in the Panjab plains, and take their goods by rail to all the Gangetic cities, or by boat and steamer to Karachi and Bombay. Even in Asam or in distant Rangoon the Povindah is to be seen, pre-eminent by stature and by lofty air, not less than by rough locks and filthy clothes. In March they rejoin their families, and move up again to the Ghilzai highlands, sending on caravans anew to Kabul, Bokhara, Kandahar, and Herat, the whole returning in time to accompany the tribe down the passes in the autumn. The Povindah trade by all the passes is now estimated to reach £1,500,000 in value annually.

INHABITANTS OF AFGHANISTAN.—These may first be divided into Afghan and non-Afghan, of whom the Afghan people are predominant in numbers, power, and character.

The Afghans themselves do not recognise as entitled to that name all to whom we give it. According to Bellew they exclude certain large tribes, who seem, nevertheless, to be essentially of the same stock, speaking the same language, observing the same customs, and possessing the same moral and physical characteristics. These are recognised as *Pathâns*, but not as *Afghans*, and are all located in the vicinity of the Sulimani mountains and their offshoots towards the east. We do not attempt to name them, because the information on the subject seems contradictory. There are tribes of somewhat similar character elsewhere, such as the Wardaks, to the south of Kabul; and there are again some tribes, in contact with these and with Afghan tribes, who speak the Afghan language, and have many Afghan customs, but are different in aspect, and seem not to be regarded as Pathan at all. Such are the Tûris and Jâjis of Kurram.

Of the Afghans proper there are about a dozen great clans, with numerous subdivisions. Of the great clans the following are the most important:—

The *Durrânis*, originally called Abdalis, received the former name from a famous clansman, Ahmed Shah. Their country may be regarded as the whole of the south and south-west of the Afghan plateau.

The *Ghilzais* are the strongest of the Afghan clans, and perhaps the bravest. They were supreme in Afghanistan in the beginning of last century, and for a time possessed the throne of Ispahan. They occupy the high plateau north of Kandahar, and extend, roughly speaking, eastward to the Sulimani mountains, and north to the Kabul river (though in places passing these limits), and they extend down the Kabul river to Jalalabad. On the British invasion the Ghilzais showed a rooted hostility to the foreigner, and great fidelity to Dost Mahommed, though of a rival clan. It is remarkable that the old Arab geographers of the 10th and 11th centuries place in the Ghilzai country a people called *Khilijis*, whom they call a tribe of *Turks*, to which belonged a famous family of Dehli kings. The probability of the identity of Khilijis and Ghilzais is obvious, and the question touches others regarding the origin of the Afghans, but it does not seem to have been gone into.

The *Yusufzais* occupy an extensive tract of hills and valleys north of Peshawar, including part of the Peshawar plain. Except those within our Peshawar district, they are independent; they are noted even among Afghans for their turbulence.

The *Kakars*, still retaining in great measure their independence, occupy a wide extent of elevated country in the south-east of Afghanistan, among the spurs of the Toba and Sulimani mountains, bordering on the Biluch tribes. But the region is still very imperfectly known.

Of the non-Afghan population associated with the Afghans, the *Tâjiks* come first in importance and numbers. They are intermingled with the Afghans over the country, though their chief localities are in the west. They are regarded as descendants of the original occupants of that part of the country, of the old Iranian race; they call themselves Parsiwân, and speak a dialect of Persian. They are a fine athletic people, generally fair in complexion, and assimilate in aspect, in dress, and much in manners to the Afghans. But they are never nomadic. They are mostly agriculturists, whilst those in towns follow mechanical trades and the like, a thing which the Afghan never does. They are generally devoid of the turbulence of the Afghans, whom they are content to regard as masters or superiors, and lead a frugal, industrious life, without aspiring to a share in the government of the country. Many, however, become soldiers in the Amir's army, and many enlist in our local Panjab regiments. They are zealous Sunnis. The Tajiks of the Daman-i-Koh of Kabul are said to be exceptional in turbulent and vindictive character.

The *Kizilbâshes* may be regarded as modern Persians, but more strictly they are Persianised Turks, like the present royal race and predominant class in Persia. They speak pure Persian. Their immigration dates only from the time of Nadir Shah (1737). They are chiefly to be found in towns as merchants, physicians, scribes, petty traders, &c., and are justly looked on as the more educated and superior class of the population. At Kabul they constitute the bulk of the Amir's cavalry and artillery. Many serve in our Indian regiments of irregular cavalry, and bear a character for smartness and intelligence, as well as good riding. They are Shiahs, and heretics in Afghan eyes.

It is to the industry of the Parsiwans and Kizilbashes that the country is indebted for whatever wealth it possesses, but few of them ever attain a position which is not in some degree subservient to the Afghan.

The *Hazâras* have their stronghold and proper home in the wild mountainous country on the north-west of Afghanistan proper, including those western extensions of Hindu Kush, to which modern geographers have often applied the ancient name of *Paropamisus*. In these their habitations range generally from a height of 5000 feet to 10,000 feet above the sea.

The Hazaras generally have features of Mongol type, often to a degree that we might call exaggerated, and there can be no doubt that they are mainly descended from fragments of Mongol tribes who came from the east with the armies of Chinghiz Khan and his family, though other races may be represented among the tribes called Hazaras. The Hazaras generally are said by Major Leech to be called *Moghals* by the Ghilzais; and one tribe, still bearing the specific name of Mongol, and speaking a Mongol dialect, is found near the head waters of the Murghab, and also further south on the skirts of the Ghur mountains. But it is remarkable that the Hazaras generally speak a purely Persian dialect. The Mongols of the host of Chinghiz were divided into *tomans* (ten thousands) and *hazaras* (thousands), and it is probably in this use of the word that the origin of its present application is to be sought. The oldest occurrence of this application that M. de Khanikoff has met with is in a rescript of Ghazan Khan of Persia, regarding the security of roads in Khorasan, dated A.H. 694 (A.D. 1294–95).

Though the Hazaras pay tribute to the Afghan chiefs, they never do so unless payment is enforced by arms. The country which they occupy is very extensive, embracing the upper valleys of the Arghand-ab and the Helmand, both sides of the main range of Hindu Kush, nearly as far east as the longitude of Andarâb, the hill country of Bamian, and that at the head waters of the Balkh river, the Murghab, and the Hari-Rud; altogether an area of something like 30,000 square miles. The Hazaras are accused of very loose domestic morals, like the ancient *Massagetæ*, and the charge seems to be credited, at least of certain tribes. They make good powder, are good shots, and, in spite of the nature of their country, are good riders, riding at speed down very steep declivities. They are said to have a *yodel* like the Swiss. They are often sold as slaves, and as such are prized. During the winter many spread over Afghanistan, and even into the Panjab, in search of work. Excepting near Ghazni, where they hold some lands and villages, the position of the Hazaras found in the proper Afghan country is a menial one. They are Shiahs in religion, with the exception of one fine tribe called the Zeidnat Hazaras, occupying the old territory of Badghis, north of Herat.

Eimâk is a term for a sept or section of a tribe. It has come to be applied, much as *hazara*, to certain nomadic or semi-nomadic tribes west of the Hazaras of whom we have been speaking, and immediately north of Herat. These tribes, it is said, were originally termed "the four Eimaks." It is difficult in the present state of information regarding them, sometimes contradictory, to discern what is the broad distinction between the Eimaks and the Hazaras, unless it be that the Eimaks are predominantly of Iranian or quasi-Iranian blood, the Hazaras Turanian. The Eimaks are also Sunnis. Part of them are subject to Persia.

Hindkis.—This is the name given to people of Hindu descent scattered over Afghanistan. They are said to be of the *Kshatri* or military caste. They are occupied in trade; they are found in most of the large villages, and in the towns form an important part of the population, doing all the banking business of the country, and holding its chief trade in their hands. They pay a high poll-tax, and are denied many privileges, but thrive notwithstanding. The *Jats* of Afghanistan doubtless belong to the same vast race as the Jats and Jâts who form so large a part of the population of the territories now governed from Lahore and Karachi, and whose origin is so obscure. They are a fine athletic, dark, handsome race, considerable in numbers, but poor, and usually gaining a livelihood as farm-servants, barbers, sweepers, musicians, &c.

Bilûchis.—Many of these squat among the abandoned tracts on the lower Helmand; a fierce and savage people, professing Islam, but not observing its precepts, and holding the grossest superstitions; *vendetta* their most stringent law; insensible to privation, and singularly tolerant of heat; camel-like in capacity to do without drink; superior to the Afghans in daring and address, which are displayed in robber raids carried into the very heart of Persia.

There remain a variety of tribes in the hill country north of the Kabul river, speaking various languages, seemingly of *Prakritic* character, and known as Kohistanis, Laghmanis, Pashais, &c.; apparently converted remnants of the aboriginal tribes of the Kabul basin, and more or less kindred to the still unconverted tribes of Kafiristan, to the Chitral people, and perhaps to the Dard tribes who lie to the north of the Afghan country on the Indus.

An able officer of the staff in India (Col. Macgregor) has lately made a diligent attempt to estimate the population of Afghanistan, which he brings to 4,901,000 souls. This includes the estimated population of Afghan Turkestan, the people of Chitral, the Kafirs, and the independent Yusufzais. We shall deduct the three first:—

		4,901,000
Afghan Turkestan	642,000	
Chitralis and Kafirs	150,000	
		792,000
		4,109,000

which may be thus roughly divided—

Eimaks and Hazaras	400,000
Tajiks	500,000
Kizilbashes	150,000
Hindkis and Jats	500,000
Kohistanis, &c.	200,000
Afghans and Pathans, including 400,000 independent Yusufzais, &c.	2,359,000
Total	4,109,000

The Afghans, in government and general manners, have a likeness to other Mahommedan nations; but they have also many peculiarities.

Besides their division into clans and tribes, the whole Afghan people may be divided into dwellers in tents and dwellers in houses; and this division is apparently not coincident with tribal divisions, for of several of the great clans, at least a part is nomad and a part settled. Such, *e.g.*, is the case with the Durrani and with the Ghilzai.

Nomad Afghans exist in the Kabul basin, but their proper field is that part of their territory which the Afghans include in Khorasan, with its wide plains. These people subsist on the produce of their flocks, and rarely cultivate. They may, perhaps, pay something to the Kabul government through their chief, and they contribute soldiers to the regular army, besides forming the bulk of the militia; but they have little relation to the government, and seldom enter towns unless to sell their produce. They are under some indefinite control by their chiefs, to whom serious disputes are referred. Petty matters are settled by the "greybeards" of the community, guided by the Afghan traditional code. Many of the nomad tribes are professed and incorrigible thieves. Among certain tribes the ceremony of naming a male child is accompanied by the symbolical act of passing him through a hole made in the wall of a house, whilst a volley of musketry is fired overhead.[1]

The settled Afghans form the village communities, and in part the population of the few towns. Their chief occupation is with the soil. They form the core of the nation and the main part of the army. Nearly all own the land on which they live, and which they cultivate with their own hands or by hired labour. Roundly speaking, agriculture and soldiering are their sole occupations. No Afghan will pursue a handicraft or keep a shop, though, as we have seen, certain pastoral tribes engage largely in travelling trade and transport of goods.

As a race, the Afghans are very handsome and athletic, often with fair complexion and flowing beard, generally black or brown, sometimes, though rarely, red; the features highly aquiline. The hair is shaved off from the forehead to the top of the head, the remainder at the sides being allowed to fall in large curls over the shoulders. Their step is full of resolution; their bearing proud and apt to be rough.

The women have handsome features of Jewish cast (the last trait often true also of the men); fair complexions, sometimes rosy, though usually a pale sallow; hair braided and plaited behind in two long tresses terminating in silken tassels. They are rigidly secluded, but intrigue is frequent. In some parts of the country the engaged lover is admitted to visits of courtship, analogous to old Welsh customs.

The Afghans, inured to bloodshed from childhood, are familiar with death, and are audacious in attack, but easily discouraged by failure; excessively turbulent and unsubmissive to law or discipline; apparently frank and affable in manner, especially when they hope to gain some object, but capable of the grossest brutality when that hope ceases. They are unscrupulous in perjury, treacherous, vain, and insatiable, passionate in vindictiveness, which they will satisfy at the cost of their own lives and in the most cruel manner. Nowhere is crime committed on such trifling grounds, or with such general impunity, though when it is punished the punishment is atrocious. Among themselves the Afghans are quarrelsome, intriguing, and distrustful; estrangements and affrays are of constant occurrence; the traveller conceals and misrepresents the time and direction of his journey. The Afghan is by breed and nature a bird of prey. If from habit and tradition he respects a stranger within his threshold, he yet considers it legitimate to warn a neighbour of the prey that is afoot, or even to overtake and plunder his guest after he has quitted his roof. The repression of crime and the demand of taxation he regards alike as tyranny. The Afghans are eternally boasting of their lineage, their independence, and their prowess. They look on the Afghans as the first of nations, and each man looks on himself as the equal of any Afghan, if not as the superior of all others. Yet when they hear of some atrocious deed they will exclaim—"An Afghan job that!" They are capable of enduring great privation, but when abundance comes their powers of eating astonish an European. Still, sobriety and hardiness characterise the bulk of the people, though the higher classes are too often stained with deep and degrading debauchery.

The first impression made by the Afghans is favourable. The European, especially if he come from India, is charmed by their apparently frank, open-hearted, hospitable, and manly manners; but the charm is not of long duration, and he finds that under this frank demeanour there is craft as inveterate, if not as accomplished, as in any Hindu.

Such is the character of the Afghans as drawn by Ferrier and other recent writers, and undoubtedly founded on their experience, though perhaps the dark colour is laid on too universally. The impression is very different from that left by the accounts of Elphinstone and Burnes. Yet most of the individual features can be traced in Elphinstone, though drawn certainly under less temptation to look on the darker side, owing to the favourable circumstances of his intercourse with the Afghans, and touched with a more delicate and friendly hand, perhaps lightened by wider sympathies. Sir H. Edwardes, who had intimate dealings with the Afghans for many years, takes special exception to Elphinstone's high estimate of their character, and appeals to the experience of every officer who had served in the country. "Nothing," he sums up, "is finer than their physique, or worse than their morale."

Many things in Afghan character point to a nation in decadence—the frank manners and joyous temper, the hospitable traditions, the martial and independent spirit, the love of field sports, the nobility of aspect, suggest a

[1] Of one tribe, at least, of which this is told, the Afghan blood is doubtful.

time when these were more than superficial and deceptive indications of character, and were not marred by greed and treacherous cruelty

Political Institutions.—The political institutions of the Afghans present the rude and disjointed materials of a free constitution. . The nation is theoretically divided into four great stocks, supposed to spring from four brothers. But these four divisions are practically obsolete, and only come up in genealogies. Each tribe has split into several branches, and in the more numerous and scattered tribes these branches have separated, and each has its own chief. They retain, however, the common name, and an idea of community in blood and interests.

The type of the Afghan institutions is perhaps best seen in some of the independent tribes near the British frontier. These cling most closely to the democratic traditions. Their rude state of society is held together by a code as rude, which is acknowledged, however, and understood by every one, and enforced by the community, every member of which considers its infringement as an act committed against his own privileges. The *Maliks* or chiefs are the representatives of the tribe, division, or family to which they each belong, but they possess no independent power of action, and before they can speak in council, they must have collected the wishes of the bodies which they represent.

The men of the section (*kandi*) of a village, having come to a decision, send their representative to a council of the whole village, and these again to that of the sept (*khail*), and the appointed chiefs of the septs finally assemble as the council of the *ûlûs* or tribe. These meetings, in all their stages, are apt to be stormy. If persuasion and argument fail to produce unanimity, no further steps can be taken, unless one party be much the weaker, when sometimes the stronger side will forcibly extort assent. When once a council has decided, implicit compliance is incumbent on the tribe under heavy penalties, and the maliks have the power of enforcing these.

Justice is administered in the towns, more or less defectively, according to Mahommedan law, by a kâzi and muftis. But the unwritten code by which Afghan communities in their typical state are guided, and the maxims of which penetrate the whole nation, is the *Pukhtûnwali*, or usage of the Pathans, a rude system of customary law, founded on principles such as one might suppose to have prevailed before the institution of civil government.[1]

A prominent law in this code is that called *Nanawatai*, or "entering in." By this law the Pathan is bound to grant any boon claimed by the person who passes his threshold and invokes its sanctions, even at the sacrifice of his own life and property. So also the Pathan is bound to feed and shelter any traveller claiming hospitality. *Retaliation* must be exacted by the Pathan for every injury or insult, and for the life of a kinsman. If immediate opportunity fail, a man will dodge his foe for years, with the cruel purpose ever uppermost, using every treacherous artifice to entrap him. To omit such obligations, above all the *vendetta*, exposes the Pathan to scorn. The injuries of one generation may be avenged in the next, or even by remoter posterity. The relatives of a murdered man may, however, before the tribal council, accept a blood-price.

Crimes punished by the Pathan code are such as murder without cause, refusal to go to battle, contravention of the decision of a tribal council, adultery.

The Afghans are Mahommedans of the Sunni or orthodox body, with the exception of a few tribes, perhaps not truly Pathan, who are Shiahs. They are much under the influence of their Mullahs, especially for evil; and have a stronger feeling against the Shiah heretic than against the unbeliever; their aversion to the Persians being aggravated thereby. But to those of another faith they are more tolerant than most Mahommedans, unless when creed becomes a war-cry. They are very superstitious in regard to charms, omens, astrology, and so forth; and greatly addicted to the worship of local saints, whose shrines (*ziyârat*) are found on every hill-top. The shrine, a domed tomb, or mayhap a heap of stones within a wall, sometimes marks the saint's grave, but is often a cenotaph. The saint may have been unknown in life for his virtues, but becomes after death an object of veneration, for reasons often hard to discern. In the immediate environs of Ghazni there are no less than 197 of these shrines.

A very marked feature in Afghan character is the passionate love of field sports, especially hawking. Deer-stalking in the open plains, the driving of game to well-known points by a host of beaters, and wild-fowl shooting with decoys, are others of their sports. They are capital horsemen, and unerring marksmen with the native rifle (*jezail*).

Among themselves the people are convivial and humorous. Festive gatherings are frequent, where they come together, not to buy or sell, or even to quarrel, but to make a noise and be happy. Tilting, shooting, racing, and wild music vary the amusements.

They have a wild dance called the *âtan*, in which the men work themselves into great excitement. Among some Kakar tribes it is said the atan is sometimes danced by both sexes together.

Government.—Afghanistan is now, and has been before, under one prince, but it is hardly a monarchy as we are used to understand the term. It is rather the government of a dictator for life over a military aristocracy, and within this a congeries of small democracies. Elphinstone compares it with Scotland in the middle ages; some things suggest a comparison with Poland, in spite of difference of physical geography; but in neither was there the democratic constitution of the Afghan *ulus*. The sirdars govern in their respective districts, each after his own fashion; jealous, ambitious, turbulent, the sovereign can restrain them only by their divisions. There is no unity nor permanence; everything depends on the pleasure of a number of chiefs bound by no law, always at variance, and always ready to revolt when they have the slightest interest in doing so—almost always ready to plunge into strife with a wild delight in it for its own sake. In war, as in peace, chiefs and soldiers are ready to pass from one service to another without scruple. It is a matter of speculation, and no disgrace.

The spirit of Afghan character and institutions was tersely expressed by an old man to Elphinstone, who had urged the advantages of quiet and security under a strong king: "We are content with discord, we are content with alarms, we are content with blood; but we will never be content with a master."

Revenues.—The revenues of Dost Mahommed Khan were estimated in 1857 at 4,000,000 rupees, or about £400,000. This included Afghan Turkestan, but not Herat, which he did not hold. The Herat revenue was estimated some years before (probably too low) at £80 000. In the later years of Dost Mahommed the net revenue is stated to have amounted to £710,000, of which the army cost £430,000.[1] Information on this subject is very imperfect, and not always consistent. There seems to be a tax on the produce of the soil, both in kind and in money, and a special tax on garden ground. A house-tax of about 5 rupees is paid by all who are not Pathans. The latter pay a much lighter tax under another name; and

[1] Elphinstone.

[1] See *Edin. Review*, July 1873, p. 273.

the Hindus pay the separate poll-tax (*jazeya*). Taxes are paid on horses, &c., kept, and on the sale of animals in the public market.

The aggregate of taxation is not great, but the smallest exaction seems a tyrannical violence to an Afghan. Nor does payment guarantee the cultivator from further squeezing. In many parts of the country collections are only made spasmodically by military force. The people are let alone for years, till need and opportunity arise, when a force is marched in, and arrears extorted.

Customs dues at Kabul and Kandahar are only $2\frac{1}{2}$ per cent. nominally, but this is increased a good deal by exactions. There is a considerable tax on horses exported for sale, and a toll on beasts of burden exporting merchandise, from 6 rupees on a loaded camel to 1 rupee on a donkey.

Military Force.—According to the old system the Afghan forces were entirely composed of the *ulus*, or tribesmen of the chiefs, who were supposed to hold their lands on a condition of service, but who, as frequently as not, went over to the enemy in the day of need. As a counterpoise, the late Amir Dost Mahommed began to form a regular army. In 1858 this contained 16 infantry regiments of (nominally) 800 men, 3 of cavalry of 300 men, and about 80 field-pieces, besides a few heavy guns. The pay was bad, and extremely irregular, and punishments were severe. The men were fine, but recruited in the worst manner, viz., the arbitrary and forcible seizure of able-bodied men. There were also *Jezailchi* (riflemen), irregulars, some in the Amir's pay, others levies of the local chiefs; and a considerable number of irregular cavalry. We have failed to obtain recent data on this subject.

Language and Literature.—Persian is the vernacular of a large part of the non-Afghan population, and is familiar to all educated Afghans. But the proper language of the Afghans is *Pushtû*, or *Pukhtû* (these are dialectic variations). Currency has been given to the notion that this language has a Semitic character, but this appears to be quite erroneous, and is entirely rejected by competent authorities, the majority of whom class Pushtu positively as an Aryan or Indo-Persian language. The Pushtu vocabulary preserves a number of ancient forms and connections with words that remain isolated in other Aryan languages. Interesting illustrations of this and other points connected with Pushtu will be found in a paper by Isidor Löwenthal in the *J. of the As. Soc. of Bengal*. vol. xxix.

Pushtu does not seem to be spoken in Herat, or (roughly speaking) west of the Helmand.

There is a respectable amount of Afghan literature. The oldest work in Pushtu as yet mentioned is a history of the conquest of Swat by Shaikh Mâli, a chief of the Yusufzais, and leader in the conquest (A.D. 1413–24). In 1494 Kâjû Khan became chief of the same clan; during his rule Buner and Panjkora were completely conquered, and he wrote a history of the events. But these works have not been met with. In the reign of Akbar, Bayazîd Ansâri, called Pîr-i-Roshan, "The Saint of Light," the founder of an heretical sect, wrote in Pushtu; as did his chief antagonist a famous Afghan saint called Akhund Darweza.

The literature is richest in poetry. Abdarrahman (17th century) is the best known poet. Another very popular poet is Khushâl Khan, the warlike chief of the Khattaks in the time of Aurangzîb. Many other members of his family were poets also. Ahmed Shah, the founder of the monarchy, likewise wrote poetry. Ballads are numerous.

History.—The Afghan chroniclers call their people *Bani-Israil* (Arab. for Children of Israel), and claim descent from King Saul (whom they call by the Mahommedan corruption *Tâlût*) through a son whom they ascribe to him, called Jeremiah, who again had a son called Afghâna. The numerous stock of Afghana were removed by Nebuchadnezzar, and found their way to the mountains of Ghur and Feroza (east and north of Herat).[1] Only nine years after Mahommed's announcement of his mission they heard of the new prophet, and sent to Medina a deputation headed by a wise and holy man called Kais, to make inquiry. The deputation became zealous converts, and on their return converted their countrymen. From Kais and his three sons the whole of the genuine Afghans claim descent.

This story is repeated in great and varying detail in sundry books by Afghans, the oldest of which appears to be of the 16th century; nor do we know that any trace of the legend is found of older date. In the version given by Major Raverty (Introd. to *Afghan Grammar*), Afghanah is settled by King Solomon himself *in the Sulimani mountains;* there is nothing about Nebuchadnezzar or Ghur. The historian Firishta says he had read that the Afghans were descended from Copts of the race of Pharaoh. And one of the Afghan histories, quoted by Mr Bellew, relates "a current tradition" that previous to the time of Kais, *Bilo* the father of the Biluchis, *Uzbak* (evidently the father of the Uzbegs), and *Afghana* were considered as brethren. As Mahommed Uzbeg Khan, the *eponymus* of the medley of Tartar tribes called Uzbegs, reigned in the 14th century A.D., this gives some possible light on the value of these so-called traditions.

We have analogous stories in the literature of almost all nations that derive their religion or their civilisation from a foreign source. To say nothing of the farce of the *Book of Mormon*, there is in our own age and in our own country a considerable number of persons who seriously hold and propagate the doctrine that the English people are descended from the tribes of Israel, and the literature of this whimsical theory would fill a much larger shelf than the Afghan histories. But the Hebrew ancestry of the Afghans is more worthy at least of consideration, for a respectable number of intelligent officers, well acquainted with the Afghans, have been strong in their belief of it; and though the customs alleged in proof will not bear the stress laid on them, undoubtedly a prevailing type of the Afghan physiognomy has a character strongly Jewish. This characteristic is certainly a remarkable one; but it is shared, to a considerable extent, by the Kashmîris (a circumstance which led Bernier to speculate on the Kashmiris representing the lost tribes of Israel), and, we believe, by the Tajik people of Badakhshan.

In the time of Darius Hystaspes (B.C. 500) we find the region now called Afghanistan embraced in the Achæmenian satrapies, and various parts of it occupied by *Sarangians* (in Seistan), *Arian* (in Herat), *Sattagydians* (supposed in highlands of upper Helmand and the plateau of Ghazni), *Dadicæ* (suggested to be Tajiks), *Aparytæ* (mountaineers, perhaps of Safed Koh, where lay the *Parycta* of Ptolemy), *Gandarii* (in Lower Kabul basin), and *Paktyes*, on or near the Indus. In the last name it has been plausibly suggested that we have the *Pukhtun*, as the eastern Afghans pronounce their name. Indeed, *Pusht*, *Pasht*, or *Pakht*, would seem to be the oldest name of the country of the Afghans in their traditions.

Alexander's march led him to *Artacoana* (Herat?), the capital of *Aria*, and thence to the country of the *Zarangæ* (Seistan), to that of the *Euergetæ*, upon the *Etymander* (Helmand river), to *Arachosia*, thence to the *Indians* dwelling among snows in a barren country, probably the highlands between Ghazni and Kabul. Thence he marched to the foot of Caucasus, and spent the winter among the *Paropamisadæ*, founding a city, *Alexandria*, supposed to be Hupian, near Charikar. On his return from Bactria he prosecuted his march to India by the north side of the Kabul river.

The *Ariana* of Strabo corresponds generally with the existing dominions of Kabul, but overpasses their limits on the west and south.

About 310 B.C. Seleucus is said by Strabo to have given to the Indian Sandrocottus (Chandragupta), in consequence of a marriage-contract, some part of the country west of the Indus, occupied by an Indian population, and no doubt embracing a part of the Kabul basin. Some 60 years later occurred the establishment of an independent Greek dynasty in Bactria. Of the details of their history and extent of their dominion in different reigns we know almost nothing, and conjecture is often dependent on such vague data as are afforded by the collation of the localities in which the coins of independent princes have been found. But their power extended certainly over the Kabul basin, and probably, at times, over the whole of Afghanistan. The ancient architecture of Kashmir, the tope of Manikyala in the Panjab, and many sculptures found in the Peshawar valley, show unmistakable Greek influence. Demetrius (*circa* B.C. 190) is supposed to have reigned in Arachosia after being expelled from Bactria, much as, at a later date, Baber reigned in Kabul after his expulsion from Samarkand. Eucratides (181 B.C.) is alleged by Justin to have warred in India. With his coins, found abundantly in the Kabul basin, commences the use of an Arianian inscription, in addition to the Greek, supposed to imply the transfer of rule to the south of the mountains, over a people whom the Greek dynasty sought to conciliate. Under Heliocles (147 B.C. ?), the Parthians, who had already encroached on Ariana, pressed their conquests into India. Menander (126 B.C.) invaded India at least to the Jumna, and perhaps also to the Indus delta. The coinage of a succeeding king, Hermæus, indicates a barbaric irruption. There is a general correspondence between classical and Chinese accounts of the time when Bactria was overrun by Scythian invaders. The chief nation among these, called by the Chinese *Yuechi*, about 126 B.C. established themselves in Sogdiana and on the Oxus in five hordes. Near the Christian era the chief of one of these, which was called Kushan, subdued the rest, and extended his conquests over the countries south of Hindu Kush, including Sind as well as Afghanistan, thus establishing a great dominion, of which we hear from Greek writers as Indo-Scythia.

Buddhism had already acquired influence over the people of the Kabul basin, and some of the barbaric invaders adopted that system. Its traces are extensive, especially in the plains of Jalalabad and Peshawar, but also in the vicinity of Kabul.

Various barbaric dynasties succeeded each other, among which a notable monarch was Kanishka or Kanerkes, who reigned and conquered apparently about the time of Our Lord, and whose power extended over the upper Oxus basin, Kabul, Peshawar, Kashmir, and probably far into India. His name and legends still filled the land, or at least the Buddhist portion of it, 600 years later, when the Chinese pilgrim Hwen Thsang travelled in India; they had even reached the great Mahommedan philosopher, traveller, and geographer, Abu Rihân Al-Birûni, in the 11th century; and they are still celebrated in the Mongol versions of Buddhist ecclesiastical story.

In the time of Hwen Thsang (630-45 A.D.) there were both Indian and Turk princes in the Kabul valley, and in the succeeding centuries both these races seem to have predominated in succession. The first Mahommedan attempts at the conquest of Kabul were unsuccessful, though Seistan and Arachosia were permanently held from an early date. It was not till the end of the 10th century that a Hindu prince ceased to reign in Kabul, and it fell into the hands of the Turk Sabaktegin, who had established his capital at Ghazni. There, too, reigned his famous son Mahmûd, and a series of descendants, till the middle of the 12th century, rendering the city one of the most splendid in Asia. We then have a powerful dynasty, commonly believed to have been of Afghan race; and if so, the first. But the historians give them a legendary descent from Zohâk, which is no Afghan genealogy. The founder of the dynasty was Alâuddin, chief of Ghur, whose vengeance for the cruel death of his brother at the hands of Bahram the Ghaznevide was wreaked in devastating the great city. His nephew Shahâbuddin Mahommed repeatedly invaded India, conquering as far as Benares. His empire in India indeed—ruled by his freedmen who after his death became independent—may be regarded as the origin of that great Mahommedan monarchy which endured nominally till 1857. For a brief period the Afghan countries were subject to the king of Kharizm, and it was here chiefly that occurred the gallant attempts of Jalaluddin of Kharizm to withstand the progress of Chinghiz Khan.

A passage in Firishta seems to imply that the Afghans in the Sulimani mountains were already known by that name in the first century of the Hegira, but it is uncertain how far this may be built on. The name *Afghans* is very distinctly mentioned in 'Utbi's *History of Sultan Mahmud*, written about A.D. 1030, coupled with that of the *Khiljis*. It also appears frequently in connection with the history of India in the 13th and 14th centuries. The successive dynasties of Dehli are generally called *Pathan*, but were really so only in part. Of the *Khiljis* (1288-1321) we have already spoken. The Tughlaks (1321-1421) were originally Tartars of the Karauna tribe. The Lodis (1450-1526) were pure Pathans. For a century and more after the Mongol invasion the whole of the Afghan countries were under Mongol rule; but in the middle of the 14th century a native dynasty sprang up in western Afghanistan, that of the *Kurts*, which extended its rule over Ghur, Herat, and Kandahar. The history of the Afghan countries under the Mongols is obscure; but that régime must have left its mark upon the country if we judge from the occurrence of frequent Mongol names of places, and even of Mongol expressions adopted into familiar language.

All these countries were included in Timur's conquests, and Kabul at least had remained in the possession of one of his descendants till 1501, only three years before it fell into the hands of another and more illustrious one, Sultan Baber. It was not till 1522 that Baber succeeded in permanently wresting Kandahar from the Arghuns, a family of Mongol descent, who had long held it. From the time of his conquest of Hindustan (victory at Panipat, April 21, 1526), Kabul and Kandahar may be regarded as part of the empire of Dehli under the (so-called) Moghul dynasty which Baber founded. Kabul so continued till the invasion of Nadir (1738). Kandahar often changed hands between the Moghuls and the rising Safavis (or Sofis) of Persia. Under the latter it had remained from 1642 till 1708, when in the reign of Husain, the last of them, the Ghilzais, provoked by the oppressive Persian governor Shahnawâz Khan (a Georgian prince of the Bagratid house) revolted under Mir Wais, and expelled the Persians. Mir Wais was acknowledged sovereign of Kandahar, and eventually defeated the Persian armies sent against him, but did not long survive (*d.* 1715).

Mahmud, the son of Mir Wais, a man of great courage and energy, carried out a project of his father's, the conquest of Persia itself. After a long siege, Shah Husain came forth from Ispahan with all his court, and surrendered the sword and diadem of the Sofis into the hands of the Ghilzai (Oct. 1722). Two years later Mahmud died mad, and a few years saw the end of Ghilzai rule in Persia.

Nadir Shah (1737–38) both recovered Kandahar and took Kabul. But he gained the goodwill of the Afghans, and enrolled many in his army. Among these was a noble young soldier, Ahmed Khan, of the Saddozai family of the Abdali clan, who after the assassination of Nadir (1747) was chosen by the Afghan chiefs at Kandahar to be their leader, and assumed kingly authority over the eastern part of Nadir's empire, with the style of *Dur-i-Durrân*, "Pearl of the Age," bestowing that of *Durrani* upon his clan, the Abdalis. With Ahmed Shah, Afghanistan, as such, first took a place among the kingdoms of the earth. During the twenty-six years of his reign he carried his warlike expeditions far and wide. Westward they extended nearly to the shores of the Caspian; eastward he repeatedly entered India as a conqueror. At his great battle of Panipat (Jan. 6, 1761), with vastly inferior numbers, he gave the Mahrattas, then at the zenith of power, a tremendous defeat, almost annihilating their vast army; but the success had for him no important result. Having long suffered from a terrible disease, he died in 1773, bequeathing to his son Timûr a dominion which embraced not only Afghanistan to its utmost limits, but the Panjab, Kashmir, and Turkestan to the Oxus, with Sind, Biluchistan, and Khorasan as tributary governments.

Timur transferred his residence from Kandahar to Kabul, and continued during a reign of twenty years to stave off the anarchy which followed close on his death. He left twenty-three sons, of whom the fifth, Zamân Mirza, by help of Payindah Khan, head of the Bârakzai family of the Abdalis, succeeded in grasping the royal power. For many years barbarous wars raged between the brothers, during which Zamân Shah, Shujâ-ul-Mulk, and Mahmûd, successively held the throne. The last owed success to Fatteh Khan, son of Payindah, a man of masterly ability in war and politics, the eldest of twenty-one brothers, a family of notable intelligence and force of character, and many of these he placed over the provinces. The malignity of Kamrân, the worthless son of Mahmud, succeeded in making the king jealous of his minister; and with matchless treachery, ingratitude, and cruelty, the latter was first blinded, and afterwards murdered with prolonged torture, the brutal Kamran striking the first blow.

The Barakzai brothers united to avenge Fatteh Khan. The Saddozais were driven from Kabul, Ghazni, and Kandahar, and with difficulty reached Herat (1818). Herat remained thus till Kamran's death (1842), and after that was held by his able and wicked minister Yar Mahommed. The rest of the country was divided among the Barakzais—Dost Mahommed, the ablest, getting Kabul. Peshawar and the right bank of the Indus fell to the Sikhs after their victory at Naoshera in 1823. The last Afghan hold of the Panjab had been lost long before—Kashmir in 1819; Sind had cast off all allegiance since 1808; the Turkestan provinces had been practically independent since the death of Timur Shah.

In 1809, in consequence of the intrigues of Napoleon in Persia, the Hon. Mountstewart Elphinstone had been sent as envoy to Shah Shuja, then in power, and had been well received by him at Peshawar. This was the first time the Afghans made any acquaintance with Englishmen. Lieut. Alex. Burnes visited Kabul on his way to Bokhara in 1832. In 1837 the Persian siege of Herat and the proceedings of Russia created uneasiness, and Burnes was sent by the Governor-General as resident to the Amir's court at Kabul. But the terms which the Dost sought were not conceded by the government, and the rash resolution was taken of re-establishing Shah Shuja, long a refugee in British territory. Ranjit Singh, king of the Panjab, bound himself to co-operate, but eventually declined to let the expedition cross his territories. The "Army of the Indus," amounting to 21,000 men, therefore assembled in Upper Sind (March 1838), and advanced through the Bolan Pass under the command of Sir John Keane. There was hardship, but scarcely any opposition. Kohandil Khan of Kandahar fled to Persia. That city was occupied in April 1839, and Shah Shuja was crowned in his grandfather's mosque. Ghazni was reached 21st July; a gate of the city was blown open by the engineers (the match was fired by Lieut. afterwards Sir Henry Durand); and the place was taken by storm. Dost Mahommed, finding his troops deserting, passed the Hindu Kush, and Shah Shuja entered the capital (7th August). The war was thought at an end, and Sir John Keane (made a peer) returned to India with a considerable part of the force, leaving behind 8000 men, besides the Shah's force, with Sir W. Macnaghten as envoy, and Sir A. Burnes as his colleague.

During the two following years Shah Shuja and his allies remained in possession of Kabul and Kandahar. The British outposts extended to Saighân, in the Oxus basin, and to Mullah Khan, in the plain of Seistan. Dost Mahommed surrendered (Nov. 3, 1840), and was sent to India, where he was honourably treated. From the beginning, insurrection against the new government had been rife. The political authorities were over-confident, and neglected warnings. On the 2d November 1841 the revolt broke out violently at Kabul, with the massacre of Burnes and other officers. The position of the British camp, its communications with the citadel, and the location of the stores were the worst possible; and the general (Elphinstone) was shattered in constitution. Disaster after disaster occurred, not without misconduct. At a conference (23d December) with the Dost's son, Akbar Khan, who had taken the lead of the Afghans, Sir W. Macnaghten was murdered by that chief's own hand. On 6th January 1842, after a convention to evacuate the country had been signed, the British garrison, still numbering 4500 soldiers (of whom 690 were Europeans), with some 12,000 followers, marched out of the camp. The winter was severe, the troops demoralised, the march a mass of confusion and massacre; for there was hardly a pretence of keeping the terms. On the 13th the last survivors mustered at Gandamak only twenty muskets. Of those who left Kabul, Dr Brydone only reached Jalalabad, wounded and half dead. Ninety-five prisoners were afterwards recovered. The garrison of Ghazni had already been forced to surrender (10th December). But General Nott held Kandahar with a stern hand, and General Sale, who had reached Jalalabad from Kabul at the beginning of the outbreak, maintained that important point gallantly.

To avenge these disasters and recover the prisoners preparations were made in India on a fitting scale; but it was the 16th April 1842 before General Pollock could relieve Jalalabad, after forcing the Khybar Pass. After a long halt there, he advanced (20th August), and gaining rapid successes, occupied Kabul (15th September), where Nott, after retaking and dismantling Ghazni, joined him two days later. The prisoners were happily recovered from Bamian. The citadel and central bazaar of Kabul were destroyed, and the army finally evacuated Afghanistan December 1842.

Shah Shuja had been assassinated soon after the departure of the ill-fated garrison. Dost Mahommed, released, was able to resume his position at Kabul, which he retained till his death in 1863. Akbar Khan was made vazir, but died in 1848.

The most notable facts in later history must be briefly stated. In 1848, when the Sikh revolt broke out, Dost Mahommed, stimulated by popular outcry and by the Sikh offer to restore Peshawar, crossed the frontier and took Attok. A cavalry force of Afghans was sent to join Sher Singh against the British, and was present at the battle of Gujerat (21st Feb. 1849). The pursuit of the Afghans by Sir Walter Raleigh Gilbert, right up to the passes, was so hot that the Dost owed his escape to a fleet horse.

In 1850 the Afghans re-conquered Balkh.

In January 1855, friendly intercourse, which had been renewed between the Dost and the British government, led to the conclusion of a treaty at Peshawar.

In November 1855, after the death of his half-brother, Kohandil Khan of Kandahar, the Dost made himself master of that province. In 1856 came the new Persian advance to Herat, ending in its capture, and the English expedition to the Persian Gulf. In January 1857 the Dost had an interview at Peshawar with Sir J. Lawrence, at which the former was promised arms and a subsidy for protection against Persia. In consequence of this treaty a British mission under Major Lumsden proceeded to Kandahar. The Indian mutiny followed, and the Afghan excitement strongly tried the Dost's fidelity, but he maintained it. Lumsden's party held their ground, and returned in May 1858.

In 1863, Dost Mahommed, after a ten months' siege, captured Herat; but he died there thirteen days later (9th June), and was succeeded by his son Sher Ali Khan.

Since then the latter has passed through many vicissitudes in rivalry with his brothers and nephews, and at one time (1867) his fortunes were so low that he held only Balkh and Herat. By the autumn of 1868, however, he was again established on the throne of Kabul, and his competitors were beaten and dispersed. In April 1869 Sher Ali Khan was honourably and splendidly received at Amballa by the Earl of Mayo, who had shortly before replaced Sir J. Lawrence. Friendly relations were confirmed, though the Amir's expectations were not fulfilled. He received the balance of a donation of £120,000 which had been promised and partly paid by Sir John Lawrence. A considerable present of artillery and arms was made to him; since then some small additional aid in money and arms has been sent, but no periodical subsidy.

Sher Ali Khan now reigns over all Afghanistan and Afghan Turkestan, whilst Badakhshan is tributary to him. In the latter part of 1872 a correspondence which had gone on between the Governments of Russia and England resulted in a declaration by the former that Afghanistan was beyond the field of Russian influence; whilst the Oxus, from its source in Lake Sirikol to the western limit of Balkh, was recognised as the frontier of Afghan dominion.

ANTIQUITIES.—We can afford space for only the briefest indication on this subject. The basin of the Kabul river especially abounds in remains of the period when Buddhism flourished, beginning with the Inscribed Rock of Shahbâzgarhi, or Kapur-di-giri, in the Peshawar plain, which bears one of the *repliche* of the famous edicts of Asoka (not later than B.C. 250). In the Koh-Daman, north of Kabul, are the sites of several ancient cities, the greatest of which, called Beghram, has furnished coins in scores of thousands, and has been supposed to represent Alexander's *Nicæa*. Nearer Kabul, and especially on the hills some miles south of the city, are numerous *topes*. In the valley of Jalalabad are many remains of the same character. In the Peshawar plain and on the adjoining heights are numerous ancient cities and walled villages, in many cases presenting ruins of much interest, besides the remains of topes, monasteries, cave temples, &c.; and frequently sculptures have been found on those sites, exhibiting evident traces of the influence of Greek art. The Mahâban mountain, near the Indus, which has been plausibly identified with the *Aornos* of the Greeks, and the hills more immediately compassing the Peshawar valley, abound in the ruins of very ancient fortresses. At Talash, on the Panjkora river, are extensive ruins of massive fortifications; and in Swat there are said to be remains of several ancient cities.

In the valley of the Tarnak are the ruins of a great city (Ulan Robat), supposed to be ancient *Arachosia*. About Girishk, on the Helmand, are extensive mounds and other traces of buildings; and the remains of several great cities exist in the plain of Seistan, as at Pulki, Peshawaran, and Lakh, relics of ancient *Drangiana*, as yet unexamined. An ancient stone vessel, preserved in a mosque at Kandahar, is almost certainly the same that was treasured at Peshawar in the 5th century as the begging-pot of Sakya-Muni. Of the city of Ghazni, the vast capital of Mahmud and his race, no substantial relics survive, except the tomb of Mahmud and two remarkable brick minarets.

To the vast and fruitful harvest of coins that has been gathered in Afghanistan and the adjoining regions, we can here but make an allusion.

(Elphinstone's *Caubool;* various papers in *J. As. Soc. Bengal;* Ferrier's *Journeys*, and *Hist. of the Afghans;* Bellew's *Journal*, *Report on the Yusufzais*, and *Notes on Flora of Afgh.;* James's *Report on Peshawar District;* Raverty's *Afghan Grammar; Panjab Trade Report;* Baber's *Memoirs;* Kaye's *History;* papers by Major Lumsden, and by Lieut.-Col. C. M. Macgregor, &c. The paragraph on the *Animal Kingdom* has been revised by Prof Henry Giglioli of Florence.) (H. Y.)

AFGHAN TURKESTAN is a convenient name applied of late years to those provinces in the basin of the Oxus which are subject to the Amir of Kabul. BADAKHSHAN and its dependencies, now tributary to the Amir, are sometimes included under the name, but will not be so included here. The whole of the Afghan dominions consist of AFGHANISTAN as defined under that heading, AFGHAN TURKESTAN, and BADAKHSHAN with its dependencies.

The territories included here will be, beginning from the east, the khanates or principalities of Kunduz, Khulm, Balkh with Akcha; and the western khanates of Sir-i-pul, Shibrghân, Andkhûi, and Maimana, sometimes classed together as the *Chihâr Vilâyat*, or "Four Domains;" and besides these, such part of the Hazara tribes as lie north of the Hindu Kush and its prolongation, defined in the article AFGHANISTAN. The tract thus includes the whole southern moiety of the Oxus basin, from the frontier of Badakhshan on the east to the upper Murghâb river on the west. The Oxus itself forms the northern boundary, from the confluence of the Kokcha or river of Badakhshan, in $69\frac{1}{2}°$ E. long., to Khoja Salih ferry, in 65° E. long. nearly. Here the boundary quits the river and skirts the Turkman desert to the point where the Murghâb issues upon it. Along the whole southern boundary we have a tract of lofty mountain country. Thus, in the east, above Kunduz, we have the Hindu Kush rising far into the region of perpetual snow, and with passes ranging from 12,000 to 13,000 feet and upwards. Above Khulm and Balkh is the prolongation of Hindu Kush, called Koh-i-baba, in which the elevation of the *cols* or passes seems to be nearly as high, though the general height of the crest is lower. The mountains then fork in three branches westward, viz., *Koh-i-Siâh*, "The Black Mountain," to the south of the Herat river; *Koh-i-Safed*, "The White Mountain," between the Herat river and the Murghab, and a third ridge north of the latter river. The second branch (Safed-Koh) has been assumed in the article AFGHANISTAN as the boundary of that region. We know almost nothing of these mountains, except from the journey of Ferrier, who crossed all three watersheds in four days of July 1845. He describes the middle range as very lofty, with a good deal of snow on the pass; the southern range not so high, the northern one not nearly so high.

RIVERS.—We shall first describe the rivers of this region in succession.

For the Oxus itself, see that article.

Beginning from the eastward, its first tributary within our limits is the river of Kunduz, known also as the river of Aksarai, the Surkhâb, and what not. As the principal source of this river we may regard the stream of Bamian, fed close under the Koh-i-Baba by a variety of torrents which join from the pass of Akrobat and other gorges of the Hazara country, adjoining that famous site (8496 feet above sea level). The names of some of these seem to preserve a tradition of the ancient population; such are the "Cutlers' Vale," "the Smiths' Vale," the "Valley of Eye-paint." At the eastern end of the valley the Bamian stream receives another of nearly equal bulk, descending from the pass of Hajjigak, the most important crossing of the mountains between Kabul and the Oxus, and from which the road descends upon Bamian, and thence by Saighân, Khurram, and Haibak, to Khulm, in the Oxus valley. On the volcanic rock which parts the streams stand extensive ruins, the name of which, Zohâk, connects them with the most ancient legends of Persian history.

From this the river turns nearly north, passing the country of the Sheikh 'Alis, one of the most famous Hazara clans, and closely skirting the great range of Hindu Kush. About 40 miles N.N.E. of Zohak it receives from the left two confluents, of size probably almost equal to its own—the rivers of Saighan and of Kâmard, both rising to the westward of Bamian, and crossing the highway from Bamian to Khulm. Hereabouts the river seems to take the name of Surkhab. The first considerable confluent on the right is the Andarâb river, draining the valley of that name, and joining at Doshi, about 85 miles in a direct line N.E. of Zohak. About Ghori, still a place of some note, the valley widens out greatly, and becomes in places swampy, with expanses of tall grass, a character which it thenceforth retains. The river is, or has been, bridged at Thomri, a few miles beyond Ghori, a work ascribed to Aurangzib. It then receives from the right the Baghlân river, coming from Nârin and the hills of Khost. The only remaining confluent is the important one which joins immediately below the town of Kunduz, sometimes called the Khânâbâd river, sometimes by the names of its chief contributaries, the Farokhar and Bangi.

The Farokhar, or river of Talikan, is the most easterly, coming out of Badakhshan, the boundary of which runs along the watershed on its left bank. The Bangi flows through Khost from the highlands of Badakhshan, east of Andarab. A third tributary, the Shorâb, salt, as its name implies, drains the high range called Esk-mushk, above Narin.

The Surkhab or Kunduz river enters the Oxus at a point approximately (no traveller has visited the confluence) 32 miles N.W. of Kunduz, its whole length, exclusive of minor windings, being about 220 miles.

From Ghori downwards, the hills which bound the valley on either side appear to be of no great elevation, and to be tolerably clothed with grass, and occasionally with fir trees; the aspect of the country gradually approximating to that of Badakhshan, in contrast to the more sterile offshoots of Koh-i-Baba to the westward.

Kunduz itself lies very low, scarcely 500 feet above sea level, and the roads approaching the town have to pass over piles amid the swampy vegetation. The adjacent plain is in the main richly cultivated and thickly peopled, but it is interspersed with extensive tracts of jungly grass, and is extremely and proverbially unhealthy. The plains, which extend, though not unbroken, from Kunduz to the Oxus, are free from the bare and repulsive character of those further west, and are described as covered in part with rich cultivation, thick with groves and hamlets, and in part with splendid pasture.

Proceeding westward, the next tributary to the Oxus basin is the Khulm river. The traveller from Bamian northward first touches the Khulm river, on descending from the Kara-Kotal, at a spot called Doâb Shâhpasand, probably 5000 feet above the sea, where its two main sources join, and the main road to Turkestan keeps on or near the river till its exit on the Oxus plain. The character of the mass of mountains which extends from the Koh-i-Baba to Khulm is utter rocky aridity, but broken sometimes in the sudden trench-like valleys by an exuberant vigour of vegetation. Along a chain of these trench-like gorges, walled by stupendous cliffs seeming sometimes almost to close overhead, the traveller descends towards Khulm. At Haibak the valley opens out, but closes in again before Khulm is reached. Here he emerges from a narrow gorge upon the plain of the Oxus, some 20 miles from the great river, and leaves the mountains suddenly, as one leaves the gate of a fortress, still rising behind in a bold rampart to the height of 2500 feet. The river is believed to be spent in irrigation before reaching the Oxus.

As far north at least as Khurram, half-way from Bamian to Khulm, the offshoots of Koh-i-Baba, west of the Khulm defile, must reach a height of 11,000 or 12,000 feet; for here Ferrier found bitter cold and snow on the top on the 7th of July (latitude nearly 36°).

The next river westward is the Balkh river, sometimes called Dehâs. It rises not far from some of the tributaries of the Surkhab, nor from the sources of the Herat river, at a remarkable spot which, under the name of the *Band-i-Barbar*, or Barbar dam, is the subject of various legends, though we have no distinct account of it. The valley of Yekâlang, on the upper waters of this river, at a height of 7000 feet above the sea, was visited by A. Conolly, and is described by him as fertile, well-watered, and populous, about 15 miles in length by ¼ to ½ mile in width. Ferrier is the only traveller who has crossed the mature stream, and he merely mentions that he forded it, and that it was rather rapid. We thus know almost nothing of the river. In length it cannot come far short of the Surkhab. Beyond the lofty mountains recently spoken of, some of the hills towards the Balkh-ab have a thin clothing of wood, and the valleys opening on the river are wide and not unfertile. The main valley expands into level tracts of pasture, covered by long grass, and intersected by artificial water-courses; but (as with the Khulm river) the gorge from which the stream issues on the Oxus plain is narrow, and walled in by very high hills on either side. The ruins and gardens of ancient Balkh stand about 6 miles from the hills, but no part of the river appears to reach the site in its natural bed, nor does any part of its waters reach the Oxus in a running stream.

The plains that slope from the gardens of Balkh to the Oxus are naturally white hard steppes, destitute of spontaneous verdure save sparse brush of tamarisk and other meagre growths; but the soil responds richly to irrigation whenever this is bestowed.

The next stream that we meet with, and the last that can be considered even as an indirect tributary of the Oxus, is that which fertilises the small khanates of Shibrghan and Andkhui, on the verge of the Turkman desert; whilst the two confluents that contribute to form it have previously watered the territories of Siripul and Maimana. The river, or whatever survives of its water after irrigating Andkhui, is lost in the desert. The taste of the water is abominable, and, though the inhabitants are accustomed to it, strangers suffer from its use.

The last river that we have to notice is the Murghab, which rises between the two northern branches of the Koh-i-Baba or Paropamisus. Ferrier is the only traveller who has been on the upper waters of the Murghab. He takes no notice of the river itself, but describes a remarkable plain or basin, about 120 miles in circuit, entirely surrounded by mountains, well-watered, and rich in vegetation. The people are Mongol Hazaras, and, according to Ferrier, idolaters. Their country is a part of the old territory of Garjistân. At Shah Mashad, about half-way between this and the plains, the river was crossed by Major Eldred Pottinger, but we have no access to his report. Further down, as the river approaches the foot of Murghab Bâlâ, on the road from Maimana to Herat, it runs with great violence, and the valley narrows to a defile. At Panjdeh, 35 to 40 miles below Murghab, it begins to flow through a valley of clay soil, bounded by sandy heights, and gradually opening into the plain of Merv. Hereabouts, too, it quits the Afghan territory, but the boundary does not seem as yet to have been precisely fixed. About 100 miles from Panjdeh the river reaches Merv, where formerly there was a great dam, securing the fertility of that oasis, the nucleus of ancient *Margiana*. This was destroyed by the Amir Massum (otherwise Shah Murad) of Bokhara, about 1785, when he carried off the whole population into slavery. Beyond Merv the river is lost in the desert.

PROVINCES AND PLACES OF NOTE.—We do not know the precise divisions maintained under the Afghans, but they coincide generally with the old principalities or khanates, the hereditary rulers of which, in several cases, continue in authority under the Afghan governor of Turkestan. Bamian, Saighan, and the higher valleys belong, it is understood, to a special command over the Hazara tribes.

I. *Kunduz.*—Beginning again from the east, the first province is *Kunduz*, having on the east Badakhshan, on the west Khulm, on the north the Oxus, and on the south Hindu Kush. The districts of Kunduz are approximately as follows:—(1.) *Kunduz*, with the chief town of the province, a wretched place, as described by Wood, of some 500 or 600 mud huts, intermingled with straw sheds, Uzbek tents, gardens, and corn-fields, and overlooked by a mud fort on an extensive mound. (2.) *Hazrat Imâm*, on the irrigated and fertile Oxus plain. The town, known in the Middle Ages as *Arhang*, is described as about the same size as Kunduz, with a better fort, protected by a wet ditch. (3.) *Baghlân*, and (4.) *Ghori*, in the swampy valley of the Surkhab. (5.) *Doshi*, further up the same valley, at the confluence of the Andarab stream. (6.) *Killagai* and *Khinjân*, near the lower part of the Andarab stream. (7.) *Andarab*, at the foot of the Tul and Khâwak passes over Hindu Kush, often supposed to be the *Adrapsa* of Alexander's historians. This secluded town was a favourite minting place of the Samanid sovereigns of Persia and Turkestan, in the 10th century, probably owing to the vicinity of silver mines at Paryân. (8.) *Khost* lies between Andarab and Kunduz. The name often occurs in the history of Baber and his successors. (9.) *Narin* and *Ishkimish* lie to the east of Baghlan, at the sources of the Baghlan stream and of the Shorab branch of the Kunduz river. The second name appears to be the same as *Eshk-mushk*, which Wood applies to a high mountain in this quarter. (10.) *Farhang* and *Châl* lie on the borders of Badakhshan, and are utterly unknown. (11.) *Tâlikân* also lies on the borders of Badakhshan, but is pretty well known, being on the main road between Kunduz and Faizabad, the capital of Badakhshan. It is now a poor place, but is ancient, and was once famous. A fortress here stood a long siege from Chinghiz Khan, and the place is mentioned by Marco Polo as *Taican*. During the rule of Murad Beg of Kunduz this was the seat of a government that included Badakhshan. (12.) *Khanabad*, on the river of that name, pleasantly elevated above the swampy level of Kunduz, is, or was, the usual summer residence of the chiefs of that territory.

II. *Khulm* was the next of the khanates, lying between Kunduz and Balkh. The districts, as far as we know them, are the following:—(1.) *Tâshkurghân.* The old town of Khulm stood in the Oxus plain, surrounded by watered orchards of famous productiveness; but it lay so exposed to the raids of the Kunduz Uzbeks that the chief, Killich Ali, in the beginning of this century, transferred his residence to Tashkurghan, 4 miles further south, and just at the month of the defile—a cheerless group of villages, consisting of mud houses with domed roofs, connected by gardens and enclosed by a mud wall; it is supposed to contain at least 15,000 souls, and is a place of considerable trade. (2.) *Haibak.* The town presents rather an imposing aspect, clustering round a castle of some strength on an isolated eminence; the domed houses, however, are compared to large brown bee-hives. The Khulm river valley here opens out, and is very fertile; the banks are shaded by luxuriant fruit trees. The site is a very ancient one, and, under the name of *Samangân*, was famous in Persian legend. One traveller describes there a remarkable relic of antiquity called the *Takht* or Throne of Rustam. This, from the account, would seem to have been a Buddhist dagoba.[1] (3.) *Khurram Sarbâgh*, so called from two villages in the upper defiles of the Khulm river.

III. *Balkh.* *Balkh* proper is the populous and well-watered territory upon the eighteen canals which draw off the waters of the Balkh-ab, and on which there are said to be 360 villages.

No trace has been recovered of the ancient splendours of *Bactra*, nor do the best judges appear to accept Ferrier's belief that he saw cuneiform inscriptions upon bricks dug up there. A late Indian report by an intelligent Mahommedan speaks of a stone throne in the citadel, to which traditional antiquity is ascribed, but of this we know no more. The remains that exist are scattered over some 20 miles of circuit, but they consist mainly of mosques and tombs of sun-dried brick, and show nothing even of early Mahommedan date. The inner city, surrounded by a ruined wall of 4 or 5 miles in compass, is now entirely deserted; a scanty population still occupies a part of the outer city. In 1858 Mahommed Afzal Khan, ruling the districts of Turkestan on behalf of his father, Dost Mahommed, transferred the seat of the Afghan government and the bulk of the population to Takhtapul, a position which he fortified, some 8 miles east of the old city; and this remains the capital of the Afghan territories on the Oxus.

The only other place of note in the district is *Mazâr-i-Sharîf*, or the "Noble Shrine," on the road to Khulm, where a whimsical fiction has located the body of 'Ali, the son-in-law of Mahommed. It is the object of pilgrimages, and the scene of a great annual fair. Vámbéry speaks of the roses, matchless for colour and fragrance, that grow on the pretended tomb.

Of the districts lying on the Balkh river within the hills we know nothing.

Akcha, some 40 to 45 miles westward from Balkh, was an Uzbek khanate before the last Afghan conquest. It is small, but well-watered and populous. The town is fortified, and has a citadel. Accounts differ as to the population; one writer calls them Uzbeks, another Sarak Turkmans.

IV. The provinces known as the Four Domains are:—(1.) *Shibrghan*, some 20 miles west of Akcha. This was another small Uzbek khanate. The town, which contains about 12,000 Uzbeks and Parsiwans, has a citadel, but is not otherwise fortified. It is surrounded by good gardens, and excellent cultivation, but its water supply is dependent upon Siripul, and, in the frequent case of hostility between the two, is liable to be cut off. Ferrier speaks highly of the climate and the repute of the inhabitants for valour. Shibrghan (Sapurgan) and its fine melons are mentioned by Marco Polo. (2.) *Andkhui*, about 20 miles north-west of Shibrghan, forms an oasis in the desert, watered by the united streams from Siripul and from Maimana. It was once a flourishing city, and the oasis was reckoned to contain 50,000 inhabitants, but the place has scarcely recovered from the destruction it endured at the hands of Yar Mahommed of Herat in 1840. It was at Andkhui that Moorcroft died in 1825; but his grave is at Balkh. Trebeck, the last survivor of his party, died and was buried at Mazar. (3.) *Maimana*, 105 miles from Balkh, and some 50 south-west of Andkhui, contains some ten or twelve villages or townships, besides the capital, and a population estimated at 100,000 souls. It is a district of considerable productiveness, industry, and trade, and the Uzbek inhabitants have a high reputation as soldiers. The chief was formerly a notorious slave-dealer. (4.) *Siripul.* This khanate lying within the limits of the undulating country south-west of Balkh and east of Maimana, is of about the same calibre as the latter, but somewhat lower in estimated population. Two-thirds of the people are Uzbeks, the rest Hazaras. From the last a tribute of slaves is, or used to be, exacted; and Hazara widows, it is said, were claimed as government property, and sold by auction. The town of Siripul is an irregular mass of houses clustered on the slope of a hill crowned by a fort. Many tents gather round it also, and Ferrier estimates the population of town and tents as high as 18,000. The valley below is abundantly watered, and the breadth of orchards and tillage is considerable.

POPULATION.—In the estimate of population cited under AFGHANISTAN, that of Afghan Turkestan is reckoned at 642,000. This includes 55,000 for Badakhshan (no doubt too low an estimate); and the remainder, for the provinces included under our present article, excluding Hazaras, will be 587,000. Anything but a round number is entirely inappropriate to such an estimate; but we shall probably not be far wrong if we reckon the population at 600,000.

The Tajiks, or people of Iranian blood, are probably the representatives of the oldest surviving race of this region. They are found in some districts of Balkh and valleys of Kunduz. Khost, for instance, is said to be chiefly occupied by them. Uzbeks seem to be the most numerous race; and there are some other Turk tribes not classed as Uzbeks.[2] There seem to be a good many families claiming Arab descent; Afghans, especially about Balkh and Khulm; and in the towns some Hindus and Jews.

PRODUCTS AND INDUSTRY.—We have no means of giving any systematic account of the products of these provinces, either in natural history or industry. Rock-salt is worked at Chal, near the Badakhshan frontier, as well as beyond that frontier. Pistachio nuts are grown largely in the hill country of Kunduz, as well as the adjoining districts of Badakhshan, and the whole supply of India, Central Asia, and Russia is said to be derived from this region. Fruit is abundant and excellent, especially in Khulm and Balkh. Andkhui, before its decay, was famous for the black sheepskins and lambskins which we call *astrakhan*; and also for a breed of camels in great demand. Kunduz produces a breed of horses, highly valued in the Kabul market under the name of *Kataghan*. Maimana also is famous for horses, which are often exported to India; and is a mart for carpets and textures of wool and camels' hair, the work of Turkman and Jamshidi women. Slave-dealing and man-stealing have long been the curse of this region, but late changes have tended to restrict these, and the Russian conquest of Khiva will probably have a most beneficial effect in this respect at least.

History.—Ancient Balkh, or *Bactra*, was probably one of the oldest capitals in Central Asia. There Persian tradition places the teaching of Zoroaster. Bactriana was a

[1] Burslem, *A Peep into Turkestan*, p. 125.

[2] The Uzbeks were, however, a confederation of many Turk and Tartar tribes, not one race.

province of the Achæmenian empire, and probably was occupied in great measure by a race of Iranian blood. About B.C. 250, Theodotus, governor of Bactria under the Seleucidæ, declared his independence, and commenced the history, so dark to us, of the Greco-Bactrian dynasties, whose dominions at one time or another—though probably never simultaneously—touched the Jaxartes and the Gulf of Cutch. Parthian rivalry first, and then a series of nomad movements from inner Asia, overwhelmed the isolated dominion of the Greeks (*circa* B.C. 126). Powers rose on the Oxus, known to the Chinese as Yuechi, Kweishwang, Yetha, Tukhâras, and what not; dimly to western Asia and Europe as Kushâns, Haiâthala, *Ephthalitæ* or White Huns, and *Tochari*. Buddhism, with its monasteries, colossi, and gilded pagodas, spread over the valley of the Oxus. We do not know what further traces of that time may yet be revealed; but we see some in the gigantic sculptures of Bamian. The old Arab historians of the Mahommedan conquest celebrate a heathen temple at Balkh, which they call *Naobihâr*, which Sir H. Rawlinson has pointed out to have been certainly a Buddhist monastery (*Nava-Vihâra*). The name Naobihar still attaches to a village on one of the Balkh canals, thus preserving, through so many centuries, the memory of the ancient Indian religion. The memoirs of the Chinese pilgrim Hwen Thsang, in the first part of the 7th century, give many particulars of the prevalence of his religion in the numerous principalities into which the empire of the Tukharas had broken up; and it is remarkable how many of these states and their names are identical with those which still exist. This is not confined to what were great cities like Balkh and Bamian; it applies to Khulm, Khost, Baghlan, Andarab, and many more.

As *Haiathalah*, or *Tokhâristân*, the country long continued to be known to Mahommedans; its political destiny generally followed that of Khorasan. It bore the brunt of all the fury of Chinghiz, and the region seems never to have effectually recovered from the devastations and massacres which he began, and which were repeated in degree in succeeding generations. For about a century these Oxus provinces were attached to the empire of the Dehli Moguls, and then fell into Uzbek hands. In the last century they formed a part of the dominion of Ahmed Khan Durrani (see AFGHANISTAN), and so remained under his son Timur. But during the fratricidal wars of Timur's sons they fell back under the independent rule of various Uzbek chiefs. Among these, the Kataghans of Kunduz were long predominant; and their chief, Murad Beg (1815 to about 1842), for some time ruled Kûlâb beyond the Oxus, and all south of it from near Balkh to Pamir.

In 1850 the Afghans recovered Balkh and Khulm; by 1855 they had also gained Akcha and the four western khanates; Kunduz in 1859. They were proceeding to extend their conquests to Badakhshan, when the Amir of that country agreed to pay homage and tribute.

We have noticed, in the conclusion of the article AFGHANISTAN, the correspondence which recently took place (1872–73) with Russia regarding the recognition of the Oxus as the boundary of Afghan Turkestan.

Antiquities.—These are known but very imperfectly. The best known, and probably the most remarkable, are the famous colossi at Bamian, with the adjoining innumerable caves. In the same locality are the ruins of the mediæval city destroyed by Chinghiz, the great fort called Sayadabad, and the ruins of Zohak. At Haibak are numerous caves like those of Bamian. Balkh seems to have little or nothing to show, though probably excavation would be rewarded. The little known or unknown valleys of Badakhshan probably contain remains of interest, but our only notices of them are so highly spiced with imagination as to be worthless. General Ferrier saw remarkable rock sculptures in a defile in the Hazara country, south of Siripul, and curious rock excavations a little further south.

(Wood's *Journey*, 2d ed., 1873, with Introductory Essay; Ferrier's *Caravan Journeys;* Burnes's *Travels;* Indian official documents; Vámbéry's *Travels;* &c., &c.) (H. Y.)

AFIUM-KARA-HISSAR, a city of Asiatic Turkey, in the pashalic of Anatolia, nearly 200 miles E. of Smyrna, and 50 miles S.S.E. of Kutaiah. It stands partly on level ground, partly on a declivity, and above it rises a precipitous trachytic rock 400 feet in height, on the summit of which are the ruins of an ancient castle. From its situation on the route of the caravans between Smyrna and western Asia on the one hand, and Armenia, Georgia, &c., on the other, the city is a place of extensive trade, and its bazaars are well stocked with the merchandise both of Europe and the East. Opium in large quantities is produced in its vicinity, and forms the staple article of its commerce; and there are, besides, manufactures of black felts, carpets, arms, and saddlery. Afium contains several mosques (one of them a very handsome building), and it is the seat of an Armenian bishop. The population is estimated at about 60,000.

AFRAGOLA, a town of Italy, in the province of Napoli, 6 miles N.N.E. of Naples. It has extensive manufactures of straw bonnets. Population of commune (1865), 16,493.

AFRANIUS, LUCIUS, a Latin poet who lived about a century before Christ. He wrote comedies in imitation of Menander, and was commended by Cicero and Quintilian for his acute genius and fluent style. The fragments of his works which are extant have been collected by Bothe in his *Poetæ Scenici Latini*, and by Neukirch in his *De Fabula Togata Romanorum.*

AFRANIUS, LUCIUS, whose early history is unknown, was a devoted friend and adherent of Pompey, whom he served with distinction as one of his lieutenants in the Sertorian and Mithridatic wars. In the year 60 B.C., and chiefly by Pompey's support, he was raised to the consulship, but in performing the duties of that office he showed, like many other soldiers both before and since, an utter incapacity to manage civil affairs. In the following year, while governor of Cisalpine Gaul, he had the good fortune to obtain the honour of a triumph, and on the allotment of Spain to Pompey, 55 B.C., Afranius and Petreius were sent to take charge of the government of that country. On the rupture between Cæsar and Pompey, they were compelled, after a short campaign in which they were at first successful, to surrender to Cæsar at Ilerda, 49 B.C., and were dismissed on promising not to serve again in the war. Afranius, regardless of his promise, joined Pompey at Dyrrhachium, and at the battle of Pharsalia, 48 B.C., he had charge of Pompey's camp. On the complete defeat of Pompey, Afranius, despairing of pardon from Cæsar, repaired to Africa, and was present at the battle of Thapsus, 46 B.C., which ruined the hopes of the Pompeians in that part of the world. Escaping from the field with a strong body of cavalry, he was afterwards taken prisoner, along with Faustus Sulla, by the troops of Sittius, and handed over to Cæsar, whose veterans, disappointed at their not being led to immediate execution, rose in tumult and put them to death.

AFRICA

THIS vast continent, though associated from the dawn of civilisation with traditions and mysteries of the most stimulating kind, has remained until recently one of the least known, and, both commercially and politically, one of the least important of the great divisions of the globe. The knowledge of Africa possessed by the ancients was very limited, owing principally to its physical construction. The great desert, which in a broad belt stretches quite across the continent, forbade every attempt to pass it until the introduction of the camel by the Arabs. The want of any known great river, except the Nile, that might conduct into the interior, contributed to confine the Greek and Roman colonists to the habitable belt along the northern coast. The Phœnicians are known to have formed establishments on the northern coast of Africa at a very early period of history, probably not less than 3000 years ago; and the conquest of Egypt by Cambyses dates as far back as the year B.C. 525. We may consider, therefore, the coasts of Egypt, of the Red Sea, and of the Mediterranean, to have been settled and well known to the ancient Asiatics, who were constantly passing the narrow isthmus which divided their country from Africa and led them immediately from parched deserts into a fertile valley, watered by a magnificent river. But whether they were much or little acquainted with the western coast, which bounds the Atlantic, and the eastern coast, washed by the Indian Ocean, is a question that has exercised the research and ingenuity of the ablest scholars and geographers, and has not yet been satisfactorily answered.

estern ast. This question being one of curiosity rather than utility, we shall only state the case, and the results of the several inquiries, without entering into the merits of the arguments advanced by the different parties. We are told by Herodotus, that Necho, king of Egypt, sent out an expedition under the command of certain Phœnician seamen, for the purpose of circumnavigating Africa; and that, on their return, they asserted that they had accomplished this undertaking. Few of the ancient writers give credit to the story; but, among the moderns, the Abbé Paris and Montesquieu have contended that this voyage was actually performed. Isaac Vossius and D'Anville have strong doubts; and Dr Vincent and M. Gosselin maintain that such an expedition, at such a period, exceeds all the means and resources of navigation, then in its infancy. Last of all comes Major Rennel, who, in his elucidation of the geography of Herodotus, has done more than all the rest in clearing away the doubts of history; and *he* argues the possibility of such a voyage, from the construction of their ships, with flat bottoms and low masts, enabling them to keep close to the land, and to discover and enter into all the creeks and harbours which any part of the coast might present. At all events, one thing is evident: if such an expedition ever circumnavigated the African continent, the fruits of it have nearly, if not entirely, perished.

About half a century after this supposed expedition, the account of another voyage, down the western coast, is contained in the *Periplus* of Hanno, which has also called forth many learned and elaborate discussions among modern geographers, some of whom would carry Hanno to the Bight of Benin, others only to Sherbro Sound or the river Nun in lat. 28° N.

The extent to which ancient discovery proceeded along the eastern coast of Africa, has divided the opinion of the learned nearly as much as its progress on the western coast. Delisle, Huet, and Bochart, made the discovery of the coast to extend as far south as Mozambique and Madagascar. D'Anville could trace such discovery no farther than to Cape Delgado; and M. Gosselin contends that the ancients never proceeded down the coast beyond Brava. But Dr Vincent, who has entered more profoundly into the subject than any of his predecessors, and brought a great fund of learning to bear on the question, in his *Periplus of the Erythrean Sea*, has with great plausibility extended these boundaries to Mozambique and to the island of Madagascar.

Sketch Map of Africa.

Egypt, under the Ptolemies, the great patrons of science and promoters of discovery, possessing the advantage of the only great river which falls from the African continent into the Mediterranean, made no progress beyond its ancient boundaries; and though the Romans, who subsequently possessed Egypt, penetrated beyond the limits of their own dependencies, they extended their discoveries no further than Fezzan in one direction, and, at a later period, beyond Nubia as far as Abyssinia, and the regions of the Upper Nile. We know nothing of the progress made by the Carthaginians in the discovery of Interior Africa; but The Carthaginians. although it has been asserted that their merchants had reached the banks of the interior river, which we call the Kawara or Niger, they have left nothing on record that will warrant such a supposition. The story told by Herodotus, of some Nasamonians crossing the desert, and arriving at a large river, can only be applicable to some western arm of the Nile. The people from whom we derive the first information concerning the interior of Northern Africa are the Arabs, who, by means of the camel, were able to penetrate across the great desert to the very centre of the continent, and along the two coasts as far as the Senegal and the Gambia on the west, and to Sofala on the east. On this latter coast they not only explored to an extent far beyond any supposed limits of ancient discovery, but planted colonies at Sofala, Mombas, Melinda, and at various other places.

The 15th century produced a new era in maritime discovery. The voyages of the Portuguese were the first to give anything like an accurate outline of the two coasts, and to complete the circumnavigation of Africa. The discovery of America and the West India islands gave rise to that horrid traffic in African negroes, which has since been suppressed; but this traffic has been the means of acquiring a more extended and accurate knowledge of that part of the coast which lies between the rivers Senegal and the Cameroons, as well as of the manners and character of the people who inhabit this extended line of coast. With the English and French settlements in Africa began a systematic survey of the coast, and portions of the interior.

The uncertainty and confusion that prevailed in the geography of the interior of Africa induced a few learned and scientific individuals to form themselves into an association for promoting the exploration of Inner Africa. This society was formed in London in 1788, and under its auspices important additions were made to the geography of Africa by Houghton, Mungo Park, Hornemann, and Burckhardt. Repeated failures, however, at length discouraged the association from engaging other missionaries, and it subsequently merged in the Royal Geographical Society in 1831.

During the last sixty years more has been done to make us acquainted with the geography of Africa than during the whole of the 1700 previous years, since Ptolemy, taken together. With Mungo Park, strictly speaking, commences the era of unceasing endeavours to explore the interior.

Mungo Park proceeded in 1795 from the river Gambia on the west coast, to the Joliba (commonly called Niger), traced this river as far as the town of Silla, explored the intervening countries, determined the southern confines of the Sahara, and returned in 1797. In 1805 this adventurous traveller embarked on a second journey in the same regions, for the purpose of descending down the river Joliba to its mouth. This journey added little to the discoveries already made, and cost the traveller his life. He is ascertained to have passed Timbuktu, and to have reached Boussa, where he was killed by the natives. In 1798 Dr Lacerda, a scientific Portuguese traveller, who had already acquired fame through his journeys in Brazil, made the first great journey in South-Eastern Africa, inland from Mozambique, and reached the capital of the African king, known as the Cazembe, in whose country he died.

Hornemann, in 1796–98, penetrated from Cairo to Murzuk, and transmitted from that place valuable information respecting the countries to the south, especially Bornu. He then proceeded in that direction, but it is supposed that he soon afterwards perished, as no accounts of his further progress have ever reached Europe. The first actual crossing of the continent that has been recorded was accomplished between the years 1802 and 1806, by two *Pombeiros* or mercantile traders in the employment of the Portuguese, who passed from Angola eastward through the territories of the Muata Hianvo and the Cazembe, to the possessions on the Zambeze. In 1816 an expedition was sent out by the English Government, under the command of Captain Tuckey, to the river Congo, which was at that time believed to be the lower course of the Joliba. This was a disastrous undertaking, and the geographical additions were but slight, the river having been ascended a distance of only 280 miles

In 1819 Lyon and Ritchie penetrated from Tripoli to Murzuk, and a little distance beyond that place.

In 1822 Denham, Clapperton, and Oudney set forth from Tripoli in the same direction, crossed the Great Desert, and reached, on the 4th February 1823, the great lake Tsad or Chad. The surrounding countries were explored as far as Sakatu in the west, and Mandara in the south. This journey was altogether one of the most successful and important into the interior. Oudney died in Bornu, but Clapperton undertook a second journey from the coast of Guinea, crossed the Kawara, and arrived at Sakatu, at which place he also died. His servant, Richard Lander, returned to England, after having explored a part of the adjoining regions.

Major Laing succeeded in reaching Timbuktu from Tripoli, but was murdered on his return in the desert.

In 1827 and 1828 Caillié set out from the Rio Nunez on the western coast, reached Timbuktu, and returned from that place through the Great Desert to Marocco. A second Portuguese journey was undertaken in 1830 from Mozambique to the Cazembe's dominions, and Major Monteiro, the leader of the expedition, more fortunate than his predecessor Dr Lacerda, was enabled to complete a map of the country traversed, and to bring back a complete account of this portion of the interior.

The termination of the Joliba, Kawara, or Niger, remained in obscurity till 1830, when it was ascertained by Lander and his brother, who succeeded in tracing the river from Yaouri down to its mouth. They embarked on a second expedition, which sailed in 1832, for the purpose of ascending the Kawara as far as Timbuktu. But only Rabba was reached, and the general results of the expedition were most disastrous.

Niger expedition.

The great Niger expedition, similar to the foregoing, consisted of three steam-vessels, and was despatched by the Government in 1841, under Captain Trotter. It proved a failure, and resulted in a melancholy loss of life.

In the region between the Kawara and the coast, Mr Duncan, one of the survivors of the Niger expedition, made some additions to our geographical knowledge by his journey to Adafoodia, in 1845–46. This enterprising traveller met with an untimely death in a second attempt in the same region for the purpose of reaching Timbuktu.

The preceding journeys were confined chiefly to the northern and western portions of the continent. A much greater number of travellers explored the regions drained by the Nile, the salubrity of which, particularly of Abyssinia, is so infinitely greater than that of Western Africa, that among the many explorers of the former, a very small proportion have died as compared with the immense loss of life in Western Africa. Among the most distinguished of the earlier East African travellers are Bruce (1768–73), Browne (1793), who reached Darfur, Burckhardt (1814), Cailliaud (1819), and more recently Rüppel (1824–25), Russegger (1837), D'Abbadie (1838–44), Beke (1840–44), D'Arnaud and Werne on the White Nile (1840–42), and Brun Rollet (1845).

South-African travellers

Though the Dutch settlement in South Africa was founded as early as 1650, not much information of the interior of that portion of the continent was gained till the end of the 18th century, when a series of journeys was commenced by Sparrmann, and followed up by Vaillant, Barrow, Trotter, Somerville, Lichtenstein, Burchell (1812), Campbell, Thomson, Smith, Alexander (1836–37), and Harris.

Mombas mission

A station of the Church Missionary Society was established near Mombas, in about 4° S. lat. on the east coast of Africa, in 1845, and the zealous missionaries in charge of it began to make exploring journeys into the interior. Thus, early in 1849, the Rev. Mr Rebmann discovered the great snow-clad mountain of Kilima-njaro, rising on the edge of the inland plateau; and his companion, Dr Krapf, taking a more northerly route, came in sight of a second huge mountain named Kenia, also snow-clad, though directly beneath the equator. Frequent reports reached these missionaries of vast lakes in the interior beyond the mountains they had discovered, and their information awakened a great interest in this region at home.

About this time an embassy, for the purpose of concluding commercial treaties with the chiefs of Northern Africa, as far as Lake Chad, by which the legitimate trade of these countries should be extended and the system of slavery abolished, was originated by Mr James Richardson, who left England for this purpose in 1849, accompanied by Drs Barth and Overweg. The expedition had already almost reached the scene of its labours when Richardson died; **Barth.** Overweg also fell a victim to his exertions, but Dr Barth continued his explorations till 1856. During this time he traversed in many directions almost the whole of the northern Soudan, completing a series of journeys which must always remain most conspicuous in North African travel, and upon which we are still dependent for the greater part of our knowledge of the central negro states.

In the summer of 1849, Dr Livingstone, who, as an agent of the London Missionary Society, had laboured and travelled in the countries immediately north of the Cape Colony since 1840, began those remarkable journeys in the interior of Southern Africa, which have continued until the present time, and have given to him the first place among African discoverers. The finding of Lake Ngami, the central point of the continental drainage of South Africa, was the great discovery of the first year.

Two journeys from the west coast now claim attention. In 1846 a Portuguese trader named Graça succeeded in again reaching the country of the South African potentate, named the Muata Yanvo, from Angola; he was followed by a Hungarian named Ladislaus Magyar, who explored the central country in various directions from 1847 to 1851.

Livingstone (the Zambeze). Between 1851 and 1853 Livingstone made two journeys northward from his station in the land of the Bechuanas, and was the first European to embark upon the upper course of the Zambeze. From the Makololo country, in the central part of the river basin, he now led a party of natives westwards up-stream to the water-parting of the continent at the little Lake Dilolo, and thence to the western slope, reaching the Portuguese coast at Loanda in 1854.

Galton. During 1851 Galton explored a part of the south-western country inhabited by the Damaras and Ovampo, from Walfisch Bay to a point in lat. 17° 58′ S., and long. 21° E., determining accurately a number of positions in this region. On the south-east, also, Gassiot made an interesting journey from Port Natal north-westward through the mountains to the river Limpopo.

Two most remarkable journeys across the whole continent now follow in order; **Silva Porto.** the one, made by Silva Porto, a Portuguese trader, who leaving Benguela in 1853, took an eastward route, parallel to but considerably northward of the Zambeze, over perfectly unknown country. He then rounded the southern end of the Lake Nyassa (afterwards explored by Livingstone), and made his way across the east coast-land to the mouth of the Rovuma river, having spent a year and two months in his tedious march. **Livingstone (Victoria Falls).** The other was executed by Livingstone, who in returning (1855–56) by a somewhat more northerly route than that travelled over in going westward to Loanda, descended the Zambeze to its mouth at Quilimane, discovering the wonderful Victoria Falls of the river on his way.

In 1856 an important addition was made to the more exact geography of Africa, in a survey of the greater part of the course of the Orange river, by Mr Moffat, a son of the veteran South African missionary.

The following year was one of great activity in African exploration. Damara Land, in the south-west, was traversed by Messrs Hahn and Rath as far as the southern limit of the Portuguese territory at the Cunene river; Dr Bastian was exploring the interior of Congo and Angola, and Du Chaillu had begun his first journey in the forest country of the Fan tribes on the equatorial west coast. Under the auspices of the Royal Geographical Society, Captains Burton and Speke, already distinguished by their perilous journey to Harar, a trading centre in the Somali and Galla country of the east African promontory, set out from Zanzibar, to ascertain the truth about the great inland lakes which had been reported by the Mombas missionaries. Their most successful journey (1857–59) resulted in the discovery of Lake Tanganyika, in a deep basin, between 3° and 8° S. lat., and of the southern portion of a perhaps greater lake northward, supposed by Speke, its discoverer, to be the head reservoir of the Nile.

In a new journey in the Zambeze region in 1859, Dr Livingstone, accompanied by Dr Kirk, traced the Shire river, a northern tributary of the Zambeze, to its outflow from the Nyassa, the most southerly of the great African chain of fresh lakes.

About this time also several travellers (Petherick (1858), Lejean, Miani, the Poncets, Antinori, Debono, Peney) were adding much to the existing knowledge of the Upper White Nile from the Egyptian side; and in the north the Algerian Sahara was being explored by the French scientific traveller Duveyrier.

In 1860 Captain Speke, anxious to extend knowledge of the great inland reservoirs which had been discovered in his former journey, and to connect them with the known countries to northward, accompanied by Captain Grant, again left Zanzibar. Reaching a point on the north-western shores of the great lake which he had previously made known, and which he now named the Victoria Nyanza, the traveller thence traced the outflowing river to the White Nile at Gondokoro, thus completing a great link in the chain of African discoveries, which binds the country known from the east coast to that explored from the side of Egypt.

Livingstone (L. Nyassa). Meanwhile Dr Livingstone had endeavoured to find a way to his newly-discovered Lake Nyassa from the mouth of the Rovuma, a large river which flows to the Indian Ocean near Cape Delgado, and which was also reported to take its rise in this lake, but the river proved to be unnavigable beyond a point not far from the sea. He returned then (in 1861) to the Shire river; and, carrying a boat past its rapids, launched out to explore the whole length of Lake Nyassa.

Rohlfs (Marocco). Von Decken. A series of important journeys by Gerhard Rohlfs had now (1861) begun in Marocco and in the Maroccan Sahara; and on the equatorial east coast region, Baron von der Decken had extended Rebmann's information in the region of the snowy mountain, Kilima-njaro.

Baines. In the south the artist Baines had crossed the Kalahari Desert from Damara Land to the falls of the Zambeze. In 1862 Petherick made an important journey of exploration in the Nile region west of Gondokoro.

Baker (Albert Lake). The year 1864 was marked by the discovery of a second great reservoir lake of the Nile, near the latitude of the Victoria Nyanza, by Baker, pushing southward from Gondokoro. This lake the discoverer named the Albert Nyanza. During this year also, Rohlfs extended his travels from Marocco to the oasis of Tuat, thence making his way to Ghadames and Tripoli; in Western Africa, the officers of the French marine stationed at the Gaboon explored the delta region of the great Ogowai river; **Du Chaillu.** and Du Chaillu, in a second journey (1864–65), entered the gorilla country of Ashango, south of this river; whilst, on the east coast, Baron von der Decken attempted the navigation of the Juba, but was destined to fall a martyr to the jealousies of the Galla and Somali tribes, whose territories the river divides.

After a short stay at Tripoli, the traveller Rohlfs again turned southward, and in a journey which lasted from 1865 to 1867, crossed the whole northern continent—first reaching Lake Chad by almost the same route as that formerly taken by Barth, and thence striking south-westward by a new path to the Bight of Benin.

In 1866 some progress was made in discovery in the west, by the navigation of the Ogowai river by Walker, for 200 miles from its mouth. Hahn and Rath also extended their exploration of Damara Land. On the eastern side Messrs Wakefield and New, the successors of Krapf and Rebmann in the Mombas Mission, made numerous short journeys in the Galla country, and the former collected very valuable native information respecting the countries lying between this coast-land and the great lakes of the Nile basin. In this year also Dr Livingstone had again entered the Rovuma river, beginning that greatest of all his journeys from which he has not yet (1873) returned, and the outline of which we shall notice further on.

Still farther south, in 1866–67, the discovery of gold in the mountains between the Zambeze and Limpopo rivers, by the pioneer Mauch, gave great impetus to exploration in this part of the continent. The years 1867–68 brought the memorable Abyssinian campaign, and the accurate records kept of the line of march on the high land from Massowah to Magdala formed a most valuable contribution to African geography.

Most important in the following years (1869-71) were the researches of the botanist, Dr Schweinfurth, in the region of the complicated network of tributaries received by the White Nile west of Gondokoro, during which he passed the water-parting of the Nile basin in this direction, and came into a new area of drainage, possibly belonging to the system of Lake Chad; and the outsetting of a great Egyptian military expedition (1869) by Sir Samuel Baker, for the purpose of exploration of the Upper Nile and of the extermination of slave traffic on the river, and to plant Egyptian military posts in the regions visited.

Livingstone.

The letters received from time to time in this country from Dr Livingstone enable us to trace roughly his movements from 1866 to the present time as follows:—Arriving from Bombay, on the East African coast, near the mouth of the Rovuma, he passed up the course of this river to the confluence of its main tributary branches, one coming from the north-west, the other from south-west. Following the latter arm, the traveller appears to have gone round the southern end of the Lake Nyassa, and, marching then in a north-westerly direction, he crossed the head waters of the Aruangoa tributary of the Zambeze, near the track of Lacerda, in the previous century; ascending a high land, he came upon a portion of the Chambeze river, belonging to a different basin, and continuing in a north-westerly direction, discovered Lake Liemba, a southern extension of Lake Tanganyika, in April 1867. Thence he turned to the Cazembe's town, and in journeys northward and southward from this point, made known the two great lakes, Moero (Sept. 1867), and Bangweolo or Bemba (July 1868), which form part of a new system, connected by the Chambeze (also named the Luapula and Lualaba) river in a basin south and west of that of the Tanganyika. In 1869 Livingstone had made his way to Ujiji, Burton's halting-place, on the eastern shore of the Tanganyika. Hence, crossing the lake, he penetrated the dense tropical forests and swamps of Manyuema country, in the heart of the southern portion of the continent, and during 1870–71 traced the vast river (Lualaba) flowing out of the Lake Moero, in its north and westerly course, to a second, and then a third great expansion—Lake Kamalondo the one, and the other a still unvisited body of water lying in about 3° S. lat., and 25° or 26° E. long; also learning, by native report, that the Lualaba (which is in all probability the upper course of the mighty Congo river) received a great tributary from south-westward. This south-western arm also expands into a vast lake which Livingstone has named, in anticipation, Lake Lincoln.

(Lake Liemba). (Lakes Moero and Bangweolo). (Manyuema).

Though the untruth of a report of Livingstone's death, near the Nyassa, had been proved by an expedition sent out on his track by the Geographical Society of London in 1867, yet, at the time of his Manyuema journey, the probable fate of the great traveller, from whom no news had come out of Africa for more than two years, became a matter of the greatest anxiety among all classes in Europe and America. This led to a special mission for Dr Livingstone's aid, generously fitted out at the cost of the proprietor of an American newspaper. Stanley, the leader of this expedition, made a bold march from Zanzibar to Ujiji, on Lake Tanganyika, and was fortunate in meeting the great traveller there, returning from Manyuema, broken down by the severity of the task which he had accomplished, and in need of everything. A boat voyage round the northern end of Tanganyika, undertaken in the latter part of 1871 by Livingstone and Stanley together, proved that this great lake has no apparent outlet in a northerly direction, and leaves the question of its drainage in considerable doubt.

Recruited in health, and supplied with stores and followers, Livingstone is believed to have started afresh from Unyanyembe, a point midway in the route from Zanzibar to Ujiji, where he parted with Stanley, in autumn of 1872, to carry out a projected journey, in which he will clear up all doubts respecting the ultimate direction of the great Lualaba river.

Of the expeditions which have been progressing in Africa contemporaneously with these later journeys of Dr Livingstone, that of Sir Samuel Baker is perhaps the most important, though its story has until now been one of almost continuous hardship and disaster. Up to the middle of the year 1870, at which time the expedition, consisting of upwards of 1500 men, with numerous vessels, had safely reached a point on the Nile in 9° 26′ N. lat., all appears to have gone well; but beyond this the passages of the river had become choked with overgrowth of vegetation, and each yard of advance had to be cut through this living barrier; disease broke out among the troops, and the expedition was reduced to the greatest straits. In the end, however, it appears to have been completely successful, and before Sir Samuel Baker's return to Egypt in 1873, the whole country, as far south as the equator, had been taken possession of in the name of Egypt, and several garrisons had been planted to maintain the hold.

Knowledge of the rich country between the Transvaal Republic and the Zambeze has extended with wonderful rapidity, through the exertions of the pioneers Mauch, Mohr, Baines, Elton, and St Vincent Erskine, so that this region has now almost passed out of the category of lands in which geographical discoveries can be made. A point of great interest in the progress of the exploration of this country was the discovery by Mauch, in 1871, of the ruins of an ancient city or fortress, named Zimbaoe, certainly not of African construction, about 200 miles due west from Sofala, in lat. 20° 15′ S., long. 30° 45′ E., through which it has been sought to identify this region with the Ophir of Scripture. The finding, in 1869, of rich diamond fields in the upper valley of the Orange river, and in that of its tributary the Vaal, caused a rush of emigration to these districts, and tended still further to develop this portion of Africa.

North African exploration is also vigorously progressing. In the west, during 1869, Winwood Reade made a journey from Sierra Leone to the head of the Niger, and from 1867 onwards M. Munzinger, consul at Massowa, has greatly extended our knowledge of Northern Abyssinia. A notable journey of exploration in the Sahara remains to be mentioned. In 1869 Dr Nachtigal was appointed to carry presents from the King of Prussia to the Sultan of Bornu, on Lake Chad, in acknowledgment of that potentate's aid to former travellers. Besides accomplishing this mission, this explorer has added very considerably to our knowledge of the Eastern Sahara by investigating the central mountainous country of Tibesti, hitherto only known by report; and in more recent journeys, still being continued, he has proved the existence of an outflowing river from Lake Chad, which has hitherto been believed to be a terminal lake, the freshness of its waters having on this account appeared an anomaly in physical geography.

With the double purpose of affording support to Dr Livingstone, and of adding to the geography of Equatorial Africa, two expeditions were fitted out by the Royal Geographical Society in 1872. One of these, led by Lieut. Cameron, was planned to follow the footsteps of Livingstone in his present journey from the eastern side, entering the country by the ordinary trade route from Zanzibar towards the Tanganyika. This expedition started from Zanzibar early in 1873, under the auspices of Sir Bartle Frere's mission, and has now made considerable progress towards the interior. The other, named the "Livingstone Congo Expedition," under Lieuts. Grandy, is to pass from the west coast to the interior, by following the river Congo, which is almost without doubt the lower course of the great Lualaba river, about to be further explored by Dr Livingstone coming to it from the eastern side. The latest accounts from this expedition are also in the highest degree favourable, and an advance of upwards of 150 miles has already been made from Loanda. A new expedition, under the leadership of the indefatigable traveller Rohlfs, is now in preparation, and is destined to explore the unknown portions of the Libyan desert.

Thus the exploration of the great continent is slowly advancing year by year, but with earnest and unceasing progress. As yet the only portions of Africa of which we possess any approach to an accurate topographical knowledge are, the Cape Colony and Natal under British rule in the south, the French colony of Algeria, the Portuguese possession of Angola, and Egypt and Tunis, dependent on the Turkish Empire, in the north.

Throughout the rest of the continent, a network of routes accomplished by travellers gives in most parts the great outline of its features; where these lines interlace more closely, as in the South African Republics, and in Abyssinia, the general aspect of the land is now so well known as to preclude the possibility of any important geographical discovery there; elsewhere, however, the gaps between the tracks are wider. In the vast inhospitable region of the Sahara there are great areas still unknown to civilised man, and the equatorial region of dense forests in Central Africa is still one of the greatest *terræ incognitæ* of the globe.

The origin and meaning of the name of this great continent has been a fertile subject for conjecture among philologists and antiquaries. By the Greeks it was called Libya, Λιβύη, and by the Romans Africa. Varro believed he had found the etymology of the former in *Libs*, the Greek name of the south wind; and Servius, the scholiast on Virgil, proposed to derive the other from the Latin word *aprica* (sunny), or the Greek word *a-phrikê* (without cold). It is more probable that the name Libya was derived by the Greeks from the name of the people whom they found in possession of the country to the westward of Egypt, and who are believed to have been those that are called in the Hebrew Scriptures *Lehabim* or *Lubim*. With respect to the word *Africa*, Suidas tells us that it was the proper name of that great city which the Romans called *Carthago*, and the Greeks, *Karchedon*. It is certain, at least, that it was applied originally to the country in the immediate neighbourhood of Carthage, that part of the continent first known to the Romans, and that it was subsequently extended with their increasing knowledge, till it came at last to include the whole continent. Of the meaning of the name, the language of Carthage itself supplies a simple and natural explanation; the word *Afrygah*, signifying a separate establishment, or in other words a colony, as Carthage was of Tyre. So that the Phœnicians of old, at home, may have spoken of their Afrygah, just as we speak of our colonies. Be that as it may, the Arabs of the present day still give the name of Afrygah or Afrikiyah to the territory of Tunis. It may also be remarked, that the name seems not to have been used by the Romans till after the time of the first Punic war, when they became first acquainted with what they afterwards called *Africa Propria*.

Africa lies between the latitudes of 38° N. and 35° S., and is of all the continents the most truly tropical. It is, strictly speaking, an enormous peninsula attached to Asia by the isthmus of Suez. The most northern point is the Cape, situated a little to the west of Cabo Blanco, and opposite Sicily, which lies in lat. 37° 20′ 40″ N., long. 9° 41′ E. Its southernmost point is Cabo d'Agulhas, in 34° 49′ 15″ S.; the distance between these two points being 4330 geographical, or about 5000 English miles. The westernmost point is Cabo Verde, in long. 17° 33′ W., its easternmost Cape Jerdaffun, in long. 51° 21′ E., lat. 10° 25′ N., the distance between the two points being about the same as its length. The western coasts are washed by the Atlantic, the northern by the Mediterranean, and the eastern by the Indian Ocean.

Form

The form has been likened to a triangle, or to an oval, but such a comparison is scarcely warranted, it being of an irregular shape, the northern half rounding off, the southern one contracting and terminating in a point.

Superficial extent.

The superficial extent of Africa has never been accurately determined, but may be taken at 9,858,000 geographical square miles, exclusive of the islands. It is larger than either Europe or Australia, but smaller than Asia and the New World.

Coast line and indentations.

The coast line of Africa is very regular and unbroken, presenting few bays and peninsulas. The chief indentation is formed by the Gulf of Guinea, with its two secondary divisions, the Bight of Benin and the Bight of Biafra. On the northern coast, the Gulf of Sidra and the Gulf of Kabes must be mentioned, and on the eastern coast the Gulf of Arabia.

Physical configuration.

The physical configuration may be considered under two heads, the great lower-lands and plains of Northern Africa, and the great table-lands, with their mountain ranges and groups, of Central and Southern Africa. The great northern lower-land comprises the Sahara, the Lake Chad region, and the valley of the Lower Nile. The Sahara is by no means a plain throughout, but for the greater part it rises into table-lands, interspersed with mountain groups of 6000 feet elevation, and probably more, and the term lower-lands can only be applied to it in a general way, to distinguish it from the more elevated region to the south.

The Sahara has often been pictured as a monotonous and immense expanse of sand; but nothing could be more erroneous, as the greatest variety exists in the physical configuration of its surface, as well as in its geological features. Our knowledge is as yet too scanty to enable us to trace its features in every part. On the north, this great desert is fringed with extensive table-lands, which in some places rise abruptly from the Mediterranean, as the great plateau of Barbary, extending through Marocco, Algeria, and Tunis, and the table-land of Barca, elevated 1500 feet, and gradually descending towards the Delta of the Nile. This elevated ground is succeeded to the south by a depressed region, which extends from the Great Syrtis or Gulf of Sidra, in a general direction as far as Middle Egypt, and comprises the oases of Augila and Siwah. So greatly depressed is this region, that the level of the oasis of Siwah is 100 feet, and in one place (Bahrein) even 167 feet below the level of the sea. The western portions of this country, between the oases of Augila and Siwah, explored in

1869 by the traveller Rohlfs, were found to be everywhere from 100 to 150 feet beneath the level of the Mediterranean; and M. de Lesseps, in conducting a survey from the Egyptian side, found the eastern part to be much beneath the level of the Nile. Here then must be one of the greatest areas of depression in the land of the globe, comparable with that which surrounds the Caspian Sea. This depressed region is again followed by a table-land of considerable extent and width, extending from the Gulf of Kabes in a southerly direction, along the Tripoline shores, and probably traversing, in the same direction, the Libyan Desert, and reaching as far as the Nile, near the first cataract. Its north-western part, as far as Sokna, consists of the Hamadah, a stony, dreary, and extensive table-land, of from 1500 to 2000 feet high, "which seems to be like a broad belt intercepting the progress of commerce, civilisation, and conquest, from the shores of the Mediterranean to Central Africa." Near Sokna this plateau breaks up and forms what are called the Jebel-es-Soda, or Black Mountains, a most picturesque group of cliffs; and again, on the route from Murzuk to Egypt, it also breaks into huge cliffs, and bears the name of El-Harouj. The whole of the central portion of the Northern Sahara, as far south as the plateau of Air or Asben, is occupied by similar bare table-lands, with lower areas of sand dunes between. Numerous wadys, the only inhabited parts of the country, intersect the slopes of these plateaux. The country of Ahaggar, between 23° and 29° N. lat., and 5° E. long., appears to form the central elevation from which the greater of these dry water-courses radiate; from it a series of long wadys—one of them, the wady Rharis or Igharghar, being about 600 miles in length—run northward towards a depressed country which lies inland from the Gulf of Cabes, and contains several salt lagoons, covered with a few feet of water in winter, but dried up in summer, and lying considerably below the Mediterranean level. Other wadys radiate west and south-west from Ahaggar to the unknown region of the Sahara, which lies between this and the northern bend of the Niger. The most truly desert region of the Sahara is an irregular belt of shifting sand dunes, the "Erg" or "Areg," which stretches from the lagoons above referred to near the Mediterranean coast south-westward to near the river Senegal and the Atlantic, in an unbroken chain for upwards of 2000 miles, and having an average width of perhaps 200 miles. In this sand belt the wadys of the inward slope of the plateau of Barbary terminate, excepting the Wady Saura, which crosses the Erg to the important oasis of Tuat, near the centre of its southern border, and the Wady Draa, which turns to the Atlantic coast. From Wady Draa a great plain extends along the western shore as far as the river Senegal, and probably continues as such to the east towards Timbuktu, and thence to Lake Chad. Thus it appears that the western half of the Sahara is surrounded by a broad belt of plains and depressions, the central parts being formed by extensive table-lands, with occasional mountain knots, such as that which forms the fertile kingdom of Air and Asben, the culminating points of which are from 4000 to 5000 feet high.

The eastern portion of the Sahara appears to have nearly the same general elevation as the western half, and near its centre several fertile mountain regions, comparable with that of Asben, are known. Such is the mountainous country of Borgu, north-east of the kingdoms which surround Lake Chad, and Tibesti, north of it, in the centre of the Tibbu district, recently explored by Dr Nachtigal, who found rich vegetation and abundant animal life in the valleys of this mountain group.

To the south and east of the region just described Africa may be considered as one connected mass of elevated land, comprising the most extensive table-lands, as well as high mountain groups and chains.

The great mass of the African plateau land is to southward of the 10th parallel of N. latitude, but it is prolonged on the eastern side almost to the north coast of the continent by the wedge-shaped table-land of Abyssinia, the highest surface in Africa, and by the mountains which extend from it between the lower course of the Nile and the Red Sea. The terminal point of the high land in this direction may be said to be Jebel Attaka, which rises immediately west of Suez to a height of 2640 feet. From this point to the southern extremity of the continent the eastern, and generally higher edge, of the great plateau runs in an almost unbroken line. Passing southwards along its margin, the most prominent heights before the table-land of Abyssinia is reached are Mounts Elba, 6900, and Soturba, 6000 feet in elevation, near the middle of the African coast of the Red Sea. There may, however, be greater heights in the little known region of Nubia, which lies between these mountains and the Nile.

The eastern slope of the Abyssinian plateau begins immediately south of the port of Massowah, and is a uniform line of steep descent, unbroken by any river, falling abruptly from an average height of 7000 feet to the depressed plain which here skirts the coast of the Red Sea. This edge, which extends southward for at least 800 miles, forms the water-parting of the rivers which have furrowed deeply into the opposite slopes of the plateau, and appears to be higher than the general surface of the country; yet several lofty groups of mountains rising from the level of the high land attain a much greater elevation, and Mount Abba Jared, the highest known point, is estimated at 15,000 feet above the sea. Between the most southern part of Abyssinia which is known and the equator, where the edge of the plateau has again been partly explored, a long space of unknown country intervenes; but there is every reason to believe that the slope is continuous. Mount Kenia, 18,000 feet, and Kilimanjaro, 18,715 feet, the highest points in all Africa, mark the eastern edge under the equator; further south on the inland route from Zanzibar to the Tanganyika, the edge is known as the Rubeho Mountains, with a height of 5700 feet at the pass by which they are crossed on the caravan route. Still further, the edge is again known where it forms a rampart, called the Njesa, walling in the Nyassa Lake. From this point Mount Zomba, 7000 feet high, near Lake Shirwa, Mount Milanje, 8000 feet, and Mount Clarendon, 6000 feet, carry it south to where the Zambeze river makes the first break in its uniform line. The narrows and rapids of Lupata, below the town of Tete, mark the point at which the river breaks through the plateau land to the coast slope beneath it. Passing the river, the eastern edge is again followed in the Mashona and Matoppo Mountains (7200 feet) of Mosilikatse's kingdom, from which heights the chief tributaries of the Limpopo river flow. At the head-waters of that river the plateau edge forms the Hooge Veldt of the Transvaal Republic which joins with the Kathlamba or Drakenberg. The portion of the edge which bears this name is specially prominent: it runs southward in a huge wall of rocky crags which support the table-land behind for 500 miles, almost parallel with the coast, and at a distance of 150 miles from it, having Zulu Land, Natal, and Caffraria on the slopes of the spurs which it throws down to the coast. In the Transvaal Republic, where the Drakenberg joins the Hooge Veldt, the edge attains a height of 8725 feet in the summit named after the explorer Mauch, but it is highest where it forms the interior limit of Natal, and where Cathkin Peak rises to 10,357 feet above the sea.

As in Abyssinia, so here, this part of the eastern plateau edge is the great water-parting of the continent, and the streams which form the Orange river flow down its inward slope. There is no break in the continuance of the edge where it passes round from the Drakenberg to form the inmost and highest of the alternate ridges and terraces of the Cape Colony. It is now named in successive parts from east to west the Storm Berge, the Zuur Berg, Schnee Berge, Nieuwe-veld, and Rogge-veld, the last-named portion of the edge turning northward with the bend of the western coast. Its greatest height within the Cape Colony is in Compass Berg, the summit of the Schnee Berge, 8500 feet above the sea.

Southern edge of the plateau.

The outer terraces of the Cape Colony, in which two chief ridges may be traced, lie closer together, and much nearer the coast; between these and the inmost or chief edge is the dry elevated region known as the Great Karroo. Their elevation is also very considerable, though they are broken through by lines of drainage sloping from the chief edge; the part of the middle ridge, which is named the Little Zwarte Berge, attains 7628 feet, and several points in both are upwards of 6000 feet above the sea. Table Mountain, a well-known and flat-topped mass of granite overhanging Cape Town, 3550 feet high, is the nucleus of the peninsula which extends south to form the Cape of Good Hope, but is altogether separated from the mountain ridges of the colony.

Western edge of the plateau

The western edge of the great African plateau is generally lower than the eastern, since the whole slope of the continent is more or less from the great heights on its eastern side, towards the west, but it is also clearly traceable, and of great height throughout. Rounding the western side of the Cape Colony, the three ridges above-noticed run together, and decrease somewhat in elevation as the mouth of the Orange river is approached. Their elevation at the point of union in Little Namaqua Land is still very considerable; and here Mount Welcome attains 5130 feet, and Vogelklip, to north of it, 4343 feet above the sea. Beyond the Orange river in Namaqua and Damara Lands, the western edge continues in one or more terraces parallel to the coast. Mount Omatako, in the latter country, rises to 8800 feet. Northward, through Benguela and Angola, a more broken series of ridges and terraces mark the descent from the interior plateau, and the great Congo river breaks through to the coast-land at the place where it forms the cataracts of the narrow gorge of Yellala. Sierra Complida is the name given by the Portuguese to that part of the western edge which runs between the Congo and the rapids of the lower Ogowai river on the equator. On the plateau edge at the southern side of this river, Du Chaillu has made known a mountain of 12,000 feet in elevation; and the furthest point which has been reached on the Ogowai was in the vicinity of high mountains. Passing the Ogowai, and following the coast of the Bight of Biafra, the edge is now known as the Sierra do Crystal. The Camaroon mountains, at the head of the gulf, form a high peninsula of volcanic mountains, rising to 13,700 feet; but are isolated from the plateau lands, and belong rather to the remarkable line of volcanic heights which shows itself in the islands of Fernando Po, Prince's Island, St Thomas, and Annobon, stretching away into the ocean in the direction of St Helena. From the Sierra do Crystal the plateau edge inclines towards the lower course of the river Niger to a point above its delta, and below the confluence of the Benue. and then turns abruptly to the east.

The heights which skirt the northern coast-land of the Gulf of Guinea, and which stretch as far as the head-waters of the Senegal and Gambia. and in the inner slope of which the Niger also has its sources, may be considered as an extension from the great plateau. But they are of smaller general elevation; and that best known part of the ridge, which has the name of the Kong Mountains, is apparently not higher than from 2000 to 3000 feet.

The northern edge of the great African plateau is almost unknown; but there are evidences that it runs eastward between the 4th and 8th parallels of N. latitude, to a point at which it is well known, and where the Nile falls over its slope, forming the succession of rapids above Gondokoro. The character of the upper Benue river is that of a mountain-born river; and Mounts Alantika, 10,000 feet high, and Mindif, 6000 feet, which rise to southward of Lake Chad, seem to be the outliers of the plateau edge in which the Benue has its sources. Beyond the Nile the margin of the plateau curves northward, to form the inner slope of the Abyssinian table-land.

The general elevation of the surface of the great African plateau, the limits of which have now been traced, may be taken at from 3000 to 4000 feet above the sea; but its surface presents very great undulations, from the depressions which are occupied by some of the great lakes, to the high mountains which rise above its average level. The most prominent of these interior masses yet known are the Blue Mountains, discovered by Baker, rising from the western shore of the Albert Lake to a height of perhaps 10,000 feet, and which are believed to extend southward to unite with the Balegga Mountains, made known by Livingstone in his journey of 1871, north-west of Lake Tanganyika; these again are believed to join with the mountains which rise midway between the Victoria, the Albert Nyanza, and the Tanganyika, dividing the drainage to these vast lakes, and rising here in Mount M'fumbiro to upwards of 10,000 feet. Another great central line of heights which also had an important part in directing the water-shed of the interior of South Africa, runs from the north of the Nyassa Lake, where it is named the Lobisa plateau, through the Muchinga Mountains, which separate the drainage of the Lualaba and its lakes from that of the Zambeze basin, westward to the heights in the far interior of Angola, known as the Mossamba Mountains, and from which rivers flow in all directions.

Plateau of Barbary.

The plateau of Barbary, in the north of the continent, beyond the lower land of the Sahara, is a distinct and separate high land, stretching from Cape Bon, on the Mediterranean coast opposite Sicily, in a south-westerly direction to the Atlantic coast, through Tunis, Algeria, and Marocco. The eastern portion of it in Algeria and Tunis rises in a broad plateau from 2000 to 3000 feet in general height, with outer heights, enclosing an elevated steppe, at a distance of about 100 miles apart. On the west, where it enters Marocco, these outer ridges draw together and form the high ranges of the Atlas Mountains, rising to a much greater elevation, and attaining 11,400 feet in the summit named Mount Miltsin.

The African continent, as far as it has yet been explored, seems to be the portion of the globe least disturbed by volcanic action. The known active volcanoes in the continent are those of the Camaroon Mountains, on the coast of the Gulf of Guinea in the west, and the Artali volcano in the depressed region of the salt desert which lies between the Abyssinian plateau and the Red Sea. This latter volcano is probably a part of the system with which the volcanic island of Jebel Tur, in the Red Sea, near the same latitude, is connected. One other active volcano only is known by report,—the Njemsi volcano, in the country between Mount Kenia and the Victoria Lake. Shocks of earthquake appear to be almost unknown in any part of the continent. It has been pointed out by the late Sir Roderick Murchison that the older rocks which are known to circle round the continent, unquestionably included an interior marshy or lacustrine country, and that the present centre zone of waters, whether lakes, rivers, or marshes, extending from Lake Chad to Lake Ngami, are but the great modern residual phenomena of those of a mesozoic age. The surface of the South African continent has not been diversified in recent times by the outpouring of lava streams, or broken up by the efforts of subterranean heat to escape. Nor has it been subjected to those great oscillations by which the surfaces of many other countries have been so placed under the waters of the ocean as to have been strewed over with erratic blocks and marine exuviæ. The interior of South Africa may therefore be viewed as a country of very ancient conservative terrestrial character. Knowledge of the special geology of Africa is yet confined to the few parts of the continent in which Europeans have permanently settled. In this respect the southern region of the Cape Colony and Natal have advanced furthest, and their geological features have been mapped out with some accuracy. Elsewhere in the continent, excepting in Algeria and Angola, light has only been thrown along the line followed by the few explorers who have given attention to this subject.

Among the minerals of Africa, salt is widely distributed, though in some districts wholly wanting. Thus in the Abyssinian high land the salt, which is brought up in small blocks from the depressed salt plain on the Red Sea coast beneath, is so valued as to be used as a money currency; and in the native kingdoms of South Central Africa, the salt districts are royal possessions strictly guarded. Metals seem nowhere very abundant. Gold is perhaps the most generally distributed. The gold-fields of the Transvaal Republic and of the country which extends thence to the Zambeze, are numerous; but no yield has as yet been discovered of sufficient quantity to overcome the difficulties of working, and of transport to the distant sea-ports, to which no navigable rivers lead from this region. Copper is known to exist in large quantities in the mountains of native kingdoms of the centre of South Africa; and one of the objects of Dr Livingstone's present journey is to visit the famed copper country of Katanga south-west of the Tanganyika Lake. The diamond-fields in the districts of the Vaal and Orange rivers north of the Cape Colony are now steadily worked, and give good returns.

General nature of the surface of Africa.

Africa is the only one of the continents of the globe which lies equally to north and south of the equator, and the portions of it which extend beyond the tropics do not advance far into the temperate zones. From this it results that Africa, besides being the warmest of all the continents, has also the most equal distribution of the sun's heat during the seasons over the parts which lie north and south of the central line. Winds and rain, depending on the distribution of heat, are also correspondingly developed in these two great divisions of the continent, and the broad landscape zones, passing from humid forest to arid sandy desert, also agree exactly with one another north and south of Equatorial Africa.

Equatorial forests

Between 10° N. and 10° S. of the equator, but especially in that portion of it the outskirts of which have only as yet been reached by travellers, Africa appears to be a land of dense tropical forest. Wherever it has been penetrated, travellers speak of an excessively rank vegetation; passage has to be forced through thick underwood and creeping plants, between giant trees, whose foliage shuts out the sun's rays; and the land teems with animal and insect life of every form and colour. Describing the forests of Manyuema country, west of the Tanganyika Lake, Livingstone says—"Into these [primæval forests] the sun, though vertical, cannot penetrate, excepting by sending down at midday thin pencils of rays into the gloom. The rain water stands for months in stagnant pools made by the feet of elephants. The climbing plants, from the size of a whipcord to that of a man-of-war's hawser, are so numerous, that the ancient path is the only passage. When one of the giant trees falls across the road, it forms a wall breast high to be climbed over, and the mass of tangled ropes brought down makes cutting a path round it a work of time which travellers never undertake." Here there is a double rainy season, and the rainfall is excessive. To north and south of this central belt, where the rainfall diminishes, and a dry and wet season divides the year, the forests gradually open into a park-like country, and then merge into pastoral grass-lands. In North Africa this pastoral belt is occupied by the native states of the Soudan, from Abyssinia westward, in the parallel of Lake Chad, to the Gambia on the Atlantic coast; and corresponding to this in the south, are the grass-lands stretching across the continent from the Zambeze to southern Angola and Benguela. The pastoral belts again gradually pass into the dry, almost rainless desert zones of the Sahara in the north, and the Kalahari desert in the south, which present many features of similarity.

Deserts.

The extremities of the continent, to which moisture is carried from the neighbouring oceans, again pass into a second belt of pastoral or agricultural land, in the northward slopes of the plateaus of Barbary, Marocco, Algeria, and Tunis, corresponding with the seaward terraces of cultivated land in the Cape Colony in the south.

Taking a broad view of the hydrography of Africa, there are two great areas of continental drainage, one in the north, the other in the south, from which no water escapes directly to the ocean. These correspond almost exactly with the two desert belts of the Sahara and the Kalahari above described. The whole of the remaining portions of the continent, its forests and pastoral districts, in which the greater rainfall gives greater power to the rivers, are drained by streams which find their way to the ocean on one side or other, generally forcing a passage through some natural or waterworn gorge in the higher circle of mountains which run round the outer edges of the great plateau.

By far the larger portion of the oceanic drainage of the continent is to the Atlantic and its branch the Mediterranean, to which the Nile, Niger, Ogowai, Congo, and Orange rivers flow. The great rivers which drain on the opposite side, to the Indian Ocean, are the Juba, Zambeze, and Limpopo; whilst the northern continental basin, by far more extensive than the southern, has only one great river, the Shari, which supplies Lake Chad.

It must be noticed that the capabilities of the African rivers, as highways of approach to the interior of the continent, are exceedingly small in comparison with those of the other great continents of the globe, most of them being either barred at their mouths, or by rapids at no great distance from the coast. It is owing to this physical cause mainly that the African continent has remained for so many centuries a sealed book to the civilised world. On the other hand, it must be observed, that when these outer barriers have been passed, the great interior of the land, in its most productive regions, possesses a network of vast rivers and lakes, unsurpassed in extent by those of any country of the world, by means of which the resources of Central Africa may in future be thoroughly developed.

The Nile is the oldest of historical rivers, and afforded the only means of subsistence to the earliest civilised people on earth, and yet the origin of this river remained an enigma almost to the present day. Though it drains a larger area than any other river of Africa, upwards of 1,000,000 square miles, and in this respect is one of the largest rivers of the globe, the Nile, passing for a great portion of its lower course through the desert belt of North Africa, and receiving no tributaries there, loses much of its volume by evaporation, and is far surpassed in the quantity of water conveyed to the ocean by the Congo, in the moist equatorial zone. The great labours of Dr

Livingstone, in the lake region of Central Africa, have so narrowed the space within which the sources of the Nile can exist, that, though no traveller has yet reached the ultimate feeders of the great river, their position can now be predicated almost with certainty. The limit of the Nile basin on the south is formed by the high mountains which rise to westward of the Albert Lake, and which divide between this great reservoir and the Tanganyika, extending eastward to the plateau of Unyamuezi, on the northern side of which the Victoria Nyanza lies. The ultimate sources must then be the feeders of these great equatorial lakes, the Victoria and Albert. The river issuing from the former lake, at the Ripon Falls, 3300 feet above the sea, to join the northern end of the Albert Nyanza, may be considered as the first appearance of the Nile as a river. At the Ripon Falls the overflow is from 400 to 500 feet in breadth, and the descent of 12 feet is broken in three places by rocks. Further down, where the river turns westward to join the Albert Lake, it forms the Karuma and Murchison Falls, the latter being 120 feet in height. From the Albert Lake, the Nile, called the Kir in this part, begins its almost due northward course to the Mediterranean, and has no further lake expansion. Between the Albert and Gondokoro, in 5° N. lat., which lies at 2000 feet above the sea, the Nile descends at least 500 feet in a series of rapids and cataracts. Beyond Gondokoro, up to which point it is navigable, it enters the northern lower land of Africa, which is here a region of swamps and forests, and several tributaries join it from the west. The largest of these, named the Bahr-el-Ghazal, unites with the main stream below the 10th parallel; and, not much further on, a main tributary, the Sobat river, joins the Nile from the unknown region which lies to the south-east. Hence, onward, the Nile is known as the Bahr-el-Abiad or White River. The two remaining great tributary rivers descend from the high land of Abyssinia on the east. The first of these, the Bahr-el-Azrek or Blue River, its waters being pure in comparison with those of the Nile, has its source near Lake Dembea or Tzana, through which it flows, in the western side of the Abyssinian plateau, 6000 feet above the sea; forming a semicircular curve in the plateau, the Blue Nile runs north-westward to the confluence at Khartum, 1345 feet above the sea. Between this point and the union of the next tributary, the Nile forms the cataract which is known as the sixth from its mouth. In about 18° N. it is joined by the Atbara or Black River, the head stream of which is the Takkazze, flowing in a deep cut valley of the high land. This tributary is named from the dark mud which it carries from the high land, brought down to it by streams which swell into rushing torrents in the rainy season. It is to these rivers that the fertility of Lower Egypt is mainly due, for each year a vast quantity of Abyssinian mud is borne down to be spread over the delta. Hence the Nile pursues its way in a single line through the dry belt of desert to the Mediterranean without a single tributary, descending by five cataracts, at considerable distances apart. The delta of the Nile, in which the river divides into two main branches, from which a multitude of canals are drawn off, is a wide low plain, occupying an area of about 9000 square miles. The most remarkable circumstance connected with the delta is the annual rise and overflow of the river, which takes place with the greatest regularity in time and equality in amount, beginning at the end of June, and subsiding completely before the end of November, leaving over the whole delta a layer of rich fertilising slime.

The Sheliff in Algeria, and the Muluya in Eastern Marocco, are the chief streams flowing to the Mediterranean from the high land of Barbary.

Passing round to the Atlantic system, the Sebu, the Ummer Rebia, and the Tensift, from the Atlas range, are permanent rivers flowing across the fertile plain of Western Marocco, which they serve to irrigate. Next is the Wady Draa, a water-course which has its rise on the inner slope of the high land in Marocco, and which bends round through the Maroccan Sahara to the Atlantic, near the 28th parallel. Its channel, of not less than 500 miles in length, forms a long oasis in the partly desert country through which it flows, and water remains in its bed nearly throughout the year.

A stretch of 1100 miles of waterless coast, where the desert belt touches on the Atlantic, intervenes between the Draa and the Senegal river, at the beginning of the pastoral belt in lat. 15° N.

The Senegal rises in the northern portion of the belt of mountains which skirt the Guinea coast, and has a north-westerly course to the sea. During the rainy season it is navigable for 500 miles, from its mouth to the cataract of Feloo, for vessels drawing 12 feet of water, but at other times it is not passable for more than a third part of this distance. The Gambia has its sources near those of the Senegal, and flows westward in a tortuous bed over the plain country, giving a navigable channel of 400 miles, up to the Falls of Barra Kunda. The Rio Grande, from the same heights, is also a considerable river.

The Niger is the third African river in point of area of drainage and volume; it is formed by the union of two great tributaries, the Quorra and Benue,—the former from the west, the latter from the country in the east of the river basin. The Quorra, called the Joliba in its upper course, has its springs in the inner slope of the mountains which give rise to the Senegal and Gambia, not far from the Atlantic coast. At first its course is north-eastward to as far as the city of Timbuctu, on the border of the desert zone; then it turns due east, and afterwards south-east to its confluence with the Benue, at a point 200 miles north from the coast of the Gulf of Guinea. The chief tributary of the Quorra is the Sokoto river, coming from the elevated country which forms the water-parting between the Niger basin and that of Lake Chad on the east, and its confluence is near the middle of the portion of the channel of the Quorra which bends to south-east.

At a distance of about 100 miles from its sources, the traveller Park, the first European who reached the Joliba, found it flowing in a wide fertile valley, and navigated by canoes which kept up a constant traffic. Above Timbuctu the commerce of the river is busily carried on in barges of 60 to 80 tons burden; further on, where the river touches upon the desert belt in the most northerly portion of its course, its fertile banks form the most marked contrast to the arid desert lands beyond. From the confluence of the Sokoto to the union with the Benue, the river course is only navigable after the rainy season, since at other times rocks and shoals interrupt the passage. The sources of the Benue are unknown as yet, but it is believed to have its rise in the northern edge of the great plateau of Southern Africa, almost due south of Lake Chad; its known course is westward, and at the furthest point to which it was easily navigated by the traveller Baikie, nearly 400 miles from its confluence with the Kawara or Quorra, it was still half a mile in width and about 10 feet in average depth, flowing through rich plains. From the confluence of the Quorra and Benue the Niger has a due south course to its delta, and the united river has an average width of about a mile. At a distance of 100 miles from the sea, minor branches which enclose the delta separate from the main stream on each side. The delta is much more extensive than that of the Nile, and measures about 14,000 square miles of low alluvial plain, covered with forest and jungle, and completely intersected by branches from the main river, the outmost of which reach the sea not less than 200 miles apart. Unlike the Nile, the Niger possesses one main channel through the centre of the delta, called at its mouth the Nun river.

Old Calabar river, the Camaroon river, and the Gaboon, are the best known of a number of wide inlets or estuaries of the sea, which occur on the west coast immediately north of the equator; but these are merely the receptacles of a number of minor streams, not the mouths of great rivers, as at one time supposed.

The Ogowai (pron. Ogowee) river, the delta of which forms Cape Lopez, immedaitely S. of the equator, is a great stream which is believed to drain a large area of the forest zone between the Niger and the Congo; as yet, its lower coast is only known to a distance of 200 miles from the sea. Above the delta the main stream of the river, named the Okanda, breaks through the edge of the plateau, and is joined by the Onango, a tributary from the coast range of the Sierra Complida. Below this confluence the river is a mile and a half in average width, its depth varying from 15 to 50 feet. The delta is formed by the two main branches into which the Ogowai divides at about 30 miles from the coast, and is a swampy flat, covered with mangroves.

Congo. The Congo or Zaire must be considered the second river of Africa in point of area of drainage, and it is the first in respect of the volume of water which it discharges to the ocean. There remains but little doubt that the head streams of this vast river are those which supply the great lacustrine system discovered by Dr Livingstone in his recent journeys south and west of Lake Tanganyika. Through these lakes the river, which rises in the upland north of Lake Nyassa, named in different parts of its course the Chambeze, Luapula, or Lualaba, flows in great bends to west and northward, to where it passes into the unknown country still to be explored in the heart of the continent. The Lualaba has a great tributary named the Lufira, from the south; and it is almost certain that the Kassabi river, which springs in the Mossamba Mountains, in the interior borders of Angola, is also one of the feeders of this great river. The Guango river, rising in the same mountains, nearer Angola, must also join the Congo lower down in its valley. At the furthest point on the Lualaba reached by Livingstone, in about lat. 6° S. and long. 25° E., the great river had a breadth of from 2000 to 6000 yards, and could not be forded at any season of the year. Every circumstance connected with this river—its direction, the time of its annual rising, and the volume of its water which could be discharged by the Congo mouth alone—point to its identity with this river. The explorer Tuckey, who, in 1816, followed up the Congo from its mouth on the west coast further than any one, found it, above the cataracts which it forms in breaking through the coast range, to have a width of from 2 to 4 English miles, and with a current of from 2 to 3 miles an hour; and his statement that at the lowest stage of its waters it discharges 2,000,000 of cubic feet of water per second, has been confirmed by more recent surveys. Forty miles out from its mouth its waters are only partially mingled with that of the sea, and some nine miles from the coast they are still perfectly fresh. The Congo is the only one of the large African rivers which has any approach to an estuary, contrasting in this respect with those which have delta mouths.

The Coanza, the most important river of Angola, in respect of its affording a navigable channel for 140 miles from its mouth, rises in a broad valley formed by the Mossamba Mountains in the interior of Benguela, and curves north-westward to the ocean. Its upper course is rapid, and its navigation only begins after the last of its cataracts has been passed; the mouth is closed by a bar. The Cunene river has its rise in the opposite watershed of the mountains, its springs being close to those of the Coanza, and its course is south-westward, forming the southern limit of the territory of Mossamedes. It is the most southerly river of the central fertile zones of Africa on this side of the continent, and appears to be suitable for navigation throughout the greater part of its length—rising from 15 to 20 feet at times of flood, but having such a depth, at its lowest stage, as to be only passable by canoes.

From the Cunene, in lat. 17° S., to the Orange river in 29° S., the dry belt of the South African desert zone intervenes, and there are no permanent rivers on the land sloping to the sea. The coast lands from the edge of the plateau are, however, furrowed by numerous water-courses, which are filled only after the occasional rainfalls.

The Orange river also belongs for the greater part of its lower course to the water-courses of the arid belt, but it receives such a constant supply from its head streams, which descend from the high lands near the east coast of the continent, as to be able to maintain a perennial flow in its channel, which, however, is so shallow as to be of no value for navigation. Its main head streams are the Vaal and Nu Gariep or Orange, which rise on the opposite slopes of one of the summits of the Drakenberg range, called the Mont aux Sources. After encircling the Orange River Free State, these rivers unite near the centre of this part of the continent to form the Orange, which continues westward to the Atlantic, but without receiving any permanent tributary. The chief water channels which periodically carry supplies to it from the south are Brak and the Great Hartebeeste; from the Kalahari region in the north come the Molopo and Nosob channels. Midway between the union of the head streams and the ocean the river forms a great fall of 150 feet in height.

Drainage to the Indian Ocean. The rivers which flow down from the terraces of the Cape Colony are numerous, but have little permanent depth of water, shrinking almost to dryness excepting after rains, when they become impetuous torrents; some have cut deep channels, much beneath the level of the country, and the banks of these cañons are choked with dense vegetation. Passing round to Natal and Zulu Land, the coast country is well watered by frequent streams which descend from the base of the cliff-wall of the Drakenberg; these have generally the character of mountain torrents, with rapid flow between high banks and changing volume, and are almost without exception closed at their mouths by sand bars, which in most instances shut in considerable lagoons. One of these, the lake of Santa Lucia, is more than 40 miles in length.

Limpopo. The first large river of the Indian Ocean system is the Limpopo or Crocodile river, so named from the great number of these animals found in its bed. Its basin lies centrally in the southern tropic, also in the desert belt, and on this account it barely maintains a shallow flow of water throughout the year. Its sources are in that part of the plateau edge in the Transvaal Republic which is known as the Hooge Veldt and Magalies Berg; from this it forms a wide semicircular sweep to north-east and south, reaching the ocean not far north of Delagoa Bay, in 25° S. Its chief tributary, the Olifant or Lepalule, has its rise in a part of the Hooge Veldt which is nearer the coast. Many of its minor tributaries in its lower course are periodical streams known as *sand rivers*, only filled after heavy rains.

The Zambeze is the great river of the pastoral belt of South Africa, and the fourth in point of size in the continent, draining nearly 600,000 square miles. As far as its basin has yet been explored, the Zambeze has three head streams from the great water-parting ridge which extends from the Mossamba Mountains of inner Angola to the high lands north of Nyassa Lake, about the 12th parallel of S. latitude. There are the Lungebungo river from the Mossamba Mountains, the Leeba river from Lake Dilolo, on the water-parting which separates between the Zambeze and the Kassabi river, and the Leeambye or Jambaji, probably the main-source stream, coming from the unknown lands south-west of the Cazembe's territory. From the union of these streams the general course of the Zambeze is in two wide curves eastward, through the plateau and over its edge to the Indian Ocean, in about 19° S. lat. From the north its main tributaries are the Kafue and Loangwa or Aruangoa rivers, and the Shire river, flowing out of Lake Nyassa. Above this point, on its middle course, where it forms the great Victoria Falls, the Zambeze receives the Chobe from the north-west; and from southward numerous minor tributaries join its lower channel. The Zambeze forms a delta with many mouths, the outmost of which are nearly 100 miles apart, and their entrances are generally barred by sand banks; but if these be passed, the main river is continuously navigable for 320 miles to the town of Teté, and its tributary the Shire may also be followed up for nearly 150 miles, to where its cataracts stop navigation. At the Victoria Falls the great river contracts from its general width of nearly a mile, to 60 or 80 feet, and plunges over a height of 100 feet, into a remarkable zig-zag gorge rent in the hard basalt rocks.

The Rovuma, which has its chief tributaries from the plateau edge on the eastern side of Lake Nyassa, is the next great river of the drainage to the Indian Ocean. It has been navigated by Livingstone for 150 miles from the coast, and formed part of his route in entering the continent on the journey from which he has not yet returned, but its basin has not yet been explored.

Still farther north the mouths of a great river named the Rufiji are known, on the coast opposite the island of Monfia, south of Zanzibar; but no part of its course has yet been traced by any European.

The Kingani and the Wami are two streams from the plateau edge, in the country of Usagara, and reach the sea in the channel formed by Zanzibar island. The Pangani river, further north, rises in the snowy mountain Kilimanjaro. The Sabaki and Dana, which embouch on the opposite side of Formosa Bay, in 3° S., flow over the same coast plains, having their head springs in the spurs of Mount Kenia. The latter river might be navigated during the rainy season for 100 miles from the coast.

The Juba river is the most considerable on the eastern side north of the equator. It is believed to have its rise in the high lands immediately south of Abyssinia, and its general direction is south-eastward to the Indian Ocean; but nothing is known of its higher course except by report. The ill-fated expedition under Baron von der Decken explored this river for about 180 miles upwards from its mouth, but as yet no traffic is carried on by its means. The Webbe or Haines river flows down from the high lands in a direction nearly parallel to the Juba, a little farther north, but its outlet on the coast is completely barred by sand dunes of from 400 to 500 feet in height, behind which it forms a lagoon of varying extent. The desert zone is now again reached, and the water supply fails. No permanent rivers reach the Red Sea from the Abyssinian highlands or from the heights of Nubia which continue these northward; the largest water-course is that of the Barca, which is periodically filled by its tributaries in the northern part of the Abyssinian plateau.

Turning now to the great areas of continental drainage, it is observed that in North Africa there is a vast space of upwards of four millions of square miles, extending from the Nile valley westward to the Atlantic coast, and from the plateau of Barbary in the north to the extremities of the basin of Lake Chad in the south, from which no single river finds its way to the sea. The whole of this space, however, appears to be furrowed by water channels in the most varied directions. From the inner slopes of the plateau of Barbary numerous wadys take a direction towards the great sand-belt of the Erg, in which they terminate; a great series of channels appears to radiate from the higher portion of the Sahara, which lies immediately north of the tropic of Cancer and in about 5° E. of Greenwich; another cluster radiates from the Mountains of Tibesti, in the eastern Sahara.

Lake Chad, on the margin of the pastoral belt, is supplied by a large river named the Shari, coming from the moist-forest country which lies nearer the equator; and the lake, which till recently was believed to have no outlet, overflows to north-eastward, fertilising a great wady, in which the waters become lost by evaporation as they are led towards the more arid country of the Sahara.

The southern area of continental drainage is of much smaller extent, and occupies the space of the desert zone which lies between the middle of the Zambeze basin and Damara Land. It centres in Lake Ngami, to which the Tioge river flows from the pastoral belt on the north-west. Several water-courses from the high Damara Land also take a direction toward this lake. The river Zuga carries off the overflow of Lake Ngami towards a series of salt lagoons which lie eastward near the edge of the plateau; but it becomes narrower and less in volume as it approaches these, and in some seasons scarcely reaches their bed.

Smaller spaces of continental drainage exist at various points near the eastern side of the continent. One of these occupies the depressed area between the base of the Abyssinian highland and the Red Sea, and is properly a continuation of the Sahara desert belt beyond the intervening plateau. In this space the Hawash river, descending from the plateau, terminates before reaching the sea. Another interior basin lies in the plateau between the edge on which mountains Kenia and Kilima-njaro rise and the country east of the Victoria Lake, and includes several salt lakes. It is probable that the great Tanganyika Lake is the centre of a third basin of no outflow on this side of the great plateau; and Lake Shirwa, south-east of the Nyassa, constitutes a fourth.

The great lakes, which form such a prominent feature in African hydrography, are found chiefly in the southern and eastern regions of the continent, but they are distributed over all the systems of drainage. The Victoria and Albert Lakes of the Nile basin are great seas of fresh water; and if their extent should ultimately prove to be nearly that which is at present believed, they rival the great American lakes for the place of the greatest expanse of fresh water on the globe. The former, the Victoria Lake, is at an elevation of about 3300 feet above the sea; and its outline, as at present sketched on our maps, occupies an area of not less than 30,000 square miles. The Albert Lake, 2500 feet above the sea, is believed to have an extent not far short of this. Lake Baringo, north-east of the Victoria, is reported to be a great fresh lake, discharging towards the Nile by a river which is possibly the Sobat tributary. Lake Tzana or Dembea, 60 miles in length, at a level of 6000 feet above the sea, on the Abyssinian plateau, is the only remaining great lake of the Nile basin.

Lakes.

Nile lakes.

The great expansions of the Chambeze-Lualaba river, presumably belonging to the river Congo, are the only other considerable lakes of the Atlantic drainage. The highest of them, Lake Bangweolo or Bemba, is described as being 150 miles in length from east to west, and at an elevation of 4000 feet; Lake Moero, the next, extends through 60 miles; Lakes Kamalondo or Ulenge, and the yet unvisited lakes of the same drainage, are described as of vast extent, and lie at an elevation of about 2000 feet above the sea.

Belonging to the drainage system of the Indian Ocean are, Lake Nyassa, 1500 feet above the sea, and stretching meridionally over an area of nearly 9000 square miles in the basin of the Zambeze; and Lake Samburu, a reported lake of great extent, lying in the plateau edge north of Mount Kenia, and probably belonging to the basin of the Juba river. The great Lake Tanganyika, upwards of 10,000 square miles in area, and united by a broad channel with Lake Liemba in the south, occupies a deep longitudinal basin, girt with mountains; it is 2800 feet above the sea level. As yet no outlet has been discovered for this vast lake, and the question whether it has or has not an overflowing river, is still undecided; but its waters are not perfectly fresh, the drainage to it is small, and the probability is that the Tanganyika is a continental lake. Lake Shirwa, enclosed by mountains on the plateau edge southeast of Lake Nyassa, and 2000 feet above the sea, has brackish water, and no outlet.

Lake Chad, the greatest lake of the continental system of North Africa, is a shallow lagoon of very variable extent, with numerous islands: it lies at about 1100 feet above the sea; its waters are fresh and clear, and its overflow is carried off to north-eastward by the wady named Bahr-el-Ghazal.

Lake Ngami, the corresponding lake in the southern continental system, at an elevation of about 2900 feet, is also a shallow reedy lagoon, varying in extent according to the season. The Zuga river carries off its surplus water to eastward.

Salt lakes. Salt lakes are of frequent occurrence in the areas of continental drainage; perhaps the most remarkable of these is the Assal lake, which lies in a depression east of Abyssinia comparable with that of the Dead Sea, 600 feet beneath the level of the Red Sea; the Sebka-el-Faroon or Schott Kebir, south of Tunis, is a great salt lagoon, 100 miles in length, dried up in summer, when its bed is found to be thickly encrusted with salt, and in winter covered with water to a depth of two or three feet. It lies several feet beneath the level of the Mediterranean.

Climate. Africa lies almost entirely in the torrid zone, and is the hottest continent of all. The greatest heat, however, is not found under the equator, since the whole of the central belt of the continent is protected by a dense covering of forest vegetation, supported by the heavy rainfall, and has in consequence a more equable climate, but in the dry, bare exposed desert belts, which lie on the margins of the tropics, the Sahara in the north and the Kalahari in the south, where the climate is extreme. The highest temperature is found throughout the Sahara, particularly in its eastern portions towards the Red Sea. In Upper Egypt and Nubia eggs may be baked in the hot sands; and the saying of the Arabs is, "in Nubia the soil is like fire and the wind like a flame." The regions along the Mediterranean and Atlantic coasts are rendered more temperate by the influence of the sea. To the south of the Great Desert the temperature decreases, chiefly on account of the increasing moisture and protection of the land surface from extreme heating by its tree growth, but also because of the greater elevation of the land as the great southern plateau is approached. Both on account of its elevation and its narrower form, which gives greater access to the equalising influence of the surrounding ocean, the southern half of the African continent has a less high temperature than the northern, though the same gradations of climate outward from the centre belt are clearly marked in each division. Regular snowfall does not occur even in the most southern or northern regions; and this phenomenon is only known in the most elevated points of the continent, as in the Atlas Mountains in the north, the summits of which retain patches of snow even in summer, in the Abyssinian peaks, in the highest points of the mountains of the Cape Colony, and most remarkably in the lofty summits of Mounts Kenia and Kilima-njaro, which rise on the plateau directly beneath the equator. The intensity of radiation and its influence upon the temperature are very great in Northern Africa; while in the day time the soil of the Sahara rapidly absorbs the solar rays, during the night it cools so rapidly that the formation of ice has often been known to occur.

The observed average temperatures of the extreme months of the year at various points of Africa, from N. to S., are given in the following table:—

	Jan.	July.		Jan.	July.
Las Palmas, Canary Islands, .	61·9	73·6	Kobbé, Darfur, .	67·1	87·8

Africa is not much under the influence of the regular winds, except the monsoons of the Indian Ocean, the great movement of the atmosphere depending chiefly on the oscillation of the continent beneath the sun during the seasons, as will be afterwards explained. The wind currents over the whole continent have a prevailing direction from the east. There are the trade winds, modified by interruptions of changing heat and elevation of the land surface. In the northern part of the Indian Ocean the year is divided between the south-west monsoon, blowing from March till September, away from Africa, towards the then heated continent of Asia; and the north-east monsoon, or rather the normal trade wind, blowing towards the African coasts, from October till February. It will be seen in the next paragraph, that the monsoons, although they extend only to about a third portion of the East African shores, have an extremely important bearing upon the physical economy of the whole African continent. From hurricanes Africa is nearly exempt, except in its south-eastern extremity, to which at times the Mauritius hurricanes extend. At rare intervals these have visited the east coast as far as Zanzibar. Northern Africa is much exposed to the hot winds and storms from the Sahara, which are called in Egypt Khamsin, in the Mediterranean Scirocco, Shume or Asshume in Marocco, and Harmattan on the west coasts of the Sahara and in the countries bordering on the Gulf of Guinea. These always blow directly across the coast from the interior, and seem to move round the compass during the year, beginning in Egypt in April, in Algeria in July, in Marocco in August, in Senegambia in November. Similar dry electrical winds are experienced in the Kalahari desert in the south. Whirlwinds, frequently carrying sand up into the atmosphere, are of frequent occurrence in these deserts, and are also known in the dry region of Unyamuezi, between Zanzibar and the Tanganyika, and in the Limpopo basin farther south. Extreme heat and dryness are the characteristics of these winds, which, raising the sand, filling the air with dust, and prodigiously favouring the powers of evaporation, are often fatal to the vegetable and animal creation in the regions visited by them.

In Africa the dependence of the winds and rains upon the movement of the land beneath the sun is more clearly marked than in any other intertropical region of the globe. The high temperature caused by the vertical heat of the sun over a particular area induces an indraught of air to that place, an ascending current is produced which carries up with it the warm and moist air; condensed in the higher regions of the atmosphere, the moisture falls as rain, and the condensation makes way for a further indraught. It is thus that in Africa the winds and rains follow as a rule the pendulating movement of the continent beneath the sun, and the rainy season of any space begins almost immediately after the sun has reached its zenith. Between the tropics and the equator the sun comes twice to the zenith of each belt during the year, at the tropical lines the sun is only once in the zenith; thus it follows that a double rainy season is observed in all places lying in the central belt of the tropics, and a single rainy season in those which are nearer the skirts of the zone. These wet and dry seasons correspond to the cooler and hotter periods of the year, and take the place of the summer and winter of the temperate regions. Various circumstances tend to interfere with and modify the working of this general rule of the rotation of seasons. In Southern Africa that rainy season which follows the apparent movement of the sun northward, is greater than that which ensues after his passage south, since in the former case the winds are drawn inwards from the ocean and carry greater quantities of moisture, whereas in the latter the winds are drawn from the land north of the equator, and their moisture is already in great part spent. In the northern and eastern regions of Africa the winds and rains are governed as much by the heating and cooling of the Asiatic continent as by that of Africa itself, but in the central and western portions of the continent the rule is well exemplified. Thus in Damara Land, bordering on the southern tropic, there is one short rainy season from February till April, beginning only with the northing sun; at Loanda in Angola the greater rains last from February till May, the lesser rainy season, when the sun has passed this place going south, occurs in November only. At Annobon island, surrounded by wide sea, April and May are the rainy months of the northing sun, October and November of the southing. The Guinea coast, facing the sea to southward, has its greater rainy season from March to June, when the northing sun draws the ocean winds on to the coast; and its lesser rains occur in October and November, when the sun has passed southward from the land. Nearing the northern tropical line, the coast-land from Sierra Leone to the Senegal river has a simple wet and dry season during the year.

On the eastern coast-land the rains are more dependant on the direction of the monsoon winds; about the mouths of the Zambeze and on the Mozambique coast the rains begin in November, after the north-east monsoon wind has set in over the northern part of the Indian Ocean, bringing with it the vapours drawn from the sea to condense on the coast slopes. The rains continue here till March, when the south-west monsoon begins to blow away from the land towards the then heated surface of Asia. At Zanzibar there is a double rainy season, a stronger in the months of March, April, and May, with the northing sun, beginning immediately after the south-west monsoon has set in, and a weaker in September and October with the southing sun. Under the equator on the east coast the rains begin in April with the south-west monsoon, continuing till June, and during this period the sky is obscured by heavy clouds. The second rainy season here is only marked by a few showers in September and October. While the north-east monsoon is blowing the sky remains of a cloudless blue. In the interior of the continent, between these tropical coasts, the rainy seasons appear rather to precede than follow the advancing sun. In the region of the central Zambeze the greater rains last through February, March, and April, the lesser occurring in October and November. The worst droughts are experienced in December and January. Nearer the centre of the continent the two rainy seasons become so lengthened as almost to merge into one period of rains, extending over about eight months of the year. In the newly-explored country south-west of the Tanganyika, Dr Livingstone found that the rains began in October, and that the last showers fell in May; but there is probably a drier period between these limits. At the Tanganyika Lake the rainy season begins in September, lasting till May, and the same rainy reason has been observed in the interior country of the west coast immediately north of the equator. Between these points, in Manuyema country, Dr Livingstone found that the rains continued till July, or almost through the year. Northward in the interior the rainy seasons are again clearly divided into a greater and lesser, and in the regions west of the Upper Nile between 5° and 10° N. lat., the stronger rains occur from August till October, the weaker come with the northing sun in April and May. The plateau of Abyssinia, rising high above the general level of the north of Africa, and intercepting and condensing the moist winds, has also a double rainy season,—a greater from June to September, when the sun is passing southward; a lesser in February and April, with the northing sun. The rainy seasons in Central Africa are ushered in and accompanied by violent thunderstorms and by occasional falls of hail. The quantity of the rainfall, which is excessive in the regions near the equator, diminishes rapidly to north and south of this belt as the dry regions on the borders of the tropics are approached.

The Sahara, and also the Kalahari of Southern Africa, are almost rainless regions, but wherever a sufficient elevation occurs to intercept a cooler stratum of the atmosphere, rain is not wanting, even in the midst of the Great Desert. A striking instance of this is related by Mr Richardson. That traveller relates that when on the borders of the mountain knot of "Aïr, in about latitude 19° N., on the 30th Sept. 1850, there was a cry in the encampment, 'The wady is coming.' Going out to look, I saw a broad white sheet of foam advancing from the south between the trees of the valley. In ten minutes after a river of water came pouring along, and spread all around us, converting the place of our encampment into an isle of the valley. The current in its deepest part was very powerful, capable of carrying away sheep and cattle, and of uprooting trees. This is one of the most interesting phenomena I have witnessed during my present tour in Africa. The scene, indeed, was perfectly African. Rain had been observed falling in the south; black clouds and darkness covered that zone of the heavens, and an hour afterwards came pouring down this river of water into the dry parched-up valley."

The causes of want of rainfall in the vast region of the Sahara appear to be mainly these—that the winds advancing towards it come from a cooler and moister to a warmer and drier region, indeed to the hottest and driest of all, and so are constantly losing in moisture and gaining in temperature as they approach; the high plateau of Abyssinia forms an effective screen from the winds of the Indian Ocean, wringing out their moisture before the Sahara is reached, and on the Atlantic side the north-east trade wind constantly blows away from the land; a barrier of mountains also deprives the Sahara of rain from the south-west. Another cause of dryness is the low level of great areas of the Sahara. We have seen that wherever there is a considerable elevation, even in its midst there is a periodical rainfall. The Kalahari region is almost rainless, on account of the great heat to which it is subjected; but specially because the winds coming towards it from the eastward, the prevailing winds, expend their moisture on the high slopes of the plateau which face the Indian Ocean. Heavy dews, consequent on the rapid changes of day and night temperature in these bare regions, partly compensate the deficiency of rain.

The portions of the continent which lie beyond the tropics north and south, the outer slopes of the plateau of Barbary and of the Cape Colony, have no marked rainy season, and the times of the occurrence of rain are altered, the summers of both being drier, the showers more frequent in winter. In Natal, and on the slopes of the plateau in its neighbourhood, rain may be expected in any month; but the greatest falls occur from October to March. The absolute quantity of rain which falls in Africa has as yet been measured at so few points, that no definite conclusions can be arrived at respecting it.

Although Africa belongs almost entirely to the torrid and warm zones, its vegetable productions are essentially different in different parts. Thus, in the extreme north, groves of oranges and olives, plains covered with wheat and barley, thick woods of evergreen oaks, cork-trees, and sea-pines, intermixed with cypresses, myrtles, arbutus, and fragrant tree-heaths, form the principal features of the landscape. On this northern coast the date-palm is first found; but its fruit does not arrive at perfection, and it is chiefly valued as an ornamental object in gardens. Various kinds of grain are cultivated. Beyond this region of the coast and the Atlas chain, with the borders of the Sahara, commences a new scene. It is in this region, extending to the borders of Soudan, that the date-tree forms the characteristic feature. Being peculiarly adapted to excessive dryness and high temperature, it flourishes where few other plants can maintain an existence. Were it not for the fruit of the invaluable date-tree, the inhabitants of the desert would almost entirely depend on the products of other regions for their subsistence. With the southern boundary of the Sahara, the date-tree disappears, the baobab or monkey bread-tree takes its place, and, under the influence of the tropical rains, a new, rich, and highly-developed flora presents itself. These trees, together with huge cotton-trees, oil-palms, sago-palms, and others of the same majestic tribe, determine the aspect of the landscape. The laburnum expands its branches of golden flower, and replaces the senna of the northern regions, and the swamps are often covered with immense quantities of the papyrus plant. Instead of waving fields of corn, the cassava, yam, pigeon-pea, and the ground-nut, form the farinaceous plants. The papaw, the tamarind, the Senegal custard-apple, and others, replace the vine and the fig. In Southern Africa, again, the tropical forms disappear, and in the inland desert-like plains, the fleshy, leafless, contorted, singular tribes of kapsias, of mesembryanthemums, euphorbias, crassulas, aloes, and other succulent plants, make their appearance. Endless species of heaths are there found in great beauty, and the hills and rocks are scattered over with a remarkable tribe of plants called *Cycadaceæ*. Plants of the protea tribe also add to the extraordinary variety in the vegetable physiognomy of that region.

Of the characteristic African plants, the date-tree is one of the most important, as it is likewise among the nearly one thousand different species of palms. It furnishes, as it were, the bread of the desert, beyond which it occurs only in Western Asia, wherever a similar dry and hot climate prevails. This tree requires a sandy soil, and springs must not be absent. The dates furnish food not only for man, but for the camel and the horse. For the latter purpose the stones are used in many parts, and are said to be more nourishing than the fruit itself. The Arabs make a great variety of dishes of which dates form the chief part. Of the sap of the tree palm-wine is prepared, and the young leaves are eaten like cabbage.

Heath.

In Southern Africa are the extensive miniature woods of heaths, as characteristic as the groves of date-palms in the north. No less than five hundred species have already been discovered. These plants, of which some reach the height of 12 to 15 feet (*Erica urceolaris*), are covered throughout the greater part of the year with innumerable flowers of beautiful colours, the red being prevalent.

Papyrus.

The papyrus is an aquatic plant, having a stem from 3 to 6 feet high. It inhabits both stagnant waters and running streams, and is common in the countries of the Nile, particularly Egypt and Abyssinia. Its soft, smooth flower-stem afforded the most ancient material from which paper was prepared, and for this reason it is one of the noticeable African plants. It has, however, also been used for other purposes; its flowering stems and leaves are twisted into ropes; and the roots, which are sweet, are used as food.[1]

The following table, compiled from the "synonymic lists of species of mammals" given by Mr Andrew Murray,[2] affords a general view of the distribution of terrestrial mammals in the different parts of Africa,—the figures denoting the number of species found in each of the divisions, those in the last column being the number peculiar to Africa:—

Orders.	Distributed over Africa.	N. Africa, Marocco, Egypt, and the Sahara.	Abyssinia and the Upper Nile District.	Senegambia to Lake Chad District.	East Africa, Somali Land, Zanzibar, Mozambique, and Zambezia.	Madagascar.	S. Africa, Natal to Damara Land and C. Colony.	W. Africa, Benguela to Guinea.	Total Species in Africa.	Species peculiar to Africa.
Quadrumana,	..	2	10	8	10	32	8	41	97	94
Carnivora,	5	17	23	10	18	9	30	20	91	76
Ungulata,	3	9	19	14	20	1	32	12	84	74
Multungulata,	1	...	1	1	5	...	4	5	8	8
Edentata,	...	...	2	2	2	...	2	2	7	7
Insectivora,	1	22	16	8	26	11	29	10	104	92
Rodentia,	1	86	18	10	20	...	46	16	132	121
Marsupialia and Monotremata,	...	...	...	...	...	...	...	..	...	...
Total,	11	86	89	53	101	53	151	106	523	472

The order Quadrumana is well represented, more particularly within the tropics, whence they decrease northwards and southwards. The most important members of this family are the anthropoid monkeys, the chimpanzee and gorilla, in Tropical and Western Africa. Baboons and mandrils, with few exceptions, are peculiar to Africa. Only a few species of the genus *Macacus*, which is East Indian, are found in Africa. The only short-tailed species (*Macacus Innuus*)

[1] See *Flora of Tropical Africa*, by Daniel Oliver, F.R.S., F.L.S. London, 1868.

[2] *The Geographical Distribution of Mammals*, by Andrew Murray, London, 1866.

is North African, and is also found wild on the opposite coast at the Rock of Gibraltar. In Madagascar the place of the true monkeys is supplied by the peculiar tribe of the true Lemurs or makis. Many species have close affinities with those of Asia; thus the orang-outang of Borneo is represented in Africa by the chimpanzee. The gibbons are entirely wanting.

Carnivora. Of the larger Carnivora the bear is almost entirely wanting, and occurs only sparely in the Atlas Mountains in Barbary. The true martens are unknown, but otters occur. Of the *Canis* family the jackal is characteristic, and roams over the whole of Africa; it differs from the Asiatic species in its paler skin, which approaches the colour of the prevailing deserts. The wolf and fox do not extend beyond the northern margin of Africa. Hyænas are true African tenants; the striped hyæna extending from Asia over North Africa, the spotted hyæna over the remainder of the continent; in the southmost part of the continent the brown hyæna is also found, and with it the aardwolf, or earth wolf of the Cape colonists, allied to this genus. Africa is the chief home of the lion, which there remains undisturbed as king over the lower animal creation, though it has been driven inwards from the more settled portions of the coast-land; while in the extreme south-western parts of Asia, to which it is now confined, its power is divided with that of the tiger. The leopard, serval, caracal, chaus, and civet cat (the locality of the true civet being North Africa), are the other principal representatives of the cat tribe. The herpestes or ichneumons have the same distribution as the civets; the species which destroys the eggs of the crocodile is found in Egypt and the North of Africa.

Ungulata. (Hoofed Mammalia, Ruminantia, and Pachydermata). Of wild horses the asinine group is characteristic of Asia, and the hippotigrine of Africa. The quagga, exclusively African, inhabits the most southern parts of the continent, and is scarcely found north of the Orange river, but occurs in great herds, associated with the white-tailed gnu; the zebra (*Equus Burchellii*), or zebra of the plains, is widely distributed over Africa, from the limit of the quagga to Abyssinia and the west coast; the zebra of the mountains (*Equus zebra*), more completely striped than the rest, is only known in South Africa. The true onager or aboriginal wild ass is indigenous to North-East Africa and the island of Socotra. A species inhabiting the high land of Abyssinia is distinct from these. The horse, domesticated in other parts of Africa, excepting the region of forests, is not found in the eastern intertropical region; and, for some cause not yet clearly ascertained, it appears to be impossible to acclimatise it there. The single humped camel or dromedary is used over the whole of North Africa, as far south and west as the river Niger and Lake Chad. The Indian buffalo has spread by introduction to North Africa; the Cape buffalo, a species peculiar to Africa, reaches as far north as a line from Guinea to Abyssinia; the *Bos Brachycerus* is a species peculiar to West Africa, from Senegal to the Gaboon. Of sheep, the *Ovis Tragelaphus* is peculiar to North Africa; the Ibex goat extends into Abyssinia. The family of the antelopes is essentially African, five-sixths of the species composing it being natives of that country, and chiefly of the portion lying south of the Sahara, occurring in dense herds. Lastly, the giraffe, one of the most celebrated and characteristic of African quadrupeds, ranges from the limits of the Cape Colony as far as the Sahara and Nubia.

Of Edentata the seven species known to occur in Africa are also peculiar to it. The aardwark (*Orycteropus capensis*) is essentially burrowing in its habits; and the burrows formed by these animals are the source of frequent danger to the waggons and horses of the Cape colonists.

A genus of moles is met with in South Africa, but is not found in the tropical regions. The Cape or gilded mole, *chryso-chlore*, is so called from its iridescent glossy fur; two or three species of hedgehog occur in the continent, and Madagascar has a peculiar family resembling these in appearance, but without the power of rolling up into a ball for defence. Bats are numerous in Africa, but few are peculiar to it.

Of Rodents the burrowing kinds prevail. The African species of porcupine are known in the northern and western coast-lands and in South-Eastern Africa. The hyrax extends over Eastern Africa and a portion of the west coast. Hares are only known in the countries north of the Sahara and in the Cape colony. Among squirrels, those with bristles or spines in their fur are peculiar to the southern regions of the continent.

The ornithology of Africa presents a close analogy in many of its species to those of Europe and South Asia. Thus on its northern coasts, there is scarcely a single species to be found which does not also occur in the other countries bordering on the Mediterranean. The ornithology of the region of the Nile and the northern coasts is identified with that of Arabia, Persia, and Spain. The deserts are inhabited by species adapted to its solitudes; while Southern Africa presents different species.

The ostrich, the hugest of birds, which has been described as the feathered camel, or the giraffe among birds, is found in almost every part of Africa. But its chief home is the desert and the open plains; mountainous districts it avoids, unless pressed by hunger. The beautiful white feathers, so highly prized by the ladies of Europe, are found in the wings of the male bird. The chase is not without its difficulties, and it requires the greatest care to get within musket-shot of the bird, owing to its constant vigilance and the great distance to which it can see. The fleetest horse, too, will not overtake it unless stratagem be adopted to tire it out. If followed up too eagerly, the chase of the ostrich is not destitute of danger: for the huntsman has sometimes had his thigh-bone broken by a single stroke from the leg of a wounded bird.

The large messenger or secretary-bird, which preys upon serpents and other reptiles, is one of the most remarkable African birds. It is common near the Cape, and is not seldom domesticated. Of gallinaceous fowls adapted to the poultry-yard, Africa possesses but a single genus, the guinea-hens, which, however, are found in no other part of the world. These birds, of which there are three or four distinct species, go in large flocks of 400 or 500, and are most frequently found among underwood in the vicinity of ponds and rivers. There are, besides, many species of partridges and quails in different parts of Africa. Water fowl of various species are also abundant on the lakes, and rivers, as are likewise various species of owls, falcons, and vultures, the latter of which are highly useful in consuming the offal and carrion, which might otherwise taint the air and produce disease.

Among the smaller birds of Africa are many species remarkable for the gaudiness and brilliancy of their plumage, or the singularity of their manners and economy. Of the former kind may be mentioned the sunbirds, the lamprotornis, the bee-eaters, the rollers, the plantain-eaters, the parrots, the halcyons, and numerous smaller birds that swarm in the forests. Of the latter kind it will be sufficient to mention the honey-cuckoo (*Cuculus indicator*).

Though Africa is not exempt from the scourge of venomous or dangerous reptiles, still it has comparatively fewer than other tropical countries, owing to the dryness of the climate. The reptiles harboured by the desert regions consist chiefly of harmless lizards and serpents of a small size, though often venomous. The frog and tortoise tribes are represented in but few species and numbers.

The most important among the reptiles is the crocodile, which inhabits nearly all the large rivers and lakes within the tropics, and is still abundant in the Nile below the first cataract.

The chameleon is common in Africa. Among the venomous species of snakes are the purple naja. the cerastes or horned viper, the ringed naja, and the darting viper.

Edible fish are found almost everywhere in great variety and quantity. The fresh waters of Egypt produce the gigantic bishir, the coffres. and numerous species of the pimelodes. Many varieties of fish exist in the great interior lakes; five large species found in the Tanganyika are described by Burton. The greater number of the fish of the Red Sea resemble the saxatiles of the warm seas of Asia. On the west coasts are found the fish belonging to equatorial latitudes, while the shores of the Mediterranean produce those of France and Spain. The seas of the southern extremity possess the species common to the latitudes of the antarctic. south of the three great capes. The fish of the east coast are the same as those of the Indian Sea.

Of the insect tribes Africa also contains many thousand different kinds. The locust has been, from time immemorial, the proverbial scourge of the whole continent; scorpions, scarcely less to be dreaded than noxious serpents, are everywhere abundant; and the zebub, or fly, one of the instruments employed by the Almighty to punish the Egyptians of old, is still the plague of the low and cultivated districts. In the interior of Africa a venomous fly occurs in certain regions of the south and east, which is fatal to nearly all domestic animals. It is called tsetse (*Glossina. morsitans*), and its size is almost that of the common blue fly which settles on meat; but the wings are larger. On the absence of this insect greatly depended the success of recent explorers in that quarter, as, where it appeared, their cattle infallibly fell victims to its bite. There are large tribes which cannot keep either cattle or sheep, because the tsetse abounds in their country. Its bite is not, however, dangerous to man; wild animals likewise are undisturbed by it. The termites or white ants are likewise a scourge to the country where they occur in great numbers. This destructive creature devours everything in the shape of wood, leather, cloth, &c., that falls in its way; and they march together in such swarms, that the devastation they commit is almost incredible.

Of the class of zoophytes, the brilliant polypi of every variety, and madrepores, abound on the coasts of Africa. The shores of the Mediterranean produce the finest coral, and those of the Red Sea bristle with extensive reefs of the same mollusca

From the shores of the Mediterranean to about the latitude of 20° N., the population of Africa consists largely of tribes not originally native to the soil, but of Arabs and Turks, planted by conquest, with a considerable number of Jews, the children of dispersion; and the more recently introduced French. The Berbers of the Atlas region, the Tuaricks and Tibbus of the Sahara, and the Copts of Egypt, may be viewed as the descendants of the primitive stock, while those to whom the general name of Moors is applied, are perhaps of mixed descent, native and foreign. From the latitude stated to the Cape Colony, tribes commonly classed together under the title of the Ethiopic or Negro family are found, though many depart very widely from the peculiar physiognomy of the Negro, which is most apparent in the natives of the Guinea coast. In the Cape Colony, and on its borders, the Hottentots form a distinct variety in the population of Africa, most closely resembling the Mongolian races of Asia.

The Copts, or as they are correctly pronounced. either Ckoobt or Ckibt, are considered to be the descendants of the ancient Egyptians. They do not now compose more than one sixteenth part of the population of Egypt, their number not exceeding 145,000, about 10,000 of whom reside at Cairo. Conversions to the Mohammedan faith, and intermarriages with the Moslems, have occasioned this decrease in their numbers; to which may be added the persecutions which they endured from their Arabic invaders and subsequent rulers. They were forced to adopt distinctions of dress. and they still wear a turban of a black or blue. or a grayish or light brown colour, in contradistinction to the red or white turban. In some parts of Upper Egypt there are villages exclusively inhabited by the Copts. Their complexion is somewhat darker than that of the Arabs, their foreheads flat, and their hair of a soft and woolly character; their noses short, but not flat; mouths wide, and lips thick; the eyes large, and bent upwards in an angle like those of the Mongols; their cheek-bones high, and their beards thin. They are not an unmixed race, their ancestors in the earlier ages of Christianity having intermarried with Greeks, Nubians, and Abyssinians. With the exception of a small proportion, the Copts are Christians of the sect called Jacobites, Eutychians, Monophysites, and Monothelites, whose creed was condemned by the Council of Chalcedon, A.D. 451. They are extremely bigoted, and bear a bitter hatred to all other Christians; they are of a sullen temper, extremely avaricious, great dissemblers, ignorant, and faithless. They frequently indulge in excessive drinking; but in their meals, their mode of eating, and the manner in which they pass their hours of leisure, which is chiefly in smoking their pipes and drinking coffee, they resemble the other inhabitants of the country. Most of the Copts in Cairo are employed as secretaries and accountants, or tradesmen; they are chiefly engaged in the government offices; and as merchants, goldsmiths, silversmiths, jewellers, architects, builders, and carpenters, they are generally considered more skilful than the Moslems. The Coptic language is now understood by few persons, and the Arabic being employed in its stead, it may be considered as a dead language.
